Studies have also found that poor and minority patients often fare less well under managed care policies, as compared to traditional fee for service. These disparities range from issues of access to timely and appropriate levels of treatment.

END-OF-LIFE CARE: AN OPPORTUNITY TO ADVOCATE

Social work has played an integral part in representing the concerns of the elderly at the end of life, especially in hospice care. Hospice care demonstrates an ideal model of integrating key elements of social work practice into the management of health, mentally and physically. Alternatives to hospice, such as palliative care programs, to facilitate access to quality end-of-life care are being developed across the country. In an integrated managed care system or HMO, successful reallocation of health dollars to improve end-of-life care is possible, while traditional fee-for-service structures lack the fiscal incentives and face regulatory barriers to this helpful reorganization of the funding mechanism for this kind of care model. A major study at Kaiser in California demonstrated a 45% cost reduction under an innovative palliative home care model, but traditional reimbursement outside that contained system makes it very difficult to implement the same model in non-managed-care settings. Models like this tend to incorporate social work, as it is a discipline that helps to integrate care and improve the effectiveness of other disciplines.

TODAY'S SOCIAL WORK CHALLENGES

Social workers in managed care environments must seek to optimize the opportunities for health care reform in managed care and also engage in a battle between quality-of-care issues and cost-containment strategies, fighting to identify a middle ground where both social work ethics and organizational forces can effectively cohabitate. Two primary challenges faced by social workers in managed care have been identified:

First, we want to retain the core values of the profession—advocacy, self-determination, and client focus—often considered at odds with corporate for-profit health care. Second, we need to develop the business acumen to demonstrate so-

cial work's effectiveness in a service industry where demonstrated outcomes predominate. (Schneider, Hyer, & Luptak, 2000, p. 276)

Yet in some managed care settings, social work is a perfect fit with the ideal goals of the nonprofit managed care system that focuses on early intervention, improved self-care, prevention, health maximization, and the right care in the right place at the right time. Here social work's contribution is valued and has a key role to play.

To maintain the delicate balance between core values of the profession and the evolving needs of the service industry, social workers must be prepared to expand their roles and change practice in response to new research and evidence of effective practice models. Further, in meeting the challenges in any host practice setting, the health and mental health social workers must address the following.

- Marketing social work services and linking them to cost-benefit measures
- Presenting social work as an essential role of the interdisciplinary team
- Anticipating and addressing the environment and roles that political and social forces have on service delivery
- Moving beyond traditional roles and developing new and innovative strategies to optimize health and assure the social work contribution is properly designed
- Taking an active role in macro issues to advocate for better patient quality
- Being “flexible, open, and ready to embrace the future,” while staying focused on the ethics of clinical social work
- Engaging in time-limited brief interventions that produce outcomes valuable to patients, families, and the organization
- Changing from a curative focus to a patient-centered focus. Social work does not cure patients but provides training and education for patients to support them in changes
- Attaching cost-benefit analysis to all care provided—services must be linked with health care dollar savings

These components will not only strengthen the impact of social work practice, but also substantiate and validate the role of the social worker within managed care settings.

More than many other social policy constituencies, older Americans have long benefited from the presence of planning agencies at both the state and substate levels. Passage of the Older Americans Act (OAA) in 1965, in addition to creating the Administration on Aging (AoA) in the federal government, authorized creation of State Units on Aging (SUAs). Amendments to the OAA in 1972 mandated creation throughout the country of substate regional planning bodies: Area Agencies on Aging (AAAs). Initially using OAA funds (and, later, Medicaid and state-level appropriations), these agencies contracted with local service providers to fund social, nutritional, transportation, legal, and other direct services to residents of their planning and service areas. Since the late 1970s, this array of agencies has constituted what has since become known as “the aging network.”

DEVELOPMENT OF AREA AGENCIES AND THE AGING NETWORK

In its roughly 30-year existence, this network has evolved in important ways. In its nascent stage, the aging network engaged in basic start-up and capacity-building activities. By the 1980s, the network was well established and widely recognized, and had come to represent a substate and local political presence unique among population-based human services constituencies. Beginning in the late 1980s and continuing to this day, the network has been increasingly drawn into the large and challenging world of community-based long-term care.

Early Developments

Both rational and political elements lay behind the creation of area agencies (Hudson, 1974). Passed with considerable fanfare in 1965, the OAA was also better understood as symbolic rather than substantive legislation. The initial appropriation for FY 1966 was \$7.5 million, and the fledgling SUAs could use no more than \$15,000 each for state-level administration. By 1969, total funding had risen to \$23 million, with the amount available for their own operations having risen to \$25,000 (Hudson, 1973). States were encouraged to appropriate additional funds, but, as Congressman John Brademas noted in hearings in 1969, Nebraska was typical in contributing no more than 16 cents per older resident to augment the federal funds. By the early 1970s, criticism of the OAA, the AoA, and

ROBERT B. HUDSON

Social Service and Health Planning Agencies

42

the SUAs was widespread; one report spoke of “ram- pant tokenism” (Greenblatt & Ernst, 1972), and another was entitled “The Administration on Aging—Or a Successor?” (Sheppard, 1971).

Against this backdrop, a White House Conference on Aging was convened in 1971, bringing some 4,500 older Americans to Washington to press for additional federal programming across a range of aging-related arenas, including social services. In a moment of high political theater, President Nixon—as a means of deflecting attention from his opposition to a proposed 20% increase in Social Security benefits—seized on the OAA as a vehicle for showing his commitment to the well-being of senior citizens. To the surprise of nearly everyone in the auditorium, Nixon announced:

We want to begin by increasing the present bud- get of the Administration on Aging nearly five- fold—to 100 million dollars. Now, you may wonder where I got that number because . . . it was 80 million dollars last night, and I decided why not 100 million dollars! (White House Con- ference on Aging, 1971)

In light of this surprise announcement, there immediately arose a need to address the planning and administrative problems that were seen as endemic among both the AoA and the SUAs. The answer lay in drawing on a “substate planning strategy” then in vogue within the Department of Health, Education, and Welfare. This led to creation of the AAAs through the 1972 amendments to the Act. Being “closer to the people,” these agencies were seen as better positioned to set priorities and engage in a meaningful planning process. Beyond creation of the AAAs, amendments in 1972 and 1973 also created a new elderly nutrition program (centrally involving the AAAs) and a new older Americans community service employment program (involving a delicate distribution of contracts between the SUAs and “federal contractors,” including such aging-based interest groups as the American Association of Retired Persons, Green Thumb, the National Council of Senior Citizens, and the National Council on Aging). While many SUA directors and Democrats had objected to creation of AAAs—fearing they would further weaken the SUAs—enactment of the employment program and dramatic appropriations increases swept away the opposition. Ultimately, overall appropriations for the OAA rose to \$227 million in 1974, \$324 million in 1976, \$749 million in 1978, and \$919 million by 1980.

Recent Developments

By the late 1970s, the aging network was firmly in place. In addition to the 57 SUAs (including territories, and the District of Columbia), 655 AAAs had come into being, funding thousands of direct service providers. The 1980s represented a period of consolidation for the network. While funding under the OAA essentially leveled off at roughly \$1 billion (not counting Department of Agriculture commodity contributions associated with the nutrition program), the National Association of State Units on Aging (2004) reports that these expenditures now annually fund:

- 145 million home-delivered meals
- 115 million congregate meals
- 40 million rides
- 30 million hours of combined personal care, homemaker, and adult day services
- 3.8 million hours of case management
- Over 13 million information and assistance con- tacts and other supportive services to elders and their caregivers

Additional legislative changes over this time pe- riod included new authorizations for in-home ser- vices for frail elders, a long-term care ombudsman program, health education and illness prevention programs, programs for preventing elder abuse and neglect, and a heightened emphasis on the needs of older people with the greatest economic and social needs. New attention was also brought to bear on in- tergenerational concerns and the needs of those pro- viding care to the frail elderly. The latter effort was institutionalized in 2000 with the passage of the Family Caregivers Support Act, the most significant legislative addition to the OAA in 30 years. Organi- zationally, the biggest change was the elevation of the commissioner on aging—charged with adminis- tering the OAA—to the rank of assistant secretary for aging within the Department of Health and Human Services.

PLANNING CHALLENGES

Social and health planning for the nation’s aging pop- ulation has long been a complicated endeavor. Ques- tions about the planning function tap into different dimensions. The first centers on comprehensiveness, the most basic question being whether the public sec-

tor should take on the task of “planning” for the well-being of millions of older people. Or if not all older people, whom among them should it plan for? And if such planning is to be undertaken, at what level(s) of government should it take place? Second, should planning in aging be organized by population or by function, that is, should it be conducted centrally by an “aging planning agency” or should planning be organized along functional lines such as health, transportation, income, or housing, with the needs of older persons being addressed in conjunction with those of the larger population? Finally, should planning be a separate, quasi-abstract activity, or should it be integrated with the provision of the services that concretize the planning function?

Planning for Whom: Eligibility

Because the very notion of “planning” is marginally suspect in the American political culture, no one has called for policy-relevant blueprint planning for the future of the older population. Symbolically, Title 1 of the OAA resolves to improve most aspects of older people’s lives, but it is little more than a wish-statement. Social Security and Medicare are larger and more concrete programs, directing over \$600 billion annually in federal funding to senior citizens, but they have no formal planning component to them.

Formal planning for the aged has been left largely to the network of aging agencies operating under the OAA. Although these programs are neither purely symbolic nor especially large, thorny questions around planning have long arisen here as well (Justice, 1997). Because there is no formal means-testing under the OAA, a nominal case can be made that all older people are eligible for planning services. Resource constraints preclude such broad-based efforts, but in selected areas, such as the nursing home ombudsman program and elder abuse and neglect services, SUAs and AAAs have assumed population-wide intervention roles.

What has transpired for the most part, however, has been administrators of the OAA at all levels of government struggling with the how to best target their limited resources. Much debate during bouts of OAA reauthorization has centered on this question. Early guidelines that centered on “those with greatest economic and social need” later evolved into an enumeration centered on older populations of color, those living in rural areas, and those who were frail or disabled (Hasler, 1990). Apart from these often being

overlapping categories, important selection questions remained: Is being over age 70 or 75 “to be disadvantaged”? What proportion of services should be directed to older populations of color? What is an adequate measure of “social need”? And so on.

Beyond these relatively nuanced distinctions, the energies and resources of the aging services network, beginning in the 1980s, have clearly gravitated toward those elders who could be deemed especially vulnerable by one measure or another. And this is a far different emphasis from that found in the planning and services network’s early years. In global terms, this transition was largely about moving away from early efforts under the OAA, directed at providing socialization and educational opportunities for older people living in the community (including, for example, funds for senior center construction and operation) toward concerted efforts centered on allowing frail older people to remain at home or in other community settings rather than being relegated to nursing homes or other institutional placements.

The most recent and equally important chapter in eligibility standards for these agencies began largely during the late 1980s. Having lessened emphasis on service provision to relatively well elders in the community, many states now extended the coverage of the vulnerable from the frail old to younger adults with disabilities. In this way, the “eligibility axis” began to swing from elders in various circumstances to frail and disabled adults of all ages. Thus, in 21 states today, the SUA is charged with serving both elderly and adult disabled clients (National Association of State Units on Aging [NASUA], 2004).

Planning for What: Program Benefits

The substance, as well as the targets, of planning efforts has also been subject to controversy and evolution in the three decades of the aging planning and services network. One subject of debate has long been the degree to which the network should concentrate its efforts on services delivery and coordination or on broader advocacy efforts directed at the so-called functional arenas not under its purview. Major efforts were made in the late 1960s and 1970s to undertake advocacy or “leadership planning,” wherein SUAs and AAAs would press health, transportation, and other agencies to direct more of their efforts (and comparatively larger budgets) to better serving older people (Binstock, Cherington, & Woll, 1974). Activi-

ties of this kind were undertaken with limited success, but the odds were long that new, small, and constituency-based agencies could meaningfully move the agendas of these larger bureaucratic entities (Hudson & Veley, 1974).

In the years before the advent of the AAAs, services planning was rudimentary at best, with the nascent SUAs seeking to distribute small community grants across their states in ways that were both programmatically and politically defensible. With the coming of the AAAs and the very significant increase in OAA funding, new efforts were made to coordinate as well as fund service provision. Toward this end, the AAAs themselves were forbidden to engage in direct service delivery. As with the question of client eligibility, efforts were made to prioritize services, moving from an original list of 18 discrete services found in the 1973 amendments to a later three-part listing of access, in-home, and legal services and the requirement that at least 50% of the AAAs' Title 3 funds be used for these purposes. Pressures from the network later led to this provision being softened, so that an "adequate proportion" of their funds were used for these purposes (Hudson, 1994).

During the 1970s and early 1980s, these debates centered almost exclusively on social services alone. By the mid-1980s, however, pressures increased to add more health-related services to the mix. In this way, the larger reality of the aging of the population and, in particular, the aging of the older population began to impact directly the aging planning and services network. The programmatic mandate of the aging network agencies began shifting toward developing home and community-based services (HCBS) to maximize the possibilities for older residents' "independent living." The political mandate came from officials who wanted to please constituents, save money, or, if possible, both.

The principal impetus to network involvement in HCBS has been implementation of Medicaid waiver programs, beginning in 1981. These state-based waivers typically allow states to bypass statewide income eligibility requirements in order to develop regionally specific or site-specific community service alternatives. Services such as home health, case management, personal care, and adult day health care, which traditional Medicaid cannot offer in noninstitutional settings and which OAA funds alone are not sufficient to support, are now offered nationwide. In 21 states, such programs for the elderly and disabled are administered under the auspices of the SUA; in an additional 12 states, these programs serve elderly per-

sons alone; in 25 of these state efforts, the AAAs participate in the Medicaid waiver program (NASUA, 2004).

Planning by Whom: Organization of the Delivery System

From both a planning and a political perspective, what has made the aging services delivery system nearly unique among the social services is the vertically integrated network represented by AoA, the SUAs, the AAAs, and the host of direct service agencies with whom the state and area agencies contract. The creation of this network is the lasting legacy of Arthur S. Flemming, who served as AoA commissioner under Richard Nixon and who saw in the newly formed AAAs a political as well as a services infrastructure for the old. Political and programmatic advantage was seen in the "vertical" protection afforded regional and local agencies by federal and state-level legislative, regulatory, and accountability language requiring that monies be spent for the old (and later the disabled) in specified ways. Planners and providers in other service domains are in many respects envious of this aging-based services system and have sought at times to emulate it (Grason & Guyer, 1995).

Even in this earlier period, however, there were drawbacks to this organization of aging services. As noted, the larger functionally oriented systems, such as health, mental health, and transportation, operated outside of this network. Two particular problems arose. Much as the aging network might lobby these agencies to do more for its older client base, the network has had little leverage to move them in that direction. Moreover, these larger agencies, having seen that there was aging services network in place, were induced to do less rather than more for older consumers. Transportation provides one example, where a regional bus service may not have felt it necessary to tailor its routes and schedules to older riders because the aging network might have been providing specialized bus or van services to older people (e.g., the Older Americans Transportation Service [OATS] program in rural Missouri).

Public health provides a second example. A recent study by the Chronic Disease Directors and National Association of State Units on Aging (2003) finds coordination between the two networks quite limited. The SUA respondents identified several issues that are critical to health promotion among the aged that they

felt were not sufficiently recognized by state health departments (SHDs). Even more to the point, the report finds that “there appears to be widespread confusion about which agency in a state has lead responsibility for health promotion and disease prevention for older adults” (Chronic Disease Directors [CDD] and NASUA, 2003, p. 24). As the authors note as well, there is some irony in health departments’ limited role in aging-related activities, in that decades of public health successes may have more to do with the numerical rise of the old than any other single factor.

State and local officials have long struggled with how to integrate these “vertical functional autocracies” (Wright, 1972) into broader service agendas such as those in transportation or health. Because more particularistic agencies, such as those in aging, may be constrained (or protected, depending on one’s vantage point) by federal law and regulation, it has often been difficult for general-purpose government officials (mayors, county commissioners, governors) to coordinate otherwise interrelated services agendas. Thus in the case of health, federal funding, usually from the Centers for Disease Control, is often disease specific rather than population specific. Only in a time of crisis—as in the case of the flu vaccination shortage of fall 2004—do agendas and agencies come together; thus, the assistant secretary on aging was in Florida one week before the 2004 election, reassuring seniors that more vaccine would soon be on the way (Harris, 2004).

PRESSING ISSUES IN SOCIAL AND HEALTH SERVICES PLANNING

The aging planning and services network has gone through growth, consolidation, and, most recently, redefinition phases. For many network agencies, it is hard to exaggerate the shift in their organizational environments between the period of around 1970–85 and the period since then. The earlier period was marked by a role of symbolic affirmation, a limited programmatic mandate, and resources adequate to the relatively modest tasks at hand. The more recent period finds SUAs and AAAs increasingly drawn into larger policy-relevant issues associated with the “aging of America.” The foremost of these centers on HCBS, but governors, county commissioners, and mayors could increasingly point to SUAs and AAAs to be “point agencies” around larger health care, housing, transportation, and legal issues.

Concern with long-term care is clearly now very much in play within the erstwhile aging network. In most jurisdictions, earlier organizational issues have been shunted aside by the emergence of community-based, long-term care as a pressing state-level issue. The rise of the “old old,” earlier hospital discharges under Medicare, and cost-containment efforts in institutional long-term care services under Medicaid have brought HCBS issues increasingly to center stage. In addition to the Medicaid waiver programs, many states allocated so-called state only funds toward HCBS services. Demonstration projects, such as “Channeling” in the 1980s and the Program of All Inclusive Care for the Elderly (PACE) adult day health services programs, have attempted to develop truly integrated services packages for community-based frail residents in many parts of the country. In these efforts, health, housing, social, respite, and other services are brought together to maximize elders’ independence in community settings.

Without question, pressure to extend these services and devise ways to pay for them will continue to build. The aging of the population and vigorous advocacy efforts on the part of the impaired elders and the disabled are “expanding the scope of conflict” around these traditional bureaucratic divisions. With expenditures for the old and disabled already accounting for two-thirds of spiraling Medicaid budgets (which themselves account for nearly one fifth of all state-level expenditures), long-term care has risen to the top of gubernatorial agendas. In the words of Governor Bob Taft of Ohio, a Republican, “this is a huge national issue both because of the aging population and with regards to the costs of caring for this population” (Tanner, 2004).

The SUAs and AAAs have increasingly assumed major roles in these efforts, and such efforts have become central to their mission. Thus, National Association of Area Agencies on Aging (N4A), the AAAs’ national trade association, lists as its top policy priority in 2004 “the development of a home and community-based services system which provides consumers access to the most appropriate services in the least restrictive environment” ([N4A], 2004). Because the Medicaid and state-only dollars are substantially greater than those available through the OAA, the AAAs are widely assuming the role of facilitators and guides for elders wishing to access the services system. Thus, N4A (2004) sees AAAs as “the front door” into aging services, and Massachusetts, for example, has renamed its substate service and planning agencies Elder Services Access Points.

In conclusion, there is a dynamic at work among “social and health services planning agencies,” and that dynamic is in the direction of health-related services on behalf of frail elders and away from social services for elders able to live in relative comfort in the community. To be sure, traditional services such as nutrition and transportation continue to be offered, and non-health-related services such as adult protective services have been developed. But the historical and rather insular service set associated with the vertical “aging network” metaphor has been notably supplanted by a more involving and challenging role in the arena of community-based long-term care.

The Workplace

43

■ Jan has been a highly productive food preparer at the local hospital. She is the one the supervisor could always count on to be there, to have trays ready on time, filled with the foods ordered by each specific patient, and properly labeled. But in the last month, Jan has been absent frequently, is making errors in her tray preparation, and always seems behind in the work. Her supervisor does not know that Jan, a worker whose employment is possible because she holds a green card, is experiencing serious family problems that interfere with her concentration and, indeed, frequently keep her at home.

Jan's mother came for a visit from China. While here, she was diagnosed with cancer and operated on successfully at the hospital. She is still receiving aftercare treatment. Now, however, her visitor's visa is up. Jan wants her to stay, but Jan's husband is afraid that keeping her mother, whom he now perceives as being here illegally, will jeopardize their own hope to become citizens. They quarrel incessantly, and he has threatened to turn Jan's mother in to the authorities if she does not leave within the month.

Thus, Jan, a good worker, has become a problem worker. ■

■ Juanita, an accounts supervisor at a branch bank, is a divorced mother with two daughters, aged 8 and 11. She has been with the bank for 6 years and has had two promotions during that time. She is highly regarded by her peers, customers, and supervisors, and there is general agreement that she will be a branch manager before long. Juanita has a "secret weapon," in that her mother has been the primary caregiver for the two girls, allowing Juanita to work without concern.

Two months ago, all this changed. Juanita's mother experienced a severe cardiovascular incident and now requires almost constant care. Since then, Juanita has used up all her accrued vacation time, and she has been on unpaid leave under the provision of the Family and Medical Leave Act for several weeks. Now she has visited human resources, indicating that she will have to resign since she does not believe she can manage her new caregiving responsibilities, for both her mother and her daughters, and the demands of her job.

Thus, Juanita, a worker featured significantly in the firm's succession planning, is about to leave the firm's employ. ■

These two scenarios are matched in workplaces all over the country every day, sharing many of the same ingredients. A competent, valued worker confronts a serious problem involving an aging family member or is sandwiched between the needs of an aged person and children. The problem disrupts the family's situation and relationships and is reflected in poor job performance. A valued worker turns into a problem worker whose continued performance and employment are in jeopardy because of absenteeism, late arrival, early departure, work interruption, and even resignation from work (Dautzenberg et al., 2000).

Research has confirmed that caregiving needs of the aging and other family members may have a severe negative impact on the work connections and performance of members of the labor force, and thereby on the employers' organizational efficiency, productivity, and profits (Akabas & Kurzman, 2005; Dunham & Dietz, 2003; Lyon, Hallier, & Glover, 1998; Zimmerman, Mitchell, Wister, & Gutman, 2000). Few people work alone in the workplace. One person's poor performance can disrupt the usual functional processes and may impede a whole work group. The special demands resulting from the crisis an individual worker faces may be resented by coworkers, compromising work group morale and productivity (Fischel-Wolovick et al., 1988; McNeely, 1988). Furthermore, just as good performance sets a model for other workers, poor performance can be contagious in a workplace. Even if these significant costs are borne by the employer in the hope that they are a passing glitch in a fine performance record, there is no guarantee that the individual will maintain his or her work connection. The key asset of most organizations is its employees. Employers make significant investments in developing their labor force, recognizing such action as vital to long-term organizational effectiveness (Lyon et al., 1998). For the employer, therefore, the scenario of deteriorating performance or losing key workers as a result of the demands of their caregiving roles is potentially significant.

The cost of caregiving is not only levied against the employer. It becomes an important issue as well for women, in particular, and society in general. Whereas marriage used to be the road to economic security for women, their economic well-being now is intimately tied to their work experience (Carmichael & Charles, 2003; Morgan, 2000; Wilson & Hardy, 2002). Soci-

ety's expectation that caregiving is primarily a private, personal, and female responsibility makes caregiving a problem for working women and their economic well-being and, lacking their availability, an issue for employers and society (Sands & Goldberg-Glen, 1998).

The purpose of this chapter is to review the demographics and trends that are making the role of caregiver to the aged central to the lives of many, with consequences for the well-being of workers and their families and for the effectiveness of their employing organizations. We will then explore what workplaces and society have done in response and suggest additional possibilities for both prevention and intervention and the role social workers can play in achieving their implementation.

DEMOGRAPHICS AND TRENDS IN CAREGIVING AFFECTING EMPLOYMENT

Dentinger and Clarkberg (2002, p. 857) note that "an estimated one quarter of the entire American wage and salaried workforce provided informal care to their elders during 1996." Innes (2001, p. 12) reports that "before 2010, almost half the workforce will be parent-caring!" The impact of this demographic tidal wave can influence employers to develop greater interest in making it feasible for women to combine caregiving and employment—to keep them at work and productive. But several other trends emerge to feed employer interest in responding to caregiving demands. First, as baby boomers age, they will leave the labor force in large numbers (Kinsella & Velkoff, 2001). A labor shortage is expected because the smaller generational cohort that follows (often referred to as the baby bust generation because of the reduced birth rate from 1964 to 1980) will not meet the replacement demand for workers in an expanding economy (Doeringer, Sum, & Terkla, 2002; Faight, 1998). In addition, the baby boomers, now primarily caregivers, can be expected to develop their own massive needs for care in the not-too-distant future, requiring care that will distract the already depleted replacement pool from full-time work.

Second, the demand for women in the labor force is increasing, attributable to the change in occupational mix that favors women's jobs over traditionally male employment (Cotter, Hermsen, & Vanneman, 2002). Keeping men in the labor force longer or encouraging higher rates of immigration of young adults may help to meet employers' labor demand. The largest potential pool of workers to draw on, however, is women whose labor force participation

rate, though increasing, still does not equal men's participation rate at any age grouping.

Third, at the same time that the demand for their labor force participation is increasing, women's caregiving responsibilities are expanding. Women are postponing childbearing (Anonymous, 2001). Simultaneously, longevity has increased. As a result, many working women have family members in their late eighties and nineties. It is likely that, while still caring for a child, a worker will be confronted with the responsibility to care for a parent (Robinson, Barbee, Martin, Singer, & Yegidis, 2003). In fact, today's "typical" couple has more living parents than children (Perkins, 1993).

IMPACT OF DUAL ROLE AS WORKER AND CAREGIVER

As mentioned, caregiving can have an impact on a woman's economic well-being. Caregiving often requires women to leave work or to accept part-time and/or low-paying jobs that maximize their flexibility, with negative impact on their economic well-being (Evandrou & Glaser, 2003; Pohl, Collins, & Given, 1998). In a British study, for example, "One-in-five mid-life women who have ever had caring responsibilities reported that, upon starting caring they stopped work altogether, and another one-in-five reported that they worked fewer hours, earned less money or could only work restricted hours" (Evandrou & Glaser, 2003, p. 583).

Research indicates, furthermore, that economically poor caregivers are more likely to reduce employment than those who are well off, reflecting realistic decision-making in light of the immediate opportunity costs of caregiving (White-Means, 1992). Thus, not only are present earnings likely to be reduced but also eventual retirement income is affected for women who leave work to provide care, because by leaving work they reduce the base upon which their eventual Social Security benefit is calculated (Dunham & Dietz, 2003).

Concepts of role strain, role conflict, and role overload are the usual context for studying the experience of employed providers of eldercare (Dentinger & Clarkberg, 2002). Researchers report findings of stress when the role of caregiver is added to the role of employee (role overload), particularly when one faces psychological uncertainty in defining priorities (role conflict) and difficulty finding sufficient time to meet all responsibilities (role strain) (Akabas, 1988; Mark, 1988). The result of these influences is usually reduced

labor force participation. Caregiving also influences the continued participation of women in the workforce through its impact on the transition to retirement. Caregiving causes women to retire and make caregiving primary, while it motivates men to continue to work to secure financial resources to afford care (Dentinger & Clarkberg, 2002). Evidence shows that wives caring for husbands are more likely to retire than caregivers in other relationships. Also influential is how sick the person getting the care is, as well as the number of persons to whom the caregiver must give care, each having an impact in the expected direction.

Not all caregiving has negative consequences. Younger cohorts of caregivers who are more accustomed to work may be more adept at balancing the multiple responsibilities of work and care than older ones (Laditka & Laditka, 2000). Further, participation in outside work may mitigate the stress associated with caregiving and improve the balance in life (Dunham & Dietz, 2003; Mark, 1998). Differences also may be offset by ability to purchase some care (Laditka & Laditka, 2000). Full-time workers acknowledge the significance of work as a support and positive component of their complex lives and try to balance their multiple roles without time off in any significant amount (Pohl, Collins, & Given, 1998). Evidence indicates that employed daughters provide less instrumental help to their mothers than unemployed daughters, but employed daughters arrange for additional support by purchased help. Research confirms that employment reduces the chances of being a helper and that employed caregivers tend to reduce caregiving hours rather than work hours (Dautzenberg et al., 2000). From a policy point of view, this is desirable behavior, since maintaining work results in improved earnings throughout the life cycle, and having a better economic position is associated with improved well-being (Zimmerman et al., 2000). The National Long-Term Care Survey and National Survey of Informal Caregivers study of almost 2,000 caregivers of impaired elderly found that although one-third of caregivers made significant adjustments to their employment by quitting their jobs, "the higher the caregiver's family income (opportunity cost of employment time), the less likely are hours to be allocated away from the labor market" (White-Means, 1992, p. 82). Also on a positive note, the alternative concepts of role accumulation and role expansion suggest that the individual can expand role sets, even under circumstances of increasing role strain. If the worker feels committed to each role, the strain of multiple roles is less severe (Dautzenberg et al., 2000).

The intersection among later-in-life child-bearing, the increasing numbers of persons who are aging, the expanding labor force participation of women, and their dependence on work for economic well-being poses a serious dilemma for women, to wit: How should they prioritize the demands of work and family and the competing demands among family members? The dilemma facing individual women can, in concert, create a social and world-of-work problem of crisis proportions, in view of the fact that there will be fewer younger caregivers to employ to meet the caregiving responsibilities of those women who might opt to continue work because of their high earning capacity, necessary income, and/or their own personal preferences (Hochschild, 1997). It is clearly in the self-interest of employers, unions, and society in general to mitigate the burden of caregiving. Not surprisingly, therefore, the parties have taken some action, and these are described here.

RESPONSES TO THE DEMANDS OF CAREGIVING

There are few public social policies that support the function of caregiving, though it is widely recognized that growing poverty is related to this domestic role for women (Bullock, Crawford, & Tennstedt, 2003; Dunham & Dietz, 2003; Zimmerman et al., 2000). Furthermore, employer dependence on women to fill the gap in replacement workers while their role as caregivers is increasing magnifies the need for a responsive workplace policy dealing with caregiving (Akabas, 1990; Spillman & Pezzin, 2000). Currently, however, workplace responses are relatively new, and their effectiveness, for the most part, is unknown.

Social policy. The social policy of a society is expressed in its legislation. In the case of caregiving, the response in the United States has been minimal. Despite the obvious need for assistance to families who provide extensive informal care to adults who are aging, there are no financial supports unless the individual receiving care is a dependent of the caregiver, in which case the usual personal tax exemption applies. The only federal law that assists those who provide informal care is the Family and Medical Leave Act of 1993 (FMLA). The first legislation passed by the Clinton administration, it had been rejected during the earlier Bush administration as too demanding of business. The law provides that full-time workers may take up to 12 weeks of unpaid leave in any calendar year to meet their own “serious” health condition

needs or those of an immediate family member (spouse, parent, or child under 18). Worksites with 50 or more workers located within a 75-mile radius are covered. Health benefits for their employees are continued during leave, and their job return to the same or a similar position is guaranteed. Advance warning, when possible, is required, but leave may be taken without notice and in increments of less than a full day, depending on circumstances. Employees may have to liquidate any accrued leave against the allowed 12-week leave period. Employees may be asked to provide medical evidence of the need for leave. Employers may request that employees submit to a medical examination. Employers’ top 10% of earners may be excluded from the Act’s protection at the discretion of the employer. Claimed denial of any right covered by the law can be filed for review at the nearest office of the Employment Standards Administration of the Wage and Hour Division of the U.S. Department of Labor (U.S. Department of Labor, 1995).

The Act publicly recognizes the impact of caring and is a great stride forward in social policy. Its requirements put employers on notice that society expects them to adopt reasonable policies to support employees in caregiving roles. Continuing health benefit coverage and a guaranteed right of job return certainly help reduce the stress that an employed caregiver is likely to experience in a crisis medical situation. The right to leave on an intermittent basis recognizes caregiving realities and the need to balance work and the demands of aged family members.

These are all-important protections and are among the conditions necessary to promote the well-being of employed persons, but they are not sufficient conditions to assure employee/caregiver well-being. The fact that the law’s requirements apply only to employers of 50 or more employees eliminates almost half the workers in the United States, who work for smaller employers. Noteworthy is the fact that smaller employers tend to pay less and offer less extensive benefit structures, so that employees of small employers experience double jeopardy. They have less money to purchase care than their counterparts who work for larger employers, and they have no job protection if they take time to provide the care themselves. In addition, specified relationships do not include in-laws or friends, both groups who receive a great deal of actual attention from working caregivers (Medjuck, Keffe, & Fancey, 1998).

The fact that the leave is unpaid, however, is the legislation’s greatest deficit. Those who cannot afford to purchase formal caregiving are probably the most

in need of leave for family medical emergencies. Most can ill afford to miss even a day's pay, let alone lose income for an extended period. Thus, they have a right that they cannot afford to exercise. There have been suggestions that unemployment funds should be used to cover associated leaves or that other provision be made for paid leave, but none of these recommendations have been adopted. Several states and municipalities have laws with more generous protections, but these are far from universal. New York, New Jersey, Rhode Island, California, and Hawaii have state laws providing financial coverage when the employed person requires personal disability-related leave. Nowhere can one find paid leave to provide care to a family member who is aged.

There is also a more subtle problem in assuring the benefits promised by the law. Anecdotal evidence suggests that workplaces can have a culture that, while it does not deny the benefits of the Act to those who seek to use them, discourages access to those benefits in both clear messages and suggestive behavior. Most employees in such settings understand and abide by these suggestive statements and give up their right to the benefit supposedly guaranteed by law (Akabas & Kurzman, 2005; Medjuck et al., 1998). Other workplaces have established policies that require employees to use any leave to which they are entitled before they utilize unpaid leave, with all leave counting toward the 12 weeks allowable under FMLA. The law permits employers to exercise this policy, although it seems to abrogate the intent of the legislation, and effectively deny employees the right to vacation, since for most workers the only accrued leave they have is vacation time. These problems have been identified in research studies and anecdotal evidence (Akabas & Kurzman, 2005). The law has not been the subject of amendment in the 12 years since its passage, suggesting a lack of society's commitment to recognize the contribution of the informal care provided by those who work.

Employers' responses. Employers are concerned about the bottom line. They are aware that well-motivated employees are instrumental to profitability. Maslow (1943/1974) suggests that motivation is related to a hierarchy of levels of satisfaction in which self-actualization is the pinnacle. Enlightened management that addresses and meets the needs of workers that are lower on the hierarchy will be rewarded with workers who reach the top hierarchical level, that is, self-actualizing workers who are motivated to do their best work without prodding. Herzberg (1987) points out that there are hygiene factors, such as pay, that are required to keep employees working, but it is neces-

sary to offer other forces to motivate employees to maximize productivity. Conditions that promote feelings of being valued are positive motivators. The successful workplace is one that achieves full motivation from all its employees. Distractions from employees' focus on productivity become employers' concerns.

As trends indicate, since those most likely to take on caregiving responsibilities are women, the general demographics of the company become important. An employer with a majority of female employees over 40 years of age will have greater need to respond than one with a largely male, and/or younger workforce (Gresing-Pophal, 2003). If the employees are largely baby boomers, the expectation is that caregiving for their older parents will increase, causing absenteeism to rise and job performance and satisfaction to diminish. For example, a study among deans of schools of social work found that caregiving affected organizational effectiveness. Deans who participated in the survey identified that caregivers missed obligations for covering classes, attending meetings, and carrying out scholarly research. There was evidence of chronic stress through requests for leaves and delays toward tenure and search for support from other colleagues (Robinson et al., 2003).

There is enough basis for concern to cause employers to deal with eldercare issues, that is, to provide a benefit structure that removes or mitigates obstacles to employees' ability to concentrate on work schedules and productivity (Lambert, 1993). The ambiguity of outcome in the face of caregiving demands, that is, the fact that caregiving is stressful but satisfying, clarifies the potential value to employers for acting to neutralize the negative impact of caregiving on the employed caregiver's behavior. Although they may feel that it is an employee's responsibility to solve caregiving problems, employers would rather help with these problems than be ordered to do so by government, or lose a valuable employee's services to these problems.

The challenge faced by workplaces is to develop the mechanisms of support. Employee assistance programs (EAPs), membership assistance programs (MAPs), and family/work programs constitute the structure for providing policy and service in the workplace to respond to the consequences of caregiving on employment. Offering these programs confirms employers' awareness of this reality. Employee assistance programs exist in most medium- and large-scale workplaces and are often available to employees in relatively small companies. A 1995 survey found that 82.3% of all companies with over 1,000 workers

had an EAP (Cohen, Gard, & Hefferman, 1998). Employee assistance programs, and related MAPs in unions, were first established in a few very large corporations in the 1940s in order to deal humanely with workers with alcoholism problems. It became clear that the mechanisms for helping employees resolve issues related to substance abuse could be applied to other presenting problems as well (Caldwell, 1993). Employee assistance programs have become widespread as the first line of defense in meeting the varied needs that employees may present that threaten to interfere with their ability to maintain job performance. As services expanded to respond to a more varied menu of needs, trained professionals were introduced to the staffing pattern. Increasingly the programs were staffed by mental health professionals, with social workers in the majority (Akabas & Kurzman, 2005; Kurzman, 1993).

With the rise of dual earner and single parent families, employers discerned that caring for family and work were frequently in conflict, resulting in stress and burnout of the employee, followed by lowered production, increased absenteeism, and high job turnover (Spillman & Pezzin, 2000). Although EAP/MAP initiatives remain dominant, some solely work/family initiatives have emerged, to apply a policy analysis to the problems that arise, and to implement responsive practices. Today these programs take many forms. Some employing organizations have in-house staff who, through EAPs, cover the gamut of needs, including work/family situations that employees may present, and offer information, referral, and even counseling on-site to resolve the problem that endangers productivity (Anonymous, 1994). At the other extreme, corporations may contract with two separate outside service providers. A general EAP acts as gatekeeper to carved-out managed care mental health benefits to deal with generic problems, while a work/family referral service offers intake interviews that identify need, and then assigns a care manager to suggest resources in the community to assist with the identified need or to offer advice on how to manage the complex situation that presents itself. Between these two extremes, there are varied patterns for providing coverage, but almost all initiatives include a response to the competing demands of employment and the care of parent or spouse that may interfere with full attention to work. Many unions, through MAPs and other collectively bargained contract provisions, have mirrored the structures established by employers, though their motivation is membership loyalty rather than productivity.

The employers' interest in minimizing, or eliminating, if possible, any disruption in the employees' job performance suggests the value of prevention (Robinson et al., 2003). Caregiving often occurs as an unexpected, crisis event that is transitory in the work life of an employee, although it may not necessarily be short-term (Faight, 1998; Lefkovich, 1992). Through educational seminars, eldercare fairs, and distribution of informative written material that provide information on public benefits, the availability of care management services, help with household tasks, home health care resources, how to secure Meals on Wheels and other in-home care, and selection of nursing home and other long-term care facilities (Grensing-Pophal, 2003; Parus, 2004; Scott, 2002), the EAP/MAP or the specialized work/family initiative can prepare the labor force to identify the signs of a potential need. The expectation is that once alerted, an employee will recognize the need at the onset of a problem and act to assure his or her own continuous and seamless maintenance of productive employment. Notably, these services become extremely important when an employer hopes to relocate a caregiver, or when the concerned employee lives at a distance from the older adult in need of care (Sunoo, 1997).

Add-on services can include continuing support groups for caregivers. Increasingly, work organizations offer policies that allow for reduced quantity of work, hoping that thereby the quality of performance will be sustained. Arrangements for flex-time, telecommuting, job sharing, and other work schedule adjustments are the most valued (Dunham & Dietz, 2003; Lefkovich, 1992). In organized settings, these services may be offered by labor/management partnerships ("Labor/Management Partnerships," 1992). The gamut of services is based on a realistic understanding by cost-conscious corporate financial officers of the costs of loss from work, attrition, displaced careers, and other negative factors (Faight, 1998).

Union responses. Unions are concerned about the well-being of members and build membership loyalty by attending to their needs (Dunn, 2000). The AFL-CIO Web site notes that "workers who care for elderly relatives have an average loss over a lifetime of more than \$600,000 in wage, pension, and Social Security benefits." Not surprisingly, the AFL-CIO has defined eldercare as a significant issue ([AFL-CIO], 2001). They advise unions to bargain for eldercare during contract negotiations. As a result, many organized workers are covered by benefits that relate to the issue of employment while caring for older adults. For example, by contract the United Auto Workers at

General Motors are provided with a 24/7 Elder Care Response Line, where 24 qualified care managers provide personal consultation, educational materials, and individualized referrals and are also available for home assessment of eldercare needs. The International Union of Electricians, in their contract with General Electric, secured a flexible spending account that allows all employees to set aside up to \$5,000 per annum, tax free, to pay for eldercare-related expenses. The San Francisco Multiemployer Hotel Group has agreed with the Hotel Employees and Restaurant Employees Union, Local 2, that the group will deposit 15 cents per worker per hour to a fund from which members can draw up to \$150 per month for nonreimbursable expenses related to health needs of spouses, parents, in-laws, grandparents, or the members themselves. Finally, the California State Employees Association, the Service Employees International Union, and the State of California have contractually provided that employees may make donations of their own leave to be drawn on by fellow employees facing financial hardship due to illness of self or a family member, with the employer bearing the cost of administration of the provision.

SOCIAL WORK ROLES

The need to resolve the conflict between employment and the demands of caring for an aged adult is important now and can be expected to grow more so in the near future. Social workers can find many significant roles in promoting this agenda at the individual, organizational, and community level, both within workplace settings and in their own practice as self-employed therapists, in agency settings, and in government policy positions. A good starting point would be for social workers themselves to become more aware of the significance of work in people's lives and the importance of support systems that can help those who work maintain their work role, regardless of the other roles they carry.

Individuals need information on resources and entitlements, help thinking through how they wish to manage their multiple demands, encouragement to engage in self-advocacy at the workplace to negotiate the conditions necessary to succeed at both roles, referral to community resources that can fill any gap between the care they can offer and the care that is needed, and ongoing support from case managers who know local facilities. Social workers can incorporate financial and health education in their counsel-

ing activities, so that people are better prepared to deal with their own old age, as well as the aging of those who are dependent on them for care.

Work organizations need assistance in becoming more sensitive to the problems involved in managing eldercare and work. Social workers can help business and union settings develop policies that maximize flexibility, train supervisors to be empathetic and structure a supportive workplace culture, build communication systems that assure the flow of information necessary for workers to know their rights and entitlements, and then exercise them, and utilize corporate philanthropy to make contributions to community services that help caregivers. Social workers can also encourage community social services to be more responsive to the needs of women.

Ultimately, there is a need for a public redefinition of responsibility, so that care is not an informal effort, with women as the assumed providers. Government must act to provide and finance formal institutions that can share the caregivers' burdens. Social workers can do the analysis needed to inform public policy decisions and use community organizing skills to lobby for policies that might revise Medicaid requirements of indigence, support Social Security credits during periods when women "drop out" to provide care, so they are not penalized for their unpaid contribution to society; offer tax incentives to businesses to support caregiving employees; and do so in a gender-neutral manner, so that men and women can begin to share, more equally, the demands of giving care to their parents and other aging relatives.

In a telling remark, an IBM communications director summed up the importance to employers of initiatives that assist employees with meeting the care needs of older adults: "such policies are not merely altruistic, but an 'absolute business imperative.' . . . If we do not build flexibility into the way we work then we are going to turn our back on half of the workforce" (Centaur Communications Limited, 2003, p. 8). That seems to say it all.

Substance Abuse Networks

44

Older adults are the fastest growing segment of the U.S. population and, in health and social services settings, are frequently characterized by the nature of their more prevalent acute and chronic conditions and higher utilization of health care services than the population at large (see Gonyea, Hudson, & Curley, 2004). A significant proportion of older adults experience mental health disorders as well, for example, they have the highest suicide rate of all age groups (U.S. Centers for Disease Control, 1999). In the case of suicide, alcohol and other drugs may be a precursor of suicide and even the cause of the death. Yet older Americans continue to be among the lowest utilizers of mental health and substance abuse/dependence services.

While services targeted to this population are limited (Cummings & Bride, in press), there is a pressing need to address new cohorts of older adults, whose patterns of substance use and abuse are more intense than those of previous generations (e.g., the baby boomers who will turn 65 in 2011). In addition, differentiating early-onset alcoholism and late-onset alcoholism and its impact (McGinnis-Dittrich, 2002) is critical (e.g., late-onset alcoholics are less likely to see their alcohol use as a problem). Further, defining what constitutes “problem drinking” is controversial, since older adults may not demonstrate the more prominent impairments seen in younger populations, such as financial and/or occupational challenges. Instead, the health impacts (e.g., increased falls; high blood pressure; memory loss) may be masked and only treated symptomatically (McGinnis-Dittrich, 2002).

This chapter addresses the epidemiology of substance abuse in older adults, including discussion of the accompanying challenges of diagnostic validity and assessment issues, and an overview of treatment settings.

EPIDEMIOLOGY AND DIAGNOSTIC VALIDITY

The treatment of alcohol and substance use disorders in the older adult is inherently tied to the assessment procedures used to diagnose these disorders and the segments of the population found to manifest these problems. In other words, *how* and *where* these disorders are identified influence the *ways* they are treated. The next section presents the prevalent characteristics of substance use disorders among the subpopulation of older adults, and the challenges of identifying older

adults with these disorders are discussed in the section thereafter.

Epidemiological Studies

Epidemiological studies to date have largely ignored issues of mental disorders in the elderly by excluding older people from the sampling frame, presumably because of the difficulty of separating psychiatric problems from the physical disorders that become more common with age (Hybels & Blazer, 2002; Lynskey, Day, & Hall, 2003). Other studies report sweeping age ranges (e.g., “over the age of 35”) that make conclusions about specific periods of adult development difficult to determine. Findings across studies are often difficult to compare, due to inconsistent definitions of alcoholism (Fingerhood, 2000; Lakhani, 1997). Related to exclusion from study, age reporting, and inconsistent definitions are issues of diagnostic validity that will be discussed later in this chapter.

With regard to specific substance abuse disorders listed in the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV; American Psychiatric Association, 1980), the Epidemiological Catchment Area Study (ECA) stands as the landmark survey for addressing mental disorders among community- and institutional-dwelling older adults in the United States (Hybels & Blazer, 2002; Robins & Regier, 1991). When 12-month prevalence for alcoholism was examined, 3.1% of men over the age of 65 and 0.46% of women met criteria for diagnosis of alcoholism in the past month. Rates steadily decreased among all age categories, with men reporting higher rates than women. Among ethnic groups, Hispanic men over the age of 65 showed the highest alcoholism rates (6.57%), while Hispanic women reported no alcoholism. Whites reported rates of 2.85% and 0.47% for men and women, respectively. Comparable rates were found for older black men and women at 2.93% and 0.60% (Helzer, Burnam, & McEvoy, 1991). Lifetime illicit drug use for this cohort in the ECA was remarkably low, with men reporting 2.88% and women 0.66%. (Anthony & Helzer, 1991).

Although there is scant information on prescription drug abuse among older adults, there is evidence that it often accompanies alcohol disorders and is more common among women (Finlayson & Davis, 1994). The use of benzodiazepines (e.g., Librium, Valium, Xanax) has been associated with automobile accidents, falls, and lower functional status (Hem-

melgarn, Suissa, Huang, Boivin, & Pinard; Neutel, Hirdes, Maxwell, & Patten, 1996; Ried, Johnson, & Gettman, 1998).

Recent studies comparing the National Institute on Alcohol Abuse and Alcoholism’s (NIAAA) surveys in 1991–1992 and 2001–2002 confirmed the trends discussed here (Grant et al., 2004). Within the two surveys, successively older age groups reported decreasing rates of DSM-IV abuse and dependence compared to the younger groups. However, comparisons of the 65-plus age across the 10-year period showed significant increases in alcohol abuse, from 0.25% to 1.21%. This increment was shown for men as well as women, with men showing steeper increases. However, the prevalence of alcohol dependence for the older age group decreased during the 10-year period (from 0.39% to 0.24%), but the decrease was not significant.

While higher prevalence of alcoholism is typically observed in younger adults within the community, this does not mean that drinking in older adults is insignificant. An analysis of Medicare records revealed that hospitalizations for disorders related to alcohol use were as prevalent as those for heart attacks and carried significant costs (Adams, Yuan, Barboriak, & Rimm, 1993). In addition, clinical literature dating from the 1980s suggests that some individuals actually increase their consumption as they age. Within this group, increased consumption may be reactive to age-related stresses such as retirement, widowhood, disability, and other types of losses (Atkinson, Turner, Kofoed, & Tolson, 1983).

Diagnostic Validity and Difficulties in Assessing Substance Abuse in Older Adults

The defining characteristics for alcoholism may not be consistently meaningful or significant across age groups. In other words, *diagnostic validity* may not be congruent: the presence or absence of certain symptoms may not uniformly predict the presence, course, or outcome of substance use disorders across the lifespan. General criteria from the *Diagnostic and Statistical Manual of Mental Disorders* (American Psychiatric Association, 1994), for substance abuse and dependence were formulated with a younger adult population in mind, presumably those most likely to seek help from mental health professionals. For example, DSM-IV (1994) criteria for substance abuse that rely heavily on disruption of role function, financial sta-

bility, and social networks may not be obvious or appropriate for those older people with limited family and work responsibilities and fewer social connections. Further, many professionals are unfamiliar with existing screening instruments outside of specialized treatment settings (see chapter here for more on specific instruments).

Clinical guidelines, such as the standard for excessive drinking of more than two drinks a day for men or one for women, may also not be valid for an older population with limited discretionary income, increased sensitivity to alcohol, and reduced efficiency in metabolism due to cooccurring physical problems (McCracken, 1998; Moore et al., 1999). While alternative diagnostic schemes have been proposed based upon the interaction of alcohol with cooccurring disease, associated medications, and altered ability to function in daily life (Fingerhood, 2000; Moore et al., 1999; Scott & Popovich, 2001), *DSM-IV* (1994) criteria remain predominant in determining how alcohol problems are identified and subsequently how routes for treatment are opened.

Recognition of substance abuse disorders are also hindered by ageist assumptions held by clinicians and the larger society. While older people tend to visit primary care providers regularly, they do not actively seek or receive treatment for their mental health concerns (Bartels, 2003; Whelan, 2003). This lack of attention to mental health is compounded with substance abuse concerns because of clinicians' assumptions that long-term substance users do not survive into old age (Atkinson, Ryan, & Turner, 2001), that such disorders do not arise in later adulthood, and that older adults show the same symptoms and patterns of abuse and dependence as younger people.

In addition, many older adults prompt the attention of family members and ultimately the health care system for issues that do not immediately suggest problematic substance use. For example, falls, injuries, confusion, neglect, depression, memory loss, emotional lability, sleep disturbances, and adverse drug interactions may be attributed to chronic medical conditions, dementia, or the consequences of aging rather than alcohol use (Egbert, 1993; Eliason & Skinstad, 2001; Graham & Schmidt, 1998; Klein & Iber, 1991). Beginning solutions to these problems include education, both for the older adults who are typically interested in health promotion (Fink, Beck, & Wittrock, 2001) and for providers to increase their sensitivity to older individuals' substance abuse issues (Coogole, Osgood, & Parham, 2000). Careful and consistent screening of the older individual's intake of

substances, consideration of chronic health conditions and medications that may have negative interactions with substance intake, and investigation of falls, memory difficulties, and other functional problems that may suggest substance abuse will point the way to more efficient problem formulation and referral to treatment resources.

SUBSTANCE ABUSE NETWORKS

The screening, assessment, and treatment of substance use disorders may take place in a variety of settings. The screening typically occurs in settings not commonly considered the "substance abuse service network" (such as the workplace and medical-related settings), while the assessment and treatment are part of the mission of the "substance abuse service network." In actuality, all of these services comprise the "substance abuse service network," because *screening and identification* (addressed in the first part of this section) must precede *assessment and treatment* (the second part of this section). However, treatment of substance abuse disorders is the focus of what is commonly referred to as the "substance abuse service network." This network of services consists of various types of settings that utilize various interventions and approaches.

Accessing treatment through these settings is typically congruent with the life stage, health and mental status, and economic status of the older adult. For instance, many older persons who are employed may have their behavioral health needs addressed through an employee assistance program or an occupational health service. On the other hand, those who are unemployed or retired may access behavioral health services (e.g., as comorbid conditions) through primary care facilities or specialty treatment physicians. Still others may access services for substance use disorders through community faith-based programs. Older veterans have traditionally accessed the substance abuse service network designed specifically for veterans, and other older persons might utilize community-based public health, mental health, or substance abuse treatment programs. An overview of primary treatment settings follows.

Screening and Identification

Because older adults are less likely to be involved in the traditional substance abuse service network,

screening needs to take place in the settings in which they interact regularly—the workplace and the offices of health care/social service providers.

Employee assistance programs and occupational health programs. Employee Assistance Programs (EAPs) are designed to assist workers who may have personal concerns that may impact job performance or, conversely, to assist workers whose job performance has deteriorated. In this setting an assessment is conducted to determine the nature of the problems and make referrals for appropriate treatment. Especially with older workers, social workers in this setting need to be sophisticated in their understanding of the presentation of substance use disorders, age-related cognitive deficiencies, psychiatric disabilities, drug interactions, and the interrelationship between all of these comorbid conditions.

In conjunction with the EAP, another initiative of today's workplace is the maintenance of a drug-free workplace. It is estimated (Center for Substance Abuse Treatment [CSAT], 1998) that about 17% of adults age 60 and older abuse alcohol and/or legal drugs, prescribed and over-the-counter, and that approximately 50% of older adults use these drugs in combination with alcohol (CSAT, 1998). Many of these older adults are employed and work in environments that utilize routine, random, or for-cause toxicology screens. Depending on the substances used or misused, and their impact on the behavioral and cognitive functioning, older workers may find it difficult to continue working in a drug-free environment (CSAT, 1998). It may be this dynamic that will identify them as having a substance use disorder worthy of treatment.

The workplace, via the EAP or occupational health medical unit, typically refers a worker to treatment. Therefore, the EAP may serve as a gatekeeper or point of entry into the substance abuse service network for workers. Referral decisions are typically made based on individual client needs. However, despite the fact that studies have shown that older adults are more likely to respond to and complete treatment for substance abuse disorders when such treatment is designed specifically to address their needs, either as a separate treatment track in a mainstream setting or in an entirely separate program (CSAT, 1998), most treatment programs are not designed with the needs of older adults in mind. The reality is that very few of these types of programs exist. Since it is expected that in the next few decades a growing percentage of the workforce will be comprised of older workers, it will be necessary for the workplace, along with its influ-

ence on the managed care health delivery system, to address the treatment needs of older workers if it wants to maximize the efficiency of health care costs spending, and if it wants to retain older workers as employees.

Primary care and specialty care health providers. Older persons have more contact with primary care physicians than any other health care providers ("Treating Elderly Patients: Primary vs. Specialized Care," 2000). Because many older adults are concerned about their health and receive health care regularly, this setting is ideal for such screening—especially since many of their health problems may be substance related. For instance, a study by Adams (2002) found that Medicare is billed for alcohol-related hospitalizations among elderly patients as commonly as for acute myocardial infarction. On the other hand, mental health and substance abuse problems are not likely to be identified during routine office visits because the focus is typically on the presenting medical issue, not necessarily issues of substance use that may have caused or exacerbate those medical conditions. Furthermore, office visits have become increasingly short, and many providers are not trained to screen for such disorders ("Treating Elderly Patients: Primary vs. Specialized Care," 2000).

On the horizon is the growth of programs such as the Older Adult Substance Abuse Program of the Broward County (Florida) Elderly and Veterans Services Division. Multiple levels of care are targeted to persons age 55 and older, including a substance abuse prevention curriculum, outpatient services (both individual and group), and aftercare (S. Ferrante, personal communication, June 6, 2004). Brief screening, intervention, and treatment for a variety of conditions (alcohol abuse, medication misuse, illicit drug use, depression, anxiety, and suicide risk) was initiated in 2004 in collaboration with aging and health care providers. In addition, a pilot project on compulsive gambling among older adults is in process, in partnership with the Florida Council on Compulsive Gambling; gambling as an addiction among older adults is a growing concern and can be linked with alcoholism.

Assessment and Treatment

Assessment of the elderly presents special challenges because of their life stage circumstances, which may put them at risk of developing depression, anxiety, and substance abuse problems. While transitions such as retirement and widowhood may offer expla-

nations for abusing substances, this should not minimize the need for treatment. Quite the contrary, they need to be considered in developing a treatment plan.

The treatment for substance use disorders for the elderly depends on a variety of variables. For instance, studies of managed care organizations (MCOs) (Garnick et al., 2002; Lish et al., 1995) found that few MCOs require alcohol, other drug, or mental health screening by primary care physicians, and that despite the availability of effective treatments, most individuals who had cooccurring mental health and substance use disorders were not receiving effective treatment. These studies noted the need for more systematic screening and more of a focus on strategies that increase the delivery of effective treatment. This is especially important, since treatment is no longer a monolithic modality that takes place in a substance abuse-specific setting.

A nationwide study funded by the Substance Abuse and Mental Health Services Administration (SAMHSA) (2000) that started in 1998 was designed to answer the question: Do older people with mental health and substance abuse problems do better when they receive treatment for these disorders within a primary care setting or when they receive referrals for specialized treatment? This study found that minor mental health problems and patients with mobility problems may be more responsive in a primary care setting. On the other hand, the study found that some patients require the more intensive services of specialized settings.

In recent years, treatment modalities attempt to address the needs of and differences among subgroups. For instance, gender-specific treatment takes into account the unique needs of women. Similarly, there are attempts to identify and address the needs of “elder-specific” or “age-specific” treatment (CSAT, 1998). In these programs, older patients as a group are in a specialized treatment setting that is entirely age specific, or they may be involved in age-specific treatment groups within a mixed-age mainstream treatment program. The results of effectiveness are mixed. In general, it has been found that older patients do just as well as younger patients in age-integrated programs (Blow, 2000).

It appears that as with all patients, treatment outcomes are most effective when the multiple and unique needs of patients are considered. However, substance abuse treatment providers must have knowledge of the age-specific needs of older adult patients and their circumstances, in general, as well as an assessment and understanding of the unique needs

and circumstances of each patient. Such treatment must also include building support for persons at risk using community-based treatment and referral, with long-term follow-up and services to pertinent family members and significant others. Although they are beyond the scope of this chapter, there are additional considerations in working with persons who abuse or are addicted to multiple substances and in addressing those persons who may also have a psychiatric history. Access to care and follow-up for those with multiple treatment needs is often inadequate and sometimes inappropriately provided.

While it is beyond the scope of this chapter, there are several components in the continuum of approaches that are essential in addressing the growing issues related to substance use disorders in older adults. First, *prevention* is key. Throughout the various networks where older adults are involved (see Corley, Takamura, & Siegel, 2004), there are opportunities to highlight some of the important problems that can arise from misuse/abuse of alcohol and other drugs. *Intervention* is critical in breaking through the denial when an older adult is identified by family members, coworkers, and/or others who are compelled to find pathways to help, yet this is understudied and often ends up happening as a result of an emergency room visit or other crisis. *Relapse prevention* is an additional element of the continuum receiving continued attention (e.g., Barrick & Connors, 2002; Corley, Lawton, & Gray, in press) and is important in promoting the overall well-being impaired older adults.

CONCLUSION

In spite of the growing numbers of older adults in the United States, and a more prominent history of substance use disorders in their incoming cohorts, service delivery systems and their providers are not well equipped to address the needs of older adults with substance dependence disorders. On the national level, SAMHSA has made available a comprehensive “Toolkit” (Michaud, 2004), and older adults with substance use disorders are considered to be a priority population. The National Association of Social Workers’ special section Alcohol, Tobacco and Other Drugs (ATOD) was initiated by a group of SAMSHA-funded faculty fellows in the 1990s, some of whom addressed issues of older adults in bringing more substance abuse content into the social work curriculum. The American Society on Aging (2005) offers a

series of seven modules that are user friendly and informative, in a free Web-based training, *Alcohol, Medication and Other Drugs*. These are promising approaches to broaden awareness and increase knowledge of substance abuse/dependence among social workers serving older adults.

Although most health education programs focus on younger drinkers, older adults are receptive to health promotion programs that present alcohol information tailored to their social contexts and specific health issues (Fink, Beck, & Wittrock, 2001). An approach that incorporates motivational strategies “that draw on motivational interviewing principles and a client’s motivational readiness to change” (Hanson & Gutheil, 2004, p. 364) is an example of how social workers can incorporate essential skills in identification of older adults with substance abuse/dependence and help them to get into, and stay in, treatment.

Networks and services for older adults with substance dependency reflect the larger challenges of the lack of continuity of care in the field of aging at large (Corley, Takamura, & Siegel, 2004). In the case of substance abuse, the flow of services is complex, including: screening, assessment, intervention, treatment, relapse prevention, and support for long-term recovery (see Corley et al., in press). Since older adults in any kind of treatment setting are most likely to present with medical issues, the social, financial, legal, and spiritual challenges that bring younger persons into treatment settings for substance abuse are less likely to be recognized. It is often family members who bring their older relatives into treatment, again, more typically when a health crisis is the precipitating event, and family members may not recognize or want to admit the role that alcohol and other drugs (prescription or otherwise) may play in the larger picture. Social workers are well poised to serve as liaisons with other health care providers, particularly as they are noted for their expertise on the interdisciplinary team in assisting older adults and their families when transitioning across levels of care (Damron-Rodriguez & Corley, 2002).

It is imperative for social workers in all settings to be familiar with the signs and symptoms of substance use disorders, the complexities of assessment and diagnosis given the variations of presentation in older adults, and the critical need to provide appropriate services to older adults and their families across the continuum of care. Promoting research on the prevalence and cooccurring disorders among the nation’s older adults who are increasing in number and diversity is imperative. In the larger picture, social workers

must be part of research teams where gaps in data on the prevalence of substance use disorders can be examined, and where evidence-based practice can be identified to increase the availability and accessibility of services along the continuum of care tailored to the growing and diverse needs of older adults.

SECTION **IB**

**Social Service Resources Available
Through Community Settings**

This page intentionally left blank

OVERVIEW

In this section, our focus shifts from community settings to the services provided in those settings. As in the previous section, each chapter examines the legal basis of social work practice, as well as the population served and the roles filled by social work professionals. Culturally relevant practice is a recurring theme.

With the growth of the older population has come increased demand for case management or care management services. Matthias Naleppa offers a detailed look at case management as a venue for social work practice. He discusses the national demonstration projects that have served as the proving grounds for case managers and then highlights the tension over who “owns” case management. The chapter then turns to a description of this practice modality and the services typically accessed by a professional care manager.

Leah Ruffin and Lenard Kaye examine the role of counseling services and support groups in helping the elderly maintain active and engaged lives. This chapter offers a careful description of both treatment groups and support groups, highlighting the positive philosophy that is reflected in these interventions.

Sandra Crewe and Sandra Cipungu describe services designed to support those who care for older adults. Their chapter reviews the social and demographic trends affecting caregiving, which is described primarily as a family matter. It then offers a profile of family caregivers and examines the special concerns of minority and immigrant groups in the United States. It closes with a valuable discussion of the programmatic resources now in place to support family caregivers.

Jordan Kosberg, Max Rothman, and Burton Dunlop consider services that provide advocacy and protection to older adults, including the ombudsman program, adult protective services, and services provided in legal settings. Their chapter highlights the numerous opportunities for social workers to serve as advocates for older adults, both within and outside their formal job responsibilities, and argues that these opportunities will increase in coming decades.

Judith Gonyea describes housing services available for older adults, noting that shelter is a basic need and describing the programs designed to meet that need. The chapter notes the role of income disparities in determining the housing options available to seniors and uses the concept of “environmental press” to argue that “goodness of fit” is an appropriate yardstick for determining the quality of a housing setting for adults with disabilities. She places the profession of social work squarely in the middle of housing decisions, arguing that our assessment skills and commitment to serving vulnerable populations leave us well positioned to improve the way the nation’s seniors are housed.

Bradley Zodikoff offers an overview of services for lesbian, gay, bisexual, and transgender (LGBT) older adults. He examines broad considerations, such as the difficulty in providing an accurate description of this population and the special concerns of LGBT older adults. The chapter then describes available services throughout the country and offers practice guidelines for social workers serving this group.

Charles Emlet and Cynthia Poindexter consider social work practice in settings that serve HIV-infected “or affected” older adults. In an eye-opening discussion, these authors describe the growing number of older Americans who are experiencing HIV/AIDS and the system of care that minimally addresses their needs. This system is authorized under the Ryan White CARE Act, the Older Americans Act, and home- and community-based Medicaid waivers. These authors call for improved coordination between the aging and HIV service organizations, even while noting that it is unclear how this is to be achieved.

Once again, these chapters reflect the diversity of social work roles and emerging opportunities for our profession. As our nation prepares to meet the challenge of an aging population, the traditional tools of social work practice should serve us in good stead. Social work professionals bring a unique perspective to assessment of human needs and a commitment to social justice that is sorely needed in today’s market-driven environment.

Case management, also referred to as care coordination or service management, is a process commonly characterized by a series of activities undertaken to address a client's lack of resources and required services. This section will provide some basic information on case management, primarily focusing on services frequently accessed and coordinated by geriatric case managers working with older adults in community settings.

MODELS OF CASE MANAGEMENT

Case management can be defined as a

method of providing services whereby a professional . . . assesses the needs of the client and the client's family, when appropriate, and arranges, coordinates, monitors, evaluates and advocates for a package of multiple services to meet the client's complex needs. . . . Case management is both micro and macro in nature; intervention occurs at both the client and system level. (National Association of Social Workers [NASW], 1992, p. 5)

Case management consists of a series of activities that a case manager undertakes together with clients and, in many cases, their caregivers. Core functions of geriatric case management typically include access to the case management program, screening, a thorough multidimensional needs assessment, the development and coordination of a care plan, access and linkage to the required resources, monitoring of the services coordinated, and a regular reassessment (Austin, 2001; Austin & McClelland, 1996; Rothman, 1994). Additional case management tasks often include resource indexing, interagency coordination, advocacy, and collection of data on practice outcomes (Naleppa & Reid, 2003; Rothman, 1994). Clinical case management should be considered a key intervention approach in gerontological social work (Morrow-Howell, 1992).

An extensive range of geriatric case management models exists and has been tested and evaluated during the last three decades. In her comparative analysis of community-based case management models, Hyduk (2002) classifies programs into service provider-initiated models and demonstration models. Examples of service provider-initiated models include health maintenance organization (HMO) case management, community-based long-term care (CBLTC), outpatient geriatric evaluation and man-

MATTHIAS J. NALEPPA

Case Management Services

45

agement (GEM), postacute case management, and physician practice case management (Hyduk, 2002).

Demonstration projects were created as a response to problems in the service delivery system that included structural fragmentation, duplication and discontinuity of services, and lack of integrating mechanisms. Single-service responses (e.g., acute medical care, skilled nursing facilities, or home health services) alone could not solve the growing problem, which led to the development of several system alternatives of structural integration (merging funding and services into a single system) and service integration (referral systems, care coordination, and case management). A waiver program established through the Omnibus Budget Reconciliation Act of 1981 made it possible to combine health care, personal care, and case management costs (Quinn, 1993). Examples of waiver demonstration projects include the On Lok project in San Francisco and its successor projects (i.e., the Program of All Inclusive Care for the Elderly [PACE]), the Multi-purpose Senior Services Project (MSSP) in California, and the Nursing Home Without Walls project in New York state. Another set of demonstration projects, the National Long-Term Care “Channeling” Demonstrations, were started in 1980 by the federal government in an effort to direct services to elderly persons who were considered at high risk for entering a nursing home. Two types of channeling projects were implemented. In the basic channeling model, case managers were considered brokers of services, that is, their primary responsibility was to assist elderly clients to access and coordinate services. The financial channeling model, on the other hand, applied pooled funding and financial caps (Applebaum & Austin, 1990).

Another demonstration project, called the Social Health Maintenance Organization (S/HMO), began in the mid-1980s. These organizations were created through the Deficit Reduction Act of 1984 (Applebaum & Austin, 1990; Quinn, 1993). Differing from many other demonstration projects, the S/HMOs incorporated acute and long-term care and covered elderly clients with all levels of functioning (Abrahams, Capitan, Leutz, & Macko, 1989). All of the demonstration projects incorporated some form of case management (Applebaum & Austin, 1990; Zawadski, 1984).

PROFESSIONAL ORIENTATION AND ROLES OF CASE MANAGERS

While there has been some debate between the social work and nursing professions in the past over the

“ownership” of case management, social work, nursing, and other health care workers are the primary professional reference groups of case managers. Most geriatric case managers today are either licensed social workers or nurses; however, licenses are currently not required in all states (American Association of Retired Persons [AARP], 2005). The educational level of geriatric case managers ranges from no degree to doctoral degree. This variation has an impact of the array and quality of tasks that are performed. For example, nonprofessionals are not suitable to carry out certain case management activities, such as clinical counseling or direct care tasks, and concern exists whether even bachelor’s level education is adequate to carry out the range of responsibilities with sufficient expertise (Schmid & Hasenfeld, 1993). Research by the American Association of Retired Persons (AARP, 2005) found that the professional reference group can impact on the types of tasks performed by a case manager. The social work case managers were found to be more likely than nurse case managers to include family counseling (84% vs. 58%), while they were less likely to assess clients’ health status (62% vs. 94%).

A survey of the members of the National Association of Professional Geriatric Care Managers (NAPGCM) indicates that approximately two-thirds of geriatric case managers hold a master’s degree (AARP, 2005). The two largest professional groups providing geriatric case management were licensed social workers (37%) and licensed nurses (30%). Several credentials and certifications are available for geriatric case managers (AARP, 2005). The National Academy of Certified Case Managers (NACCM) confers the care manager certified (CMC) credential, and the Commission of Case Management Certification (CCMC) offers the certified case manager (CCM) credential. Both require a postsecondary degree in a field related to the practice requirements, as well as certain additional prerequisites. The National Association of Social Workers (NASW) offers two case management credentials. A certified social work case manager (C-SWCM) credential requires a BSW degree, a minimum of 1 year and 1,500 hours of supervised practice experience, and a state-level BSW-level license, or passing of the Association of Social Work Boards (ASWB) basic exam (NASW, 2005b). The certified advanced social work case manager (C-ASWCM) credential calls for, among other requirements, an MSW degree from an accredited social work program, 1 year and 1,500 hours of supervised post-MSW practice experience, a state social work license, or the NASW credentials of the Academy of

Certified Social Workers (ACSW) or a Diplomate in Clinical Social Work (DCSW) (NASW, 2005b).

The roles of case managers and the models of staffing can vary considerably. The most basic case management staffing option is the individual generalist case manager, that is, the same professional carrying out the complete set of functions from intake through service coordination and monitoring, with a high degree of authority. The benefit is that the client has one practitioner to relate to. A second common approach is the multidisciplinary case management team approach, which combines professional expertise from various disciplines. Frequently the multidisciplinary team takes over some case management functions, such as assessment, while linkage and coordination is carried out by one team member. Comprehensive service centers that provide and coordinate a range of services under one roof could be considered a third approach. Examples of this approach can be found in the On Lok program and its PACE replication sites (Kane, Illston, & Miller, 1992).

The survey by the AARP assessed the services that geriatric care managers directly provide to their clients. The most common services include: finding services for clients (95%), arranging services (94%), family and social support assessment (94%), functional assessment (90%), health status assessment (73%) development of care plans (93%), and management of care plan (90%). Family counseling services were included in the service mix of 70% of the respondents (AARP, 2005).

FINDING A CASE MANAGER

Case managers typically work for nonprofit service providers, private case management agencies, or as self-employed private geriatric case managers. Common nonprofit agencies providing case management include local Area Agencies on Aging, home health care providers, hospitals, senior or family service agencies, and other human services providers such as the Veterans Administration. Private case management agencies and private geriatric case managers provide their services for a fee, while fees for nonprofit providers range from free to integrated with other service delivery costs and fee-for-service.

Case managers and referrals for case management or care coordination programs can be found through local Area Agencies on Aging, hospitals and health care providers, senior centers, HMOs, and Medicaid offices. Several online services are available to assist in

locating case managers and case management resources, for example, the Web sites of the eldercare locator (www.eldercare.gov), Family Care America (www.familycareamerica.com), the Area Agencies on Aging (AAAs; www.n4a.org), and the National Association of Professional Geriatric Care Managers (NAPGCM; www.caremanager.org). The NAPGCM Web site also includes a useful guide for elderly clients and their caregivers on how to select and interview geriatric case managers.

COMMON SERVICES IN CASE MANAGEMENT

Many services available to elderly clients residing in the community are created, authorized, and funded through the Older Americans Act (OAA). First enacted in 1965 and signed into law by President Lyndon B. Johnson, the OAA has been amended several times since, most recently in 2000. Some, but not all, of the services coordinated by case managers and presented in this chapter are funded directly or indirectly through the mandates of the OAA. The remainder of this chapter will focus on such services, addressing the areas of personal care, homemaker and chore services, transportation, personal emergency response systems, information and referral programs, financial assistance, and nutrition programs.

PERSONAL CARE SERVICES

According to the U.S. Census Bureau (2000), approximately 14% of the elderly population living in the community have problems with performing activities of daily living (ADLs), and 21% have difficulties with instrumental activities of daily living (IADLs). Moreover, approximately every third person above 75 years and every second person above 85 years of age has one or more disabilities. Consequently, a great need exists for services that assist elderly individuals who are residing in the community with home and personal care tasks.

An older adult's need for assistance with personal care can range from light household chores to specialized personal care. Professional and trained non-professional workers are involved in the delivery of personal care. *Homemakers* assist with household chores, cleaning, laundry, errands, and shopping (see also the following section). They do not provide any health care-related services. A *personal care aide*

(*companion*) will assist with household chores, personal care, and ambulating. The *home health aide* may assist with household chores but can also provide personal care, medication management, and monitoring of medical status. *Licensed practitioner nurses* (LPNs) and *registered nurses* (RNs) monitor vital signs, dispense medication, and provide wound care and other skilled nursing services.

CHORE SERVICES AND HOMEMAKER SERVICES

It is common for elderly clients to need home maintenance, particularly light and heavy housecleaning. Problems with heavy housecleaning, especially, are frequently encountered with clients who are otherwise independent enough to continue living on their own. Several approaches can be taken to address this need. Informal support systems, such as family members or local community groups, are often available and willing to help with both light and heavy housecleaning. Professional cleaning services, some specializing in housecleaning for elderly persons, may also be available. Case manager tasks include reviewing informal support systems for possible help with housecleaning, trying to enlist help from family, friends, or members of the local community, and educating clients about formal service options for housecleaning.

Chore and *homemaker services* are generally offered by religious groups, nonprofit agencies, and private agencies and usually require a fee for service, but on a sliding scale. Chore services typically provide assistance with heavy housework, such as snow shoveling, lawn mowing, and small home repairs, while homemaker services help with light housework, such as laundry, cleaning, and sometimes cooking.

Elderly clients are often unable to carry out parts of regular maintenance or required repairs, which can lead to safety problems and deteriorating conditions that may lead to the condemnation of the house. Common reasons for not undertaking needed maintenance include high costs, inability to repair due to poor health, and not knowing how to undertake repairs. Not only low-income but also middle-income elderly often require assistance. Types of formal assistance with repairs include neighborhood conservation programs, emergency repair programs, repair and maintenance programs, and weatherization. However, many smaller repair and maintenance jobs may be undertaken by local private businesses.

TRANSPORTATION AND ESCORT SERVICES

Transportation and *escort services* encompass a wide variety of service options that aim at increasing the mobility of older adults living in the community. Transit services range from the regular bus or train system to specialized senior transportation. The most common transportation service options include regular bus service (fixed-route system), deviated route systems, paratransit or demand-responsive systems, incidental transit, and escort services (U.S. Department of Transportation, 1997).

Funding and legal authority for transportation services are provided through the mechanisms of a wide variety of laws and regulations. The Social Security Act, Title 19 (Medicaid) regulates the transportation of low-income elderly persons to and from medical appointments. The OAA, Title 3, provides funding for transportation to senior centers, congregate meals sites, and medical appointments. Title 3 of the Intermodal Surface Transportation Efficiency Act of 1991, also called the Federal Transit Act, mandates reduced off-peak fares for elderly riders and provides capital purchase assistance for operators transporting elderly and disabled riders. The most important legislation impacting the transportation of older adults, however, is probably the Americans with Disability Act of 1990 (ADA), providing protection from discrimination against persons with disabilities, including elderly persons with a disability. The ADA mandates, for example, that all new buses must be wheelchair accessible. Fixed route systems are must be offered to persons with disabilities who are unable to use the regular bus system by providing a comparable paratransit system.

In a *fixed-route system*, public transportation or traditional transit services follow a predetermined route and schedule. The *deviated-route system* describes a transit system that generally follows a fixed route but will deviate from this route if a qualified rider requests it.

Paratransit describes transportation services that use smaller buses and vans and provide transportation to older adults and persons with disabilities. Usually they follow a *demand-responsive* approach, that is, a rider makes a request for transportation by phone and is either picked up in front of the home (curbside or at the door) or, in some cases, inside the home. Some demand-responsive systems require an advance request up to a day ahead of time, while others respond in an immediate time frame.

Incidental transit describes the transportation services provided by social service agencies to their clients, such as an adult daycare center that operates a van to transport its clients to and from the program site.

Escort and errand services are usually offered through private and nonprofit providers. In addition to personal transportation, they often provide other services as well, such as accompanied walks, companionship, and light housekeeping.

PERSONAL EMERGENCY RESPONSE SYSTEMS

Personal emergency response systems (PERSs) are devices that can be activated and send a signal to an emergency contact if a person is in distress. A trained professional answers the distress call immediately, usually over a speaker system integrated into the transponder unit in the home. The responder assesses the situation and activates the appropriate emergency response. If there is no response by the elderly person, an emergency response team is dispatched to the person's home. Two types of PERS are common, a push button worn around the neck or wrist or a push-button or pull-cord device placed on the wall, usually in the bedroom or bathroom. A variety of private providers offer PERSs. Some providers integrate the service with medication management.

Two additional procedures can provide added security to older adults living at home or in assisted living. Telephone reassurance is a procedure in which a volunteer makes a daily phone call at a predetermined time to ensure that the elderly person is well. In case the person does not respond, a call is made to an emergency contact. A so-called vial-of-life can provide vital information about the person to the emergency responders. A sticker is positioned at a place that will be seen by an emergency response professional when entering the home, alerting him or her to the fact that a small vial with vital information such as blood type, chronic health problems, and medications used can be found inside the refrigerator.

INFORMATION AND REFERRAL

In 1965, in an effort to improve the knowledge of resources available to older adults living in the community, a mandate by the OAA, funded through OAA, Title 3-B, created information and referral (I & R) services. The goals of these services can be summarized

as follows: offering up-to-date information on local services for older adults; providing information on assistive technology; assessment and linkage to appropriate services; monitoring service delivery; and a focus on all older persons living in the community (Wacker, Roberto, & Piper, 2002).

Local AAAs implement and coordinate I & R services in different ways, with some offering the services themselves and others contracting with outside providers. Some communities house their I & R efforts in public libraries or government institutions. In other communities, I & R services are provided through private or nonprofit organizations.

Two I & R efforts on the national level are the 2-1-1 Initiative and the Eldercare Locator. The 2-1-1 initiative, modeled after the 9-1-1 emergency phone number, is a program with the goal of making information and referral data on health and human services available to callers on an around-the-clock basis (Wacker et al., 2002). The Eldercare Locator is a program jointly sponsored by the Administration on Aging, the Area Agencies on Aging, and the State Units on Aging. Using the Eldercare Locator, a caller can easily obtain information about services in his or her community by providing the ZIP code and type of need for which services are requested.

FINANCIAL MANAGEMENT AND LEGAL ASSISTANCE

Daily money management is a service that assists older persons in managing their finances and coordinating other paperwork. Daily money managers (DMMs) help with balancing checkbooks, paying bills, reconciling medical statements, and organizing personal records and files. They ensure that bills are paid in a timely fashion and intervene on their client's behalf in Medicare and health insurance matters. Some DMMs also provide accounting and income tax preparation, as well as relocation management. These managers charge on a fee-for-service basis, usually \$40–80 per hour, and should be bonded and insured.

Eldercare attorneys are licensed attorneys who specialize in legal services for older adults. On a fee-for-service basis, they assist elderly clients and their families with estate planning, preparing wills and trusts, establishing a durable power of attorney and advance health care directives, long-term care planning, guardianship, and Medicare and Medicaid issues. The American Bar Association provides several useful programs for elderly persons, such as lawyer re-

ferral and information services and volunteer lawyer panels (see also chapter 48 here).

NUTRITION PROGRAMS

Nutrition programs for older adults include nutritional screening, home-delivered meals and meals-on-wheels, food stamps, congregate meals, emergency food services, and food banks, as well as shopping assistance programs and grocery delivery. The goal of these nutrition programs is to provide older adults with a healthy diet and to prevent malnutrition and inadequate food intake. Several of the nutrition programs are administered through the OAA (originally OAA, Title 4, and now OAA, Title 3).

Wacker, Roberto, and Piper (2002) summarize factors that affect the nutritional status in elderly persons as physical (e.g., cognitive status, chronic and acute illness, oral and dental health problems, medication usage, digestive system) and psychosocial (economic status, ethnicity, social supports, access to nutrition programs, advanced age). Moreover, age-related changes to taste and smell may impact food intake.

The *National Nutrition Screening Initiative* is a program offered by organizations such as the American Academy of Family Physicians, the American Dietetic Association, and the National Council on the Aging to improve the nutritional status of older adults (Wacker et al., 2002). A key element of this initiative is the development of a 10-item screening tool called DETERMINE, that assesses the risk of nutritional deficiencies. The screening instrument is widely used by nutritional programs and by health care professionals working with older adults. Nutrition programs that receive funding through the OAA require a nutritional screening, and certain nutritional standards apply. For example, hot meals offered at congregate meals sites and through home-delivered meals programs should provide at least one-third of the recommended daily nutritional allowance for adults.

The OAA, Title III, established the *Elderly Nutrition Program*, and it provides funding for congregate nutrition services and home-delivered meals. *Congregate meals* programs funded through the OAA provide one hot meal per day for at least 5 days a week. Only a few congregate meals sites offer breakfast or dinner. Congregate meals programs can be found in a range of community settings such as senior centers and churches. Many congregate meals sites provide nutritional screening, information, and education, and other community-based long-term care services.

They also serve an important social function for their visitors.

Meals-on-wheels and *home-delivered meals programs* are offered by community, county, and nonprofit providers. They are targeted at older adults who cannot prepare meals themselves and are not able to visit a congregate meals site. Home-delivered meals programs receiving funding through the OAA; they must provide the delivery of at least one meal per day to the person's home for at least 5 days a week. According to Wacker, Roberto, and Piper (2002), the costs of these meals are covered by a little over one-third through OAA funding and about two-thirds through other funding such as local, state, and federal sources and private donations. Volunteers deliver meals to the elderly person's home. Home-delivered meals programs usually ask for a donation and have a sliding fee scale.

Food stamps are an income-based nutrition program available to low-income older adults. The aim of food stamps is to reduce malnutrition among all low-income populations. Any person receiving Supplemental Security Income benefits also qualifies for food stamps. Food stamps can be used in regular grocery stores, and, with the exception of some items, the person can decide what to purchase with them.

Emergency food services and *food banks* are also targeted toward low-income populations. Food banks receive food donations from a variety of sources and distribute them to those in need, including older adults. The Emergency Food Assistance Program (TEFAP) and the Commodity Supplemental Food Program (CSFP) are administered by the Department of Agriculture's Food and Nutrition Service. Both programs provide low-income persons with basic food items such as butter, flour, cereal, rice, and vegetables at no cost.

Shopping assistance programs and *grocery delivery* aim to help older adults who are living independently but lack transportation or have mobility problems. A variety of shopping assistance programs have been established by communities, volunteer organizations, and similar groups. In most programs, a volunteer escorts the older adult to the store, assists with shopping, and then accompanies his or her home. A growing number of grocery stores also provide grocery delivery. Usually the elderly person calls in his or her order or orders online, and the groceries are delivered the same day by a volunteer. Some grocery stores offer grocery delivery to all customers for a fee.

This chapter focused on a brief overview of some of the primary services coordinated through geriatric

case management. Additional information on some of these programs can be found in chapters in this section.

Counseling Services and Support Groups

46

HISTORICAL AND PHILOSOPHICAL CONTEXT

Counseling and support services for older adults have reflected changing philosophies over time. For much of the 1900s, especially prior to 1945, older adults were conceived largely as a dependent population for which the charitable efforts of social workers and other human service professionals were needed. Arguably, the prominent interventive philosophy at that time emphasized inevitable decline, incapacity, and impairment in the older adult. Elders, according to this perspective, were viewed as having entered an extended period of loss, experienced across multiple domains of living, including the physical, social, emotional, and economic. The older individual was likely to be experiencing not only loss of physical strength but also diminished social networks and financial resources. In other words, the older person's physical, social, and psychological environment was shrinking or contracting. In response, human services professionals sought to both help the older person prepare or adjust to such losses and, to the degree possible, slow the process of decline by buttressing remaining personal resources.

The 1960s saw the passage of the Older Americans Act of 1965 (OAA, 1965), which, for the first time, legislated an extensive range of social services as rights for older adults. Since then, albeit gradually, an increasingly optimistic or positive orientation to service intervention has been evidenced. In large part because of the changing profile of the aging population, human service professionals in the last 10 to 15 years have been increasingly working with a more active, educated, and vocal older adult population. These individuals often bring to the professional-client relationship higher expectations, including the desire to maintain active and engaged lives. Rather than accepting or passively adjusting to shrinkage or contraction in their social and psychological lives, they seek opportunities to continue to live active lives even in the face of physical challenges. It is in the context of these shifting population profiles and philosophies of what it means to grow old that we consider the range of clinical counseling and support services available to older adults.

COUNSELING SERVICES

Kirst-Ashman & Hull (1999) describe the generalist role of social work counselor as a useful one in pro-

viding guidance to clients while assisting in planned change or the problem-solving process, while Naleppa & Reid (2003) note a more traditional view of counseling as providing psychotherapy and family therapy. Because social work skill levels and practice abilities vary from practitioner to practitioner, depending on training, education, and experience, for the purposes of this chapter, *counseling services* is used as an encompassing term to describe a variety of direct services ranging from traditional psychotherapy to consumer and financial counseling services.

Counseling Service Locations

Older adults access counseling and support services through a combination of public and private, community-based, and institutional organizations. The counseling services system consists of private providers funded by third-party insurers and private-pay consumers, and publicly mandated, not-for-profit, and privately owned providers funded by the federal government, as well as states, counties, and municipalities. Institutional or facility-based counseling services include those provided by acute and long-term providers, residential treatment centers, and foster, boarding, or group homes (U.S. Department of Health and Human Services [USDHHS], 2001).

Community-based mental health services may include outpatient psychotherapy, partial hospitalization/day treatment, crisis services, case management, and home-based and “wraparound” services. Many community-based organizations, especially those operating under public or governmental auspices, provide services regardless of the elder’s ability to pay (USDHHS, 2001).

Other community social service organizations, including Area Agencies on Aging (AAAs), health care facilities, community action programs (CAPs), and senior citizen centers provide non-mental health counseling services. Services may be offered directly at an agency or delivered in the elder’s home. Over time, there appears to have been a tendency to offer services more centrally at the agency site. At the same time, increasing use of video, telehealth, and internet technology has figured in making such services more available remotely.

Classic techniques of counseling intervention include: supportive counseling, where the worker uses supportive listening techniques to help the client feel understood; financial counseling, in which the worker or agency helps the client set a budget or plan for fu-

ture expenses; and eligibility or entitlements counseling, where the worker helps the client understand which social service programs, benefits, and services he or she may be eligible for. Typically, a person with an undergraduate degree in social work provides these services.

The foregoing counseling programs are often paired with other services, including assessment, case management, referral, and case coordination (National Council on the Aging [NCOA], 2001). Sometimes peers or volunteers may provide these services, through retired and senior volunteer programs, senior companion programs, or community telephone reassurance and friendly visitor programs. Local community treatment centers may also team up with substance abuse programs or homeless shelters to provide care for those programs’ older clientele.

Many agencies provide counseling and support services via telephone hotlines. The Alzheimer’s Association, with local offices situated throughout the United States, staffs a 24-hour support and referral service for persons with Alzheimer’s disease and their caregivers (call 800-272-3900). The Alzheimer’s Association also employs clinical professionals to provide more in-depth counseling support.

Special geriatric care managers may also provide counseling services, depending on the qualifications of the worker. These are commonly master’s level professionals in social work, nursing, and other helping professions who have demonstrated competencies in geriatric case management and are affiliated with a professional care management association. Geriatric care managers are often self-employed or employed by a private fee-for-service organization. You can visit the Web site of the National Association of Professional Geriatric Care Managers, Inc. (www.caremanager.org) to find a professional care manager in a particular region of the country (Parker & McNattin, 2002).

Faith-based counseling programs are also an option for many elders. Faith communities, with long histories of social and spiritual support, are beginning to consider their formal role in the health and well-being of their members. Buijs & Olsen (2001) describe faith communities as ideal settings for a focus on health and health promotion, citing traditional values of support, personal skills, and social justice. Pastoral counselors and ministers provide counseling services, often on a sliding fee scale, or make such service available at no cost to members of their faith communities. Some faith communities employ social workers or nurses as a unique method of delivering health and social service information and referral services to their congregants.

SUPPORT GROUPS

The Social Work Dictionary (Barker, 2003, p. 185) defines a group as “a collection of people, brought together by mutual interests, who are capable of consistent and uniform action.” Perhaps this definition best helps the practitioner understand the beginnings of social work group practice in the settlement houses of the late nineteenth and early twentieth centuries, where the focus was on mutual aid and democratic process to change the social environment and address the needs of tenement dwellers (Garvin, 1997).

During those early days of social work practice, social groups for older adults flourished in the settlement houses, community centers, homes for the aged, and state mental institutions. Crowded conditions and limited staffing made groups an effective and efficient vehicle to meet the needs of elderly residents (Toseland, 1995). It was not until the early 1950s, however, that social work publications began focusing on group therapy in a variety of settings. Today, group work with older adults is informed by a well-established theory base, structure, range of services provided, and roles that social workers can assume (Garvin, 1997).

There are many different types of groups used in social work practice. Most groups fall into one of two categories in terms of purpose: groups that provide direct treatment or service to their members and those that do not. Groups that meet for purposes other than direct service, sometimes called task-centered groups, are created to do just what their name implies—complete a specific task or set of objectives. The purpose of these groups is not to focus on the individual needs of their members (Henry, 1992).

The membership of these groups is likely to be based on individual skills, roles, and/or knowledge of members. Work goals are often determined outside the group, perhaps by the governing agency, on the basis of a stated purpose or task, or by means of group mandate. Depending on the nature of the group, member roles may be more structured and decision-making processes organized through democratic tradition (Henry, 1992). Committees, boards of directors, legislative bodies, supervision, staff development, consultation, interdisciplinary teams, and social action groups are all examples of social work task-centered groups (Henry, 1992; Kirst-Ashman & Hull, 1999) in which older adults certainly may play a valuable role.

In contrast, social work treatment-centered groups meet to focus on the individual needs of the members.

Examples of treatment-centered groups include therapy groups, education groups, socialization groups, and support groups (Hartford, 1985; Kirst-Ashman & Hull, 2002). Treatment-centered groups may have an open or closed membership, depending on the needs and intent of the group. Referral to the group may or may not be required, depending on program philosophy, participant eligibility, and funding.

Some treatment groups tend to be time limited, such as therapy or education groups, while others are more likely to be ongoing, open to new participants as long as members express interest in continuing the program. Often socialization groups have open admission policies, as do some support groups. Social work roles in these groups will vary depending on the needs and structure of each group. Possible social work roles include facilitator, leader, and consultant.

The following list (Kirst-Ashman & Hull, 2005, p. 261) outlines social work roles with groups.

Social Work Leadership Roles

Broker: Social workers use the role of broker to help clients obtain resources by connecting them to community services.

Mediator: The social work mediator helps the group resolve conflicts by helping each side voice their concerns, recognize the opposing argument’s validity, and come to negotiated agreement.

Educator: Social work educators provide clients with new information and skills.

Facilitator: The social work facilitator helps the group stay on task, encourages participation, and open discussion.

TYPES OF SOCIAL WORK TREATMENT GROUPS

Therapy groups focus on changing participant behaviors. Membership may be determined on the basis of a particular treatment issue, age group, or location, or the profile of a given agency’s client base. Membership may be open or closed. Members will often participate in determining the group’s structure, goals, and decision-making processes. Treatment theory rationale will also vary on the basis of group need, outcome-based indicators, social worker training, and agency orientation. Typically, the social worker may assume more of a leadership role in treatment

groups, particularly in the early stages of group formation. Therapy groups with elders may focus on such topics as coping with loss, depression, substance abuse, or a particular mental health diagnosis (McInnis-Dittrich, 2002).

Education groups are formed to provide education to the membership concerning a particular issue or topic. These groups do not focus on changing behavior, but rather provide information. In education groups, the social worker commonly assumes the role of teacher or trainer, often utilizing a formal curriculum or plan of presentation (Kirst-Ashman & Hull, 2005). Examples of education groups for older adults include those teaching new computer skills at the library media lab, healthy cooking for one at the local community meal site, managing diabetes skills at the health clinic, and parenting skills for older relatives providing care to younger relatives, at the university daycare.

Sometimes groups exist to serve the social and recreational needs of their members. These socialization groups usually draw together members who are from different backgrounds and with different talents but have similar interests in companionship, sharing interests, or learning something new. In these groups, the social worker's role is that of facilitator, encouraging participation and active communication between members, assisting in planning activities, and gathering needed information and resources. Many older adults join travel or interest-based groups held at senior centers and nursing facilities sponsored by social work agencies, or hosted by informal older adult networks (Toseland, 1995).

Support groups meet to provide encouragement and a safe environment for members to share their experiences. Support groups for older adults may address a particular type of loss, difficult life experience, or health issue, such as widowhood, employment transition, or chronic illness. They may also provide opportunities for particular subgroups of older adults, such as older women, to strengthen their informal networks and experience a sense of personal empowerment (Kaye, 1997b). Elements of therapeutic growth, socialization, and educational learning may be used separately or combined at different points in time in support group facilitation (McInnis-Dittrich, 2002). Support groups may have an open or closed membership. Typically little formal referral is required. The term *support group* is also used to describe self-help groups, which differ in their formal structure, likely having member facilitators, and may or may not follow a social work theoretical orienta-

tion. In any case, the term *support group* usually indicates a group that is attentive to the emotional needs of the membership as they pertain to a particular life event or challenge.

Regardless of the structure and intent of the group, certain dynamics will surely play a part in the life of the group. Special considerations in terms of designing and marketing support groups to appeal to particular subgroups of older adults may need to be considered as well (Kaye & Applegate, 1993). While not all groups will undergo exactly the same process, social work group theory has outlined typical stages of group development, as follows (Henry, 1992; Kirst-Ashman & Hull, 1999; McInnis-Dittrich, 2002; Toseland, 1995).

Group Formation Stages

Before the Group: The social worker or group leader begins to outline the basic structure of the proposed group. Location, time requirements, general purpose, and membership are all considered. The worker will need to review expectations with potential members.

Beginning Phase: The group meets for the first few times. It is important, when working with older adults, to make sure the group purpose is clearly defined. Initially, the leader takes a strong role while members establish individual roles, group norms, and group identity. As the group gains a cohesive identity, the worker assists this transition by promoting group decision-making and support-seeking among the membership.

Middle Phase: Conflict is not always a negative factor during group development. Most groups experience a stage of conflict or disequilibrium that serves to reexamine group ownership, goals, and objectives. Individuals may vie for power within the group or try to sway the group to serve their own personal needs. Many times, group members, particularly older adults, will not be comfortable addressing conflict and will shy away from direct expressions of tension, perhaps even dropping out of the group. It is important for the leader to address the conflict with the members and encourage the group to deal openly with the problem and possible solutions.

Once the group has confronted conflict, the members enter a period of productiveness. This is

when the bulk of the work of the group is completed. This stage is a time of cohesion, bonding, and growth. Group members take on responsibility for both completion of tasks and attendance to the needs of members. In this stage, the worker's role is typically that of consultant or advisor.

Ending Phase: Groups cannot continue indefinitely. As the group completes its work and nears the time of termination, members begin to disengage themselves from the group. It is important that the leader address the termination before the event to allow members time to express their feelings. Often members feel sadness or engage in mourning. The leader can help members recap the skills and growth they have achieved through group affiliation.

FUNDING FOR COUNSELING SERVICES AND SUPPORT GROUPS

Counseling services and group work with older adults are funded in a variety of ways. Private agencies provide services through private insurance and participant copayments. Many community social service agencies provide counseling treatment as part of billable social work practice, depending on state and federal regulations, through private insurance, Medicaid, and Medicare programs. Agencies may also incorporate funds for treatment groups in federal and state grant requests, or charge clients fees to participate.

The OAA, most recently amended in 2000, also provides a source of funding for certain counseling and support services (Older Americans Act as Amended in 2000). Under Title 3 (Grants for State and Community Programs about Aging), part B (Supportive Services and Senior Centers), the OAA authorizes funding for health services (including mental health) and information and assistance services, as well as other services, including transportation, housing, long-term care, and legal assistance (Langer & Tirrito, 2004).

Title 3, part D (Disease Prevention and Health Promotion Services), provides for health risk assessments, routine health screening, nutritional counseling and education, health promotion programs, exercise and fitness programs, home injury control services, screening for prevention of depression, educational programs on medication management, information concerning diagnosis, prevention, treatment, and rehabilitation of age-related diseases and

conditions, gerontological counseling, and counseling regarding social services (Langer & Tirrito, 2004).

Medicare, the federal health insurance program for people 65 and over, as well as people with certain disabilities or end-stage renal disease, has undergone many changes with the recent passage of the Medicare Prescription Drug, Improvement and Modernization Act (MMA) of 2003. For older adults who decide to stay with the original Medicare plan, or the fee-for-service option, mental health and counseling treatment is available on a limited basis. Through Medicare part A, the insured pays the same deductibles and copayment as for non-mental health hospitalization. For participants who purchase the Medicare part B insurance, community mental health treatment is covered at about 50% of the Medicare-approved amount. The older adult is responsible for the remainder, as well as certain copayments and deductibles (USDHHS, 2004).

Coverage for older adults choosing Medicare Advantage Plans, a program that gives participants choices and, in some cases, extra benefits, by letting private companies offer Medicare benefits, is likely to vary from plan to plan. Medicare Advantage Plans must offer at least the basic coverage of the original Medicare plan (USDHHS, 2004), although insurance options will vary from region to region.

Similarly, Medicaid is another federal health insurance program that covers people with low incomes, pregnant women, children, teenagers, and people who are aging, blind, or disabled. Funds are distributed to states, which then set eligibility and service provision levels. In order to receive federal funds, Title 19 of the Social Security Act (Grants to States for Medical Assistance Programs, 1965) requires that certain basic services be offered to eligible recipients, including hospitalization, physician services, and nursing services. States may also provide home- and community-based care waiver services to eligible individuals through the Medicaid program, including case management, personal care services, respite care services, adult day health services, homemaker/home health aide services, rehabilitation, and so on.

Often self-help groups or support groups will find an organizational sponsor that is willing to make an in-kind donation of space, while members take turns bringing snacks and sharing material costs (if any). Faith communities may regularly hold groups as part of their community outreach, relying on laity donation for support. While some self-help groups are affiliated with national parent organizations, for many member-driven groups, fund raising is the sole responsibility of the group (Beigel, Farkas, & Wadsworth, 1994).

Community centers and YM/YWCAs may charge a fee to join the organization; afterward, participants pay minimal amounts per event or may only need to cover the cost of supplies for particular groups. Typically, senior discounts or scholarships are available. These types of community organizations may also hold capital campaigns in the local business community, as well as receiving support from charitable organizations such as the United Way.

COUNSELING SERVICES AND SUPPORT GROUPS FOR OLDER ADULTS TYPICAL OF MANY COMMUNITIES

Disease-Specific Supports

For many communities, support groups and self-help groups are commonly available for people seeking disease-specific supports. Such groups are sometimes offered in affiliation with a local hospital or rehabilitation center, as well as through community faith-based organizations and consumer-driven advocacy groups; support group locations and schedules are often published in the local newspaper. The regional Area Agency on Aging should also have a good listing of local resources.

According to the National Center for the Aging's 2001 nationwide survey of health and support services in the aging network, approximately 35% of programs surveyed used a nationally recognized treatment model when designing their programs. Nationally recognized, disease-specific models that exist in many communities may include, but are certainly not limited to, Arthritis Foundation programs, Ohio State University's Body Recall, an exercise program for those recovering from an operation or facing chronic illness, Tuft University's Strong Living Program, an exercise program to improve overall health, and the YWCA's ENCOREplus, designed to help women diagnosed with cancer (NCOA, 2001).

Many skilled nursing facilities or day treatment programs also provide disease-specific counseling services, particularly addressing dementia. For older adults with mild to moderate dementia, social work reality orientation groups may be helpful. Often used in nursing facilities and day treatment programs, reality orientation groups focus on helping the older adult maintain or relearn current information such as names, time, place, and current events. Leaders use verbal repetition, visual cues, and sensory stimulation to engage clients (McInnis-Dittrich, 2002). Care must

be taken when assessing the elder's functioning level at the time of reality orientation group assignment, so as not to lump persons who have less confusion or memory loss with those who have greater needs (Greene, 2000).

Health Education

In the past, older adults were often not seen as appropriate candidates for health promotion and education programs because goals invariably included long-term change. As the focus of health education for older adults has shifted to prevention of illness and injury, the maintenance of present functioning, and enhancement of health, this treatment bias has lessened (Wacker, Roberto, & Piper, 1998).

Health education programs promote healthy choices. Education may be provided through organized groups and health fairs or incorporated into existing programming. Groups may be disease specific, such as those targeting a reduction in high blood pressure or building bone density, or encompass a whole body perspective. A general health promotion group may include sessions on healthy lifestyles and health promotion, chronic disease prevention, nutrition, exercise, and medication education (Huang, Chen, Yu, Chen, & Lin, 2002). Health education groups are found at hospitals, health centers, skilled nursing facilities, senior centers, and elsewhere in the community. Participants should always consult with their physician before beginning any diet and exercise change. Education programming is most likely to succeed if it adheres to the following fundamentals.

Fundamentals of Successful Education Programming

- Focus on positive and healthy aging
- Ensure community presence and outreach
- Use peer support networks
- Develop age-appropriate materials
- Promote family involvement
- Emphasize active roles for participants
- Use respected experts
- Focus on improvement of health habits
- Provide health screening

Mental Health

For many older adults, particularly in rural areas, mental health treatment is underutilized (Bane &

Bull, 2001; Wacker et al., 1998). Unutzer et al. (2003) reported depression rates of 5–10% in older adults visiting a primary care provider, while the 1999 report of the Surgeon General estimated 19.8% of the older adult population has a diagnosable mental disorder during any 1-year period. Of these, anxiety disorders, cognitive disorders, and mood disorders were most prevalent (USDHHS, 1999).

Although stigma and embarrassment may prevent elders from seeking treatment, many elders simply do not have access to specialized mental health services, the resources available to pay for such services, or the appropriate types of services available in the community. Service providers themselves face deficits in needed funding, lack of interagency collaboration, and chronic worker shortages (USDHHS, 2001).

Outreach on the part of the social worker in the form of mental health education groups or informational sessions can be helpful (Bane & Bull, 2001) when seeking to inform the community of treatment availability. The use of “gatekeepers,” that is, nontraditional supports like local businesses, hairdressers, and utility service persons, can provide useful referral information to older adults they come in contact with (Wacker et al., 1998). Primary care physician offices can also be partners in the care of an older adult with mental illness, screening for depression and making referrals as needed.

There are many different types of clinical social work therapeutic approaches to working with older adults. Historically, many felt that elders would not benefit from individual counseling, operating on the premise that learning in later life was difficult to achieve; however, research has shown this to be inaccurate (Davis & Collerton, 1997). Some authors suggest that elders feel less stigmatization when treatment is brief, although a particular treatment strategy will likely best be determined by the specific training of the clinician, the clinician’s assessment of client need, and the relative comfort level of the client (Davis & Collerton, 1997). Today’s clinicians may employ traditional psychotherapy, cognitive behavioral therapy, family therapy, brief therapy, or crisis intervention methods (Corwin, 2002).

Reminiscence may also be a helpful tool in the social work counselors’ practice with older adults. Reminiscence group work has been used to cope with grief, reinforce sense of life meaning, and improve social relationships (Adamak, 2003; Westcott, 1983). Theorists see reminiscence addressing Erickson’s final stage of development, integrity versus despair (Greene, 2000; Toseland, 1995). Reminiscence can be used to help

group members share experiences and weave a sense of mutual understanding among members.

Substance Abuse

Although in the past most social work research was focused on the substance abuse of younger and middle-aged adults, older adult substance abuse, including problem drinking, is now recognized as a growing area of concern. In general, the number of people in the general population who drink is known to decline with age (USDHHS, 2000). However, older adults are certainly not immune to alcohol- and drinking-related problems. As the nation’s population ages, the number of older adults with alcohol problems and alcohol related problems is expected to rise.

Although numbers vary, a recent survey showed a prevalence of older adults with alcohol-related problems ranging from 20% to 22% nationwide (Fink et al., 2002). Others report alcohol abuse and dependence rates of 5–10% in older primary care outpatients (Kraemer et al., 1999) and up to 50% of older patients utilizing psychiatric hospitalizations (Hinkin et al., 2001). Between 25% and 50% of nursing home residents display active symptoms of problem drinking (Klein & Jess, 2002).

For many adults, even continuing moderate alcohol use may cause significant health related problems as they age (USDHHS, 2000). Alcohol-related hospitalizations are reported to rival the rates of hospitalization for myocardial infarction among older adults (Fink et al., 2002) and the National Highway Traffic Safety Administration reports that 11% of all drivers aged 65–74 involved in fatal automobile crashes in 1994 were positive for alcohol use (USDHHS, 2000). Other health risks linked to alcohol abuse include hypertension, congestive heart failure, liver disease, stroke, and alcohol-induced dementia.

Ruffin and Kaye (2004) note that many older adults may respond to treatment practices that are nonconfrontational, focus on coping and skill building, and offer health links. In this respect, group therapies may be particularly helpful for many older adult drinkers. Several self-help groups also offer substance abuse meetings specifically for older adults.

CONCLUSION

Counseling and support services can be expected to be used by increased proportions and numbers of

older adults in the years ahead. Leading-edge baby boomers entering retirement will represent a generation quite familiar and comfortable with using counseling and support group services. There will be less stigma attached to their use. A positive, strengths-based, productive aging philosophy should be reflected in such interventions, with the focus on active community engagement and personal growth. It can be expected that certain subgroups of older adults will exhibit greater resistance to participation in programming than others (e.g., minority ethnic groups, older men) (Kaye, 1997a). As the older adult population becomes increasingly diverse culturally, racially and ethnically in the years to come, such services will need to be increasingly sensitive to the myriad of needs expressed and issues faced by a heterogeneous older adult population.

APPENDIX 46.1

Selected Counseling and Support Groups

Education and Prevention

Health Enhancement Program, Seattle/King County, Washington

www.seniorservices.org

Operating as one of three complementary programs of the Senior Wellness Program, the Health Enhancement Program centers around helping seniors adopt healthy behaviors. The Health Enhancement Program's client-driven practice also helps seniors to recognize and take advantage of health improvement opportunities. Participants initiate their involvement by completing a self-evaluation. Once completed, the participants partake in a comprehensive health and social assessment, which identifies improvement opportunities. Nurse feedback is offered for each area of concern. After the assessment is completed, participants formulate goals to be addressed through self-management programs, counseling, and support groups.

Screening, Referral, Intervention, and Treatment

Over 60 Health Center, Berkeley, California

www.lifelongmedical.org

By combining primary care and mental health services, Over 60 Health Center offers health promotion, disease prevention, screening, diagnosis, and treatment, as well as substance abuse services. Drawing older members of the community, Over 60 Health Center offers primary care provided by physicians, informal screenings, and referrals to mental health, so-

cial, and substance abuse service clinical staff as appropriate. By using an interdisciplinary team of a clinical social worker, a clinical psychologist, a primary care physician, and a nurse, Over 60 Health Center is able to address and treat many key concerns in the aging community.

Service Improvement through Coalitions and Teams

Elders Wrap-Around Team, Concord, New Hampshire

www.riverbendcmhc.org

Serving adults over 60, the Elders Wrap-Around Team, at the Riverbend Community Mental Health Center, joins with community agencies to coordinate services to make certain that no elders slip through service-delivery cracks. The Elders Wrap-Around Team consists of representatives from 12 core agencies, and an additional 40 community agencies who lend support and participate when necessary, to review specific cases and discuss community implications. Clients and their families may also attend a Wrap-Around meeting to participate in the discussion of their needs and services.

Education and Prevention

Positive Aging Theater, Madison, Wisconsin

www.madstage.com/companies/PATG.html

The Positive Aging Theater provides an environment where local older adults can connect and energetically create an entertainment revue. The traveling theater performs at local senior centers, adult daycare centers, and low-income housing developments. Even though the performance changes every year, the themes, which focus on issues such as living life to the fullest, debunking myths of aging, and alcohol and drug abuse prevention, stay the same.

Financial Counseling Service

Money Minders, Scarborough, Maine

www.smaaa.org

The Money Minders Program is sponsored by the Southern Maine Agency on Aging in collaboration with the American Association of Retired Persons (AARP). The Money Minders Program provides bonded, carefully screened, trained volunteers who offer in-home support with financial matters to older adults wishing to live independently and worry free. Volunteers provide help with budget development and implementation, checkbook balancing, check writing, and organizing and sending out mail and provide support to the client who is dealing with creditors. Help is confidential, and all financial decisions about the handling of a participant's money are made by the participant.

Support Groups

National Alliance for the Mentally Ill

www.nami.org

A nonprofit, self-help, support, and advocacy group for persons with severe mental illness and their families, NAMI has chapters in all 50 states, the District of Columbia, Puerto Rico, the Virgin Islands, and Canada. NAMI hosts support groups, education for consumers and families, and advocacy at the state and federal level. Visit NAMI's Web site to find local chapters and contact information.

The Alzheimer's Association

www.alz.org

The Alzheimer's Association is the world leader in Alzheimer's research and support. The nationwide network of chapters offers support to individuals affected by Alzheimer's disease. Services include information and referral, education, and support groups. The Alzheimer's Association also sponsors Safe Return, a nationwide program that assists in the identification and reunification of persons with Alzheimer's who have become lost. Since 1993, the program has assisted in the recovery of 8,000 people. Visit the Web site to find information about Safe Return and local support services.

Services to Support Caregivers of Older Adults

47

Among the things most hoped for and treasured is a long life. People are living longer, and with their increased longevity, it is likely that at some point they will either require the assistance of a family caregiver or become a family caregiver. Parent care has become a normative experience in American families (Brody, 1990, as cited by Martire, 2003). In 1988, the U.S. Administration on Aging reported that for the first time in history, couples had more parents than children to care for (Hooymann & Gonyea, 1995). In addition, the report indicated that women would spend 18 years caring for aging parents, as compared to 17 years caring for children. By the year 2040, the older population is expected to more than double, and the number of people age 85 and older will triple (Kramer, 2000), and one half of them are likely to require assistance with one or more activities of daily living (Kart & Kinney, 2001; Siegel, 1999). The unprecedented growth of older persons, and in particular the projected increase in the 85-and-older population to 8.5 million by 2030 (American Association of Retired Persons [AARP], 2004), make it urgent for the nation to aggressively plan and develop caregiving resources.

These realities summon social workers to respond to the nation's growing caregiving responsibilities. Today's realities also point to the need to examine and plan for the diversity of needs of caregivers. Among the new realities are the changing role of women (more in the outside-of-home workplace), growing minority elders with cultural expectations, more male caregivers, the "sandwich" and "club sandwich" generation, and technological advances that prolong independence and care-receiver freedom (Stowe, 2004). The sandwich generation refers to those sandwiched between aging parents needing help and their own children while the club sandwich generation is responsible for three generations, including parents, grandparents, children, or grandchildren.

This chapter discusses the background and prevalence of family caregivers, the definition and profile of family caregivers, the legal authority for services to family caregivers, social work roles and practices with family caregivers, support services available to family caregivers, and the next generation of family caregiver resources.

DEFINITION, BACKGROUND, AND PREVALENCE

The *Encyclopedia of Social Work* defines caregiving as the "custodial or maintenance help or services rendered for the well-being of individuals who cannot

perform such activities themselves” (Hooyman & Gonyea, 1995, p. 953). The authors note the multidimensionality of caregiving by stressing the emotional ties associated with caring for and about older relatives. Caregiving is primarily a family matter. Historically, families have been responsible for the needs of their older relatives. This has been especially true in the case of minority elders, where kinship and informal community arrangements have been dictated by inequality of resources and cultural traditions. This family caregiving tradition is further documented by a 1997 study by the National Alliance of Caregivers and the AARP that reported over 22.4 million U.S. households provide unpaid help to elders, giving an average of 18 hours a week of assistance. Consistently, a 1991 U.S. Senate Special Committee on Aging reported that 4.9 million seniors with some type of impairment in activities of daily living (ADLs) live in the community, and 70% of them rely exclusively on the unpaid assistance of family and friends (Garner, 2000). Nearly 90% of disabled older persons who were not in nursing homes received assistance from relatives and friends. This is another compelling indicator of the vital role of the family in caring for elder members.

The *Compendium of HHS Caregiver Support Activities* (U.S. Department of Health and Human Services [USDHHS], 2003, p. 1) indicates that

informal caregiver and family caregiver are terms that refer to unpaid individuals such as family members, friends, neighbors and volunteers who provide help or arrange for help. These individuals can be primary or secondary caregivers, full time or part time, and can live with the person being cared for or live separately.

Some family caregivers receive pay as a part of a family arrangement; however, they are usually considered as unpaid caregivers because they are not associated with paid care providers. In addition, some receive benefits, such as public housing, that exempt their income from rent determination because of their caregiver status.

LEGAL AUTHORITY: THE OLDER AMERICANS ACT AND THE AGING NETWORK

The Older Americans Act of 1965 (OAA) created the “aging network” to address concerns and provide services to older Americans (Administration on Aging

[AoA], 2004; DiNitto & McNeece, 1997; Gelfand, 1999; Hooyman & Kiyak, 2002). The OAA has 10 goals that are carried out through the federal, regional, state, and local levels of the aging network. The aging network includes governmental and private resources as noted in Table 47.1.

The aging network. The National Family Caregiver Support Program (NFCSP), was established by Older Americans Act Amendments of 2000 (Public Law 106-501) and was based in large part on felt and expressed needs of caregivers across the country (AARP, 2004; AoA, 2004; Guthiel & Chernesky, 2001). Authorized for 5 years, it is the first federal legislation specifically addressing the needs of the millions of Americans caring for older relatives (Guthiel & Chernesky, 2001). The NFCSP was funded for \$125 million in its first year and offered grant flexibility to allow states to provide a continuum of caregiver services that best meet caregivers and individual needs. These may include information, assistance, and other services. Services support family caregivers of persons age 60 and older and grandparent and relative caregivers of children not more than 18 years of age.

The NFCSP program was developed in recognition of the fact that over 70% of older persons are cared for in home by family caregivers “and are an important component of any home and community-based care system” (p. 1). As noted by DiNitto and McNeece (1997), most diagrams of the aging network fail to include the family that provides the bulk of services for this population. Despite the extraordinary service of caregivers, many older people who receive assistance from family members also receive assistance from other sources. A typical source of support is provided through OAA-funded home- and community-based services such as home-delivered meals, personal care, transportation, and chore services. These services help lessen the burden on family caregivers and help them maintain their caregiving role in a healthy way.

Findings from a survey of a random sample of 413 individuals who provided caregiver support to older people who also used OAA-funded services in 2004 showed that caregivers find OAA services to be vital in helping them support the older people they care for, and 86% reported that OAA services helped them provide care longer than they would have been able to without the services. In addition, a majority of the states (86%) reported a need for additional caregiver support, the greatest of which is for additional respite and supplemental service support (AoA, 2004).

Family caregiver profile. Family caregivers are made up of spouses, children, parents, and other relatives

TABLE 47.1. Aging Network

<i>Service and Funding Entities</i>	<i>Major Functions</i>
Federal government Administration on Aging (AoA), U.S. Department of Health and Human Services	<ul style="list-style-type: none"> • Funds programs • Coordinates federally operated programs for older persons (i.e., nutrition programs) in the 10 regional offices of the United States • Conducts evaluation of programs and research on aging, including a clearing-house on aging-related information • Provides advocacy function for older persons and their caregivers
State government Usually a part of the human services department	<ul style="list-style-type: none"> • Assists in implementing federal policies • Acts as advocate for older persons and their caregivers
Local government Area Agencies on Aging (AAAs); approximately 700 AAAs are located in communities throughout the country, and each is guided by an advisory council	<ul style="list-style-type: none"> • Provides advocacy functions • Conducts community-based needs assessments • Distributes funding to community agencies • Provides services such as information and referral, respite, legal council, day-care, telephone assurance
Private agencies Public and private nonprofit and for-profit agencies; churches and faith-based affiliated social services	<ul style="list-style-type: none"> • Provide direct services through OAA programs such as daycare, respite care, and case or care management • Provide assistance at market rates for those who can afford to pay • Provide support groups for caregivers
Families Unpaid caregivers, including primarily daughters, spouses (wives)	<ul style="list-style-type: none"> • Provide wide range of instrumental and emotional support to older person to assist with ADLs and IADLs

who have loved ones who are ill or have disabilities that require care ranging from minimal to 24-hour assistance. The 1997 National Alliance for Caregiving and the AARP collaborated on a report on family caregiving in the United States that provides the following profile of a family caregiver (National Alliance for Caregiving and the AARP, 1997).

- Average age is 45
- 12% are 65 years and older
- 73% are female
- Two thirds are married
- 41% have children under the age of 18 living in the home
- 64% are working
- 52% work full-time

A second study in 2003, *Caregiving in the United States*, co-authored by National Alliance for Caregiving and AARP, shows an increase in caregivers to 22.9 million (21% of U.S. households) as compared to 22.4 million in 1997 (National Alliance for Caregiving and

the AARP, 2005). This updated nationwide sample estimated 44.4 million caregivers age 18 and older who provide unpaid care for an adult. Demographics were similar to those in the 1997 study with the notable exception of more male caregivers in the sample (39% as compared to 25% in 1997). The 2003 study also emphasized that most caregivers were working with over 62% having to make adjustments to their work schedules to accommodate their caregiving roles. Although the study found that males were more likely to be working than females, females were providing more hours of care and higher levels of care (burden). The 2003 study listed the top unmet needs as finding time for self, managing emotional stress, and balancing work responsibilities. Also, cultural differences in the caregiving experience emerged in this report—there were specific differences related to methods of coping with stress and levels of caregiver burdens. For example, African Americans were more likely than Whites to report praying as a way of coping as well as caregiving being a financial burden. They also report performing

more IADLS. The study findings report Asians as least likely to be stressed by caregiving and having the highest incomes. The cultural differences seen in caregiving reflect other inequities in society such as health problems and income disparities. These disparities result in cumulative disadvantage (Crewe, 2005) that increases caregiver burdens especially for economically disadvantaged groups.

A 2004 survey of caregivers receiving services under the Older Americans Act (OAA) offers additional information about caregivers. It reported that 24% report difficulty providing care because of their own physical limitation; 37% also care for someone else; 33% are over 65 years old themselves; 74% of the elders cared for are at least 75 years old; and 32% of the elders cared for are 85 or older. These caregivers provide a variety of services for the elders they care for, including 88% who provide transportation assistance, 79% who provide help with meals, laundry, and household chores, and 73% who provide help with financial matters (AoA, 2004).

As individuals age, caregiver support will become more and more critical to keeping them at home or in a noninstitutionalized setting. According to the National Alliance on Caregiving and the AARP study (1997), 52% of caregivers are employed full-time, and more than 50% report tension between work and caregiver needs that has resulted in work-related changes, including reduction in hours, rearranged work schedules, or taking unpaid leave. They also reported caregiving as taking a toll on their physical health. Thus support is needed to meet the interdependent emotional, economic, health, and social needs (Hooyman & Kiyak, 2002) of the caregiver. When one of these needs is neglected, the caregiver-receiver dyad is placed at risk, and the quality of the relationship is compromised. Thus, programs and services that focus on keeping harmony and balance in the caregiver-receiver relationship serve as protective factors related to financial, physical, and emotional caregiver stress.

SOCIAL WORK ROLES

As noted by McInnis-Dittrich (2002), the caregiver serves as a vital member of the caregiving team not only to the older person but also to the gerontological social worker. Social work has historically provided services that embraced the entire family system, using a range of micro and macro interventions. In addition, strength-based assessment skills and the ecological

perspective acknowledge a dual caregiving network: an internal one that includes the family and an external network that includes the community and mezzo structures. Using the professional mantra of “starting where the client is,” social work uses frameworks such as the “life-course perspective” and the “convoy model” and integrates them into practice. The life-course perspective is a framework (Hooyman & Kiyak, 2002) that concentrates on age-related transitions through recognizing that aging is a lifelong process that influences and is influenced by social processes and is experienced differently by different age, ethnic, racial, economic, and geographical cohorts (Hooyman & Kiyak, 2002; Kart & Kinney, 2001; Stoller & Gibson, 1994).

All of the traditional social work functions and roles are needed to help family caregivers navigate through a system that is sometimes not “user oriented.” Drawing upon the work of Miley, Omelia, and DuBois (2001), social work has three major functions: (1) consultancy; (2) resource management; and (3) education. Through consultancy, social work seeks to find solutions, drawing upon knowledge, skills, and values. The resource management function fosters or stimulates exchanges with existing and undeveloped or unrecognized resources, and the education function focuses on information exchange and is grounded in understanding that dialogue is essential to problem solving. Within these three functions, social workers can assume various roles such as facilitator, planner, broker, and educator. Table 47.2 provides an example of social work roles in working with caregivers, showing that social workers have multiple ways of connecting with caregivers and multiple points of contact. This indicates the numerous opportunities afforded to social workers to access caregivers and offer needed instrumental, emotional, appraisal, and informational support as decisions are made about older relatives.

As employees of departments of social services agencies that are charged with adult and protective services, social workers have the opportunity and responsibility to work with caregivers. In addition, private social service agencies employ social workers to make decisions about placing children in homes where the caregiver of the child is also the caregiver of an older adult. This arrangement also creates the opportunity for social workers in the school system to intervene with caregivers of older adults (Crewe, 2004). Similarly, social workers employed by housing agencies interact with caregivers as they seek to meet the housing needs of families with older members.

TABLE 47.2. Social Work Roles

Social Work Roles	Micro Level	Midlevel	Macro Level	Social Work Profession
	Individuals, Families, Small Groups	Organizations and Formal Groups	Communities and Societies	The System of the Social Work Profession
Consultancy • enabler • facilitator • planner • mentor	Counseling with caregivers and family members, i.e., facilitating support groups	Facilitating change in organizational culture to understand and act upon needs of caregivers	Participating in community planning process for aging community	Support of programs and public policy aimed at providing direct support to caregivers (NCFSP, FMLA)
Resource management • broker/advocate • convener/mediator • activist • catalyst	Linking caregivers with additional community resources	Coordinating service delivery planning among multiple community-based resources	Identifying potential funding sources that are flexible enough to serve caregivers—critically assessing silo funding	Spearheading national alliances and partnerships that bring attention to the needs of caregivers and the lack of funding
Education • teacher • trainer • outreach • research/scholar	Providing educational resources that lead to better understanding of illness or disabling condition	Conducting staff development training that focuses on the caregivers as the primary target of intervention	Informing the public of the role of the family caregiver and involving them in advocacy for a continuum of service in their communities	Publicizing through qualitative and quantitative research the “hidden public costs” of family caregiving, especially for populations at risk

Note: Adapted from *Generalist Social Work Practice*, by K. K. Miley, M. Omelia, and B. DuBois, 2001. Boston: Allyn and Bacon.

Social workers are also employed in a range of roles in offices on aging, employee assistance programs (EAPs), and mental health delivery systems. Faith communities also use social workers to provide services for their congregations. Finally, social workers are sometimes assigned to constituent services in congressional offices where they hear about the needs of caregivers and care receivers. This list is not exhaustive. By expanding their knowledge about community-based caregiver resources (Family Caregiver Alliance, 2004) and working outside of their networks, social workers can maximize their sphere of influence.

SUPPORT SERVICES AVAILABLE FOR FAMILY CAREGIVERS

A healthy caregiver-receiver dyad consists of support services that meet the needs of the caregiver and older person in a manner that is sensitive to their distinct lifestyles and culture. Antonucci (as cited by Tirrito,

Nathanson, & Langer, 1996, p. 128) defines social support as “interpersonal transactions involving key elements such as aid, affect and affirmation.” While a myriad of services and programs are emerging to address caregiver needs, the social work profession must be in the forefront in advocating for programs that respond to shared needs yet distinctive family characteristics and circumstances. For example, social workers can advocate for families to get needed time to make caregiver arrangements. Equally important is the professions’ advocacy for direct rather than indirect services to caregivers and historical emphasis on self-determination and promoting programs and services that maximize family choice. Similarly, social workers can become more involved in raising public awareness of the need for family members to begin care dialogues before crises erupt and truncate planning time.

A review of the literature shows a cadre of support services that are currently available to support caregivers of older persons. These services include both formal and informal resources, in-home and com-

munity based, and traditional and innovative services. They include respite care, adult daycare, support groups, technological resources, and EAPs aimed at enhancing quality of life.

Respite services. Respite care is the use of short-term temporary services that use trained sitters to provide relief for caregivers (Kart & Kinney, 2001; Kropf, 2000; Montgomery, 2002; Staicovici, 2003). This is extremely important, considering the evidence that the stress of providing long-term care is associated with compromised mental and physical health (Feinberg & Whitlach, 1998). Kart and Kinney (2001) describe four models of respite care: (1) home-based; (2) group daycare; (3) group residential care; and (4) residential programs providing respite care as an adjunct service. The Government Accountability Office, formerly the General Accounting Office (GAO), states that “respite care offers support to caregivers so that they can continue to provide care for the frail elderly” (Kart & Kinney, 2001, p. 464). Numerous studies have shown that respite care benefits both caregivers and care receivers. There is evidence that respite care results in improved emotional and physical health for care providers and has resulted in the decline of institutionalization of the elder family member (Staicovici, 2003). There is also research that documents that respite care does not offer rest and relaxation but rather freedom to perform other required tasks (Bedini, 2002). This suggests the need for models that include information, education, and support in addition to respite care (Gutheil & Chernesky, 2001). Ethnicity is also an important predictor of levels of respite care use, and different ethnic groups have distinct trajectories of service use over time (Cox, 1998; Montgomery, 2002). In addition, some of the services have a limited number of days available, and this may also limit the use of the services.

Adult daycare. Another form of respite for caregivers, adult daycare (ADC) provides a community-based, supervised environment for the elderly who are unable to stay at home (Kropf, 2000). Respite services are scheduled around certain events and times, while ADC centers require regular attendance; they include a wide range of tailor-made therapeutic services for older persons who have mental or physical impairments (Kart & Kinney, 2001). Adult daycare centers allow the older person to remain at home while receiving some health and social services (Hooyman & Kiyak, 2002). Some ADC centers are based on a health-rehabilitative model sometimes referred to as adult day health care (ADHC), while others have a focus more social-psychological. Both

models may provide recreation, meals, and transportation and are governed by individualized treatment plans that are jointly developed by the care receiver, the caregiver, and the center staff (McInnis-Dittrich, 2002). Adult daycare centers allow the primary caregiver to continue to work and perform other responsibilities with the assurance that their older relative is being properly cared for. *The Encyclopedia of Social Work* (Gordon, 1995) lists providing respite, support, and education for family caregivers as one of the seven goals of ADC. Recent studies have found that the use of ADC centers by the care recipient reduces caregiver stress and, when coupled with counseling, can delay institutionalization (Takamura, 2000). Increasingly, ADC centers are developing or adapting to providing services to clientele with special needs such as dementia, AIDS, mental illness, visual impairment, hearing loss, or communication disorders (Gordon, 1995). In addition, intergenerational centers are available where older adults and children are brought together in the same program (Kropf, 2000) to increase interactions between older and younger generations and offer older persons meaningful roles.

Support and educational groups. One of the 10 tips for caregivers offered by National Family Caregivers Association is to “seek support from other caregivers” (McInnis-Dittrich, 2002, p. 322). This advice is grounded in the belief that there is great value and strength to caregivers’ knowing that they are not alone. There is general agreement that support groups foster caregivers’ taking care of themselves (Monahan, 1994). Caregivers can benefit from support and education groups for themselves and their elder care receivers. Support groups are intended to offer emotional support to protect the caregiver-receiver dyad from stress buildup, as well as serve as a source of information and referral. Participating in support and educational groups is a way to relieve stress, because they focus on caregiving and provide information on the specifics of the care receiver’s disease or chronic condition (Hooyman & Kiyak, 2002). Caregiver support groups provide resources and techniques that ameliorate caregiver stress and offer a safe haven for caregivers to voice their concerns and frustrations. Caregiver support groups are particularly helpful for new caregivers and assist in sifting through the myriad new demands on their time and help them better control their lives (McInnis-Dittrich, 2002; Monahan, 1994; Williams & Barton, 2003/2004).

Available technological resources. Increases in the older adult population are accompanied by an in-

crease in technology that can be used to enhance quality of life for both the caregiver and receiver (Chambers & Connor, 2002; Cortes et al., 2003; Meadows, 2001; Shellenbarger, 2002b). Zarit and Edwards (1996) relate that the provision of information to caregivers is key in managing stressors. Older persons and their caregivers now have greater access to online resources that offer them the advantage of up-to-date information on health care, support groups, community-based resources, and family members (close by as well as far away). For example, the AoA has a Web site for caregivers with links to the National Family Caregiver Support Program and other federal, state, and local resources (Meadows, 2001). The resulting partnership between caregivers and health organizations can result in greater efficiencies in the health care system and ultimately assist caregivers with some of the financial burden.

Advances in technology have been helpful in the following ways:

1. Increasing access between caregiver and care received (Shellenbarger, 2002a)
2. Facilitating communication with physician, resulting in reduced in-office visits (Hooymann & Kiyak, 2002)
3. Maintaining or improving the functional capacity of individuals (Gilson, 2000)
4. Enhancing clinical support capabilities by giving caregivers remote access to client data and clinical alerts (Meadows, 2001)

Internet-based social support is primarily used to expand one's social network of status-similar others. Participants report they use it because of psychological distress, including isolation, loneliness, and desperation (Colvin, 2003). However, this technology is also used to address the desire of caregivers to keep relatives in the least restrictive environment. This desire often raises concerns about the safety of their relative in the home. Low-tech tools such as door alarms and intercoms are being supplemented by Internet-based monitoring systems.

Kinney, Kart, Murdoch, and Ziemba (2003) found that affordable technologies such as computers, Web cams, mobile telephones, and wireless devices have great potential to reduce caregiver burden and distress. They conclude that electronic technologies will be critical components of caregiving, and caregivers' voices will be needed to inform those who design, develop, and implement them. Assisted technology is being designed to be used by not only professional

caregivers but also family caregivers (Cortes et al., 2003). For example, the Link2Care resource has as a goal increasing caregiver well-being and coping skills through convenient access to information, connection to caregivers, and other services provided in the home via electronic delivery (Kelly, 2003/2004). These assisted-technology devices are defined as mechanical devices and instruments used to communicate, see, hear, or maneuver (Gilson, 2000). These and other forms of technology can help increase the autonomy of caregivers, free them from some of the caregiving roles, and offer greater ease when they have to be away from the home or are remote or distance caregivers. Because of these potential benefits, Bradley and Poppen (2003) advocate for social policy that increases the use of assisted technology. Some examples follow of technological innovations that are being used to support caregivers.

Web-based radio broadcast: Coping with Caregiving is a weekly broadcast that features guests and speakers of a range of caregiving topics. It also airs via Internet. Caregivers need no appointment to discuss the topic or offer advice for other listeners (www.wsradio.com/copingwithcaregiving).

Interactive voice response (IVR) offers caregivers support through stress monitoring, counseling information, personal voicemail linkage, and telephone support groups (Mahoney, Tarlow, & Jones, 2003).

Transponders (E-gear) are electronic monitors, placed around the neck, that communicate the activities of the care receiver to the caregiver by way of an electronic device that can be accessed by the remote caregiver's computer. They also function as alarms, room keys, and location monitors. The equipment allows remote/distance caregivers to have a more active role with elder and reduces some of the stress associated with not seeing their elder on a regular basis. The equipment serves as their eyes and ears and helps to monitor the elder for signals of worsening health such as loss of weight and so on. (Shellenbarger, 2002a, 2002b)

Similarly, technology is also used to assist the professional social worker in meeting caregiver needs. Although a broad range of instruments are used by professionals to assess caregiver stress and burden, Chambers and Connor (2002) advance the concept of a computer-based, systematic self-assessment and conclude that the software was helpful by providing

reassurance and emotional support that enabled caregivers to assess their coping capacity and information to enhance their skills. In summary, technological advances can offer assistance to the caregiver, care receiver, and professional staff.

Employment assistance programs (EAPs). These programs provide a variety of assistance to employees in the public and private sector. An increasing number of people in the workforce are actively involved in caregiving for an older relative or friend (Metlife, 2003). Family Caregiver Alliance (2003) indicates that a majority of the 25 million family caregivers are employed and forced to make work-related changes to accommodate caregiving. Employment assistance program services are offered to offset the loss in employee productivity and increased absenteeism and interrole conflict, which results in estimated costs of \$29 billion yearly to employers in terms of lost productivity (Franklin, 2001; Martire, 2003) and \$659,000 in wages, pensions, and Social Security for the caregiver (Family Caregiver Alliance, 2003). Workers also miss promotion opportunities because of caregiving responsibilities. Caregiver services, including counseling and eldercare search, are increasingly sought by caregivers (Franklin, 2001; Metlife, 2003). A 2000 survey of Hewitt Associates found that nearly half of large employers (over 1,000 employees) offer some type of eldercare assistance, with information and referral being the most common (Franklin, 2001). Franklin (2001) reports that Fannie Mae and companies like

the Federal Deposit Insurance Corporation (FDIC) offer services, through social workers, to guide workers, bring in speakers, and offer resources.

THE NEXT GENERATION OF SERVICES AND SUPPORT FOR CAREGIVERS

Toseland and Rivas (2001) state that a major role of social workers is to “facilitate hope for the future and motivate members to improve coping skills through self-help and mutual aid” (p. 24). Rieske, Holstege, and Faber (2000) describe the need for “coordinated information distilled from gerontological research” (p. 759) to maximize the quality of life of both the care recipient and the caregiver. The resource list at the end of the chapter shows selected online resources that are available to both caregivers and social workers as they work cooperatively to maximize the quality of the caregiving experience for both the caregiver and the care receiver. The new generation of caregivers will need services that allow maximum flexibility and deemphasize governmental control of the caregiving process.

Old mindsets and conventional wisdom about caregiving must be addressed. To respond to current realities, traditional programs and caregiving roles must be “unlearned” and replaced by new resources. For example, the assumption that caregiving is exclusively the domain of women must be reexamined, on

the basis of evidence such as the Metlife Study of Sons at Work, which reported that one in three caregivers are men. Findings of the survey of 1,400 employed caregivers at three Fortune 500 companies found men caregivers increasingly in the workplace. They reported feeling uncomfortable discussing their responsibilities and therefore not seeking to receive support from colleagues and supervisors (Metlife, 2003). In addition, cultural and ethnic differences must be addressed (AARP, 2001) to maximize subjective and objective quality of life for caregivers. Considering that many members of the new generation of caregivers are likely to serve as caregivers for longer periods, the social work profession must be a leader in providing “emotional insurance,” through informed social work practice that offers a myriad of caregiver-centered services and programs at both micro and macro levels that are responsive to the diversity of caregivers and caregiving experiences.

Society gives family caregivers a dual message. On the one hand, they are praised for assuming the responsibility of their relative, and on the other hand, they are marginalized by the full burden being placed on their shoulders. Caregivers who find themselves enmeshed in the multiple roles of caregiver are likely to look for professional and formal interventions that are responsive to their lifestyles. Through understanding the complexity of the caregiving relationships and becoming familiar with the various programs and services available in the community, social workers can maximize the quality of life of family caregivers by connecting families with needed resources that are affordable, accessible, and culturally appropriate. Today’s families are managing multiple tasks, and unplanned changes in their internal or external environments can interrupt established routines. Caregiving of older persons is an example of unplanned change that can impact a family’s equilibrium. The success of caregiving for older persons can be maximized by social work professionals recognizing and helping families to plan for the changes that are needed for successful caregiving and can result in mutual benefits and protect families from experiencing unnecessary stress. Without proper support, the caregiving experience can be stressful and end with final memories that are painful and overshadow the positives of the relationship.

The needs of caregivers are going to increase as the population requiring care increases. Addressing the increased needs will require changes in policies and the coordination and collaboration of social workers, doctors, nurses, families, and other community-

based organizations to meet these needs. Finally, informed social workers can ensure that the tradition of family caregiving is embraced by families and supported by policy and practice initiatives that make the caregiving experience one that is positive and causes minimal disruption to the family system. When you think about it, caregiving is the anchor of the beginning and end of life. Often the last memory of a loved one is experienced in a caregiver-receiver relationship. Social workers must continue to make a concerted effort to make this a positive experience that completes the life cycle with the same optimism it began with. In the words of a caregiver:

Taking care of my mother was a lasting memory that I cherish because I received the support from my family, friends, church, and social services programs that helped me to make the needed changes in my lifestyle to really get to know her and enjoy spending time with her.

Advocacy and Protection of Older Adults

48

We focus in this chapter on those who are vulnerable to possible adversity and the mechanisms by which social workers can be engaged in the surveillance and protection of such persons. Specifically, this chapter will provide an overview of the ombudsman program, concerned with the quality of care within long-term care facilities; adult protective service (APS) programs, created to intervene in cases of community-based abuse, neglect, and maltreatment; and legal efforts designed to safeguard the elderly and their resources.

THE OMBUDSMAN PROGRAM

Over the years, ombudsman programs have played an important role in seeking to ensure the quality of care given to institutionalized older populations through different activities. Social workers have been intricately involved in programs as paid staff members or as volunteer participants. Although the quality of institutional care has improved over the years, institutionalized persons can be the victims of abusive acts of omission and commission.

Legislative History and Authority

To counter potential problems, the long-term care ombudsman program is the major mechanism having responsibility for advocacy and protection of residents within nursing homes, board and care facilities, assisted living units, and similar adult care settings. *Ombudsman*, as both a word and a concept, comes from Sweden. The Swedish Parliament established the office of Justiticombudsman in 1809, and this person received complaints and protected citizens from injustice, no matter where that injustice might have arisen (Lowy, 1980). (Inasmuch as the term *ombudsman* is of Swedish origin, without gender specificity, it is customary to continue the use of the term.)

In the early 1970s, several states passed patients' rights legislation in response to the belief that the personal rights and liberties of patients were being lost following institutionalization (Gelfand, 1999). In 1974, the federal government developed regulations that established a set of patients' rights for individuals in skilled and intermediate care facilities. These rights, which relate to individual liberties, were to be readily displayed, explained to the patients, and assigned to nursing home personnel for enforcement. Programs were to identify, investigate, and resolve

complaints regarding the care given within long-term care facilities.

In 1978, the ombudsman program, with statutory definition of ombudsman functions and responsibilities, was incorporated into the Older Americans Act (OAA), to be administered by the Administration on Aging (AoA) and state laws (Administration on Aging [AoA], 2004). Under the act, every state is required to have an ombudsman program that addresses complaints and advocates for improvements in the long-term care system.

Significant amendments to the OAA were enacted by the Ombudsmen Budget Reconciliation Act (1987), which required states to provide for ombudsman access to residents and residents' records, immunity to ombudsmen for the good-faith performance of their duties, and prohibitions against willful interference with the official duties of an ombudsman and/or retaliation against an ombudsman, resident, or other individual assisting representatives of the program in the performance of their duties. In 1992, the program was strengthened and transferred to a new title in the OAA, Title 7, Vulnerable Elder Rights Protection Activities, which also includes Programs for Prevention of Elder Abuse, Neglect and Exploitation and Elder Rights and Legal Assistance Development.

Program Design

The program is federally mandated in the OAA, but it is managed on the state level, resulting in a multitude of program designs. Huber, Borders, Badrak, Netting, and Nelson (2001) indicate that local ombudsmen exist in all 50 states to identify, investigate, and work to resolve complaints initiated by, or on behalf of, residents in nursing homes, board and care homes, or similar adult care facilities. In 1999, there were 587 local and regional ombudsman programs (AoA, 1999). In 1995, the Institute on Medicine (IoM) published a report (Harris-Wehling, Feasley, & Estes, 1995) that was based upon their study of ombudsmen programs. The study, commissioned by AoA, concluded: Given variability in organizational location, funding sources, and staffing characteristics of ombudsmen programs, each state has a different model (Harris-Wehling et al., 1995).

Currently, most ombudsman programs are affiliated with the State Units on Aging and work through the Area Agencies on Aging (Gelfand, 1999). Each state has a different configuration for its ombudsman

program, in part dependent upon the size of the population, government, and budget. Some states rely primarily on paid staff, while others make extensive use of trained volunteers. While programs are administered by state governments, federal sources (mainly from the OAA) provide about 60% of the funding, supplemented by state and local support and from Area Agencies on Aging, the United Way, and foundations.

Volunteer involvement can be considered the "backbone" of ombudsman programs. According to the Administration on Aging Resources (2004), there are about 1,000 paid and 14,000 volunteer staff investigating over 260,000 complaints and providing information, referrals, and consultation on a myriad of topics (such as how to select and pay for long-term care) to more than 280,000 people each year.

Social Work Roles and Responsibilities

As mandated in the OAA, there are many responsibilities for ombudsmen, who may be either paid members of the staff or volunteers. First and foremost is the need to identify, investigate, and resolve complaints made by or on behalf of residents (Netting, Paton, & Huber, 1992). The identification of possible problems (such as abuse, maltreatment, neglect, infringements of resident rights) can result from visits to long-term care facilities by ombudsmen or from calls made to the ombudsmen program office. Complaints can come from residents, members of their families or friends, and staff members of a facility, among others. Investigation by an ombudsman necessitates the collection of information from individuals, reports, records, and so on, so as to verify the alleged complaint that can pertain to the acts of omission (i.e., neglectful behavior, failure to provide needed care) or commission (i.e., inappropriate use of restraints, theft of possessions) by a staff member (including administrators) from an institution. The need to document and verify the complaint is vital.

Social workers are well suited for the performance of these diverse responsibilities in conflict resolution, mediation, and information gathering, as well as advocacy efforts and knowledge of community resources. Netting, Huber, Paton, and Kautz (1995) have written about social workers' roles as reporters of abuse, advocates for change, educators, and coordinators of community efforts on behalf of institutionalized older persons. The ombudsman can act proactively in visiting nursing homes, board and care

or assisted living facilities, or other settings within his or her sphere of responsibility. The ombudsman often reacts to (and investigates) complaints about care, and to proposed policies and practices that are believed to be contrary to the best interest of long-term care residents. Each ombudsman program, although retaining the important role of being the focal point for complaints regarding nursing home care, also acts as a nursing home referral service and organizes friendly visiting programs.

Resolution Efforts

The tactics of an ombudsman to resolve a documented and confirmed adversity against a resident or patient within a long-term care facility exist on a continuum from collaboration to confrontation. Gelfand (1999) suggests that the ultimate enforcement of standards and principles for good care is difficult to undertake, inasmuch as “the only disciplinary tool available is decertification of the facility” (p. 219), a recourse that is perceived to be too severe for individual violations. Indeed, it has not been uncommon for long-term care facilities to respond to violations in standards or practices by threatening to close the doors of their facilities and “putting the residents on the street.” When and where the need for long-term care beds exceeds supply, there are often lengthy “periods of grace” before compliances are required to occur.

Gutheil (1990) suggests that grievances are resolved within the nursing home in collaboration with the administrator and staff, and that when appropriate outcome cannot be reached at the facility level, the ombudsman will make use of outside resources (such as the state health department). Adversarial tactics, including nonviolent protest, confrontations, boycotts, and litigation, are chosen by a very few advocacy organizations, although a case could be made for an approach that, while accenting cooperation, includes the possibility of confrontation. In discussing the collaborative model, Atchley and Barusch (2004) state:

This approach works when the nursing home is open to this kind of participation. But in many cases, the nursing home is defensive about criticism, and regulatory agencies may be reluctant to investigate complaints. In these cases, a more assertive ombudsman process may be needed. (p. 414)

The National Long Term Care Ombudsman Resource Center provides support, technical assistance, and training to state ombudsman programs and statewide networks of almost 600 regional (local) programs (www.ltombudsman.org). Representing ombudsman and private nursing home resident advocacy organizations is the National Citizens’ Coalition for Nursing Home Reform (available online at: www.nccnhr.org).

ADULT PROTECTIVE SERVICES

The term *adult protective services* refers to “publicly funded programs that investigate and intervene in reports of abuse, neglect, and exploitation of adults who are physically or mentally impaired and unable to protect themselves from harm” (Mixon, 1995, p. 69). Most APS workers (also referred to as practitioners and case managers) function within agencies that are covered by state statutes to receive reports, conduct investigations, evaluate client risk, assess clients’ capacity to agree to services, develop and implement case plans, and monitor ongoing service delivery (Otto, 2000).

Legislative and Program Background

“The history of adult protective services [APS] in the United States is difficult to trace” (Elder Justice, 107th Cong., 1st Sess., 2002). Teaster (2001) suggests that it emerged from the government’s concern for adults who were vulnerable and dependent, and Mixson (1995) indicates that the idea of such services originated in 1958, when the National Council of Aging created an ad hoc committee of social workers to discuss the potential need for some type of protective service for older people. In 1961 the White House Conference on Aging recommended that social agencies be created and that legal associations and medical professionals cooperate in some manner to facilitate the provision of protective services to older persons. The Administration on Aging (AoA) funded a number of demonstration projects in the 1960s, but “by 1968, there were still less than twenty community protective services programs in the country” (Mixon 1995, p. 70). In 1974, the Title 20 amendment to the Social Security Act gave permission for states to utilize Social Services Block Grant funds for the protection of adults (as well as children) (Older Americans Act, 1974). By 1981, “all the states, in one way or an-

other, noted that they had an office with responsibility to provide protective services to some segment of the population” (H.R. Doc. No. 97–277, 1981). The focus of APS has expanded and evolved from treating the impaired, low-income elderly to treating all adults over 18 years of age without regard to income, and more recently to treating elder abuse and neglect victims as a special population (Quinn & Tomita, 1986).

By the early 1990s, many states had mandatory elder-abuse reporting laws that mandated the reporting of suspected cases of abuse, maltreatment, exploitation, and neglect to APS agencies. Those required to report suspected abuse vary between states. Quinn and Tomita (1986) state:

Clients are referred often by practitioners from other agencies such as utility companies, meals on wheels, senior center programs, and law enforcement. Concerned citizens are becoming more aware of the needs of frail elders and the agencies that serve them. Reports of endangered elders are made increasingly by friends, neighbors, apartment managers, and relatives. (p. 236)

In fact, generally, those required to report suspected cases of abuse include employees of departments of social and health services, law enforcement agents, social workers, professional school personnel, employees of social services, and social welfare and mental health agencies, as well as home care, hospice, home health, and adult daycare services workers, or employees of nursing homes, boarding homes, or adult family homes, and health care providers (nurses and doctors).

Funding and Administrative Issues

With the origin of APS in the 1960s, Otto (2002a) notes:

Nearly forty years later, there are still no federal statutes regulating the delivery of Adult Protective Services (APS), no federal agency charged with responsibility to collect data and issue reports, and no discrete funds provided to states to support and enhance service delivery. (p. 1)

Thus, some programs provide protection to all those 18 and older, and others focus upon those persons considered old.

Some programs operate out of the state offices on aging, state human service agencies, or private contracting agencies, and the funding of state programs may be based upon Social Services Block Grants or state general funds. While APS always conducts investigations in independent domestic settings within communities, in some states APS agencies also have responsibility for abuse investigations within congregate settings (i.e., board and care facilities) and within long-term care institutions.

APS Activities

APS programs are the principal public source of response to reports and cases of vulnerable adult abuse, neglect, and exploitation. Social workers have been very prominent in APS programs and services, in general, as well as in the study of elder abuse and maltreatment, in particular. Adult protective services programs are empowered by states and local communities to accept and investigate reports of abuse, neglect, and financial exploitation of the elderly and younger persons with disabilities (Otto, 2002a). Some protective services may be provided without cost, and some are provided on a sliding-fee basis.

Adult protective services workers are trained to investigate allegations of physical, sexual, mental, or emotional abuse, neglect or self-neglect, financial exploitation, or abandonment. The report of suspected elder abuse is often made by telephone, either to a local elder abuse agency or through an “800” line of the state APS agency, and is transferred to the local elder abuse agency. An APS worker is then required to investigate the case by a deadline that is determined by the severity of the case (Hwalek, Goodrich, & Quinn, 1996).

Following an investigation, and in consultation with others, a determination is made whether there is evidence to substantiate the claim of alleged abuse. It should be noted that some competent older persons, suffering abuse, may refuse the assistance of APS workers; given the right of self-determination for a cognitively competent adult, the worker cannot ignore the older person’s wishes. The mentally competent individual, although living within an abusive situation, should not be subject to involuntary relocation or interventions. As Hwalek, Goodrich, and Quinn (1996) state: “Unlike abused children, elderly victims have the right to refuse interventions, even if this means their lives are in danger” (p. 126).

For those victims who seek assistance, once the report of abuse is substantiated, the APS intervention process begins. A care plan is developed for the victim that includes needed services and resources. The client-specific plan is typically multidisciplinary in nature and intended to ensure the safety, while maximizing the autonomy, of the older adult. The service plan may involve informal care provision by family or friends, or formal social, health, or mental health services offered by public, private, and/or voluntary agencies. Interventions may include home care, referrals, pursuit of guardianship, or institutionalization (if the abused victim is frail and impaired).

Challenges to Program Effectiveness

The recent down-turn in the economy has resulted in freezes and reductions of APS staff, cutbacks on travel and training, as well as the adoption of waiting lists for abuse investigations. These reductions put victims in increased danger of additional and more serious abuse. (Otto, 2002a)

Given this forewarning, APS case managers and administrators, many of them social workers, face very real challenges for the future.

State budgetary limitations, priorities given to the needs of children, and general ageism in society often result in insufficient training for APS workers involved in protecting and focusing upon the needs of older persons and their relationships with others. In part, this is a result of a lack of leadership by the federal government. Although most states require training for new workers, strained budgets might preclude complete training for some newly hired APS workers. In this regard, the only national group advocating for changes on behalf of APS is the National Association of Adult Protective Services Administrators (NAAPSA), a nonprofit volunteer organization made up of state and local APS administrators. The association is in partnership with the National Center on Elder Abuse (available online at: www.elderabusecenter.org) and is funded in part by AoA.

SOCIAL WORK ROLES IN LEGAL SETTINGS

Legal resources can play an important role in protecting the rights and resources of older persons. The role of social workers within the legal system has been slow to be recognized and slower to be utilized. Overall, the

placement of social workers in private law practices is rather uncommon (Arnason, Fish, & Rosenweig, 2001).

Current Exceptions

Perhaps the most notable exceptions to this pattern occur in elder law offices specializing in family, probate, and estate planning law. Public or quasi-public agencies such as prosecutor, public defender, and Legal Aid offices, on the other hand, more frequently have employed social workers to deal with the psychosocial and extralegal needs of their older clients. Brownell and Roberts (2002) argue that the roles of forensic social workers have been substantial and growing but largely unrecognized by the profession. Bassuk and Lessem (2001) point out that it is not uncommon in geriatric community-based organizations for geriatric case managers (mainly social workers) and attorneys to work collaboratively.

Trial courts increasingly include social workers and psychologists on their staffs. This growing trend is enhanced within specialized, problem-solving courts, which are likely to follow one or both of the relatively recent judicial developments: therapeutic jurisprudence and, to a lesser extent, trial court performance standards (TCPS). These developments have come, in part, as a reaction to widespread dissatisfaction and even distrust of the courts. In response, trial courts have sought ways to improve their responsiveness to the public, to streamline dockets and other court processes, and to improve outcomes and reduce recidivism by linking with community-based services. In the country's two elder justice centers, both of which have emerged in Florida, social work has a significant function (Rothman & Dunlop, 2004).

Roles for Social Workers

In a recent study of the elder justice centers and six other trial court systems scattered throughout the country, Rothman and Dunlop uncovered numerous ways in which social workers fill roles in the courts. Their study was designed to examine the implications of the growing number of elderly persons in America on the courts and judicial administration, access to the courts, and resolution of the underlying issues that often precipitate court involvement by older adults (Rothman & Dunlop, 2004). Because of the de-

mographics of older persons, and their increasingly complex physiological, psychological, and social profiles, there will be an increasing number of older persons who come into regular contact with court systems having more varied and complex circumstances. Thus, courts need to have the capacity to identify problem areas, as well as the practical ability to intervene and mobilize appropriate services. Social workers can play significant advocacy roles for such older persons.

The philosophy of therapeutic jurisprudence looks at the law and courts as social forces that produce consequences that may be therapeutic or antitherapeutic (Wexler & Winnick, 1996). Thus, for example, in addressing criminal areas involving substance abuse, mental problems, or domestic violence, courts have to make decisions that promote the health of all parties concerned, including the offender, while still ensuring justice for the victim (Rottman & Casey, 1999). Inevitably, this process involves establishing linkages with the community's health and social services systems.

In Florida, two "elder justice centers," in Tampa and West Palm Beach, represent approaches that courts have developed to address issues presented by the increase of older people. The purpose of these centers is to remove access barriers and to enhance linkages between elders and the courts, as well as with the legal, health, and social service systems (Rothman & Dunlop, 2004). The Tampa center, directed by an attorney, focuses on assistance to the probate court on guardianship cases, as well as serving victims of abuse and other crimes and providing general assistance to elders with other issues. The Palm Beach center, with a director having a master's degree in social work, assists older persons who are arrested for criminal activity, including those jailed, as well as older persons with a variety of other legal issues who need assistance or referrals. Staff members also assist the probate court. Both centers employ staff members with social work backgrounds and appropriate experiences for providing assistance and counseling. In both jurisdictions, these centers are offices of the judicial systems, and staff members are not independent case managers or advocates for individual elders. Rather, they assist the older person as appropriate, while advising the court of specific needs for services. It is a sophisticated role for social work professionals that will continue to increase with the aging of the population.

Rothman and Dunlop (2004) found additional roles and responsibilities carried out by social workers employed by, or working in collaboration with,

court systems. For example, a social worker may be employed as the Americans with Disabilities Act coordinator responsible for compliance. Social workers will be needed to educate judges and staff about issues of older people and how to address them effectively. Drug and mental health courts provide models for how other courts can utilize social workers to help provide assessments and obtain services. Social workers can also manage self-help centers, which courts have established to educate potential litigants about their rights under the law, including the ability to file certain legal documents without having to employ an attorney. Court social workers also are needed to educate law enforcement and health, mental health, and social services organizations about issues and barriers affecting the participation of older people in the court system. They are also needed to educate older adults and the general community about issues of access to the courts and typical legal issues that may affect them. Finally, social workers can be utilized to help identify funding opportunities and to prepare grant proposals to obtain additional funding.

Special Concerns Regarding Guardianships

One of the more obvious ways social work involvement is necessary is in a court or legal context, with regard to guardianships. In fact, guardianship is the single largest area of judicial activity involving older persons (Rothman & Dunlop, 2004). Social workers may be involved, first of all, in assessments to determine the competency of potential wards in guardianship applications before the court. In doing this, social workers presumably will conduct a multidimensional evaluation of potential wards and their circumstances (Hull, Holmes, & Karst, 1990). Bassuk and Lessem (2001) indicate the following potential roles for social workers in the area of guardianships: (1) identifying the need for guardianship services, (2) initiating or supporting guardianship appointments, (3) providing expert testimony at hearings, (4) investigating guardianship applications for the court, (5) offering guardians professional assistance, and (6) serving as a private or public guardian.

Whatever the role for the social worker, the prospects of guardianship for the potential ward are very serious, indeed. In a plenary guardianship, wards lose all of their liberties, from the right to vote to deciding where they will live. Rarely are these rights returned. Thus, in this context, social workers may at

times see the need to assume the role of advocate for older persons, to protect them.

Many states allow limited or partial guardianships that apply to only one or a limited number of life's activities. In the area of financial decisions, for example, a conservatorship preserves freedoms in other areas as well (Nolan, 1990). The only potential detriment of the option of limited guardianships is that it may be more appealing and, thus, more likely that a guardianship is ordered by the court in borderline cases. This presents a situation in which social workers may become involved in advocacy efforts for those older persons facing such possibilities.

To avoid the prospect of guardianship, a number of experts (see Alexander, 1990; Armstrong, 2000) have proposed the alternative of advance directives, especially the durable power of attorney and the living will, and even representative payee services that are sometimes used for Social Security and Supplementary Security Income beneficiaries (Dejowski, 1990). The extent to which older persons have advance directives is not known. Yet it is abundantly clear that many older adults are unaware of the need for such measures, especially those with few assets, and many persons cannot (or perceive that they cannot) pay a lawyer to draw up these documents, even in the face of increasing efforts by social workers and others who educate the public on such matters. Despite the growing number of older persons who will eventually adopt advance directives, it appears there will be a need in the foreseeable future for guardianships/conservatorships among a significant segment of the older population, especially the oldest old, who are most likely to suffer from dementias. The role for social workers in this context can be very substantial.

Social Work in Legal Settings

While there have been, at least, limited roles for social workers in legal settings for quite some time, opportunities for the practice of social work within these venues are clearly on the increase. First of all, this is due to the growing use of guardianships for (allegedly) incapacitated older adults. Within the past 15 years, the emergence of both the philosophy of therapeutic jurisprudence and problem-solving courts, in particular, has added significantly to the value of social workers functioning on behalf of vulnerable older persons. This results from the need to foster linkages between the legal community and social service community in order to deal with underlying issues that

cause individuals to come before the courts in the first place. With the rapid aging of the population, courts seem destined to be the locus of more and more social work practice.

CONCLUSION

Whether or not they function within APS, ombudsman, or legal programs, there are many opportunities for social workers to advocate for vulnerable older persons. "Social workers have always been engaged in advocacy roles, and their participation in consumer-patient rights movement has blended well with the values of the profession" (Netting et al., 1995, p. 355). Many social workers have played important roles in local, state, and national ombudsman programs, as social science researchers, and as observers and advocates (see Netting et al., 1995). Indeed, Arcus (1999) has indicated that with increased attention to the quality of care for those within long-term care facilities, social work "methodologies" become increasingly important. Many APS workers, and their administrators, are social workers, and their professional skills are greatly needed by their vulnerable or abused clients. Although the legal system has only recently, and possibly cautiously, added social workers into its programs, it is quite evident that they are needed to protect and represent the best interests of older persons.

Given the increasing number and proportion of older persons, especially among the oldest of the old, the need for advocacy and protection will increase. A "demographic imperative," resulting from the aging of the population, is confronting the profession of social work, and there will be increasing roles for social workers in a variety of settings, especially within ombudsman programs, APS, and the legal field.

JUDITH G. GONYEA

Housing, Health, and Quality of Life

49

Housing, or the need for shelter, is one of our most basic human needs. For most people, however, housing is about much more than a physical space or structure. Rather, a home serves multiple functions and has a deeper meaning. A home offers individuals a safe haven and protection from the intrusion of the outside world. One's home and neighborhood are a crucial piece of one's self-identity and evoke a sense of belonging. For many older adults, a home is a highly cherished symbol of their independence and dignity (Brown & Perkins, 1992).

Achieving a "secure old age" for most Americans depends upon three pillars: an adequate retirement income, quality health care, and appropriate and affordable housing. However, many of our nation's housing policies and programs for older Americans have been developed and implemented with little reference to this population's health care or supportive service needs. This disconnect between the two fields of health care and housing, particularly the failure of our nation to develop an affordable and effective community-based, long-term care system, has placed some older citizens at risk of losing their homes and, for others, led to premature institutionalization. A key theme emphasized throughout this chapter is that the diversity of America's senior population requires a wide range of dwelling types and assistive supports that meet or match seniors' household sizes, budgets, and physical or mobility limitations. Despite the historical disconnect between the two fields—health care and housing—several recent trends suggest grounds for optimism. There does appear to be growing recognition that our nation must pursue a more comprehensive or holistic approach to protecting older citizens' health and housing security if we are to ensure America's seniors a safe, secure, and dignified old age. Social workers can play a pivotal role through advocacy on both the clinical and macro levels in promoting affordable and appropriate housing options that maximize all older Americans' ability to age successfully.

DEMOGRAPHIC TRENDS, HOUSING, AND "AGING IN PLACE"

Most older Americans express a strong desire to maintain their independence, to stay in control of their life decisions, and to age with dignity. Central to "successful aging" is having appropriate and affordable housing. The dramatic growth in America's older population has increasingly drawn attention to the

challenges our nation will confront in meeting seniors' housing needs both now and in the near-term future. According to demographers, the number of Americans over 65 years of age will double between 1990 and 2025; and by 2030, the ranks of the elderly population will swell to 70 million, with one out of every five Americans being 65 and older. Much of this predicted surge in the senior population is the result of the baby boom cohort's arrival at old age (U.S. Census Bureau, 2002).

Equally important to the growth in our nation's older population are the longevity gains experienced by older Americans. The older population is itself aging, as more persons are surviving to their eighties and nineties. Indeed, the 85-and-over population is currently the fastest-growing segment of the older population. In 2000, approximately 2% of the U.S. population, or about 4 million Americans, were age 85 and older; by 2050, the ranks of the oldest old is projected to increase to almost 5% of the U.S. population, or almost 19 million Americans. Based on increasing life expectancies, the Census Bureau's population projections suggest that by the middle of this century, over 40% of adults age 65 and older can expect to live to at least age 90 (U.S. Census Bureau, 2000). These longevity gains will profoundly affect America's housing market. Chronic health conditions, which lead to a loss of function and mobility, increase with age. Whereas only about 3% of community-based Americans ages 65 to 74 reported problems performing activities of daily living (ADLs) such as dressing, bathing, and eating, this figure rises to almost 10% of community-based Americans age 75 and older. Similarly, while only slightly more than 6% of community-based Americans ages 65 to 74 cited having limitations in the instrumental activities of daily living (IADLs) such as meal preparation and house cleaning, almost one in every five (19.3%) Americans age 75 and older reported such restrictions (National Center for Health Statistics, 2002). Thus, for a significant number of older Americans, particularly the very old, the aging process will bring changing realities in personal health, functional abilities, and necessary home accommodations.

Income disparities present among today's older population will unfortunately continue to exist as the baby boom generation ages. Currently 9.2% of adults ages 65 to 74 and 11.2% of adults age 75 and older are among the ranks of the poor. However, older women and persons of color face a much greater risk of poverty in old age than white men. The interactive effects of gender, race, and age on the experience of

poverty are underscored by the fact that the poorest group of older individuals is black or African American women, followed by Hispanic women. For example, African American women are four times more likely than older white men to experience poverty in later life (28% versus 7%) (U.S. Census Bureau, 2002). The disparity in economic well-being in later life will be increasingly important as America's older population becomes more racially diverse. By 2050, the percentage of the older population that is non-Hispanic white is expected to decline from 84% to 64%. Hispanic persons are projected to represent 16% of the older population; 12% of seniors will be non-Hispanic black; and 7% of adults over 65 will be non-Hispanic Asian and Pacific Islanders (U.S. Census Bureau, 2000). Whereas seniors of all income strata face the risks of institutionalization, isolation, and neglect due to declining health and diminished social supports, these risks are greatest for older Americans with low incomes, who are disproportionately women and persons of color.

Recognizing the diversity of America's graying population is important, as seniors' housing choices vary by characteristics such as age, income, race/ethnicity, marital status, availability of children, and need for assistance. Yet, despite the heterogeneity of America's older population, research has consistently shown that our nation's seniors overwhelmingly prefer to remain in their longtime homes and never move. The American Association of Retired Persons (AARP), which has conducted surveys of midlife and older Americans on a regular basis over the last decade, has consistently found that over 80% of respondents age 55 and older prefer to remain in their current residences as they age (84% in 1992; 89% in 2000) (AARP, 2000, 2003). This aspiration to "age in place" is now viewed as an important objective in the design and implementation of formal support services.

HOW AMERICAN SENIORS ARE HOUSED

Much of our understanding of how Americans are housed comes from the American Housing Survey (AHS). This survey, conducted by the U.S. Bureau of the Census for the Department of Housing and Urban Development (HUD), collects data nationally every two years on a wide range of housing characteristics, including apartments, single-family homes, mobile homes, vacant housing units, household characteristics, income, housing and neighborhood quality, hous-

ing costs, equipment and fuels, size of housing unit, and recent movers. Using the AHS data, in 1999 HUD published a seminal report, *Housing Our Elders*, which highlighted the current housing status and challenges confronting vulnerable elders living in our nation's communities (U.S. Department of Housing and Urban Development [HUD], 1999). In addition to HUD, a second helpful resource for obtaining information on national trends in America's housing, including seniors' living arrangements, is the Joint Center for Housing Studies (JCHS) of Harvard University (available online at: www.jchs.harvard.edu/publications/seniors/index.html). Finally, the AARP, which has identified community living as one of the organization's priority research and policy areas, periodically conducts national surveys focused on assessing America's seniors' shifting housing preferences and needs (available online at: www.aarp.org/research). Together, these three resources—HUD, JCHS, and the AARP—offer social workers up-to-date information and analysis on the housing status of our nation's older population.

In fact, national data underscore that the vast majority of older Americans—82%—reside in conventional housing in the community. Approximately three out of four households over age 62 live in single-family homes, about one in five older households lives in a multiunit structure, and approximately 6% live in mobile homes. Social workers are therefore most likely to encounter seniors who are aging in place in their long-term communities (HUD, 1999).

The JCHS's analysis of the 1993 Assets and Health Dynamics of the Oldest-Old (AHEAD) survey offers further information on the living arrangements of Americans who are age 70 and older (Schafer, 1999). As reflected in Figure 49.1, the JCHS also found that three-quarters of over-age-70 households are living in conventional housing. Not surprisingly, married couples were the most likely to reside in conventional housing types. In addition, the AHEAD data revealed that about 10% of the 70-and-older population live in a "shared housing" arrangement, in which a nonolder member of the household provides assistance to the elder, and another 5% reside in "supported housing," which involves a non-family member living outside the home who provides supportive services. These supportive home environments—"shared housing" and "supported housing"—were more likely to be used by older adults who were separated, divorced, widowed, or never married. Shared housing was also an option that was chosen more often by older persons of color. Only a small percentage—1 out of every 10 individuals age 70 or older—lives in an age-

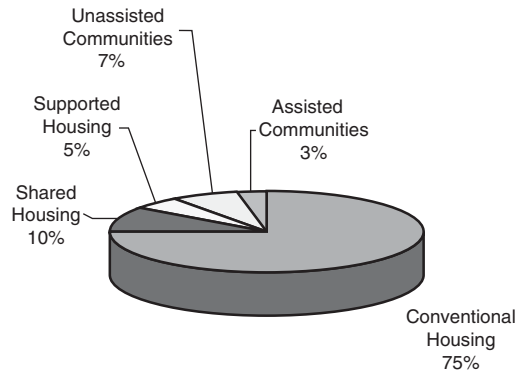

FIGURE 49.1. Living Arrangements of Persons Age 70 and Older. Reprinted from *Housing America's Seniors*, with permission from the Joint Center for Housing Studies of Harvard University. All rights reserved.

restricted community. Of this 10%, approximately 7% live in unassisted, 60-plus communities, and just 3% reside in assisted living communities, a term used for multifamily housing with congregate and personal care services (Schafer, 1999).

This chapter focuses primarily on the approximately 80% of American seniors who reside as homeowners or renters in conventional housing. As previously noted, very few seniors currently reside in assisted living, although this figure does rise with advanced old age. Similarly, only a very small percentage of the young-old—approximately 1% of persons ages 65 to 74 and 4.7% of persons ages 75 to 84—reside in nursing homes. This figure does rise dramatically, however, with advanced old age; slightly more than one in five (22.2%) persons age 85 and older are nursing home residents (National Center for Health Statistics, 2002).

Older Americans have a very high rate of homeownership. Of the almost 22 million households headed by older persons in 2001, 80% were owners, and 20% were renters (Administration on Aging [AoA], 2002). Yet again, there are significant race disparities in homeownership. The homeownership rate is 81% for older non-Hispanic whites, whereas this rate declines to 65% for older African Americans and 60% for older Hispanics (HUD, 1999). Among older renters, approximately 70% live in private market-rate housing rather than government-subsidized or rent-assisted housing. The 1995 AHS database lists 6.2 million rent-assisted units in the United States, of which 1.4 million (or 22%) were occupied by individuals over the age of 62 (HUD, 1999). The AHS survey

also revealed a high level of unmet housing need; there are almost six times as many seniors in need of rent-assisted housing, compared to those that are currently served by these programs. In 1999, approximately nine older applicants were on the waiting lists for each Section 202 rental unit that became vacant within a year (HUD, 1999).

Compared to their homeowner counterparts, the approximately 5 million older householders who are renters tend to be poorer, more often women and persons of color, and more likely to be living alone and in urban communities. Public housing residents are among the most vulnerable of our nation's seniors. Faced with few housing options, most older public housing residents are aging in place. Fifteen percent of senior public housing households are headed by someone age 85 or older, compared to 9% of older households nationwide. It is estimated that over one-quarter of seniors living in public housing have a disabling condition. Finally, the median annual income of older public housing residents is only \$7,451, versus \$20,761 for the older U.S. population (HUD, 1999).

In fact, residential mobility declines throughout our lives (see Figure 49.2). Only about 5% of persons

between the ages of 65 to 85 change residences in a given year. Almost half of all older homeowners have lived in the same home for more than 25 years. Aging in place means that the housing stock in which seniors live is also aging. For homes occupied by older householders in 2001, the median year of construction was 1963 (AoA, 2002). Despite the age of their housing stock, the vast majority of seniors live in dwellings that are in good condition. The 1995 AHS survey does, however, identify a segment of the 65-and-older households who are "at risk" in terms of their housing costs and quality. Almost 3.9 million senior households—owners and renters—are defined by HUD as having "priority problems," as determined by paying more than 50% of their monthly income on their housing costs or occupying dwellings with severe physical problems. An almost equal amount, another 3.9 million senior households are labeled as having "less serious problems," defined as a housing cost burden of 30% to 49% of their monthly income or occupying dwellings with moderate physical problems (Seniors Commission, 2002). The strongest predictor of physical housing problems is race or ethnicity. Confronted by discrimination in the housing market, along with lower lifetime earnings, elders

FIGURE 49.2 Residential Moves Annually by Age Group. Moves per 100 persons, 1996–1997. Tabulations of 1997 Current Population Survey. Reprinted from *Housing America's Seniors*, with permission from the Joint Center for Housing Studies of Harvard University. All rights reserved.

of color often live in the least desirable dwellings and neighborhoods. For example, although African Americans represent less than 10% of America's older population, they reside in 23% of all the housing units with severe housing problems and 30% of housing with moderate problems (HUD, 1999).

The interrelationship between the aging individual and his or her aging dwelling can create or exacerbate health problems. As Lawler (2001) notes, a circular relationship exists between health and housing:

When a living environment is affordable and appropriate, an aging individual is more likely to remain healthy and independent. When an individual maintains good health, he or she is more able to keep up with the maintenance of his or her living environment. As the population ages in an aging housing stock, it becomes difficult to distinguish a health concern from a housing concern. (p. 1)

An aging body and an aging home may simultaneously demand attention and resources from an individual. Poor health and a fixed income may result in an older homeowner or renter being unable to perform and/or purchase home repairs, while substandard housing conditions may further compromise an individual's health. For example, confronted with diminished strength and/or energy and escalating prescription drug expenses, a senior may neglect replacing a broken or malfunctioning stove or refrigerator. However, having a broken stove or refrigerator may result in a poor diet and exacerbate existing health problems, such as diabetes or hypertension.

ENVIRONMENTAL CHALLENGES AND HOUSING DECISIONS

Individuals—across all age groups—choose living arrangements to meet their physical and social needs based on the resources available to them. Relocation or migration *triggers* are often characterized in terms of *push factors* and *pull factors*. Push factors are life events or circumstances that loosen an individual's attachment to his or her current residence and lead him or her to consider relocation. Pull factors are life events or circumstances that occur at another location and draw an individual toward a new residence (Wiseman, 1980). The specific push and pull factors that influence housing decisions vary across the life

course. Although the primary push or reason older households seek alternative housing arrangements is escalating health problems and the need for assistance with the activities of daily living, these difficulties may be further compounded by declining economic and/or social resources. For example, the death of a spouse is often a push factor, particularly if the frail elder lives alone and does not have caring family members nearby. Loss of a spouse may also reduce or end some sources of income, thus creating greater financial burden for the widow(er) in meeting household expenses (e.g., utility bills, property taxes) and forcing a relocation or move. It is important to remember, however, that there is a great deal of diversity in the disablement process or the pathway to disability. While some seniors may experience a gradual and prolonged period of functional decline, for others it is a sudden event, such as a stroke or a fall, that abruptly changes their ability to function independently and/or safely in their current home. Pull factors might be the opportunity to relocate closer to one's adult children, the availability of a lower-rent apartment in a safer neighborhood, or the chance to move into a single-story dwelling closer to public transportation. Again, many of the triggers for older adults center on health concerns, either current or anticipated. It is important to remember that individuals' environments include not only their homes but also their neighborhoods. Neighborhoods present both opportunities and constraints to older residents as they age, including access to resources such as public transportation, parks, senior centers, doctors, groceries, and pharmacies.

Although most seniors do age in place, persons age 65 and older represent 10% of new homebuyers. As Schafer (2000) notes, the vast majority—approximately 80%—are local moves; only about 1% of seniors move across state lines. Those seniors who do migrate longer distances (e.g., Florida, Arizona) are typically younger, healthier, and wealthier. The slight rise in relocation after the age of 85 (see Figure 49.2) typically reflects the growing mismatch between an individual's assistance needs and his or her physical space.

The environmental press paradigm articulated by Lawton and Nahemow (1973) focuses on the "fit" of the older person with his or her home environments. A leader in the fields of environmental gerontology and environmental psychology, much of Lawton's lifelong work, underscores that an individual's ability to function may be either enhanced or impeded by one's immediate environment. Verbrugge and Jette

(1994) note that disability has two aspects: *intrinsic ability* and *actual ability*. Intrinsic ability refers to an individual's abilities regardless of the environment, whereas actual ability focuses on how a person's intrinsic abilities interact with one's social and physical environment. In fact, a growing body of literature suggests that environmental interventions or physical manipulations of the home environment (e.g., home modifications, home repairs, assistive technologies) can postpone or prevent functional decline in older adults (Day, Carreon, & Stump, 2000; Gitlin, 1998; Mann, Ottenbecker, Frass, Tomita, & Granger, 1999).

Yet despite evidence that older individuals with disabilities could benefit from environmental supports, over 1 million senior households, particularly the households headed by the very old, report needing home modifications, such as ramps, and kitchen and bathroom access (Pynoos, 2001). The 1995 AHS survey, for example, revealed that 12% of households headed by a person age 85 and older have unmet household modification needs, as compared with 3% of households headed by a person ages 62 to 74 (HUD, 1999). Similarly, analysis of 1984 data from the Longitudinal Study of Aging (LSOA), a large panel study of Americans 70 years and older, revealed that although almost one third of seniors reported needing a bedroom, bathroom, and kitchen on the same floor, 11% lived in homes in which these rooms were on different floors (Tabbarah, Mihelic, & Crimmins, 2001). As dwellings age and incomes dwindle, seniors' out-of-pocket home modification expenses are more typically for replacing worn-out systems and critical repairs (e.g., furnaces, siding) rather than for adding, enlarging, or modifying rooms (Schafer, 2000). Given the existing level of unmet home modification need, coupled with the reality that the United States adds less than 2% yearly to the new housing stock, Pynoos (2001) stresses that it is critical we make home modifications more available and work to retrofit existing multiunit housing to meet seniors' needs.

LINKING HEALTH CARE AND HOUSING

Addressing the *suitability of fit* between seniors' assistance needs and their environments to maximize their competence also requires that the older adults be able to access the informal and formal services they require. Despite the fact that the health and housing concerns of seniors are highly interrelated, our current systems of health and housing delivery are typi-

cally independent and separate services. This lack of integration or coordination between these two systems—that is, the failure of the United States to develop an integrated approach to community-based long-term care—creates significant challenges for frail seniors who are seeking to remain in the community as they age. Lawler (2001) notes that because of this disconnect between health care and housing, seniors are often faced with two equally undesirable choices as they become frailer—*overcare* or *undercare*:

They are often forced to choose between entering an expensive, restrictive elderly institution before the need arises, or remaining in their homes alone, to face the pressures of rising medical expenses and a deteriorating shelter while on a fixed income. (p. 5)

Recent social trends and policy directions suggest, however, some grounds for optimism. There is a growing convergence between the government's focus on cost containment and its encouragement of self- and community-based care and seniors' desire to age in place within their own homes. Indeed, it is increasingly being recognized that for most older Americans, the home is the primary setting in which long-term care occurs. In 1999, Congress, under the mandates of Public Law 106-7-4, established the Commission on Affordable Housing and Health Facilities Needs for Seniors in the 21st Century. The commission was empowered to study and report back to the Congress on the health and housing facility needs for America's seniors, both now and in the future. The commission was charged with developing specific policy and legislation recommendations to increase the range of options available to current and future generations of seniors. In June 2002, the commission issued a report to Congress, *A Quiet Crisis in America* (Seniors Commission, 2002), in which it states a vision for America:

The Seniors Commission believes that all older Americans should have an opportunity to live as independently as possible in safe and affordable housing and in their communities of choice. No older person should have to sacrifice his or her home or an opportunity for independence to secure necessary health care and supportive services. (p. 6)

The extensive testimony and research that comprises this report, however, underscores that achieving this vision will not be easy. Barriers identified in

the report include a long history of policy disconnects between the health and housing fields, poor communication, differing vocabulary, limited opportunities to interact between health care and housing professionals, and different financing and regulatory structures for the two domains. To develop public and private sector housing programs that are “flexible,” in order to maximize the choices of seniors of all income strata, the commission recognized that it would be necessary for the Medicare, Medicaid, and HUD programs to move beyond a silo approach and develop broad-based solutions. Ultimately, the commission developed five principles to guide its policy recommendations:

- Preserve* the existing housing stock
- Expand* successful housing projection, rental assistance programs, home- and community-based services, and supportive housing models
- Link* shelter and services to promote and encourage aging in place
- Reform* existing federal financial programs to maximize flexibility and increase housing production and health and service coverage
- Create and explore* new housing and service programs, models, and demonstrations (p. 62)

HUD, too, has begun to initiate several more comprehensive programs focused on integrating health and housing services since the release of its 1999 report, *Housing Our Elders*. For example, the HUD Service Coordinator Program, in which the coordinator acts as a broker of community services for seniors, was expanded in 2001 to allow these professionals to work with seniors in the surrounding communities as well as residents of the HUD multifamily developments. Recognizing that low-income seniors might also benefit from assisted living environments, in 2001 HUD made available funds for the conversion of some of its multifamily developments to assisted living facilities (ALFs) to promote vulnerable elders’ ability to age in place. The U.S. Supreme Court decision in *Olmstead v. L.C.* (1999), affirming the right of persons of all ages with disabilities to live and receive services in the least restrictive setting they desire if at all possible, gives further impetus to government coordination to create a more holistic system of care. Despite these advances, overcoming the existing regulatory, structural, financing, and implementation barriers to develop a comprehensive approach to the health and housing needs of older Americans continues to be a significant challenge.

IMPLICATIONS FOR SOCIAL WORK PRACTICE

In addition to their aspiration to age in place, the importance of home to seniors is evident by the fact that, particularly for the very old, it is the physical space in which they spend the vast majority of their time and most of their daily activities occur (Horgas, Wilms, & Baltes, 1998; Moss & Lawton, 1982). For older people who may be coping with multiple personal losses (e.g., death of a spouse, declines in physical health), one’s home can offer a sense of normalcy and coherence about one’s personhood (Rubenstein, 1989). The social work profession’s emphasis of strengths-based and empowerment-oriented paradigms suggests a commitment to honor seniors’ desires to age in place.

Currently, older adults experience a number of difficulties as they attempt to negotiate the separate systems of health and housing services to maintain a quality of care as they age. As noted in the Seniors Commission (2002) report,

the ultimate consumer—the senior citizen—faces the daunting task of obtaining care from these two disconnected sources. Confronted with complex entry requirements, insurance coverage limitations, and high costs, many seniors become overwhelmed just when they need help the most. (p. 19)

Social workers, positioned in community agencies, can play a critical role in accessing and coordinating services that allow older persons to live in their own residences and communities as long as possible, despite frailty and/or debilitating health conditions. Moreover, social workers can identify those older individuals who are at risk for housing instability. Within public housing, social workers often play a sensitive but critical role in facilitating the needs of the older residents and the housing management. One of the primary reasons for older adults’ eviction from public housing is behavioral problems. Eviction is often a tragic outcome for these vulnerable older adults who have few alternative housing options.

The social work profession’s *person-in-the-environment* perspective fits well with understanding the *importance of place* in older persons’ lives. Through their professional orientation and clinical training, social workers are both attuned to and skilled in assessing the environment-behavior interaction—that is, the interaction between the senior’s home environment and his or her well-being and daily life functioning. Social

workers' clinical assessments of the suitability of fit, however, must extend beyond a focus strictly on how the home and neighborhood environments enhance or impede the senior's *functionality* and *security* to examine their impact on the older adult's level of *comfort* and *social connection*, as well as *personhood*.

It is evident that clinical assessments must incorporate both objective and subjective aspects of the environment to understand seniors' perceived quality of life. Is it critical to gain an understanding of how the older adults themselves assess the suitability of fit between their homes and neighborhood environments and needs and their preferences and expectations for future living arrangements. Moreover, social workers must strive to understand how older persons' assessments of their current environment, as well as future housing choices, are influenced by the context and meaning of their past environments, life-course changes, and the disablement process (Golant, 2003; Robison & Moen, 2000). Also key is a sensitivity to how an individual's assessment of suitability of fit and housing expectations may be shaped by one's cultural values and norms. Although these distal experiences are not typically included in clinical assessments, failure to frame seniors' housing choices as a process may seriously jeopardize treatment plans.

Attention has generally been focused on how environment supports or impinges upon seniors' physical health. It is also important to understand the impact of the home environment on mental health. The degree to which an older adult with a disabling condition is able to use the home environment to assert some control over the circumstances of daily life may affect his or her sense of self-efficacy and lead to higher morale (Gitlin, 2003; Schulz, Heckhausen, & O'Brien, 1994). In addition, the extent to which the home environment supports opportunities for social interaction or engagement may positively impact the older person's quality of life.

Older adults express confusion about the meaning of many of the types of housing options such as assisted living, supportive housing, adult care facilities, life care communities, continuing care facilities, and reverse mortgages. Social workers can play a valuable role in educating seniors about housing options so that they are able to exercise informed choices.

As a profession that has historically engaged in interdisciplinary practice, social workers can also contribute to community-based efforts to forge stronger linkages between health care and housing programs. For example, as highlighted in the Seniors Commission Report, the two worlds of health care and housing are

even separated by language and vocabulary. Aging in place and community living for health care professionals is about beds, lengths of stay, and insurance, as well as the seniors' ADL skills and ability to access and pay for community services. In contrast, housing professionals typically speak about these issues in terms of dwelling units, turnovers, and subsidies, as well as the seniors' income as a percentage of area median income (AMI) (Seniors Commission, 2002).

Finally, on the state and federal level, social workers can actively advocate for policies that promote a more comprehensive and holistic approach to community-based long-term care. Central to this advocacy are the issues of affordability and accessibility, if we as a nation are to create a system of care that works effectively for *all* older citizens. A secure retirement for both current and future generations of older Americans requires all three pillars to be in place—appropriate and affordable housing, adequate income, and quality health care.

BRADLEY D. ZODIKOFF

Services for Lesbian, Gay, Bisexual, and Transgender Older Adults

50

The purpose of this chapter is to present an overview of community-based social services for lesbian, gay, bisexual, and transgender (LGBT) older adults. Specialized programs for LGBT older adults exist in several communities in the United States. However, nationwide, there is a severe shortage of specialized services for LGBT older adults (Cahill, South, & Spade, 2000; Senior Action in a Gay Environment [SAGE], in press). Most LGBT older adults requiring social work intervention obtain services from mainstream (rather than LGBT-specific) health and/or social service programs. Many of these LGBT older adults encounter obstacles in accessing services sensitive to their specific needs in mainstream settings (Cahill et al., 2000; SAGE, in press). With few exceptions, aging services organizations continue to design programs that presume the heterosexuality of their prospective clients, creating a barrier for LGBT older persons who present to these agencies for social work assistance. At the same time, LGBT older adults are often reluctant to disclose their sexual orientation to mainstream service providers, fearful that by doing so, they may subject themselves to potential stigmatization, hostility, and discrimination (Barranti & Cohen, 2000; Brotman, Ryan, & Cormier, 2003; Kochman, 1997). For the current cohort of LGBT older adults, the fear of stigmatization is grounded in a long historical experience of structural heterosexism, homophobia, and oppression (Kochman, 1997; Rosenfeld, 1999). Though cultural attitudes toward LGBT persons have evolved considerably and dramatically since the birth of the modern gay liberation movement (dating back to the Stonewall rebellion of 1969), there is evidence that LGBT older adults today continue to encounter heterosexism, homophobia, and discrimination in health and mental health settings (Brotman et al., 2003; Cahill et al., 2000). Negative reactions documented toward gay and lesbian patients (across the age spectrum) have included embarrassment, anxiety, direct rejection, refusal of treatment, hostility, excessive curiosity, avoidance of physical contact, and breach of confidentiality, among others (Brotman et al., 2003).

Demographically, the proportion of LGBT older persons in the United States remains difficult to estimate accurately, largely because national surveys asking respondents their sexual orientation or gender identity are very scarce (Cantor, Brennan, & Shippy, 2004). One recent report estimates that at least 1 to 2.8 million persons over the age of 65 living in the United States are gay, lesbian, or bisexual (Cahill et al., 2000). By 2030, the number of gay, lesbian, and bisexual per-

sons age 65 and over is expected to increase to the range of 2 to 6 million seniors (Cahill et al., 2000). Given the unique challenges of estimating population parameters for lesbian and gay persons from available national data sources (Black, Gates, Sanders, & Taylor, 2000), these figures most likely undercount the total lesbian, gay, bisexual and transgender older population (Cahill et al., 2000).

In terms of race, ethnicity, socioeconomic status, health status, geographical location, and availability of social support from partners, children, family, friends, and neighbors, the LGBT older adult population is as diverse and heterogeneous a group as the older population as a whole (see chapter 22 here). It must be emphasized that LGBT older adults and their family members encounter the same range of problems in aging as heterosexual older adults. For this reason, LGBT older adults seek services in *all* types of geriatric settings, just as heterosexual older adults do. However, LGBT older adults face additional challenges in accessing health and social service programs that are sensitive and responsive to their individual needs. Culturally competent social work practitioners, administrators, policy makers, advocates, and researchers must understand LGBT older adult clients as consumers of the *full* spectrum of aging services and must work to develop sensitive and inclusive approaches to address the needs of this persistently underserved population.

Toward this goal, this chapter will focus specifically on service delivery issues with respect to LGBT older adults. (For a comprehensive literature review describing the LGBT older population in detail, please refer to chapter here.) Beginning with a discussion of the specific service concerns of the LGBT older adult population, drawing from current research, this chapter will then describe the availability of services for LGBT older adults across the country, including information to assist providers in locating existing services in their own communities. Key practice principles for working with LGBT older adults and for promoting LGBT-sensitive services within mainstream organizations will also be highlighted. Finally, this chapter will identify selected policy issues that directly affect the health and well-being of LGBT older adults and their families.

SPECIAL CONCERNS OF LGBT OLDER ADULTS

Barranti and Cohen (2000, p. 343) aptly refer to LGBT older adults as “an invisible minority.” Many LGBT

older adults, though certainly not all, have learned to cope with discrimination throughout their lifetimes by choosing to hide their sexual orientation in specific settings as a means of survival (Barranti & Cohen, 2000; Brotman, 2003; Kochman, 1997). Brotman et al. (2003) emphasize that LGBT older adults’ strategy of “hiding” may be understood as an adaptive, long-term coping mechanism for dealing with ongoing discrimination. Many individuals from the current cohort of LGBT older adults came to terms with their sexual orientation long before the modern gay liberation movement began in the 1970s or before the American Psychiatric Association decided in 1973 to remove “homosexuality” from its list of mental disorders in its *Diagnostic and Statistical Manual* (Barranti & Cohen, 2000). Such individuals were faced with the extraordinary challenge of sustaining adult lives during whole decades in which familial, social, and cultural institutions remained intensely homophobic and repressive. “This cohort when they were young was labeled sick by doctors, immoral by clergy, unfit by the military, and a menace by the police” (Kochman, 1997, p. 2). Some LGBT older persons were subjected to treatments that attempted to “cure” their homosexuality using electroshock therapy, aversion therapy, or other means now scientifically discredited (Brotman et al., 2003). A deep sense of shame and stigma, particularly with respect to interacting with health professionals and institutions, remains very acute for some LGBT older adults today (Brotman et al., 2003). Yet at the same time, professionals must recognize the remarkable resilience of this diverse population, as many LGBT older adults have reached old age with affirmative self-identities, and armed with effective coping skills honed from surviving years of discrimination and oppression (Barranti & Cohen, 2000).

A number of research studies have appeared in the literature describing health and social service needs of LGBT older adults. Brotman et al. (2003) provide a highly recommended up-to-date literature review on this topic, in conjunction with their qualitative exploratory study on the service needs of LGBT older adults in Canada. Other research studies include the social service needs of older lesbians and gay men in Chicago (Beeler, Rawls, Herdt, & Cohler, 1999); the health care needs of older lesbians in rural Maine (Butler & Hope, 1999); the social support needs of older lesbians, gay men, and bisexual persons in San Diego County, California (Jacobs, Rasmussen, & Hohman, 1999); elder abuse and neglect issues in les-

bian, gay male, bisexual, and transgender elders (Cook-Daniels, 1997); housing issues of LGBT older adults (Hamburger, 1997); long-term care and hospice needs of older lesbians and gay men in California (Connolly, 1996); and the long-term care plans of older lesbians and gay men in three mid-Atlantic states (McFarland & Sanders, 2003). These studies have contributed to the emerging knowledge base regarding the needs of a historically overlooked and neglected research population. Most of these studies have relied on relatively small convenience samples of predominantly white, middle-class, self-identified LGBT older adults recruited from LGBT-identified organizations in various regions of the United States. Therefore, the generalizability of these studies is limited. Notably, there is a dearth of empirical research literature on the characteristics and social service needs of LGBT older adults of color.

The following brief case vignettes, derived from my social work practice, describe the presenting concerns of two older gay male clients referred to an LGBT-identified social service program. These vignettes illustrate the relationship between the *uniquely experienced* aspects of an individual client's sexual orientation and the use of mainstream community-based aging services.

■ W., an 82-year-old gay white German Jewish male, lost his life partner to illness after they had been together in a committed partnership for over 40 years. W., a Holocaust survivor, has no living family and no gay friends and has been an active member of his local senior center, where virtually all his acquaintances are heterosexual contemporaries. Senior center members and staff knew W.'s "friend," as W. had always referred to his partner in public. However, after W.'s partner died, no one at the senior center acknowledged the magnitude and significance of his personal loss. During his bereavement, W. became severely depressed and socially isolated. He stopped attending the senior center completely, even after multiple attempts by senior center staff to reach out to him. In actuality, W. had never had a conversation with any staff or center members that acknowledged that the "friend" he had lived with for over 40 years was indeed his beloved life partner. "These are not the kind of things you discuss over there," he said about the senior center in the first interview

with a social worker from an LGBT-identified social service agency. ■

■ Z., a 69-year-old single gay African American male with end-stage renal disease, lives alone in an apartment in the city and goes to dialysis three times per week. Due to declining health and increasing frailty, the dialysis treatment team has recommended home care to assist Z. with activities of daily living. Z. repeatedly refuses the home care help, even though his insurance and financial resources cover the expense. Z. will not disclose to any health care staff the "real" reason why he does not want a home care worker in his home. Finally, a social worker from an LGBT-identified organization (whom Z. contacted independently) learned during the first home visit that Z. is extremely afraid to hire an unknown home care worker. He fears that upon entering his home and seeing his personal collection of art, books, and photography on the walls of his apartment, the home care worker would learn he is gay. He fears the home care worker might say or do something harmful to him because he is a gay man. Z. said he did not want to feel vulnerable and self-conscious within the comfort of his own home, especially in such weak physical condition. The social worker from an LGBT organization, in coordination with Z. and his dialysis team, helped arrange the hiring of a home care worker from an agency that had undergone sensitivity training working with LGBT older clients. Z. found this to be an acceptable plan and then agreed to hire the home care. ■

LGBT-SPECIFIC PROGRAMS FOR OLDER ADULTS

In categorizing services to LGBT older adults, it is useful to distinguish between *LGBT-specific* versus *generic* services (Humphreys & Quam, 1998). *LGBT-specific* services are programs designed uniquely for LGBT older adult clients. Most LGBT-specific services for older adults are located within LGBT-identified community-based agencies, mental health centers, community centers, and social activity groups (SAGE, in press). However, a program does not need to be located within an LGBT organization to be considered LGBT specific. For example, there is at least one program cited in the literature describing an LGBT-specific, professionally moderated support

group delivered within a mainstream outpatient geriatric medical clinic (Slusher, Mayer, & Dunkle, 1996).

Are the service needs of LGBT older adults “best” met in LGBT-specific or mainstream LGBT-sensitive programs? To meet the complete range of service needs, there is clearly a need for both approaches, ideally offering clients choices. There is also diversity within the LGBT older adult population regarding the degree to which LGBT older adults self-identify as LGBT persons and the degree to which they may choose to seek services from LGBT-identified organizations (Slusher, Mayer, & Dunkle, 1996). Many LGBT older adults prefer the services of LGBT-specific agencies. Jacobs et al. (1999) found that gay and lesbian community-based programs were considered more adequate in meeting needs in times of emotional crisis, compared to nongay and lesbian programs.

The oldest and perhaps most widely recognized LGBT-specific agency for older adults is SAGE New York. Founded as “Senior Action in a Gay Environment” in 1977, the organization recently changed its official name (while retaining its acronym) to “Services and Advocacy for Gay, Lesbian, and Transgender Elders” in order to more clearly articulate the organization’s current professional mission (Hamilton, 2004). A community-based social service agency, SAGE New York provides a comprehensive range of social work, mental health, community organizing, advocacy, and education programs exclusively focused on the LGBT older adult population. It has been successful in securing both private philanthropic and public governmental funding to support many of its programs. Notably, SAGE New York has worked actively with other communities in the United States and Canada to develop similar service programs for LGBT older adults. As an organization, SAGE occupies a unique leadership role by organizing national conferences on LGBT aging issues. The organization also developed a training curriculum to sensitize long-term care providers to the needs of LGBT elders (SAGE & Brookdale Center on Aging [BCOA], 2003) and conducted the first national needs assessment report on the availability of services for LGBT older adults (SAGE, in press).

Other LGBT-specific programs for older adults operate across the country; however, most are located in large urban centers. In San Francisco, a well-known LGBT-specific program for older adults is “Gay and Lesbian Outreach to Elders” (GLOE). In the 1990s, GLOE transformed into New Leaf Outreach to Elders (NLOE). Funded by grants from the California Endowment, San Francisco Foundation, and Horizons

Foundation, NLOE provides geriatric mental health services to LGBT seniors. The organization funds a mobile mental health team, consisting of a psychiatrist, psychiatric nurse, and social worker, that conducts home visits for isolated LGBT elders in need of mental health services, substance abuse treatment, and medication monitoring (White, 2004).

These organizations are but two examples of LGBT-specific service organizations/programs that provide professional social work and mental health services to LGBT older adults. They are frequently referred to in the research literature as model programs (Humphreys & Quam, 1998). There are other LGBT-specific organizations focused primarily on advocacy and policy, rather than the provision of direct service, that address the issues of LGBT older adults as well. Cahill et al. (2000) describe the activities of many of these service, advocacy, and political organizations focused on the critical issues affecting the health and welfare of LGBT older adults. Examples of advocacy organizations working on issues affecting LGBT older adults include the National Gay and Lesbian Task Force Policy Institute, Human Rights Campaign, Old Lesbians Organizing for Change (OLOC), and Pride Senior Network. Space does not permit a full listing of LGBT organizations here; therefore, the reader is encouraged to access Cahill et al.’s (2000) report and additional sources discussed hereafter.

Fortunately, for social workers seeking further information about LGBT-specific organizations/programs in their own communities, a number of excellent Web-based resources are available. The Lesbian Gay Aging Issues Network (LGAIN), a constituent group of the American Society on Aging, maintains a comprehensive Web site notable for not only its national list of LGBT organizations but also its useful annotated bibliography of LGBT aging-related topics, including sections on AIDS/HIV, caregiving, health, housing, and issues of older lesbians, older gay men, and older transgender persons (www.asaging.org/lgain). LGAIN also publishes *Outword*, a newsletter focused on the concerns and service needs of LGBT elders. SAGE posts an LGBT Senior Service Directory, listing programs for LGBT older adults throughout the United States (www.sageusa.org). The Policy Institute of the National Gay and Lesbian Task Force (NGLTF) is another excellent resource (www.thetaskforce.org); it offers several publicly available reports on the health and welfare of LGBT older adults and their families. On the NGLTF Web site, readers will find Cahill, South and Spade’s (2000) report, providing a com-

prehensive listing of organizations working on LGBT aging issues, an extensive bibliography of research literature on LGBT aging, and national policy recommendations to address the needs of LGBT elders. In addition, Cantor, Brennan, and Shippy's (2004) report presents a comprehensive survey on LGBT caregivers over the age of 50 living in New York City, as well as a thorough analysis of policy issues affecting the lives of LGBT older adult caregivers and the members of their families of origin and choice for whom they provide care.

AVAILABILITY OF LGBT-SPECIFIC SERVICES FOR OLDER ADULTS

Until recently, there has been a dearth of national data to assess the availability and scope of programs for LGBT older adults across the country. To obtain much-needed data on this issue, SAGE recently completed the first national needs assessment study of services for LGBT older adults (SAGE, in press). This landmark study utilized snowball sampling to identify service providers from LGBT-specific and mainstream aging service organizations in diverse urban, suburban, and rural areas. The study collected data via key informant interviews, an online survey, five regional "town hall" meetings (held in Bangor, Maine, Boston, Seattle, Chicago, and Fort Lauderdale, Florida), and one transgender focus group. Study respondents reported on the availability, quality, and sensitivity level of existing services for LGBT older adults nationwide.

The report found that there is a severe national shortage of specialized and sensitive services for LGBT older adults. LGBT agencies providing a broad range of formal services to LGBT older adults exist in only a few large urban settings. In smaller cities and towns, often the only services currently available for LGBT older adults, if any, are social activities. While socialization activities are important to enhance social support and reduce social isolation of LGBT older adults, the SAGE national needs assessment study concluded that nationwide, LGBT older adults seeking LGBT-specific comprehensive services have very few options in most communities (SAGE, in press).

The SAGE report further documented a consistent concern among providers that LGBT elders do not believe they are welcome in mainstream aging services programs, or that existing mainstream service programs would be sensitive to their specific concerns and life experiences. In addition, the report found

that LGBT older persons of color and transgender older persons did not feel welcome within existing LGBT senior programs. Unfortunately, the SAGE findings provide further support to the contention of Cahill et al. (2000) that the aging services network remains ill prepared to meet the specific needs of this vulnerable population. Readers are strongly encouraged to refer to the full SAGE report for a comprehensive discussion of service availability issues, including policy and advocacy strategies that address the report's key findings (SAGE, in press).

WORKING WITH LGBT OLDER ADULTS: PRACTICE CONSIDERATIONS

To develop cultural competence practice skills for working with LGBT older adults, social workers must begin by examining their own values, attitudes, and assumptions about gay, lesbian, bisexual, and transgender persons (Bergh & Crisp, 2004; Berkman & Zinberg, 1997; Brotman et al., 2003; Metz, 1997). Bergh and Crisp (2004) propose a framework for defining cultural competence with sexual minorities (of all ages) in the domains of attitudes, knowledge, and skills, drawing on the gay affirmative practice model described by Appleby and Anastas (1998). Bergh and Crisp (2004) encourage practitioners to develop self-awareness regarding their own potentially negative attitudes about LGBT clients and to actively pursue practice knowledge relevant to LGBT populations through continuing education, in-service trainings, and clinical supervision. They also suggest practical ideas for communicating a safe, gay-affirmative agency environment, such as making literature or events on LGBT-related topics publicly available to *all* clients or placing a rainbow flag (a widely recognized symbol of LGBT community diversity) in a noticeable place in the agency setting (Bergh & Crisp, 2004).

Community-based agencies communicate a great deal about their attitudes toward LGBT older clients through the psychosocial assessment process. Several authors highlight the critical need for agencies to review outreach and intake procedures (Brotman et al., 2003; Humphreys & Quam, 1998; Metz, 1997). Prospective older LGBT clients, by virtue of their life-course experience, are highly attuned to subtle and overt forms of heterosexism in agency settings and therefore may interpret heterosexist attitudes as an indication that they are not welcome as clients (Metz, 1997). At intake, social workers should *assess* (rather

than *assume*) a client's sexual orientation (Bergh & Crisp, 2004). Consider one of the most common intake questions: "What is your marital status?" or "Are you married?" Social workers might consider phrasing this question in a more neutral way. For example: "Please describe those relationships that are or have been most important to you" (Metz, 1997, p. 37). The alternative wording of this question demonstrates sensitivity to a prospective LGBT older client who may now feel more comfortable describing to the worker the significant same-sex relationships (past and present) in his or her life.

Humphreys and Quam (1998) highlight several important practice principles that agencies may consider in order to increase sensitivity and cultural competence regarding working with older LGBT clients, as follows.

- *Respect a client's right to privacy/confidentiality.* A client who "comes out" to a worker may not feel equally comfortable disclosing his or her sexual orientation to other agency staff and/or to other clients. Clients' wishes about privacy and confidentiality must be explored and respected.
- *Recognize diversity within LGBT communities.* Clients may differ significantly in their level of comfort with respect to discussing and/or accepting their own sexual orientation. In addition, the level of acceptance older LGBT clients experience from family members, friends, neighbors, and colleagues may also differ dramatically, depending on a client's unique life experience.
- *Not all problems a person has are associated with being gay or lesbian or with being old.* Like all seniors, older LGBT clients present to social workers with complex, multidimensional problems, many of which may have little or no relationship to "sexual orientation" or "old age."
- *Treat a client's identified family as family.* Social service agencies must recognize, validate, and support members of older LGBT clients' *chosen* families. Many older LGBT clients have committed partners and close friends whom they consider to be members of their chosen families, in addition to members of their families of origin. Agencies should honor LGBT older clients' decisions as to whom they choose to include regarding their treatment and other decisions about care.

POLICY ISSUES

Cantor et al. (2004), in a research survey documenting the caregiving experiences of LGBT older adults in

New York City, identify several critical national policy issues that affect the lives of LGBT older adult caregivers, care recipients, and their families of origin and choice. They point out, for example, that language in the National Family Caregiver Support (NFCS) program (passed by the U.S. Congress in 2000) employs a definition of "caregiver" that is inclusive of individuals providing informal care to a same-sex partner, close friend, or family member. They strongly encourage LGBT-specific community-based agencies to apply for Area Agency on Aging funding to provide caregiver services through the NFCS program. They further emphasize the need to build awareness among LGBT older adults and their caregivers that they are currently eligible for existing services under the NFCS program and may access these services in their local communities (Cantor et al., 2004).

Another critical U.S. policy issue concerns the lack of legal same-sex partner recognition and its negative effects on gay and lesbian older adults in committed same-sex relationships. Legal marriage between same-sex partners is not, as yet, recognized across the United States. Though domestic partnership policies exist in a number of state and local jurisdictions, these policies do not assign all the rights and protections specifically afforded to legally married heterosexual couples. Bennett and Gates (2004) provide a detailed analysis of this issue with respect to LGBT seniors. Surviving partners in gay and lesbian partnerships are denied Social Security survivor benefits, are charged an estate tax on the inheritance of a jointly owned home, and are taxed on retirement plans inherited from a deceased partner. Among same-sex couples in which one member must enter a nursing home, the community-dwelling partner is at serious risk of losing his or her home because federal Medicaid spend-down regulations (while protecting heterosexual married spouses, who are allowed to keep their homes) do not protect community-dwelling partners of same-sex relationships (Bennett & Gates, 2004). These inequities in U.S. Social Security law, tax law, property law, and Medicaid law pose serious economic and social consequences for LGBT older Americans. As professionals committed to social justice for all oppressed groups, gerontological social workers need to understand how the lives of LGBT older adults are profoundly negatively affected by current government policies. As a profession, we must continue to work to effect policy reform at the local, state, and federal levels to address the negative consequences of discrimination against LGBT older adults and their families.

CYNTHIA POINDEXTER

Services for HIV-Infected or HIV-Affected Older Adults

51

Adults age 50 and over who are living with HIV¹ or AIDS have been called hidden (Emlet, 1997) or invisible (Genke, 2000) because they are not readily acknowledged by gerontologists and service providers, although they have always comprised at least 10% of the incidences of AIDS in the United States (Centers for Disease Control [CDC], 1998). HIV disease has often been regarded as affecting primarily younger persons, but HIV researchers and advocates have increasingly recognized midlife and older adults as being at risk for HIV infection. Recent data point to a graying of the HIV epidemic. As Levy, Ory, and Crystal (2003) point out, the cumulative number of AIDS cases reported to the Centers for Disease Control in adults age 50 and over quintupled between 1990 and 2001. By the end of 2001, 18.9% of persons living with AIDS were 50 years of age or older (Mack & Ory, 2003).

In addition to an increasing number of HIV-infected older adults, a growing number of older adults are *HIV-affected*, referring to “those family members who have responsibilities of caregiving for an adult or child who has HIV disease” (Poindexter, 2001, p. 525). Estimates suggest that one-third to one-half of persons living with AIDS are dependent upon older relatives (often parents or grandparents) for financial, emotional, and physical support (Allers, 1990; Joslin, 2000).

This chapter provides human service practitioners with information related to service delivery systems and their legislative underpinnings so that they can be more prepared to provide case management and referrals to older adults affected by HIV and AIDS. Commonly available services will be outlined, as well as the roles that social work can play in these organizations. The ways in which such services can enhance quality of life and be culturally relevant will be discussed.

SYSTEMS OF CARE AND FEDERAL PUBLIC POLICY

Historically, systems of care, influenced by public policy, have centered on particular needs or populations. Such foci have tended to separate issues that may be connected, such as aging and HIV (Emlet & Poindexter, 2004). While we may need to view pieces of legislation separately (by necessity), we must at the same time direct our attention to how, at the local level, we can improve care and services through coordination and collaboration. We discuss here three of the most vital federal programs for this population.

Ryan White Comprehensive AIDS Resources Emergency (CARE) Act

The CARE Act of 1990 was the first federal service delivery mechanism to aid persons with HIV. The act addresses the unmet health needs of persons living with HIV disease by funding primary health care and social support services. Enacted in 1990, it was amended and reauthorized in 1996 and 2000. The act services benefit 533,000 individuals each year, making it the federal government's largest program specifically for people living with HIV disease (U.S. Health Resources and Services Administration [USHRSA], 2002–2003). (See Poindexter, 1998, and Emler & Poindexter, 2004, for details on the provisions of the Act.)

While it is not the purpose of this chapter to provide an extensive overview of relevant public policy, many social workers employed in settings serving older adults may be unfamiliar with the CARE Act. We have therefore included an overview of the various titles and their purposes in Table 51.1. Worthy of note are the AIDS Drugs Assistance Programs (ADAPs), which can provide HIV-related medications to those who do not have insurance coverage for drugs. The graying of the HIV epidemic is reflected in services provided through this program. According to a recently released study, 29% of the people served through Title 1 and 26% of the people served through Title 2 were age 45 or older in 2000, compared to 20% in 1998 (USHRSA, 2002–2003).

Service Delivery

Services for persons of all ages living with HIV may be provided through numerous mechanisms, including public health and social services, university medical centers and clinics, and AIDS service organizations (ASOs). ASOs are community-based agencies that developed to ensure the delivery of health-related and social services to HIV-affected individuals and families (Burrage & Porche, 2003). Historically, most ASOs were small grassroots organizations founded and operated by members of the gay community who raised funds in order to provide services (Lewis & Crook, 2001). Many of these organizations continued to grow and now provide a majority of services to HIV-positive individuals.

AIDS service organizations and other providers of services may not specifically target midlife and older adults through the CARE Act; however, CARE Act programs can easily be used to serve older persons

with HIV, as well as offer support to older persons who are taking care of HIV-infected adult or child family members. The CARE Act requires consumer participation at the local level by stipulating that one third of local Title 1 planning councils or Title 2 consortia members be HIV infected. In this way the needs of older HIV-infected individuals and HIV-affected older caregivers can be taken into account when funding is discussed at the local level, and midlife and older persons can be given opportunities to participate on consortia and planning councils. The act also targets women, children, and families through set-asides and demonstration projects, which can include older caregivers.

Social Work Roles

Social workers should keep the following tasks in mind regarding the CARE Act.

- Being familiar with services and eligibility requirements of local ASOs and other organizations funded by the CARE Act
- Engaging in advocacy for older adults through participating in Title 1 planning councils or Title 2 consortia
- Encouraging and empowering older infected or affected persons to participate in educational and advocacy activities
- Working directly with ASOs to provide support groups or other services for serving midlife and older adults

Older Americans Act (OAA)

The OAA of 1965 was one of several major federal initiatives of President Lyndon B. Johnson's Great Society programs designed to benefit older persons (Estes, 1979). The act created the Administration on Aging (AoA) and authorized grants to states for community planning and services programs, as well as for research, demonstration, and training projects in the field of aging. The OAA calls for specific attention to those elders who are in the greatest social and economic need; anyone who is over 60 or the legal spouse of someone over 60 can access OAA services. Today the OAA has firmly established the aging network, which includes 57 State Units on Aging (SUAs), approximately 650 Area Agencies on Aging (AAAs), and 220 tribal organizations representing 300 native tribes (Takamura, 2001).

TABLE 51.1. Overview of CARE Act Titles and Subparts

Title or Program	Purpose	Types of Services Funded
Title 1	Provides emergency assistance to eligible metropolitan areas (EMAs) that are most severely affected by the HIV/AIDS epidemic.	<ul style="list-style-type: none"> • Outpatient and ambulatory health services, including substance abuse and mental health treatment • Early intervention that includes outreach, counseling, and testing, and referral services designed to identify HIV-positive individuals who know their HIV status • Outpatient and ambulatory support services, including case management • Inpatient case management services that expedite discharge and prevent unnecessary hospitalization
Title 2	Provides grants to all 50 states, the District of Columbia, and U.S. territories; grants are used to provide a variety of services, as listed here. Unlike Title 1, grants may include nonprofit as well as public entities.	<ul style="list-style-type: none"> • Ambulatory health care • Home-based health care • Insurance coverage • Medications • Support services • Outreach to HIV-positive individuals who know their HIV status • Early intervention services • HIV Care Consortia, which assess needs and contracts for services
Title 3	Early Intervention Services (EIS) program; funds comprehensive primary health care for individuals living with HIV disease.	<ul style="list-style-type: none"> • Risk-reduction counseling on prevention, antibody testing, medical evaluation, and clinical care • Antiretroviral therapies; ongoing medical, oral health, nutritional, psychosocial, and other services for HIV-infected clients • Case management to ensure access to services and continuity of care • Attention to other health problems that occur frequently with HIV infection, including tuberculosis and substance abuse
Title 4	These programs specifically serve women, infants, children, and youth living with HIV disease.	<ul style="list-style-type: none"> • Primary and specialty medical care • Psychosocial services • Logistical support and coordination • Outreach and case management
AIDS Drug Assistance Programs (ADAP)	A specific program under Title 2; these programs provide medications for the treatment of HIV disease. Program funds may also be used to purchase health insurance for eligible clients.	Congress “earmarks” funds that must be used for the ADAP, an important distinction, since other Title 2 spending decisions are made locally
Special Project of National Significance (SPNS)	This program advances knowledge and skills in the delivery of health and support services to underserved populations diagnosed with HIV infection. SPNS is considered the research and development arm of the CARE Act and provides the mechanisms for the services listed here.	<ul style="list-style-type: none"> • Assess the effectiveness of particular models of care • Support innovative program design • Promote replication of effective model

Note: From *Ryan White CARE Act Programs*, by U.S. Department of Health and Human Services, Health Resources and Services Administration, HIV/AIDS Bureau, 2002. Available: <http://hab.hrsa.gov/programs.htm>.

Titles 3, 5, 6, and 7 provide a wide array of services that may be relevant to older adults who are living with HIV disease, as well as HIV-affected caregivers. As shown in Table 51.2, Title 3 authorizes funds to states and AAAs for a variety of in-home and supportive services (Administration on Aging [AoA], 2001). Part C focuses on the provision of nutrition services, nutrition education, and counseling, while part D provides disease prevention and health promotion services to older adults (AoA, n.d.). Title 5 provides a means to increase individual economic self-sufficiency to those age 55 and over. Title 6 provides grants to Native Americans, and Title 7 focuses on the protection of vulnerable older adults and the prevention of elder abuse.

Service Delivery

The hallmark of the OAA at the local level is the development and maintenance of the AAA network. The act requires coordination and planning of aging services at the state as well as local and regional levels. Each state is divided into one or more planning service areas (PSAs) operated under the auspices of an AAA. The AAAs are important resources for gerontological social workers or those working with HIV-infected or -affected elders, as they not only provide social services directly but often contract with other agencies and organizations for the provision of services. These agencies are therefore a clearinghouse for information and resources available to older adults and their families (Kisor, McSweeney, & Jackson, 2000). The AoA provides a listing of each SUA and AAA at its Web site (www.aoa.gov/eldfam/How_To_Find/Agencies/Agencies.asp).

Social Work Roles

The following tasks may be useful for social workers as they utilize the OAA's services.

- Identifying venues to educate social workers employed in the local aging network (including Area Agencies on Aging) about HIV disease
- Participating in AAA activities such as public hearings or annual plan developments
- Seeking a seat on the AAA advisory council and advocate for the inclusion of HIV education and services
- Helping forge partnerships or task forces among AAA providers and the HIV network

Home and Community-Based Waiver Programs

Medicaid is typically viewed as a payment source for institutional long-term care or medical care for low-income populations. In recent years, however, Medicaid has made substantial contributions to transform the long-term care system from institutionally based into community-based care through the home and community-based waiver (Miller, Ramsland, & Harrington, 1999).

The home and community-based waiver, added to the Social Security Act by the Omnibus Reconciliation Act of 1981, authorized the waiver of certain Medicaid limitations to allow states to cover home and community-based services to individuals as an alternative to institutional care in hospitals, nursing homes, or other facilities such as intermediate care facilities for persons with developmental disabilities (U.S. General Accounting Office [USGAO], 2003; Miller et al., 1999). The Omnibus Reconciliation Act was amended in 1985 to allow the creation of waiver programs specific to persons living with AIDS (Buchanan & Chakravorty, 1997). These home and community-based waiver programs provide a wide range of services to targeted subgroups of individuals. The original focus was on frail older adults and those with developmental disabilities; the targeted populations have been expanded to include individuals with AIDS, working-age individuals with physical disabilities, and children with a variety of conditions. Waiver programs are developed on a state-by-state basis and may provide nonmedical services such as case management, homemaker services, personal care services, and adult daycare, as well as medical care such as nursing services in the home (Miller et al., 1999).

A recent report from the U.S. General Accounting Office (2003) documented a substantial rise in the number of Medicaid waiver programs throughout the United States. Home and community-based waiver programs increased in number from 155 in 1991 to 263 in 2001 (USGAO, 2003). According to this report, every state except Arizona (which operates a different type of waiver program) operates at least one waiver for the elderly as of June 2002.

Service Delivery

An older adult with HIV could, depending upon age, disability status, and diagnosis, be eligible for services through a variety of waiver program categories. Waiver programs may target frail elderly specifically

TABLE 51.2. Overview of the Older Americans Act

<i>OAA Title and Part</i>	<i>Purpose</i>	<i>Services</i>
Title 3B	To improve the lives of older people, in particular the rural elderly, those with greatest economic and social need, including specific objectives for low-income minority older persons	<ul style="list-style-type: none"> • Access services, i.e., information and assistance, transportation and outreach • In-home services, including homemaker, visiting, and telephone reassurance; chore and supportive services; case management and supportive services for families of older individuals with Alzheimer's disease and related disorders • Legal services, including financial, insurance, and tax counseling
Title 3C	Provides for the establishment and operation of congregate and home-delivered nutrition programs	<ul style="list-style-type: none"> • Congregate meal program • Home-delivered meal program • Nutrition education, counseling, and screening
Title 3D	Provides disease prevention and health promotion services and information at senior centers, meal sites, and other appropriate locations	<ul style="list-style-type: none"> • Health risk assessments and screening • Health promotion, exercise, and fitness programs • Home injury control services • Screening for prevention of depression • Medication management & education programs • Information concerning diagnosis, prevention, treatment, and rehabilitation of age-related diseases and conditions • Gerontological counseling • Counseling regarding social services
Title 3E	The National Family Caregiver Support Program: provides services to family caregivers, grandparents, or other older individuals who are relative caregivers of a child under age 18	<ul style="list-style-type: none"> • Information to caregivers about available services • Assistance to caregivers in gaining access to supportive services • Individual counseling, organization of support groups, and caregiver training in making decisions and solving problems relating to their caregiving roles • Respite care • Supplemental services
Title 5	The Senior Community Service Employment Program: fosters and promotes useful part-time opportunities in community service activities for unemployed low-income persons.	<ul style="list-style-type: none"> • Part-time employment training • Job placement at community and government agencies • Available to individuals age 55 and over
Title 6	Serves older individuals who are Indians, Alaskan Natives, and Native Hawaiians; services are provided to 241 Tribal and Native organizations and two organizations serving Native Hawaiians in a manner that preserves and restores their dignity, self-respect, and cultural identities	<ul style="list-style-type: none"> • Supportive and nutrition services that are comparable to services provided under Title 3 • The Native American Caregiver Support Program assists caregivers of Native American elders who are chronically ill or disabled
Title 7	To protect and enhance the basic rights and benefits of vulnerable older people who may need advocacy on their behalf because of physical or mental disabilities, social isolation, limited educational attainment, or limited financial resources	<ul style="list-style-type: none"> • Long-term care ombudsman services • Programs for the prevention of elder abuse • State legal assistance development programs

Note: From U.S. Department of Health and Human Services, Administration on Aging. Available at: www.aoa.gov/.

and combine frail older adults with disabled adults over 18 years of age, as well as specifically targeting those disabled from AIDS. According to Buchanan and Chakravorty (1997), most states do not have separate waiver programs differentiating disabled adults and the frail elderly. Buchanan and Chakravorty's analysis of home and community-based waiver programs identifies 35 states with waivers for combined aged/disabled individuals. Sixteen states operated separate waiver programs for persons living with HIV disease. In five instances, AIDS waiver programs existed in states without waiver programs for younger disabled (non-HIV-related) individuals, suggesting the availability of waiver services in a minimum of 40 states.

While the existence of home and community-based waiver programs provides another important source of help for older adults with HIV, some important limitations exist. First, services are limited to certain individuals based on types of disability and may be limited to specific geographical regions within states (Miller et al., 1999). Second, waiver programs targeting those with AIDS are obviously more severely limited to 16 states (those with AIDS waiver programs). Finally, income and functional status criteria limit an individual's eligibility for waiver services. The individual must meet the state's criteria for needing a level of care provided in an institution, must be able to receive care in the community at a cost not exceeding that of institutional care (USGAO, 2003), and must be Medicaid eligible in his or her state. For older adults living with HIV, particularly those who are seriously disabled from HIV disease or other age-related disabilities, these programs can provide a substantial amount of home and community-based help and support. The availability of home and community-based waiver programs will vary from state to state, but local Area Agencies on Aging, senior information and assistance programs, ASOs, and local public health departments are good sources of information.

Social Work Roles

Social workers can use waivers in the following ways.

- Maintaining an up-to-date awareness of Medicaid waiver services, eligibility criteria, and limitations
- Advocating for the development of expanded or additional waiver services in one's local area
- Seeking out and collaborating with health care agencies who offer Medicaid waivers to ensure cross-training, appropriate referrals, and coordinated case management

IMPROVING CARE FOR HIV-INFECTED AND HIV-AFFECTED ELDERS AT THE LOCAL LEVEL

This brief overview of several important federally sponsored or funded programs suggests a wide array of services that can assist HIV-infected or HIV-affected midlife and older persons. Joslin and Nazon (1996) suggest that older HIV-positive persons present themselves to service providers with needs that can only be partially met within one service system. For social workers working in the area of case management, the benefits of integrating services across systems can be easily seen from the following examples.

- A 63-year-old low-income Latina who is impaired by AIDS, in addition to multiple age-related chronic conditions, could benefit from an OAA-sponsored nutrition program and senior transportation while receiving homemaker services and nursing care from a locally administered Medicaid waiver program. She can receive medical care from a CARE Act-funded medical clinic and help with her HIV medications from the AIDS Drug Assistance Program.
- A 56-year-old HIV-infected gay man whose health has improved dramatically with the advent of highly active antiretroviral therapy might seek assistance through reemployment opportunities through Title 5 of the OAA (Community Service Employment for Older Americans), while maintaining needed support through the local AIDS service organization.
- A 74-year-old African American grandmother providing care to her 12-year-old HIV-infected grandson could be helped by the National Family Caregiver Support Program, as well as Title 4 of the CARE Act, providing services to women, children, and families.

While it seems obvious that HIV-infected or HIV-affected older adults could benefit from improved coordination and collaboration between aging and HIV service sectors, the best method for achieving this goal is less clear. Is service integration necessary in order to improve care, and if so, what do we mean by integration? Recently, Messeri, Kim, and Whetten (2003) presented a taxonomy for the integration of HIV services. They suggest that service integration may be accomplished on a continuum from minimal (client-centered) to maximum (government/funding-centered) integration. They suggest that "the for-

mer are efforts that work directly with clients without altering the delivery of services . . . the latter involve major reorganization and consolidation in the way state and federal government funds and administer health and human services” (p. 25). Once service providers recognize that older adults are infected with and affected by HIV, discussion about methods for improving service delivery across systems could take on a variety of approaches. In what follows, we supply examples that outline various ways services have been approached for older adults affected by HIV disease; these examples fall at various points on the continuum suggested by Messeri and colleagues.

Emlert (2004) studied 41 adults age 50 and over diagnosed with HIV or AIDS who were primarily clients of an ASO. Respondents were surveyed as to what services from the AIDS network they were familiar with and which services they had personally used. They were asked to respond to a similar list of services from the aging network. Respondents used a significantly greater number of HIV services compared to those from the aging network. Nearly 20%, however, did use in-home or chore services provided through the local AAA, and approximately 10% had used home-delivered meals and adult day health care programs. Integration of services, for these individuals, appeared to be effectively accomplished at the client level (with the help of case managers) with little or no need for more formalized mechanisms of service delivery (client-centered integration).

In 1997, the Senior HIV Intervention Project (SHIP) was created through a model of shared resources between the Florida Department of Elder Affairs and the Florida Department of Health (Nichols et al., 2002). Initial funding from OAA sources was organizationally housed in the Florida Department of Health, Bureau of HIV/AIDS (J. Mullins, personal communication, June 8, 2004). Focusing on three counties, and administered through the Broward County Health Department, SHIP trains volunteers as peer educators and provides educational seminars and workshops in a variety of venues. While changes in funding have over time diminished the OAA role in the project, SHIP has gained support from a Center for Disease Control and Prevention grant. Collaboration continues to exist between the local health departments of Broward, Miami-Dade, and Palm Beach Counties and local senior centers, community centers, and senior housing complexes. This collaboration is an exemplar of a continued relationship between the AAAs and their providers and the public health sector. Staff from the SHIP estimate the project

reaches between 30,000 and 40,000 seniors each year. Recent funding from a local community foundation (private) will allow a focused prevention effort targeting older gay men of color (J. Mullins, personal communication, June 8, 2004) (program-centered integration).

An example of systems coordination overseen by shared governance can be found in the New York Association on HIV Over Fifty. The New York City HIV/AIDS and Aging Task Force was created in 1991 to “bring professionals from AIDS and aging networks together to address the impact of the HIV/AIDS epidemic on older adults” (Nokes, 2004, p. 182). The association currently has approximately 80 members, including health and social service professionals and consumers who are living with HIV and are over 50 years of age. The association was formally incorporated in January 2003 and allows both individual and organizational membership. Once a loosely structured coalition, this body has evolved and become more formal, taking on additional structure (policy-centered as well as program-centered integration).

SUGGESTED RESOURCES

If social workers are to improve their knowledge of issues related to older adults and HIV disease, they will need to become familiar with tools and resources to improve their understanding of these issues. In addition, they may then serve as resources themselves to improve the knowledge and understanding of other players in the community. It is through such a “ripple effect” that we can begin to increase society’s understanding of the myriad of issues that affect this often overlooked and hidden population. A brief list follows of Internet and other resources social workers can use to begin this process.

National Association on HIV Over Fifty (NAHOF) was founded at the National Conference on AIDS and Aging in October 1995 in New York City. Its mission is to promote the availability of a full range of educational, prevention, service, and health care programs for persons over age 50 affected by HIV (available at: www.hivoverfifty.org).

HIV Wisdom for Older Women is an organization dedicated to prevention and care. Recognizing a need for awareness and support for older women affected by HIV, the group was formed

in 2002 to serve this underrepresented community and to educate older women about HIV (available at: www.hivwisdom.org/).

Senior Action in a Gay Environment (SAGE) is the nation's oldest and largest social service and advocacy organization dedicated to lesbian, gay, bisexual, and transgender (LGBT) seniors. This organization provides education and advocacy on LGBT aging issues nationwide (available at: www.sageusa.org/).

SUMMARY

We have provided an overview of three important sources of federal funding for services to HIV-infected and HIV-affected midlife and older adults. Social workers, as case managers, counselors, and advocates, have always strived to coordinate diverse human services programs for the benefit of those who are in need of support. An integrated continuum of care is vital for adults who are dealing with both aging and HIV. It is hoped that this chapter “primes the pump” and encourages practitioners and managers to offer outreach and targeted services to those who may be falling through the cracks.

NOTE

1. The human immunodeficiency virus (HIV) is an infectious retrovirus leading to an incurable, life-threatening condition known as HIV disease or AIDS (acquired immune deficiency syndrome). Persons living with HIV are also called “HIV-positive” or “HIV-infected”; those who are significant to them are called “HIV-affected.” HIV diminishes and then destroys the human immune system, so that the infected person is more susceptible to cancers and bacterial, viral, parasitic, fungal, and other opportunistic infections. Despite effective and promising pharmaceutical developments, HIV remains highly life-threatening, and to date there is no vaccine or cure.

**Social Work Practice With Older Adults and
Their Families in Long-Term Residential Care**

This page intentionally left blank

OVERVIEW

Social work as a profession has a long history of working within residential settings for older people and a record of concern for the well-being of the residents of such settings. As a practice field for social work, residential care is dominated by nursing homes because of half a century of federal rules that require a social work presence in nursing homes. But as the chapters in this section testify, the residential settings where older people live and receive care have always been more varied than nursing homes alone, and they continue to evolve and change. Regardless of where social workers who practice with older people are employed, they must be keenly aware of the residential options available to older people who need care and the typical stresses involved with life in residential care settings. Such settings form a backdrop within the family life of older people with whom social workers might work as case managers or as clinicians in many health and social service settings.

This section discusses a range of group residential settings that constitute home to older people who also need help with health care and daily living. My beginning chapter ruminates on a century or so of developments related to older people receiving care in settings other than their own homes and presents a somewhat idiosyncratic view of our current challenges and opportunities. In keeping with the domination of the nursing homes in the residential sector, the setting-specific chapters begin there. Betsy Vourlekis and Kelsey Simons provide an incisive discussion of the context and roles for social work practice in nursing homes, taking into account trends and changes in the characteristics of nursing home residents. Next, Marylou Guihan discusses residential care within the Veterans Administration (VA), a setting where social workers are very much in evidence; her chapter treats the nursing homes on the campuses of VA medical centers, the contract program for veterans in community care, and some new residential settings under consideration by the VA. Then, Ruth Huber, Ellen Netting, Kevin Borders, and H. W. Nelson describe the nursing home ombudsman program, an area of practice that also primarily deals with nursing homes but does not entail employment in them. For those social workers who become nursing home ombudsmen, the role utilizes the full range of social work skills, including casework around individual complaints, group work and the formation of resident and family councils, and legislative and other advocacy. Jeanette Semke describes residential settings

for older people with severe and persistent mental illness. Wendy Lustbader and Carter Catlett Williams describe the Pioneer Network and culture change efforts, a movement that Williams herself inspired in a magnificent example of social worker as change agent. Following that, Lisa Gwyther and I discuss specialized dementia care units, largely as they have emerged in nursing homes but also in some programs licensed as assisted living.

Moving away from nursing homes, literally, Robert Mollica's chapter describes efforts to help nursing home residents return to the community; some of these efforts have been fostered by specific grants from the Centers for Medicare and Medicaid Services (CMS) beginning in 1999 under the federal New Freedom Initiative to help states affect transitions from reliance on nursing homes for care of people with disability of all ages. Nursing home social workers have a responsibility to help residents leave nursing homes just as much as they are responsible for facilitating their adjustment on admission and promote their well-being during their stay. The discharge-planning role in nursing homes is a rather awkward role for nursing home social workers to play, especially if they are expected to maintain the nursing home census. Perhaps for this reason, the efforts described in Mollica's chapter often are conducted by persons coming into the nursing home from outside, some of whom are social workers employed as community care managers.

The next chapters consider other group residential settings. F. Ellen Netting and Cindy Wilson describe continuing care retirement communities, which typically offer escalating levels of care on a single campus, from independent housing, through residential care facilities, to nursing homes. In writing about assisted living, Sheryl Zimmerman, Jean Munn, and Terry Koenig describe the full range of entities that go by that name. Vera Prosper's chapter discusses small family homes, sometimes called adult foster homes, which serve just a few residents, perhaps two or three, certainly no more than six, in an ordinary residential house. Such small homes are important in rural areas, and they have often been the setting of choice for minority people of color. Both apartment-style assisted living and small family homes, discussed, respectively, in the Zimmerman et al. and Prosper chapters, offer the possibility of a more normal life within a group residential setting. The challenge is to be sure that the settings are affordable and that they provide sufficient health care without altering their basic residential character or threatening resident autonomy.

The last two chapters bring us to the boundaries where residential care and home care are truly blurred. Nancy Sheehan and Waldo Klein discuss congregate housing programs, which in both public housing and subsidized low-income housing is characterized by private apartment, but which provide an opportunity for services for those aging in place. Social workers with an official social work title are unlikely to be on the scene, but the inclusion of care coordinators or case managers in the units has provided some roles for social workers, especially at the bachelor's level. Moreover, community social workers enter these settings in other capacities, particularly as case managers for Medicaid waiver programs, and they need to understand how to help their clientele age in place and remain in those settings as long as possible. Finally, Fredda Vladeck describes programs developed in naturally occurring retirement communities (NORCs), which are buildings or neighbor-

hoods where older people cannot be "discharged" because their NORC is simply where they live. Those who work to overlay a service structure on such NORCs draw on a wide range of social work skills, as Vladeck shows.

The choices people make about where to live in their later years may affect the amount, type, and costs of support available to them at a crucial period of need. An older person's home should surely be a place of comfort and an expression of personal identity, and the environs of that home should help define that older person's community. It is in this spirit that social workers and others are coming to consider the wide range of group living settings where older people receive care, including nursing homes, with the aim that they be not only "homelike" but actually home. The chapters in this section illustrate many different ways that social workers might converge on that task.

GOALS FOR THE GROUP RESIDENTIAL SECTOR

When older people contemplate their lives after age 70, 80, or 90, their most basic list of needs includes a home to shelter them from the elements, food to sustain their bodies, and health care as needed. Realists may anticipate that their needs for medical care could increase dramatically in the decades before their deaths and that they might need ongoing nursing help and personal assistance. Using the evocative title “Survival of the Unfittest,” scholars from the United Kingdom predicted in 1972 that a large number of old people would need labor-intensive care in their last years (Isaacs, Livingstone, & Neville, 1972). When care needs become too difficult or expensive to arrange and coordinate in one’s own home, and especially when the older person lacks family members able to assist with the arrangements, a move to a residential setting where the care is provided seems sensible and perhaps even inevitable. A nursing home brings together housing, room and board, health care, and personal care in a package deal. Other group residential settings, such as assisted living, to some extent also package care and housing.

Social workers concerned about the well-being of old people in group residential care must note the nature of both the care and the housing. At some points in our history, and in some circumstances right up to the present, both the housing and care components of typical residential service provisions fell far short of the ideal. One’s home carries powerful social images: a sanctuary; an expression of personal history and interests; a gathering place for family and friends; a repository of memories, some of which adhere to cherished possessions; a place that one controls, as in “my home is my castle.” The cliché that a nursing home aims to be home to residents is transparent and fails to reassure, nor do all other residential care settings carry the image of home to their residents.

Older people have other goals beyond the basic need for security and shelter. They seek enjoyment, friendship and companionship, and interests to stimulate their minds. Despite physical frailty, they often retain a wish to contribute to their families and communities. Well-being in later years also includes experiencing a sense that their lives have meaning and also retaining control and choice in their lives. Unfortunately, many of the residential care settings that have evolved for seniors compromise the quality-of-life outcomes defined in a federal project, which include security, comfort, relationships, meaningful activity,

A Social Worker’s Historical and Future Perspective on Residential Care

52

enjoyment, dignity, individuality, and autonomy (R. A. Kane, 2003). Sometimes even the basic sense of identity of the older person is compromised by moving to a residential care setting (Tobin, 1999). Social workers who practice in such settings must engage in the struggle to help their clients meet their basic needs for a viable home where they feel secure and safe and receive excellent technical care in an atmosphere that promotes other quality-of-life outcomes.

HISTORICAL PERSPECTIVES ON NURSING HOMES

Prior to the industrial revolution and on through the 19th and the first half of the 20th century, older people made few residential choices. They tended to remain in the geographic areas where they lived and worked most of their lives, perhaps moving to smaller homes or apartments as family size shrank. If they needed constant or very frequent nursing care and the help of others to manage their households, their options were few: Singly or in combination, they could rely on family to help, hire paid help, or move to a place where more care was available. In the earliest years of organized philanthropy in the United States, beginning at the end of the 19th century, the places where seniors moved were variously called homes for the aged or nursing homes. The nursing home, like the orphanage and the mental hospital, claims as its common ancestor the poorhouse—a stigma-ridden last refuge for indoor relief for the bereft of all ages who lacked the financial wherewithal or family support to keep them at home (Holstein & Cole, 1995). Social work as a profession also has roots in poor laws, poorhouses, and parish relief. A pleasant “homelike” atmosphere was not a goal for indoor relief.

With the gradual differentiation of social welfare programs and facilities in the late 19th and early 20th centuries, elderly people with health needs became construed as a population deserving of respect and care. Charitable (usually sectarian) organizations established the first homes for the aged early in the century. In many states, counties also maintained a system of county homes, which largely became old age homes as other populations (children, mentally ill, blind people) were cared for in more differentiated programs. In the 1930s, older people began using private boarding homes for care, partly stimulated by the fact that they could not receive payments from the new Social Security program in public institutions like county homes. Over time, with the increase of available health

care technology and the rising acuity of seniors, all of these settings became more medically oriented. Also, the post–World War II period saw a boom in proprietary nursing homes, particularly as a result of construction payments for nursing homes in the 1950s and Medical Assistance payments to support poor people in nursing homes under the Kerr–Mills provisions.

Elias Cohen (1974) identified six periods in the development of nursing homes from Colonial times to 1974, ending with the post-1965 period. With the advantage of hindsight, I would carry his last period forward to about 1986, when another period begins. In the post-Medicare years, nursing homes were expanding even more rapidly, with increased regulation and reaction against regulation, punctuated by frequent quality scandals (Mendelson, 1974; Moss & Halamandaris, 1977; Smith, 1981; Vladeck, 1980). The National Citizens’ Coalition for Nursing Home Reform emerged during this period as a citizens’ group advocating better nursing home care. The period culminated in the work of an Institute of Medicine committee, which between 1983 and 1985 examined the relationship between regulation and quality in nursing homes (Institute of Medicine, 1986).

The Nursing Home Reform Act of 1987, also known as OBRA 87, marked a period of major reforms related to the quality standards used (emphasizing quality of life, residents’ rights, and accurate assessment) as new conditions for nursing homes to receive federal funds, the quality assessment used (adding components of direct interview and observation of residents, changing the inspection intervals to introduce a modicum of surprise, and calling for a two-phase inspection for facilities showing problems at screening), and the enforcement procedures (encouraging states to use intermediate sanctions short of license removal and developing scope and severity modifiers for deficiencies). The practice of physical restraints in nursing homes was circumscribed in this period, partly because of the leadership of social worker Carter Catlett Williams. The analogous practice of using medications to control resident behavior (so-called chemical restraints) was also curbed, with new guidelines for appropriate medication use.

The period from 1987 to 2005 could be considered a new period for nursing homes, characterized by efforts to apply the OBRA 87 stipulations, including reduction of physical and chemical restraints in nursing homes, the development and testing of the minimum data set (MDS) as a fulfillment of the assessment tool, and the development of the new enforcement procedures. This period also saw the rise of dementia spe-

cial care units in nursing homes, the development of Medicare-funded postacute care units (which were encouraged by incentives to shorten hospitalizations because of prospective payment of hospitals), the refinement of nursing home payment systems based on resident characteristics at admission (i.e., case-mix adjusted payment systems), the use of data generated from the MDS to create quality indicators and comparative quality reports, and the federal quality initiative of the late 1990s that promoted comparative Web-based quality reports that could be used by consumers. These reports emphasize comparative rates of negative outcomes, such as development of new bedsores and infections, prevalence of untreated depression, incidence of deterioration in late-loss activities of daily living, and physical restraints use.

The last several decades have been a heady time for nursing homes in the United States. The OBRA implementation was a long process, lasting more than 10 years. The market also changed in a variety of ways, responding to new pressures on hospitals for early discharge, more differentiated approaches for people with dementia, and opportunities for wealthier and healthier old people with care needs to choose a place other than a nursing home. Unfortunately, however, another Institute of Medicine report (Wunderlich & Kohler, 2001), completed at the turn of the century, found that although nursing home quality of care had markedly improved since OBRA 1987, quality problems remained; just a little dent had been made in improving the quality of life in nursing homes.

OTHER GROUP RESIDENTIAL SETTINGS: ENTER ASSISTED LIVING

Nursing homes were never the sole residential care setting in the modern era for older people with care needs. The boarding home is an old tradition in American life, and in many such boarding homes and retirement hotels, older people “aged in place” and manifested a range of care needs. Low-income and public housing for seniors, often built in the 1970s, also came to house many individuals who have aged in place and demonstrate care needs. Purpose-built apartment-type assisted living expanded rapidly in the 1990s, with loans readily available and publicly traded companies emerging and building rapidly.

The residential care market, apart from nursing homes, in the United States is largely regulated by states, if regulated at all. In the last quarter of the 20th century, the residential care market outside nursing

homes became quite differentiated. Older people with care needs live in small family homes (sometimes called adult foster homes), in social-model residential care facilities that ranged from institutional-style dormitories with shared rooms to upscale residential hotels with private rooms and restaurant-type dining, and in new-style assisted living apartments. Those with mental health needs may live in specialized therapeutic settings, but they also may be found in single-room-only residential hotels. As noted, purpose-built assisted living expanded, and at the same time, many states renamed their residential care facilities “assisted living facilities.” Some states developed a licensure that allowed for multiple types of assisted living, such as adult family homes, traditional board and care homes with rooms that were often shared, and new-style apartment-type assisted living (Mollica & Lamarche, 2005). In some states, notably Florida, the number of assisted living settings exceeds the number of nursing homes.

Idealists who first envisaged assisted living sought a setting where residents experienced autonomy, privacy, and dignity in single-occupied apartments, while receiving a high level of care and service. The model that evolved in Oregon required that assisted living settings offer privately occupied private apartments with locking doors, kitchenettes, and full bathroom and that they also offer three meals a day and ongoing assistance with personal care and routine nursing. The term *tenant* was encouraged to suggest a philosophy of resident control over their space and care (K. B. Wilson, 1990). Those with greater financial resources were most able to select the new assisted living, however, and often states developed admission and retention rules for the setting that prohibited assisted living from becoming a true option in lieu of nursing homes. In a large national probability sample of assisted living settings serving more than 12 people, researchers found that only 11% offered both high privacy and high service levels, that substantial numbers offered neither, and that there was a trade-off between privacy and quality of life features and care capacity, with the highest level of care available in settings that were most institutional in nature (Hawes, Phillips, & Rose, 2000).

Gradually, under Medicaid or Medicaid waivers, states began to cover some of the costs of care in residential care settings other than nursing homes, leaving room and board to be covered out of income. This uncoupling of room and board from care could be seen as a positive development, rendering care in group residential settings more like home care and af-

foring more control to consumers (R. A. Kane, 1995). But if people eligible for Medicaid and other low-income people cannot afford the rent component, their care subsidies will be utilized, if at all, in the least appealing settings.

Assisted living now occupies an unsettled and controversial place in public policy. Historian David Barton Smith referred to the growth of assisted living as a “killer application,” alluding to a computer term for a new application that throws all others out of kilter (Smith, 2003). As neither an institution like a nursing home nor a private home, assisted living is a confusing program, raising issues about who should be in assisted living settings, what care they should receive, and what responsibility governments should have for both payment and quality oversight. Combining housing and services carries its complexities. For example, if the housing is truly seen as separate from the services, then Fair Housing Act and Americans with Disabilities Act standards should apply before residents are evicted. If the housing is a “facility,” then discharges can be made because disabilities exceed the perceived capability of the program. Further, services detached from housing may be provided exclusively by the facility or by a contracted service provider, or the resident-tenant may have a choice of provider. If the model allows for choice of provider, the facility is unlikely to achieve economies of scale, and its prices may rise. To further illustrate the difficulties of the new model, depending on the assisted living program and the state in which it is licensed, the residents may be able to receive services from any combination of facility staff, outside home care agencies, private duty personnel hired by the consumer, and family. Those who would regulate the settings by proposing a staff-to-resident ratio may be stymied by the difficulty in counting the arrangements that are pieced together on an individual basis.

CRITIQUES OF RESIDENTIAL CARE FOR SENIORS

The very phrase “nursing home” evokes fear and dread in older people and many of their family members. Very soon after Medicare was enacted, nursing homes were likened to Goffman’s “total institution” (Goffman, 1961), where inmates are processed in batches and subject to rules designed for the benefit of the organization, not the residents (R. G. Bennett, 1968).

The importance of privacy to seniors and their family members has received growing recognition, al-

though old ideas still linger, and some commentators may still believe that companionship is fostered by forced sharing. For the most part, however, commentators are coming to recognize that loneliness occurs in the midst of group settings and that true friendships rarely flourish in crowded spaces. During the same years that some reformers sought to improve nursing home care, a raft of anthropologists and ethnographic researchers filed studies of nursing home life (Agich, 1993; Lidz, Fischer, & Arnold, 1992; Shield, 1988); one such writer was an enlightened nursing home administrator who could not tolerate even two weeks in the facility where he had checked himself in as a pseudo-patient (C. Bennett, 1980). Others concentrated on the difficulties this environment put in the way of staff workers who wished to develop primary relationships with residents, exercise judgment, and nurture residents’ quality of life (Diamond, 1992; Henderson & Vesperi, 1995; Vesperi, 1995). Sociologist Jaber Gubrium coined the phrase “bed and body work” to encapsulate the focus expected of nurse’s aides (Gubrium, 1975).

The Nursing Home Pioneers, now known as the Pioneer Network in Long-Term Care, a social movement to change the culture of nursing homes, largely sprang from a realization that the status quo was antithetical to the well-being of both residents and staff (see chapter 57 by Lustbader and Williams in this section). Thus, in the 1990s, more basic reforms were advocated, falling under the rubric of culture change and proposing changes in the power structure and operating practices and developing a caring community of residents and direct care staff to improve quality of life for both (Fagan, Williams, & Burger, 1997; Weiner & Ronch, 2003). Innovations suggested by the Pioneer Network tend to fall into three categories of change: changing physical environments to make them smaller and more normal, for example, creating neighborhoods in nursing homes and advocating private spaces; empowering and developing more capacity for caring among line caregivers; and instituting a philosophy that individualizes the approach to residents. One of the pioneer examples is the Eden Alternative, an approach developed by William Thomas to combat boredom, loneliness, and lack of meaning, which to him are “the three scourges” of nursing home life (Thomas, 1999). Although it is widely associated with advocating animals and plants in nursing homes, the Eden Alternative’s more difficult changes are flattened hierarchies and individualized care. More recently, William Thomas articulated another model, known as Green Houses, which further dein-

stitutionalizes nursing homes into small houses where certified nurse's aide-level elder assistants provide a fuller range of care for 7 to 10 elders, preparing and serving meals, doing household laundry, and providing personal care. A group of Green Houses are linked administratively as a licensed, certified nursing home, and all professionals, including the social worker but also the nurses and medical director, form a clinical support team to assist the elders and the elder assistants (Thomas, 2003).

The culture change movement brings to a head some tensions between quality of care and quality of life. Although the two pursuits should be compatible, the quality of care emphasis typically centers on further regulation, including mandating higher staffing ratios of direct nursing staff to residents and enforcing "zero tolerance" policies for outcomes associated with poor quality of care, such as dehydration, falls with injuries, and bedsores. In contrast, some advocates for culture change prefer not to reify current staffing patterns by mandating higher ratios of staff in the nursing department, nor do they want to perpetuate the view that someone must be blamed and punished for all bad outcomes in nursing homes (Kapp, 1997).

Further, the culture change movement needs to come to grips with assisted living. To the extent that residents with the same disability levels as nursing home residents live in normalized assisted living settings, this is the biggest culture change of all. Authorities disagree about the extent to which it is appropriate for residents with true nursing home levels of need to experience the lack of oversight associated with assisted living. Government watchdog organizations and the media have both highlighted quality problems in assisted living. However, if assisted living settings adopt the rules, routines, and conventions of nursing homes, some commentators fear that they will lose the very characteristics that have made them popular to seniors. Meanwhile, some of the proposed changes in the culture of nursing homes and in the physical plans would accentuate the blurring of the lines between nursing homes and assisted living, whereas some of the proposed changes in assisted living would accentuate the blurring between assisted living and home care.

One helpful formulation envisages desirable residential care services for seniors as a three-legged stool, each leg having two prongs (see Figure 52.1). The first leg on which reform depends is a residential environment in both the private space and the public or shared spaces. The building and the materials influence whether the setting is homelike, or even whether

one gets beyond "homelike" to home itself. The second leg is a residential capacity; one prong is the capacity for routine services (some of which can be scheduled in advance, and some of which cannot), such as personal care and medication management, and the other prong is specialized services that may be needed from time to time for particular residents. The routine services must be managed in-house, whereas consultants could be brought in for specialized services: psychiatric care, speech therapy, pharmacological review, ordering of prosthetic equipment, and the like. What is considered routine may expand if the general acuity and frailty of the population increases. The final leg of the stool is a philosophy that emphasizes consumer control; one prong is control over the amount, type, and timing of care, and the other is control over what happens in one's private space—who enters, how furnishings are arranged, what is done there, and at what times of day. Though the model was first developed for assisted living, all residential care, including nursing homes, could be examined and compared in terms of success in all three arenas.

SOCIAL WORK AND RESIDENTIAL CARE

Relevance of Social Work Skills

Although social workers have historically had periods when they considered work in residential care settings to require less skill than presumably more psychodynamic treatment settings, a consummate level of skill is needed to help nursing home residents deal with the psychic insult and social changes attendant on moving to a residential care setting. Social work skills are also required to help an older person make decisions about whether to enter residential care outside their own home, what sort of residential setting to seek, and how to choose a particular setting within a type of setting. Typically, this painful decision is a family matter, and many of the family members will be elderly, not just the people contemplating the move. Although such advice and consultation sometimes gets dismissed in the unfortunate phrase "nursing home placement," the importance of the task and the skill and knowledge needed to help are both high. Moreover, the nursing home calls forth the need for the full range of social work skills, including direct counseling of individual and family members, social group work and group therapy, community organization, systems management, and system change.

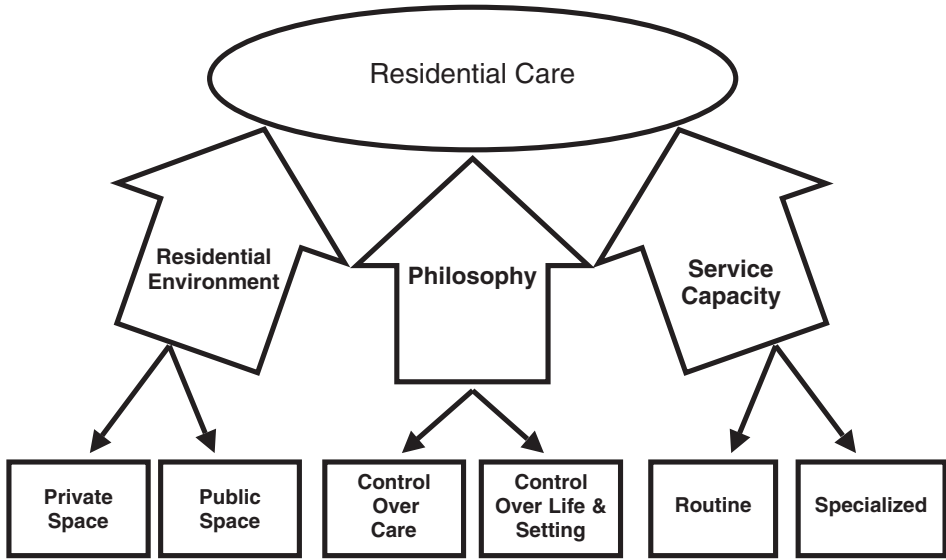

FIGURE 52.1 Three-legged stool model for evaluating attributes of any residential care setting. Source: This model was developed by Keren Brown Wilson, Portland, Oregon, and is described in *The Heart of Long-Term Care* by R. A. Kane, R. L. Kane, and R. C. Ladd, 1998, New York: Oxford University Press.

The challenges to social work to help meet the needs of older people who live in group residential settings and to help older people in the community decide about moving to group residential settings are legion. Part of the solution is to have enough social workers in the settings (either working directly in them or coming to them under other auspices), and part is for social workers to develop creative approaches for when they get there. Only the nursing home is a regulated entity requiring social work presence. Social workers are less likely to practice in assisted living or residential care facilities, unless those settings are part of a community with a nursing home attached. In some states, social workers may fill care management roles, through which they oversee the experience of older people in adult foster homes, residential care, and assisted living. In most of the roles just mentioned, social workers with bachelor’s-level training are more frequently found than those with master’s degrees. Further, in most of these settings qualified social workers, be they MSWs or BSWs, are likely to be somewhat alone in their practice, needing to determine their own roles and interpret what they can do under administrators from other disciplines. Unfortunately, the profession has not as yet provided much practice guidance for direct practice in residential settings where seniors are served, nor has research reached the stage where evidence-based advice can reach any depth.

Historical Leadership

Towering figures in the social work profession have addressed the urgency of the social work tasks in nursing homes and other residential settings. In her early guide to social work in nursing homes, Elaine Brody (Brody & Contributors, 1974) recognized the trauma of moving to an institution and the folly of considering the social component of care “a luxury to be avoided” (p. 66). She called even then for an emphasis on strengths, not deficits. An early model of practice-based researcher, during her career at the Philadelphia Geriatric Center, she brought to light important concepts that remain pivotal, including the need to avoid excess disability and the likelihood that aggression among nursing home residents, including those with dementia, was a life-prolonging strength rather than a behavior problem to be adjusted or medicated away.

Similarly, Herbert Shore, nursing home administrator and social worker, tirelessly pointed to the need to individualize and humanize the nursing home environment and to recognize that first and foremost a nursing home resident is a person with the same aspirations, hopes, fears, pleasures, and displeasures as any other human being. In an edited book in which he wrote many chapters (Leeds & Shore, 1964), his contributions suggested approaches to transforming dining, to developing a more intellectual and learn-

ing-oriented approach to activities, and to eliciting resident feedback and opinions about the programs. In a report to his board of directors in 1970, he wrote in terms that anticipated the culture change movement:

Older people *need* security—economically (in terms of shelter, housing, and spending money), physically (in terms of medical care and adequate diet), and socially (in terms of status, friendship, and belonging). Older people *want* recognition—for what they can do mentally and manually, for their capacity to make a contribution to their community, country, and world, for social and political consciousness, and their ability to plan for themselves. Older people want response: to be liked for what they are, to hold friends and make new acquaintances; and older people want new experiences and adventures: to continue to learn and grow and develop, to enjoy the new and different, to extend interests, expand horizons, satisfy curiosity, to create for expression in artistic and aesthetic areas. . . . Like every other human being, they need social contact.

In that 30-year-old report, Shore also suggested that if staff are to give, “they need to be secure in self, gain satisfaction in giving, and must receive recognition, love, and compensation.” He deplored “cultural hangups on who does what”—a precursor of the universal worker ideas of today. He concluded that “the major challenge is to provide for a continuity of life experience (no showcase for public relations, not tokenism but meaningful life—with freedom of choice, when and if to participate, a program of social health, personal identity, independence, privacy, stability, self-direction, re-engagement, discovery and re-institution of normal elements of daily social living).” These principles are almost identical to those enunciated by the Pioneer Network, discussed previously.

Social workers were instrumental in the formation and leadership of the National Citizens' Coalition for Nursing Home Reform, an advocacy organization that fought for the nursing home reforms of 1987 and that provides public information about nursing homes (Burger, Fraser, Hunt, & Frank, 1996). Social workers are often found in the ranks of the nursing home ombudsman program, a nationwide complaint resolution program initiated by the Older Americans' Act in 1975. In each major movement to improve the options for older people in residential care, social workers can be found, for example, leading the charge

against physical restraints (Williams, 1991), developing specialized dementia care (Gwyther, 2001), suggesting structural ways to identify and resolve ethical issues (R. A. Kane & Caplan, 1990), and testing approaches to combat learned helplessness (Mercer & Kane, 1979).

Trends and Challenges

Several trends already mentioned have implications for social work practice and research related to residential care for older people. First, the growing emphasis on quality of life as an outcome and the effort to measure quality of life give attention to social work issues and offer tools to examine practice (R. A. Kane et al., 2003). In the same vein, a new study from the United Kingdom provides evidence that entertainment and enjoyable, meaningful activity are crucial to a good-quality home (Mozley et al., 2004); these are outcomes that social workers could influence. Opportunities abound to test both the therapeutic interventions, and even more important, the environmental prerequisites that promote quality of life. Social workers should also examine the effects of various kinds of residential care arrangements on residents' involvement with their own families and on outcomes for family members per se.

Second, the culture change movement in long-term care, discussed previously, is offering hope for a new way of doing things, new scope for skills related to team building and leadership for organizational change, and new opportunities for leadership. Indeed, some social workers are joining leaders in other disciplines as culture change agents and have developed stage models to help organizations with which they consult move through the steps of culture change.

A third trend is the proliferation of a confusing array of residential settings, the overlap in resident functioning across settings, and the end of the quest to slot residents into the “most appropriate setting” based on functioning. Possibly, such judgments were never wise, but at present, such hubris is certainly contraindicated. Older people can have their care needs met in a wide range of settings, including their own homes and a diverse array of other group settings. Social workers who act as advisers can no longer seek refuge in the idea that there is an “appropriate” residential setting for the individual that matches his or her needs. At the same time, the recognition of overlap in resident characteristics in a wide array

of settings challenges social workers and colleagues from other professions to consider how some of the most challenging situations can be handled in any group residential care setting. These include care of people with Alzheimer's disease and other dementias, care of people with severe mental health problems, provision of physical rehabilitation for those whose functioning can improve, and care of people who are dying. Any of these situations could occur in any of the care settings. The differentiation described for nursing homes in chapters 56 on mental health and 58 on dementia care can now be seen in other settings. Small family homes and larger assisted living settings have been known to specialize in conditions as various as ventilator dependency, multiple sclerosis, and deafness.

Fourth, we see growing recognition that older people often do and should be able to continue to take risks in their daily lives, just as any people do. Bioethical treatments of long-term care emphasize this right. Negotiated risk contracting was developed as both a process and a product to enable older people to live in ways that health professionals see as risky (R. A. Kane & Levin, 1998; K. Wilson, Burgess, & Hernandez, 2001). Determining what safety should mean in operational terms in the light of the human right to take risks is an important challenge for practitioners. Falls, for example, do not always imply that care is poor. Beyond enhancing the autonomy and individual goals of each resident, ethical challenges in residential settings entail balancing the needs and interests of the individual with that of the collective. As privacy is enhanced in group residential care settings, this challenge is easier but by no means resolved.

Fifth, the Supreme Court *Olmstead* decision and the New Freedom Initiative of the federal government have clarified the duty to offer older people care in the setting that is least restrictive and most integrated in the community. Much energy now is devoted to keeping people out of institutions, and those who practice in residential care settings must work in the spirit of that injunction. It means that social workers in nursing homes will be more engaged in assisting those who come into the nursing home for rehabilitation so that they make a smooth transition back to the community. It also means being open to the idea that former long-stay residents can move to less restrictive settings.

Taking all these trends together, social workers may find a need to reinvent themselves in residential care for older people. In direct practice, one would expect to see social workers utilize a fuller array of skills

in individual, family, and group interventions, and one would expect to see social workers in the forefront of evolving the practices that render the setting a pleasant place to live—a place where the older person may develop to the fullest. In the future, we will expect a continuation of social workers occupying roles beyond the job title “social worker.” In nursing homes, they may be administrators, program developers, or unit coordinators. They may be responsible for a wide range of efforts beyond social work, including spiritual programming, activities, and volunteer coordination. In assisted living, they may be administrators, community liaisons, or marketers. They may be involved in the design of regulations. They are likely to be in the forefront of the struggles for innovation and reform. Because of the wide variety of job titles and roles social workers hold, they may not easily be able to find each other or a reference group from their own profession to help sharpen their skills and guide their work.

Social workers are likely to keep their professional compass properly set if they adhere to social work's historical mission as they interact with older people in group residential settings—assisting the individual in the environment—and if they perceive the adjustment of the environment as a goal as important as the adjustment of the individual. They will also be well guided if they remember, along with Herbert Shore, Elaine Brody, Carter Williams, and others, that older people in group residential settings wish for and deserve to live lives as normal and as rich as the disabilities that brought them into care permit. Like those earlier leaders, they should never gloss over the shock and losses involved in moving to a group residential setting, a move that is rarely wholly voluntary or without ambivalence. Moreover, in the midst of facilitating therapy, including health care and also mental health therapies where social workers may play a direct provider role, we social workers need to recall that the individual's meaning in life will not be realized through adherence to a therapeutic regimen. In the place where they live to receive care, social workers can be a force that helps each individual make the connections inside and outside the residential setting that will make life worthwhile. In that pursuit, no policy or practice that might affect the way the senior perceives the world of the residential setting should be beneath the dignity of the social worker's attention. Although difficult to achieve, one overriding goal should be to help as many people as possible perceive the place where they live as their home in the true sense of what home means.

Nursing Homes

53

The nursing home provides an ideal opportunity to implement social work's unique person-in-environment perspective and skills. The complex psychosocial needs of residents and their families during a period of major life transition interact with an institutional environment that is both comprehensive in care and highly controlled, offering pervasive opportunities to craft a more adaptive fit. With average lengths of stay ranging from 272 days for discharged residents to 892 days for current residents (Jones, 2002), nursing home social work practice frequently can be conducted within the framework of longer-term helping relationships, a quality increasingly hard to come by in today's health care environment.

More than 3 million people are cared for in nursing homes each year (Centers for Medicare & Medicaid Services [CMS], 2003). They are among the most vulnerable members of our society. Nursing homes often are the least preferred alternative of older Americans and their loved ones and, unfortunately, more frequently make news and headlines because of poor care and concerns about quality than for their exemplary service. Nonetheless, nursing homes are an essential component of the health care continuum and an important arena for social work practice. Social work's focus on overall quality of life and its professional obligation to advocate for those who may lack capacity to defend themselves are especially relevant to the nursing home setting. To introduce the practice domain, this chapter (a) briefly examines the nursing home context and regulatory environment; (b) discusses the needs and strengths of nursing home "clients" and the home as a system in its own right; (c) describes key features of the social work role and functions, including the monitoring and quality improvement of social work services; and (d) identifies key research needs to support practice.

PRACTICE CONTEXT

Trends in Nursing Home Care

There are approximately 16,500 nursing facilities in the United States certified for Medicare, Medicaid, or, most commonly, both programs. Of this number, the vast majority are classified as skilled nursing facilities (SNFs), which provide "short-term, residentially-based skilled nursing and therapy care" (CMS, 2003, p. 5). The typical SNF is large, ranging from 104 beds among nonprofit SNFs to 120 among government-owned facilities. Most facilities are freestanding

(85%), and the rest are located in hospitals (15%). The majority of homes have for-profit status (65.4%), more than a quarter are nonprofit (28.4%), and a small number are government (city or county) owned (6.1%) (CMS, 2003). Chain ownership characterizes two thirds of all for-profit facilities but only 40% of nonprofits and 8% of publicly owned facilities (CMS, 2003; Harrington, Woolhandler, Mullan, Carrillo, & Himmelstein, 2001). Research suggests that greater quality of care and quality of life concerns exist within for-profit, chain facilities (Harrington et al., 2001).

The number of nursing home residents has been declining in recent years. Between 1985 and 1995, the percentage of those age 65 and over residing in nursing homes fell from 46.2 to 42.4 per thousand, a decline of 8.2%. Likewise, the average occupancy rate dropped from 92% to 87% during this time period (Bishop, 1999) and was 84.3% as recently as 2001 (CMS, 2001). Researchers cite a decline in disability among older adults (Lakdawalla et al., 2003), increased use of home health services, and competition from the assisted living industry (Bishop, 1999) as a few of the factors contributing to this decrease. However, future cohorts of older adults are predicted to have greater disability because of the rise in chronic health conditions such as obesity and asthma, which could reverse this trend and create an increased need for nursing home care (Lakdawalla et al., 2003).

Despite the apparent gains made in reducing the nursing home population, there has been an accompanying increase in nursing home resident acuity, as well as rapidly escalating costs for their care. Harrington and Carrillo (1999) reviewed federal nursing home data (the Online Survey and Certification Reporting [OSCAR] dataset) for the years 1991–1997 and identified statistically significant increases in the numbers of bedfast residents (from 3.5 to 7.2% of all residents) and residents with dementia (from 34.7 to 41.7%) and depression (9.3 to 12.4%). Meanwhile, total annual expenditures for U.S. nursing homes increased from \$28 billion in 1987 to \$70 billion by 1996, or 150% (Rhoades & Sommers, 2003). Among free-standing nursing homes with Medicare certification, the rise in expenditures has been most dramatic: from \$307 million in 1980 to \$9.6 billion by 1997, an annual increase of 30% (CMS, 2003). The prospective payment system (PPS) put into effect July 1, 1998, following the passage of the 1997 Balanced Budget Act (BBA), attempts to control the escalating costs of postacute care, paid through Medicare Part A, by setting fixed, predetermined payment rates that are adjusted for case mix and geographic variations in

wages. Prior to PPS, nursing facilities were reimbursed retrospectively, according to their reported actual costs of care (CMS, 2003). Researchers have cited quality of care concerns as a result of cost-cutting measures under the PPS system, including shorter stays for rehabilitation (Yip, Wilber, & Myrtle, 2002), decreases in professional staffing, and greater regulatory deficiencies (Konetzka, Yi, Norton, & Kilpatrick, 2004).

Regulation, Licensing, and Financing

By definition (Jones, 2002), nursing homes today are settings providing nursing care that are certified by the federal government through the Medicare/Medicaid (M/M) program (and therefore entitled to receive reimbursement) and/or licensed by state departments of health. As assisted living facilities proliferate and tend to accommodate more affluent seniors who can pay for services (Hawes, Phillips, Rose, Holan, & Sherman, 2003), one critical distinction between nursing homes and assisted living facilities is the highly regulated nature of the nursing home industry. Approximately 80% of nursing homes are M/M certified (Jones, 2002), and the remainder must meet state licensure requirements, even if all residents are paying privately. To operate as a licensed and certified nursing home, a facility must meet extensive mandated requirements, including those especially relevant to social work (discussed later), and undergo periodic inspections that establish the degree of compliance with specified regulations as outlined in the Conditions of Participation for Long Term Care Facilities (42 CFR Part 483, Subpart B). CMS, an agency within the Department of Health and Human Services, oversees the federal government's nursing home program. CMS recently established the Nursing Home Compare Web site (<http://www.cms.hhs.gov/quality/nhqi/>), where the public can contrast homes' performance across a set of quality indicators.

The financial stake for a home to maintain certification status means that federal nursing home regulations play a predominant role in shaping the structure, processes, and services of nursing home care. This reality has important implications for social work practice in this setting, and nursing home social workers must understand and keep themselves informed about the regulatory process, the content of certification and licensing standards, and the specific procedures maintained by the home to prepare for and demonstrate compliance with mandated stan-

dards. Federal reimbursement to homes is also controlled by regulation. Social work services are covered as part of the overall facility operating costs, in the same way as in hospitals. Homes are reimbursed on a per capita basis, according to a daily rate or a case-mix-adjusted formula. Social workers need to understand the cost of their service to the home and be aware of the inevitable fiscal “bottom line” of costs versus reimbursement that drives administrators’ decisions. For example, certain mental health services and hospice services (which include social work care) are considered auxiliary to the daily rate. Homes can bill separately for eligible residents under their Medicare Part B coverage, contracting with providers (including social workers) external to the home (Beaulieu, 2002), with the facility social worker serving as a liaison through referrals and follow-up.

Social Service Regulation

Since the original Medicare regulations of 1966, which required a professional social worker available to every Medicare-certified home, the federal government has explicitly regulated the provision of social services in nursing homes. Regulations were significantly weakened in the 1970s (Kosberg, 1973). Homes could use a “social service designee” to provide direct services, with a social work “consultant” to provide oversight. There were no specified educational requirements for the designee, and no required minimum amount of time for the consultant. Nursing home reform legislation in 1987 (Omnibus Budget Reconciliation Act of 1987 [OBRA]) strengthened federal requirements for psychosocial care and social work services in nursing homes. Current regulations (implemented in 1990) require all facilities to identify the medically related social and emotional (psychosocial) needs of each resident and develop a plan to help each resident adjust to the social and emotional aspects of his or her illness, treatment, and stay in the nursing home. Homes of more than 120 beds must provide a full-time social worker (BSW, MSW, or “educational equivalent”). Although the regulations require use of licensed personnel in facilities, this obligation has not yet been applied in the case of social work. Federal guidelines to state surveyors (who do the inspections) with respect to judging the adequacy of social services focus on the sections of regulations pertaining to quality of life and residents’ rights in addition to the “over 120 bed” rule for staffing.

The National Association of Social Workers (NASW, 2003) recently revised its standards for prac-

tice in long-term care settings, providing guidelines for nursing home social worker qualifications above and beyond federal regulations. The standards place greater emphasis on professionalization by recommending that all social work staff have either BSW or MSW degrees. Further, they advocate licensing all social work staff according to state requirements and encourage all nursing home social workers to belong to professional organizations, including the NASW, and to attend continuing education programs.

THE “CLIENT”

The nursing home social worker needs a general understanding of the needs and strengths of the people living in the home, their families, and their significant others and of the home itself as an organization, keeping in mind that each of these systems levels can be a target for intervention. Although familiarity with medical and rehabilitative diagnostics, typical symptoms, and therapeutic regimens is necessary for effective practice and communication with other health personnel in the home, here the focus is on aspects of the psychosocial reality of life and care in the nursing home.

Resident Characteristics

The typical nursing home resident is female (68%), White (84.8%), and over the age of 75 (75%), although 40% of all nursing home residents fall into the demographic category of “oldest old,” those age 85 and over (CMS, 2001). More than a third of all residents receive extensive assistance with four of five activities of daily living (CMS, 2001), such as bathing (93.8%), dressing (86.5%), toileting (56%), eating (47%), and transfers (29%) (Jones, 2002). Likewise, only slightly more than a quarter of residents have no cognitive impairment (CMS, 2001). Although racial minority groups currently comprise only a small portion of the nursing home population, the numbers of racially diverse residents are likely to increase in accordance with the changing racial profile of the U.S. population, including increasing numbers of Asian and Hispanic Americans (U.S. Census Bureau, 2004). Meanwhile, disparities in the quality of nursing home care by race and socioeconomic status have been identified, creating a “two-tiered system” not unlike other sectors of the U.S. health care system (Mor, Zinn, Angelelli, Teno, & Miller, 2004).

Social workers need to recognize nursing homes as mirroring the socioeconomic and cultural circumstances of the local community and of society at large. In many sections of the country, significant numbers of direct care staff are members of recent immigrant groups, who are therefore serving elderly individuals from cultures very different from their own. Culturally sensitive and competent social work practice requires awareness and understanding of the culturally distinctive aspects of residents' and their families' attitudes, preferences, and behaviors throughout the course of the nursing home experience. For example, family members' underlying reasoning and feelings about the placement decision may vary culturally (Calderon & Tennstedt, 1998; Fitzgerald, Mullavey-O'Byrne, & Clemson, 2001), and resident preferences and subjective well-being, including end-of-life care, are likely to be influenced by culture (Ejaz, 2002; Field, Maher, & Webb, 2002; Ingersoll-Dayton, Saengtienchai, Kespitchayawattana, & Aunguroch, 2004; Shibusawa & Mui, 2001). Moreover, social workers can be helpful in recognizing and mediating cultural differences between staff and resident or family members and among culturally diverse staff members that may contribute to misunderstandings, conflicts, and insensitive care.

Quality of Life

Clients themselves provide a critical perspective for understanding needs and capabilities, all the more important to recognize and reach for when cognitive and physical diminishments erode the confidence and assertiveness to speak up. From this perspective, quality care in nursing homes is understood to involve not just medical and personal care and functional assistance but also resident quality of life. Quality of life (QOL) was an important focus of the influential Institute of Medicine report (1986) on nursing home quality that preceded nursing home reform legislation in 1987. Considerable effort has gone into better defining what is meant by the concept from the points of view of the individual resident and of the facility as a whole in an effort to more meaningfully promote and measure QOL outcomes. Kane and colleagues (Kane, 2003; Kane et al., 2003) delineated 11 domains for QOL: autonomy, functional competence, privacy, dignity, meaningful activity, individuality, enjoyment, security, relationships, spiritual well-being, and comfort.

Residents have stressed the importance of staff attitudes and continuity of staff, choice and variety of food, and opportunities for individualized activities

(Holder, 1987). Their families describe poor care as the failure of the facility to help the resident maintain dignity, hope, control of the environment, and family ties, factors they also viewed as contributing to residents' depression (Bowers, 1988). Although all providers and staff in the home and many aspects of the home environment itself contribute to QOL, the overlap with social work's practice focus on meeting social and emotional needs is substantial, and high-quality psychosocial care should connect in meaningful ways to improved quality of life.

Psychosocial Needs

Whether for a short stay or a long one, the person entering a nursing home confronts the stress of adjusting to a drastically new social environment at a time of diminished personal capabilities and emotional vulnerability. For family members, the transition, both in terms of the scope and shape of their relationship to their loved one and the interjection of the new and complex caretaker system into that relationship, generates an array of needs as well. During the time in the home, both the resident and the family may sustain multiple losses, whether of relationships, roles, or independence, and may confront dying and death. Ideally, care and activities are reflective of each resident's unique preferences and capabilities, but many obstacles stand in the way. These include residents' physical and cognitive impairments that impede communication, staff members' lack of attention and/or recognition of social and emotional needs, and facility procedures and attitudes that preclude individualized options.

From a social work perspective, the realm of psychosocial care requires definition and classification, just as exists for medical and nursing care. The undertaking is important to transform general but diffuse and wide-ranging concerns into specific and distinguishable needs. Social workers encounter a formal classification and specification of certain psychosocial needs in the minimum dataset (MDS) that has been a mandated part of resident assessment in nursing homes since 1990. However, the MDS fails to capture many areas that are of central importance to social work practice, and nursing home social workers require a more comprehensive understanding of the needs that are the focus of their efforts. One such list, professionally generated by a diverse group of nursing home experts (Vourlekis, Gelfand, & Greene, 1992), is presented in Table 53.1.

TABLE 53.1. Nursing Home Residents' Psychosocial Needs: Social Work Perspective

-
- Emotional support and assistance in coping with transition of move to the nursing home
 - Orientation to the home, its staff, policies, and procedures, including rights, responsibilities, and grievances
 - Recognition of status and wholeness of one's life history
 - Ongoing relatedness and intimacy with family and loved ones
 - Choice concerning important daily routines
 - Choice and control over decisions affecting care
 - Recognition and opportunity for expression of religious/ethnic/cultural identity
 - Independence in functioning and the opportunity to do for oneself whenever possible, whatever the level of functioning
 - Contributing to the life and functioning of the nursing home community
 - Structured social and group interaction opportunities inside and outside the home
 - Maintaining contact with friends, associates, and community ties outside the home
 - Help with feelings of loss that occur throughout the stay in the home
 - Help with fears and anxieties that may occur throughout the stay in the home
 - Specific help in preparing for and coping with death
 - Recognition by staff that "difficult behavior," including aggressiveness and withdrawal/apathy, may signify emotional distress; interventions based on a specific understanding of that distress
 - Help with financial planning and decision making prior to coming to the home and assistance in locating and accessing financial resources at any point during the stay in the home
 - Opportunity and assistance as needed with access to activities and events within the home that are diverse enough to match each resident's capabilities and interests
 - Informal social opportunities with other residents
 - Opportunity and assistance as needed with access to activities and events outside the home
 - Help with acquiring or replacing needed personal belongings or other practical transactions
 - Emotional support to family members and significant others in response to their needs or reactions
 - Family collaboration in care planning and decision making
 - Family/resident input into survey/certification and accreditation processes
 - Opportunity for formal feedback to home personnel on level of satisfaction with aspects of home care
 - Opportunity for structured dialogue between families/residents and home personnel concerning care management
 - Security that appropriate care will be in place at points of transition whether into, within, or out of the home
 - Assurance that care and resources that are supposed to be provided/available, in fact, are
-

Facility

The nursing home as a system is at the same time an institution and a potential community. The difference lies in the meaning given and uses made of the structures, rules, roles, and routines that constitute the home's functioning.

Institutions run the risk of depersonalizing and suppressing uniqueness through standardized operations and routines that are viewed as central to efficiency and quality control. They can be dehumanizing when multifaceted, life-accumulated identity is reduced to the single status and role of "resident." Im-

portant improvements in medical care and nursing routines do not guarantee an improved quality of life when residents continue to spend almost half of their time in their rooms (Harper Ice, 2002) and continue to have little or no say over their lives (Kane, 2001).

The social worker focused on the "home-as-a-whole" will find no shortage of opportunities for influence. These may include, for example, providing or arranging additional structured resident group experiences, addressing barriers to family involvement (Peak, 2000; Port, 2004), or designing staff development to facilitate greater cultural sensitivity in the home (Mizio, 1998).

Culture Change

Within the last 10 years, a movement to supplant the institutional qualities of nursing homes with more humanistic or social models of care has taken hold. This effort, termed “culture change,” seeks to improve the quality of life and the quality of care for nursing home residents through organizational and environmental changes. The principles of culture change include promotion of resident choice and decision making, supporting intergenerational relationships and relationships with the natural world, reshaping the physical environment to make it more homelike rather than institutional, and flattening the bureaucratic structures of traditional homes to empower frontline staff and residents (Fagan, Williams, & Burger, 1997). Perhaps most notable are the architectural differences between traditional nursing facilities and those that embrace the physical transformations of culture change. For example, the Green House Project introduces a model of care more closely resembling group homes, with residents housed in clusters of 8 to 10 private rooms, each with its own bath but sharing common areas, including a full kitchen (Green House Project, 2004). This brief introduction is meant to familiarize the reader with the concept of culture change.

Resident Rights

As with health care more generally, rights of nursing home residents as consumers have received considerable attention and are defined by law and supported by specific structures. Beginning in 1975, state agencies on aging that were established under the Older Americans Act of 1965 received federal funds to establish a nursing home ombudsman program to monitor the implementation of regulations protecting patients’ rights in nursing homes and to receive and investigate complaints. State laws ensure the ombudsman access to facilities, residents, and records. Regulations promulgated in response to nursing home reform legislation (Omnibus Budget Reconciliation Act of 1987) detail facility responsibilities to ensure specific resident rights as a requirement of Medicare/Medicaid certification. Among the many rights are (a) nondiscrimination in admission and care regardless of source of payment; (b) freedom from unnecessary physical and chemical restraints; (c) the right to be informed about all care and to participate in care planning; (d) freedom from verbal, sexual, physical, and mental abuse, corporal punish-

ment, and involuntary seclusion; and (e) the right to personal property, access to the telephone, and privacy of mail and the right to share a room with a spouse who is also a resident of the facility (Knee & Vourlekis, 1995).

SOCIAL WORK PRACTICE

Social Service Staffing

Nursing home social service departments are predominantly small, with 30 to 43% employing only one social worker (Simons, 2005; Vourlekis, Bakke-Friedland, & Zlotnik, 1995). As a result, the typical caseload of a nursing home social worker is 90 to 95 residents (Kruzich & Powell, 1995; Simons, 2005). In prior research, job tenure in this setting averaged between 2 years, among a general population of social service staff (Gleason-Wynn & Mindel, 1999), and 6 years, among professionals with social work degrees (Vourlekis, Greene, Gelfand, & Zlotnik, 1992). Salaries do appear to be competitive. A recent national survey of social service directors identified an average salary of \$39,290 (SD = 11,612); however, directors earned significantly more when they had degrees in social work, especially master’s degrees, and were employed in not-for-profit or government-owned facilities that were not part of multifacility chains (Simons, 2005). It is known anecdotally that social workers are hired in nursing homes for a variety of roles other than provision of social services, such as director of admissions, unit head, or volunteer coordinator. There are also social work home administrators and homeowners. However, the extent to which nursing facilities employ people with social work degrees in other facility functions is unknown and should be an area for further investigation.

A recent federal government investigation of psychosocial services at Medicare-certified nursing homes, conducted by the Office of Inspector General, found that nearly all of these facilities (98%) met the minimum regulatory staffing requirement (Department of Health and Human Services, Office of Inspector General, 2003). Yet prior and recent research reveals that only three fifths to two thirds of social service staff have degrees in social work (Kruzich & Powell, 1995; Quam & Whitford, 1992; Simons, 2005; Vinton, Mazza, & Kim, 1998; Vourlekis, Bakke-Friedland, & Zlotnik, 1995) and that most (52.6%) are not licensed (Simons, 2005).

Roles and Functions

National Association of Social Workers (NASW) Guidelines

Years of professional conceptual and empirical effort have led to a well-articulated model of social workers' roles and functions in the nursing home, as both staff members and consultants. Building from this body of work, in 1993, NASW developed an important consensus statement on the mission and roles of the nursing home social work practitioner. This practice guideline embraces a comprehensive intervention field to include the resident, the resident's family, facility staff, and the institutional environment—that is, direct services to promote psychosocial well-being and, as a member of the multidisciplinary team, efforts to “foster climate, policy, and routines” that respect residents' cultural diversity, individual uniqueness, dignity, independence, and choice (NASW, 1993). Services provided by social workers include assessment of psychosocial needs and development of a care plan, facilitating the admissions process, facilitating the social and psychological well-being of nursing home residents and their families, promoting resident empowerment and choice, crisis intervention, linkage to resources, discharge planning, and advocacy for psychosocial needs facility-wide (NASW, 1993).

In addition, NASW's *Standards for Social Work Services in Long-Term Care Facilities* (2003), although not exclusive to nursing home practice, provides further guidance regarding the necessary and appropriate functions for social workers in this setting: “advocacy, care planning, discharge planning and documentation; participation in policy and program planning; quality improvement; staff education pertaining to social services; liaison to the community; and consultation to other staff members” (p. 13). Specifically, the standards recommend social work's participation in several key areas of service provision including, but not limited to,

1. preadmission services for potential residents to determine the need and readiness for placement
2. interdisciplinary care planning
3. the medical and legal decision making of residents and/or their family members
4. room or facility transfers, as well as discharge planning and follow-up
5. helping residents create or maintain positive interpersonal relationships

6. advocacy for appropriate care and treatment
7. ensuring the availability of psychosocial services
8. policy planning and development at the facility level
9. orientation and in-service training of employees
10. serving as a staff resource in behavioral interventions
11. orientation and supervision of volunteers and/or social work field students
12. development and/or facilitation of resident and family councils
13. development and/or implementation of independent or collaborative research projects

Such responsibilities challenge the professional social worker in the nursing home to use a range of clinical, organizational, and research skills in working directly with residents and their families and indirectly with facility staff and policies to improve psychosocial outcomes and QOL for residents.

Psychosocial Services

The research and practice literature identifies and elaborates on critical tasks and strategies that social workers carry out in meeting residents' psychosocial needs. These include approaches to supporting resident empowerment and choice, such as discussions and decisions concerning advanced directives (Ingersol-Dayton, Schroepfer, Pryce, & Waarala, 2003; Mercer & Kane, 1979; Reinardy, 1999), and facilitating residents' adjustment to multiple losses and to a radically new environment (Brody, 1975; Brody & Spark, 1966; Hirsh, 1987; Silverstone & Burack-Weiss, 1982; Toseland & Newman, 1982). The social worker's ongoing involvement with family members centers on promoting maintenance of residents' family ties; mediating issues and conflicts that arise among residents, families, and staff; ameliorating family emotional distress; and involving the family in care planning (Dobrof & Letwak, 1979; Greene, 1982; Peterson, 1986; Vinton et al., 1998; York & Colson, 1977). Other research has found that facilitation of the admissions process, development of individualized care plans, and discharge planning are typical tasks fulfilled by social workers in nursing facilities (Parker-Oliver & Kurzejeski, 2003).

Social workers are commonly the only nursing home staff designated specifically for the provision of psychosocial care; therefore, they may be best able to identify and address mental health conditions among residents. From a regulatory perspective, they are

often responsible for completion of the cognitive, mood, behavioral, and psychosocial portions of the mandated assessment tools used in nursing homes, namely, the minimum dataset (MDS) and their accompanying resident assessment protocols (RAPs) and care plan sections (Beaulieu, 2002). The Department of Veterans Affairs further recommends that its nursing home social workers screen for mental disorders and provide, if appropriately credentialed, individual, group, and family counseling (Department of Veterans Affairs, 2001). Still, given the great need for mental health services in nursing homes and the typically high caseloads for the social worker, it is more likely that a nursing facility will refer to external providers for mental health services. Therefore, the social worker may more often be viewed as a member of a team of mental health providers, perhaps a first point of contact for the resident and his or her family, and tasked with recognition of need and making a referral, rather than as the provider of mental health treatment (Beaulieu, 2002).

Practice Realities and Issues

The nursing home social work research and practice literature has been invaluable in explaining and reinforcing the highly skilled nature of social work functions for administrators, policy makers, and consumers. Even so, nursing home social workers confronting the realities of practice circumstances are likely to encounter problems of role overload and misunderstanding about role expectations on the part of administrators and other providers in the home (Greene, Vourlekis, Gelfand, & Lewis, 1992). Preoccupation with case-by-case needs may cloud the practitioner's perception and inclination to address home-as-a-whole circumstances with an impact on all residents. Significant barriers to direct service exist, such as extensive paperwork and documentation and being assigned responsibilities in addition to provision of psychosocial care (Department of Health and Human Services, 2003). Time constraints resulting from minimal social service staffing require social workers to prioritize among functions, not provide them all (Kosberg, 1973; Vourlekis, Greene, et al., 1992). Social work consultants who are used when full-time qualified staff are not required or are unavailable often face severe time limitations, constraining their ability to adequately oversee, let alone directly provide, priority psychosocial care (Vourlekis, Greene, et al., 1992).

Despite these limitations, there is beginning to be evidence of consistency in implementation of the central elements of the staff social work role. Professionally prepared practitioners reported their highest frequency functions were (a) orientation to the facility for resident and family; (b) help in coping with the transition of the move to the nursing home; (c) crisis intervention; (d) mediating among resident, family, and staff; and (e) assessment, with assessment and care planning accounting for close to half of working hours, much of it in documentation (Brooks, 2003; Vourlekis, Greene, et al., 1992). Social workers and home administrators have expressed considerable consensus on priority resident psychosocial needs in the home, including transitional support, help with loss, and ongoing relatedness and intimacy. Furthermore, administrators shared social workers' view of most of their highest-frequency functions to meet these needs (Vourlekis, Gelfand, et al., 1992). Evidence of greater role clarity and consistent performance expectations in this limited number of high-priority care activities can provide a practical road map to connect high-quality practice with high-quality care outcomes.

The nursing home setting presents the practitioner with both ethical dilemmas and values conflicts. The potential for conflict of interest exists when discharge or supplementary service referrals are expected to be within an integrated health care system of which the nursing home is one part, or with certain precontracted providers. Ethical questions can arise in end-of-life decisions and care, particularly if mental competency is in question. Finding balance between resident self-determination and autonomy and legitimate staff or family concerns can be difficult throughout the stay in the home. Willingness to advocate for the resident and/or family when this pits the social worker against the home's administrators requires a high degree of professional sound judgment, self-confidence, and ability to clarify whose "good" is of paramount concern.

Practice Networks

Nursing home social workers will find that opportunities to network with colleagues are an important resource. Some states have independent organizations of professional nursing home social workers, and a number of NASW state chapters have long-term care committees with active continuing education and social action agendas. Practitioners with an interest in the consumer point of view and advocacy for overall

quality improvement can find information, activities, and social work colleagues through the National Citizens' Coalition for Nursing Home Reform (<http://www.nccnhr.org>).

Accountability

Social work processes and interventions, while conceptually sound, rarely have been linked to empirically demonstrated clinical outcomes and measurable QOL, leaving them vulnerable in today's outcome-oriented and evidence-based practice environment. Social work practice needs to demonstrate the high quality of its services in the nursing home and the difference these services can make to resident well-being and the quality of facility care overall. This evidence is crucial for visibility, accountability, and credibility, especially in this setting, where the professionalization of social services remains uneven and incomplete, and budget-constrained administrators lack compelling reasons to hire more (or higher-cost) social service providers.

Federal conditions of participation for nursing homes assign responsibility for meeting psychosocial needs to the facility as a whole, not to a specific discipline. Therefore, in determining facility compliance, surveyors do focus on aspects of quality of life and psychosocial care to which social work directly contributes, but current outcome measures and surveyor questions and protocols do not provide direct evidence of social work service quality, quantity, or effectiveness. Therefore, conceptual and measurable links between social service care processes and surveyors' facility-specific assessment of quality of care and quality of life must be designed at the level of the home.

For example, surveyors focus on the emotional and behavioral conduct of the residents, especially evidence of distress such as crying out, disrobing, agitation, and pacing, with a particular interest in whether and how staff are responding. Social work crisis intervention activities frequently address stressful and disruptive resident reactions, both to respond to the resident's underlying social-emotional circumstances and to help other staff recognize the meaning of the "difficult behavior." Whether through chart documentation or through a more formal process of monitoring the incidence and outcomes following social work intervention in this type of "problem," the nursing home social worker can heighten his or her visibility and accountability with respect to this im-

portant area. In the area of resident assessment, surveyors look for identification of psychosocial needs, which is a frequently performed social work function. However, when surveyors examine quality of care, they may not focus attention on follow-through for these particular needs—or may not find evidence if they do. Federal investigators recently conducted a nursing home chart review of a sample of Medicare beneficiaries and found that 39% did not have assessed psychosocial needs addressed in their care plans and 41% were not receiving all of the psychosocial services that were in their plans (Department of Health and Human Services, 2003). Social workers, the only providers in the home with an exclusive psychosocial focus, can be proactive in designing simple tracking systems to document actions taken to address needs that could be part of the home's formal accountability system.

Working in the continuous quality improvement framework, the National Association of Social Workers developed a set of six clinical indicators for social work practice in nursing homes (NASW, 1993), including measures of both social work care processes and resident outcomes. The indicators are timely psychosocial assessment, comprehensive psychosocial assessment, resident and family involvement in care planning, resident satisfaction with choice, and psychosocial problem resolution. Developed through extensive field reviews, the indicators can serve as a specific and uniform approach to demonstrating the level of performance of key social work functions and to linking these functions to resident outcomes in domains typically surveyed by regulators (Vourlekis et al., 1995).

For example, evidence of resident choice as well as affirmation of a key resident right could be devised using "presence of advance directive" as the operational "choice" outcome and linking this to the social work process of explaining, discussing, and negotiating this important decision. Barriers to accomplishing this task could be documented, providing opportunities for facility-as-a-whole examination of care improvement efforts.

RESEARCH FOR NURSING HOME PRACTICE

Precedents for social work's contribution to research to improve nursing home quality of care and quality of life have been established. Two notable examples are the work of prominent social work researchers

Elaine Brody and Rosalie Kane. Beginning in the 1960s, Brody's body of work on social components of nursing home care and the needs of the mentally impaired elderly led to publication of her seminal book (Brody, 1974), which still remains a linchpin of practice. For 20 more years, her research on filial care, particularly care provided by daughters, and many aspects of the realities of the dependent elderly, whether living at home or in the nursing home, provided findings that have influenced both policy and social work practice. Kane's widely recognized research dealing with nursing home quality, ethics, and, currently, resident quality of life has provided guidance for federal policy. Her research provides direction and support for social work practice in areas such as interventions to enhance resident choice and control and in outcomes measurement.

Nevertheless, the research base for social work practice is a limited one. Systematic tests of the effectiveness of social work interventions in the nursing home comprise a critically needed agenda for social work's research establishment. Intervention research focused on the social worker's potential contribution to improving mental health care (identification, assessment, and treatment) that is more accurate and offers a greater variety of nonpharmacological and pharmacological interventions is an example of a promising avenue (American Geriatrics Society, 2003; Burnett, Morrow-Howell, & Chen, 2003; Simmons et al., 2004).

A range of research efforts, including randomized controlled studies, cost analyses, and evaluation research, is necessary to provide the evidence base for practice that is now an expectation for health care in all settings. It is also needed to demonstrate the value added by a costly practitioner in an increasingly cost-conscious and cost-constrained environment. Practical and applied tools to monitor quality of care and connect social work care processes to current accreditation and/or surveying processes that are central to home certification and licensing can and should be crafted, whether the oversight approach is one of compliance or one of continuous quality improvement.

To date, the necessary national statistical profile for the profession's presence and contribution in nursing home care is lacking. Current federal and state regulatory processes do not routinely or systematically assess more than the structural absence or presence of a social service provider, who may, as discussed previously, possess a variety of credentials. A feasible blueprint to guide the development of evi-

dence for a set of consistently implemented social work roles and functions, guidelines for expected "best practice" in those roles, and demonstration of the link between practice and valued resident and home-as-a-whole outcomes must be crafted, with the social work profession taking the lead. The parameters, key issues, and potential resources for this critical enterprise were laid out in a recent national multidisciplinary working conference, sponsored by the Institute for the Advancement of Social Work Research (2004) and funded by the federal Agency for Health Care Research and Quality.

CONCLUSION

Nursing home social work practice today presents worthy challenges to the practitioner and to the profession. For the practitioner, managing the demands and expectations of a large caseload and an extensive practice mission and role requires an ability to initiate, not just react, prioritize, and teach others how to make the best use of social work skills and time. The potential of social work interventions that can have an impact on the facility as a whole appears to be underutilized, or at least not well documented or described in the professional literature. Obtaining a better "working picture" of macro social work practice in the home that targets organizational and environmental change would be beneficial for practitioners, educators, and policy makers.

Professional social workers, partnering with their research colleagues, need to demonstrate their impact in this setting, especially when those with degrees in other human service professions are considered adequate substitutes and command lower salaries. The profession as a whole has a critical advocacy agenda with state and federal policy makers. It must argue convincingly and well for continued improvement of conditions and life in the nursing home, for professionally qualified social workers in every home, and for progress in the quality and effectiveness of social work practice itself.

Residential Care Settings for Veterans

54

The role of social workers in the Veterans Administration (VA) began in 1926, with the establishment of the social work program in the Veterans Bureau. In its first year, the VA had 14 social workers in psychiatric hospitals and 22 in regional offices throughout the country. At present, the Veterans Health Administration (VHA) employs almost 4,000 master's-prepared social workers in VA medical centers (VAMCs) all over the country. From their original focus on veterans with tuberculosis and psychiatric problems, VHA social work staff have addressed the needs of many distinct veteran populations, including the homeless, the aged, HIV/AIDS patients, spinal cord injury, former prisoners of war, and veterans and their families from World Wars I and II, Korea, Vietnam, and the Persian Gulf.

The Department of Veterans Affairs (DVA) health care system has one of the most comprehensive programs focused on the needs of older disabled persons in the United States. VA long-term care programs have their roots in care provided by the federal government for soldiers who became disabled in the Civil War.

In fiscal year 2002, the VA provided long-term care services to almost 67,500 veterans at a cost of more than \$3.3 billion. The VA provides for the health care of veterans of all ages across the entire continuum of care. Veterans may receive acute care, outpatient care, or community-based or institutional long-term care through a variety of services and programs provided directly by VA or contracted or arranged with agencies in the community. Long-term care (LTC) in VA refers to all postacute programs and services provided to individuals who are frail, chronically ill, disabled, mentally ill, and/or in need of postacute rehabilitation. Within VA, the term *LTC* is also sometimes used interchangeably with the terms *chronic care* and *extended care*, particularly with respect to nursing home and home health care services. Long-term care services may be provided by a VA medical center, through a VA contract with a community agency, or arranged by VA staff and provided in a non-VA setting.

VA NATIONAL LEADERSHIP IN GERIATRICS AND GERONTOLOGY

In the mid-1970s, VA planners began to focus on the large number of World War II and Korean War veterans who were rapidly approaching or who had already reached age 65. In 1977 approximately 25% of adult males over age 65 were veterans; by 1995, this

percentage exceeded 60%. It has been estimated that 1,000 WWII veterans are dying every day. As a result of these projections, VA made a significant commitment to dealing with the needs of its aging population. As a result of this commitment, VA has become widely known for its education and training, its research, and its contributions to clinical innovations.

Contributions to Education and Training

VA is the largest single provider of geriatric training in the United States. The American Geriatrics Society estimates that up to 80% of the nation's academic leaders in geriatrics today received some VA training. Special fellowship programs in geriatrics have been designated for psychiatrists, dentists, nurses, and psychologists. Beginning in 1994, additional positions were allocated to support training of medical residents in long-term care settings. Also, of the approximately 112,000 health professions students who receive clinical training experiences in VA facilities annually, many gain experience in care of the elderly by rotating through one or more of VA's geriatric and extended care clinical programs.

As part of its commitment to care for older veterans, VA also established centers of excellence in geriatrics called Geriatric Research, Education, and Clinical Centers (GRECCs) in 1975. The mission of the GRECCs is to improve the health and care of elderly veterans through research, education, and training and to develop improved clinical models of care. VA supports 16 GRECCs throughout the VA system, each with a distinct programmatic focus, including interdisciplinary approaches to treatment of prostate cancer; neurobiology, epidemiology, and management of dementia; falls and instability; geropharmacology; cost-effective delivery of health care services to the elderly; and bioethical aspects of medical decision making in aging.

Contributions to Research

VA's commitment to the health problems of aging veterans can also be seen in its intramural research program, which includes basic biomedical and clinical medicine research, as well as research in health services, rehabilitation, and large-scale clinical trials. VA funds a large number of studies related to health problems of the elderly, including cancer, stroke, degenerative bone and joint diseases, dementias, and diabetes.

Contributions to Clinical Innovation

VA also pioneered the Geriatric Evaluation and Management (GEM) program. GEMs provide both primary and specialized care services to a targeted group of elderly patients. On inpatient GEM units, an interdisciplinary team of geriatric experts performs comprehensive, multidimensional evaluations of frail, elderly patients to improve their functional status, stabilize their acute and chronic medical conditions and/or psychosocial problems, and discharge patients to home, residential care, or the least restrictive environment feasible. GEM clinics provide similar comprehensive care for geriatric patients on an outpatient basis in addition to providing primary care for frail, older patients to prevent unnecessary institutionalization. The geriatric staffs also are available for specialty consultation on elderly patients with complex problems who are being cared for by primary care and other specialty services. Currently, 110 VA medical centers have GEM programs that include inpatient units and/or outpatient clinics, as well as consultation services.

PEOPLE SERVED BY VA

As a result of its demographic imperative, VA realized that it was facing an unprecedented demand for its LTC services. Although the total number of veterans is expected to decline between 2004 and 2014, the number of older veterans, especially those age 85 and older, will more than double to a total of 1.3 million by 2012. This is expected to significantly strain existing resources and increase the need for VA's long-term care. Although disability may strike at any age, older individuals are considerably more likely to develop disabilities and to need LTC as a result. Data from the National Health Interview Survey (Department of Health and Human Services, 1994–1995) indicate that 4.8% of those 65 to 84 years old report a disability (defined as two or more activities of daily living [ADL] deficiencies) and that this proportion nearly quadruples to 18.1% among those 85 and older.

Although the overwhelming majority of older veterans are male, in 2002, the female veteran population of 1.7 million constituted 6.5% of all veterans. VA has seen a significant increase in the number of women veterans who receive benefits and health care services from the department. The number of women veterans enrolled in VA's health care system grew from 226,000 in 2000 to 420,000 in 2002, an increase of 86%.

Data from the National Survey of Veterans indicates that as a group, female veterans are younger than male veterans, which, in turn, may explain their better health. Almost 83% of women veterans are younger than 65 years old, compared with only about 63% of male respondents. When the functional limitations of male and female veterans are compared, a higher percentage of female veterans (70.8%) than male veterans (67.0%) also reported having no ADL or instrumental ADL (IADL) difficulties. A higher percentage of male veterans reported difficulties with three or more ADLs than did female veterans (9.4% vs. 7.6%, respectively).

DESCRIPTION OF LTC PROGRAMS AND SERVICES

Veterans may receive one or more of a number of LTC services, depending on eligibility and need. Social workers outside VA need to be aware of veterans' benefits for which their clientele might be eligible. Broadly speaking, VA uses two methods of determining eligibility and need for LTC services: (a) service-connected disability status and (b) functional need for LTC.

Service-Connected Disability

Service-connected disability status is attained by a veteran who incurred a disability from a disease or injury that was sustained or aggravated by military service. Individuals are compensated according to the severity of their disability. Individuals with a 30% or higher rating of disability receive additional monies for spouses and/or dependents. Special monthly pensions may be authorized for veterans whose service-connected disabilities are very severe and meet certain statutory requirements (e.g., spinal cord injury). Service connection for a disability may be granted for certain chronic and tropical diseases (even if the conditions were not manifest or diagnosed during the veteran's military service). Service connection may also be established for a secondary disability or disease that is proximately the result of a service-connected disease or injury. A service-connected disability may entitle a veteran to receive additional benefits, such as VA medical care, vocational rehabilitation, and/or adaptive equipment or homes. The Millennium Act (discussed later) describes VA's new priorities for LTC services provided to veterans.

Functional Assessment

As of this writing, VHA is in the process of rolling out a new assessment tool, the Geriatrics and Extended Care (GEC) referral tool, that assesses functional criteria. At this time, clinical staff assessing a veteran's need for nursing home care is not required to adhere to standard functional criteria to determine eligibility.¹ Instead, individuals are defined as needing VA LTC services when a chronic condition, trauma, or illness limits their ability to carry out basic self-care tasks (ADLs) or household chores, such as using the phone or preparing a meal (IADLs), or when care is required following acute care discharge that cannot be effectively managed in an outpatient setting (e.g., postoperative wound care/dressing changing, IV antibiotics, rehabilitation, or catheter care).

VA provides two general types of LTC programs to veterans: (a) institutional long-term care and (b) home- and community-based care.

VA Institutionally Based LTC Programs and Services

For veterans in need of postacute or institutional long-term care services, services may be provided through (a) VA nursing home care units, (b) VA's contract nursing home program, or (c) state veterans' homes. About 73% of VA's budget for fiscal year 2000 nursing home care was for care in VA nursing homes; the remainder was for veterans' care in the state-owned and operated veterans' nursing homes (15%) or in community nursing homes under contract to VA (12%).

Nursing Home Care Units (NHCUs)

Nursing home care in VA NHCUs is provided to veterans under the auspices of Title 38 U.S.C. 610. Veterans may receive postacute and long-term care in 134 VA NHCUs. Veterans cared for in NHCUs are cared for by VA physicians, nurses, and/or nursing assistants. Nursing home care may include dietetic services, social work, dental work, supplies, equipment, and medical and skilled nursing services, such as assessment, planning, intervention, and evaluation of nursing care. Veterans may be cared for in VA NHCUs over an extended period of time depending on eligibility and availability of resources. Services may be directed toward veterans demonstrating a potential for improvement or maintenance of existing function.

Community Nursing Home (CNH) Program

To improve access to geographic locations closer to veterans' homes, VA created the CNH program in 1964. VA currently contracts with more than 3,400 community facilities in 43 states. In fiscal year 2002, more than 28,800 veterans were treated in community nursing homes at VA expense. Veterans who require nursing home care for a service-connected disability can receive care from a community facility for an indefinite time at VA expense; others may be placed in a community facility at VA expense, with the expectation they may leave or convert to self-pay or Medicaid.

VA's Community Nursing Home program² is managed by VA social workers, who are responsible for placing veterans and overseeing quality assurance aspects of care for the homes VA contracts with. VA sends its social workers out to conduct the initial assessment of nursing homes it wishes to contract with and then visits contract facilities on a monthly basis to oversee all aspects of care for veterans placed in these homes.

State Veterans' Homes

Although this program dates back to the post-Civil War era, it has grown dramatically since 1990, by 2004 encompassing 103 nursing homes in 47 states. The state home program substantially augments VA's capacity to provide a continuous residence for veterans in need of long-term care, especially veterans in rural areas. State homes are owned and operated by the state, with VA contributing up to 65% of the cost of construction or acquisition of state nursing homes or domiciliaries or for renovations to an existing home. VA also provides per diem payments for eligible veterans in state homes. VA does not directly place veterans in state veterans' homes. Instead, veterans must apply for admission, and eligibility and admission requirements vary by state. VA assures Congress that state homes provide high-quality care through inspections, audits, and reconciliation of records conducted by the local VAMC.

VA Community-Based LTC Programs and Services

In fiscal year 2002, approximately 37% of VA's total long-term care population received care in noninstitutional settings, a marked departure from the histor-

ical dependence on hospital-based services. The list below describes the remainder of VA's community-based LTC programs and services.

Community-Based Long-Term Care Programs and Services Offered by VA

- **Adult day health care:** health maintenance and rehabilitative services provided to frail older veterans in an outpatient day setting.
- **Alzheimer's/dementia care:** specialized outpatient services such as behavioral and medical management provided to veterans with Alzheimer's disease or related dementias.
- **Community residential care:**³ a service in which veterans who do not require hospital or nursing home care—but who (because of medical or psychosocial health conditions) are unable to live independently—live in VA-approved community residential care facilities; VA provides staff to coordinate services for veterans in the community residential programs as well as pay for costs of services for which the veteran is eligible.
- **Geriatric evaluation:** evaluation of veterans with particular geriatric needs, generally provided by VA through one of two services: (a) geriatric evaluation and management (GEM), in which interdisciplinary health care teams of geriatric specialists evaluate and manage frail older veterans, and (b) geriatric primary care, in which outpatient primary care, including medical and nursing services, preventive health care services, health education, and specialty referral, is provided to geriatric veterans.
- **Home-based primary care:** primary medical care provided in the home by VA physicians, nurses, social workers, and other VA health care professionals to severely disabled, chronically ill veterans whose conditions make them unsuitable for management in outpatient clinics.
- **Homemaker/home health aide:** home health aide and homemaker services, such as grooming, housekeeping, and meal preparation services.
- **Home/institutional-based respite care:**⁴ home- and institutional-based services provided to veterans on a short-term basis to give veterans' caregivers a period of relief or respite.
- **Hospice care:**⁵ home- and institutional-based palliative and supportive services for veterans in the last phases of incurable disease so that they may live as fully and as comfortably as possible.

- **Skilled home health care:** medical services provided to veterans at home by non-VA health care providers.

The availability of community-based LTC services varies by VAMC. A recent Government Accountability Office (GAO) report concluded: “Veterans’ access to the [adult day health care, geriatric evaluation, respite care, home-based primary care, homemaker/home health aide, and skilled home health care] is limited by service gaps and facility restrictions” (GAO, 2003). Only 13 of the 134 VAMCs offer all six community-based services. Skilled home health care is most available ($N = 127$), and respite care is least available ($N = 28$ VAMCs). About half ($N = 64$) reported offering community residential care. Veterans’ access may be further limited by waiting lists or restrictions that individual facilities set for use of the services they offer. Thus, considerable disparity exists in what community-based LTC services are offered by individual VAMCs.

THE CHANGING FACE OF VA

In 1997, VA established the Federal Advisory Committee on the Future of VA Long-Term Care, composed of national leaders in LTC. The committee was asked to evaluate VA long-term care services and develop a strategy for meeting future LTC needs. The committee’s report found that VA long-term care was unevenly funded and recommended that VA expand its use of noninstitutional long-term care services and emphasize these services, when clinically appropriate, for veterans needing long-term care (Department of Veterans Affairs, 1998).

With congressional support, VA has taken a number of steps to address this challenge. Congress has allocated \$413 million since 2000 to expand VA’s own nursing home (NH) program, with another \$105 million to follow. VA has also taken several steps to increase the availability of community-based LTC services and has seen some success: The proportion of VA’s long-term care costs for noninstitutional care has doubled from 4% to 8% of its total budget over the past decade. This progress lags behind that of the Medicaid program. And it is clear that the demand for LTC over the coming years cannot possibly be met by using the current mix of care.

Historically, VA LTC was generally provided on a first-come, first-served basis within budget constraints. However, the passage of the Veterans Mil-

lennium Health Care and Benefits Act (PL106-117, 1999) sets priorities for who should receive nursing home care, defined as any veterans who (a) need such care for a disability connected to his or her military service and (b) who is at least 70% disabled by a service-connected condition (i.e., resulting from their military service) and who needs nursing home care, regardless of whether the care is required specifically for the disabling condition.

The Millennium Act also mandates VA to make significant changes in how LTC services are delivered to older veterans, agreeing to increase the allocation of overall spending to increase community-based LTC by 37% over the next three years. In particular, VA will be focusing on increasing the availability of adult day health care, geriatric evaluation, and respite care to veterans.

The Millennium Act mandated VA to examine innovative ways to provide community-based LTC to help families. The act funded two research demonstration and evaluation projects to assess private-sector models of care for veterans: (a) the all-inclusive care program and (b) the assisted living pilot program. These demonstrations are expected to be completed in 2005. Results are embargoed until released by Congress at the completion of the evaluation periods. The purpose and design of these projects are as follows.

All-Inclusive Care Program

The Millennium Act authorized VA to implement three pilot programs based on PACE (Program for All-Inclusive Care for the Elderly), a replication of the model of care developed by On Lok Senior Health Services in San Francisco, California. The goal of these projects is to assess the comparative effectiveness of three models of all-inclusive care (AIC) delivery in reducing the use of hospital and nursing home care by frail older veterans. The PACE program offers and manages all medical, social, and long-term care services their enrollees need to preserve or restore their independence, remain in their homes and communities, and maintain their quality of life. One of the program’s most notable features is its use of an adult day health care center as the primary means of delivering the full range of medical and long-term care services to enrollees. At the heart of the model is the interdisciplinary team, with professional and paraprofessional staff, which assesses enrollees’ needs, develops care plans, and delivers and arranges for

services, which are integrated for a seamless provision of total care for the veterans and their families.

The three models VA is evaluating are (a) VA staffed, (b) community provided with VA care manager, and (c) VA partnership with community provider. The objectives of the evaluation are (a) describing the implementation and operation of each of the three models of AIC, including the organizational and structural characteristics of each model; (b) describing the characteristics of veterans enrolled in each of the three models to a comparison group; and (c) assessing the use of institutional care and other health and support care services, veterans' and caregiver satisfaction, and quality under each model of AIC and between comparison groups.

Assisted Living Pilot Program (ALPP)

The Millennium Act authorized VA to establish a pilot program to determine the “feasibility and practicability of enabling veterans to secure needed assisted living services as an alternative to nursing home care, to enter into contracts with appropriate facilities for the provision for a period of up to six months of assisted living services.” Through a competitive process, a group of clinicians located at VAMCs in the Pacific Northwest (covering the states of Alaska, Idaho, Oregon, and Washington) was selected to conduct the demonstration. VA is contracting with all Medicaid-approved providers of assisted living, including adult family homes, assisted living, and residential care facilities. Evaluation goals are to (a) describe the veterans placed in assisted living settings; (b) describe the facilities that contract with ALPP and assess the satisfaction of veterans and their family caregivers, VA referring staff, and assisted living providers with the program; and (c) describe the costs and outcomes of care for ALPP participants and a comparison group.

ROLE OF SOCIAL WORKERS IN VA LTC RESIDENTIAL SETTINGS

The role of social workers in VA LTC programs varies by the program and by their position. Master's-prepared social workers provide psychosocial assessment and intervention, screening, family and caregiver support, individual and group therapy treatment and discharge planning, case management, advocacy, and education.

Community Residential Care Program

For example, VA's oldest extended care program, the community residential care (CRC) program, is coordinated through local VA social work departments or mental health service lines. To enable the CRC program to be cost-effective, basic room and board and limited personal care and supervision are provided to veterans who are not able to live independently and/or do not have family to provide the needed care but do not require nursing home or hospital care. Veterans enrolled in CRC use their VA pensions or Social Security payments to subsidize the placement costs. VA social workers provide supervision and ensure that they receive a level of care appropriate to their needs, without which they would require readmission or be among the homeless population.

Social Work Education

The Department of Veterans Affairs is affiliated with more than 100 graduate schools of social work and operates the largest and most comprehensive clinical training program for social work students—training 600 to 700 students per year. As a leader in this area, VA has a major impact on the health care social work curriculum, establishing and applying standards for social work clinical practice, and expanding the roles and functions of the clinical social worker in interdisciplinary teams practicing health care service delivery. VA social workers are also involved in developing policy and in developing and conducting research to inform social work practice.

Social Work Role in Coordinating Care

As health care in general continues to change, VA clinicians have had to adjust to factors inside and outside the VA health care system. As health care in VA moves from a traditional inpatient model to a primary care outpatient-based model, VA social workers play an increasingly critical role in the delivery of services and in integrating VA and non-VA services used by veterans. Social workers play an important role in making community planning, coordination, and integration of services become a reality on federal, state, county, and local levels. Decentralization, accessibility, relevancy, continuity, and effectiveness of service delivery are all concepts that continue to be improved through implementation. The leadership, flexibility,

and commitment of VA social workers to “Putting Veterans First” enable social work to thrive as a profession in the current health care environment. VHA now has an Office of Care Coordination where social workers and nurses use a full range of tele-health equipment in order to monitor the health of veterans in their own homes.

Assessment, Screening, and Discharge Planning

Crises, such as illness, that result in hospitalization create anxiety, fears, and issues to be resolved for veterans and their families. Regardless of the setting, the goal of VA social workers is to help veterans and their families help themselves. They assist families who are coping with troubling situations such as traumatic and chronic illness, alcoholism and/or drug dependency, the financial and emotional strain of disability, marital difficulties due to illness, abuse, and bereavement.

As discharge planners, the social workers’ role is varied and complex, but in all cases, he or she plays a vital part in maximizing wellness during the hospital stay and in easing the transition back home or to a health care facility. During a veteran’s hospital stay, social workers assess the veteran’s family situation, including their involvement with the entire treatment team, keep the family apprised of the veteran’s progress, and explain how the family can help the veteran recover. Physicians, nurses, and others provide medical support, but it is the responsibility of the VA social worker to provide the emotional support to ensure a positive outcome. VA social workers have been specially trained to work with individuals and families in dealing with personal and interpersonal crises caused by illness and hospitalization.

In their role as discharge planners, social workers help the veteran, family, and medical team identify the veteran’s needs and target appropriate resources for follow-up care. Whether a veteran is going home or transferring to another health care facility, social workers make the transition as smooth as possible by identifying the resources, within VA or in the community, that are best suited to the veteran’s medical and financial situation. They also recommend alternative care if the individual cannot return home.

Social workers are specially trained to assist veterans with the myriad issues related to financial problems and eligibility for services they may need after leaving the hospital. They also assist in completing ad-

vance directives to enable veterans to communicate about their wishes to health care providers.

Case Managers

Historically, VA has collected information at the program level, with little ability to track veterans across a variety of inpatient, community, and special programs. Person-centered case management has the potential to change that. This is a new and challenging area in which social workers have great potential to help.

For social workers, functioning as case managers is a natural extension of the care that social workers typically provide as discharge planners; that is, they assist individuals across and within programs. As an example, in the VA’s Assisted Living Pilot Program, social workers functioned as case managers for the veterans throughout their entire stay in assisted living (and, in many cases, beyond). They were responsible for assessing the veteran’s appropriateness for assisted living and helping to educate the veterans and their families about what assisted living was and what different kinds of facilities were available. In many cases, they accompanied the veterans on their visits to the facilities.

They also worked with the assisted living providers to educate them about the VA contracting and inspection processes, how to work with VA providers, and how to obtain the necessary services for the veterans they were caring for. Once the veteran was placed, the case managers visited them monthly. In addition, they made weekly (or more frequent, as determined by veteran needs) phone contacts to both the veteran and the facility. They facilitated all paperwork and contacts required to obtain financial assistance, such as compensation and pension, Social Security, Medicaid, and other sources so that veterans can transition from VA funding to other form(s) of funding. They coordinated follow-up care (appointments, transportation, and other needs related to VA care) for the veteran at the local VA facility. They worked to develop positive relationships with a number of facilities to promote acceptance of veterans for placement. They coordinated all pharmacy, equipment, and other special needs. They developed relationships with other community-based agencies to build social support networks for the veteran, including services such as transportation for the disabled, adult day care, senior centers, and leisure activities. They also provided education about ALPP to their VA colleagues, including

administrative staff and clinical staff, social work departments, discharge planners, clinic staff, domiciliary staff, and non-VA clinical staff in areas where veterans are admitted to community hospitals. Presentations were also done to veterans' service organizations and state governmental organizations.

Facility Inspections/Monitoring Quality

VA generally requires its staff to conduct annual inspections of VA-approved community residential care homes, state veterans' homes, and community nursing homes. Monthly staff visits to veterans in community residential care homes and community nursing homes are also required. VA social workers are required to conduct annual inspections of all community nursing homes with which they have local contracts and to visit veterans in those homes monthly. If VA finds problems in a community nursing home, it can (a) stop placing veterans in the home, (b) withdraw veterans from the home, (c) terminate the home's contract, or (d) allow the contract to expire without renewal.

CONCLUSION

Social workers play a critically important role in VA LTC programs. Social workers are important team members with key roles in assessment and screening and in providing crisis intervention, discharge planning, case management, advocacy, and education. They educate veterans and their families about options within VA and in the community. They educate others within the VA system about the needs of veterans and their families.

We anticipate that VA will continue to be in the forefront of developing geriatric technologies and hope that VA will exercise the same leadership and human capital development in community care as it did in hospitals, nursing homes, geriatrics, and the GEMs. If so, VA will continue to be an important employment setting for social workers, and it will also be important for all social workers in geriatrics to be aware of VA.

The Long-Term Care Ombudsman Program

55

Long-term care (LTC) ombudsmen investigate complaints from, or filed on behalf of, residents of LTC facilities. In 2000, these consisted of 17,799 nursing homes and 43,102 board and care (and similar) facilities. In this chapter, we first provide a brief history of the National Long-Term Care Ombudsman Program, which is followed by an overview of the program's mission and how it functions. We then describe the various structures across states of this publicly mandated program, how complaints are handled, and the roles for social workers in this advocacy (and sometimes adversarial) program. The chapter closes with a discussion of the quality of care and life to which these most vulnerable seniors are entitled, noting that it can emerge only from a culture of care in the larger society.

The long-term care ombudsman program (LTCOP) is federally mandated to investigate complaints about the care that people receive in LTC facilities. Long-term care ombudsmen inherited the public watchdog and citizen defender tradition (Ziegenfuss, 1985) that ultimately derived from Sweden's 1809 creation of the ombudsman,¹ who investigated and resolved the people's complaints about government. Today, states have a good deal of freedom in designing and implementing their LTC ombudsman programs. Consequently, there are many models and differing philosophical approaches to this role. Major differences can be found, such as (a) where the program is housed and (b) whether and in what capacity local programs use volunteers. In addition to investigating and resolving complaints, ombudsmen educate professionals and the public on relevant issues and advocate for residents of long-term care facilities.

In this chapter, we provide (a) a brief history of the program's origins and legislative authority and (b) the program's mission and functions. We then describe (c) the structure of the LTCOP, (d) how complaints are handled, and (e) the roles that social workers play in and with the ombudsman program. We close with a brief discussion of (f) the quality of life and care that elders experience in the nation's long-term care facilities.

HISTORICAL OVERVIEW

The need for specific LTC ombudsmen arose from social and demographic changes that fundamentally altered the structure and role of the family in caring for its infirm older members. Shifts away from the extended family to the more attenuated nuclear family left many indigent and chronically ill or disabled elderly to fend for themselves or turn to almshouses to survive. Their plight found resonance in sea changes in public policy: the passage of the Social Security Act in 1935 and the adoption of Medicare and Medicaid in 1965, which fueled a rapid spread of today's highly medicalized LTC facilities. Unfortunately, these facilities were plagued by recurring scandals. In the 1970s, these problems mobilized a new era of grassroots reformers who were dedicated to improving the basic quality of care and life in these institutions.

National Citizens' Coalition for Nursing Home Reform

A strong and important mover and shaker in this sea change was the National Citizens' Coalition for Nursing Home Reform (NCCNHR), formed in 1975. At that time, the National Gray Panthers' Long-Term Care Action Project, along with 12 citizens' groups and a number of ombudsman programs, convened in Washington, DC, prior to a conference of the American Health Care Association. Public outcries about substandard care in the nation's nursing homes spurred the coalition into action under the leadership of Elma Holder, as NCCNHR's founder, who was working for the National Gray Panthers at the time. NCCNHR became the advocacy organization for the consumer's voice.

Since its founding, NCCNHR has issued information papers and reports on nursing home issues, held annual meetings, expanded its focus to include board and care home issues, conducted national surveys on long-term care issues, published consumer information, developed the Campaign for Quality Care to push for the 1987 Nursing Home Reform Act (commonly referred to as OBRA 87, from the Omnibus Budget Reconciliation Act), and has worked continuously for legislative change. Among other advances, OBRA 87 (a) severely restricted the circumstances under which LTC facilities can physically or chemically restrain residents (e.g., tie them in wheelchairs)

and (b) gave ombudsmen a role in the licensing agencies' site visits to evaluate LTC facilities.

In 1993, the Administration on Aging (AoA) awarded NCCNHR the first of a series of multiyear grants to operate the National Long-Term Care Ombudsman Resource Center in cooperation with the National Association of State Units on Aging. The resource center provides support, technical assistance, and training to the 53 state ombudsman programs and their statewide networks. Its objectives are to enhance the knowledge, skills, and capacity of ombudsman programs and to advocate for residents' interests. (For information on NCCNHR and the resource center, see <http://www.nccnhr.org>.)

The LTCOP and NCCNHR continue to work with local, regional, and state citizens' organizations created to advocate for residents in long-term care facilities. Depending on the state, these organizations vary in what they do, but their efforts are part of a nationwide advocacy network targeting issues faced by vulnerable elders and their families. For example, Citizens for Better Care is a nonprofit organization with five offices in lower Michigan. Begun in 1969, they take on long-term care discrimination, regulatory enforcement, elder abuse, and related concerns. Another example is the Center for Advocacy for the Rights and Interests of the Elderly (CARIE), another nonprofit advocacy group, located in Philadelphia. Founded in 1997, CARIE is a leader in providing assistance to elders, their families, and professionals in aging. Yet another example is the Minnesota Alliance for Health Consumers, which has organized resident and family councils through a set-aside from the licensure fee, for which the ombudsman program lobbied. Each state has its own story of how citizens' groups have worked with local and state ombudsman programs, some more formally and others more informally, to advocate for high-quality resident care and systemic change.

The sea change, however, did not end abuse and neglect in LTC facilities; they continue into the 21st century. A U.S. House of Representatives report commonly referred to as the Waxman Report (2001) reported that 5,283 nursing homes (almost 1 in 3) were cited for abuse violations from January 1, 1999, through January 1, 2001. All citations "had at least the potential to harm nursing home residents. In over 1,600 . . . the abuse violations were serious enough to cause actual harm . . . or place the residents in immediate jeopardy of death or serious injury" (p. i).

THE BIRTH AND DEVELOPMENT OF THE LONG-TERM CARE OMBUDSMAN PROGRAM (LTCOP)

One of President Nixon's eight initiatives to improve nursing home care in 1971 called for "state investigative ombudsman units" (Harris-Wehling, Feasley, & Estes, 1995, p. 43). Thus, the LTCOP was born in 1972, when five states (ID, MI, PA, SC, and WI) were awarded demonstration grants by the Department of Health, Education, and Welfare's Health Services and Mental Health Administration. Demonstration programs were added in Oregon and Massachusetts in 1973, when AoA became responsible for the LTCOP; it has retained implementation and oversight to this date (Harris-Wehling et al., 1995). In 1975, Commissioner on Aging Arthur Flemming invited proposals from all states to develop community LTC ombudsman programs, and all except Nebraska and Oklahoma were funded (Harris-Wehling et al., 1995).

Legislative Authority

Mandated by the Older Americans Act in 1978, three major reauthorizations (in 1987, 1992, and 2000) have slowly strengthened the program (Harris-Wehling et al., 1995; Sue Wheaton, personal communication, June 6, 2004). Today there are programs in all 50 states, the District of Columbia, and Puerto Rico. The most recent reauthorization was signed by President Clinton on November 13, 2000, following 6 years of congressional hearings, debates, and votes, and established the LTC Ombudsman Program through fiscal year (FY) 2005. There were seven key factors in the 2000 reauthorization: (a) guidelines for conflicts of interest, (b) the importance of coordinating services with local law enforcement officers, (c) funding allocation patterns, (d) current funding levels, (e) the continuation of the National Ombudsman Resource Center, (f) policies on accepting voluntary contributions, and (g) a new focus on family caregivers (Turnham, 2000). The changes in the four reauthorizations of the Older Americans Act that have directly affected the LTCOP since its birth in 1965 (Sue Wheaton, personal communication, June 6, 2004) are summarized in Table 55.1.

MISSION AND FUNCTIONS

The mission of the LTCOP is to investigate and resolve complaints lodged by, or on behalf of, residents

of LTC facilities, to educate both the health professions and the public about the needs and rights of residents of LTC facilities, and to advocate for those needs and rights. Notice, however, that Harris-Wehling et al. (1995) included the notion of *identifying* problems, and the philosophies of state ombudsmen vary on this point.

LTC ombudsmen have been accused of *looking for* wrongdoing or harmful situations in long-term² and similar facilities (AoA, 2002a) so that they can lodge complaints, and this may actually occur in a few states. To avoid the troublemaker label, however, a few state ombudsmen have policies that the local ombudsmen will not lodge complaints themselves but investigate only those that are called to the attention of the ombudsman's office. Most state ombudsmen encourage their local ombudsmen to visit their assigned facilities at random times so that any practices or policies that are harmful to the residents' physical and socioemotional well-being can be seen, reported, and, hopefully, fundamentally resolved. Most state ombudsmen do not, however, encourage their local ombudsmen to look for problems, as they feel that they already receive more externally lodged complaints than they can optimally handle. They also wish to avoid alienating facility staff with whom ombudsmen must collaborate to promote the best care, all of the time.

Growing research suggests that volunteer ombudsmen (a) fill a service gap between professionals and clients (Monk & Kaye, 1982; Monk, Kaye, & Litwin, 1984), (b) produce a sentinel effect (Litwin & Monk, 1984), (c) heighten regulatory activity (Nelson, Huber & Walter, 1995), (d) improve nursing care (Cherry, 1991), (e) challenge corporate and government policies that are not in residents' best interests (Harris-Wehling et al., 1995), and (f) seem to be appreciated by residents (Monk & Kay, 1982; Nelson, Netting, Huber, & Borders, 2004).

Oversight and accountability requirements for ombudsmen emanate from national, state, and local entities. At the national level, Edwin L. Walker is AoA's director of the Office of the Long-Term Care Ombudsman Program, and Sue Wheaton implemented the program at the national level from 1974 to 1985 and again from 1991 to the present.

The actual legal authority of ombudsmen is quite limited. Their unique power lies in their abilities to informally persuade and advocate—a role that is distinct from the regulators' due process-bound inspection and punitive enforcement function. Officially, however, all ombudsmen, paid or volunteer, have the authority to enter any LTC facility and, with resi-

TABLE 55.1. Summary of Changes in the Four Reauthorizations of the Older Americans Act

1981	Expanded ombudsman coverage to include board and care homes. The name was changed from Nursing Home Ombudsman to Long-Term Care Ombudsman to reflect this change.
1987	Required states to provide for ombudsman access to residents and residents' records and immunity to ombudsmen for the good faith performance of their duties and prohibitions against willful interference with the official duties of an ombudsman and/or retaliation against an ombudsman, resident, or other individual for assisting representatives of the program in the performance of their duties.
1992	Strengthened the program and transferred it to a new title in the act, Title VII, Vulnerable Elder Rights Protection Activities, which also included programs for prevention of elder abuse, neglect, and exploitation; the state elder rights and legal assistance development program; and an outreach, counseling, and assistance program (which was subsequently deleted).
2000	Retained and updated ombudsman provisions in Titles II, III, and VII, including guidelines for conflicts of interest, the importance of coordinating services with local law enforcement officers, funding allocation patterns, current funding levels, the continuation of the National Ombudsman Resource Center, policies on accepting voluntary contributions, and a new focus on family caregivers (Turnham, 2000).

From: AoA, 2004.

dents' permission, access medical charts and other records. And although they are not enforcers, ombudsmen invariably use the LTC system's tight regulation to leverage their entreaties and arguments.

THE STRUCTURE OF THE LONG-TERM CARE OMBUDSMAN PROGRAM

At minimum, every state must have a full-time state ombudsman, and most states have one or two layers of offices below that, regardless of the organizational auspice of the state program. One state ombudsman reports directly to the governor, and others, as noted previously, are located in state units on aging. The first layer under the state ombudsmen might be regional if, for example, a state has discrete service regions, such as the western, central, and eastern parts of the state, or some other design for geographically delivering services by district or service area. Some states, however, including New Hampshire and Oregon, do not have local offices under the state programs.

The second organizational layer may be in place if there are local ombudsman offices, and these are found under various auspices. For example, 7 of the 15 local programs in Kentucky are located in service units that were historically called area development districts (ADDs), and 3 are located in legal aid agencies. A local program may monitor the LTC facilities in a town, a county, or several counties; in some large areas, for instance, Washington, DC, there are local offices throughout the district. Another difference be-

tween states is whether volunteers are used and, if so, in what capacities or roles.

If the office of the state ombudsman is situated in the state unit on aging (as are 38, or 73%), the state ombudsman reports to the director of the state unit on aging, as well as to the ombudsman program specialist on the national policies, guidelines, and reporting requirements of the National Ombudsman Reporting System (NORS). Sixty-one percent of local ombudsmen are organizationally located in Area Agencies on Aging (AAA) and report to the local AAA director, as well as to the state LTC ombudsman (AoA, 2002b).

Auspices of State Long-Term Care Ombudsman Programs

All but 14 (AK, CO, DC, KS, ME, MI, NH, OR, RI, VA, VT, WA, WI, & WY; AoA, 2003) state long-term care ombudsman programs are organizationally situated in the state units on aging, and there are opposing views on this structure. One perspective is that an ombudsman program should be overseen by the state units on aging, because it is an aging program that needs oversight. Advantages to programs being located in AAAs were thought to include faster access to information and funds (Huber, Netting, & Kautz, 1996). Among the concerns voiced by local ombudsmen whose programs are located in state units on aging are (a) budget cuts leading to less effective programs, (b) lack of sufficient independence within their organizational placements to advocate on behalf

of residents, (c) conflicts of interest (e.g., LTC facility owners serving on AAA governing or advisory boards), and (d) less focus on the needs of the institutionalized elders than on those living at home in the community.

Given the differing views between ombudsmen and the managers of their sponsoring agencies, are there differences in the types of complaints and how they are resolved by local long-term care ombudsmen operating in or not in AAAs? This question was posed for Kentucky in 1996 by Huber, Netting, and Kautz, who found some evidence that AAA-based LTC ombudsman programs were less likely than non-AAA-based programs to focus on resident quality of life and care and less likely to file complaints against facilities. AAA-based programs were more likely to address rights and administrative issues. The percentage of local ombudsman programs located in AAAs dropped by about 10 percentage points between 1996 (71%) and 2002 (61%).

Staffing for Long-Term Care Ombudsman Programs

The 1995 Institute of Medicine (IoM) report recommended one full-time equivalent (1 FTE) ombudsman for every 2,000 licensed LTC beds (Harris-Wehling et al., 1995; Turnham, 2000). According to AoA data (2002c), the ombudsman program nationwide is short by 328 ombudsmen to meet the standard of 1 FTE ombudsman for every 2,000 licensed beds. Ombudsmen are also to include in their NORS reports the number of facilities that are “served by the program on a ‘regular basis,’ which means visited at least quarterly, not in response to complaints” (NORS Instructions and Sue Wheaton, personal communication, June 6, 2004).

The IoM report also recommended that every 20 to 40 volunteers should be supported by 1 FTE paid staff ombudsman (Harris-Wehling et al., 1995; Turnham, 2000), and AoA’s statistics are not clear enough to determine how this compares with reality. According to AoA (2002d), there were 11,333 volunteers nationwide and 1,065 FTE paid program staff. This results in 1 FTE paid staff person for every 11 volunteers. There is nothing to indicate, however, whether any of those paid staff FTEs were available to manage the very large job of recruiting, training, and monitoring volunteers. Clearly more specific data are needed to address this issue.

In FY 2000, there were approximately 970 paid staff FTEs and 14,000 volunteers. From FY 1996 to FY 2000, the number of paid program staff increased by 12.6%. The program relies heavily on volunteers to carry out ombudsman responsibilities. However, only 60% (8,400) of those volunteers were trained and certified to investigate complaints (an increase of 1,034 from FY 1998; AoA, 2002d).

Some state ombudsmen encourage local programs to use volunteers and usually certify them at the state level for each level of training they complete. Local programs are sometimes free to decide whether to use volunteers, and some pay them stipends or mileage and a token payment for their volunteer services.

Oregon has an exemplary program of recruiting, training, and monitoring volunteers to be the eyes and ears of paid staff in one centralized state office (Nelson, Netting, Huber, & Borders, 2003, 2004). Nelson and his colleagues have written extensively about both the benefits and the challenges of using volunteers in LTC ombudsman programs (Nelson, 1995, 2000; Nelson et al., 1995, 2003, 2004; Netting, Huber, Borders, Kautz, & Nelson, 2000), including a study of complaints *against* volunteer ombudsmen (Nelson et al., 2003). Thirteen states (AR, HI, IA, ID, IN, MI, MD, NV, SC, SD, VA, WI, WV) do not report using certified volunteers (AoA, 2002e).

There is a wide range in salary levels for local ombudsman staff. A study by the National Long-Term Care Ombudsman Center (NCCNHR, 1999) found that yearly full-time salaries for local ombudsmen ranged from \$12,480 to \$24,960 (Montana) to \$34,278 to \$61,540 (Maryland) (Choi, nd; personal communication with Sue Wheaton, AoA, June 7, 2004). A directory of ombudsman programs by state is on AoA’s Web site (AoA, 2002b).

Although national ombudsman demographics are scant, Netting et al. (2000) reported from a six-state database of complaints investigated by 285 ombudsmen, 75% of whom were volunteers, and 74% of whom were women (who investigated 84% of the complaints); the 26% who were men investigated 16% of the complaints. In addition to reporting the differences in the kinds of complaints investigated by paid staff and volunteers, these researchers also reported that nearly two-thirds of the complaints handled by volunteers, both men and women, concerned routine events. Paid male ombudsmen, on the other hand, investigated about one-third each of routine, moderate, and complex complaints, and paid female ombudsmen investigated a higher percentage of complex

complaints than paid men or than both female and male volunteers (Netting et al., 2000).

Paid staff and certified volunteers (9,363) investigated 231,889 complaints in 2000 and provided information to more than 297,268 individuals on myriad topics, including how to select and pay for care in a long-term care facility (AoA, 2002g). Concerns that ombudsman volunteers do not have adequate training, supervision, or support have been voiced by numerous writers (Harris-Wehling et al., 1995; Litwin & Monk, 1984); however, ombudsmen have made giant strides in training since those reports. Nelson et al. (2004) studied the factors that affected volunteers' continuing their volunteer activities. The two strongest encouraging factors were that (a) the work was meaningful and (b) their work affected residents for the better. The stronger discouraging factors were role ambiguity, boredom, and role conflicts. Some programs have different levels of training and assigned duties—that is, from friendly visitors who are the eyes and ears of paid ombudsmen but who are not expected to investigate and take action on potentially contentious problems and policies to those who are academically and specifically trained in areas such as conflict resolution.

HANDLING COMPLAINTS

Complaint handling is the main function of the ombudsman program. As noted earlier, complaints about the care that elders receive may be reported to the LTC ombudsman's office by phone from a resident, family member, or health/mental health workers in the community or even in the facilities being monitored. Complaints may also be identified by the ombudsmen, both paid and volunteer, who visit LTC facilities. The goal for most ombudsman programs is to visit every facility at least once a month—some more often.

Ombudsmen then work to resolve complaints to the satisfaction of the resident or complainant. This is problematic for some ombudsmen because residents or family members sometimes withdraw their complaints for fear of retaliation against the resident if the ombudsman becomes involved. When this happens, ombudsmen can be faced with ethical dilemmas. On one hand, they must discontinue their investigation and resolution process. On the other hand, it is ethically difficult, and in some cases legally impossible, for ombudsmen to ignore abusive, neglectful, and other harmful behaviors. Furthermore, ombudsmen usu-

ally have in mind a higher standard of care, or resolution to the problem, than that of residents and/or family members and friends. Nelson and his colleagues conceptualized different approaches to resolving problems based on a taxonomy of the severity and scope of the problem and the degree of resistance from the target of change efforts, the LTC facilities (Nelson, Netting, Huber, & Borders, 2001).

NORS offers eight different resolution conditions, from the least to the most desired outcomes (AoA, 2002b).

1. Regulatory or legislative action was required (so satisfactory resolution was not possible)
2. Not resolved to the satisfaction of the resident or complainant (some problems just cannot be fixed)
3. Withdrawn by the resident or complainant
4. Referred to another agency that did not report back
5. Referred to another agency that failed to act
6. No action was needed or appropriate
7. Partially resolved but some problem remained
8. Resolved to the satisfaction of the resident or complainant

In 2002, 77% of the programs' 261,257 complaints nationwide were partially or fully resolved to the satisfaction of the resident or complainant.

Other Services and Activities of the LTC Ombudsman Program

The other services of the ombudsman program fall generally under prevention, intervention, and advocacy (Table 55.2). More specifically, Table 55.3 details some of the extant services provided by ombudsmen nationwide (AoA, 2002g). They also monitored and worked on laws, regulations, policies, and actions at all levels of government.

Although originally known as the nursing home ombudsman program, subsequent changes in the Older Americans Act have extended the program's purview to virtually any type of elder-oriented or long-stay facility, including board and care facilities, assisted living facilities, adult residential care facilities, subacute care facilities (if they are licensed as long-stay institutions), and other congregate care settings. Several states have enabled their ombudsman programs to provide services to settings outside the normal long-term care continuum, including home and hospice care settings, and at least one ombudsman

TABLE 55.2. Summary Chart of Long-Term Care Ombudsman Activities

Prevention

- 1 Education and consultation to both staff and individuals on issues affecting residents in long-term care facilities
- 2 Problem solving before a crisis occurs and making recommendations to facility administration and staff concerning needed changes in policy and procedures
- 3 Information and referral to help connect persons to the best available resources
- 4 Regular visitation services to residents by certified long-term care Ombudsman Volunteers to try and identify and resolve issues before they become complaints or serious problems

Intervention

- 5 Investigation of problems and complaints, negotiation, and intervention to help residents and their family members resolve conflicts or problems

Advocacy

- 6 Service gap assessment and recommendations for the development of programs and supports to meet the needs of elder long-term care residents
- 7 Representing the interests of residents before governmental agencies and seeking administrative, legal, and other remedies to protect the health, safety, welfare, and rights of the residents

From: AoA, 2004.

program has expanded its advocacy role to include case management services.

This service creep—asking ombudsmen to take on more and more responsibilities—rings true to the old adage, *if you really need something done, give it to the busiest person you know*. In other words, those who are already doing myriad things well will also do additional tasks well. However, the ombudsman program’s ability to meet these unfunded responsibilities is questionable. Insufficient numbers of paid and volunteer staff, for example, have long been recognized as limiting the program’s ability to routinely visit nursing

homes, let alone board and care facilities and home-based settings. Nevertheless, the National Association of State Long-Term Care Ombudsman Programs recommends that ombudsmen visit community-based facilities “at least once per month” (Grant, 2002, p. 19). This is little more than an ideal, however, as many of the nation’s nursing homes are visited by an ombudsman no more than “once or twice a year and for no longer than 1 to 3 hours” (Brown, 1999, p. 12). The gap between nursing home visitation rates and community-based visitation rates might be crudely surmised from data showing that while ombudsmen visit 83% of

TABLE 55.3. Other Ombudsman Activities Nationwide for FY 2002

<i>The Number of Times in FY 2002 That Long-Term Care Ombudsmen . . .</i>	<i>Local</i>	<i>State</i>	<i>Total</i>
1 Participated in facility surveys	9,968	658	10,626
2 Met with resident councils	14,913	779	15,692
3 Met with family councils	5,310	199	5,509
4 Presented community educational sessions	8,999	1,110	10,109
5 Provided training sessions for staff and volunteers	8,195	1,390	9,585
6 Provided training sessions for facility staff	6,985	637	7,622
7 Consulted with facilities	99,991	10,648	110,639
8 Provided information and consulted with individuals	252,804	44,464	297,268
9 Participated in media discussions and interviews	1,509	667	2,176
10 Issued press releases	3,110	1,184	4,294
Totals	411,784	61,736	473,520

From: AoA, 2002g.

all nursing homes annually (from once a week to once a year), they annually visit only 47% of all community-based facilities (at probably even lower rates of “routine” visitation) (AoA, 1999).

SOCIAL WORK ROLES

Social workers and ombudsmen are “natural allies” (Arcus, 1999, p. 196), and many social workers are, or have been ombudsmen, such as Iris Freeman, Sarah Hunt, Ruth Morgan, and Sam Arcus. Ombudsmen have been called the “community presence” in LTC facilities (Cherry, 1993, p. 336), and one of the key guiding principles of social work is for social workers to encourage community individuals and agencies to become involved in LTC facilities (Arcus, 1999; National Association of Social Workers, 2003). All of the jobs to be done by LTC ombudsmen are jobs that fit the values of social work professionals: investigators, advocates, lobbyists, public speakers, fund-raisers, teacher/trainers, community organizers, managers, and mediators. In short, both LTC facility social workers and ombudsmen are change agents and advocates with an intended priority to promote residents’ socioemotional health. But the LTC facility social worker’s role can be beset with difficulties. First, they are often obvious by their absence. Smaller facilities are not required to have social workers, and the larger facilities that are required to have social workers may contract for social services rather than employ a licensed social worker on staff. Social workers, therefore, work in host facilities when it comes to long-term care facilities, and the mental health needs of residents may take a back seat to admissions and discharge paperwork, activities, and volunteer coordination. They may also be responsible for implementing and coordinating resident and family councils.

Second, the vast majority of long-term care facility social workers and their medical colleagues are just that—colleagues working together in the best interest of the residents. We would be less than honest, however, if we did not acknowledge that social workers’ abilities to make pro-resident changes are sometimes limited by their ancillary status in medical host settings. Social workers can sometimes find themselves with conflicting interests between residents’ wishes and their employers’ interests, including, chiefly, the legitimate needs for risk management and efficiency (Nelson et al., 2001). In such situations, ombudsmen are advocates and supporters of facility social workers who could put their jobs at risk if they challenge certain facility policies, whereas the outside ombudsman

can sometimes address issues more forcefully without that risk. The result is that residents receive assistance that they may not have otherwise realized (Nelson et al., 2001).

All advocates need expertise in conflict resolution, systems, and social interactions. The LTCOP offers many opportunities for social workers’ specialized expertise in planning, social policy, and research; for general practitioners who can conceptualize and implement training curricula and evaluate the results; and for those who can create databases to capture the activities, work, and outcomes of the ombudsmen’s work, which could provide powerful evidence for systemic change. Also needed are those who have contacts and influence with political forces and the media. All of these are jobs for social workers who care about the care that older people receive in LTC facilities and are committed to working in larger systems to improve the care being provided to residents of LTC facilities.

OMBUDSMEN’S CHALLENGES

In addition to the problems inherent in trying to solve elders’ problems, ombudsmen face other professional and systemic challenges: inadequate funding, conflicts of interests, confidentiality dilemmas, and balancing reactionary and supportive stances. There are many more, but a brief review of these will give you the idea.

Inadequate Funding

Depending on organizational placement, local and state ombudsman programs may not be allowed to conduct fund-raising activities that would allow them to, for example, recruit, train, and capitalize on volunteers, develop educational programs and materials, and lobby for legislative actions that would benefit residents of LTC facilities. This may be more of a problem for AAA-affiliated programs in which agency directors are concerned that fund raising by the ombudsman program could distract from similar agency-wide activities.

Conflicts of Interest

Conflicts of interest can be lurking in many cases and at all levels of the system. For example, what would you have done in the situation in the following example?

■ **Confession of a Patients' Rights Advocate: Empowering Disaster—the Irony of Autonomy**

I remember when Pete called me. He got right to the point: “I just want to know if I have the right to go home,” he asked.

“Well, that’s a big question. Tell me, where are you now and where’s home?”

He shot back: “I’m in a home with a bunch of old people who don’t do a thing but sit and stare at the TV. I own a home in town, on the river, and I want to go back. Can I?”

I questioned him enough to determine that he was unquestionably decisionally capable (*de facto* competent). So I gave him the short answer:

“You’re not a prisoner, and you have the right to return home. However, it is an entirely different matter as to whether or not you are actually *able* to go home.” He was silent for a moment, then asked if I would come out to talk to him. I agreed.

Peter’s adult foster home was prim and tidy, and as his caregiver led me past the blaring TV and the four residents riveted to it, I thought it was a very nice place. Peter was a wiry little man, but he couldn’t walk without assistance, so it was immediately clear that he couldn’t live independently. He recognized this but explained that he had some pension money and that he could pay someone to bring him groceries. “I think you’ll need more help than that,” I warned. He asked about the availability of home support programs. “They’re out there,” I replied, “but I doubt if you’d qualify, but we’ll see.” I discussed all the possible challenges he would face, but he was determined to go home.

After again confirming his right to return to his home, he asked me to drive him there directly. I explained that this was against agency policy but assured him that no one could block him from making his own arrangements. He could hire movers, for example, and if he had trouble making phone contacts, the caregiver would have to assist him in making connections.

Three weeks later he was home. Shortly thereafter, I received a pained phone call from his daughter. She was distraught, angry and in tears. She wanted to let me know what I had done to her father. “Daddy was doing so much better in the care home,” she sobbed. “He’d gained weight and was settling in, then you came along to tell

him his rights. Don’t I as a daughter have a right to my dad, to be involved in his life, to protect him from himself and from do-gooders like you?”

“Well, I hope you’re happy,” she continued, “he’s back home now, drinking again. I hope you’re real thrilled with yourself. He’s drunk all the time,” she sobbed, “just like before. He’s been drinking for 20 years and that’s the only reason he wanted to go home. His damn liver nearly killed him. He had osteomalacia [soft bones caused by a deficiency of vitamin D], and the falls—why do you think he can’t walk!” she sobbed in grief and anger. “Why didn’t you check his medical records? Why didn’t you call me? What kind of advocate are you? I’m getting a lawyer and I’m getting your job. What gives bureaucrats like you the right to meddle into other people’s lives!”

I offered some inane, soothing, apologetic answers. I felt both guilty and deeply sympathetic. I didn’t want to get legalistic, but I told her that her dad had the legal right to make bad decisions, just like she does. After the call, I ruminated and reassessed the whole situation.

I went home that night thinking that I would not have done things any differently. I didn’t ask detailed questions about his medical background because they weren’t pertinent to the rights issue at hand. Even if he had told me he wanted to drink his life away, that would have been his right. Oh, I would have tried to further dissuade him by pointing out that his drinking would only make him more dependent in the future, that it kill him. But I doubt if it would have mattered. ■

What would you have done if your client had been Pete’s daughter? Further, if a doctor is insisting that Pete must not go home because of his physical condition, the social worker is swimming in an ethical conflict of interest. If you support the resident, you may lose the confidence of the resident physician and medical staff, which could easily diminish your voice in future situations. But if you support Pete and he goes home to inadequate care, the results could further deteriorate his condition and his ability to be in his own home—or worse.

Other conflicts can occur between ombudsmen’s personal and professional ethics and their political and job realities, briefly discussed earlier in terms of whether the ombudsman is employed by a long-term

care facility or as an outside professional under contract. Another possibility is that a nurse's aide tells you, the facility social worker, that another aide (related to the owner) routinely steals from elderly residents but fears being fired if you take any action on that information. What would you do?

Confidentiality Dilemmas

The patient advocate's confession in the box included the element of confidentiality in that the advocate had no right to discuss Pete's intentions with his daughter or anyone else. Dilemmas are not just hard decisions to be made but decisions that have some good on both sides and/or some potentially harmful elements, regardless of the choice made. Had the advocate not determined that Pete was decisionally capable, he might have felt obliged to contact Pete's daughter about his plans to return home to see that he would be going to a safe place, thereby violating the resident's right to confidentiality and, no doubt, thwarting his plans to return to his home regardless of his reasons.

In short, this dilemma is similar to the autonomy versus beneficence debate. *Autonomy* refers to the client or resident's self-determination, and *beneficence* means doing the right thing. The catch is in determining *doing the right thing*—according to whom? In this case, Pete? His daughter? The advocate? In practice, the social worker cannot live solely at either end of the autonomy-beneficence continuum, as two extreme scenarios will demonstrate. Although self-determination is one of the profession's core values, could social workers stand by and watch Pete walk out into traffic to try to go home without assistance? Of course not. At the other extreme, could the social worker stand by while facility staff physically restrain Pete to keep him from going home? Again, of course not.

Balancing Reactionary and Supportive Stances

Another kind of challenge can plague those who are trained in advocacy and comfortable with conflict yet must develop and nurture collegial relationships with facility staff (or the industry) if they hope to be able to work with them in the long run for better care for residents. The very nature of advocacy work attracts devoted, committed, assertive, and sometimes even aggressive individuals, which is good. Those with

fainter hearts need not apply. On the other hand, neither should ombudsmen come from the ranks of those who tend to be comfortable with the status quo, people who may not have the fortitude to effectively advocate against systemic odds.

QUALITY OF LIFE AND CARE

Most long-term care facilities attempt to provide excellent care most of the time. But when quality of care breaks down, the investigational, educational, and advocacy work of the LTCOP is vital to the commitment to care for the nation's most vulnerable citizens. By studying the frequencies of various complaints that can (or often) result in neglect, we see from AoA's statistics that neglect may be more prevalent than abuse (AoA, 2002g). Of the 208,762 complaints lodged against (only) nursing homes in 2002, 8,781 (4.2%) pertained to physical, sexual, or verbal/mental abuse. Complaints categorized as gross neglect totaled 2,610, or 1.3% of the total. However, when we add other types of complaints that we know often result in neglect, this percentage quickly becomes nearly 16% (Table 55.4).

Elders in residential facilities cannot enjoy a good quality of life unless they have high-quality physical, emotional, and social care, which, in turn, does not occur outside of a *culture* of care. Sometimes it is this culture of care that falls by the wayside in the space between elders being cared for at home and cared for by strangers who are generally the least skilled and lowest paid members of the workforce. It is not that these facility staff are uncaring but rather that they are overworked, understaffed, overstressed, and frequently overtaxed when facing behavioral emergencies or handling complex socioemotional problems.

Until these basic problems with formal caregivers are resolved, there will be a strong need for LTC ombudsmen to advocate on behalf of individuals and groups of residents, provide information to residents and their families about the long-term care system, and work to effect systemic changes at the local, state, and national levels. Ombudsmen must continue to monitor caregiver practices and facility conditions and to speak out for those who cannot speak for themselves; this sentinel work remains the essential bulwark against harmful practices for the foreseeable future.

TABLE 55.4. Selected Complaint Categories That Pertain to Abuse and Neglect from 208,762 Complaints Against Long-Term Care Facilities

<i>NORS Complaint #</i>	<i>Abuse Complaints</i>	<i>Number</i>	<i>Percentage</i>
1	Physical abuse	4,777	2.30
2	Sexual abuse	749	0.36
3	Verbal/mental abuse	3,256	1.56
	Total Abuse	8,781	4.22
<i>Neglect Complaint</i>			
5	Gross neglect	2,610	1.30
33	Staff nonresponsive to complaints	1,379	1.00
41	Call lights/requests for assistance unanswered	9,885	4.70
45	Personal hygiene unattended	7,519	3.60
47	Pressure sores	1,928	0.92
48	Symptoms unattended	4,886	2.30
69	Not helping with eating/eating devices	1,952	0.94
70	Fluid not available/dehydration	2,442	1.20
75	Weight loss due to inadequate nutrition	759	0.36
	Total Neglect	33,360	15.98

A Culture of Care

A brief word on a culture of care seems to be a fitting way to close this chapter. All of the workers in America's LTC system, regardless of education, position, ethnicity, or gender, are products of an overall societal culture that does not, as a whole, value older people. When we cross the threshold into caring or advocating for elders, however, we must create a more caring culture than the one behind us.

Just as with a continuum of care, each person in each link in the LTC chain of events and services must work from a caring heart; then, perhaps, a larger *culture of care* can embrace this most vulnerable population. It is critical, therefore, that a culture of care prevail in every service, agency, and facility that serves our nation's elders. The long-term care ombudsman program is designed to advocate for that culture of care and to investigate instances in which it has not been realized.

NOTES

1. No gender was attached to the term, and most *ombudsmen* in the United States are women.

2. The term *long-term care (LTC) facility* is used throughout this chapter to refer to the nation's 17,999 nursing homes and 43,102 board and care (and similar) facilities (AoA, 2002a).

JEANETTE SEMKE

Long-Term Residential Settings for Older Persons With Severe and Persistent Mental Illness

56

The majority of the nation's long-term residential care population is made up of older persons with severe and persistent mental disease (SPMD). Mental illness in older persons includes

- dementia and related behavioral symptoms, including psychosis
- depression
- schizophrenia and paranoia
- behavioral and emotional consequences of brain disease and dysfunction other than dementia
- psychotoxicity of prescription drugs (American Psychiatric Association, 1994; Fogel, Gottlieb, & Furino, 1990)

Although most of this population receives care in private homes in the community, a sizable group resides in for-profit or nonprofit group residences. Typically, these clients have cognitive, mood, and behavioral problems that interfere with their ability to fully and independently perform personal activities involved in living from day to day. Difficulty in performing these activities of daily living (ADLs) can limit an individual's quality of life and lead to serious health problems. For example, individuals with memory and neurological problems can have difficulty in caring for themselves and experience an avoidable decline in physical health.

Long-term residential settings for older persons with mental illness provide a shared environment for people who are not able to live on their own. In many cases, this congregate form of care allows for long-term care that is more affordable than care provided in private residences (Kane, Kane, & Ladd, 1998). Facilities are varied in design and in the residential and personal care services that are provided. The quality of care may range from poor to excellent (Pynoos & Golant, 1995).

Some residential settings are institutional (e.g., nursing homes and state mental hospitals).¹ As of 1997, about 1.6 million Americans lived in nursing homes (Kane et al., 1998). The Administration on Aging reports a high prevalence of mental illness in nursing homes, with one study estimating that more than 88% of nursing home residents have symptoms of mental illness (Lombardo, Fogel, Robinson, & Weiss, 1996; Smyer, She, & Streit, 1994; U.S. Department of Health and Human Services, 2001).

As of the end of 1993, about 10,500 older persons lived in state mental hospitals, accounting for about 45% of the population of adult state mental hospital patients nationally (Semke, 1996). State mental hospitals provide both short-term and long-term services

to a varied population, including older persons with mental illness. In fact, individual states vary widely in the extent to which they rely on state mental hospitals for care of older persons with SPMD and the extent to which the institution becomes a long-term residence for older persons (Semke, Goldman, Fisher, & Hirad, 1998). The economics of scale in relatively large facilities make specialized medical treatment and personal care more affordable. Often, older mental hospital patients receive care on specialized geriatric units. Some nursing homes have specialized dementia care units. They tend to be hospital-like, with housing as a secondary concern.

Another type of residential setting has special design features not readily available in conventional housing settings yet tends to be more “homelike” than the institutional setting. It includes a range of group housing environments in which concerns about housing and homelike amenities are primary. Some of these supported housing options specialize in care for older persons with mental illness. However, many long-term residential settings in which older people with mental illness reside have a varied population, including younger disabled persons and older persons with physical disabilities who do not have a mental illness.

HISTORY

In the 1960s, federal and state policy led to deinstitutionalization of state mental hospitals and encouraged the use of nursing homes. However, by the mid-1980s, the shift to nursing home care as an alternative to mental hospitals came to be seen as a failed policy. A report by the Institute on Medicine revealed that care for those with mental illness was inadequate (Institute of Medicine, 1986). Also, excessive use of physical and chemical restraints was documented. In response to this, Congress passed the Nursing Home Reform Act of 1986 as part of the Omnibus Budget Reconciliation Act of 1987 (Public Law No. 100-203), restricting inappropriate use of restraints.

The act also required that all persons suspected of having a serious mental illness be screened prior to admission to a nursing home. The purpose of this screening, called the preadmission screening and annual resident review (PASARR), was to assure that persons with mental illness receive appropriate mental health treatment. Policy makers saw it as a way to triage persons with mental illness seeking nursing home services to acute psychiatric hospital treatment

or to long-term community care, when appropriate. Unfortunately, the tool does not screen for dementia, a mental health condition that is commonly experienced by nursing home patients.

Also, the act was seen as a means to encourage appropriate mental health treatment within nursing homes. Unfortunately, inadequate nursing home reimbursement policies have limited improvement of mental health services in nursing homes. Although federal financing of mental health services for older persons creates incentives to use nursing homes rather than state mental hospitals, it imposes limits on reimbursement for mental health services. For example, Medicaid does not pay for care in mental hospitals or nursing homes that specialize in mental health services, creating an additional disincentive to deliver mental health services in nursing homes (Taube, Goldman, & Salkever, 1990). Also, the increased role of managed care is influencing mental health services in residential facilities. Komisar, Reuter, and Feder (1997) estimate that 35% of all Medicare beneficiaries will be in managed care plans by 2007. A number of reports suggest that, under managed care, current services for older persons tend to be inadequate (Friedman & Kane, 1993; Kane et al., 1997).

During the period when the locus of care for older persons with mental illness shifted from mental hospitals to nursing homes, another development emerged. A growing emphasis on potentially less costly community-based care led to a shift in the locus of residential care for older persons with mental illness to board and care settings, sometimes referred to as assisted living, and to small group homes, also referred to as adult foster homes, personal care homes, domiciliary care homes, and adult family homes. In 1998, approximately 521,500 people resided in assisted living facilities. Data from the 1991 National Health Provider Inventory indicate that more than half a million people were served by personal care homes that year.

In the past, it was commonly accepted that community-based group residences were intended for residents who could no longer stay with their natural families but were not so disabled as to require nursing home care. More recently, however, they are seen as a substitute for nursing home care for a more disabled population, who in the past would have been placed in a nursing home (Bachrach, 1996; Barton, 1983; Goldman, 1982; Goldman, Adams, & Taube, 1993; Lutterman, 1994; Roybal, 1988; Semke & Jensen, 1996; Talbott, 1983). Thus, the boundaries between homelike community-based residential care and “institutional care” are blurring (Kane et al., 1998).

COMMUNITY-BASED GROUP CARE

Most people prefer to live in their own homes and, short of that, in a homelike environment. The preference for community alternatives to nursing home care is in keeping with a philosophy referred to as “aging in place” (Klein, 1994; Rowles, 1994), which refers to residential stability in one’s home or a homelike milieu with minimal disruptions. Aging in place is made possible with the aid of a range of health and personal care services that maximize residential stability without compromising quality of life and health outcomes. The concept has great appeal for care recipients, families, providers, and funders because of its potential to provide cost-effective services in a homelike milieu while enhancing an individual’s independence.

Typically, health and social services can be provided more flexibly in the community than in nursing homes and other institutional settings. Different types and amounts of services can be bundled or unbundled, depending on the differing and changing health circumstances of long-term care clients. Thus, there is the potential to maintain aging in place and to match services more closely to the needs of the client than is possible in institutional settings, where a “one size fits all” approach tends to dominate.

Although skilled nursing and nurse monitoring are sometimes provided as part of a package of services for board and care and small group home clients, the greatest amount of care is provided by personal care workers. Services include, for example, assistance with bathing, transferring, supervision of medications, shopping, meal preparation, and laundry. Other health services important for positive outcomes, yet not necessarily administered by the residential care provider, include hospital services and outpatient mental health services offered by a variety of health care professionals in a variety of settings.

SPECIAL NEEDS

Dementia

Many residential care clients have some form of dementia with accompanying memory problems, difficulty in performing routine tasks, impairment in judgment, and disorientation. Personality change, difficulty in learning, and loss of language skills are typical for those with dementia.

The losses associated with dementia can cause the person to be unintentionally difficult, irrational, stub-

born, and angry. People with dementia may feel out of control when they are unable to explain their needs and exhibit aggressive or unsafe behaviors. The anguish and burden experienced by the client and the caregiver can be reduced through interventions aimed at identifying and ameliorating triggers for acting-out behavior, environmental modifications, meeting concrete personal care needs, and assistance to caregivers with emotional reactions to the client’s changed behavior. Because chapter 58 is a detailed discussion of dementia care, this chapter focuses on mental illness other than dementia.

Depression

An estimated 12 to 22.4% of long-term residential clients have a diagnosis of major depression and an additional 17 to 30% are diagnosed with minor depression (Burrows, Satlin, Salzman, Nobel, & Lipsitz, 1995; Katz, Parmelee, & Streim, 1995). Older persons with depression are at higher risk for death from suicide and from cardiovascular disease. Also, depression among older persons with physical illness or disability is associated with poor functioning (Gurland et al., 1986; Harris et al., 1988). Depression in older persons may be overlooked because symptoms such as withdrawal may not draw the attention of caregivers. Also, major depression symptoms that are physical rather than mental may escape the mental health system. Residential care providers need to be aware that life-threatening illnesses and losses of loved ones and independence may trigger a clinically significant depression or anxiety state.

There is general agreement on the effectiveness of antidepressant medications in treating depression in older persons. Research studies report that more than half of older persons treated with antidepressants experienced 50% or greater reduction in depressive symptoms. Among psychosocial treatments, cognitive therapy, behavioral therapy, and cognitive-behavioral therapy are shown to be most effective (Bartels et al., 2002).

Schizophrenia and Paranoia

Older persons with chronic schizophrenia are estimated to make up a third of the elderly in state hospitals and nursing homes (Katz, Curlik, & Nemetz, 1988). Symptoms include delusions, hallucinations, disorganized speech, disorganized or catatonic be-

havior, flattened affect, poverty of speech, and lack of goal-directed behavior (U.S. Department of Health and Human Services, 1999). Most individuals with schizophrenia experience the onset of the illness prior to middle age. Some individuals with chronic schizophrenia may show less dramatic symptoms than do younger individuals with schizophrenia. Often, their symptoms overlap with those of individuals with dementia (e.g., impaired abstract reasoning, memory, and diminished capacity to cope with life) (Harrow et al., 1987). A fraction of older persons with schizophrenia experience its onset in late life. Another small fraction of older persons with schizophrenia-like symptoms have persecutory ideation, or paranoia, but do not experience the full schizophrenia syndrome. About half of this group are cognitively intact, and half are cognitively impaired (Christenson & Blazer, 1984). All of the symptoms associated with schizophrenia and paranoia can be problematic and require skilled psychiatric care.

Reports and reviews generally suggest that atypical antipsychotic medications should be considered in treatment of schizophrenia in older persons. Atypical antipsychotics have been demonstrated to be safer for older persons because they tend to have few side effects. Unfortunately, there has been little research on the efficacy of psychosocial interventions for schizophrenia in older persons.

Behavioral Consequences of Brain Disease Other Than Dementia

This is a heterogeneous group of disorders that includes delirium (acute confusional state), Parkinson's disease, stroke, epilepsy, hypothyroidism, and vitamin B₁₂ deficiency (Fogel et al., 1990). Most of the behavioral and emotional consequences of these conditions are treatable, if not reversible. They are important to include among mental health issues in residential care because they may be at greatest risk of misdiagnosis or lack of diagnosis.

Psychotoxicity of Prescription Drugs

Older persons are three to seven times more likely than other age groups to have adverse reactions to prescription drugs (Caird & Scott, 1986). Problematic prescription drugs include cardiac drugs, anti-inflammatory drugs, most psychotropic drugs, antidepressants, and sedatives (Besdine, 1988). Common adverse reactions

include depression, anxiety, memory loss, insomnia, apathy, and confusional states. Awareness of these reactions is important in the residential care setting.

ACCESS TO MENTAL HEALTH TREATMENT

As addressed previously, a number of specialized interventions can address the mental health needs of residential care clients. However, these interventions may not be easily accessible by residents. The Institute of Medicine defines *accessibility* as "the ease with which a patient can initiate an interaction for any health problem with a clinician" (Donaldson & Vanselow, 1996). A key precursor to this interaction and a condition of efficacious mental health interventions is *access* to specialized mental health providers, primary medical care providers, and adult day services. The fact that these mental health interventions are often provided by an array of health care professionals in settings outside the residential care homes raises the concern that the mental health needs of residents may be neglected in nonspecialized residential care homes.

Also, there is evidence that many older persons with mental illness do not receive appropriate mental health services even when they do have contact with medical and mental health professionals (Bartels et al., 2002). For example, primary care providers, who may be diligent in treating physical ailments, may not recognize that a person with depression has symptoms that are treatable. Also, specialty mental health providers may not view dementia as a "true mental illness" for which they are charged to provide services (Bartels et al., 2002). This is problematic because dementia is often accompanied by psychosis and agitation.

In addition to specialized mental health services, other interventions can help the older adult function better and increase quality of life in the residence itself. Individual interventions include interpersonal skill training, psychotherapy, reality orientation, self-care training, and social interaction. Group interventions may include interpersonal skill training, education and discussion, group therapy, and socialization therapy. Any of these can be used to help residents gain orientation to their surroundings and encourage those who are withdrawn to join social activities.

Mental health interventions can be provided by facility staff, including psychiatrists, nurses, and social workers. For example, some nursing homes and assisted living facilities hire social workers trained as mental health professionals who screen residents for

symptoms of mental illness, provide direct services, and consult with other staff on how to be supportive of specific clients. Another approach is a partnership or formal contractual arrangement between a residential facility and a specialty community mental health program or home health care agency in which staff trained in geriatric psychiatry are called in on an as-needed basis to provide mental health treatment. Regardless of whether the residential care mental health program approach is psychiatrist centered, nurse centered, or multidisciplinary team centered, strong lines of communication among the multiple residential staff who interact with the older resident is critical to good outcomes.

For many older persons with mental illness, the small-group, homelike setting, in and of itself, may be more therapeutic than the larger institutional setting. In addition, interventions in nursing homes and community group residences that focus on the environment of the residence can significantly improve the quality of life of residents, including those with mental illness. Also, family-based interventions can help family members understand the challenges of the resident and enhance their ability to support their loved one in the residential living situation.

To assure access to mental health care, residential care providers who frequently interact with clients must have a basic knowledge about mental health issues. They must be aware of signs of mental illness, able to assist the client in coping with symptoms of mental illness, and prepared to consult with and refer to skilled mental health professionals when appropriate. A concern is that staff in residences based on socially driven models may not recognize or understand the complex care needs of older residents with mental illness. Care providers in these less “medicalized” settings may not be trained or equipped to give the specialized care required for people with serious mental illness. Nonetheless, there is ample evidence for the potential of community-based group residences to provide a therapeutic, supportive, homelike environment for older persons with mental illness (Kane et al., 1998).

Roles of the Federal and State Government

Government intervention in long-term residential care is especially salient because it is traditionally charged with protecting the most vulnerable of our citizens and with providing a safety net for those who

do not have the personal resources to get the care they need. Nursing homes are mainly under federal regulation. Community-based group residential care is mostly regulated by the states. Therefore, there is considerable variation in community residential services across the states. Federal and state governments play roles in defining long-term care services derived from public laws designed to

- prevent injurious behavior
- create and finance social programs
- control how public resources are used
- assure the quality of services provided to citizens
- establish and protect personal rights (Kapp, 1996)

Prevention of Injurious Behavior

An important piece of federal legislation designed to protect nursing home residents from injury falls under the Omnibus Budget Reconciliation Act (OBRA). It affects facility design, informed consent, types of interventions, staffing, and limits on physical and chemical restraints. State laws pertaining to the prevention of injurious behavior vary widely.

Funding of Social Programs

Federal and state funding for Medicaid, Medicare, and various services supported by the Older Americans’ Act target the social and health needs of older persons.

Control of Use of Public Resources

Federal and state governments control the circumstances under which public funds can be used for social and health services. For example, mechanisms for that control include licensure statutes for particular businesses and professions and funding for educational programs.

Quality Assurance

Government is responsible for assuring that services provided to consumers achieve a certain level of quality. For example, the Nursing Home Quality Reform Act that is a part of OBRA provides standards for the structure and process of long-term nursing home facilities that serve residents supported by Medicare and Medicaid.

Establishing and Protecting Personal Rights While Protecting Public Safety

Rights to privacy, religious practice, and unwanted intrusions by nursing home staff are extensively covered in the Nursing Home Quality Reform Act. States vary in the extent to which protection of personal rights is monitored in community-based group residences. Also, through involuntary commitment laws, government bodies oversee legal processes for involuntary commitment to treatment in a psychiatric facility, some of which occurs for the long term.

SOCIAL WORK ROLES

Disability and frailty bring older persons with mental illness into long-term care systems. Typically, assessment of the need for services by medical professionals focuses on health problems. Too often, the whole person is forgotten when the focus of assessment and intervention is an unmet need. This circumstance offers an opportunity for social workers to intervene, because their involvement stresses the social and psychological aspects of a problem more than the medical. The value base of the social work profession supports a strengths-based, holistic approach to practice, emphasizing the positive aspect of life in a context of matching needs to social and health interventions.

Most professional social work programs offer training in multidisciplinary teamwork and team leadership. The skill set that results from this training is of special value in service provision within long-term residential settings, because a variety of professional disciplines are often involved in care for the older adult with mental illness. Skill in teamwork can be applied to a team within the residence. However, broadly defined, teamwork may involve social and health practitioners and family members outside the residence. Especially in community-based group residences, knowledge and awareness of how to enhance continuity of care is crucial in circumstances in which providers are based in different social and health organizations and across different sites.

CONCLUSION

If cost savings is the main driver of the trend toward housing older persons with severe mental illness in

board and care and small group homes, a concern is that deprofessionalization of caregivers could put clients at risk of inadequate care. Assurance of well-paid, well-trained staff in long-term residential settings for older persons with severe and persistent mental illness will continue to be a key policy issue for the foreseeable future. Social work has a strong tradition of advocacy for the poor, vulnerable, and disenfranchised. Older persons with mental illness may be especially vulnerable to poor care, because they often do not have the ability or motivation to speak up on their own behalf. Social workers have an important role in advocating for quality of care for these individuals.

NOTE

1. Private psychiatric hospitals tend to specialize in short lengths of stay. No statistics are available for the number of long-stay patients residing in private psychiatric hospitals.

Culture Change in Long-Term Care

57

In health care settings, the social worker's role has always been clear: to oppose the narrow scope of physical care, to reveal the person behind the patient or resident. Necessarily, other members of the health care team have focused on pathology. When the acute care hospital model was transposed onto nursing homes in the 1960s (Vladeck, 1980), social workers faced a further need to advocate for the nonphysical dimensions of life that impart wholeness, even when the overarching model of care pointed in narrower directions.

The restraint-free movement in nursing homes, which began in the 1980s, exemplified this approach. Research confirmed what many social workers already knew on a clinical basis: that physical restraint was destructive to both body and spirit. A social worker, Carter Williams, working closely with nurse researchers and others, was a leader in this change movement (Williams, 1989a,b, 1997).

As a direct outgrowth of this work, Williams and nurse Sarah Burger of the National Citizens' Coalition for Nursing Home Reform identified a small group of providers in long-term care who were practicing approaches radically different from those of the traditional nursing home. They were brought together in 1997 through the coordinating work of Rose Marie Fagan, a Rochester, New York, ombudsman (Fagan, Williams, & Burger, 1997). During this gathering, long-existing practices and those that had been newly initiated were probed to define the *culture* of the nursing home as "expressed in its traditions, style of leadership, social networks, patterns of interaction, relations with the outer community, degree of connectedness to the natural world, use of language, and ways in which the community celebrates and mourns" (Lustbader, 2001). These innovators were then challenged to identify a common set of values and principles to guide future change efforts. The values and principles were:

- Know each person
- Each person can and does make a difference
- Relationship is the fundamental building block of a transformed culture
- Respond to spirit, as well as mind and body
- Risk taking is a normal part of life
- Put person before task
- All elders are entitled to self-determination wherever they live
- Community is the antidote to institutionalization
- Do unto others as you would have them do unto you
- Promote the growth and development of all

- Shape and use the potential of the environment in all its aspects: physical, organizational, psychosocial/ spiritual
- Practice self-examination, searching for new creativity and opportunities for doing better
- Recognize that culture change and transformation are not destinations but a journey, always a work in progress

Throughout the culture change process, these and other initiatives have been bolstered by the Nursing Home Reform Law of 1987 (often referred to as OBRA), which, in addition to establishing the resident's right to be free of physical restraint, requires nursing homes to "provide services and activities to attain or maintain the highest practicable physical, mental, and psychosocial well-being of each resident in accordance with a written plan of care which . . . is initially prepared, with participation to the extent practicable of the resident or the resident's family" (Nursing Home Reform Amendments of the Omnibus Budget Reconciliation Act of 1987, Public Law 100-203).

This chapter depicts how social workers continue to play a key role in changing the nursing home culture from one in which dignity has been forfeited for the sake of care into one in which dignity is affirmed and meaning can be restored.

THEORETICAL BACKGROUND

To abide being in a hospital, a patient must accept being seen primarily in terms of a problem list. Members of the health care team come to the bedside and address the specific problems that stand between the patient and going home. The goal, *going back home*, is shared by all, except—occasionally—visiting family members who may be exhausted from caregiving. The patient surrenders to the will of the body and tries to heed instructions from those who claim to be advocating for the body's best possible recovery from the insult of the illness.

Arthur Frank, a sociologist who has written extensively about illness, insists that to be fully human, "a person must be recognized *as* fully human by someone else" and that "recognition becomes a thing: something given, or extracted, and then held as one's own." He claims that medical settings that deprive us of such recognition are dangerous places on the level of the soul:

In a secular society we seek to evade asking what makes life meaningful in conditions of suffering,

when intactness is permanently jeopardized and bodily integrity gone. When suffering no longer allows this question to be evaded, but when lack of spiritual resources do not allow it to be answered either, that is the existential crisis of illness. Because so few of us can answer what our lives are for, we fear those who pose this question, whether they pose it explicitly or through the implicit witness of their suffering bodies. This fear then leads to withholding recognition of the existential suffering of the ill. (Frank, 1991)

When someone ends up residing in a traditional nursing home, to be addressed repeatedly in terms of a medical problem list is to cease to exist as a person. There is no homecoming to anticipate that will bring relief from this nothingness. There are few objects in the environment that suggest meaning or affirm personal identity. This *is* home, yet it feels like the opposite. One researcher, striving to define *home*, found through interviews with nursing home residents that it is "a whole that cannot be broken down into parts without losing the sense of meaning of the whole" and that the experience of home "thus acts as a center to the individual's existence: it provides meaning in a chaotic world and lies at the core of human existence" (Carboni, 1990).

Maggie Kuhn, the founder of the Gray Panthers, was interviewed in the mid-1970s about the fragmented care her brother received in the last months of his life. Her observations about his hospital stay contain the elements of how health care roles could be made responsive to all dimensions of a person's experience, regardless of the setting.

My brother died after being hospitalized for three months. . . . There was a succession of six different nurses who saw him. Each spent a few seconds—a couple of minutes at the most—but nobody looked at him as a whole person. . . . There was no primary nursing care, where one nurse looks at the whole case. It was the nurse's aides who had more continuous contact with him and who saw to it that he was looked after. How accurate can the reports be when each primary nurse is responsible for an incredible number of patients, with very little time to spend with each? The charge nurse who was supervising never came to visit him. The one person who was the kindest and most loving was a priest. He came to visit every day and was a friend to everyone—Catholic and non-Catholic. . . . Pastoral

skills should be transferable to other fields . . . (and) providers ought to be encouraged to function as teams, not pyramids of power topped by physicians. (Hessel, 1977)

Shifting these “pyramids of power” turns out to be the essence of a transformed culture of long-term care. Those who have the most contact with the ill person, the nurse’s aides, must be given a primary voice on the health care team, and the locus of control must be returned to the individual, rather than retained by the institution and its staff. This shift requires a revision, at a deep systemic level, of organizational structures, professional roles, and practices for hiring, training, and supervising staff. Only then can someone in need of daily assistance receive such help without forfeiting the ordinary freedoms of which dignity is comprised.

FLATTENED HIERARCHIES

In any institutional structure, deep transformation of the status quo is almost always accompanied by heated disagreements and burgeoning resentments, especially at the beginning of the process. Social workers make a primary contribution to the change process at the outset by ensuring that such feelings and perceptions are voiced and resolved openly. Otherwise, negative feelings tend to go underground, where they exert a corrosive effect and bring change to a standstill. For instance, an administrator declaring in a facility-wide memo “all opinions are respected” differs greatly from instituting management practices that ensure a respectful reception for all points of view, including the negative, and guarantee that divergent opinions are heard from the bottom up.

Warning against a top-down approach, many culture change advocates emphasize that “everyone must be involved in the process” and that this can be achieved “only when management encourages the voices of residents and staff” (Fagan, 2003). Culture change tends to advance fundamentally as soon as certified nursing assistants (CNAs) are given multiple avenues for voicing their points of view and employing their intimate knowledge of the people they assist. To accomplish this, some nursing homes are implementing learning circles, an Eden Alternative concept introduced by Bill Thomas, one of the original leaders of the culture change movement.

Learning circles are small groups of people who meet regularly to learn about and discuss areas of

concern with the purpose of planning ways to resolve issues. Learning circles can be initiated for neighborhood work teams, residents, residents and work teams, families, leadership/management, or any configuration of people who have a need to communicate regularly. . . . In a learning circle, participants take turns one-by-one expressing their thoughts, preferences and opinions. After everyone has spoken, the topic is opened for discussion. (Norris-Baker, Doll, Gray, & Kahl, 2003)

The Eden Alternative was one of the first culture change models to insist on placing decision making as close to residents as possible, ensuring that residents could determine their own daily schedules and make their own choices about eating, bathing, dressing, and mobility. CNAs were empowered to respond to spontaneous wishes and to carry residents’ unmet desires back to the care team for further consideration, particularly when loneliness, boredom, or emptiness was at stake. Fostering specific changes that proceed from the point of view of residents and those who serve them so closely produces the right conditions for transforming a sterile monoculture into a warm, human habitat (Thomas, 1994). The Eden model further suggests providing anonymous ways for direct-care workers to give feedback to management, as a counter to common barriers such as shyness and shame about writing or speaking skills (Thomas, 1999).

Researchers have found that CNAs given an efficacious voice in how their own care teams are managed tend to stay longer, display more positive attitudes about their work, and treat residents with more kindness (Eaton, 1998). Brewster Place, a nursing home in Topeka, Kansas, began including a CNA in each of their interview teams, reasoning that this person would be working directly with the candidate selected for the job. They also established self-directed teams in which CNAs negotiate their own schedules and work out on-the-job conflicts through learning circles. As a result of these changes, Brewster Place’s turnover rate “has gone from over 100% to 56%,” and they “anticipate this rate will go even lower over time as their workforce becomes more and more stable” (Norris-Baker et al., 2003).

Staff turnover and the resulting need to fill staff shortages with agency help are some of the costliest burdens that nursing homes with traditional management practices must bear. Conversely, a changed management culture can lead to cost efficiencies because staff who are more satisfied with their work en-

vironment stay longer and become more adept at what they do. At the same time, those who receive assistance from these satisfied workers benefit hugely from the opportunity to know and be known by the people they depend on so intimately.

FLUID PROFESSIONAL ROLES

Striving to foster cross-training and a dynamic exchange of skills across disciplines is another major social work contribution to culture change. Kevin Bail, a social worker who contributed to the formative stages of culture change, served as a Neighborhood Coordinator at Providence Mt. St. Vincent in Seattle, one of the earliest pioneering facilities. Instead of traditional nurse-managed units, this facility established neighborhoods of 12 to 20 residents run by coordinators who did not have to be nurses. The idea was to use nursing expertise where it was essential, such as in wound care management, and to open up the role definition of *coordinator* to include those with special skills in community building among staff and residents (Bail, 1999).

All professions benefit from increased fluidity in role definition and flexible management structures that support the strengths that each discipline contributes to the team. Yeatts and Seward (2000) studied self-managed work teams in a midsize nursing home in Wisconsin. One of the teams in the study consisted of eight central people in the facility's management structure, "the nursing home administrator; the directors of nursing, social work, and mental health; the assistant directors of nursing and social work; and the managers of grounds and dietary." The other two teams in the study were each made up of three CNAs. Interestingly, the high-performing team was the one in which the CNAs made their own decisions about resident care, often in quick "stand-up" meetings in the hallway. Observers found that these team members "held a high level of respect for one another and one another's viewpoints." In the low-performing team, care decisions were being made by the RN in charge, with "almost no decision-making at the team level." The RN is quoted as saying, "The main difference between before and now is that now I provide explanations of what's happening, why decisions are being made."

The RN's perception of change in this example relates to the provision of explanations for her decisions to her CNA staff. In effect, she admits that previously she would not have taken the time to say why she had

chosen one course of action rather than another. The fact that supervisory structures had not been altered and staff still could not make their own decisions based on immediate knowledge of residents' needs demonstrates how a superficial change in practice is often enacted, rather than true culture change for which a change in systems is necessary. A deeper shift would have been to transform her RN role into one of supporting the decisions made by her staff and providing her expert guidance whenever the CNAs were grappling with an arena of care beyond their scope of practice.

A CARING ATMOSPHERE

Social workers often excel at group process, working hard to promote effective teamwork at staff meetings and during casual encounters between nursing home staff. Sandy Meyers, a social worker in an urban nursing home, attends as much to how a team meeting feels as to the content of the discussion. She writes, "The key is for caregivers to be in touch with feelings, vulnerabilities, and anxieties, and to use the resources of a supportive environment to transform these into positive experiences for our work" (Meyers, personal communication, 2002). Similarly, in his pioneering work on dementia care, Tom Kitwood observes:

Care is much more than a matter of individuals attending to individuals. Ideally, it is the work of a team of people whose values are aligned, and whose talents are liberated in achieving a shared objective. It is unlikely that this will happen just by chance; if teambuilding is neglected it is probable that staff will form their own small cliques, and begin to collude in avoiding the less obvious parts of care. Some developmental group work may be necessary in order to facilitate self-disclosure and to lower interpersonal barriers. . . . A rough boundary should be drawn between issues that are genuinely work-related, and those of a more personal kind (which might need to be dealt with through counselling outside the workplace). However, it is appropriate for supervision to provide some kind of "containment" for painful feelings arising directly from work. (Kitwood, 1997)

Facilitating self-disclosure and lowering interpersonal barriers has long been a strength that social workers bring to the health care team. When the preservation

of dignity is at stake, these social work skills become vital in prompting staff to identify ways that they may be inadvertently detracting from residents' lives. Just as important, social workers often help staff speak up about their own needs for recognition and affirmation, as well as the hurt that ensues when these needs are not met. Such discussions serve to lessen team sabotage, such as calling in sick unnecessarily, being overly critical of others' mistakes, and backbiting others on the team rather than speaking directly.

Supporting the well-being of nursing assistants becomes critical when they must minister to sorrowful junctures in residents' lives. While giving a bath, for example, a nursing assistant may wash a bereaved person's hair so tenderly that long-pent-up tears emerge and finally receive comfort. Because grief heals when it is received by a caring other, nursing assistants often become central to promoting the mental and emotional health of those they assist. Researchers have found that "proven methods for improving mental health treatment and the quality of life for nursing home residents exist, but they rely on the skill and adequacy of nursing assistants" (Beck, Doan, & Cody, 2002).

Social worker Cathy Unsino was one of the first to affirm and develop this role in the transformed culture, finding that improved communication between shifts helped nursing assistants convey important breakthroughs in residents' emotional lives and to exchange ideas on ways to best individualize the care they were providing (Unsino, 1998). Researchers have confirmed that when social workers and other professionals take the time to teach compassionate responses to residents and family in distress, they help direct-care workers empathize with those "who may be demanding as they deal with profound loss" and show them how not to "personalize these demands" (Beck et al., 2002).

PUTTING THE PERSON BEFORE THE TASK

Culture change becomes most telling in the personal aspects of residing in a nursing home. Joanne Rader, a nurse who is one of the leaders of the culture change movement, has long asserted that the goals in bathing and dressing "are to keep decision making very close to the resident and to help that person maintain the highest possible level of independence and function." When someone refuses to bathe, the caregiver "needs to determine what must be cleaned for compelling

health reasons and have the skills to identify and carry out the most pleasant, least invasive way to do it." In a changed culture of care, the nursing assistant would not simply walk away from someone who said "no" to a standardized bath but would work with other team members to devise an individualized solution in keeping with that person's dignity and lifelong habits. Thus, the experience becomes pleasant for both the giver and receiver.

If the job is viewed strictly as a number of tasks to be completed on a group of bodies (washing, dressing, feeding, changing) day after day, there is little reward and caregiving will be seen as an unattractive field of work. If instead, the job is viewed and supported as an opportunity to enter into meaningful and caring relationships with people in need of assistance, it provides a way to be of service to others, and can be quite attractive. To recruit and retain good caregivers, the organizational system should be set up to support relationship and caring. (Rader, McKenzie, Hoeffler, & Barrick, 2002)

The transformed culture celebrates the uniqueness of each person as a fundamental principle, particularly the need to individualize care in its most minute details. It takes time to get to know someone's idiosyncratic preferences and habits, rather than imposing standardized practices that seem to make the institution run more efficiently. To respect someone's autonomy, personal knowledge and understanding must take the place of routine practices, or the care can quickly revert to a deprivation of basic human rights under the guise of "doing what's best."

Rosalie Kane, one of the first to study everyday life in nursing homes, cites the case of a woman in her 80s who preferred returning to prison to remaining in a nursing home. She had taken up residence there as a result of a fall while out on probation. Kane observes, "Unable to tolerate the shared room and the confused environment, she committed a technical parole violation and returned to prison where she had a room of her own. . . . [The fact that she] preferred a prison to a nursing home is a severe indictment of our national provisions for the frail elderly." Kane points out that infringements of personal autonomy "are so commonplace and efforts to protect agreed-upon areas of autonomy so unsuccessful that many observers have come to accept rather severe limits in personal autonomy as the *way things are*" (Kane, 1990).

A SENSE OF COMMUNITY

Relationships are at the heart of life and must also be central to a care setting that wishes to promote well-being for those who live and work there (Williams, 1999). This key principle in a transformed culture emphasizes the importance of establishing and maintaining a sense of community. Barry Barkan, one of the pioneers in culture change, insists on “the conscious and consistent cultivation of a community developed with the intention of connecting people to who they are, to one another and to a positive vision of what it means to be an elder in this culture” (Barkan, 2003).

To observe a community meeting at a Live Oak Regenerative Community is to witness staff, residents, and family members respecting and beholding each other’s humanity. For instance, residents’ spouses who still live at home are encouraged to attend community meetings at the nursing home, thus becoming active participants in the life lived there. They develop relationships with other residents and staff that expand their feeling of being welcomed and appreciated each time they visit. Staff attending such meetings and joining in the discussions gain knowledge of residents on dimensions of life far beyond the needs of the body, while the residents become acquainted with aspects of staff members’ lives beyond the work that they do.

Bringing family members’ input into care discussions is another component of transforming a care setting into a community. Advocating for families has been a long-standing social work practice in most care settings, but the transformed culture seeks to integrate the family’s knowledge of the person into what happens for their relative on a daily basis. Relatives provide valuable life history information, as well as details about individual preferences, accelerating staff’s capacity to know the people they assist. Lisa Gwyther, a social work pioneer in dementia care, points out that “families appreciate the opportunity to get to know the special staff over time, and to share observations and tricks with the hands-on staff.” She emphasizes how family members understand the variability and unpredictability of people with dementia, because they tend to be aware from their own caregiving that “what works today may not work tonight or tomorrow” and that “the best teacher is often experience with each patient over time” (Gwyther, 1985).

The need to be embraced by a community is most urgent for people with Alzheimer’s disease and the other forms of dementia. They are often unable to

convey their habits and preferences, and it is imperative for their caregivers to communicate what is known with one another. How each person with dementia is best calmed, which kinds of touch yield comfort, and particular ways to bring good cheer must be passed among staff and visitors alike. Astrid Norberg, a researcher in Sweden, declares that people with dementia suffer when they come to feel “disconnected, disintegrated, and homeless” and urges researchers and practitioners to consider how dementia is being experienced by each individual and to see each person’s behavior as a meaningful expression of this experience. This approach contrasts dramatically with the prevailing tendency to study and manage “behavioral disturbances.” Eloquently, Norberg depicts an attitude toward people with dementia that affirms each person’s value and uniqueness while interacting on the level of feelings (Norberg, 2001), another principle of culture change.

ETHICAL PROBLEM SOLVING

Social workers in health care settings are often called on when ethical dilemmas leave a care team stymied and unable to move forward. For instance, a nursing home may have someone they term a *problem resident* who gets along with no one. Each roommate placed with this person complains to family members, who in turn demand a room change for their relative. Finally, the nursing home social worker may be asked to find someone to put in that room who has no family to provide noisy advocacy and therefore will have no choice but to abide the situation. One researcher portrays a social worker often faced with these predicaments who “does not like to move people around like dominoes” and therefore “tries her best to match people well and to handle problems creatively” (Kane, 1990).

Such situations are rife with tough ethical issues. Should the needs of the institution ever supersede the needs of the individual? What about the rights of a resident who is unable to complain or has no advocates from outside the facility? Should a social worker obey an instruction from a supervisor that is unethical? Social work as a profession possesses an extensive code of ethics, yet to invoke inconvenient ethical issues to an administrator pressured by budgetary considerations can provoke conflict or imperil one’s job standing in traditional settings. In a facility striving to transform its culture, however, a social worker would be able to bring the values and principles of culture change to the

fore and function as part of a team whose philosophy and ethics accord with social work ethics.

Instead of seeking to impose a solution on the problem resident, a transformed culture calls for including this resident, direct-care staff, and family members in an open discussion of options. It is more respectful to inform someone of the difficulties others are experiencing than to assume that this person is incapable of change. Occasionally, such a person may seize on this opportunity to deal with problems that have beset other relationships, grateful for the chance to learn more compatible behaviors. In other instances, the social worker's creative problem solving may include input from direct care staff on other shifts who can identify concerns not apparent to daytime observers. Addressing these concerns may resuscitate the relationship between a current pair of roommates, making the upheaval of a room change unnecessary. In a transformed culture, solutions are sought under the principles that behavior has meaning and that each person can, and does, make a difference. The fact that it is often time-consuming to arrive at such individualized solutions is recognized and respected by administrators who perceive culture change as an ongoing process, rather than a firm set of protocols.

BARRIERS AND OPPORTUNITIES

In *Aging: The Fulfillment of Life*, Henri Nouwen and Walter Gaffney argue that "care is more than helping people to accept their fate." They claim that all aspects of personhood must be engaged, and that this process requires honest engagement between the generations on issues many prefer to avoid.

Real care includes confrontation. Care for the aging, after all, means care for all ages, since all human beings—whether they are ten, thirty, fifty, seventy, or eighty years old—are participating in the same process of aging. Therefore, care for the aging means, more often than not, confronting all men and women with their illusion of immortality out of which the rejection of old age comes forth. (Nouwen & Gaffney, 1974)

Acknowledging this reality, leaders in the culture change movement recognize that long-term care evolves in a wider cultural context than that of the facilities where care takes place. Restoring meaning and life satisfaction to the lives of frail elders ultimately must have its basis in the lives elders led prior to the

constraints illness imposes. To this end, the Pioneer Network for Culture Change declares in its vision statement: "In-depth change in systems requires change in the individual's and society's attitudes toward aging and elders; change in elders' attitudes toward themselves and their aging; change in the attitudes and behavior of caregivers toward those for whom they care and change in governmental policy and regulation."

The immediate goal is to create warm, homelike environments, where sources of dignity can be renewed and individual identity can be expressed, despite losses mandated by illness or frailty. In American nursing homes, the change process has been steady, but slow. Staff still entrenched in the traditional culture of control over those receiving care frequently react as if they have a lot to lose as residents gain autonomy and jurisdiction over their own lives. Simultaneously, the prospect of more satisfying work roles and happier residents motivates many to abide the "subtle and difficult art" of the transformation process, remembering that "warmth demands persistence, patience, forgiveness, tolerance and respect," virtues that "flourish only when cultivated" (Thomas, 2003). Social workers will continue to be the chief cultivators of such warmth, charged as the profession always has been with honoring the individual as the starting place of service to others.

Dementia Special Care Units in Residential Care

58

A high proportion of nursing home residents have a primary or secondary diagnosis of Alzheimer's disease, other dementias, or significant cognitive impairment. The Alzheimer's Association estimates that proportion to be 60% of all nursing home residents. Estimates on the numbers of people with dementia in nursing homes fluctuate, depending on the definitions and measurements used, but it is generally assumed that at least half of nursing home residents experience significant cognitive disability.

Nursing homes are typically structured into nursing units. Nursing units vary in the number of residents residing in them, though typically a unit serves at least 40 residents. Nursing homes vary, too, in the number of units (obviously, correlated with overall size) and the extent to which units are autonomous in management, consistent in staff, and organized to offer dining, communal activities, and various amenities right on the unit. The more disabled the resident, the more likely he or she is to be dependent on the environment of his or her own room and the immediate nursing unit, in terms of both physical attributes and the mix of residents and staff who influence his or her daily life.

Special care units (SCUs) in nursing facilities developed in response to concerns expressed by families, advocates, and providers about the quality and adequacy of dementia long-term care. Although innovations in SCUs originated in the nonprofit sector, the majority of SCUs are part of for-profit chains (Gwyther, 2003). Dementia SCUs are functionally defined as specific geographical areas of a nursing home that are licensed by a state as SCUs or that market themselves as SCUs that serve residents with dementia. Depending on state policy, dementia SCUs may be locked units. Typically, each nursing home has criteria to determine which residents are eligible for or appropriate to receive care in an SCU. Depending on the nursing home, the dementia SCU may be targeted for ambulatory residents and/or residents who require close supervision of behavior that may disturb other residents; in such cases, the resident may be discharged from the SCU when skilled nursing needs and loss of mobility become more challenging than behavioral disruptions. SCUs may discharge residents with disruptive behavior as frequently as nonspecialized units. These residents are frequently discharged to inpatient psychiatric facilities. In some facilities, the SCU is designed as a care setting for a person with dementia through his or her entire nursing home stay, and a few SCUs specialize in late-stage or palliative dementia care.

The prevalence of SCUs expanded rapidly in the late 1980s and the 1990s. A 1992 survey funded by the American Association of Retired Persons of a national sample of nursing homes, with results weighted to all Medicare and Medicaid nursing homes, suggested that about 14% of facilities had an SCU (Morris & Emerson-Lombardo, 1994). During the same period, Leon conducted a national study of homes with more than 30 beds and identified 9% with SCUs and much state variation in the rate (Leon, 1994). A 1992 population study of all Minnesota nursing homes found that 15% (66 of 434) of the nursing homes had at least one SCU, and five had more than one SCU. Facilities with SCUs were similar to the statewide profile except that larger facilities and facilities in urban areas were more likely to have SCUs (Grant, Kane, & Stark, 1994). A national survey in 1995 reported that 19% of nursing homes had SCUs, with an average capacity of 34 beds (Leon, Cheng, & Alvarez, 1997). Estimates of the prevalence of SCUs in nursing homes vary because of varying sample frames and varying operational definitions of SCU, but the phenomenon of specialized programs for dementia centered in a special living area seems increasingly common in nursing homes large enough to have three or more units, and the trend is international. Various Alzheimer's Association and industry Web sites in 2004 put the prevalence above 20% of nursing homes in the United States.

Given the preponderance of residents with dementia in nursing homes, it is obvious that many residents receive care in general units rather than in specialized SCUs. Even in facilities with SCUs, more people with dementia are likely to be cared for in conventional non-SCU units. An estimate from Ontario, Canada, suggested that in homes with SCUs, about 60% of residents with moderate or severe dementia were served in the traditional units rather than the SCUs (Flett & Davis, 1992), a figure that would be similar in the United States. Those admitted to SCUs tend to be younger males who are admitted from home earlier in the course of their dementia, when they are still independently mobile. Nursing facility SCU residents are also more likely to be private pay and have a clinical diagnosis of Alzheimer's disease and fewer other physical limitations. Nursing facilities with older SCUs are often forced to develop late-stage, palliative, or hospice model units for residents aging in units designed, programmed, and staffed for social-model, less intense nursing care. This is especially true when family members and staff resist returning residents to the general population because

established relationships among staff, residents, and families have been forged.

WHAT IS SPECIAL ABOUT SPECIAL CARE?

Advocates for people with Alzheimer's disease have endeavored to understand the theoretical and actual implications of the rapid spread of segregated care units for dementia in order to decide on an appropriate policy position. For example, a contrasting strategy would be to develop dementia-capable programs in every unit in every nursing home and facility-wide staff training about dementia-specific care. Also feasible are dementia "pull-out" day programs within a nursing home, analogous to pull-out special educational programming in mainstream schools. These enriched day programs are more likely in nonprofit facilities. Thus, the Alzheimer's Association (1992) released *Guidelines for Dignity*, which discusses specialized care for Alzheimer's disease in nursing homes without reference to the resident being in an SCU.

STUDIES OF SPECIAL CARE UNITS

In 1992, the former Congressional Office of Technology Assessment convened a panel to explore what was known about SCUs to that time (U.S. Congress, 1992). Some panelists perceived that the development of segregated services for dementia would benefit the person with dementia by establishing more appropriate physical environments, making individualized therapeutic approaches and dementia-appropriate group activities more feasible, reducing pressure on the residents to conform to expected behaviors, and utilizing a specially trained staff or deploying a different mix of staff on a different schedule that might be more appropriate to dementia care. Skeptics worried that dementia special care might in reality be a marketing ploy, a chance to increase private-pay rates for special care without discernible added services, or an attempt to circumvent moratoriums on nursing home bed construction with waivers for specialized unmet needs. Under nursing home regulations, each resident is expected to receive individualized care according to an individually tailored care plan, so that alone should not be seen as a special feature. Advocates express concern that SCUs segregate but fail to provide for special needs. There is increasing consumer and professional consensus that SCUs are most appropriately used to develop and characterize de-

mentia care models that can be adapted to all levels of residential and institutional care.

In the early 1990s, the National Institute on Aging funded 10 cooperative studies on dementia special care. The investigations varied in scope and scale. Some entailed an intervention, whereas others followed populations over time. All investigators agreed to use a common core of measures for the study, making some comparisons possible. Initially, the grantees spent much effort trying to identify the special features that normatively should define dementia SCUs. Special care was originally conceived to include a “special” philosophy of care; staff specification, selection, and training; activity programming to accommodate cognitive impairment; specialized personal care strategies; segregated and modified physical and social environments; and admission and discharge policies profiling which residents are appropriate or most likely to benefit. A 1997 consensus conference determined a core philosophy of SCU care that included promoting safety and security, enhancing connections to others, mitigating disruptive emotional and physical behaviors, supporting cognitive function, maximizing independent function, and regulating stimulation. Unfortunately, practice does not necessarily reflect philosophy.

MODELS FOR SPECIAL CARE UNITS

There are four primary models of specialized dementia care. Variations in size and target population probably preclude a single approach. The curative model is based on treating all medical conditions to reduce “excess disability.” The habilitation model focuses on maintaining or enhancing function through specialized programming and personal care. Environmental models adapt or modify the physical and human environment to achieve an elusive “optimal” amount of stimulation and retreat over the degenerative course of dementia. Palliative models provide a safe, comfortable environment with aggressive treatment of physical and emotional pain (sometimes expressed in screaming or repetitive disruptive vocalizations) and attention to spiritual needs of residents and families at the end of life.

The desirable special features of SCUs as identified through the cooperative trials and other work tended to fall into three general categories: the physical environment features (Day, Carreon, & Stump, 2000), the programmatic features (including the way ordinary daily routines are managed), and the way staff are

trained and deployed. However, no consistent philosophy or theory guides SCUs, and a wide variety of physical designs and program plans can be found in SCUs.

The marketing of SCUs has focused on physical design, despite the fact that most units are minimally retrofitted. The most common and frequently the only change may be the addition of a security system to limit egress without use of physical restraints. The ideal small, secure, dignified, and stable personalized environments were lost when the industry concluded that a cost-effective unit must have a minimum of 30 beds. Cost, access, and a relative lack of positive outcome data still limit SCU development.

RELEVANT HISTORY OF THE SPECIAL CARE INITIATIVES

One of the first SCUs established in the United States was developed in 1972 at the former Philadelphia Geriatric Center (PGC). The physical and program design was based on observations made by researchers working under M. Powell Lawton, who carefully noted the circumstances that seemed associated with less anxiety and greater engagement and social participation. PGC also engaged in planning over a period of many years, bringing in experts from many disciplines and conducting meetings with staff and with cognitively intact residents. The result of efforts to maximize stimulation that residents received from sitting in crowded corridors without the corresponding danger and barriers to function was a building comprised of small private rooms around the periphery of the unit and a huge central space where activity could take place or be observed. In this example, a clear effort was made to design the building and program according to theories of need-driven behavior. In 2000, Lawton and Elaine Brody, who was director of social work when the unit was built, were interviewed for a history project. Both commented on the efforts to maximize positive behavior and minimize “excess disability,” though Lawton suggested that the scale and design in some ways led to overstimulation (Katzman & Bick, 2000).

In the proliferating SCUs of the 1980s and 1990s, some were designed to mimic normal household life as much as possible and to provide stimulation to residents, whereas others were designed to minimize anxiety by muting stimulation and providing serene, noise-free shared spaces and minimalist private space. Some dementia care units are eclectic, drawing prag-

matically on a variety of sometimes opposing theories. Validation therapies (where the staff members respond to the feelings of the person with dementia) coexist with reality therapy (where efforts are made to orient the resident to time and place), and initiatives designed to stimulate residents coexist with those designed to soothe or reassure them. Still, some common principles seemed to emerge. The ideal model was expected to provide predictable familiarity, stable routines, and flexible stimulation without overload in “homelike” living units that were safe but enriched with redundant cues like signs, pictures, familiar items, and reminders. Experts urged the reduction of noise, glare (with an increase in natural light), and traffic with small units and a higher ratio of selectively deployed, nonrotating staff. The focus was discrete perimeters that facilitate unobstructed safe movements under staff surveillance between private areas and group, dining, and outdoor spaces. Ideally, activities are designed for short segments of time, meals and snacks are served and available on the unit, finger foods and other strategies are utilized to help residents maintain weight, and families are drawn deeply into the lives of the units.

CURRENT STATUS OF SPECIAL CARE UNITS

Some dementia units have 100% private rooms and many amenities in well-designed private and communal space that would be welcomed by all residents. Others show few efforts to change the physical space or to tailor programs and training to dementia. Hoffman and Platt (2000) are highly critical of many SCUs. Among the common problems they cite are lack of training for staff, inadequate staffing levels (especially at night, when many people with dementia are awake), inadequate admission criteria, poorly designed environments, and lack of anything for residents to do, which in turn increases agitation.

Dementia SCUs potentially benefit residents with and without dementia indirectly, in addition to the direct benefit they provide to participating residents and their families. In many instances, they provide a nucleus for learning more about dementia and training the entire staff. Sometimes, they draw away from the general census those residents who are most disruptive. Though more controversial, it is now widely believed that dementia care units offer benefits to residents who are cognitively intact because they are less likely to be in close contact with other residents whose behavior is disturbing to them or lowers the level of

discourse in the facility. By the same token, however, some advocates for people with dementia worry about their segregation into dementia-specific units, where their needs and care may not be subject to sufficient family and community monitoring.

Research findings to date are mixed and do not show differences in resident outcomes on SCUs compared with residents who have dementia in the rest of the nursing home, once baseline characteristics are controlled for (Sloane, Zimmerman, & Ory, 2001). For example, when controlling for baseline characteristics, Phillips et al. (1997) and colleagues found no difference in functional outcomes, and Leon and Ory (1999) found no differences in aggressive behavior between SCUs and units not designated as an SCU. A similar large Canadian study found SCUs were not homogeneous, nor did SCU status or the individual dimensions of “special care” relate to better outcomes (Chappell & Reid, 2000). Outcome studies often identify more benefits of SCUs in reduced staff turnover and increased staff and family satisfaction. Some studies found reduced aggressive behavior was related to increased use of psychotropics and decreased use of restraints rather than programmatic aspects. Even the addition of wandering areas failed to document use of these areas, and there were additional safety issues.

Much less research is available that compares dementia SCUs with each other, and this might be a fruitful line of endeavor. Zeisel et al. (2003) effectively used hierarchical analysis to show that variations in SCU environments in assisted living affect measurable resident quality of life. At the time of this writing, a number of controlled clinical trials are being conducted within programs in both nursing homes and assisted living facilities to identify effective program, staffing, and training approaches. Also, dementia SCUs with internal research capacity afford the opportunity to provide evidence-based guidance to practitioners on clinical matters, such as how to enhance social engagement and positive emotions, curb or manage aggression, build on individual biographies, or discourage wandering. Such research-rich dementia environments facilitate the development and use of observation tools for examining interventions, such as dementia-care mapping or systematic rating of facial expressions. For examples of positive interventions in dementia care along these lines, see the collection of research results edited by Lawton and Rubinstein (2000). In this way, SCUs could become laboratories for more effective approaches to dementia care that could be exported to the mainstream of residential long-term care.

SOCIAL WORK IN NURSING HOME SCUS

Social workers have played leadership roles in developing generally effective approaches to dementia care within nursing homes. For example, Lisa Gwyther's 1985 Alzheimer's Association manual for nursing home staff on care of Alzheimer's patients preceded the widespread advent of SCUs and is replete with practical examples. The latest edition of this Alzheimer's Association book is used by social workers in training and program development in both nursing home and assisted living SCUs (Gwyther, 2001a). An SCU environment offers a focused opportunity to expand a social work role in comprehensive dementia care. SCUs often emphasize a team approach with nursing, activities, therapy, and social work personnel that has some blurring of discipline responsibility so that residents' person-centered needs can be addressed consistently by all available staff. Social work communication skills in working with teams, individuals, families, family conflict, and groups are especially relevant to the SCU environment. Latest estimates suggest that 70% of nursing facility residents have involved family, and social workers are uniquely positioned to address staff-family conflict and family issues (Port et al., 2001; Yamamoto-Mitani, Aneshensel, & Levy-Storms, 2002). Social workers may be involved, too, in marshaling resources for the residents and their families and in taking and communicating the kind of social history that makes the resident and family become known to the staff.

Typically, social workers are involved with the initial selection of residents to enter the SCU and (depending on the model) with recommendations that some residents no longer need or receive benefit from the SCU. This latter recommendation is often received poorly by family and even SCU frontline staff. The frontline staff in SCUs ideally are selected and self-selected because of an interest and capacity to work well with residents with dementia. As certified nursing assistants (CNAs), they are ideally encouraged to contribute to and knowledgeably support the overall care plan, not just the nursing plan. Social workers may well be involved in group and individual efforts to help staff understand the purposive nature of behavior and identify what it is that the individual is trying to communicate.

Social workers in the nursing home should act as members of the management team in suggesting strategies for the development of a dementia SCU or for refinement or expansion of dementia-capable programming throughout the facility. Nursing homes

vary in the resources that they have available to develop and staff SCUs. The social worker's expertise should be helpful on a management team that establishes the philosophy of care; defines admission and discharge criteria; sets priorities for use of funds; suggests ways to tailor the human, physical, and social environment for person-centered care; designs staff and family education and support activities (McCallion, Toseland, & Freeman, 1999); and develops community partnership programs (Gwyther, 2001b; Murphy et al., 2000). Like many other leadership opportunities in nursing homes, the social worker may need to initiate activities and express interest, because administration may not be familiar with the social worker's skills and full arena of practice.

Opportunities also exist for social workers to be leaders on the SCUs. Although nursing is the most frequent background for coordinators of dementia SCUs, activity therapists and social workers have also filled the jobs. Social workers frequently direct development and monitoring of nursing home chain SCUs on a regional and national level. Both unit management and overall development and oversight roles are consistent with social work skills and training. The most likely effects of dementia SCUs will be found in improved quality of life for residents, improved family-staff communication, and greater family involvement and satisfaction, goals that are within the expertise of professional social work to assess and to measure the degree to which desired outcomes are attained.

DEMENTIA SPECIAL CARE IN OTHER RESIDENTIAL SETTINGS

A nursing home may not be the best setting for people in the early to moderate stages of dementia. It is argued that the 24-hour nursing supervision and high care levels may not be needed by the majority of residents with dementia until later in their illnesses and that they might thrive in a less institutional, more homelike, and perhaps smaller setting. Estimates of the proportion of older people in residential care who have some degree of cognitive impairment reach 44% in the most current studies (Gruber-Baldini, Boustani, Sloane, & Zimmerman, 2004; Rosenblatt et al., 2004). Thus, the adult foster homes and adult family homes described in chapters 61 and 62 serve substantial numbers of residents with dementia in their general populations.

Some individual residential care facilities and assisted living facilities also provide specialized dementia care (Sloane et al., 2001). One model is that an

entire freestanding setting—whether a small family care home serving five or six people, or a larger setting—is designed to serve dementia exclusively. The small family home has proven particularly felicitous for dementia care because of the familiarity of the settings, and those homes that specialize in dementia can further build specific programs to meet those needs. Some entire chains of freestanding assisted living programs specialize in dementia care.

Some specialized dementia programs are operated by firms that also operate nursing homes and other long-term care programs on a single campus. Not uncommonly, some exemplary and nationally known programs were started by nursing homes, but the innovators sought a residential care license to enhance the flexibility of the physical design and service. Thus, the Corinne Dolan Center for Memory and Aging in the Cleveland area is licensed as residential care. The Dolan Center pioneered the use of behavioral mapping in individualized care plans. It is designed to serve people with early and moderate dementia, and the nursing home on campus also has a dementia SCU to serve residents with more advanced dementia. Similarly, Woodside Place, an exemplary assisted living setting on the campus of Presbyterian Homes in Pittsburgh and Copper Ridge in Maryland, chose an assisted living rather than a nursing home license to facilitate its unique pod design and its planned staffing model. In such instances, the specialized dementia assisted living unit is self-contained but within easy reach of an affiliated nursing home.

Larger assisted living or residential care settings may develop dementia SCUs in somewhat the same manner as do nursing homes. Some have done so as the program ages and residents with dementia are having difficulty integrating with others in the dining room or disturbing other residents by wandering. Typically, dementia units in assisted living are locked or secured units with specially tailored environments, programs, and staff. In some large assisted living settings comprised of private, singly occupied apartments, dementia SCUs were established by having residents share apartments and creating large public spaces in the areas thus freed up. (In Oregon, where licensure of assisted living requires private apartments and single occupancy unless by choice, the dementia SCUs in such cases needed to become relicensed as residential care facilities, which carry a different reimbursement rate.) On a corporate level, large, publicly traded assisted living centers such as Sunrise Senior Living have developed branded memory care programs. In the case of Sunrise, they are called Reminis-

cence Neighborhoods and are characterized by rich and stimulating physical environments that evoke memory and pleasure. The extent to which residents can expect to remain in dementia programs based in residential care depends in part on the aspirations of the programs and in part on the licensure rules of the states. Generally speaking, it seems that residents are more likely to be retained until their deaths in the small adult foster homes or adult family homes than in the more complex apartment units, even if they are in a specialized dementia care setting.

In another variant on the theme, some firms operate dementia-specific programs within existing assisted living programs that contract for their services. An example is Hearthstone Assisted Living, which designs and operates such dementia programs within other care settings. The Hearthstone trademark will be associated with a number of innovatively designed care programs tailored to disease stages, including a program for enhanced care for those who develop health care needs, an information and quality control system developed by the principals of Hearthstone, and a day care and respite program. The Hearthstone staff are responsible for operating their dementia-specific programs independently of any of the management in the rest of the host setting. Each assisted living program is operated by an executive director. The requirements for executive director listed on the Web site are as follows: “thorough knowledge of and experience with dementia population and appropriate therapeutic interventions for this population. Candidates must also possess interpersonal skills, energy and desire necessary to work cooperatively with other staff, volunteers, families and residents. They must also have a degree in Nursing, Social Work, Counseling or comparable experience.” It is noteworthy that social work is explicitly viewed as an appropriate educational background to direct such a program, and even more significant that the knowledge, skills, and experiences listed are within the purview of the profession.

FUTURE DIRECTIONS

Many issues regarding dementia special care in nursing homes and assisted living remain unresolved. It is possible that as nursing homes begin organizing in self-contained households and provide all residents with private rooms to which they can retreat, segregated units for dementia may become less necessary. Furthermore, many of these households aspire to offer continuity of community to all residents, even if they

experience cognitive or physical decline at different rates. The notion of transferring a resident from such a household to a dementia-specific household may go directly against a care philosophy that emphasizes community. The preferences and experiences of residents in heterogeneous versus homogeneous units and especially of those who are moved because their functioning no longer matches the predominant level of the other residents require further research.

The ideal staff-to-resident ratios and staff mix for dementia-specific care are not yet known. In all likelihood, a variety of models would work. For that reason, some policy analysts have resisted the call for legislated staff ratios and patterns as too inflexible for an evolving model. Social workers have contributed widely to the development and research of these models, and they frequently provide leadership within dementia care units and programs. Because improved quality of life and improved family outcomes are expected from dementia SCUs, these units seem to be a fertile place for social work leadership, especially as more social workers develop specific competence in dementia care.

ROBERT L. MOLLICA

Transitions From Nursing Homes to Community Settings

59

Just under 1.4 million people live in nursing homes in the United States, and 90% of nursing home residents are over 65 years of age. Despite an aging population, nursing home utilization and occupancy rates remained relatively stable between 1999 and 2003. Though the percentage is shifting, 67% of all Medicaid long-term care expenditures were spent on institutional care in federal fiscal year (FFY) 2003 (Eiken & Burwell, 2004) compared with 84% in FFY 1993. Between FFY 1993 and 2003, spending for home- and community-based services (HCBS) waivers grew 565%, and personal care increased 155%. Nursing facility spending rose 71%, and spending on intermediate care facilities for persons with mental retardation (ICFs-MR) increased 38% over 10 years. However, progress has been uneven. States and advocacy groups have made real progress in serving people with mental retardation and developmental disabilities (MR/DD) in community settings. Thirty-six states spent more than half their long-term care expenditures for individuals with MR/DD care on HCBS services, and 13 states spent more than 80% on HCBS for this population. On the other hand, no state spends more than half its money on HCBS waiver services for elders and adults with disabilities. Institutional care is the primary source of care for elders and adults with physical disabilities.

State policy makers, even in states with mature home- and community-based service systems, contend that 10 to 20% of residents could live in a residential setting or their own homes with appropriate support services. States have increased their efforts to help nursing home residents move to community settings; however, they face opposition from nursing home operators, lack of available affordable housing, the need for funding to cover the costs of establishing a home in the community, and lack of financing for Medicaid home- and community-based services. State officials and case managers report that they are often able to work collaboratively with nursing home social workers because they have contact with residents and are more likely to support a person's interest in moving to the community than administrators, who tend to be more concerned with occupancy rates and operating margins. Establishing rapport with nursing home staff is a necessary component to identifying and working with residents.

During the early phases in the development of community care systems, case managers developed care plans and authorized services to support people in their own homes. When someone entered a nursing home, the home care system closed the file. As the

cost of nursing home expenditures rose and policy makers recognized that many nursing home residents could return to the community if the necessary housing and support services were available, states began to design programs to work with residents interested in moving to the community. Disability advocates have also played an important role in educating policy makers about the preferences of nursing home residents and the policies that need to be changed to support community living. The U.S. Supreme Court (*L.C. v. Olmstead*, 1999) made community options an imperative by ruling that, under the Americans with Disabilities Act (ADA), people with disabilities had the right to receive services in the most integrated setting. The ADA requires that public entities must make reasonable modifications in policies, practices, or procedures when the modifications are necessary to avoid discrimination on the basis of disability (Rosenbaum, Burke, & Teitelbaum, 2003). States are not required to make alterations that fundamentally alter policies and programs. The decision has prompted states to develop a plan to implement the ADA and given advocates grounds to press for additional funding for home- and community-based services.

STATE INITIATIVES

Between 1998 and 2000, the U.S. Department of Health and Human Services, Office of the Assistant Secretary for Planning and Evaluation (ASPE), and the Centers for Medicare and Medicaid Services (CMS) jointly funded 12 states to develop and implement nursing home transition programs. Beginning in 2001, CMS initiated the first of four rounds of Real Choice Systems Change grants under the administration's New Freedom Initiative. Nursing home transition awards have been made to 23 state agencies and 10 independent living centers. A report on start-up activities in 17 projects (Anderson & O'Keeffe, 2003) found that 370 individuals were transferred by 14 grantees and 370 individuals were in process. Several projects were developing procedures, designing outreach plans, and preparing assessment tools and did not expect to relocate residents during the first year. Eleven grantees cited the lack of affordable, accessible housing as a major barrier to helping residents move to the community. Section 8 rental assistance vouchers are in short supply, and public housing agencies often have lengthy waiting lists. Home- and community-based services waiver programs may also have waiting lists. Case managers or nursing home transi-

tion specialists must work closely with housing agencies to coordinate policy development and implementation in order to leverage resources for people who are moving from nursing homes to community settings.

In 1998, the New Jersey Department of Health and Senior Services implemented a counseling program for Medicaid-eligible nursing home residents with the potential to move to the community. The Community Choice Counseling program was developed separately from its single-entry-point agencies. The state hired 40 registered nurses and social workers to work with residents. The counselors received referrals from area agencies on aging, nursing home staff, and the ombudsman program. Counselors offered residents information about housing and service options and assisted with transition to the community. Counselors received extensive training from state leaders about state and local programs and services available under Medicaid, the Older Americans Act, assisted living and other housing resources, and local service agencies. Counselors visited local service agencies and other organizations to learn about the resources available and to build relationships. During the first three years of the program, counselors helped 3,400 people move to the community.

The State of Washington's comprehensive long-term care system assimilated nursing home transition activities as an integral part of the system. In 1987, the Aging and Adult Services Administration prepared a strategic planning document that noted that nursing home spending was growing so rapidly that it prevented expansion of in-home services, despite consumer preferences for them. The document recommended policy and budget steps to expand in-home services and curtail institutional care. Ten years later, 63% of the agency's clients were served in residential and in-home settings. The State of Washington has shifted from a reliance on nursing homes to a more balanced service system. The number of Medicaid nursing home residents has declined from a peak of just under 18,000 in 1993 to 12,500 in January 2003.¹ The number of people receiving home- and community-based services grew from about 20,000 in 1993 to 33,000 in January 2003. Of Medicaid beneficiaries receiving long-term care services, 71% are served in community and residential settings. By continuing to rebalance its system, state officials expected that the number of people receiving care in nursing homes will drop to 12,181 by January 2004 (Mollica, 2003).

Washington implemented a single-entry system to administer an array of long-term care services. The

initial assessment, functional eligibility determination, and care plan are completed by state-employed nurses and social workers. Ongoing case management is done by state staff for beneficiaries in nursing homes, adult family homes, and assisted living settings and by area agencies on aging for in-home participants.

To identify and assist nursing home residents who want to move to the community, the Aging and Disability Services Administration reassigned social workers and nurses from hospitals to nursing homes to work with residents. Case managers are required to contact residents within seven days of admission to the nursing facility to discuss their interests, preferences, plans, likely care needs, and the supports that are available in the community. State social workers work closely with nursing home social workers to understand the needs of residents and to prepare relocation plans. A full comprehensive assessment is completed when the consumer indicates a readiness to work with the social worker to relocate and the nurse/social worker develops a transition plan with the consumer. Social workers often need to find resources to cover transition needs to help residents establish a community residence. Transition needs include furnishing a home or apartment, buying cooking utensils, paying utility deposits, and modifying bathrooms, entryways, and other areas of an apartment. Discharge to the community is obviously more difficult after residents have lost their home or apartment. States can help residents keep their homes by allowing them to retain sufficient income to pay the rent or other costs. Using Medicaid rules, income that would normally be paid to the nursing home can be exempted for up to six months.

In a process developed before CMS allowed coverage of transition services, social workers in Washington can access several sources of support that include a medical institution income exemption fund (MIIE), a residential care discharge allowance, a civil penalty fund, and the assistive technology fund.

Federal Medicaid rules allow states to exempt income of beneficiaries who qualify for Medicaid under the special income level or medically needy program that would normally be paid to the nursing home. Medicaid posteligibility treatment of income rules (CFR435.832) permits states to exempt income so it can be used to maintain a home or to pay for costs related to moving to a residential or community setting. The state also allows up to \$816 in state general revenues to help a beneficiary move from a nursing home, hospital, adult residential care facility, en-

hanced residential care facility, assisted living facility, or adult family home to a less restrictive setting. The grant may be used to cover the first month's rent, damage deposits, moving expenses, furniture, utilities, groceries, cleaning services, telephone, or the purchase of necessary equipment, including handrails, ramps, assistive devices, furniture, bedding, and household goods and supplies. Civil money penalties (fines collected from nursing homes with deficiencies) may also be used to help people residing in nursing facilities that have been listed by the licensing agency as deficient to move to another nursing facility or to an alternate residential setting. The grant is limited to \$800 per resident, but exceptions may be allowed if the facility has been decertified or an emergency requires several or all residents to relocate. Requests that exceed the limit are reviewed by the regional administrator. Finally, state general revenues were used to create an assistive technology fund that can be used to pay for assistive, adaptive, or durable medical equipment; evaluations; training; or minor home modifications. Assistive technology funds are also available to cover intervention services, which are evaluations or consultations by professionals in occupational or physical therapy, independent living, nutrition, psychology, nursing, or rehabilitation. These services are available for people who are likely to gain improved functioning, health, or independence. Services must meet the consumer's need.

As a result of the early federal demonstrations, CMS established transition services as an allowable service under home- and community-based services waivers (Smith, 2002). The new policy allows states to pay the reasonable costs of community transition services, including security deposits that are required to obtain a lease on an apartment or home; essential furnishings and moving expenses required to occupy and use a community domicile; set-up fees or deposits for utility or service access (e.g., telephone, electricity, heating), and health and safety assurances, such as pest eradication, allergen control, or one-time cleaning prior to occupancy.

COVERING CASE MANAGEMENT

Social workers perform important roles as case managers in helping residents explore community options. However, finding funding to support their activities has been difficult during difficult economic periods. Medicaid is an important source of federal funds for nursing home transition activities. States

have three primary options to cover case management activities for nursing home residents under Medicaid. First, case management may be a service under a section 1915 (c) home- and community-based waivers. Second, it can be designed as a targeted case management service. Case management may also be considered an administrative activity that is necessary for the proper and efficient administration of the state plan.

The Medicaid manual describes case management as an “activity which assists individuals in gaining access to needed waiver and other State plan services, as well as needed medical, social, educational, and other appropriate services, regardless of the funding source for the services to which access is gained.” Case management services may be used to locate, coordinate, and monitor necessary and appropriate services, to encourage the use of cost-effective medical care by referrals to appropriate providers, and to discourage overutilization of costly services such as emergency room care for routine procedures. Case management services may also provide necessary coordination with providers of nonmedical services, such as local education agencies or the department of vocational rehabilitation, when the services provided by these entities are needed to enable the individual to function at the highest attainable level or to benefit from programs for which he or she might be eligible.

Case management services can be delivered to residents up to 180 consecutive days prior to discharge from a nursing home. The assessment, functional determination, and preliminary plan of care can be completed while the person is still in the nursing home. This flexibility avoids creating a gap between the person’s move to the community and the initiation of services. Federal financial participation (FFP) may be claimed by the state Medicaid agency only on the date the person leaves the institution and is enrolled in the waiver.

Targeted case management (TCM) is defined as “services which will assist individuals, eligible under the plan, in gaining access to needed medical, social, educational and other services.” TCM may be furnished to nursing home residents who are preparing to move to the community. Like the 1915 (c) waiver, TCM may be furnished during the last 180 consecutive days of a Medicaid-eligible person’s institutional stay. States may specify a shorter time period or other conditions under which targeted case management may be provided.

States must identify a target group to receive services, such as nursing home residents planning to

move to the community. States may include limitations in comparability, which means that the service is not available in the same amount, scope, and duration to all eligible recipients, and statewideness, which means that the service may be offered in specific geographic areas of a state. Medicaid recipients must be given a choice of TCM providers who meet the state’s qualifications. However, with regard to target groups that consist entirely of persons with developmental disabilities or individuals with chronic mental illness, the state may limit the providers of TCM to ensure that case managers are capable of seeing that needed services are actually delivered to these vulnerable populations.

Case management may be reimbursed “as a function necessary for the proper and efficient operation of the Medicaid State plan.” The payment rate is either the 50% matching rate or the 75% FFP rate for skilled professional medical personnel, who are employed in state or local agencies other than the Medicaid agency who perform duties that directly relate to the administration of the Medicaid program. As an administrative activity, case management must be related to covered Medicaid services and does not cover gaining access to housing, food stamps, or other non-Medicaid services.

FUNDING SERVICES

Social workers also need a funding source for the services needed to support people in community settings. A few states, Oregon and Washington, pool all long-term care funding in a single appropriation, making it easier to use appropriated funds for nursing home, personal care, or waiver services without requiring legislative approval to move funds from one program or service to another. States without this flexibility have adopted “money follows the person” strategies that allow funds appropriated for nursing home care to be used to pay for community services when an individual moves from the nursing home to the community. Texas was the first state to adopt this strategy under Rider 37, which became Rider 28 in a subsequent legislative session.

Under the Texas money follows the person program, nursing home residents call a hotline staffed by the Department of Human Services. The staff verifies Medicaid eligibility and codes the beneficiary as a Rider 28 individual. A case manager prepares a care plan and initiates services once the resident has relocated. Funds are transferred from the nursing home account to the waiver account periodically. The pro-

gram allows up to \$2,500 for transition services, and the costs have averaged \$1,962. Since September 2001, 3,400 people have moved to community settings.

Just over 37% of the individuals moved in with family members, 32% moved to an assisted living facility, and 26% moved to their own homes. Of the individuals who moved, 23% had lived in a nursing home for one year or longer, and 17% had stayed in a nursing home between 6 and 12 months.

Helping nursing home residents move to a community setting can also be a priority for capitated programs. The Utah Department of Health Long-Term Care Managed Care Initiative serves Medicaid beneficiaries who live in a nursing home. Participation is voluntary, and residents receive an assessment to determine their preferred living situation and the services needed to support that choice.

Finally, nursing home social workers and discharge planning staff also have a role in helping residents move to the community. Social workers and direct care staff have referred residents to independent living centers and other organizations that work with residents. They work cooperatively with state nurses in Washington. Staff in other nursing home transition programs described the conflicts faced by nursing home staff. The first priorities may be working with hospitals, handling admissions, and preparing discharge plans for short-term stays covered by Medicare. They may have less time available to work with Medicaid beneficiaries, especially residents who need housing, and they do not control the resources that will be needed to support individuals in the community. Some observers note that the primary role of nursing home social workers is to maintain the census, and there is less time and incentive to work with longer-stay residents who express interest in moving.

CONCLUSION

Consumer demands for services that enable them to live in the most integrated setting, the U.S. Supreme Court decision upholding the rights of individuals with disabilities to live in the community, and the rising cost of institutional care to state Medicaid budgets have led to increased efforts to help nursing home residents move to community settings. State Medicaid, aging, and other agencies and independent living centers and other community-based organizations are increasingly developing programs to promote community transitions. Among the important components of programs to help low-income nursing home residents relocate are

- Funding for community services to enable individuals with disabilities to live independently
- Availability of social workers, case managers, or transition specialists to help residents identify needs and resources to support relocation
- Availability of affordable housing options (with relatives, residential settings, or apartment buildings)
- Dedicated staff assigned to nursing homes to work with residents
- Availability of funds to cover special transition needs

Medicaid provides states with a range of options to develop these components, but the extent to which they are available depends on policy and funding decisions at the state level. However, once the policy and funding decisions have been made, the critical factors in determining whether someone leaves a nursing home is the availability of a social worker or registered nurse to work with the residents who are interested in moving.

NOTE

1. Caseload and spending figures were provided by the Washington Aging and Disability Services Administration.

Continuing Care Retirement Communities

60

As the older population increases in the United States, more and more congregate living options are emerging, particularly for persons who may need some combination of housing with social support and health care services readily accessible. Continuing care retirement communities (CCRCs) are one such option.

An earlier term, *life care community*, is often used synonymously with CCRC. Conceptually, life care dates back to the convent tradition in which persons gave their worldly possessions to a religious order in exchange for being cared for throughout their lives (Somers, 1993). “Among the precursors of the CCRCs were the medieval guilds, which were the beginnings of the postmodern attempt by self-reliant people, through prior contributions, to insure themselves against losses arising from death, sickness, injury, or old age” (Sherwood, Ruchlin, Sherwood, & Morris, 1997, p. 4). Although this chapter focuses on CCRCs in the United States, the CCRC concept is not restricted to this country. Hall (1999) reports on Gelderhorst, a Dutch CCRC for older deaf people. Carmon’s (1997) study of a 35-year-old CCRC in Israel provides insights into occupant needs. Moran, White, Eales, Fast, and Keating (2002) refer to providing “continuing care” in their work with assisted living facilities in Canada.

Between the 1980s and 1990s, the American Association of Homes and Services for the Aging (AAHSA) reported a dramatic increase (50%) in the numbers of U.S. CCRCs, with 40% located in five states (PA, CA, FL, IL, OH) (AAHSA, 2004, p. 1). Today, AAHSA estimates that 625,000 older persons currently reside in 2,030 CCRCs across the United States (AASHA, 2004, p. 2).

DEFINING CCRCs

AAHSA defines a CCRC as “an organization that offers a full range of housing, residential services, and health care in order to serve its older residents as their needs change over time.” CCRCs are typically structured as campus-like continuum of care environments, providing various levels of care. Typically, priority is given to residents in the CCRC when health care needs necessitate a change in level of care.

CCRCs offer different types of contracts that influence how residents will move between levels of care. AAHSA classifies these levels as (a) independent apartments or cottages, (b) assisted living, and (c) nursing care. It is estimated that 98% of CCRCs provide apartment-style living, 95% offer nursing care, and 81% provide assisted living or some other type of

intermediate step between independent apartment living and nursing care (AAHSA, 2004, p. 2). Typically, nursing care is offered on campus, and CCRC residents are given priority admission over persons from outside the CCRC. Basic services such as meals, maintenance, transportation, and on-site laundry, hairdressing, and even limited shopping services may be provided (Sanders, 1997, p. 4).

CCRCs offer three types of agreements.

1. The Type A extensive agreement is a traditional life care contract based on paying a large up-front investment in exchange for lifelong care. Included without substantial increases in cost are housing, various residential services, and whatever long-term health care is needed. This agreement is similar to purchasing insurance in that the CCRC assumes financial risk for long-term care costs that are not covered by third-party payers.
2. The Type B modified agreement differs from Type A in that the CCRC does not assume full financial risk for long-term care costs. Still covered are housing and residential services, but only a limited amount of nursing care is covered without costs rising. Typically, a certain number of days in nursing care are allowed each year, but once those days are used, a daily charge occurs. For CCRC residents, there may be a discounted rate for the nursing facility that is not available to someone coming in from outside, but the CCRC assumes only partial risk beyond the costs reimbursed by third-party payers.
3. The Type C fee-for-services agreement also includes housing and residential services, but residents are guaranteed access to health care only if they pay prevailing rates. Thus, residents assume full risk for the costs of services they will need as they age in place.

Differences in types of agreements center around the high cost of health care. In Type A arrangements, residents may pay a substantial up-front entry fee because they are essentially buying a long-term care insurance policy and will receive whatever amount of health care they may need. In Type B agreements, the up-front fee may be less because access is guaranteed to only a certain amount of health care. Fee-for-service agreements have a much smaller entry fee because funds do not have to be put into escrow to cover the potential cost of health care for residents who need long-term care for lengthy periods (Sanders, 1997, p. 6).

CCRCs vary, some offering two or three types of contracts, depending on the plan a potential resident wants. Costs, therefore, can vary tremendously within communities, depending on the plan selected, as well as across communities. The American Association for Retired Persons indicates that entry fees can range from \$20,000 to \$400,000, with monthly payments from \$200 to \$2,500. In some CCRCs, residents own and others rent living space (AARP, 2004).

Some Web sites list cost information, and others do not. Three examples of fees give an idea of what an accredited CCRC might cost. The Web site of Westminster Village, located in Spanish Fort, Alabama, reveals the following financial options available: "Return-of-Capital Plan in which entrance fees start at \$81,600 with monthly service fees beginning at \$1,331; this plan allows for 80% of the entrance fee to be refunded to you or your estate; Traditional Plan—entrance fees start at \$48,000 with monthly services fees also beginning at \$1,331.00; entrance and monthly fees are partially tax-deductible." The Web site of Pennswood Village, in Bucks County, Pennsylvania, reveals entry fees that range from a 504-square-foot studio apartment for \$78,700 with a \$2,194 monthly fee to a 1,470-square-foot two bedroom with den that has a \$265,500 entry fee and a \$4,271 monthly fee. An "all inclusive life care contract" is offered. And as a third example, La Posada, located in Green Valley, Arizona, offers independent apartments with entry fees from \$67,000 to \$287,500 and monthly fees of \$1,597 to \$4,111. There are garden homes with entry fees ranging from \$149,200 to \$209,700 and monthly fees from \$2,088 to \$2,806. There are assisted living suites with a nonrefundable deposit of \$3,500 and a monthly fee of \$2,886 to \$4,558.

Most CCRCs have a lump sum entry fee plus a monthly fee. Depending on the agreement, entry fees may or may not be refundable. If a refund is available, it may be on a declining scale, with less and less refunded as time passes. Full refunds are rare (Sanders, 1997, p. 7).

Winklevoss, Powell, Cohen, and Trueblood-Rapor (1984) in their landmark study of CCRCs found a great deal of confusion over the concepts of life care and continuing care. They carefully distinguished life care as those communities that offer Type A agreements (guaranteed health care) and continuing care as requiring residents to pay some or all of their own health care expenses. However, two decades later, the terms are still used somewhat interchangeably, making it important to clarify what is meant when one is talking about CCRCs and what services they provide.

REGULATION AND OVERSIGHT

Over the last 30 years, CCRCs have matured in their fiscal operations. In the late 1970s and early 1980s, there was a good deal of concern over CCRCs that were having financial troubles. Many of these communities were faith based and run with good intentions but limited financial or management savvy. The dilemma was that residents would purchase a Type A contract, move into the CCRC, enjoy all its amenities, and live a long time—longer than the actuarial tables might predict for a person aging in place in his or her home environment. As health care costs rose, residents were guaranteed long-term care by an agreement that put the CCRC at financial risk for rising costs. The CCRC, even if it had placed funds in escrow to cover health care costs, could conceivably have older residents who use long-term health care for many years without contributing more than a small monthly fee.

In addition, the life care concept was being embraced by real estate developers who saw the potential to target affluent elders as a market niche. As nonprofits were experiencing financial problems while their residents aged in place, requiring more and more costly services, for-profit developers were increasing. By the late 1980s, at least 20 states had enacted life care statutes, and another 10 were in the process of considering legislative action. As quickly as a statute was enacted, developers altered their terms and definitions to build communities outside the purview of legislative oversight. For example, statutes in the late 1980s began to use the terms “life lease” and “long-term lease” agreements (rather than “life care”) for Type B agreements (Netting & Wilson, 1987).

Studies of CCRC legislative activity (e.g., Stearns, Netting, & Wilson, 1989; Stearns, Netting, Wilson, & Branch, 1990) continued into the 1990s. Model state statutes were introduced, and the industry itself created quality care mechanisms. Sponsored by AAHSA, the Continuing Care Accreditation Commission (CCAC) was created in 1985 as a nonprofit organization “based on the belief that accreditation promotes and maintains quality and integrity in the aging services profession” (CCAC, 2004). Beginning in January 2003, the CCAC merged with the Commission on Accreditation of Rehabilitation Facilities (CARF), thus becoming CARF-CCAC and creating “an independent resource that will help consumers identify high-quality care providers—from children’s services to those for older adults” (CCAC, 2004). In 2004, there were 351 accredited CCRCs, with the following

five states having the largest numbers: Pennsylvania (67), California (49), Florida (29), Ohio (26), and North Carolina (16). Leadership from the Kendal-Crosslands communities in Pennsylvania, a group of Quaker facilities, was instrumental in establishing the accreditation process in its early days. Therefore, it is not surprising that Pennsylvania has the largest number of accredited CCRCs.

CCRC oversight is typically provided through state legislation and varies tremendously by state. Actual oversight may be typically delegated to departments of insurance and/or health and ranges from collecting basic disclosure information to more aggressive interaction. Simultaneously, the accreditation process is overseen by a nonprofit organization that has established standards and a review process that have been developed over the last 20 years. In addition, AAHSA annually publishes an industry profile, summaries of CCRC regulations by state, and consumer guides to CCRCs.

Much of the early research on CCRCs focused on their oversight and financial stability. However, over the last decade CCRCs seem to be becoming more financially stable. For example, by 1996, 86% of CCRCs were covering their debt service, up from 75% in 1993 (Pallarito, 1996, cited in Sanders, 1997). Oversight is still needed, especially for the few CCRCs that are poorly managed, but increasing financial stability has allowed CCRC researchers to turn their attention toward resident life, resident satisfaction, and quality of life, in addition to regulatory oversight.

RESIDENT POPULATION AND SPECIAL NEEDS

Residents who bought into early CCRCs had to have moderate to high levels of income, particularly in purchasing Type A extensive contracts, because entry fees can range into six figures. In the early days, when communities were focused on Type A contracts, there was concern that CCRCs were an attractive option but only for persons with means. In 1990, Bishop conducted an economic analysis to determine features of lower-cost CCRCs that might assist in targeting consumers with more moderate income and assets. She found that “CCRCs, especially those with lower costs, have the potential to make comfortable living environments and insured long-term care available to a wider segment of our elderly population, and to reduce Medicaid costs, insofar as they enroll people who would have spent down if they had entered nurs-

ing homes without the long-term care insurance provided by CCRC membership” (p. 75).

Somers (1993) and others see the CCRC as one of the most promising viable options for providing managed care for elderly persons. A 1997 study by the U.S. General Accounting Office (GAO) of 11 CCRCs in California, Maryland, Pennsylvania, and Virginia also views these types of communities as a form of managed care for elders. Nyman (2000) refers to CCRCs as representing “annuities that pay off in kind. . . . In addition to the annuity, CCRCs also provide long-term care insurance. Like an annuity, insurance enables an individual to make more efficient use of his or her resources” (p. 91).

Increasing studies on CCRC residents and their needs are appearing in the literature. For example, in 1990 Alperin and Richie surveyed CCRCs in Florida to determine just what services were provided in these communities. They found a good deal of variation, with some gaps in the continuum of care, particularly in the provision of more sheltered care. They advised elders who were considering moving to a CCRC to find out as much as possible about what is and isn’t provided in any CCRC they are considering as a retirement option.

DECIDING TO MOVE TO A CCRC

A number of studies have examined why older persons decided to move to a CCRC, as well as the decision-making process. Sherwood and her colleagues (1997) conducted one of the most comprehensive longitudinal studies of CCRCs, with approximately 2,000 residents in 19 CCRCs in four states (AZ, CA, FL, PA) with high numbers of these types of communities. They selected CCRCs with different types of agreements. They found that CCRC residents tended to be less racially and socioeconomically diverse than their age cohort in the United States. They also tended to be more educated, to be living alone, and to be older than other community-dwelling older persons. CCRC residents tended to plan ahead to access formal services rather than become dependent on their family or on informal support systems.

Sheehan and Karasik (1995) examined a cohort of 814 residents and 246 persons on the waiting list for a newly opened CCRC in the northeastern United States. Reasons for deciding to move to a CCRC for the majority of residents and applicants were primarily guaranteed health care, freedom from home maintenance, and supportive services. Results indicated

that decision making to move to a CCRC is a complex process, and for persons who were leaving a single-family home the decision appeared to occur over a long time period. Women were more likely than men to give safety, social opportunities, independence from family, educational opportunities, convenience to family, and loneliness as reasons for moving. They concluded by saying that “obviously, the salient reasons for moving to a CCRC vary among older persons. Of all factors, marital status had the most pervasive influence” (p. 120).

Identifying a panel of 92 older adults before and after their move to a CCRC in upstate New York, Moen and Erickson (2001) examined how residents framed their decisions to move into the CCRC in light of their life course, revealing just how different the decision-making process is for each individual. Whereas some persons were long term in their planning, others made the decision much more quickly. Persons with lower incomes were more planful in their decision-making process. Planning was associated with subsequent satisfaction once one was in the CCRC. Others moved to avoid a forced move in the future to a nursing home, whereas still others simply wanted someone else to take care of the burdens of home upkeep and maintenance. Some saw the CCRC as a way to avoid being burdensome to their children. Overall, Moen and Erickson (2001) reported that it is important to consider the move as a process, and their evidence suggested “heterogeneity of this process” (p. 66), underscoring the complexity also revealed in Sheehan and Karasik’s study of residents and applicants.

Moen, Erickson, and Dempster-McClain (2000) examined the same cohort that moved into the New York CCRC in terms of their social role identities. Because CCRC residents elected to enter age-segregated communities, the move was a change in which the realities of aging were present every waking hour and also meant downsizing from single-family homes and larger spaces. They examined how this move affected social role identities of residents and how they adjusted. Yet, “despite the similarity in socioeconomic status and residential environment, [there was] considerable variation in [residents’] social identities” (p. 575).

Krout, Moen, Holmes, Oggins, and Bowen (2002) examined why 91 residents moved to a CCRC in upstate New York. Residents were primarily concerned about what they would need in the future and how that future would be secure. In this particular CCRC, its location in a college town allowed younger occu-

pants to participate in cultural activities in the larger community. Not wanting to be a burden on one's family was an influence as well. Some reasons for moving differed by sociodemographics such as age, marital status, and gender. One caution was that the residents of this CCRC were financially secure and could afford the CCRC lifestyle, a finding underscored by others who have studied the industry (e.g., Sherwood et al., 1997).

LIVING IN THE CCRC

Researchers have examined what happens once the move is complete. Out of concern about whether types of housing designed for elders actually addressed their needs, a group of studies emerged in the 1960s and expanded in the last few decades. Known as the postoccupancy evaluation (POE) school, three characteristics defined this approach: (a) It is important to know what occupants think about their environment, (b) it is necessary to examine the context in which residents live after they have had time to settle in, and (c) the purpose of evaluating postoccupancy is to solve problems rather than advance theory (Carmon, 1997, p. 65).

Falconer, Naughton, Hughes, Chang-Rowland, and Singer (1992) examined moves that occurred within a Chicago-based CCRC as residents aged in place. Using a two-year longitudinal design, the functional status of 152 residents was assessed at enrollment. They found that self-reported functional status may be helpful in predicting dependency that might require a move to a less independent level of care. Similarly, Newcomer, Preston, and Roderick (1995) studied residents in seven CCRCs in the western United States to find out how much assisted living and nursing home care might be needed during residents' tenure in the community. Using a retrospective resident history model, the authors found substantial variation among facilities in utilization potential, but that "between 50 and 70% of residents can be expected to use either (or both) during their tenure. These likelihoods increase the longer one lives in the facility, and they are lower in high-rise facilities" (p. 164). Long-term care products targeted to consumers of congregate settings and relationships among facility characteristics were also examined. They concluded that "facilities have different incentives to move residents to higher levels of care, depending on who and how much is paid for this care" (p. 166). An earlier study (Newcomer & Preston, 1994) revealed

that compared with other retirees, CCRC residents were less likely to use hospital services.

A 1996 ethnographic study by Perkinson and Rockemann focused on 20 older women living in a Pennsylvania CCRC. The voices of interviewees were featured in their thick description of the trajectory of friendship formation. Public spaces allowed residents to observe one another "from afar" as they assessed the potential for developing relationships, and congregate meals and informal groups provided initial interactions that were supplemented by more structured activities in which common interests could be shared (p. 174). It was observed that this younger CCRC (open only 20 months) changed in its interactions and friendship patterns as residents aged together in place. Strategies for developing friendships varied tremendously, and observations revealed that more private residents benefited from moving among tables to engage with different dining partners, for example, in order not to be socially "overwhelmed" by the communal lifestyle. Another observation was that informal caregiving supports for wives or widows did not always spontaneously emerge.

Krout, Oggins, and Holmes (2000) examined service use in the same CCRC reported previously (Krout et al., 2002). Most frequently, residents used services such as the onsite pharmacy, insurance billing, banking, and health and fitness. Not surprisingly, residents in poorer health were greater users of services within the CCRC. Sugihara and Evans (2000) looked at physical space in one CCRC in the Mid-Atlantic region of the United States to determine how social interaction and support networks might be facilitated or hampered. They surveyed 67 residents who had lived in this new CCRC for 18 months. Social support development appeared to be facilitated by having activity space close to residential units. Attachment to place appeared to be enhanced by having outdoor gardening available.

Spears (1992) described a Pennsylvania CCRC called Pennswood Village, a Quaker facility that opened in 1980. Spears's case study is written from the experience of a practitioner who has witnessed every phase of a CCRC's development. The detail in which she describes Pennswood, combined with the research reported previously, has implications for the social work role within these communities.

SOCIAL WORK ROLES WITHIN CCRCs

Early research focused heavily on the oversight of facilities that were developing under various auspices

but had not gained a solid financial footing in the retirement community industry. Today those questions are still relevant, as social workers and others work with or in CCRCs. In advising older persons who may be considering a CCRC, it is important to ask specific questions about the types of agreements that are offered, as well as the levels of care provided on campus. Within the context of the state in which the CCRC is located, it will be necessary to investigate whether CCRCs are regulated and what regulation means within that particular state. It may simply be that a state agency files disclosure forms, or there could be a monitoring process. It is also important to recognize that there are other regulatory bodies responsible for components within CCRCs, because assisted living is regulated in some states and may be called by a number of terms. Nursing units will be overseen by state inspectors, and long-term care ombudsmen should be available to CCRC residents, families, and others who might have complaints or concerns. The social worker will want to know this information.

Screening and assessment is an important social work role to be performed within the context of a CCRC. Boustani, Watson, Fultz, Perkins, and Druck-enbrod (2003) have looked at the acceptance of dementia screening in CCRCs. Wimberly and his colleagues (2003) conducted research in a Florida-based CCRC with the intent to examine what assessment tools might assist in determining who is eligible for independent living and who needs more sheltered care within the community. Screening instruments need be used so that residents receive the appropriate level of care and services “within independent, assisted, and skilled levels of care at the least cost and for the greatest period of time” (p. 78). CCRCs may have interdisciplinary teams that perform various entry screenings and baseline and ongoing assessments. Social workers would logically be members of such a team.

Making the decision to move from one level of care to another is probably one of the most difficult processes in CCRC life. Although persons who plan for the unexpected may move into CCRCs, this does not mean that they are ready to leave their independent living unit. The inevitability of a move may be met with a great deal of anguish, depending on the circumstances surrounding that decision. Social workers and other staff need to be sensitive to the symbolic nature of such moves. Even the term *independent living* is somewhat of a setup for the resident in that it reflects the larger societal image of what it means to be able to function on one’s own. In actual-

ity, most people are interdependent throughout their lives, but the symbolism in admitting that one needs assisted living or even nursing care is rife with emotionality. Social workers and other team members (e.g., nurses, physicians) will want to recognize the delicate nature of what it means to move to a different level of care for the person, as well as for their social system within the CCRC, and be prepared to provide appropriate counseling and support. Including the older resident and his or her family members in these decisions is critically important.

Just as decision-making processes occur within CCRCs, there are times when residents are subject to the nuances of the larger environment beyond the campus. Spears’s (1992) concerns at Pennswood are particularly relevant when she talks about how residents feel that CCRC staff should be able to help them navigate the larger health care system. CCRCs are not hospitals or rehabilitation facilities. Some have nursing units that are not skilled-level care. Thus, for residents who are thrust into the larger environment, CCRC staff may not have the authority or even the capacity to intervene. Social workers in CCRCs can play the connective role between systems when this happens. Even if they cannot solve problems encountered in the larger environment, they can advocate for the resident and connect with the appropriate case manager, social worker, nurse, or physician who can address the resident’s concerns.

And last, CCRC residents buy into their communities because they recognize that at some point they will need end-of-life care. Baker (2000) and Baker and Nussbaum (1997) focus on spiritual issues for CCRC residents. Hays, Galanos, Palmer, McQuoid, and Flint (2001) conducted a cross-sectional study of 219 CCRC residents to determine their preference for place of death. For 40% of occupants, death-related planning played a role in their decision to move to the CCRC. Most respondents preferred to die at the CCRC rather than in a hospital facility. Thus, social workers within CCRCs can ask residents about their preferences and have information on file so that when death or incapacity occurs, a person’s wishes will be known. Social workers can work with hospice programs so that their team can visit residents in CCRCs.

In sum, we provide a list of questions for social workers and other professionals to consider when they are working for a CCRC or interacting with residents who reside there.

1. What types of agreements are offered (extensive, modified, fee for service)? What are the costs?

2. What levels of care are provided (independent, assisted living, nursing, other)?
3. Are Medicare and Medicaid accepted in the nursing facility?
4. In this state, what laws and regulations are in place that affect the CCRC?
5. How is this CCRC structured (e.g., nonprofit, for profit, chain, etc.)?
6. Who started this CCRC, and is it affiliated with a faith community?
7. What is the physical layout, and how does that help or hinder resident interaction?
8. How and by whom are residents screened for entering the CCRC? Are standardized tools and procedures used?
9. What are the resident demographics, and how are resident needs assessed?
10. Is there a team approach to care, and who are the members of the team?
11. How are residents oriented and welcomed into the community? Are there strategies or mechanisms that facilitate adjustment?
12. Do residents interact across levels of care, and how are transitions between levels of care made? Who makes the decision when a permanent change from one level to another level is needed?
13. Should they need it on permanent or long-term basis, are CCRC residents assured a place or given priority in the nursing unit?
14. How do residents participate in community decision making, and how is that facilitated? Is there an active residents' council?
15. What role do staff play when residents go outside the CCRC to receive medical services, acute care, or rehabilitation services? Who communicates with providers in the larger community?
16. What information is collected on end-of-life concerns, and how are decisions made about end-of-life and spiritual care?
17. What role does staff have in hospice care?

QUALITY OF LIFE AND QUALITY OF CARE IN CCRC CULTURE

Quality of life and quality of care have been concerns of researchers interested in CCRCs. Several studies have focused on the relationships that develop within the CCRC culture and how these relationships affect the lives of residents.

Stacey-Konnert and Pynoos (1992) examined friendship and social networks in one CCRC. "A

CCRC may provide a milieu in which friendships can be maintained as an individual grows old. With age, however, residents may interact less frequently with friends outside the CCRC" (p. 299). They investigated the contraction of networks, using participant observation and structured interviews over a three-month period. Overall, residents appeared to have a sense of community; however, there were limits to types of assistance that might be provided. Persons who had more difficulty becoming integrated into the CCRC's culture were "residents with cognitive deficits, depression, physical health problems, or long-standing isolative patterns. . . . In addition, caregivers, widows, and the very old were also vulnerable to social isolation" (p. 309). Confidant ties to nonkin elsewhere stood the passage of time.

A qualitative study conducted by Williams and Guendouzi (2000) in a West Coast CCRC focused on residents' personal relationships and communication with one another, families, and younger people. Focusing on the lifestyle choice to move into a retirement community as one that involves "the dialectical tensions of autonomy versus connection associated with choosing and adjusting to this lifestyle" (p. 81), the authors interviewed 15 residents in relatively good health who had moved to a nonprofit CCRC designed for retired teachers. Residents had to cope with negative stereotypes about what a move to a retirement community meant to their self-identity and to their contacts with the outside community. Residents struggled with how to maintain their family life identity when they had opted to move in order to avoid being a burden to family members. A set of contradictions about peer relationships emerged in the process, as residents often made negative comments about peers who were not as able, distancing themselves from peers whose health had deteriorated, as though poor health and frailty were "catching." The increasing fragility of the peer network was reinforced by the proximity of the health care facility behind the dining room. "It may well be wise to prepare elders to confront these issues—a preparation that would aid adjustment—rather than shrouding them in a veil of marketing positivity" (p. 81).

Jenkins, Pienta, and Horgas (2002) studied two midwestern CCRCs to find out if residents remained involved in external community activities once they became CCRC residents. Self-administered surveys returned by 167 residents revealed that higher levels of activity were associated with better health-related quality of life. Not surprisingly, residents in independent living units within CCRCs participated more in

activities beyond the immediate campus, whereas once occupants moved to assisted living units, involvement in outside activities dropped significantly. A major reason for this drop is that residents had given up driving.

These studies demonstrate just how complicated close community life is. Certainly there is the potential for CCRC living to be a culture of care in which residents feel more secure in their physical environment. However, it is also close community living, and with that come the strengths and limitations of close proximity. The primary message in these studies appears to be that adjustment and integration into the community is different for each person as they set boundaries, establish their network, and seek to maintain ties to the broader community. Thus there is no one CCRC culture, but each CCRC's culture will be distinctive.

Potential residents should not only assess the culture of a CCRC being considered but also try to assess the "goodness of fit" with their own values and expectations. Likewise, social workers and other health providers must respect the wants and needs of residents as much as possible within the constraints of existing operating procedures and policies.

CONCLUSION

CCRCs have been part of the long-term care industry for many years. Many developed out of community concerns that older people needed a place where they could be more secure and have access to various services. In trying to put together a continuum of care in one campus-like location, CCRCs essentially spawned the concept of assisted living as an option between independent living and nursing home care. Obviously, assisted living has taken off on its own as developers have realized the importance of this market niche with a rapidly aging population in the United States. Yet, the numbers of CCRCs also continue to grow, many with multiple types of financial arrangements, offering menus of options to older persons. The flexibility of their financing options, the move away from offering only life care types of contracts, the recognition of different markets, and the targeting of persons with more moderate incomes have made the industry much more flexible in addressing consumer demands. For persons who want to travel, know that their home is taken care of, reduce their responsibilities in terms of maintenance and oversight, and perhaps feel that they have gained

a little control over life's uncertainty, the CCRC is likely to remain a viable option.

Assisted Living Settings

61

Assisted living (AL) is a term applied to a wide array of residential facilities for older adults. In the broadest sense, AL includes all group residential programs not licensed as nursing homes that provide personal care in activities of daily living and can respond to unscheduled needs for assistance (Kane & Wilson, 1993). In a more restrictive sense, it refers to the values underlying the manner in which that care is provided. Thus, AL has come to refer to both a *setting* of long-term care that combines housing and supportive services in a homelike environment and a distinct *philosophy* of residential care provision. The field of AL is a complex one, because as a setting of care, AL embodies a diversity of facility types, and as a philosophy of care, it espouses principles that are inconsistently in practice (Zimmerman, Sloane, & Eckert, 2001). To understand the distinction between setting and philosophy, as well as the current state of AL and the needs of its residents, it is helpful to consider the evolution of AL within the long-term care industry.

ASSISTED LIVING AS A SETTING AND A PHILOSOPHY OF CARE

Nonnursing home residential care for older adults was first recognized in the United States in the 1940s, as small “mom-and-pop” homes and later as senior housing (Morgan, Eckert, & Lyon, 1995). Over time, there was a growing awareness of a gap in the “continuum” of long-term care between residential settings that catered to older adults who had no functional impairments and nursing facilities that catered to the chronically ill. This awareness reflected the combined impact of growing numbers of older adults, a shortage of nursing home beds, increasing costs of nursing home care, the better overall health of new generations of older adults, and dissatisfaction with nursing home care (Bishop, 1999; Borra, 1986; Korcok, 1987). Thus, the need for a new model of care was recognized, a model that would provide an “invisible support system” in a residential setting (Sullivan, 1998). The utility of this concept drew investment from nursing home chains that saw the opportunity to use AL as a feeder for their nursing level of care, into which residents could be transferred as impairment increased. At the same time, market pressure created a stand-alone AL industry, intended to provide increasingly higher levels of care to enable aging in place and avoid nursing home transfer if possible (Mollica, 2001a; Thompson & Marinaccio, 1997). Over time, a diversity of residential settings that pro-

vide or bring in supportive services, including facilities otherwise named adult foster care, senior group homes, personal care homes, sheltered housing, homes for adults, board and care, and domiciliary care (among others), have come to be known as AL.

On a more purist level, AL is those facilities that embrace a philosophy of care explicated by the Assisted Living Quality Coalition. This coalition, formed in 1996, includes representatives of the Alzheimer's Association, American Association of Homes and Services for the Aging, American Association of Retired Persons, American Health Care Association/National Center for Assisted Living, American Seniors Housing Association, and the Assisted Living Federation of America. It has set forth 17 philosophies related to the quality of care and resident quality of life that are meant to be reflected in an AL facility's mission statement, policies, and procedures (Table 61.1).

The challenge in conceptualizing AL is that while the industry promotes goals of providing a homelike environment, independence, autonomy, and privacy,

the term is used by facilities that do not subscribe to this philosophy, and it is not always used by facilities that do (Hawes, Rose, & Phillips, 1999). The result is that there is no single accepted definition of AL or guidelines for how to operationally distinguish it from other forms of care. This controversy notwithstanding, there are an estimated 37,000 such facilities in the United States today, housing between 700,000 and a million residents (Golant, 2004). Given the history of AL, it is not surprising that AL facilities range from those in private, converted houses with fewer than 10 beds to those on multilevel campuses with more than 1,400 beds; that some AL facilities have private apartments, whereas others have four residents per room; and that rates range from less than \$400 to more than \$4,000 per month (Lewin-VHI, 1996). Further, between 38 and 49% of residents have a chronic heart condition (figures vary, depending on the type of facility in which they live), 15 to 37% are dependent in at least one activity of daily living, and 23 to 42% have moderate or more severe cognitive impairment (Zimmerman et al., 2003). This diversity in

TABLE 61.1. The Philosophy of Assisted Living

-
1. Offer personalized, cost-effective, quality supportive services in a safe residential environment.
 2. Maximize the independence of each resident.
 3. Treat each resident with dignity and respect.
 4. Promote the individuality of each resident.
 5. Protect each resident's right to privacy.
 6. Provide each resident the choice of services and lifestyles and the right to negotiate risk associated with that choice.
 7. Involve residents and include family and friends in service planning and implementation when requested by a competent resident or when appropriate for incompetent residents.
 8. Provide opportunity for residents to develop and maintain relationships in the broader community.
 9. Minimize the need to move.
 10. Involve residents in policy decisions affecting resident life.
 11. Make full consumer disclosure before move in.
 12. Ensure that potential residents are fully informed regarding the setting's approach and capacity to serve individuals with cognitive and physical impairments.
 13. Ensure that specialized programs (e.g., for residents with dementia) have a written statement of philosophy and mission reflecting how the setting can meet the specialized needs of the resident.
 14. Ensure that residents can receive health services provided as they would be within their own home.
 15. Ensure that assisted living, while health care-related, focuses primarily on a supportive environment designed to maintain an individual's ability to function independently for as long as possible.
 16. Ensure that assisted living, with its residential emphasis, avoids the visual and procedural characteristics of an "institutional" setting.
 17. Ensure that assisted living, with its focus on the customer, lends itself to personalized services emphasizing the particular needs of the individual and his/her choice of lifestyle. The watchwords should be "creativity," "variety," and "innovation."

care and the increasing levels of resident need have raised concerns related to the quality of care and spurred activity to regulate AL (Kane & Wilson, 2001). It is to these regulatory activities that we now turn.

ASSISTED LIVING REGULATION

The regulatory environment in AL is dynamic, with regulations continuing to evolve as AL emerges as an alternative to other forms of long-term care. Unlike nursing homes, there is no overarching federal regulatory body for AL; instead, individual states are empowered to define, license, regulate, fund, and oversee AL. Between the years 2000 and 2002, virtually every state addressed issues of AL regulation, doing so with regulatory models ranging from those that are highly defined and prescriptive with detailed criteria, to those that are broad and general, using criteria as nonspecific as “meeting resident needs” (Mollica, 2002). To further complicate the issue, approximately one third of states do not even use the term *assisted living* in their licensing regulations. Further, only slightly more than half of the states describe their philosophy of care as part of their regulations, with the language of some (e.g., Oregon) going so far as to include terms such as autonomy, dignity, and choice.

Models of AL Licensure

Overall, there are four models of state AL licensure: board and care or institutional, new housing and services, service, and umbrella. *Institutional models* reflect a more traditional board-and-care philosophy of AL, with minimal attention paid to matters such as privacy (e.g., the proportion of shared rooms and baths). In some states, this model prohibits the provision of nursing services and the retention of residents requiring them; in other states, nursing services are allowed for limited or even longer periods of time. In general, admission and discharge requirements relate to the level of support needed for activities of daily living and medical care. In total, in 2002, 11 states embraced an institutional model (Mollica, 2002). The *new housing and services model* of licensure specifies services that are defined by law or regulation, as well as the need for apartment-type settings, thereby differentiating AL from traditional board-and-care homes. The regulations are more flexible than those in the institutional model, by allowing retention of residents who are eli-

gible for nursing home services. Twelve states embraced this model in 2002, including Hawaii, Kansas, Oregon, and Vermont. The *service model* of care focuses solely on the services provided by facilities rather than the structure of facilities themselves; in many of the 16 states espousing this model, building requirements are covered by other state or local agencies in the form of building codes. Connecticut and Texas use the service model. Finally, an *umbrella model* of licensing covers a variety of housing and services with names such as residential care, congregate care, and adult care homes, as well as AL. The commonality of these states is that they allow for two or more types of housing and services, and among the 12 states (plus the District of Columbia) that have adopted an umbrella model are Florida, Maryland, New Jersey, and North Carolina (Mollica, 2002).

Four areas that have received notable attention within the regulatory models are the living unit, the residents (admission and retention criteria), staffing requirements, and services.

The Living Unit

The living unit is perhaps the most controversial area under regulation, reflecting conflict in policy requirements. Board-and-care homes meet minimal requirements, allowing for shared bedrooms and bathrooms. Regulations more focused on the AL philosophy, however, emphasize privacy and a homelike atmosphere and specify single-occupancy and apartment-style living (Mollica, 1998). When the U.S. Senate Special Committee on Aging recently convened an AL workgroup of 49 national organizations to develop guidelines for policy, regulation, and operations, there was no agreement on the need for private rooms because restricting the living unit in this manner was seen to have the unfortunate consequence of reducing consumer choice—an antithesis to the cornerstone of AL (Assisted Living Workgroup, 2003).

The Residents

Admission and retention criteria have a profound effect on the practice of AL. These policies define the client population and the limits as to which, and the mechanisms whereby, AL residents are allowed to age in place. Across the states, they range from no specification (e.g., Alaska, Connecticut, and Hawaii) to very specific exclusionary criteria, such as number of

activities of daily living with which a resident can need assistance (e.g., Illinois). The intent of these regulations is to restrict resident need to the services that the facility is able to provide or secure—although in some states (e.g., New Jersey), acceptable levels of need may be as high as those necessitating 24-hour nursing care. Discharge criteria may relate to general needs (e.g., for 24-hour nursing), health conditions (e.g., stage III or IV pressure ulcers), functional status (e.g., bedridden or nonambulatory), cognitive status, or behavior (Bentley, Sabo, & Wayne, 2003; Mollica, 1998). One motivation behind function as a discharge criterion relates to resident safety, as residents must be able to evacuate the building on their own in case of emergency. The field of AL allows for variability across facilities, however, and Pennsylvania facilities, for example, can admit nonambulatory residents if the facility can meet additional staffing, fire, and safety regulations (Mollica, 2002).

In reference to cognitive status, approximately three quarters of the states specify requirements related to serving residents with Alzheimer's disease or other forms of dementia. Kansas requires that facilities that admit residents with dementia train staff to treat behavioral symptoms, Louisiana requires that they provide an enclosed area next to the facility for wandering, Washington requires that facilities make special safety provisions to prevent elopement, and Missouri requires that the residents be capable of self-evacuation. Tennessee is unique in stating that facilities cannot admit or permit the continued stay of any resident in the latter stages of Alzheimer's disease (Bentley et al., 2003). Many of the regulations address issues related to special care units for residents with Alzheimer's disease and other dementias, as well (Mollica, 2002).

Behavioral problems are almost universally acknowledged in state regulations as prohibitions to admission or reasons for discharge, and they are commonly referred to as those that pose a danger to self and/or others, such as wandering, or are socially inappropriate. Also, the need for restraints is frequently specified as a prohibition against admission or retention. However, once again, exceptions are allowed: Ohio, for example, instead of requiring discharge, allows staff to have training on intervening with residents who display behavioral symptoms (Bentley et al., 2003).

The Staff

Residents in more than two thirds of AL facilities contract with home health agencies to provide nursing

care, and a similar number of facilities contract with hospice agencies (National Center for Assisted Living, 1998). Thus, considerations of AL staffing levels and qualifications reflect the expectation that nonfacility staff may be providing resident care. Similar to the variability in models of care and resident characteristics, staffing requirements vary across states. Of the 15 states that specify minimum staffing levels, requirements range from one staff person per 40 residents (Missouri) to one staff person per 6 residents (Alabama); instead of ratios, other states designate a minimum number of care hours (e.g., one hour per resident day in Pennsylvania). Most states have separate staffing requirements for waking and sleeping hours and do not differentiate among different types of direct care staff (National Center for Assisted Living, 2000). Among those states without minimum staffing levels or care hours, 15 require the presence or on-call availability of a direct-care staff person 24 hours a day, Connecticut and New Jersey require 24-hour registered nurse (RN) availability, and others require the presence of an RN when medicines are administered or other nursing tasks are performed. The majority of states require that staffing be "sufficient to meet the needs of residents in the facility," allowing facility managers to decide this level and the complaint and survey process to assure that it is adequate (Hodlewsky, 2001).

Many state regulations include requirements for administrator and direct care staff background and training, including minimum age, educational level, years of work experience, and licensure requirements. For administrators, the minimum age ranges from 18 to 21 years. Although several states require only a high school diploma or its equivalent, Connecticut requires that administrators have an RN, and New York requires a master's degree in social work (MSW). Half of the states require some form of licensure, certification, or competency. Training is variably specified, in terms of required topics or hours. For example, Missouri requires administrators to be trained in medication administration, and Ohio requires "100 credit hours of post-high school education in the field of gerontology, if the administrator is not a licensed administrator or does not hold a college degree." Fifteen states have requirements for experience, either in conjunction with or in lieu of education, and 31 require continuing education. Several states require criminal background checks. Requirements for direct care staff follow much the same organizational framework but are more modest (Bentley et al., 2003).

The Services

Services required or allowed under regulation include medical services (e.g., general physician, podiatry, dentistry, nursing), social services, and support services, such as barber or beauty services. In one study of more than 1,200 AL facilities across the United States that had at least 11 beds, 71% of facilities reported having a licensed nurse on staff (Hawes, Phillips, Rose, Holan, & Sherman, 2003); this number was lower (47%) in a study that defined AL facilities as those with as few as 4 beds (Zimmerman et al., 2005). In this more inclusive examination, on-site physician services were provided by between 43 and 72% of facilities, psychotherapy/counseling by between 25 and 78% of facilities, case management/social work by between 36 and 64% of facilities, and weekly exercise and social activities by 44 and 95% of facilities (Zimmerman, Eckert, & Wildfire, 2001).

In addition to services provided in the facility, third-party services (provided by entities other than the facility staff) are common. They may be contracted by the resident, the resident's family, or the facility itself. The two most common third-party services are home health care (e.g., skilled nursing, occupational and physical therapy, dietary consultation, wound care, medication management) and hospice. Both treat the AL facility as the resident's primary home and provide the same services they do to community-dwelling individuals. Regulations in 35 states specify that home health services be allowable, although there is again variability, such as whether services need to be of a time-limited nature (as is the case in Arkansas) or expressly not interfere with services provided to other residents (as is the case in Alaska and Delaware) (Bentley et al., 2003).

An Important Caveat

The existence of state-based regulation should not be taken to assume homogeneity within states with reference to the living unit, the residents, the staff, the services, or any other component of AL care. Instead, the criteria set forth by regulation set parameters for care, and providers have the latitude to structure and provide care as they see fit within those guidelines.

ASSISTED LIVING FUNDING

With the growth of AL and its provision of services to impaired older adults, there has been an increasing

trend toward the public subsidy of AL. In 1998, 32 states provided funding for AL services, a number that increased to 41 by 2003 (Bentley et al., 2003; Mollica, 2002). Methods of payment are diverse, with states providing payment as a flat rate (32%) or tiered rate (27%) or in accordance with care plans (24%) or resident case mix (<1%). In addition, three states combine two payment methods, one varies rates by region, and another negotiates rates. Twelve states allow room and board to be covered, but doing so constitutes an ongoing controversy (Mollica, 2002): Because AL is a residential setting based on a social model rather than a medical model of care, the implication is that room and board is a primary service; however, room and board traditionally have been (and continue to be) excluded from Medicaid coverage.

Specific reimbursement strategies for AL have evolved as the industry has developed. Private sources (i.e., resident and family funds) continue to provide the majority of payments (75%), with trivial additional amounts from long-term care insurance (<2%) and managed care (<2%) (National Center for Assisted Living, 2001). The remaining costs are covered through a combination of Medicaid waivers, state funds, and supplemental security income (SSI). The most common source of Medicaid funding is the Medicaid 2176 Home- and Community-Based Care Waiver (1915[c]). This funding is available to beneficiaries who would qualify for skilled nursing home care and meet the eligibility criteria of income less than 300% of SSI. Approximately 35 states have waiver plans in place, with some setting limits on the number of recipients (Bentley et al., 2003; Mollica, 2001b, 2002). Ten state plans also use Medicaid funding but do not do so through the waiver and have more lenient enrollment criteria: Recipients need not require skilled medical services and can meet more conservative financial criteria, such as receiving SSI or qualifying for Medicaid. The state plan is an entitlement, and the services must be provided to all beneficiaries who meet the criteria. States also may provide funds directly, often to supplement SSI beyond federal levels.

ISSUES IN ASSISTED LIVING

In a field as evolving and variable as AL, a multitude of issues are of interest to the social work community. The three addressed here relate to the quality of care: socioeconomic and racial disparity in access and quality; autonomy, negotiated risk, and aging in place; and recognizing and treating psychosocial needs.

Disparity in Access and Quality

Early board-and-care type AL primarily served low-income older adults who could not live independently and relied on Medicaid, SSI, or other state and federal government funds. As AL grew and the business community recognized it as a profit-making opportunity, a schism developed between modest facilities catering to residents of lesser means and more upscale AL serving residents able to afford substantial private-pay rates (Kane & Wilson, 2001). As a consequence, the AL industry is largely private pay and unaffordable for low- or moderate-income persons, and due to these economic and other social factors, the proportion of AL residents who are minorities is minimal (i.e., 46 to 71% of facilities have no African American residents). Most African Americans reside in smaller facilities in rural, nonpoor, African American communities, which score less well on some ratings of environmental quality. This separation may result from economic factors, exclusionary practices, or resident choice, and attention is needed as to whether there are inequities in the quality of care they receive (Howard et al., 2002).

Autonomy, Negotiated Risk, and Aging in Place

The philosophy of AL is to promote control and choice, yet doing so can be a liability to providers if control and choice impede resident safety. Negotiated risk agreements are signed agreements between residents and providers that expressly state that the resident chooses to accept certain risks associated with care in order to maximize preferences (e.g., the choice to not adhere to dietary restrictions or medication schedules). Although 19 states have incorporated negotiated risk as part of their regulation, they are met by objections from the nursing home industry because they reduce nursing home admissions (Mollica, 2001b, 2002). Indeed, when a resident chooses to accept that the AL facility is not able to meet his or her needs, negotiated risk agreements are a mechanism to promote aging in place. Balancing autonomy, safety, and quality of life in AL is an ongoing challenge, however, and one of definite interest to the social worker (Kissam, Gifford, More, & Patry, 2003).

Recognizing and Treating Psychosocial Needs

Between 23 and 42% of AL residents have moderate or more severe cognitive impairment, 13% are depressed,

and although more than 90% of residents participate in at least one social activity per week, those who are cognitively or functionally impaired do so less often (Golant, 2004; Watson, Garrett, Sloane, Gruber-Baldini, & Zimmerman, 2003; Zimmerman, Gruber-Baldini, et al., 2003; Zimmerman, Scott, et al., 2003). In consideration of the limited staff training requirements noted earlier, there is cause to believe that AL providers are not expert in the care of these conditions and that there is room for social work services in AL.

THE SOCIAL WORKER IN ASSISTED LIVING

Despite earlier reference to psychotherapy and case management/social work services in AL, by and large these services are not provided by individuals with a social work degree. However, given the levels of resident need and staff training, roles similar to those filled by hospital and nursing home social workers might similarly benefit AL residents.

When older persons face increased care needs, hospital social workers assist them and their family members in considering whether long-term care placement is indicated. This decision is not an easy one, as it raises competing values such as autonomy and safety. That is, group living by design places some restrictions on choice but at the same time increases safety by providing ongoing oversight. In AL, as prospective residents and their families first tour the facility, social workers can encourage them to address these feelings and values through active participation, collaborative decision making, and problem solving (Spano & Koenig, 2003). At the same time, the social worker might function in a role similar to that in nursing homes, considering whether the placement is an appropriate one and later helping residents make the transition into the new environment. In this regard, their ability to assess mental health needs and foster communication among the resident, family members, and staff in the development and implementation of resident care plans could be especially helpful (Ingersoll-Dayton, Schroepfer, Pryce, & Waarala, 2003; Kruzich & Powell, 1995).

These hospital and nursing home social work roles must be adjusted to the AL environment, of course. Whereas older persons often experience a medical crisis as a precipitant to nursing home admission (Borrayo, Salmon, Polivka, & Dunlop, 2002), residents in AL typically are less ill and disabled than those in nursing homes (Zimmerman, Gruber-Baldini, et al., 2003). Thus, these admissions are more planned and

less crisis-driven. They are likely to be motivated by a need for assistance with activities of daily living, general oversight, or increased social interaction or in anticipation of impending need among comparatively independent older adults. Also, the decision to seek AL placement is usually intended to be for an extended period of time, whereas nursing home placement may be transient during a period of convalescence. The skills that social workers possess that make them able to serve in hospital and nursing home settings position them well for AL work, and familiarity with the AL settings and the residents will enable them to provide services to facilitate decision making, transition, care, and ultimate quality of life.

In addition to recognizing this viable social work role within AL, note that some social workers who are not directly employed by AL settings already provide services to them and their residents and families, such as case managers for Medicaid waiver programs and hospital discharge planners who facilitate AL placement. However, these workers may not understand the variability of AL services and the overlap of these residents with those of nursing homes; as a result, they may not be as expert as necessary to provide optimal social work services. Consequently, there remains a need to consider the development of a true AL social worker. Unfortunately, the inherent challenge in this quest is to secure the financial buy-in of public entities and profit-making companies to support the work. Thus, a goal of AL research should be to determine the true utility of—and therefore have an impact on the future existence of—the currently fictional AL social worker.

VERA PROSPER

Adult Foster Care and Adult Family Care

62

The terms “adult foster care” and “adult family care” are used interchangeably (Folkemer, Jensen, Lipson, Stauffer, & Fox-Grage, 1996; Sherman & Newman, 1988). Both generally refer to “a service characterized by small, family-run homes that provide room, board, and varying levels of supervision, oversight, and assistance to individuals who are unable to care for themselves alone” (Folkemer et al., 1996). In defining foster care and family care, Sherman and Newman (1988) refer to “a private host family (or a single person) taking into their home a small number of adults (usually one to three, but no more than about six).” In their research, the concept includes “the provision of support services, supervision, and/or personal care”; and residents’ “participation in the life of the family (without infantilization of the foster resident) and in the community are encouraged.” Blanchette (1997) states that “adult foster care does not have a clearly defined philosophy like assisted living, but almost all states with adult foster care programs share the goal of providing services and care to residents in a family-like environment . . .” and “place an emphasis on maintaining a family-like atmosphere for residents.”

Providing housing, care, and supervision for adults in a foster family environment has a long history as an alternative to an institutionalized environment and was used as placement for dependent adults long before it was used for children (Sherman & Newman, 1992). “Opening one’s home to unrelated, dependent adults has been in operation for centuries in Europe”; and while “adult foster home care specifically for the elderly is a relatively recent development . . . Massachusetts officially began to operate a foster family care program for mentally ill adults in 1885” (Sherman & Newman, 1988). Despite its long history and the prevalence of homes, Reinardy and Kane (1999) note that “policymakers’ and practitioners’ knowledge about adult foster care . . . is scant.”

Elsie Fetterman, an advocate for adult foster care (AFC), called these homes an “invisible” option, suggesting that the variety of names given to this concept contributes to its low visibility as an identifiable alternative (Burns, 1996). Fetterman noted that the Veterans Administration calls the option “community residential care,” while others bundle AFC programs under terms such as “county home,” “board and care,” “geriatric foster care,” “shelter home,” and “alternative home.” In the Folkemer et al. (1996) national survey of AFC, 26 states reported having a fully developed AFC program, and an additional 8 reported having a limited program or an intent to de-

velop an AFC program. Program names included adult foster care, family care rest home program, adult family care homes, adult residential care home, family-life home program, the CARE program, project home, homes plus, residential facilities for groups, family-type homes for adults, certified foster home, and domiciliary care services for adults. Other terminology for the concept includes rest homes, personal care homes, individual residence alternative, Home-share program, sheltered care, and community residential care.

In recent years, the concept of AFC has expanded beyond those operated by families to include “non-family AFC homes,” which are owned and operated by nonprofit agencies, businesses, and corporations and in which the operator does not live in the home and is not the primary caregiver. These versions are emerging in response to the growing number of elderly people, as well as younger persons with a variety of disabilities, who are living longer and with more extensive care needs. Folkemer et al. (1996) did not disaggregate their surveyed homes by ownership (except for Oregon) but reported that 12 states authorize the provision of AFC in non-family-run homes. The authors note that an increasing share of AFC homes in three states (Oregon, Washington, and Minnesota) are owned and operated by businesses.

Although names, regulatory oversight, and public funding for AFC vary among states, enough similarities exist to enable placing family-based AFC in an identifiable housing-and-care category: (a) placement is available for clients age 18 and over; (b) clients are not fully capable of living alone and include frail elderly persons and younger individuals with physical impairments, developmental disabilities, or mental illness; (c) placement is in the home of the operator; (d) clients are unrelated to the operator; (e) the operator is the primary caregiver; (f) the number of clients per home is limited (primarily, between one and four or six); (g) care provided by the operator includes room and board, socialization, supervision and oversight, assistance with instrumental activities of daily living (IADLs), and varying levels of personal care assistance with activities of daily living (ADLs) but does not include skilled nursing or medical care; (h) the philosophical intent is to allow the client to maintain as much independence as possible within a family setting; (i) both private pay and various public reimbursement options are used for payment; and (j) programs operate within a public regulatory framework.

ADULT FOSTER CARE HOMES VIS-À-VIS OTHER HOUSING OPTIONS

The term “board and care homes” is also often used interchangeably with AFC homes. The definitions, as well as the types of residents and the level of services and care provided in each, are often similar. However, board and care is often a generic term for both licensed and unlicensed options, covering “a wide range of residential environments, sometimes including life care communities, congregate housing for the elderly, and what is currently known as assisted living” (Hawes, Wildfire, & Lux, 1993). In general, several features of board and care homes distinguish them from AFC: (a) There is great diversity in the size of board and care homes, with the number of residents ranging from 2 to 200 (Blanchette, 1997; Phillips et al., 1995); (b) Blanchette (1997) states that no consistent philosophy or approach to care characterizes board and care homes; and (c) Phillips et al. (1995) report that unlicensed board and care homes may be as numerous as licensed facilities and that while some homes are family- or individual-operated, more than 80% are operated by for-profit entities, with 33% of operators owning and operating multiple board and care facilities.

Over time, trends in demographics, public policy, and consumer markets have led to a blurring of definitional lines among housing options. For example, (a) in response to the burgeoning numbers of older persons, the variety of housing options for elderly people has increased significantly. These, too, are known by many names, including:

- active adult communities
- senior housing
- supportive housing
- congregate housing
- enriched housing
- assisted living
- retirement homes
- adult homes
- residential care facilities
- continuing care retirement communities

Two major characteristics distinguish AFC homes from these alternatives: size and residents’ functional status. Typically, these senior models house more than the four to six individuals seen in AFC homes, and a considerable portion of senior housing developments are meant for individuals who can live independently on their own. (b) As do AFC homes, shared living res-

idences, Abbeyfield Houses, and apartment-based shared housing programs house both elderly and nonelderly persons. They share the small size and physical space characteristic of AFC homes, as well as the administrative involvement of a community agency, the provision of supportive services, and, sometimes, live-in staff. However, unlike family-based AFC, these models are owned and operated by a community agency. Unlike business-owned AFC homes, these models are primarily not licensed to provide assistance with activities of daily living. (c) Group homes for persons of all ages with developmental, physical, or mental disabilities have proliferated in response to public policy changes, which have evolved in response to court decrees and consumer-won legislation that focus on housing people in community-integrated living environments in place of institutionalized facilities. Group homes share the size, licensure, physical-space, and service characteristics of AFC but are not family-based. (d) There has been a recent movement to create nursing homes that house seven or eight residents and emphasize resident empowerment and “living as a family.” They share the size, physical space, and regulatory oversight characteristics of AFC homes but provide the higher levels of care required of a nursing home, and the ownership is not family based. (e) Various states’ public policy strategies to contain the costs of long-term care have led them to consolidate previously distinct levels of care and housing under a single name, licensure category, and funding mechanism. For example, “assisted living” is sometimes used to encompass several housing options and/or service programs, including AFC homes. Tied to consolidation, states are increasingly turning to Medicaid home- and community-based waivers as a funding mechanism to increase flexibility and efficiency in long-term care service delivery. The AFC program, traditionally funded primarily through the Supplemental Security Income program (SSI), is sometimes included as a covered option under a state’s Medicaid waiver.

CHARACTERISTICS OF ADULT FOSTER CARE HOMES

Prevalence

The most recent national measure of AFC homes was conducted by Folkemer et al. in 1996. Sixteen states reported limited or no AFC programs, and eight states did not respond to the survey. Twenty-six states reported their number of AFC homes: One had fewer

than 100 homes, nine had 128 to 494 homes, five had 570 to 969 homes, and five had 1,334 to 2,160 homes. Oregon had 2,242 commercial homes in addition to its 1,500 family-based homes. Twenty-two states reported a combined total of 34,386 residents living in AFC homes. For the 16 states that reported both the number of homes and the number of residents, the average number of residents per home was 3.1. In Oregon, 9,396 persons lived in 2,242 business-operated homes, for an average of 4.2 persons per home.

Providers

Folkemer et al.’s (1996) study showed that 14 of the 26 reporting states allow only family-run AFC homes and that, generally, states require providers to reside in the home and provide 24-hour supervision. Adult foster care homes are located in residential areas, with more than 50% in rural areas (Sherman & Newman, 1988). Often, housing developers do not construct and operate multiunit housing for seniors and younger people with disabilities in rural areas because they find it financially unfeasible to develop a facility that is small enough for the limited population base in these areas. Using the existing homes of AFC providers for the targeted client size of one to six people makes AFC an ideal long-term care model for rural areas.

The primary objective of AFC is placement in a “family” environment and “to provide the best opportunity for enjoyment of normal family and community life” (Sherman & Newman, 1988). The authors report that fewer than 30% of providers consisted of a husband, wife, and children; another 25% consisted of a husband and wife with no children; 11% were a single parent and children; and the remainder were single persons, primarily females. As they note, in about 20% of the homes, the provider had no other family members in the home and it was the addition of the foster care client(s) that created a family.

In the growing number of business-owned AFC homes, services and care are provided by hired staff and outside agencies. Business ownership models include nonprofit agencies and for-profit businesses, single-home and multiple-home owners, and community-based owners and those based farther away.

Resident Populations

Adult foster care residents range in age from 18 to over 90, and the majority are female. They are character-

ized by varying educational levels; varying physical and mental status, including dementia; and varying marital status, although the majority are widowed or never married (Sherman & Newman, 1988).

Residents of AFC homes are typically deemed unable to live independently on their own; however, the functional profile of these residents varies significantly. Some require the social, interactive environment of living with others, others are mildly to severely physically or cognitively impaired, others have chronic mental health issues, and yet others are physically well but have lifelong developmental disabilities. In all states, AFC operators can serve discrete (age or functional status) or heterogeneous populations. Sherman and Newman (1988) cite Mor, Sherwood, and Gutkin's 1986 national study, which showed that more than half of surveyed programs served a heterogeneous population and fewer than half served only one client group. Folkemer et al. (1996) found overall population heterogeneity: In 11 states, the majority of all AFC residents are elderly; in 6 states, the majority are nonelderly; and in one state, half are elderly and half are not. Sherman and Newman's 1988 study of homes in New York State found that segregation of residents by sex was more pronounced than segregation by age, with most homes housing either all women or all men.

Longevity and relocation patterns among the general elderly population have resulted in residents in the various senior housing models being characterized by increasing age, greater functional impairment levels, and increasing incidence of dementia. As there have been few recent studies focusing on AFC, there is little information to indicate whether, overall, elderly residents in AFC homes are following these same trends. Some evidence is provided by Folkemer et al.'s 1996 survey, which pointed to the growing trend in business-owner models as a response to residents' higher service needs. Reinardy and Kane's (1999) work in Oregon provides further insight: They found that although AFC residents had significantly less disability, on average, than nursing home residents, the populations overlapped. However, if reimbursed by Medicaid, AFC residents in Oregon must be eligible for nursing homes. The authors also reported that private-pay residents had more disabilities than the Medicaid clientele.

Services

In addition to the room and board, 24-hour supervision, and assistance with IADLs and ADLs provided by

the operator, residents can utilize additional services from the wider community, such as day care, home health care, therapy, mental health services, transportation, medical equipment, temporary skilled nursing, and, in a limited number of states where nursing facility or Medicaid waivers are employed, intensive, ongoing medical and nursing care.

Folkemer et al.'s (1996) survey of the 26 states that license or certify AFC homes showed that (a) all applicants are assessed for eligibility, (b) 17 states require a care plan for each resident, and (c) 8 provide case management for all residents, 12 require this service only for publicly funded residents, 4 provide case management for some clients (for example, mental health clients, residents with intensive needs, residents with developmental disabilities), and 2 do not require case management.

Rules regarding medication administration vary considerably. In 6 of the 26 surveyed states, AFC providers are allowed to administer medications. Eighteen states prohibit administration of medication by providers but allow administration by appropriate community-based professionals such as a licensed or practical nurse, physician, physician's assistant, or a home health agency; will allow administration by the provider if the provider holds one of these licenses or employs a staff person with such a license; or will allow temporary administration by the operator, with a physician's approval, during a recuperation phase.

Some states specify conditions for resident discharge: for example, a provider may discharge a resident who has unmanageable behavior problems, is a danger to oneself or others, wanders, is unable to ambulate, is suicidal, is bedfast, refuses services, is unable to communicate meaningfully, has certain medical care needs, or needs skilled nursing or a higher level of care than the home can provide. Other states do not state specific discharge criteria but determine the need for discharge on a case basis by judging the capacity of the provider to continue meeting a client's evolving needs.

Staffing and Training

The majority of states with licensed or certified AFC homes require providers or a formally designated person to reside in the home and provide 24-hour supervision. Nighttime supervision need not be "awake"; however, a few states state that 24-hour awake supervision is required for residents in high-care categories.

Training required or given to AFC providers ranges from none to training to provide skilled nursing care (Sherman & Newman, 1988). Folkemer et al.'s 1996 survey confirms Sherman and Newman's conclusion, finding that while 21 of 26 states "indicated that some form of initial orientation or training was required for AFC providers and staff . . . no clear pattern on the scope and nature of the orientation and training emerges." Folkemer et al. (1996) cluster states by six approaches to training: Five states require an initial orientation and annual training, seven require initial orientation or training but no subsequent annual training, five require that the operator have experience in direct service and also require initial orientation and/or annual training, and two require no initial orientation but require annual training, two states allow training and experience requirements to be determined by local staff, and in five states, no training or experience is specified. When training is required, there is significant variation in the amount of training hours required, the training topics covered, whether training is formal or informal, and whether the provider's or staff's required training status must be a specific professional level, such as a certified nurse's aide, licensed practical nurse, registered nurse, and so on.

As more states bundle AFC into a home- and community-based waiver, training requirements and staff qualifications may increase. For example, in Oregon (Folkemer et al., 1996), which includes AFC in a waiver program, AFC can be a consumer's alternative choice to a nursing home. Foster home caregivers must attend 18 hours of preservice training plus 10 hours of training annually, and staff may perform nursing tasks if they are trained and certified by a nurse.

Regulatory Environment

There are no national standards for AFC (Folkemer et al., 1996). There are an unsubstantiated number of individuals, families, and entities who provide a living environment and care that are comparable to AFC, serving similar numbers and types of clients, but are not licensed or do not require licensure or certification. For licensed or certified AFC homes, regulatory oversight varies significantly among states. Amount and type of oversight continue to evolve, but no available data provide a current national picture. Folkemer et al.'s 1996 survey is the most recent national survey, but it includes information only from the 26 states that regulate programs that include *both* elderly and

nonelderly persons among the program's residents. States with programs that do not include elderly persons are not included.

A review of the 1996 survey shows that nine states used voluntary certification standards, which are applicable to homes that wish to be identified as AFC providers or be eligible for public reimbursement programs. Certification is typically provided by local social services or aging agencies in accordance with state-determined standards and rules. Homes that do not seek name recognition (as an AFC home) or public funding (instead, residents pay for care with private resources) can legally offer services comparable to AFC without certification, and state rules or standards do not apply to their operation.

In 1996, 14 states required that all homes must be licensed by the state, and 1 state drew a distinction between homes that served private-pay residents (no need for licensure until a home has two or more private-pay residents) and homes that serve public-pay residents (must be licensed if it serves one or more public-pay residents). In 3 states, larger AFC homes required licensure, but smaller ones required certification. Definitions of *large* and *small* differed among the 3 states.

Across the country, various county, regional, and state government agencies are responsible for licensure and oversight, including departments of aging, health, public health and environment, social services, welfare, human resources, human services, family services, mental health, developmental disabilities, veterans affairs, and division of medical assistance (Folkemer et al., 1996; Sherman, 2001). Required on-site inspections of homes vary, occurring every 2 months, 6 months, annually, 18 months, or 2 years. The oversight process varies considerably among states, as well as by the type of regulatory agency and the specific population group under that agency's jurisdiction (elderly persons, mental health clients, and persons with developmental disabilities).

Funding

Licensed and certified AFC homes serve both private-pay residents and publicly subsidized residents. The major source of public funds is the Supplemental Security Income program (SSI). Folkemer et al.'s (1996) 26-state survey shows that 12 states fund the program for income-eligible residents using only the SSI program together with a state supplement to SSI; 3 states combine SSI, an SSI state supplement, and Medicaid;

2 states combine SSI, an SSI supplement, Medicaid, and other state support; 3 use Medicaid and other state support; 2 use Medicaid only; 4 use various combinations of SSI and other state and local support resources; and 1 uses only the social services block grant. Use of Medicaid funds is through a Medicaid home- and community-based waiver or through a Medicaid state plan.

WHY CHOOSE AN ADULT FOSTER HOME?

The greater majority of older people prefer to remain living where they are, in their own longtime homes (AARP, 2000). The increasing age and frailty characteristics of older people who relocate into supportive housing environments, as well as the increasing role that adult children play in making relocation decisions for their elderly family members, provide evidence of that strong preference. In general, older people are adamant about not being a burden to family members, prefer an age-integrated living environment to an age-segregated one, desire maximized autonomy and personal choice during the later years, and strongly reject the rigid, impersonal environment typically associated with nursing homes (Prosper, 1990). An adult foster family home satisfies these strong preferences.

In a study of 260 elderly AFC residents in Oregon, more than 90% reported that supervision and safety and the homelike atmosphere were the most important reasons for choosing their current AFC home, more than 80% reported that privacy was an important reason, and more than 75% said the flexible routine of the home and the personal assistance provided were important reasons (Reinardy & Kane, 1999).

For individuals with mental illness who are being transitioned out of nursing homes and psychiatric facilities and hospitals, AFC homes are an option that can “facilitate the transition of dependent adults into neighborhoods and homes . . . reserving hospitals for the most ill and threatening patients and allowing patients to adjust to community living” (Rhoades, 2000). In describing South Carolina’s Homeshare AFC program, Rhoades noted that this AFC option can allow mental health clients to assume roles within the operator’s family structure, and community integration becomes the norm in place of the segregation and isolation characterizing institutional placements.

Professionals estimate that the majority of individuals with developmental disabilities never enter the formal services system but remain living at home,

with their parents as primary caregivers. They are experienced neither with living on their own nor with living in a congregate housing environment. As with other population groups, there is increasing longevity among individuals with developmental disabilities. Increasingly, their elderly parents are dying or becoming too frail to care for them. Adult foster care homes provide an option that closely replicates their previous living-at-home arrangement, allowing them to age in place in a setting that is environmentally familiar and manageable.

Role for Social Workers

In contrast to other health care professionals, the knowledge, skills, roles, and functions of social workers can be generalized across a great variety of work venues, including AFC homes. While there is limited measurement of the utilization of social workers regarding AFC, the opportunities to take advantage of their expertise and skills are great.

Sherman (1990) describes Kahana’s theory of person-environment congruence as a framework for understanding the extent to which a person’s well-being will be maximized. A person can be characterized by the types and degrees of her or his various needs and capabilities, and a living environment can be characterized by its capacity to appropriately meet these needs vis-à-vis the person’s capabilities. The personality, character, and ambience of AFC homes vary substantially because they are family-based. In reflecting the tenets of Kahana’s theory, this presents a significant opportunity to use the talents and skills of social workers to maximize the well-being of AFC clients. As agency caseworkers, social workers can perform the crucial screening and placement task of matching a resident’s “personality characteristics, social interests, personal habits, gender, race, religion, cultural factors, smoking, pets, children, location, mental health/psychiatric needs, rehabilitation needs, support service needs, medical needs, alcohol/drug problems, wheelchair accessibility” (Sherman & Newman, 1986) with the characteristics of the provider and the provider’s home.

Following placement, social workers can help residents make a successful relocation transition, create individualized care plans, provide ongoing case management tasks, make regular client site visits, act as residents’ advocates to assure needs are adequately met, act as liaisons between providers and social service and oversight agencies, and also act as liaisons be-

tween residents and their own family members. Social workers can assist both residents and providers during relocations from AFC into higher levels of care. In their academic training, social workers may specialize in a particular area, such as family dynamics, gerontology, substance abuse, mental health, or developmental disabilities. They are a valuable resource for educating and training AFC providers about the characteristics and needs of their resident populations and are an authoritative resource for providing specialized technical assistance when providers encounter a resident situation or circumstance they feel unprepared to address.

Social workers also perform regulatory oversight tasks, assessing the physical environment, the quality of staffing and care provided, and the well-being of residents. For AFC residents who are clients of the mental health and developmental disabilities systems, social workers are members of these systems' multidisciplinary care teams responsible for the placement and care of clients.

Older persons and younger persons with various special needs are living longer lives and, when impaired, living more years with those frailties. More of these individuals, and their caregiver family members, are seeking information and counsel about the various housing and care options available, as well as assistance in negotiating the relocation decision-making process and the actual relocation itself. In response, the field of "housing counseling" has grown and is primarily staffed by professional and paraprofessional social workers. The particular training and skills of social workers make them sensitive to the importance of facilitating the client's sense of control over relocation decisions.

CONCLUSION

AFC homes, as a community-integrated, small, family-based housing and care option, can satisfy the goals of several confluent happenings: (a) The U.S. federal court decision in *Olmstead v. L.C.* requires that people of all ages with disabilities be housed in the most appropriate integrated (into the community) setting possible; (b) the preference of most people is to live in noninstitutionalized, homelike living environments; and (c) public agencies are promoting the expansion of community-based housing and care options as a means of containing the growth in long-term care costs.

Sherman (2001) notes both strengths and weaknesses of AFC as a long-term care option. Strengths

include this option's informality, sociability, spontaneity, and familism; the meaningful role AFC provides for the provider; and the greater level of integration of this option into the surrounding community because the provider's private home is less obtrusive than multiunit housing or institutions. Weaknesses include the difficulty of monitoring these small homes, which are dispersed throughout the community; the widely varying staff-to-resident ratios among homes; and the inconsistent level of professionalism of the providers.

This chapter is dedicated to the memory of Susan R. Sherman, who was an extraordinary mentor and inspiration to me. Her voluminous work covering many areas related to older people contributed immensely to the field of aging. Her extensive research and writing regarding living environments for older people, including significant work on adult foster care, made her an acknowledged expert in this subject.

Congregate Housing

63

Congregate housing, broadly speaking, is a generic term that refers to a shared living environment in which a core set of services designed to enhance elderly residents' independent functioning is provided (Golant, 1992). As a generic housing type, it encompasses a broad range of supportive residential environments intended to fill the gap between traditional independent housing and institutional care (Monk & Kaye, 1991). Other terms used to describe congregate housing are "sheltered housing" and "enriched housing." Under this definition, there are many different models that reflect unique constellations of housing and services. Furthermore, these residential options have a variety of entry points through which older adults may receive supportive services (Golant, 1992; Heumann & Boldy, 1992). These different combinations of housing and services have many different names, including board and care homes, residential care facilities, adult foster homes, continuing care retirement communities (CCRCs), assisted living facilities (ALFs), and congregate housing. Congregate housing can also refer to traditional senior housing that has been transformed by (a) adding supportive services and/or a service coordinator (SC), (b) retrofitting existing housing, and (c) converting traditional senior housing to assisted living.

For the purpose of this chapter, we restrict the meaning of congregate housing to housing-service arrangements that combine an apartment-like independent living unit with services that do not fall under the medical model (Heumann & Boldy, 1992). This definition excludes residential care facilities, such as board and care homes, adult foster homes, adult group homes, personal care homes, and domiciliary care settings, which typically have more institution-like characteristics, such as either a private or shared bedroom and three meals a day. Using this definition, some states' assisted living models that follow a residential approach fit within these parameters, whereas others that follow a medical model do not (Schuetz, 2003). Table 63.1 provides a brief description of each of the housing-service arrangements addressed in this chapter. Although many options do not use the term "congregate housing," all fall within the parameters of our definition.

LEGAL AUTHORITY

Unlike federal or state programs that involve a single agency, congregate housing involves complex constellations of agencies and programs with responsibil-

TABLE 63.1. Congregate-Type Housing and Service Arrangements

<i>Housing-Service Arrangement</i>	<i>Description</i>
Federally assisted senior housing	
• Service coordinators (SCs)	Trained social service professionals working with elderly residents. Possible funding sources: HUD SC grants, project’s residual receipts, rent increases, AAAs, foundations, and other sources.
• Assisted living conversion program (ALCP)	HUD grant program to pay for costs of converting housing to offer assisted living services. Targeted to converting individual apartments, common spaces, and other areas to accommodate providing assisted living services. No funding for services.
• Congregate housing services program (CHSP)	HUD and Rural Housing Services (RHS) grant program that provides funding for SCs and partial support for support services. Both residents and housing sponsor or other agency must contribute to the costs of services. No “new” grants since 1995.
State assisted senior housing	
• Service coordinators (SCs)	Trained social service professionals working with elderly residents in state-subsidized housing. Funding through state housing agency, PHAs, AAAs, or other sources.
• Congregate service programs	Several states (e.g., New Jersey) offer congregate grants to housing agencies, such as public housing authorities (PHAs), to offer services to residents. PHAs link with local service providers who provide services.
State-subsidized congregate housing	Some states fund the construction of purpose-built congregate housing facilities for low- to moderate-income elders that offer core services (e.g., meals, housekeeping, transportation).
State-subsidized assisted living	Group residential setting with multiple levels of support service (both instrumental and personal care). In most states, Medicaid reimbursement pays for services.
Continuing care retirement communities (CCRCs)	Market-rate multilevel group residential living offering independent through dependent care. Residency is based on contractual arrangements. Some offer comprehensive, modified, or fee-for-service contractual arrangements.
Private congregate facility	Separate apartment units with core services for all residents designed to maintain independence
• Freestanding	
• Part of CCRC	Congregate services available either in designated units or as added services to independent living units
Private assisted living	Upscale residential communities that offer personal care (such as bathing), instrumental care, and some nursing services. AL varies across states.
Other “affordable assisted living”	Coming Home Program, from the RW Johnson Foundation, provides funding and technical assistance to states to develop affordable AL

ity for financing, construction, rental subsidies, housing management, and services. Agencies that may be involved include HUD regional offices, the state housing finance agency, the state housing and economic development agency, the state unit on aging, area agencies on aging (AAAs), the state home care program, public housing authorities, public health, social service agencies, nonprofit community organizations, and private developers or management companies (Schuetz, 2003). Depending on the individual state, type of program, and funding stream, regulations governing different types of congregate housing may entail federal (U.S. Department of Housing and Urban Development [HUD], Rural Housing Services,

Federal Housing Administration) or state housing agencies (state housing agency or state housing finance agency), fair housing laws (Fair Housing Amendments Act and the Americans With Disabilities Act), federal congregate housing services program (CHSP) guidelines, Medicaid and the Medicaid waiver program, and, when appropriate, state agencies responsible for regulating or licensing either the housing or the service components. No single oversight body is responsible for regulating or monitoring different types of congregate options. Overall, because of the sheer number of agencies, distinct missions, and operational styles of the housing, social service, and health care components involved in con-

gregate housing, the integration of housing and services is extremely difficult, particularly because no one is responsible for coordinating the housing and service components (Commission on Affordable Housing and Health Care Facility Needs for Seniors in the 21st Century, 2002; Evashwick, 2000; Golant, 2003; Natchison, 1994; Pynoos & Liebig, 1995; Schuetz, 2003; Sheehan, 1992).

Most states require some type of licensing or regulatory standards when congregate-type settings provide personal care and/or health-related services. However, the regulatory standards and agencies responsible for oversight (e.g., health, health and aging, elder affairs) vary across states. The oversight agency may, in part, influence whether the emphasis of the supportive service program entails a medical model or a residential approach (Schuetz, 2003). Some states require licensing the housing facility that provides personal care and other types of assistance; others license the service agency and specific levels of care (Mollica, 2002).

PREVALENCE

Although most elders (82% or slightly more than 21.4 million) live in their own homes, more and more elders live in some type of congregate setting. Of these, some have relocated from private homes in the community to reside in multiunit residential settings, such as congregate housing, CCRCs, and ALFs, and others reside in traditional senior housing complexes that have been adapted to provide services. Given the many different approaches to congregate housing, the complexity of funding mechanisms to provide services, and the overlap among many different types of senior housing, it is impossible to derive accurate statistics concerning the numbers of older adults who live in different congregate settings. One estimate is that slightly more than 4% of persons 65 years of age and over live in some type of purpose-built supportive housing (congregate care, CCRCs, ALFs, and board and care homes) (Commission on Affordable Housing and Health Care Facility Needs for Seniors in the 21st Century, 2002). Alternately, the Administration on Aging notes that approximately 5% of elders live in some type of senior housing, many of which offer services (Administration on Aging, 2003). For older adults, as age increases, the percentage living in some type of supportive housing increases. HUD estimates that 10% of seniors ages 70 to 74 live in some type of supported housing (shared housing,

supportive housing, or government housing with services), and 60% by age 90 (U.S. Department of Housing and Urban Development, 2000b).

For many seniors, the number of supportive housing options has grown rapidly over the past several years (AARP, 2003). However, for low- and moderate-income elders, the number of options may be limited (U.S. Department of Housing and Urban Development, 1999). Current estimates suggest that 1.3 to 1.7 million older persons live in some type of government-subsidized housing (e.g., public housing, Section 202 housing, Section 515) (Commission on Affordable Housing and Health Care Facility Needs for Seniors in the 21st Century, 2002; U.S. Department of Housing and Urban Development, 1999) with no guarantee that supportive services will be available. In contrast, older adults living in CCRCs, assisted living, and congregate facilities have ready access to services. Available estimates suggest that about 350,000 older adults live in CCRCs and approximately 900,000 elders live in assisted living facilities (U.S. General Accounting Office, 2004). Finally, most recent figures indicate that there are about 240 subsidized housing sites offering service under the CHSP (U.S. Senate, Special Committee on Aging, 2004).

STRUCTURE

The structure associated with congregate housing living arrangements presents an extraordinarily complex array of domains that categorize this option.

1. Type of housing (congregate, government subsidized, CCRC, or assisted living)
2. Physical characteristics of the setting (purpose-built or retrofitted, layout, size, etc.)
3. Housing finance arrangements (federal and state low-income tax credit programs, CDBG program, mortgage revenue bonds, Section 8, Section 202, Section 515, state funding, etc.)
4. Payment source for services (private pay, CHSP, Medicaid, Medicaid waivers, Older Americans Act, SC funds, social service block grants)
5. Service package, levels of service, and state regulations governing service delivery
6. Nature of the formal and informal relationship between the housing and service components
7. Eligibility criteria for services (strict versus more general criteria)
8. Affordability (market rate or subsidized)
9. Staffing patterns

Consequently, a myriad of housing-service arrangements can be considered congregate housing.

Not surprisingly, there is a wide variety of staffing patterns among the different options. Although all congregate-type arrangements typically have a person responsible for the management of the housing (admission, rent, etc.), the availability of other staff varies as a function of several factors: (a) source of funding (e.g., CHSP, HUD SC grants, residual receipts, self-pay), (b) ingenuity of the housing manager, and (c) colocation of services. A significant number of housing options offer the services of a trained social service professional or services coordinator (SC) to work with residents, but many do not. For example, a national survey of Section 202 facilities conducted in 1999 reported that more than 37% of facilities employed SCs (Heumann, Winter-Nelson, & Anderson, 2001). In the absence of an SC, housing managers may act on behalf of residents to assist them in accessing services.

In addition to the services of an SC, other services that may be present include meals in a communal dining room, housekeeping, social and recreational programming, and 24-hour emergency coverage. Upscale, private-pay congregate facilities, including free-standing congregate facilities, CCRCs, and ALFs, provide a much more extensive array of support services and amenities. In many of these private facilities, multiple levels of services are available either as core services or as a fee-for-service arrangement. Affluent private-pay facilities may include an extensive array of services and amenities (health promotion and health screening, counseling, fitness programming, educational activities, wellness programming, escort services, transportation, shopping, cultural events, etc.), as well as on-site instrumental and personal care services. For government-subsidized housing, the service options vary widely from complex to complex. Some offer an SC to assist residents to access existing services, and others combine an SC with the provision of on-site or contracted services. For public housing, recent estimates suggest that 40% have on-site service staff (U.S. Senate, Special Committee on Aging, 2004). HUD has funded approximately 1,100 SC positions, but this number dramatically underestimates the number of SCs. According to testimony before the Commission on Affordable Housing and Health Facility Needs for Seniors in the 21st Century, an unofficial estimate puts the number of SCs in subsidized housing settings at more than 4,000 (testimony of Janice Monks, September 2001, cited in Golant, 2003). Finally, a small number of subsidized housing com-

plexes have received grants from HUD's assisted living conversion program to retrofit traditional senior complexes to better assist frail elderly residents. However, no funding is provided for the cost of services.

RESIDENT POPULATION AND SPECIAL NEEDS

Over the past 10 years, the age and level of frailty among older adults moving into congregate settings have increased significantly. The average age of elderly residents in subsidized and market-rate senior housing developments is approximately 75 and 77 years of age, respectively (American Seniors Housing Association, 2001; Heumann et al., 2001). Moreover, substantial percentages of residents in both market-rate and subsidized housing are in their 80s and 90s. Among older Section 202 projects, 39% of residents are over 80 years of age. Similar statistics apply to market-rate supportive housing options for seniors. The average age of residents in purpose-built congregate facilities is 80 (Golant, 1992). For many, the move to congregate housing may be precipitated by a critical life event, such as declining health, increased loss of vision, or death of a loved one, which limits the person's ability to be self-sufficient (Doherty & DeWeaver, 2002).

In comparison with other community-living older adults, residents in congregate-type settings tend to be older, female, living alone, unmarried, and have a smaller support network, although residents in the independent units of CCRCs are more likely to be married than residents in other congregate settings (American Seniors Housing Association, 2001). Of all residents, low-income persons in subsidized housing are particularly vulnerable or at risk. According to Golant (2003), "This group is often comprised of seniors in their 70s and 80s who have decrements in their physical and cognitive functioning and chronic health problems. . . . They may feel especially vulnerable because they are women living alone without reliable family assistance" (Golant, 2003, p. 22). It follows that residents in federally subsidized housing are especially "at risk" for nursing home placement (Wilden & Redfoot, 2002). A significant percentage of residents in federally assisted housing confront difficulties in carrying out essential activities of daily living. Golant (2003) reports that about a third of residents in government-subsidized housing need assistance with at least one activity of daily living (either instrumental or basic) and 5% experience limitations

with three or more ADLs. Figures reported by the Commission on Affordable Housing and Health Care Facility Needs for Seniors in the 21st Century (2002) for government-subsidized housing indicate that almost 470,000 elderly residents have difficulty in performing ADL or IADL activities and 163,000 have a mental disability.

SOCIAL WORK ROLES: HISTORICAL AND CURRENT

It is generally recognized the older adults prefer to age in place in their own homes. However, when that becomes impossible, the goal should be to age in an environment that is both homelike and provides necessary support. The fundamental roles of social workers in the congregate living environment address both of these needs. Social workers help to navigate the unclear territory between independent living in the community and the highly constrained lifestyle of the nursing home. The congregate housing model with its supportive services goes beyond the provision of basic shelter to smooth the continuum of housing options—from independent living without formal services in one’s own home to more supportive (and restrictive) environments like skilled nursing facilities. In this middle ground, service management by social workers or other professionals familiar with both geriatric assessment and the wide array of available supportive services becomes important. Congregate housing commonly incorporates this role within the housing-service package where it may be performed by social workers. Although the need for services by residents of congregate housing varies widely, more than 75% of assisted living facilities report admitting residents who experience at least some memory or judgment impairment, have a short-term need for nursing support, or require oxygen supplementation (U.S. Senate, Special Committee on Aging, 1999). These residents of assisted living settings may represent a more dependent segment of the congregate housing continuum; however, across the entire range of congregate settings, the need for services is common and will become more so as current residents age. The ability to add supportive services within a given residential setting is fundamental in reducing the likelihood of an additional move. This capacity allows older adults to “move on” with life rather than “moving out” (U.S. Senate, Special Committee on Aging, 2001).

Although the availability of social workers in congregate living settings is far from universal (Heumann et al., 2001), the activities and roles that they perform when they are present are wide-ranging. In part, this reflects the equally broad array of forms that congregate housing might take—from those settings that offer a fairly minimal service set to those that are characterized by a very rich service environment coordinated by social workers or other professionals. Because residents are not required to utilize any particular service offered within a congregate housing environment, social workers clearly recognize that they are working with voluntary clients who (appropriately) must actively participate in shaping their own service package. This brings to the forefront traditional social work roles of service mobilization, client advocacy, education, and empowerment. Social workers commonly provide help with transportation needs for health care, personal needs, and even discretionary activities like shopping or leisure travel. Social workers enhance opportunities for socialization for congregate housing residents by organizing programs such as workshops or classes in which residents may choose to participate. A very specific and especially important instance of such socialization programming involves welcoming new residents into the congregate housing community. The sense of “feeling at home” has been associated with successful relocation to congregate living environments (Young, 1998), and the importance of facilitating that emotional reaction to a move cannot be overstated.

Beyond these opportunities for personal enrichment and engagement, social workers in congregate living settings often arrange for or directly provide physical health screenings and psychosocial assessments. The social worker may well be among the first to become aware of a resident’s failing capacities or increased impairments, triggering the need for more comprehensive assessment to support clear care planning. In addition to the benefits of such assessment to the individual resident, regular and standardized assessment by a qualified social worker may also provide the basis for avoiding liability issues associated with failing to seek a higher level of care, should such become necessary for a particular resident (Hellman, 1990). When relocation from a congregate housing setting is required, it is often the social worker who works to develop an alternate care plan that is acceptable to the older adult and his or her family. Often, social workers are involved in communicating these needs to an older adult’s family. A myriad of other social work functions may be undertaken to reflect the

distinct characteristics of the particular congregate setting. For instance, in some, the community-organizing role may move to the fore as the worker seeks to organize and empower residents to achieve collective ends. In other settings, the worker may engage individual or group work skills to aid in achieving client goals. The common theme of these activities is to facilitate the older adult's adaptation to a complex and often demanding environment.

Inasmuch as these services may be offered by a professionally trained social worker, it is also true that services may be provided by a resident services coordinator. This is a position title that may or may not be filled by a trained social worker. Although some services like the coordination of transportation may be appropriately provided by staff trained at many different levels, others—such as a geriatric psychosocial assessment—should clearly be reserved for those with appropriate training. It has also been noted that an inherent tension or conflict may arise between housing managers and SCs (of whatever training) with respect to fulfilling the service roles for older adults (Sheehan, 1996). This conflict has been described as a clash between cultures reflecting the different service perspectives of the two roles. When social workers assume responsibility for service coordination, it is important that they bring their understanding of intraorganizational stresses to bear in developing supportive working relationships with housing management colleagues.

Unfortunately, there is little in the professional literature that speaks directly to the roles that social workers fill in congregate housing. Beyond the journal literature, a review of six texts that are commonly used to train social workers in social gerontology and practice with older adults indicates that while five of the six explicitly acknowledged congregate living programs—at least briefly—none provided significant guidance for the social work student or practitioner regarding specialized practice in that setting (Atchley & Barusch, 2004; Hooyman & Kiyak, 2002; Kart & Kinney, 2001; McInnis-Dittrich, 2002; Schneider, Kropf, & Kisor, 2000; Wacker, Roberto, & Piper, 1998) beyond acknowledging the beneficial effect of activity programming for most older adults. Generally, these training sources limited coverage to either a very short presentation of the policies supporting congregate living or an equally brief discussion of the importance of supportive services to the goal of “aging in place.” While Wacker et al. (1998) advise that the “typical” staff includes the building manager, janitor, and social/activity organizer, McInnis-

Dittrich (2002) suggests that “low-or moderate-income housing frequently have social workers on staff to provide a variety of services” (pp. 11–12).

A partial explanation for this limited focus on service delivery in congregate housing may be the housing “culture” that has developed in the United States. Housing policy in this country developed following a “bricks and mortar” approach, with services segregated in separate bureaucratic programs—most commonly health-related (“Bricks and mortar,” 1998). In addition, a societal emphasis on private homeownership has resulted in relatively modest attention by government or others to providing supportive services in congregate or other public housing environments (Schneider et al., 2000). Instead, the emphasis on providing long-term care services through highly institutionalized settings pulls service provision away from a more comprehensive housing policy that includes supportive services. As a result, public funding for services provided within congregate housing has been limited. For example, the CHSP provides some federal funding for services in subsidized housing; however, the program was never widespread, nor has it ever covered a substantial proportion of older adult residential settings.

Although there is limited empirical evidence describing the impact of successful social work practice with older adults who reside in congregate settings, there are a few studies of either SCs or social workers in congregate settings. One study examining the impact of SCs (who may be social workers) in subsidized elderly housing noted that SCs succeeded in developing new services for elderly residents (Feder, Scanlon, & Howard, 1992); a second study noted that SCs had a positive impact on frail residents' reported functional ability, social participation, and housing satisfaction (Sheehan, 1999a). Finally, an evaluation study of SCs in 20 Section 202/8 housing projects in 12 states concluded that the presence of SCs has resulted in earlier detection of frail or at-risk tenants (Schulman, 1996). Specific evidence of successful social work practice in a number of specialized practice applications with older adults who reside in congregate settings also exists. One of the earliest studies was conducted in public senior housing complexes in Boston (Lansperg, 1989). The research examined the impact of six social workers from the Boston Consortium for Health and Social Services deployed in 18 of the 35 public senior housing complexes to work with tenants and tenant organizations. Results demonstrated that after a relatively short time, the social workers “helped to empower tenants, change their attitudes, and increase

their activity” (Lanspery, 1989, p. 8). A second study addressed the loss of support that residents encounter. After observing the diminution of strong support for residents in the weeks following the death of a loved one, loss support groups were developed in a four-building, 420-resident senior apartment community (Ryan & Crawford, 2002). Participants were recruited individually to join closed groups of approximately 12 members. In addition to achieving the primary goal of coming to better terms with the loss that had been experienced, these groups also developed new friendship relationships and furthered the sense of community within the living environment.

A group work approach was also used to develop a heightened sense of empowerment and interpersonal relationships among residents of two low-income independent living complexes and one low-income assisted living facility (Cox & Parsons, 1996). Although active sponsorship of this group continued for seven months, a follow-up study done three years later found that the group was still meeting monthly. Such longevity speaks to the apparent value that these services bring to the lives of older adults.

If we look to the future, we are likely to find that the need for social work services in congregate housing will increase substantially for two fundamental reasons. First, the demographic reality that will prevail for the next 50 years will result in dramatically increased numbers of older adults needing supportive housing environments. Second, and perhaps even more important, older adults who are already residing in congregate housing environments will tend to become increasingly frail and service dependent. To be sure, evidence already documents an increasing utilization of services paralleling the increase in older and frailer residents in Section 202 housing (Heumann et al., 2001). As this transition takes place, it will be coupled with the continued goal to age in place. For some, this goal will no longer remain attainable; however, in the interim the increased utilization of services and their coordination and management by a professional social worker can help to actualize this important goal for the resident for as long as is appropriate.

FUNDING

Because we have defined congregate living to include programs that range from subsidized housing to “residential” assisted living facilities and CCRCs that operate on a private-pay model, the discussion of

funding must be equally broad. Funding for congregate-type housing options requires constructing a complex array of financing for the housing and services components. Previously, we noted some of the housing finance agencies and programs involved in creating housing with services arrangements. Funding for the service component involves a wide range of sources. In some instances, supportive services in subsidized housing result when the housing sponsor partners with local service agencies that provide discrete services (e.g., transportation, meals). This approach, however, entails a fairly low-level, uncoordinated approach. More formal service arrangements may include hiring an SC and/or providing supportive services, which may be paid for by different funding sources. For example, SCs may be funded through HUD grants, AAAs, CHSP grants, residual receipts from the housing complex, or rent increases.

Traditionally, HUD has been extremely reluctant to fund services in federally assisted housing (Sheehan, 1987). Although the Housing Act of 1970 authorized support for the construction of service spaces, such as dining rooms and kitchens, in public senior housing, no subsidies were provided to cover the cost of services (U.S. House, Select Committee on Aging, 1986; Sheehan, 1987). Subsequent legislation passed in 1974, while specifying the need for services in subsidized housing, provided no funds. Finally, by 1978, the situation was somewhat improved with the passage of the Congregate Housing Services Act, which authorized a small-scale demonstration project (CHSP) to test the cost-effectiveness of services in either public housing or Section 202 housing. The CHSP was made permanent under the National Affordable Housing Act of 1990; however, HUD has not solicited applications for this program since 1995. Although the funding formula for services has changed over the years, it currently is as follows: Federal grant funds pay 40%, housing sponsors or grantees pay 50%, and tenants pay 10%. Services include at least one meal a day, housekeeping, transportation, and limited health care. Throughout the United States, only 240 elderly housing complexes participate in this program (U.S. Senate, Special Committee on Aging, 2004). A long-term evaluation of HUD’s new CHSP and HOPE for Elderly Independence Demonstration Project (HOPE IV) concluded that most participants expressed satisfaction with the services. Further, residents receiving the services credited the program with maintaining their independence despite high levels of frailty (U.S. Department of Housing and Urban Development, 2000a). However, over the two-year

demonstration period, 25% of CHSP participants had relocated to a higher level of care.

In addition to modest federal support, different states have chosen to fund various congregate housing options (either congregate services or assisted living conversion programs) as alternatives to institutionally based long-term care. Although such involvement varies across states, these initiatives are designed to expand long-term care options (Wilden & Redfoot, 2002). For states that offer both programs, congregate service programs are easier to implement than assisted living conversion programs because, in most instances, they avoid the licensing requirements for assisted living (Shafer, 2001). As states struggle to constrain long-term care spending, more and more states are transforming different housing settings to offer assisted living with funding for services coming from state Medicaid waiver programs, and in some states, additional funding is provided by the state. Although early empirical evidence documented the feasibility of transitioning nursing home residents to congregate settings (Anderson, 1985), these “successes” may have reflected inappropriate placements of these people in overly restrictive environments rather than the actual legitimacy of congregate housing as a true alternative to skilled nursing facilities. In this case, funding for congregate housing might be better justified by the goal of enhancing the housing continuum explicitly, rather than as an alternative to any other vehicle for the delivery of long-term care. Future results from the nursing facilities transition projects funded by CMS, which are designed to move persons with disabilities out of nursing homes into the community, may be a better indicator of the viability of congregate settings as long-term care alternatives.

At the other extreme of program funding, a growing market has emerged for privately funded assisted living and CCRCs. Consistent with our definition; these programs offer individualized residential environments that are coupled with supportive services. Many assisted living facilities that had been developed in the last decade target an affluent market with prices that range to several thousand dollars a month for an apartment with a modest service package. Similarly, many CCRCs require a fairly substantial cash payment upon moving into the facility, coupled with ongoing monthly fees that are not insignificant. These housing options are important for more affluent older adults, but it is unrealistic to think of them as providing potential service options for the majority of seniors living at more modest levels. As a practical matter, the floor of the fee structure reflects capital costs for constructing these housing options and is

relatively fixed. There is little that can be done to drop the capital costs below a reasonable economic base. Increased production of these high-end housing products results in a more attractive but less affordable housing option (Moore, 2003). This appears to be the direction that most private market assisted living has taken. At the same time, however, states are looking to assisted living options as a strategy for curbing nursing home expenditures. Schuetz (2003) presents examples of how five states are developing models of affordable supportive housing.

QUALITY OF CARE AND QUALITY OF LIFE

Given the early longitudinal research in subsidized elderly housing that documented significant declines in residents' well-being, social activity, quality of life, and morale over time (Lawton, Moss, & Grimes, 1985), housing advocates have called for planned interventions in senior housing to enhance older adults' quality of life by either adding services to existing housing or constructing congregate-type settings. These interventions may be understood by the application of the Lawton and Nahemow (1973) ecological model, which posits a relationship between environment and older adults' competence and well-being. More specifically, the model assumes that there is an ideal balance between an individual's personal competence and the environmental press that he or she experiences. As we age and are more likely to have decreased competence as the result of functional limitations, the level of the environmental press must also be decreased for us to perform at our maximum levels. This is precisely the environment that is provided by supportive congregate housing. When basic and routine services are provided, time and energy are freed to engage in more fulfilling activities. When activities such as socialization are facilitated through convenient scheduling and location, a resident's limited store of energy may again be focused on the enjoyment of such activities rather than the mundane coordination of them. However, at the same time, if too many services are provided, there is a risk of encouraging dependence (Lawton, 1976).

Empirical evidence explicitly connects one's residence in the congregate housing setting with quality of life. One of the earliest evaluations of congregate services found that the availability of on-site staff and services seemed “to allay residents' fears regarding emergencies, illnesses, and disability in the future” (U.S. Department of Housing and Urban Develop-

ment, 1976, p. 246). The same study found that congregate housing had a positive role in fostering the maintenance of independent living for older adults.

Other early research, while documenting the positive impact of supportive services on quality of life, provides equivocal findings regarding its impact on social activity, particularly involvement in the broader community. On one hand, an eight-year longitudinal study of elderly residents in public senior housing with services noted that residents in housing with services tended to be more involved in various activities than older adults in noncongregate community settings (Carp, 1978–1979). This study also indicated a dramatic increase in club and hobby activity, as well as other independent activity levels. Continuity of previous friendships in the community and establishing new “close friends” within the CH environment have also been documented (U.S. Department of Housing and Urban Development, 1976). However, an early short-term longitudinal study comparing residents in congregate and traditional senior housing concluded that while congregate residents showed increased morale, housing satisfaction, and available social networks, their involvement in the broader community decreased (Lawton, 1976). More recent research examining the impact of adding assisted living services to congregate settings supports the benefits of increased services for the quality of life of residents who receive the services and also other residents, who feel a sense of relief knowing that the services are available if they need them (Sheehan, 1999b; Sheehan & Oakes, 2003).

In short, congregate housing settings offer an effective vehicle for the provision of the broad spectrum of supportive services that are commonly utilized by older adults seeking to maintain their maximum level of independent living. There is little doubt that the social work functions of assessment, service coordination, and service provision result in an enhanced quality of life for congregate housing residents. By having social work as an integral part of the congregate housing service package, the opportunity for early assessment and intervention is strengthened, and such early intervention may enhance the likelihood of living a full and satisfying life.

CULTURE OF CARE

As we have indicated throughout this chapter, the range of variation among congregate housing settings is wide; so, too, are the variations that must exist within the culture of care that is represented by these

housing and service options. Further, because the role that congregate housing plays in supporting older adults is continuing to evolve, the culture of care is necessarily dynamic. In such a context, the culture is not clearly articulated, and social workers find that they must define their role within a housing context. Furthermore, unlike in other settings with a formally defined role for social workers, social workers may often find that they are negotiating their role in the context of a particular housing setting. As a result, the culture of care in a congregate setting may vary as a function of the type of housing, the needs of the residents, the negotiated roles between the social worker and housing director or manager, and expectations. Therefore, in the absence of clear guidelines addressing the operational linkage and coordination between housing and services, social workers (and housing personnel, too) may encounter many areas of confusion as supportive services are added to housing.

Still, however, there are important dimensions that establish parameters on the culture of care within congregate housing and shape social work practice within that setting. Moreover, each of these is consistent with social work practice. First, residents of congregate housing function with high levels of *autonomy*. As service consumers, these older adults are able to make autonomous decisions about receiving or refusing services. Beyond the foundational respect for autonomy, the service-housing package that is represented by congregate housing is designed to maintain and enhance residents’ *independence*. Although independence is probably never complete at any point in human development, the desire to maintain one’s independence at the highest possible levels is a common goal for most older adults. Even when independence is compromised, the culture of care in congregate housing emphasizes *empowerment/self-determination* of residents in order to design service and support packages in a way that is most meaningful and comfortable for individual residents. These three dimensions—autonomy, independence, and empowerment/self-determination—offer a concise statement regarding the congregate culture of care.

As clear as this culture may be, unresolved issues do emerge. A number of these have been identified in a recent study examining bringing assisted living services into congregate housing (Sheehan & Oakes, 2004). Unresolved questions included

1. How much information about residents can be shared between the housing staff and the social worker?

2. Who determines the limits of when a resident with moderate to severe disability is no longer appropriate for the housing environment?
3. What safeguards are in place for assuring the right of residents to refuse services?
4. What are the limits for the number of residents who can be assisted by the social worker?

As issues such as these are further explored and resolutions are reached, congregate housing will continue to develop as a residential and service option for older adults. As it does, the increasingly comprehensive integration of supportive services within the context of personal housing will continue to provide a rich opportunity for the further development of the role social workers can play in empowering older adults to maximize their fullest potential.

FREDDA VLADECK

Residential-Based Care: New York's NORC-Supportive Services Program Model

64

The demographic changes we are experiencing and will continue to experience for years to come are producing significant changes in the makeup of many American communities. Never before in this country's history have older people constituted so large a proportion of the residents of so many communities. With people over the age of 65 expected to reach 20% of the population by the year 2030, concentrations of seniors will be living in their homes of long standing in most age-integrated communities across the country. And yet most policy discussions about housing and supportive services for older people focus on the small segment of the population living in residential care—facilities created and dressed up to look homelike.

At the same time, we have been stuck in a service-delivery paradigm that may not fit today's older population and the communities in which they live. Instead, we have been piling one categorical program on top of another to address individual needs one hip fracture at a time. Social work has been complicit in this effort, trying to fit its practice into a medicalized, reimbursement-driven construct rather than drawing from a basic tenet of social work—"Start where the client is at"—which in most cases is in the communities where they raised their families.

Age-integrated neighborhoods that for whatever reason (aging in place, in-migration of older people, or out-migration of younger people) have a high proportion of residents over 60 have come to be called naturally occurring retirement communities (NORCs). These are distinguished from purposeful retirement communities to which older people move in search of care or even a different lifestyle, such as continuing care retirement communities (CCRCs) (chapter 60) and assisted living (chapter 61).

The opportunity presented by the graying of most of America's communities—to rethink how, when, to whom, and where older people are served—has to date been largely ignored. We keep doing more of the same when we need to start doing things differently. Common to many communities of mixed ages is the heterogeneity of their older residents themselves. Be they single-family homeownership communities, large private or public housing apartment developments, or garden apartment complexes, the older generation who live there—old and young, rich and poor—have constant back-and-forth changes in health status; possess a wide range of interests, skills, and talents; and have changing needs over time. Geographic concentrations of seniors give us the opportunity to reconfigure the service system in ways that

fit better with our understanding of aging as a dynamic process and not a one-way downward spiral. Our current service-delivery system, focused on individual deficits, is not designed to incorporate this understanding into a more balanced practice. It is at the community level that we will need to build the supports and systems necessary to support “successful aging” and respond more quickly and effectively to the changes older people experience.

This chapter makes the argument that we need to build coherent services within the communities where older people live so that we can have a different policy discussion from the one we’ve been having for the last 25 years. I begin with a brief description of the prevailing paradigm that governs community-based services for older people and the role of social work within it, quickly cataloging some of the major deficiencies with the current approach. Then I suggest a new paradigm that reflects today’s understanding of aging and move quickly to illustrating how this new paradigm is applied in practice in the 27 NORC-SSPs in New York City. I conclude by identifying some lessons and implications from this experience and its replicability to other kinds of communities.

SQUARE PEGS IN ROUND HOLES

Designed at a different time, Medicare, Medicaid, and the Older Americans Act are the foundations for the myriad programs and services that have developed since 1965 to meet the needs of a growing and changing older population. These public programs were enormously successful in addressing the problems of their era—providing health insurance to almost all seniors, health care and nursing home coverage for those unable to pay for it themselves, and a nutritious meal in a social setting for the numerous seniors who were malnourished. Over the years, we have reacted to each new issue or problem by looking to the structure of one of these three programs to legislate or construct a new coverage policy or service response with the limited dollars available. The most recent example is the family caregivers support program, the latest addition to the Older Americans Act. Each add-on has its own set of complex rules, target population, limits, and regulations that providers and consumers must learn to navigate.

Often, access to a service under these three programs is reactive, triggered by a medical event that brings the older person into contact with a health or social services professional after the fact. A case in point:

■ Mrs. Smith is 77 years old, a widow who lives alone. Her two children live more than 800 miles away. She has a fall, breaks her hip, and is hospitalized. During her stay it is discovered that her thyroid level is dangerously low. She is discharged home with intermittent home care covered by Medicare and home-delivered Meals on Wheels from her local senior center so that she will have a hot meal on the days the home health aide does not come.

The prior year, Mrs. Smith had been a regular at her local senior center but 8 months earlier had stopped going. At the time, Mrs. Smith had no idea that she was having a thyroid problem. She just hoped nobody else saw that she was having a hard time keeping it together, and she did not want to go to a nursing home or have a stranger in her house taking care of her. The center staff had called her a few times to encourage her to return, and when they were not successful, they arranged for her to receive a weekly telephone reassurance call so that she would not feel isolated. Six weeks after she left the hospital, Mrs. Smith was discharged from Medicare home care, but the meals continued and telephone reassurance resumed. Her continued difficulty ambulating made it hard for her to get to the drug store to fill her thyroid prescription, leading to further confusion and decline. Six months later, after another fall and hospitalization, Mrs. Smith had become a daily Medicaid home attendant client. ■

While in the hospital after the initial fall, Mrs. Smith was assessed by a discharge planner (in the current environment, probably a nurse) to qualify her for Medicare home care services based on functional deficits and skilled care needs. The senior center social worker assessed Mrs. Smith for nutritional deficits under the Older Americans Act and qualified her for home-delivered meals and telephone reassurance calls—thus maintaining Mrs. Smith’s “connection to her community.” After her second hospitalization, when she no longer qualified for Medicare home care and it was clear that Mrs. Smith could not manage on her own and was now a discharge problem, a social worker was called in to “help” Mrs. Smith accept the need to apply for Medicaid. The social worker assessed the level of service needed, helped complete the application, and got the home attendant services in place.

In this case, each provider acted as an autonomous entity providing the contracted services from their fixed and limited armamentarium. These services might not be what is needed, but they are what the agencies have available. From the definition of her problem, the responses by the providers, the determination of eligibility for services, and the actual provision of services, Mrs. Smith and all her providers could be living on Mars. Other than assessing her for what functional deficits could be handled by a caregiver (if one exists), there is no connectedness to the community or web of social networks in which Mrs. Smith lives. Even those providers that describe themselves as community based may be located in the community, but they aren't really connected to the life of the community. They wait for the older person to self-identify or come to their attention as a result of a triggering event. Then, rather than fully assessing the strengths of the client in the context of her environment and marshaling the resources within it to provide calibrated supports and help return her to the role of a member of the community, the social work role has been reduced to a series of administrative tasks designed to qualify the client for services based on functional level and categorical need, coordinate the services, and then "manage" the case.

Gradually we are understanding that communities play a critical role in how well people age. Mobilizing at least part of those networks is often essential to delivering the kinds of services the client needs, and yet this function has largely disappeared from the social work role. "Community and neighborhood are important. So is the level of positive integration, neighborliness, looking out for others . . . which is . . . associated with higher life expectancy and better health," says Richard M. Suzman, associate director of the Behavioral and Social Research Program and the National Institute on Aging (Kilgorn, 2003). With the exception of a relatively small number of seniors whose social isolation is extreme, most older people live within a web of community, family, and social networks and are supported and provide support to others within these networks. Understanding that context is often critical to a complete assessment of a client. The common eligibility requirement that an older person must be homebound to receive services runs contrary to this imperative, serving to keep older people isolated behind their front doors, disconnected from the social fabric of their community, and stuck in the only role we have been willing to assign them—the dependent individual with a mass of needs.

REDESIGNING THE SYSTEM BASED ON THE COMMUNITY

Continuing to grow and learn new things, maintaining social connectedness, and remaining a vital and involved person in the world and surrounding community are as important to an older person's health as the public programs designed to treat or react to specific diseases or events. Our current categorical, event-triggered service systems have no way of incorporating this into their existing needs-based framework. To do so, we need to start in a different place—the community—redefining who is to be "served," what services are needed, and when and how they will be delivered.

In the new paradigm,

- Eligibility is determined by age and residence, not income or functional status.
- Health and social service providers are located on site, embedded in and accountable to the community.
- Clients have multiple roles as constituents, leaders, and consumers of service.
- Clients enter the system before a crisis through their other roles in the community.
- Comprehensive biopsychosocial assessment is based on the strengths of the individual at the time additional supports are needed.
- Additional service supports, designed to complement the public programs, are organized, utilizing the resources within the community.

Redesigning our service-delivery system based on such a new paradigm is rapidly becoming an imperative as the graying of America is happening in communities large and small, from dense urban neighborhoods and developments to sprawling suburbs and remote rural towns. Increasingly, neighborhoods and communities are becoming naturally occurring retirement communities (NORCs). Michael E. Hunt, a professor of architecture and urban planning at the University of Wisconsin, coined the term *NORC* in the early 1980s to describe neighborhoods and apartment buildings originally built for young families in which 50% or more of the residents are at least 50 years old (Hunt & Hunt, 1985).

By definition, NORCs cannot be built or developed. They evolve over time as a result of various phenomena. NORCs can emerge as a result of immigration when people at or near retirement relocate. A desire to live in warmer climates or closer to cul-

tural activities and other supports can be the impetus for some older people to relocate. The southern border of Texas is dotted with trailer parks that have sprung up as retirees from Minnesota and Wisconsin seek more temperate weather in their older years. Apartment buildings in revitalized sections of old urban centers have become magnets for retirees in search of lifestyle changes, including reduced dependence on cars for transportation and easy access to cultural activities. In a small town just outside New York City, older people are moving back from Florida—returning to the community in which they raised their families—so they can be closer to their children, who are now raising their own families in the same community where they grew up.

NORCs can also emerge in communities that have experienced a large out-migration of its younger people, leaving behind the older residents, who, for a variety of circumstances, cannot leave their homes of many years. Whole counties in rural farming and mining areas of the country have become NORCs, as the land ceases to support these livelihoods and the young migrate in search of employment. Neighborhoods in older urban areas can become NORCS as small manufacturing dries up or drugs and violence force out younger families in search of work or safer communities in which to raise their children.

However, the predominant evolution of NORCs results from the residents of a community aging in place. It is expected that many U.S. communities will become NORCs as the number of people age 65 and older, aging in place, continues to grow. Although more recent analysis is not available, Lanspery and Callahan (1994) identified nearly 4,500 census block groups across the United States as potential NORCs by using data from the 1990 census. And as far back as 1989, NORCs were recognized as an emerging phenomenon when an AARP study found that 27% of this country's older population lived in NORCs, which the study defined as age-integrated communities with large concentrations of seniors (AARP, 1992).

In many NORCs resulting from an aging-in-place process, its older residents are the pioneers who made these communities livable and good places to raise young families. They helped build the schools, playgrounds, and libraries; organize the nursery schools, after-school programs, and clubs that ensured a stimulating and safe environment in which children could grow; and wove together the social fabric of their communities by developing the mutual aid groups and formal and informal support networks necessary to help people manage their everyday lives. Few, if any, com-

parable opportunities and roles exist for older people in these communities that they helped build.

All NORCs—whether a result of in-migration, out-migration, or aging in place—differ from purpose-built senior housing or retirement communities in some significant ways. It is the only living environment that maximizes choice. Residents are free to come and go as they choose and to move in or leave on their own terms. There is no external entity or owner determining who can or cannot live in a NORC because there are no entrance criteria based on functional deficits. Conversely, the absence of an external entity or owner means that there are no exit criteria either. Residents are not forced to leave when they can no longer get to the dining room on their own, forget to take their medicine, or need help managing their finances or negotiating the world around them.

In the existing service-delivery paradigm, we react to individual residents' changing needs one at a time, disconnected from the very environment in which they live. If we continue with this approach, over time—as the balance in NORCs shifts to increasingly older and frailer residents—the social fabric begins to fray as connections are severed when residents die, are placed in facilities, or become homebound and locked behind their front doors. We can do nothing and passively watch these communities become undesirable places to live, where it appears that people are waiting to die, or we can take advantage of the economies of scale possible by such large concentrations of older people and redesign a delivery system that is responsive to the heterogeneity of older people with constantly changing needs.

SERVICE PROGRAMS IN NEW YORK CITY'S NORCS

One promising effort to redesign the service-delivery system has been under way in New York to rebuild the infrastructure in communities to help support older people as they age in place. Drawing on population-based public health principles and social work's ecosystems approach to serving older people in their environment, the NORC Supportive Service Program (NORC-SSP) model shifts the prevailing paradigm of aging services by upending the functional deficit-based programs and services we have elaborately constructed over the years to transform communities into good places to grow old.

The NORC-SSP model developed as a programmatic response to the aging-in-place phenomenon oc-

curing in many of the high-rise apartment buildings and dense communities across New York City. These are collaborative financial and programmatic partnerships between housing entities, the residents, health and social service providers, government, and philanthropy to organize and locate a range of coordinated health care and social services and group activities on-site in the housing complexes. The goal of these programs is to promote healthy and successful aging and provide calibrated supports as individual needs change.

Together, the partners assess the needs, interests, and resources in a community that help inform the design of the program. Eligibility for services and participation in activities is based on age and residence rather than on functional deficits or economic status. And, at the risk of stating the obvious, unlike in facility-based residential care, there are no exit criteria because these are people's own homes. Some of the tools that are utilized for individual service provision are the existing categorical and entitlement programs (Medicare, Medicaid, and services under the Older Americans Act), but, contrary to most service-delivery models, they are not the only ones. Additional supports and services are developed to support older people in actively managing and maintaining their health and well-being and to pick up where the public programs leave off, finding ways to reintegrate seniors into the life of their community once an acute episode has subsided.

The first NORC-SSP began in 1986 in a large 10-building moderate-income cooperative in the middle of Manhattan (Penn South Mutual Redevelopment Houses) built in 1962. Many of the building's original 6,200 residents were trying to remain active and busy, dreading the day when a fall or serious health problem might limit their ability to participate in community life. It also had its share of problems with confused residents wandering, losing keys, and forgetting to pay their monthly maintenance charge. Working with me, a social worker at a local hospital, the resident board of directors conducted a survey to determine the needs of its frailer residents and the aspirations of all its residents as they aged in place. This process led to the creation of the Penn South Program for Seniors, which was funded initially by philanthropy. Within several years, the program exceeded expectations, and the housing company became a financial partner, allocating funds from its operating budget for program support. The success of this model led to its replication in two other communities in 1992 and a growing recognition of its potential for other communities.

In 1995, New York State passed legislation creating the NORC Supportive Services Program Initiative with \$1 million (increased to \$1.2 million in 1996) granted annually to promote the development of 14 programs. Twelve are located in New York City. This was a pioneering effort by a state to create policy that would change how services for seniors are defined and organized, where they are delivered and to whom, and how they are financed. The legislation established thresholds for the senior population needed to achieve economies of scale in service delivery, defined the geographic boundaries of a naturally occurring retirement community, and established an ownership interest in the program through a public-private financing formula requiring a housing company's financial participation. In 1999, the city government allocated another \$4 million annually to this effort, which resulted in additional grants to the existing 12 state-supported programs and the development of 16 new programs. Modeled after the state legislation, the city's Department for the Aging modified some of the definitions to reflect the density of large housing developments in close proximity to one another and to increase the government financing role in these public-private partnerships (Figure 64.1).

There are now 27 NORC Supportive Service Programs in four of the five boroughs that make up New York City. Almost 46,000 seniors live in a mix of age-integrated developments. Programs range in size from a single building with 275 of its more than 500 residents over the age of 60, to a large, sprawling 12,000-unit complex of 171 different high-rise buildings in which 4,300 of its residents are seniors. Two programs are in two-story garden apartment complexes, with the remaining 25 located in high-rise apartment developments. Seventeen programs are located in moderate-income cooperatives in which the residents have an ownership interest, seven are in the public housing developments of the New York City Housing Authority, and four are in privately owned developments (two rental and two cooperative) for moderate- and low-income individuals.

New York City's NORC-SSPs are financed through a combination of public and private sources of support. Operating budgets range from a \$148,000 program to more than \$700,000 for a mature and multidimensional program. Government dollars (close to \$5 million in state and city funds) leverage matching funds from the participating housing entities (public housing is exempt), philanthropy, local fund-raising, and membership fees for activities. Specific in-kind supports provide much-needed resources for the

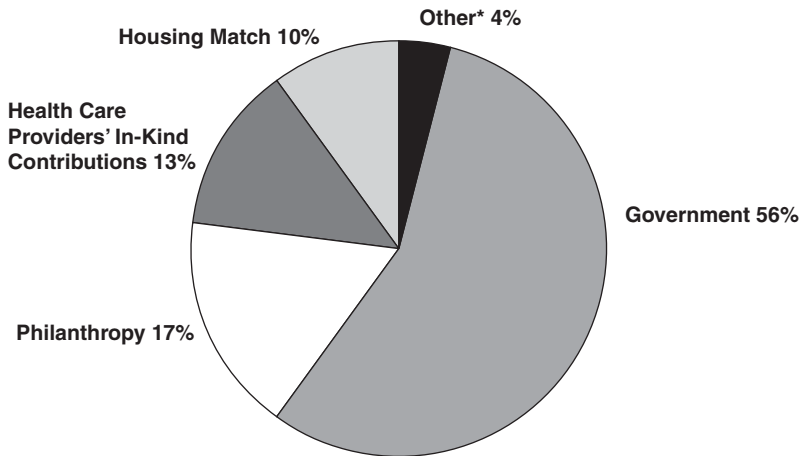

FIGURE 64.1. Funding for NORC-SSPs, New York City, Fiscal Year 2003–2004
 “Other” includes income from group, program, and membership fees; fees for NORC-program subsidized housekeeping, chore, and transportation services; local fund-raising efforts; and annual legislative grants.

NORC-SSPs. From the housing corporation’s provision of janitorial services and space for offices and activities, to the health provider’s provision of dedicated nursing staff time, the partners provide a range of in-kind resources that extend program operations.

NORC-SSP SERVICES

The structure of a NORC-SSP is predicated on the axiom that the sum is greater than its parts. It brings the diverse partners together to create a shared mission and vision of the program, establish a governance structure (including resident representatives) with accountability to the whole, and set forth the range of activities and services to be delivered. A lead agency (in most instances the social service provider) coordinates the work of the partners and provides the day-to-day management at each site.

Staffed by social workers and nurses, the NORC-SSP service design framework integrates four core elements.

- **Social work services** include information and referral; benefits and entitlements advocacy; assistance negotiating the systems and services available from the wider community; biopsychosocial assessment and casework support, case management, service coordination, and monitoring for changing status of clinically complex or fragile individuals; and education and support for clients, family members, and paid and unpaid caregivers.
- **Health care–related services** include individual care management to help seniors live with and manage chronic conditions and address acute situations; the provision of nonreimbursable but necessary monitoring, care coordination, and support to maintain frail individuals at home; physical assessments, regular blood pressure monitoring, and individual instruction; advocacy in negotiating the myriad health care systems; coordination with the primary care physicians and the on-site social workers; and health promotion, prevention, and wellness programs.
- **Educational and recreational opportunities** are diverse and designed to engage the broadest mix of seniors living in a community. Lectures on a wide range of topics, an array of classes, discussion groups, support groups, health chats with health care professionals—the list is limitless and often defined by the seniors themselves. Although organized and managed by the professional staff, many of the classes and activities are identified and led by the program participants.
- **Volunteer opportunities** make it possible for seniors to take on new roles in their community as program ambassadors, leaders, and program extenders in addition to that of consumers of service. Volunteers’ knowledge and understanding of their communities is instrumental in informing the planning process during a program’s formative stages, setting program priorities as programs evolve, and identifying the resources, talents, and skills within each community. There are more than

800 resident volunteers in New York City's NORC-SSPs, performing more than 42 different functions, ranging from the individual support services (reader of mail, mender of clothes, translator, escort, friendly visitor, and the like), to the provision of programmatic activities (discussion leader, teacher, peer insurance counselor, etc.), to the provision of administrative and development support (fund-raiser, librarian, receptionist, events organizer, writer and designer of marketing and communication materials, and statistician for community assessments).

Often additional services need to be developed to respond to each community's specific characteristics and to needs that change over time. Beyond the core service design framework just described, programs have the flexibility to develop additional supports and services tailored to the uniqueness of each community. Successful programs draw on the social capital within the housing community itself, as well as the resources in the larger community surrounding it. Quite a range of solutions to local conditions and issues result from the process of professionals and residents working together: Younger residents volunteer to provide transportation services in car-dominated or remote areas of the city, residents who are retired accountants and bookkeepers provide program-supervised daily money-management assistance in those communities in which many seniors have little or no family close by, on-site geriatric psychiatry services are leveraged from a local hospital in a significantly aged-in community, and local fund-raising efforts help subsidize emergency home care in a community with limited resources or access to in-home services. The range of additional responses and supports that can be developed gets broader as understanding (by both the professionals and the residents) grows regarding what is needed and wanted to make life better for older people in a community.

The NORC-SSP model relies on partnerships with the residents that stretch the roles and boundaries of the traditional and formal helping professional-client relationship.

In the course of a single day, a resident can be a client, a volunteer, and a partner with an ownership interest in the success of the program. As a client, she is concerned about her fluctuating blood pressure and so comes to the program every Tuesday for the nurse to check her pressure and review her medications to make sure she is taking them correctly. While there, she meets with a social worker to discuss her growing

concern about her husband's depression. Tuesday also happens to be the day that she volunteers by helping several legally blind older residents in the apartment building with their mail. When she comes back to the program office to report on her visits, she tells the director that the program needs to offer activities for those with low vision and that she intends to bring it up at the next advisory board meeting.

Building a partnership with the residents can be uncomfortable for professionals used to working in the traditional service-delivery paradigm. They must be willing to share power with the very individuals they are trying to help. In this model, the "helping" relationship takes on a new dimension in which residents are no longer clients who are acted upon but partners who have an active role in making their community a good place to grow old.

NECESSARY INGREDIENTS FOR SUCCESS

Based on the large number of programs in New York City and close to 20 years of programmatic experience, it is clear that successful development of a NORC-SSP requires different ways of working, at different levels, and in different roles than most social workers in the field of aging do today. At the macro level of community, social workers play a leadership role in assessing a community's assets (strengths) and gaps (vulnerabilities) on an ongoing basis; engaging a broad group of formal and informal leaders, constituents, health and social service providers, and other stakeholders in facilitating a community-wide discussion about their concerns and aspirations as people age in place; building consensus among the partners (each with their own objectives, language, and terminology) to define a shared mission with clear roles and responsibilities; and providing an environment that permits shared problem solving that encourages thinking outside the box, so each partner can contribute what it best has to offer. In essence, it is good old-fashioned community-organizing skills that are required to help a community pool its resources and work toward its vision of, or aspirations for, itself.

At the micro level of the older individual, social workers bring a multidimensional approach to addressing "problems arising out of disequilibrium between (*individuals*) and the environment." Moving beyond a deficits-based practice to plug the holes in functions that clients can no longer perform, social workers in NORC-SSPs utilize a strengths-based prac-

tice to help people at all functional levels remain engaged in and with the community, connect them to resources as needed, help negotiate systems and organizations, and “help people enlarge their competence and increase their problem solving and coping abilities” (Monk, 1986, p. 13). Professionals, skilled in biopsychosocial assessment and working in interdisciplinary social worker–nurse–volunteer teams, must be creative and flexible in this client-centered model.

DOES THIS KIND OF MODEL WORK?

The history of New York’s NORC-SSPs and the very principles on which they are founded suggest that current approaches to evaluation are themselves mired in the old paradigm of service delivery. At the city level, efforts to measure performance have focused on counting units of services (referrals, case management hours, etc.) that build on the data system of the city’s Department for the Aging, which has an entirely different agenda of formal accountability. At the state level, self-reporting efforts to measure outcomes have focused on the extent to which these programs have averted hospitalization and nursing home admissions to support the political desire to slow the growth of public expenditures on long-term care.

Neither of these efforts examines the extent to which the NORC-SSP model improves the quality of life for all kinds of older people living in a community. To do so, we will need to ask different questions that can measure the programs’ success in transforming communities, providing a supportive environment for older people at all levels of health and functioning in a variety of circumstances, and engaging communities themselves as active partners in making NORCs good places to grow old. We will need to understand the extent to which NORC-SSPs

- Provide avenues for older people to take on positive roles (versus the stereotype of old people as a mass of needs)
- Empower older people and promote civic engagement (versus people who are acted upon)
- Promote social connectedness and a reweaving of the social fabric as earlier connections fray (versus home care policies that keep older people locked behind their front doors)
- Develop an array of flexible and calibrated supports as needs arise (versus providing services one hip fracture at a time)

- Help older people feel secure in their community (versus not knowing how to get help when they need it)

Although we don’t yet have quantitative data on the assisted living and nursing home admissions of NORC clients to compare with residents of other communities, it is clear that many of the events that can trigger institutional admissions in other communities can, in most cases, be effectively addressed by well-functioning supportive service programs in NORCs. Such programs have developed the informal and intermittent networks of support needed to sustain frail older people at home and are skilled at mixing these supports with appropriate formal services to increase the sense of security people need to live out their days in the community.

If we are to more fully understand the potential of the NORC-SSP model, a systematic and comprehensive evaluation will need to be undertaken. Such an effort requires resources that are sufficient to develop appropriate tools and conduct the study. Absent such a commitment, descriptive information and anecdotes are the only sources for understanding the model. However, the AdvantAge Project of the Home Care Institute for Research and Policy of the Visiting Nurse Services of New York, while undertaken for different purposes, contains some useful approaches to evaluating the impact of NORC-SSPs. Seeking to measure the extent to which older people perceive their communities as “elder-friendly,” using a broad range of indicators, the project asked a representative sample of older people in a national survey and in each of 10 different communities how well their communities addressed basic needs, optimized physical and mental well-being, promoted social and civic engagement, and maximized independence for the frail and disabled (<http://www.vnsny.org/advantage>).

One of the 10 participating communities was a New York City public housing development that has a NORC-SSP. This was the only low-income minority community in the study, and the overall findings about the effects of race and poverty across a wide range of indicators (and how the program and the community are using the data to address issues of safety, hunger, and health) are quite compelling. But the most surprising finding was the extent to which older people in the Amsterdam public houses feel secure in their community. When asked if they know where to go and whom to call if they need help, 93% of the respondents in this community said they did (they’d call their NORC pro-

gram), compared with 76% of older people in the surrounding neighborhood.

LOOKING TOWARD THE FUTURE

Shifting paradigms is difficult. The system of services currently in place for America's older population, while highly variable from one place to another and frequently inadequate, is large, complex, and entrenched. The development and testing of new service-delivery models, based on the paradigm grounded in our richer understanding of the tasks in the later stages of life and the needs of older people, cannot proceed quickly enough. All sorts of efforts at developing new service models and elder-friendly communities are under way throughout the United States. In a number of retirement communities and "aged-in" neighborhoods in different parts of the country, residents are taking matters into their own hands, organizing, and developing programs and supports to make life better for themselves. Similarly, foundations and government are engaged with the professional and provider worlds in efforts to make communities more livable for older people.

New York's NORC-SSP model stands out for its scope, the number of different projects and communities involved in a single model, and the extent and duration of support from state and local governments. But what also sets the New York experience apart from all the others is the requirement that professionals and older people work together to design, develop, and maintain supportive communities, drawing on the expertise and resources each has to offer.

Communities come in all shapes and sizes. In New York City, the presence of a large number of moderate-income and public housing developments with large populations of older people who had aged in place presented a natural opportunity for the early development of the housing-based NORC-SSP model. The 27 programs currently in operation are predicated on the presence of housing management structures that define "community" and make it possible to organize a program and communalize part of the financing. Extending this model to other kinds of communities, such as those dominated by single-family homeownership, will require experimentation and systematic study to shed light on how to define the community and the elements it must possess in order to develop and support a successful program. Alternative vehicles or mechanisms (natural to com-

munities or ones that can be developed) will be needed to replace the pivotal definitional and organizational functions that build off New York City's single housing management structure. We will need to understand the minimum thresholds of community size, population, and geographic practicality below which the development of successful programs will not be possible.

Moving from abstraction to real-world application, efforts are already under way in New York City's northeast section of Queens to address these issues and develop a neighborhood-based NORC-SSP prototype. Based on what has been learned so far, New York State's NORC legislation is being modified to support the neighborhood-based model replication in similar communities across the state. A sufficient critical mass of programs in place will permit us to better understand whether the NORC-SSP model can be generalized to the more spread-out communities and neighborhoods that dot America's landscape.

Looking toward the future, demographic changes that will intensify the graying of America's communities in the coming years provide the opportunity to rethink public policy and service delivery for an aging and increasingly heterogeneous older population. We can continue to have the same discussion we've been having for the last 25 years about how to build and pay for the components of a long-term care system that targets individuals with deficits—the one-hip-fracture-at-a-time approach—or we can update policy and practice to reflect the reality of who the older population is and the world in which older people live. The fact is that the overwhelming majority of older people will remain living in their homes of long standing, with no entrance or exit criteria automatically requiring them to move as their care needs change. The challenge is figuring out how to rebuild age-integrated communities that have large concentrations of older residents into good places to grow old.

SECTION

**Assessment and Interventions With Older Adults
and Their Families/Caregivers**

This page intentionally left blank

OVERVIEW

This section of the *Handbook* is divided into three subsections. The first examines various facets of assessment; the second provides an overview of practice theories and models most relevant to work with individuals and families; the third takes a more macro perspective examining advocacy and empowerment models.

ASSESSMENT

In his chapter, Scott Miyake Geron examines the context of assessment, anchoring it in the heart and soul of social work practice. While talking about the process of assessment, Geron advises that geriatric social work consider the assessment phase as the commencement of a working relationship with a client and not an end in itself.

James Lubben makes a case for the development of valid and reliable short measures for geriatric social work practice. These abbreviated measures, which he defines as having no more than 10 items, can be practical screeners for risk factors as well as important tools for clarifying the relevance and importance of social health to the well-being of older adults. Rosalie A. Kane provides an overview of standardized measures used in geriatric assessment. Dr. Kane provides a critique of some of the traditional measures and offers suggestions for newer measures that should be considered.

THEORIES AND MODELS OF PRACTICE INTERVENTION

Kathleen McInnis-Dittrich describes a broad range of therapeutic interventions, ranging from the complicated process of cognitive restructuring to relatively simple behavior management techniques employed in some approaches to validation therapy. The interventions discussed in this chapter include cognitive-behavioral therapy, crisis intervention, and therapeutic validation interventions. The common denominator in these approaches is the focus on the older adult's thought process and how that process influences subsequent emotional and behavioral responses.

Therapeutic approaches to working with extended family and the power of the group process are the foci

of Roberta R. Greene and Joyce Riley's chapter. The authors acknowledge the importance of supporting the well-being of caregivers as part of an ecological and systemic approach to providing services to older adults. Family-centered case management methods for recognizing and alleviating the stressors involved in caring for an aging family member are described in this chapter. The authors include an in-depth discussion of the use of group treatment models for both older adults and caregivers.

M. Joanna Mellor discusses interdisciplinary team practice and its importance in providing comprehensive services to older adults. This approach is valuable for its ability to attend to the wide range of needs of the older adult, utilizing the expertise of physical and mental health professionals. Mellor identifies both strengths and weaknesses of this approach and illustrates through the use of a case presentation how a multidisciplinary approach is superior to any specific profession's approach in identifying both problems and solutions.

A psychodynamic approach to treating the emotional problems of older adults remains a controversial issue, as is illustrated in Denis P. Cronin's chapter. Although clinical social work remains deeply influenced by Freud's early dismissal of older adults as inappropriate for a traditional psychodynamic approach, Cronin makes a passionate case for the importance of the richness of this time in the life cycle for gaining deep insight and working through emotional issues. He discusses the significance of an older adult's struggle with conflicts over death, the therapeutic nature of transference based on age-related issues, and the unique challenges to the therapist in this process.

Reminiscence and life review are significant natural coping mechanisms and as treatment modalities can help older adults find meaning through reflection on their life experiences, according to Berit Ingersoll-Dayton and Angela Bommarito. Therapeutic reminiscence and life review focus on the older adults' processing and acceptance of early life events to improve emotional health and revitalize previously used coping skills. The authors identify the personality characteristics of older adults and the specific emotional issues that have been most successfully treated using these approaches.

Rosemary Chapin, Holly Nelson-Becker, and Kelley Macmillan explore how strengths-based and solution-focused therapeutic approaches can be used with older adults. Rather than focusing on deficits in be-

havior, both of these approaches identify an individual's strengths as they can be applied to problem solving and in using the richness of the solution envisioned by the older adults. These approaches focus on a strong empowerment approach, identifying what is "strong rather than what is wrong," a positive and energizing approach to working with older adults.

One of the most recent and popular approaches to working with older adults is that of recognizing and mobilizing an older adult's spirituality, described in the chapter by Holly Nelson-Becker, Mitsuko Nakashima, and Edward Canda. They describe in detail the domains included in a spiritual assessment of the older adult and the use of spiritually oriented helping activities. The authors offer a thoughtful discussion of what clinician and client characteristics are most appropriate for spiritually based interventions.

ADVOCACY AND EMPOWERMENT

Kevin J. Mahoney and Karen Zgoda illustrate the practice modality of client empowerment. The authors first provide an overview of the history of empowerment models in social work, grounding this modality in the context of practice theories. They then use the Cash and Counseling project as a case study to illustrate various facets of empowerment. Linda Krogh Harootyan and Greg O'Neill examine the practice of advocacy with and for older populations. Harootyan and O'Neill identify a number of advocacy groups, both large and small. Some, such as AARP, are well-known and broad-based, whereas others are more targeted and less well-known. Harootyan and O'Neill make a case that all are important to furthering the cause of aging policy and programs.

In the pantheon of social work accomplishments, assessment occupies a place of honor. Assessment can trace its pedigree to the earliest development of social work. As a distinct social work activity, assessment has its origins in the “scientific diagnosis” of the Charity Organization Society (Kunzel, 1995; Wenocur & Reisch, 1989). The lofty status of assessment in social work continues to this day. Any review of social work practice texts identifies assessment as a basic social work competency (e.g., Garthwait, 2004; Perlman, 1957; Pincus & Minahan, 1973; Sheafor, Horejsi, & Horejsi, 1988; Streat, 1978; Weissman, Epstein, & Savage, 1983). For example, in a recent study of social work competencies for working with older adults, conducted by the Council on Social Work Education, geriatric assessment is singled out as a core practice competency (Rosen, Zlotnik, Curl, & Green, 2000). High-touch and high-tech, with medical, psychosocial, financial, private, and public implications, assessment could also be called the quintessence of 21st-century social work. Indeed, it is somewhat ironic, at least to social workers, that other health care providers are now recognizing what social workers have long known: that patients should be assessed biopsychosocially.

What do social workers need to know about assessment with older adults? For many years, social workers had to rely on their general social work training, intuition, or practice experience in assessing older adults. Now a wide range of valid and reliable assessment tools are available. Social workers use comprehensive assessment forms, measures, instruments, and short screening tools to collect information about their clients. The use of assessment measures serves a basic clinical function for social workers working with older adults, which include helping the practitioner develop an adequate information base to understand the problems, needs, resources, and strengths in a client’s situation. Results of these measures also assist the social worker, family, and agency to make decisions about the care plan. Social workers, but also many other professionals and paraprofessionals, engage in the use of such measures in the course of providing care.

Assessment is also a process done by social workers; it is a general problem-solving approach that is particularly characteristic of social work in all fields of practice. This approach can, of course, include the use of assessment measures, but it also relies on clinical judgment, the formalized problem-solving skills that practicing social workers develop and employ in every aspect of their professional work—when they are using specific assessment measures and when they are not.

A. Assessment

SCOTT MIYAKE GERON

Comprehensive and Multidimensional Geriatric Assessment

65

The contemporary context of practice poses challenges to any type of assessment. Resources are shrinking, funding for services is rarely certain, agency staff are burdened, and social workers often lack a strong constituency or administrative support. Social work departments do not control the flow of clients, and the complexity of clients is changing and increasing. The generalized nature of social work interventions also poses challenges for assessment. Social work services are presumed to be customized, but they rarely are. As a result, geriatric social work intervention may not consist of a single service aimed at alleviating a specific problem, making the use of standardized assessment difficult. Moreover, although social workers may have a direct role in an intervention, often, especially in health settings, they play a supportive role. This type of “vertical complexity” limits the responsibilities of social workers and also their contact with clients and their families.

Nonetheless, geriatric assessment is in many ways a liminal social work activity. Viewed by many as the most basic of social work skills, geriatric assessment serves as the threshold between clients and needed services, and the skills needed to effectively complete geriatric social work assessments separate the untrained social worker from the advanced practitioner. Geriatric social work assessment has gained importance not only from the new models of assessment that are available, but also because social work roles and environments are changing, and hence the types of assessment skills needed are increasing. In this chapter, I describe the role that assessment plays in geriatric social work practice, provide basic information about geriatric assessment that practitioners need to know, and summarize some of the basic processes of conducting geriatric social work assessments.

ISSUES IN THE USE OF ASSESSMENT MEASURES

A wide variety of assessment tools are now available for geriatric social workers (e.g., Berkman, Marmaldi, Breon, & Howe, 2002; Geron, 1997; R. A. Kane & Kane, 1981). As Rosalie Kane describes in her chapter in this book, many of these are multidimensional assessment instruments that are designed to help social workers, case managers, and other health professionals develop an understanding of the problems, needs, resources, and strengths of an older client’s situation and to guide the assessor and the client in making decisions about a care plan. Frequently used by

states and agencies to determine eligibility for community-based or residential long-term care services for adults, these type of assessments are designed to provide a holistic picture of the client and his or her family across a wide range of functioning. They address multiple dimensions or domains, providing, at a minimum, information about demographic characteristics, health status, functional performance, cognitive functioning, mental health status, social and informal supports, environment, and financial status (Geron & Chassler, 1994). Other common assessment tools are brief screening tools that social workers and others use to determine the presence of cognitive impairment or depression (e.g., Berkman et al., 1999). These types of screens may be embedded inside large assessments or stand alone.

Effective administration of any assessment instrument requires preparation. At a minimum, assessors must understand the purpose of the assessments they are asked to use. As a single assessment instrument may serve multiple purposes, this can be a difficult task. Different types of information, levels of detail, even seemingly duplicate types of information may be contained in the same assessment tool; for example, different types of information may be needed for clinical purposes as compared to establishing technical eligibility for programs and services. Ideally, the social worker will understand why an instrument is being used and will be prepared to reassure the client or caregivers of the purpose and value of the assessment.

Before using any instrument, geriatric social workers should thoroughly review the measure and each question in the instrument and be clear what information each question is designed to obtain. Social workers assigned to administer a new assessment measure should receive extensive training, which should include role-plays with colleagues, observing more experienced workers use the measure, reviewing FAQs (responses to frequently asked questions), and studying Q-by-Q (question-by-question) manuals that describe any administration or interpretation issues for any item in a measure. In the use of assessment measures in research projects, training in the use of a measure can take a week or more before actual assessments are conducted with clients, and this rule of thumb should apply to agencies as well. There are several purposes of such training, including to make the geriatric social worker comfortable using the measure, to understand the purpose and meaning of every item or question, to know whether and under what conditions proxy respondents are allowed, to learn how much latitude, if any, is tolerated in the use

of probes, to become familiar with any skip patterns in the measure, and to gain experience in how to reword questions to adapt to odd or difficult situations.

The use of an assessment measure is rarely designed to be an isolated event by an individual social worker; most are designed to serve as a common assessment protocol to be used by multiple workers in a particular agency, and some are designed to be used by all workers in a state, regardless of agency affiliation or funding stream. The goal of standardization is an important feature of most assessment tools. For geriatric social workers new to these types of assessments, it is important to understand the rationale and benefits that standardization provides. Standardization is a desirable feature in assessment because it allows for the reproducibility of findings and makes interpretation and sharing of results across workers possible. Uniformity in assessment provides a common language that permits communication across disciplines and agencies and provides a safety check to ensure that important elements of an assessment are not inadvertently omitted. A uniform approach makes it possible to develop meaningful information about the physical, psychological, and social well-being of clients over time and to learn which services are most effective in meeting needs. Standardization typically encompasses any of the following:

- Content (questions, responses to questions, instructions, and format).
- Data collection methods (e.g., face-to-face, telephone, self-administered).
- Scoring algorithm (how scores are calculated).
- Analytic methods used.
- Format for displaying results.

THE PROCESS OF GERIATRIC ASSESSMENT

Whatever the intended uses of geriatric assessment, the completion of assessment measures encompasses a number of clinical social work skills. Older adults may have multiple health problems with nonspecific origins or causes, may not have reliable proxy informants, and may have functional or cognitive limitations that make it difficult to provide accurate descriptions of symptoms. Depression is particularly common in older adults with poor physical health and can become a chronic or recurrent problem for up to 50% of older adults (Alexopoulos & Chester, 1992). Between 45% and 90% of mental illnesses are not detected by primary care physicians (Blanchard,

Waterreus, & Mann, 1995; Eisenberg, 1992; Orrell, Scurfield, Clarke, & Renshaw, 2000; Watts et al. 2002). Effective assessors draw on all of their experience, observations, judgment, and clinical expertise. The specialized skills needed to perform geriatric assessments include the ability to establish and maintain empathic relationships; experience in identifying symptoms of depression and cognitive impairment while conducting standardized social and health assessments; knowledge of human behavior, family and caregiver dynamics, aging, and disability; and awareness of community resources and services (Geron, 1997; Geron & Chassler, 1994).

The range and type of assessments available for older adults are now well documented (Geron, 1997; Kane & Kane, 1990, 2000; Lichtenberg, 1999; Osterwil, Brummel-Smith, & Beck, 2000), but the actual processes of conducting geriatric social work assessments with older adults are rarely addressed. To some extent, conducting a clinical interview in any social work setting is relevant experience (e.g., see Murphy & Dillon, 2003), but geriatric assessment with older adults also involves specialized concerns and expertise. Colleen King's (1997) and other, more recent texts in geriatric social work (e.g., McInnis-Dittrich, 2002) have identified some of the important idiosyncratic processes in conducting geriatric assessments, including the following:

- Establishing rapport with the respondent.
- Explaining the purpose of the assessment.
- Using observation and clinical judgment.
- Handling difficult situations.
- Maintaining confidentiality.

Establishing Rapport

Most social workers receive training in a number of clinical methods, and none is more basic than the therapeutic skill of engaging clients and establishing rapport with them. The engagement of older clients is an equally important part of the process of conducting geriatric assessments (Schneider, Kropf, & Kisor, 2000). Establishing trust with an older respondent, who may be more reluctant to participate in assessments than younger adults, is essential. To do so, social workers conducting assessments with older adults should spend as much time as necessary to reassure them and answer any questions they have. Establishing rapport involves listening sensitively and honestly

to clients' concerns and problems, speaking in a conversational tone without the use of jargon, and showing enjoyment in talking and working with clients. The time it takes to establish this rapport varies from only a few minutes to 15 minutes or more, but failure to do so can doom an assessment.

Explaining the Purpose of the Assessment

Geriatric social workers should spend time talking to respondents about the assessment before beginning. This is necessary to explain the purpose of the assessment, reassuring clients that the procedure is important and worth their time, and, in some cases, to obtain informed consent. In research studies, for human subject protection, this step is mandatory and the language to be used is scripted. Even when consent has been obtained, the geriatric social worker should tell the client about the type of questions that will be asked and why.

An important function of this early disclosure is to anticipate questions that may be difficult or awkward for the respondent to answer, for example, asking questions about cognitive impairment of a cognitively intact respondent. Letting the respondent know that "we have to ask these questions of everyone" may help the respondent answer the questions without reticence. Geriatric social workers should not be afraid to answer any questions posed by respondents about the purpose, length, or implications of the assessment. This requires that the assessor understands and believes in the purposes for the questions, communicates those purposes to the client, and speaks to the client in a relaxed and interested way.

Using Observation and Clinical Judgment

Before, after, and during the administration of a formal assessment protocol, the geriatric social worker uses clinical judgment to assess the client and family. Clinical social work judgment is often referred to as a type of problem solving (McInnis-Dittrich, 2002; Murphy & Dillon, 2003; Perlman, 1957). If the assessment is completed at the client's home, the geriatric social worker uses clinical judgment to observe the client's behavior and interactions with others, to identify potential risks in the home environment, and to determine the level and type of caregiver support. From these observations, along with the results of a

standardized assessment, the geriatric social worker identifies potential problems and unmet needs, formulates a care plan, and begins to implement problem-solving strategies.

For social workers working in interdisciplinary health teams, the opportunity to observe and interact with the client is precious, as few physicians or nurses have the opportunity to conduct home assessments. In recent focus groups we have conducted with primary care physicians and nurses in California to explore the potential of integrating social workers into primary care practice, health providers stated that they lacked basic information on the living conditions of patients, information that social workers can provide through their assessment (Geron & Keefe, in press).

Handling Difficult Situations

Social workers conducting assessments with older adults often encounter situations unlike those experienced with younger clients. Some of the most difficult situations facing assessors are when the older client is overcome with grief, loneliness, sadness, or anger (King, 1997) or when caregivers become similarly upset. Social workers unfamiliar with older adults may find these experiences uncomfortable at first, and their training should include how to respond to these types of client responses in a professional way while showing compassion and understanding. In trying to complete the assessment, the geriatric social worker needs to be direct, polite, and sensitive. In general, it is important not to ignore the client's concerns or pretend that the client is not upset. Social workers conducting formalized assessments should stop the assessment and listen to the client. They should try to reassure clients that it is safe to express their feelings and try to make them feel comfortable and at ease. Simple comments such as "I understand" and "I'm so sorry" can be reassuring and allow the social worker a way to acknowledge clients' feelings and demonstrate an understanding of their concerns.

Maintaining Confidentiality

A basic part of the process of conducting assessments is to respect the confidentiality of the information obtained. Confidentiality requires that interviewers not discuss the information obtained during the assessment with anyone not associated with the project. The geriatric social worker may need to reassure the

client or the client's family about the confidentiality of the assessment. In agency-based assessment protocols, the client name and contact information is listed on the form, and, in these cases, it is imperative to keep the completed forms secure until they can be returned to the office. In most research studies involving geriatric assessments, client names are never associated with the completed assessments. Client names are usually listed on disposition sheets that provide directions to the client's home or telephone contact numbers, but not on the assessment form. When the completed interview forms are turned in to the office, the disposition sheet is separated from the survey. Identifying information never appears in reports, only aggregated information from a large number of clients.

Honoring the Person Assessed

I would add one other essential component of the geriatric assessment process. For many older adults who have entered the formal service system for help, the reality of their lives—their wishes, beliefs, history, likes, and dislikes—is reduced to whatever is revealed by the measurement tools used to assess them. The consequences of these assessments for the older person are enormous. The results often require coming to grips with a loss of or decline in functioning in one or more areas in which the person previously had been independent.

Because no assessment measure, however well-designed, can do justice to the person who is assessed, there is a risk that the client's beliefs, values, and preferences for care will be omitted. This is where the geriatric social worker can ensure that the client's voice is heard during the assessment process, whatever the intended purpose of the assessment. As agency workers or researchers, geriatric social workers are required to complete assessment protocols, even though most of these measures are designed to represent the interests of the agency or funder providing the services (e.g., determining whether this client is eligible for these services). Geriatric social workers can use their clinical skills to assess what is important in the lives of the clients they are assessing and to give voice to their clients' preferences and values, even if the measures they are using do not. Increasingly, assessing what is important to clients about the services they receive is becoming the focus of geriatric assessment measures (e.g., Applebaum, Straker, & Geron, 2000; R. A. Kane, 2003; R. A. Kane et al., 2004).

DISCUSSION

Geriatric social workers, like their social work colleagues in other practice settings, use assessment to guide their clinical judgments. With proper training, geriatric social workers can use assessment as a means to further the relationship they build with the client. Although not intuitively obvious, an important goal of assessment is to capture the full range of measurement for the concepts included in the assessment protocol; this is the research equivalent of the social worker's clinical objective of obtaining a holistic assessment of a client's functioning. Of course, geriatric social workers employ clinical judgment in their interactions with clients, whether formal assessment measures are used or not. Many of the most important clinical assessment skills involved in practice with older adults occur outside of the formal assessment process.

Although the science and art of geriatric assessment has come a long way, it is important for geriatric social work to move beyond assessment. There is a need to buttress this important practice competency with other interventions that social workers can implement to improve the lives of older adults. Completing assessments should never be an end in itself. Unfortunately, in some environments, there is a growing tendency to use geriatric social workers in that way. The current situation of social workers in Medicare-reimbursed nursing homes is a case in point. Current Medicare rules mandate that facilities have at least one social worker for every 120 residents, and, in facilities that hold to that minimum standard, social workers are sometimes reduced to conducting assessments of residents using the Minimum Data Set and have little time for anything else. The greatest threat to geriatric social work is that social workers will be restricted to conducting assessments, with no time to implement a care plan, no services in place to address identified problems, or, even worse, no authority to use proven interventions. Social work should not become a profession that only does assessments. Social workers should also act; they should intervene; they should conduct evidence-based interventions shown to make a difference in the lives of the clients they serve. No doubt, geriatric social workers can use the results of assessments to assist in their clinical judgment to identify and solve problems. Our challenge is to provide clients with the tools and authority to act once the assessment is completed.

JAMES LUBBEN

Abbreviated and Targeted Geriatric Assessment

66

The adoption of standardized abbreviated social health measures into social work practice and research holds much promise. Abbreviated geriatric measures that are highly reliable and valid for physical and mental health domains have existed for some time. However, a similar set of measures for the more social aspects of health and well-being in old age has only recently been developed.

Abbreviated and targeted geriatric assessment measures are those that, by definition, are very short, generally 10 items or fewer. Thus, they can be readily incorporated into clinical assessment protocols, used in wellness and health promotion clinics as quick screeners identifying groups for more intensive screening, or included in health surveys of large populations. Perhaps the most celebrated of these is the single-item measure for self-rated health that has been shown to be a powerful predictor of future health status and health care utilization. It has demonstrated so much salience to various facets of health status and service utilization that this single question has become a standard item in many geriatric assessment protocols and a normative item on health surveys.

SHORTAGE OF ABBREVIATED MEASURES FOR SOCIAL ASPECTS OF HEALTH

Whereas geriatric practitioners and health survey designers can readily identify a set of abbreviated measures for physical and mental health, there appears to be no consensus on what, if any, abbreviated and targeted social measures should be adopted. This deficiency was recently demonstrated in a federal report entitled *Older Americans 2004: Key Indicators of Well-Being* (Federal Interagency Forum on Aging-Related Statistics, 2004). This publication contains outstanding graphics and its audience is very broad, including the general public, service providers and planners, and top-level government policymakers. It contains numerous indicators of physical and mental health status with a clear message that these factors are significant aspects of well-being in old age. However, this otherwise excellent report does not contain a single indicator of social health status, such as social engagement, social support, or social isolation.

This is a serious omission. Had there been such measures included in this important overview of the state of health affairs among older persons, it would have communicated to the public in general and to older persons in particular that social health is just as important to well-being in old age as maintaining

physical and mental health. Further, data on such domains could have helped facilitate public understanding regarding the importance of geriatric social work for improving the well-being of older Americans.

The underdevelopment of abbreviated social health measures contrasts with the state of affairs in other domains. This can be illustrated by examining the domains of geriatric assessment protocols and national health status reports. Again, the *Older Americans 2004* report (Federal Interagency Forum on Aging-Related Statistics, 2004) provides a useful example to illustrate this point. It contains 16 tables that provide an abbreviated measure of the health status of older Americans and another 12 tables reporting an indicator of health behavior. For health status, the *Older Americans* report has a checklist of 9 common chronic health conditions: arthritis, asthma, bronchitis, cancer, diabetes, emphysema, heart disease, hypertension, and stroke. It also has abbreviated measures for sensory impairment (hearing and vision), oral health (number of missing teeth), memory impairment (20-word recall test), depression (Center for Epidemiological Studies Depression Scale), and functional disability (activities of daily living and instrumental activities of daily living). These are in addition to the standard single-item self-rated health question and charts indicating longitudinal trends on life expectancy and mortality. The following indicators were selected for health risks and behaviors: vaccinations, mammograms, diet, physical activity, obesity, smoking, and air quality.

There is no doubt about the importance of these health and mental health indicators to well-being in old age. However, the omission of social health measures is quite obvious. In fairness to the federal health researchers who assembled the set of health measures contained in the *Older Americans* report, a close look at other compendiums of health and well-being markers of older adults likely would have identified the same deficiency.

As a rule, the physical and mental health indicators are much better developed and accepted than those examining social health. It is true that social workers examine the biopsychosocial aspects of a client, and so all of the health status indicators mentioned for physical and mental health are considered relevant and even important to social work practice. However, the lack of readily agreed upon social health measures needs to be considered a serious deficiency for social work, if for no other reason than that the “social” is at the heart and soul of what social workers do. If federal and state health surveyors and similar

key researchers don’t count what is central to social work, it sends a serious message to multiple audiences that the social is undervalued. The solution is to develop and adopt a set of valid and reliable abbreviated measures of social health.

SOCIAL WORK AND HEALTH PROMOTION

There are other reasons why considerably more work needs to be done to develop short assessment measures of social health domains. Fostering the development of abbreviated and targeted assessment tools for domains central to geriatric social work practice expands the potential for social workers to be engaged in the growing practice arena of prevention and health promotion (Institute on Medicine, 2000). Health promotion and disease prevention programs often involve screening large populations with brief assessment instruments with the goal of identifying an at-risk population who in turn are subjected to more intensive assessments. The adoption of standardized abbreviated social health measures could be integrated into these wellness-screening batteries to identify old adults perceived to be at risk. Those identified then could be referred to more traditional practitioners, including clinical social workers, for both more extensive assessment and possible treatment.

There are a number of case examples in the literature for social work involvement in health promotion for older adults. For example, Klein and Bloom (1997) provide an overview of strategies that geriatric social workers and other helping professions could employ to foster healthy living among older adults. Dorfman and associates (1995) report on the use of social workers to screen for depression among a Medicare population. Rubinstein and associates (R. L. Rubinstein, Lubben, & Mintzer, 1994) report on a program in which geriatric social workers screen for social isolation.

Besides identifying previously undetected health problems, health promotion includes a focus on preventive measures to decrease morbidity and improve quality of life in old age. To that end, health behavior and lifestyle have become increasingly important areas of concern in geriatric practice (R. L. Kane, Kane, & Arnold, 1985; Kaplan, Seeman, Cohen, Knudsen, & Guralnik, 1987; Schweitzer et al., 1994; Stuck et al., 2000; Weiler, Chi, & Lubben, 1989). At a more macro level, the burgeoning fields of building healthy aging communities (Damron-Rodriguez & Lubben, 2001; World Health Organization, 2002) and cultivating social capital (Klein & Bloom, 1997; Wallack,

2000) suggest additional opportunities for social work engagement in this growing field. Given that the major rationale for examining behaviors is fostering behavioral change, the potential for increased geriatric social work involvement in health promotion programs becomes quite apparent.

Regardless of whether the focus of health promotion and wellness is on the early detection of health problems or the changing of health behaviors among individuals, families, groups, or communities, appropriate abbreviated measures are needed. Such measures are required to document the need, mobilize action, and mark progress toward addressing those needs.

DESIRED PROPERTIES OF ABBREVIATED MEASURES

Good abbreviated measures are the result of good compromises. On the one hand, the measures must be relatively short and unobtrusive to gain wide acceptance. On the other hand, they must be reliable; as a rule, longer assessment instruments are more reliable. Reliability is a fundamental issue in psychological measurement (Nunnally, 1978). Thus, one of the first compromises in constructing good abbreviated measures is to create reliability without the redundancy of inquiry that is often employed to foster increased reliability. Cronbach's (1951) coefficient alpha is often used to measure reliability. An acceptable range of coefficient alpha values are 0.70 to 0.90 (DeVellis, 1991; Nunnally, 1978). Assessment instruments with reliability scores higher than 0.90 are likely to suffer from excessive redundancy, whereas those with alpha less than 0.70 are likely to be unreliable (Streiner & Norman, 2003).

Abbreviated measures must also withstand a test of validity (Streiner & Norman, 2003). Although there are many ways that validity can be measured, a common approach in the development of abbreviated measures is to ascertain *criterion validity*, usually divided into concurrent validity and predictive validity. *Concurrent validity* examines whether the new measure is highly correlated with some gold standard of the construct being measured. *Predictive validity* examines whether the measure can predict future events such as increased health service use, mortality, or other outcome measure.

These aspects of validity can be demonstrated by examining two measures of mental health among elderly populations: the Center for Epidemiological Studies Depression Scale (CES-D) and the Mental

Health Inventory (MHI-5). The CES-D is a 20-item scale developed by the National Institute of Mental Health to measure symptoms of depression in community populations with emphasis on the affective component (Radloff, 1977). The CES-D has often been used in studies of elderly populations (Foelker & Shewchuk, 1992; Hertzog, Alstine, & Usala, 1990). The length of the CES-D has spawned a number of attempts to find a more abbreviated measure for mental health.

One such abbreviated measure that has been developed is the MHI-5. As the name implies, this newer measure contains 5 items and is a shortened version of the MHI developed by the RAND Corporation for the extensive RAND Health Insurance Experiment (Nelson & Berwick, 1989). The MHI-5 is indeed a valid and reliable abbreviated measure of mental health that can be used as an efficient screener for general mental health problems (Berwick et al., 1991). Correlating the MHI-5 with the longer and more established CES-D measure assesses the validity of the MHI-5. High correlations are indicative of concurrent validity. Similarly, using the MHI-5 to predict future events such as hospitalizations for mental health problems would illustrate predictive validity.

Another compromise that must be addressed in developing an abbreviated measure is the trade-off between *sensitivity* and *specificity* (Streiner & Norman, 2003). This dichotomy is also referred to as balancing false positives and false negatives. When administering any assessment test, some of the individuals classified as having a trait (e.g., depression, isolation) don't actually have that condition; thus, the assessment resulted in a false positive. On the other hand, there are individuals who indeed have the condition for which the population is being screened but the employed test reports that they do not have the condition; these results are considered false negatives. A desired trait of a good assessment measure is that it must be sensitive enough to actually identify individuals who have the condition for which screening is taking place. A sensitive measure minimizes the number of false negatives. Another desired trait for an assessment measure is that of specificity to minimize false positives, meaning that those who do not have the condition are ruled out. A special challenge in developing an abbreviated assessment measure is to find a good balance between the problems of false positives and negatives.

Another desired trait for abbreviated assessment instruments that is employed in practice settings is *open door* questions. These are questions that might be answered simply, or the response they elicit might

prompt the geriatric social worker to probe for more information. For example, if a respondent answers that he or she has no friends or is sad, a health survey researcher is likely to move on to the next set of questions; however, a geriatric social worker or other health professional would likely explore the response for more detail before returning to the remaining structured questions in the assessment protocol. Thus, an abbreviated assessment measure might both record standard information on clients and also provide the opportunity to probe responses to specific questions.

TWO CASE EXAMPLES OF DEVELOPING ABBREVIATED SOCIAL HEALTH MEASURES

There are a number of outstanding handbooks on geriatric assessment that contain sections on social health (Gallo, Fulmer, Paveza, & Reichel, 2000; R. L. Kane & Kane, 2000; Osterweil, Brummel-Smith, & Beck, 2000). Few of the social health measures contained in these handbooks are ideal as abbreviated measures because most are much too long. Thus, they generally would require additional psychometric work to hone them into valid and reliable abbreviated measures of social health. Streiner and Norman (2003) provide a very useful practical guide on how to develop health measurement scales.

Lubben and Gironda (2000, 2003a, 2003b) provide two illustrative case examples of developing valid and reliable abbreviated measures of social health from existing scales. They took two commonly used measures that were relatively long and engaged in a deliberate process to identify shortened versions that would approximate the original scales in validity and reliability. One of the scales they abbreviated was the Medical Outcomes Study Social Support Scale (MOS-SSS; Sherbourne & Stewart, 1991) and the other was the Lubben Social Network Scale (LSNS; Lubben, 1988; Lubben & Gironda, 1997).

The MOS-SSS was developed for the RAND Medical Outcomes Study and is largely a measure of emotional support. Its current length (20 items) makes it especially cumbersome for clinical settings and a very unlikely candidate for inclusion in state or national health surveys. Because of a great deal of redundancy in items, there have been many suggestions made to abbreviate the MOS-SSS (e.g., Lubben & Gironda, 1997; Steiner et al., 1996).

Lubben and Gironda (2000) developed a 3-item abbreviated version of the MOS-SSS. These 3 items

show high internal consistency and are correlated with the total MOS-SSS score. The items are scored as a Likert-type response. The MOS-SSS 3-item abbreviated version is shown in Table 66.1.

The LSNS is a 10-item scale designed to measure social networks specifically for use among an elderly population. As evidence of the demand for abbreviated measures, even the 10-item LSNS has spawned shortened versions (e.g., Martire, Schulz, Mittelmark, & Newsom, 1999). The LSNS has become widely used in both research and clinical settings (e.g., Martire et al., 1999; Pourat, Lubben, Yu, & Wallace, 2000; Steiner et al., 1996; Stuck et al., 1999). It has demonstrated criterion validity through significant correlations with a wide array of health indicators. Low scores on the LSNS have been correlated with mortality (Ceria et al., 2001), all-cause hospitalization (Lubben, Weiler, & Chi, 1989; Mistry, Rosansky, McQuire, McDermott, & Jarvik, 2001), physical health problems (Hurwicz & Berkanovic, 1993; Mor-Borak, Miller, & Syme, 1991), depression and other mental health problems (Chou & Chi, 1999; Dorfman et al., 1995; Okwumabua, Baker, Wong, & Pilgrim, 1997), and lack of adherence to good health practices (Potts, Hurwicz, & Goldstein, 1992).

Lubben and Gironda (2000, 2003a) developed a 6-item abbreviated version of the LSNS and dubbed it the LSNS-6 to distinguish it from longer versions of the test (Table 66.2). The LSNS-6 assesses two critical domains of social networks: (1) family and (2) friends and neighbors. These 6 items can be combined to form a 3-item family subscale, a 3-item friends subscale, and the composite LSNS-6. All three measures have good reliability characteristics for such short scales.

An additional advantage of the three LSNS-6 measures is that in a clinical setting, it may be useful to determine particular strengths and weaknesses in family ties separate from those of an elderly person's relationships with friends and neighbors. For this purpose, the subscales can be used individually. The two subscales can also be combined to form a composite LSNS-6 score that in turn could be used as a marker for possible social isolation and suggestive of particular types of clinical interventions. The LSNS-6 and the

TABLE 66.1. MOS-SSS Abbreviated Version

-
1. How often do you have someone to love?
 2. How often does someone show love and affection to you?
 3. How often do you have someone to share worries?
-

TABLE 66.2. LSNS-6

-
1. How many of your *relatives* do you see or hear from at least once a month?
 2. How many *relatives* do you feel at ease with that you can talk about private matters?
 3. How many *relatives* do you feel close to that you can call on them for help?
 4. How many of your *friends* do you see or hear from at least once a month?
 5. How many *friends* do you feel at ease with that you can talk about private matters?
 6. How many *friends* do you feel close to that you can call on them for help?
-

MOS-SSS-3 both illustrate the concept of open-door questions that allow a clinician to further probe particular responses.

SUMMARY

As R. A. Kane and Kane (1981) stated almost 25 years ago on the first page of the original version of their popular handbook on assessment, “Measurement is essential to good geriatric care.” Good practice, whether in social work, nursing, or any other health profession, requires good measures to denote client need and record client progress. Valid and reliable abbreviated assessment measures are important to this process to fill the gaps when the use of longer measures is impractical. Similarly, health researchers and policymakers need good data. In this era of evidence-based practice, good health and social service programs may go unnoticed if they are not able to document their merits. Further, the critical shortage of abbreviated markers of social health status and behaviors in large population surveys sends the wrong message about the relative importance of the social health domain. Thus, the only course of action is to more deliberately engage in the process of developing a valid and reliable set of social health measures that will become more widely accepted for practice and research. The future of geriatric social work will be greatly enhanced if social workers accept this challenge.

Standardized Measures Commonly Used in Geriatric Assessment

67

Standardized assessments are systematic protocols that are used to gather information using well-defined standard elements and procedures. This chapter is limited to noninvasive assessments that are composed of fixed questions posed to respondents or self-completed by respondents, or by ratings that are made by professionals after interviews and observations. (Assessments based on physical examinations, laboratory tests, and radiological tests are beyond the scope of this chapter.) In standardized assessments, questions are asked, observations made, and replies recorded according to fixed rules. Standardized measures go a step beyond assessment to yield scores to describe the attributes of the older person and the older person's world that are being assessed.

Standardized assessments and standardized measures are used extensively among health and human services professionals working with older people, and they are also widely used in research concerning older people. Some of the more commonly used assessments and measures have created their own language that is used within and across professional groups to reach common understanding about older people. The acronyms for types of measures and for specific widely used tools have become a short-hand in aging services. ADL status (i.e., the ability to perform activities of daily living) and MSQs (referring to mental status questionnaires, a class of measures used to screen for cognitive ability) are terms typically taken for granted in geriatric care teams, as are abbreviations for widely known instruments, such as the GDS (Geriatric Depression Scale; Yesavage & Brink, 1983), the MMSE (Mini-Mental Status Exam; Folstein, Folstein, & McHugh, 1975), the LSI (Life Satisfaction Index; Neugarten, Havighurst, & Tobin, 1961), and a host of others. The SF-36 (Ware & Sherbourne, 1992) is such a well-known multidimensional tool to measure general health status that the source of the acronym (short form) tends to be forgotten.

This chapter describes some of the more commonly used measures in the context of a discussion of why social workers need to be concerned about standardized assessment, the properties that should be considered in choosing and using assessment tools, and the domains or topics of assessment that are pertinent to social workers.

SOCIAL WORK AND STANDARDIZED ASSESSMENT

Social work practitioners have a variety of responsibilities related to assessment protocols and measures.

Often, social workers are part of a multidisciplinary team that uses a standardized tool to assess all clientele. Under these circumstances, social workers may be responsible for completing a portion of the tool related to psychological or social function; they may be responsible for completing an entire tool, which is then used by the entire team; or they may utilize data from an assessment tool that is completed by a team member who is not a social worker. Social workers may be designated to complete an entire tool, including components on physical health and other aspects not directly in social work's purview; because of the profession's expertise in establishing rapport and interviewing and because social workers often conduct intake for a variety of programs, such a role is natural. But regardless of the pattern for completion of an assessment protocol, social workers practicing in an environment using such tools are obliged to understand how to interpret the results. Social work practitioners may also be in a position to suggest a component to be added to a multidimensional assessment battery or to select an assessment tool to guide the work of a specific social work program. In those situations, social workers would be ill-advised to invent a new assessment tool unless a thorough search suggests that no extant instruments are appropriate for the measurements sought. Even to make such judgments, social workers need to understand something about how to judge an assessment tool. Indeed, social workers also need to be knowledgeable enough about assessment tools to recognize if the scales used by a practice team do a poor job of describing phenomena or outcomes of interest to their practice.

Assessment is employed for various purposes, and the criteria for choosing an assessment tool varies with that purpose. Assessment may be used diagnostically to characterize an older person, to decide on a therapy or plan of care, or to draw conclusions about the best place for care. Screening is a variant of diagnostic assessment where the goal is not to definitely categorize a phenomenon, but rather to narrow down the field of people or circumstances that need more detailed assessment. For example, one may screen for a disease or condition and then assess in more detail just those who are positive on the screen. Assessment may serve as the basis of eligibility for care or services, either type of care or amounts of care. It may be used as the basis for evaluating the effectiveness of a specific service or an entire program, and it may be used in quality assurance and quality improvement efforts.

In clinical research, assessments are used to establish baseline states, to measure outcomes of interven-

tions, and to adjust results by differences at baseline (known as case-mix differences). In more basic research, assessments are used to study relationships among various phenomena and other attributes. Variants of commonly used assessments are embedded in standard publicly funded population surveys that social work researchers need to become familiar with to understand trends among older people. There is no particular added credibility for social workers to use only assessment tools developed by social workers, but at times social work researchers become engaged in developing instruments to fill voids in the tool kit available to examine outcomes of interest to them. Those attempting to develop assessment tools need to adhere to conventional approaches in identifying items, field-testing instruments, establishing their psychometric properties (such as reliability and scalability), testing validity, and establishing norms. Examples of different types of tools developed under social work leadership include Lubben's Social Network Scale (Lubben, 1988), Geron and colleagues' (2000) tools to measure home care satisfaction, and R. A. Kane and colleagues' (2003) measures of quality of life for nursing home residents.

ASSESSMENT DOMAINS: TOPICS FOR STANDARDIZED ASSESSMENT

Assessment domains or dimensions refer to the topics or areas to be assessed. In 1981, this writer coauthored a book that compared assessment tools used in long-term care and aging services, raising cautions about the choice and use of assessments (R. A. Kane & Kane, 1981). That volume considered assessments in five domains: physical functioning (referring to abilities to conduct basic and more complex activities of daily living); physical health; psychological well-being; cognitive functioning; and social functioning. We also considered multidimensional tools that cross domains to yield either a single score or subscores. Sometimes such multidimensional tools are called "quality of life measures." For that book, we sifted through many hundreds of assessment tools.

When we wrote a sequel to the 1981 volume about two decades later, the caveats on the use of assessments were unchanged, but the number of assessment tools available for use in gerontology and geriatrics had increased exponentially (R. L. Kane & Kane, 2000). Moreover, the number of domains for which serious measurement work was available had also multiplied. For the 2000 volume, the domains re-

viewed included function, health and physiological well-being, cognition, emotions, social functioning, quality of life, values and preferences, satisfaction, religiosity and spirituality, family caregivers, and physical environments. Many of the topics lent themselves to further division into subdimensions.

The remainder of this chapter summarizes the state of the art of gerontological assessment in each of the domains just listed and adds the domain of personality (an area of assessment of interest to social work). For each domain, a few tools that have achieved considerable prominence are suggested along with issues related to assessment of older people compared to the general population of adults. The summaries are necessarily cursory, and the listing of tools is illustrative rather than comprehensive. The goal is to present an overview of each area in a way that will help social workers take further steps to evaluate or select tools for that domain. First, however, the chapter presents some important distinctions and attributes related to standardized assessment tools and their use. This discussion is illustrated with reference to tools in the literature, many of them commonly used.

CHARACTERISTICS OF ASSESSMENTS AND MEASURES: USEFUL DISTINCTIONS

Sources of Information

Information for assessment may come directly from the older person, or it may come from various proxies for the older person, including family members and paid caregivers. Clearly, some older people will be incapable of providing direct information because of high levels of cognitive impairment, dire health conditions that prohibit communication, or advanced illness, such as hospice clients in the hours before death. In such instances, no alternative remains but to substitute information from proxies, based on their observations or their substituted judgments (in the case of quality of life measures, which depend on subjective appraisal). Assessments from proxy respondents are more reliable if the matters assessed are objective and the person responding is in a position to know; in the census, for example, one respondent speaks for the household, a strategy to minimize the already expensive costs of census data, and it appears that little is lost. Using data from the older person interchangeably with that from proxies (although often done) creates measurement problems, and some argue that

for some domains and subdomains that deal with subjective appraisal, such as satisfaction, perceived health, spiritual well-being, and pain, it is better to omit the measure for those who cannot respond rather than to use a proxy. Certainly, direct respondents should not be eliminated because they suffer from measurable cognitive impairment. Ample evidence exists in the literature to suggest that many older people with substantial cognitive impairment can reliably and meaningfully provide the information for assessment of their own status, particularly when the domains concern attitudes, opinions, and feelings rather than actual facts about recent activity (Brod, Stewart, Sands, & Walton, 1999; Logsdon, Gibbons, McCurry, & Terri, 1999).

Proxy data may be based on systematic or unsystematic observation or records (such as clinical records or diaries kept by family). Some well-established tools do exist to approximate mood among those who cannot describe it for themselves. The MOSES (Multidimensional Observation Scale for Elderly Subjects) is one good example; it yields measures of depression and anxiety as well as social dimensions like social involvement and relationships, based on ratings by someone who had observed the person for a week and who answers very specific questions (e.g., How often did X talk about being depressed, look depressed, sound depressed, respond to social contacts, initiate social contacts?). The MOSES uses specific response categories to arrive at the number of days the observation was made and the amount of time in the day the phenomenon was observed (Helmes, Csapo, & Short, 1987). Although rapidly completed, this tool engenders more confidence than a simple rating of whether the individual is anxious, depressed, or socially engaged. Another example is the AARS (Apparent Affect Rating Scale), which is completed by making multiple 5-minute observations of the older person's facial expression to gauge happiness, sadness, anger, anxiety, and engagement (Lawton, Van Haitsma, & Klapper, 1996; Lawton, Van Haitsma, Perkinson, & Ruckdeschel, 1999). Users of this tool can be trained to high interrater reliability through available videos and practice experience.

Time Dimension

Assessments must have a referent in time; for example, the questions may be posed in terms of "right now," in the past week, in the past month, in the past 6 months, or "ever in your life." The choice of time frame is important and should be based on the frequency of the measured phenomenon and its nature (if we used

“past week” we might miss the intensity of family visits to a nursing home, and if we used “past year” to get information on the ability to dress oneself, we would lose focus on, say, the immediate poststroke period). To gather information about health conditions or history of health behavior of concern, such as alcohol consumption, the assessment may combine items cast as “ever in your life” with those related to a much more proximate time period. Also relevant is whether the information is needed to develop action plans for an individual or to gather research information on a population. If the latter, we might sacrifice utility for the individual to get the increased accuracy of recent experience. For example, we might ask about social activity or nutritional intake “yesterday” or family and paid help “this week” and achieve accuracy by taking the respondent through the hours or days. If the sample is large and unbiased and the time frame is not biasing (e.g., Christmas Day), a better approximation of eating habits, social activity, or help received in a population of interest can be gained from this approach than by asking each person to estimate over a year, which can cause recollection problems.

Recording Formats Versus Measures

Some systematic assessments widely used in gerontology are not measures, but systematic formats for recording data. The Minimum Data Set (MDS), now federally mandated for assessments at intervals for all residents in nursing homes that receive public funding, is such a recording tool (Morris et al., 1990). With few and recent exceptions, the many elements in the various iterations of the MDS were not intended to generate scores. However, after the fact, a number of approaches to scoring components of the recorded observations on the MDS have been developed, including various ADL and cognitive measures and measures of social engagement (Mor et al., 1995; Morris et al., 1994; Morris, Fries, & Morris, 1999). The assessment forms that many states use to guide their home- and community-based services also are typically recording formats not intended for scoring, though some states have incorporated specific standardized tools into their assessment formats that yield scores, and some have developed decision algorithms based on information in the assessment to establish eligibility for service and prioritize client needs. Other examples of a standardized approach to assessment developed to provide information for systematic reflection rather than scores include various assess-

ments of values and preferences, such as the Values Assessment Protocol (Degenholtz, Kane, & Kivnick, 1997), the Preferences for Everyday Life Inventory (PELI; Philadelphia Geriatric Center & Visiting Nurse Service of New York, 1999), and the Occupational Profile and the Strengths Inventory developed by Kivnick and colleagues (Kivnick & Murray, 2001; Kivnick, Stoffel, & Hanlan, 2001). The objective of such efforts is to discuss and record information about topics such as the older person’s preferences, strengths, and usual interests and activities, and no particular property is being assessed that lends itself to scoring (in contrast, say, to measures of the intensity of any particular preference).

Scoring

Scores provide a convenient way of distilling information from assessments. Once scores come into common usage, however, they tend to be treated as though they have objective meaning; intelligence scores and grade point averages come to mind. Thus, care is needed to go beyond the name of a scale and the score in using scores to draw comparative conclusions about a person or situation; at a minimum, the items, response sets, and instructions used to achieve that score should be scrutinized.

Two competing drives relate to scoring assessment batteries: the urge to consolidate and the urge to differentiate, sometimes referred to as lumping and splitting. The lumpers may seek a single score to measure a complex, multidimensional construct such as quality of life or psychological well-being, whereas the splitters may prefer to consider a host of subscores. With any kind of scoring, whether lumping or splitting is the norm, it may be necessary to weight some items as more important than others (and, therefore, worthy of more points) to the construct being measured.

It is noteworthy that scores may be derived specifically from the assessment tools or may be derived from judgments made after collecting and considering all the information. For example, one of the most venerable measures in gerontology, the OARS instrument (named for the Older Americans Resources and Services Center at Duke University, where the instrument was developed), asked a number of questions across specific domains: health, functioning, mental health, and social functioning (Fillenbaum, 1988). After the assessors collected and reviewed that information, they were to make summary judgments about well-being on each domain.

Measurement Properties

A few basic concepts are usually employed to assess the usefulness of measures. These primarily center on reliability and validity. Measures that are used to detect differences in the outcomes of a treatment may be held to additional standards, such as whether they are responsive to meaningful changes in the intervention, capable of detecting treatment effects when those effects are present, and suited to the population being assessed.

Reliability

Reliability means that the tool is a consistent measurement over time and across assessors. *Intra-assessor* reliability is achieved if the same rater gets the same results in successive measurement efforts, assuming that the older persons did not change in the interim. *Interassessor* reliability means that several assessors get the same results when assessing the same individual or phenomenon. With physical settings or other observations, they can visit simultaneously and individually complete the protocols. With interviews, reliability may be compromised by the way the interviewer's manner and approach in interaction with the subject's characteristics and the interview situation affect what the subject says. Great pains are taken to standardize both the behavior of interviewers and the circumstances, but inevitably differences will occur.

For scales developed from discrete elements, *internal scale reliability* or *scale consistency* is another relevant form of reliability. The reliable scale in this instance is one where the items composing it contribute to overall coherence. This trait is usually measured by some type of item-scale correlation, often expressed in the form of a Cronbach's alpha statistic. The goal is achieve a high level of internal reliability but not total convergence, which would mean the item adds nothing to the scale or could simply be used instead of the scale.

Validity

Validity refers to the capacity of a measure to accurately reflect the attribute it was intended to measure. A measure may be reliable but not valid; an inaccurate bathroom scale may show high reliability, and so, too, may the judgments of social workers and nurses who think they know about the happiness of, say, nursing home residents. In such a case, the responses of staff

may measure their consistent biases as they come up with the same answer consistently and similarly.

One form of validity is *face validity*, or the commonsense test. Essentially, this means that the measure appears to be measuring what it intends to measure, or reflects and covers the construct. *Concurrent validity* is achieved when the measure is highly correlated with another previous measure of the same construct. Unfortunately, we often lack a gold standard against which to test the new measure, and, for some domains (e.g., quality of life), using clinical judgment as the gold standard is likely to err by using a poorer standard than the new measure being validated. *Discriminant validity* is achieved if the measure correctly identifies those with the trait from those without; for example, a measure of depression applied to a mental health clinic population discriminates if it correctly identified those with a diagnosis of depression and fails to identify those without. *Predictive validity* refers to the measure's ability to predict the older person's future status. For example, the single item asking persons to rate their health on a 5-point scale has high predictive ability if those who rate their health as fair or poor have higher mortality 6 months later than the rest of the group.

OVERVIEW OF MEASUREMENT DOMAINS

Physiological and Health Domain

This general domain historically comprised lists of symptoms and active and past diagnoses, measures of health care utilization (e.g., hospital days, doctor visits), measures of time unable to perform usual activities because of health, use of common prosthetic and mobility devices, and self-rated health (the single item being extremely predictive of mortality, as stated earlier). In the past few years, the domain has become more differentiated. Tools are now available to objectively classify common clinical problems or risk factors, such as, among other examples, fall risk (Tinetti, 1986), nutritional status (Pendergast et al., 1989; Wolinsky, Coe, Chavez, Pendergast, & Miller, 1986), pressure sores (Goldstone, 1982), quality of sleep (Hays & Stewart, 1992), alcohol and drug problems, hearing and vision problems, and communication. Some of these paper-and-pencil measures are specific to a diagnosis.

Many tools are now available to measure the subdomain of pain and discomfort, though interpretation is still difficult because of the subjectivity of the topic (Herr & Mobily, 1993). Some type of adjectival

rating is typically used to characterize the extent to which the pain has various attributes, along with some general measure of the frequency and intensity of pain. The field is divided between those who would never accept a proxy rating of someone else's pain and those who believe it is necessary and important to get some approximation of the pain experienced by those who are dying or those who cannot speak; the latter group accept the ratings of staff or relatives as the best we can do.

Functional Measures

Measures of functional status include measures of basic self-care activities, the so-called ADL measures, and measures of more complex activities in everyday life, which have come to be called IADL (instrumental activities of daily living).

ADL activities most usually include bathing, dressing, using the toilet, getting in and out of a chair or bed (called transferring), and eating. Sometimes ADL tools include other items (e.g., grooming, continence), and sometimes they further differentiate among items (dressing can be subdivided into upper and lower body dressing, and eating can be divided into drinking from a cup and eating with a fork and spoon). Some ADL tools tap a lower level of functioning and examine differential functioning among those confined to their bed. The most common ADL tool was developed by Katz as a 6-item dichotomous rating and later refined in various ways to drop continence and expand the response categories (Katz, Down, Cash, & Grotz, 1970; Katz, Ford, Moskowitz, Jackson, & Jaffee, 1963). More elaborate ADL assessments are used to guide rehabilitation programs. Notable among these are the Barthel Index (Mahoney & Barthel, 1965) and the newer Functional Independence Measure (Kidd et al., 1995).

IADL typically include functioning at tasks such as cooking, cleaning, laundry, using the telephone, taking medications, driving a car, and using a bus or other transportation. A large number of tasks could be used in an IADL measure. One of the more widely used IADL measures is the Multilevel Assessment Instrument developed at the Philadelphia Geriatric Center (Lawton, Moss, Fulcomer, & Kleban, 1982).

ADL and IADL measures and, to a lesser extent, mobility measures are among the most ubiquitous in the field. As a dependent variable or outcome sought, functional status assumes paramount importance because maintaining, improving, or slowing decline in

functioning is what many services for older people are all about. As an independent variable—that is, something that might influence the outcomes being measured—functional status is almost as ubiquitous as the inevitable age, gender, marital status, and ethnicity as a case-mix adjustor. Baseline functional status is (and should be) taken into account when investigators examine other outcomes in the social and psychological spheres or when they examine changes in functional status itself.

With so many tools, the selection of a specific tool is less important than determining the definitions one is using, the time frame, and the decision rules. Functional measures can be directed at performance (what the person actually does) or at capability (what persons report they are capable of doing). They can use best performance or average performance. They can take into account pain, speed, or reported difficulty as criteria for judging that the person can perform the function, or they can ignore those modifiers. Some functional assessors may require that cleaning or dressing be performed to a certain standard of competence, and others may not build that into the protocol. Some tests of functioning involve actual demonstrated performance. The identical ADL items and response categories may be used, but the assumptions built into their use differ according to parameters, such as those discussed earlier. The best guide is to choose carefully based on the purpose of the measure and to take the trouble to describe in some detail the approach used to measure functioning.

Cognitive Functioning

As with functioning, the challenge of measuring cognitive abilities among older people has resulted in a huge number of instruments, some constituting brief screening tools and others more elaborate. Subdomains of cognition include recent memory, remote memory, attention, judgment, calculation, and problem solving. Tools to measure cognitive functioning have often been developed by and for the use of experimental psychologists. As such, they often entail demonstration of abilities, and their norms and psychometric properties are usually known. Instruments are less well developed to tap upper-level functioning, such as logic, creativity, and wisdom, but even here, some tools are available.

As with ADL measures, within limits, it probably does not matter which cognitive screening test is used;

many are interchangeable, though some seem less likely to alienate the older person being tested. Among the most commonly used tools are the Mini-Mental State Exam (Folstein et al., 1975), a 10-item Short Portable Mental Status Questionnaire derived from the OARS instrument (Pfeiffer, 1975), and versions of the Blessed Test (Blessed, Tomlinson, & Roth, 1968). As important as the choice is the interpretation of the results of a cognitive screening test. We may be too prone to use them to exclude direct input from older persons, deeming poor scorers unreliable. For example, it is typical to seek a proxy in a research study for anyone who falls below some preset MMSE score, despite the fact that persons scoring in the dementia range often can complete many assessments. Besides tests administered directly to the person whose cognition might be impaired, a variety of measures are available based on reports of informants (Langley, 2000). Finally, performance tests are available and are often used to develop stages for dementia. The Cognitive Performance Test is a particularly practical staging effort, used widely by occupational therapists because of its ability to suggest the need for care and support based on the demonstrated performance of common household tasks (Burns & Mortimer, 1994). For example, at early stages, a person can make buttered toast (one of the tasks), including assembling the items needed in the kitchen; at another stage, the person can perform the task if the toaster, bread, and butter are laid out in plain sight; and at a still later stage, the person may be able to make toast if asked to do each subtask separately.

Emotions and Mental Well-Being

Over the past 20 years there has been more acceptance of question-and-answer tests to gauge emotional well-being rather than exclusive reliance on a clinical interview by a qualified mental health professional. Many domains can be specified for assessment of affective or emotional functioning, including depression, anxiety, hopelessness, and anger, as well as positive domains such as hope, future orientation, and general psychological well-being. Depressive affect is the dimension most often measured, and numerous instruments are available; the best ones overcome the challenge of relying on somatic manifestations of depression that may be associated with illness in old people. Common instruments include the older Beck Depression Inventory (Beck, Ward, Mendelson, Mock, & Erbaugh, 1961) and Zung Self-

Rating Depression Scale (Zung, 1965), now overtaken in popularity by the Geriatric Depression Scale (Yesavage & Brink, 1983) and the CES-D tool used in multisite population studies (Radloff, 1977). Other instruments are available to assess anxiety and other negative emotional states. Some composite approaches attempt to tap a variety of emotions. The Affect Balance Scale (Bradburn, 1969), which counts both negative and positive emotions and generates two subscales, is widely used. Another self-report tool that includes positive and negative emotions has been well tested with people with poor cognitive functioning (Brod et al., 1999). In the general area of morale and life satisfaction, the two most commonly used tools are variants of the Life Satisfaction Index (Neugarten et al., 1961) and the Philadelphia Geriatric Center Morale Scale (Lawton, 1968). Also noteworthy to tap the positive end of psychological well-being are the scales developed by Ryff and colleagues (Ryff & Keyes, 1995), which use short scales to tap dimensions such as sense of purpose and self-esteem. For more examples and the actual items for many of these tools, see a recent review by Grann (2000).

A number of tools have been developed to assess behavioral disturbances of people with dementia. Among the more commonly used are Cohen-Mansfield's (1995) measures of agitation and several measures of disruptive behavior (Teri et al., 1992; Zarit, Reever, & Back-Peterson, 1980).

Social Functioning

Social functioning includes a wide range of phenomena. The available tools include measures of social network, of social support, and of social activity. Considerable agreement has now been reached about acceptable measures of social networks and of social support (variables that are often found as independent variables in research studies). Social well-being, which implies a value judgment, is much more difficult to measure as there is no unified body of theory that suggests the right blend of activity, stimulation, and relationships that constitutes social well-being. Moreover, this area is particularly sensitive to cultural and individual variation. The perception of meaningful relationships, of being loved by and loving others, of being trusted by and trusting others, seems pivotal to social well-being, which is probably why the questions about the reciprocal presence of a confidante (someone you trust and turn to, someone who trusts and turns to you) are a marker of the work that still

remains to be done in this area. (For a review of measures, see Levin, 2000.)

The social functioning construct remains highly susceptible to societal values. Being busy and enjoying interaction with others is generally viewed as better than being alone, but many people enjoy solo tasks like reading and doing puzzles. Whereas there is growing evidence to suggest that having someone with whom to relate (even a pet) has some protective effect, it is unreasonable to argue that the level of protection increases with the number of friends. In general, despite the large number of measures in the literature, there has been little convergence on satisfactory measures to tap domains of great interest to social work, such as productive aging (sometimes conceptualized as a blend of activities in the labor force, volunteer activities, activities within family, and activities that involve creative expression). This is an area that requires more measurement development.

Religiousness and Spirituality

Although spiritual well-being has come to be considered a fourth dimension of well-being (along with the physical, psychological, and social spheres, identified by the World Health Organization), we have made only small steps toward determining how to measure it. As independent variables, religion, religious practices, and religiosity have been measured. In contrast, spiritual well-being is typically a dependent variable that may or may not be related to religious observances. The Fetzer Institute (1999) in Kalamazoo, Michigan, in conjunction with the National Institute on Aging, has provided the most authoritative compendium of short tools that can be used to measure aspects of religion and spirituality in studies of the health and well-being of older people.

Quality of Life

Quality of life (QOL) is a multidimensional construct that has been measured in a variety of ways. Most authorities agree that QOL is a summary of physical, psychological, social, and even spiritual well-being. Health-related quality of life (HRQOL) is contrasted to more general QOL. Further, QOL tools can be identified for specific diagnoses such as stroke, arthritis, and diabetes. Those exploring this topic are referred to three edited books on QOL for older people, which show the progression of thinking about this

topic over time and offer a wealth of examples (Abeles, Gift, & Ory, 1994; Birren, Lubben, Rowe, & Deutchman, 1991; Noelker & Harel, 2001), as well as a review by Frytak (2000).

Values and Preferences

Measures of values and preferences relevant to older people are underdeveloped, though it is encouraging that development of some of these tools is under way. The current practice climate that promotes consumer control and autonomy has enhanced the felt need for measures in this domain. Most of the instruments available, perhaps appropriately, are tools to systematically record information rather than to yield scores.

Satisfaction

Satisfaction is sometimes defined as experience compared to expectations. As such, it is hard to measure because human beings reduce their expectations in response to bad experiences. Satisfaction measures are often flawed by showing a bias toward the positive, though measurement experts have suggested ways to word items to achieve a greater distribution of responses. Specific tools have been developed to assess satisfaction with health care, living conditions, nursing homes, assisted living, and home care (Smith, 2000).

Personality

Personality traits are often difficult to distinguish from moods and attitudes; the former are relatively fixed, whereas the latter may change with circumstances and interventions. Personality batteries, the province of psychologists, have been well developed for self-completed tests in younger people. Typically, they tap dimensions such as neuroticism, conscientiousness, extroversion/introversion, openness, and agreeableness, known as the Big Five (John, 1990). The problem is that many of the items pertain poorly to older people outside of the workplace. Costa and McCrae (1988, 1990) have been associated with most work on personality measurement in elderly people. This writer and colleagues developed and tested a shortened version of the Big Five, capable of being administered in an interview to nursing home residents who would not be capable of using self-completed batteries. Items were simplified and the anchoring

phrase “thinking about the kind of person you have been in your whole life” was used to avoid getting responses based on current energy levels and capabilities (R. A. Kane et al., 2004).

Family Caregiving

Until now, all the domains discussed entailed direct assessment of the older person. Family caregiver assessments pertain to people of all ages who are giving care to elderly family members. Assessment tools in this domain have proliferated. Initially, the main constructs measured were the burden of caregiving, itself a multidimensional construct including various types of burden. Among the most commonly used tools are the Montgomery Burden Scales (Montgomery, Gan-yea, & Hooyman, 1985); the Zarit Burden Scale (Zarit et al., 1980), which is specific to the burden associated with care of a person with Alzheimer’s disease; and the multiple short tools developed by Pearlin and colleagues (Pearlin, Mullan, Semple, & Skaff, 1990; Pearlin & Zarit, 1993) to make operational the stress process related to family caregiver outcomes. The Hassles Scale was developed to capture the small inconveniences and negative effects of caregiving on a daily basis (Kinney & Stephens, 1989a), and the Uplifts Scale was developed in response to an effort to identify more positive effects of family caregiving (Kinney & Stephens, 1989b).

Despite the enormous body of research available on this topic, assessment tools are still lacking for several aspects of family care. First, little attention has been given to measuring the actual activities of family care and their intensity and duration. Second, insufficient measures have been developed to assess the care recipient’s perspective on the caregiving experience. Finally, as already hinted, the overwhelming emphasis on burden should be mitigated by work on a range of effects. One cannot assume that absence of burden is the upper range of reactions to family care; qualitative studies have suggested that psychological and tangible rewards can exist for family care.

Physical Environments

Finally, systematic assessment of physical environments for older people should be an important area for social work, given the profession’s focus on the person and the environment. Elaborate approaches are available, the best known being Moos’s (Moos &

Lemke, 1996) Multiphasic Environmental Assessment Protocol, which in its entirety is often too difficult to apply even in research contexts. A number of environmental tools have been developed specifically for the assessment of care units in nursing homes, especially for dementia care units. These include the Therapeutic Environment Screening Scale (Sloane & Mathew, 1990) and the Professional Environment Screening Procedure (Lawton et al., 2000). More recently, Cutler and colleagues developed less subjective ways of assessing environments in assisted living and in nursing homes and derived measures of conceptual domains such as function-enhancing features, life-enriching features, controllability of environment, and privacy-enhancing attributes (Cutler, 2000; Cutler et al., in press). There remains a need to develop assessments for the home environment that go beyond the safety checklists that are widely used in home health and occupational therapy.

CONCLUSION

Standardized assessments in geriatrics and gerontology are extraordinarily plentiful and may be perceived as bewildering and confusing to neophyte practitioners and researchers. This chapter endeavored to offer an introduction to the many domains of assessment and dimensions within domains while providing some criteria for evaluating assessment tools either to choose an instrument or to interpret results of assessments given to clientele. The proliferation of assessment tools can be predicted to increase even further. Among the trends to watch are increasing automation of assessment tools and increasing mandates for specific assessment tools for publicly funded programs. Social workers should have little difficulty identifying assessment tools that assess many of the constructs of interest to them, though they should examine the qualities of any tool they decide to use in their practice or research.

B. Theories and Modes of Practice Intervention With Older Adults and Their Families/Caregivers

KATHLEEN McINNIS-DITTRICH

Cognitive-Behavioral Interventions

68

The phrase “cognitive-behavioral” embraces a broad range of therapeutic interventions, ranging from the complicated process of cognitive restructuring to the relatively simple behavior management techniques employed in validation therapy. The common denominator of cognitive-behavioral interventions is the focus on the older adult’s thought process and how that process influences subsequent emotional and behavioral responses. What an older adult thinks affects how he or she feels and behaves. With older adults, cognitive-behavioral approaches are most commonly used to treat mild to moderate forms of depression and anxiety. This chapter specifically examines cognitive-behavioral therapy (CBT), crisis intervention, and validation therapy.

COGNITIVE-BEHAVIORAL THERAPY

CBT is based on the assumption that both cognitive and behavioral responses to events are learned (Adler, 1963; Beck, 1995; Ellis, 1962; Lantz, 1996; Malkinson, 2001). Once the older adult recognizes the triggers for automatic responses, new and more adaptive patterns of behavior can also be learned. CBT is perhaps underutilized in treating depression and anxiety in older adults. Depression sometimes is seen as a normal consequence of the aging process rather than as a treatable psychological condition (McInnis-Dittrich, 2005; O’Hara, 2000). There are also lingering Freudian perspectives suggesting that older adults’ personality traits and behavior patterns are too rigid to respond to psychotherapy (Pinquart & Sorenson, 2001). More likely, however, the problem is the lack of training in the mental health community to address many of the emotional and behavioral problems that affect this age group.

Older Adults Who Respond Best to Cognitive-Behavioral Therapy

Accurate diagnosis of depression or anxiety in an older adult is the precursor of successful application of CBT to this population. Dementia, delirium, anxiety, and depression in older adults often mimic each other, and it may be difficult to clearly determine the cause of an older adult’s depression or anxiety (Anderson, 2001; McInnis-Dittrich, 2005; Pinquart & Sorenson, 2001).

Even with an accurate diagnosis, CBT is not appropriate for use with all older adults. Late-onset maladaptive thinking and behavior appear to respond

better to CBT than those patterns reinforced from childhood (O'Hara, 2000). It is most effective with elders who are verbal and have few, if any, cognitive impairments, even if such impairments are not due to dementia. The cognitive-behavioral process requires that an individual be able to identify thoughts and discuss feelings (McInnis-Dittrich, 2005). The ability to engage in abstract thinking and analyze behavior is the cornerstone of CBT. No matter how easily the social worker can see how cognitive distortions are causing the older adult to remain depressed or become anxious, it is the older adult's insight, not the worker's, that changes the person's feelings and behaviors.

The CBT approach has shown limited usefulness in work with older adults who are highly autonomous or have extreme difficulty asking for or receiving help (Mosher-Ashley & Barrett, 1997). This approach is also not appropriate for older adults who have exhibited suicidal ideations (Yost, Beutler, Corbishley, & Allender, 1986) or those who are actively abusing drugs or alcohol.

The Cognitive-Behavioral Process

The process of CBT, which has been adapted for use with older adults by Yost et al. (1986), Mosher-Ashley and Barrett (1997), and others, consists of four distinct stages: preparation, collaboration-identification, actual behavioral change, and consolidation. In the preparation phase, considerable time is devoted to developing the professional relationship between the older adult and the therapist. Older adults need to have a clear understanding of the cognitive-behavioral change process along with realistic expectations of how CBT can help them change emotional and behavioral responses. Individuals must be capable of, and interested in, committing to a process of intense introspection and trust the guidance and insight of the therapist.

In the collaboration-identification phase of CBT, the older adult is introduced to the process of identifying the relationship between events and feelings. The therapist explores those situations in which the older adult is acutely aware of being depressed or anxious, helping him or her see how certain situations elicit such feelings based on what the older adult was thinking. In the case of an older widow with mild to moderate depression, it is important for her to identify those times when she is acutely aware of her depressed feelings. For example, she may identify Sundays as particularly difficult times because she ex-

pects to receive a call from her son or she finds herself painfully alone on a day usually devoted to family activities. The lack of a phone call or being alone (the events) trigger sadness and feelings of being unloved (the emotions). She may have been thinking, "I am not important enough for my son to remember to call me. He must not care about me." She is learning to connect an event, the cognitive response, and the emotional response.

This degree of insight must be developed before entering the change phase of CBT. Once events, feelings, and thoughts are identified by the older adult, the therapist can explore the behavioral reaction to this change of events. For example, even though she welcomes the attention from her son when he does call later in the week, she is hypercritical and argumentative with him (the behavioral response). When she is able to see that she may be trying to punish her son for his neglect and that his unpleasant interaction with her may actually be exacerbating the problem of his not calling, she can begin to explore ways to change this chain of events. The change process occurs through the older adult's examination of distorted thinking. Cognitive distortions include globalizing, "awfulizing," mind reading, self-blaming, unrealistic demands on others, unrealistic expectations of self, and exaggeration of self-importance. It is easy to see how errors in thinking can lead this older woman to have a painful emotional reaction. If she believes that not receiving a phone call on Sunday from her son means he does not love her anymore, it is not surprising that she would be depressed. At this point in CBT, the therapist explores how she can employ corrective behavioral actions to prevent her depressed feelings from developing. Instead of brooding all day because her son has not called, she can decide to become proactive, empowering herself to do something positive to make herself feel better. Rather than fixating on the thought "He doesn't love me," she can substitute the thought "He must be very busy. I should call him and see how he is doing." Taking such positive steps empowers her to regain mastery over her environment and feel less depressed. This corrective action has the added advantage of making the interaction between mother and son more positive for both parties. If she is less difficult when he calls, perhaps he will call more.

The final phase of CBT is consolidation and termination. The therapist's job is to consolidate the changes observed during the treatment process. Reviewing with the older adult how far he or she has come, discussing what strengths have developed in identifying emotions

and thoughts, and reinforcing the belief that he or she can handle future challenges is part of this process. An older adult needs to leave the therapeutic process confident that he or she has learned the skills to continue to fight depression or anxiety in the future.

A number of other techniques can be used in CBT to supplement traditional talk therapy. These include more traditional psychodynamic approaches, progressive muscle relaxation, reminiscence, increasing socialization, and stress inoculation (Puder, 1988). Other techniques employed specifically in using CBT to treat grief include guided imagery, exposure techniques, thought-stopping, breathing exercises, and skill acquisition (Malkinson, 2001).

The Effectiveness of CBT With Older Adults

The effectiveness of CBT in reducing both anxiety and depression in older adults is widely supported in the mental health research (Arean, 1993; Beck & Stanley, 1997; McCarthy, Katz, & Foa, 1991). O'Hara (2000) found CBT to be especially effective in reducing anxiety when it was combined with relaxation techniques. While working on correcting distortions in thinking, older adults benefited from the immediate anxiety-reducing influence of a variety of relaxation techniques.

Pinquart and Sorenson (2001) found that CBT was more effective in resolving issues in depression and anxiety among older adults than psychoeducational, activity promotion, and cognitive training approaches. They found that both CBT and psychodynamic approaches significantly improved an older adult's sense of well-being and the clinician's perception of the level of depression in the older adult. These researchers and others (Zarit & Zarit, 1998) attribute CBT's success to the concrete, problem-solving nature of the approach. Pinquart and Sorenson found CBT more effective in the context of individual therapy as opposed to use in the group setting.

CRISIS INTERVENTION

Crisis Versus Stressful Events

By the nature of life's challenges at this point in their lives, older adults are at high risk for myriad stressful events. However, stressful events do not always result in a *crisis*, as it is defined in the mental health field

(Duffy & Iscoe, 1990). The extent to which stressful events become a crisis lies in individuals' perceptions that they have reached an impasse in their ability to cope with the stressful event (Caplan, 1964; Duffy & Iscoe, 1990). Individuals may perceive that previously learned coping skills are no longer either effective or sufficient to face and manage a life event. The key to defining a crisis lies in the individual's *perception* of being overwhelmed.

An older adult's reaction to a crisis may be one of acute anxiety and a sense of panic and despair. He or she may become obsessed with "doing something," although what exactly will resolve the crisis may not be clear, and such behavior may seem irrational or counterproductive. On the contrary, the older adult may withdraw and retreat as a means of coping with an overwhelming challenge (Duffy & Iscoe, 1990; McInnis-Dittrich, 2005). This may include social isolation or a retreat to alcohol, drugs, or suicide as coping mechanisms. A sustained crisis response to an event may damage both physical and psychological health.

Are Older Adults at Higher Risk for Crisis Events?

Very little empirical research has been conducted on the incidence and treatment of crisis events in the lives of older adults, yet there is conflicting evidence as to whether older adults are at greater risk for responding to a stressful event as a crisis. Ebersole and Hess (1998) conclude that older adults are at higher risk for the development of a crisis in their lives and will need more time to resolve the crisis. Other studies have found that older adults are less likely to experience a crisis event; as a result of a lifetime of coping with stress and a larger repertoire of coping skills, they will resolve a crisis episode more quickly (Norris & Murrell, 1988). In one of the few studies of its kind, Winogron and Mirassou (1983) found that although fewer older adults contacted crisis intervention services, when they or others in their support system did, the type of crisis they reported was much more severe and less amenable to traditional brief therapeutic interventions. Older adults are much more likely to come into the service system in a crisis situation identified by family, friends, or community members rather than through self-referral (Florio & Raschko, 1998).

There are a number of characteristics that place older adults as a group and specific individuals in particular at risk for a crisis event. A serious illness or sudden loss of one of the activities of daily living

(ADLs) were the most common events precipitating a crisis among older adults (Chima, 2002; Winogron & Mirassou, 1983). Others included an unanticipated loss of financial resources due to illness or retirement, placement in a nursing home (Chima, 2002), domestic violence (Brandl & Horan, 2002), and loss of a life partner. Not all older adults respond to these events with a crisis reaction, but it appears the multiplicity of events may be the precipitating factor. Each stressful event exacerbates the influence of the others.

With an increased likelihood of illness, difficulties in maintaining adequate hydration and nutrition, asymptomatic infections, and complex medication regimens, older adults are at higher risk for the development of delirium, which often mimics a crisis reaction (McInnis-Dittrich, 2005; Rapp, 2001). Delirium is characterized by dementia-like symptoms, with a sudden onset and increased agitation, but can be linked to a physiological etiology, not a personal reaction to a stressful event. Delirium is a medical emergency, not a psychosocial crisis. In such cases, the older adult should receive immediate medical treatment. When an older adult presents in crisis, delirium should be ruled out before psychosocial intervention methods are employed.

Crisis Intervention Methods

Primary Intervention

Primary intervention occurs before a crisis actually develops and is aimed at developing coping skills prior to the demand for those skills. There are a number of events that commonly accompany one's later years that do not have to become a crisis if one is prepared. For example, a reduction in income is likely upon retirement. In anticipation, a couple could develop a sample budget before retirement, alerting them to the ways they will have to change existing spending patterns. Preparing older adults for the possibility of the reduced physical strength that often accompanies degenerative arthritis can be facilitated by helping them explore strength training and exercise programs aimed at maintaining abilities rather than seeking to recover them once the disease has progressed. Preparation through education can empower older adults to anticipate events (e.g., the loss of a partner) and plan before the event occurs. All of these events (retirement, chronic disease, and loss of a partner) may still be stressful, but the older adult has developed coping skills in anticipation of a likely stressful event.

Secondary Prevention

Secondary prevention occurs once an event or condition develops but is aimed at minimizing the growth of the stressful event into a crisis (Chima, 1996, 2002). Crisis intervention techniques at this level may include support groups for newly widowed older adults or social and recreation programs for older adults who find themselves depressed due to isolation from family and friends. Encouraging the transition to more supportive living arrangements such as independent or assistive community living rather than waiting until skilled nursing care is needed for a chronic health condition is another example of secondary prevention. The key to preventing an older adult's perception that a stressful event is beyond his or her coping skills, thus becoming a crisis, is helping the person to retain mastery and control of as much of his or her life as possible.

Tertiary Prevention

Once individuals perceive themselves at an impasse in their ability to rally the necessary coping skills to manage a stressful event, tertiary intervention is indicated. Steps in crisis intervention for older adults include the following:

1. Create a quiet, nonstimulating environment for the initial assessment of the individual. Visual and audio stimulation should be minimal. Make the older adult as comfortable as possible with comfortable seating or room to pace. Use a calm, soft voice to speak to the older adult.
2. As much as possible, and using collateral information from family and friends, quickly assess whether the psychosocial crisis is actually a delirious reaction to a physical illness, medication toxicity, dehydration, or malnutrition.
3. If delirium can be ruled out, encourage the older adult to tell you as much as possible about the events leading up to the crisis. Although the individual may be very anxious (or withdrawn), it is imperative to also assess at this point whether he or she has any cognitive limitations. Older adults in middle- and late-stage dementia are extremely difficult to engage in a rational conversation and may require hospitalization to stabilize them emotionally and cognitively. Let the older adult talk as much or as little as needed without interruption. Encourage the older adult to breathe deeply and "start at the beginning."

4. Provide a safe environment for the older adult. If it's chilly, provide a blanket. If the area is too warm, cool down the room. If the individual is afraid of being hurt by family or friends, separate the older adult from what he or she fears (Brandl & Horan, 2002). The perception of being safe and cared for is essential for reducing anxiety and drawing out the elder. The goal is to provide for the older adult's immediate needs, physical and psychological.
5. Identify at least one short-term goal that can be quickly accomplished and will provide immediate anxiety relief. For example, if the older adult is having a crisis reaction to recent widowhood, make sure he or she is not left alone. This not only is a safeguard against suicide but also meets an immediate need not to be alone. If an individual has been the victim of an assault, be sensitive to the need for some physical distance from strangers until he or she is ready to reach out. If the older adult has lost a home due to fire, identify an immediate short-term solution for a place to stay.
6. When the immediate crisis has passed and the older adult has regained some basic control over his or her emotional responses, begin the discussion of a long-term plan to resolve the crisis. However, discuss the long-term goal in terms of short-term steps (Jobes & Berman, 1996). "Emphasize the realistic positive" while not denying the perception of the overlying problem (Holkup, 2003, p. 13). Accomplishing small tasks successfully helps older adults to regain a sense of mastery and control over the environment. Small successes will build confidence for long-term goals.
7. Follow-up is necessary in treating any crisis reaction in an older adult. Identifying long-term supports or mobilizing resources that will prevent a future crisis reaction is an ongoing process. It will take some time for the older adult to return to emotional equilibrium.

VALIDATION THERAPY

Although a cognitive-behavioral approach works well with high-functioning older adults, it is not recommended for addressing troublesome affect or behavior in older adults with deficits in cognitive functioning, such as in Alzheimer's disease and other dementias. One alternative therapeutic approach for work with this population is known as validation therapy. Unlike the cognitive-behavioral approach, validation therapy does not try to change an older

adult's thought patterns but rather tries to understand how the distorted thinking often associated with dementia is actually an older adult's attempt to communicate a need to those around him or her (Feil, 1996). Rather than attempt to reorient older adults with dementia to the correct time and space in their environment (the main focus of reality orientation), validation therapy communicates with older adults by validating and respecting their feelings in whatever time or place is real to them (Day, 1997).

Developed by Naomi Feil in the 1960s, validation therapy is based on the underlying belief that behavior in very old people is a complex interaction of physical, social, and biological changes that occur over the life span; failing to complete some earlier life tasks may lead to psychological problems later in life (Feil, 1967, 1984, 1993, 1996). When an older adult's memory begins to fail, he or she may attempt to restore balance to his or her life by retrieving earlier memories, which could include unresolved issues from early life experiences. Feil (1996) contends that when painful feelings are expressed, acknowledged, and validated by a trusted listener, they will diminish. If those feelings are ignored or suppressed, they will gain strength and contribute to difficulties in affective response or behavior.

Validation Therapy as a Long-Term Therapeutic Approach

Feil (1967, 1984, 1996) originally proposed validation therapy as an ongoing therapeutic approach that could be used by social workers, nurses, and nursing assistants with confused older adults over a sustained period of time. She identified four stages of confusion commonly observed in the progression of dementia: malorientation, time (and space) confusion, repetitive motion, and vegetation. She proposed specific therapeutic techniques for each of the stages coinciding with how severe confusion appeared and what seemed to work the best to calm an anxious and confused older adult in each stage. Her original work assumed that care would be provided consistently by the same group of mental health workers and staff. Working with the same older adult on a regular basis would allow these caregivers the opportunity to get to know the person, thus being capable of identifying the appropriate stage of confusion. An ongoing relationship would facilitate an accurate interpretation of the developmental challenges or problems the older adult was attempting to communicate (Babins, 1988).

The basic therapeutic techniques of validation therapy include the following:

- A conscious effort on the part of staff or family to first center themselves to dissipate the intense emotions often created by an older adult's agitated behavior.
- Using nonthreatening, factual words—such as who, what, when, where, and how—to build trust to explore what the older adult is trying to communicate.
- Rephrasing the older adult's words using the same rhythm and expression to minimize confrontation and validate what the older adult is saying.
- Using polarity, such as asking, "Is that the worst thing that happened?" The simple act of listening gives the person permission to talk.
- Reminiscing about former problem-solving skills the older adult has used in the past.
- Maintaining genuine, close eye contact to reduce anxiety on the part of the older adult.
- Using a clear, low, loving tone of voice to sooth agitation.
- Linking the observed behavior or affect to the unmet developmental need, especially the basic human needs for love, being needed, and the expression of emotion.
- Using music for those elders who are severely withdrawn to appeal to emotions and experiences from their past. (Feil, 1996)

Feil (1996) proposes that over time, the nature and extent of unresolved issues from the older adult's past will become apparent, allowing the professional helper or caregiver to help the person work through the issues. Even if the issues cannot be resolved, having the opportunity to express these feelings to a listener who validates the individual's feelings and responds with respect and empathy has its therapeutic benefits.

The Validation Approach as a Behavioral Management Technique

Ongoing relationship building between a confused older adult and a therapist or caregiver skilled in the use of therapeutic techniques may not be possible in most long-term care facilities serving this population. However, the validation approach may have its greatest usefulness in managing short-term behavior (McInnis-Dittrich, 2005; Pietro, 2002). Rather than attempt to constantly correct a confused older adult's

perception of reality, a validation approach accepts that any communication is attempting to express a need that may or may not be related to earlier unresolved conflicts.

For example, if a widow with dementia keeps asking "Where is my husband?" even though her husband has been dead for many years, the validation approach would contend that this statement reflects the woman's needs. Rather than correct the woman by reminding her that she is widowed and that her husband has been gone for many years, the response might be "You must miss your husband very much" or "I know it must be frightening to be alone right now." Rather than interpret the person's statement as a reflection of her confusion, a validation approach interprets the statement as her expression of loneliness or grief that her husband is not with her. The therapeutic benefits of such a statement come from the empathic, reassuring tone of the respondent and the lack of attempt to argue with or contradict the older adult. It can serve both as a distraction to the older adult to move him or her away from the troubling thought and as a way to minimize agitation. Not only does such an approach appear to de-escalate agitation in confused elders, but it does not allow caregivers and family members to become angry, resentful, and exhausted from constantly trying to bring a confused elder into their reality (Day, 1997).

The Pros and Cons of the Validation Approach

Feil (1993) observed improved speech, less regression, less crying, less wandering behavior, and improvements in gait, interaction, and eye contact among older adults who were treated using the validation approach rather than a reorientation approach. She also found less need for physical or chemical restraints due to the reduction in aggressive and violent behavior. Other observers found that older adults and their families were able to communicate more successfully during visits, resulting in less frustration on the part of both the older adult and caregivers (Babins, Dillion, & Merovitz, 1988; Fine & Rouse-Bane, 1995). Anecdotal evidence supports the contention that the approach can be effective in defusing potentially catastrophic behaviors by older adults who are agitated, confused, and potentially violent to self and others (Fine & Rouse-Bane, 1995). The primary advantage of the validation approach is that it is relatively safe; no medication or restraints are needed.

However, the use of validation therapy remains very controversial. Controlled studies have found no statistically significant connection between the use of a validation approach and improvements in behavior among older adults with dementia (Babins, Dillion & Merovitz, 1988; Morton & Bleathman, 1991; Robb, Stegman, & Wolanin, 1986; Scanland & Emershaw, 1993). In the studies that both supported and refuted the effectiveness of validation therapy, very small, nonrandomized samples were used without matched control groups or the establishment of credible preintervention behavior baselines. Other critics feel that validation techniques hasten confused older adults' difficulty orienting themselves to reality. That is, if confusion is not corrected, older adults will lose the ability to maintain whatever reality abilities they do have. These limitations make it impossible to discount the value of the validation approach as well as fail to support it as an effective alternative to reality orientation.

Family and Group Interventions

69

Despite the dramatic demographic changes known as the longevity revolution and the demonstrated need, older adults continue to receive inadequate mental health care. Mental health professions, including social workers, far too frequently ignore the grandparental generation, viewing aging as a time of decline. Practitioners also have tended to discount the utility of therapy with older adults, arguing that treatment is not efficacious (Newton, Brauer, Gutmann, & Grunes, 1986; Schneider & Kropf, 1992). Furthermore, professionals continue to debate how to overcome the lag existing in practice, research, education, policy, and planning (Council on Social Work Education [CSWE]/SAGE/SW, 2001; Gatz, 1996). Moreover, there is a dearth of research about what therapies work with older adults and their families (Orbach, 2003). At the same time, the allocation of resources to support caregiving families has always been routine among social work practitioners.

Ironically, research about the caregiving process has “flourished, [leading to] an intense concern about its economic, social, and psychological impact” (Pearlin, Mullen, Semple, & Skaff, 1990, p. 583). The information garnered has countered practice trends. The burgeoning of information about the impact of caregiving, and the increased recognition that informal caregiving is a typical family experience, has propelled practitioners and theorists alike to seek interventions that might alleviate caregiver stress (Toseland & Rossiter, 1989). Consequently, family therapy and group treatments have become more commonplace. That is, practitioners have gradually adopted or modified traditional family and group clinical social work approaches thought to be effective with the general population for use with frail older adults and their caregivers. By the mid-1980s, a growing interest in caregiver support began to close the gap between what is known about family functioning and clinical practice (Greene, 1989). This chapter discusses the development and nature of those social work family and group interventions.

CAREGIVING

Caregiving involves attending to the health, social, and personal care needs of people who are lacking some capacity for self-care. It encompasses the functional capacities of older adults, the caregiving patterns of families, and the use of community-based services (Greene, Dalin, & Lebow, 1991). Daatland (1983, p. 1) has proposed that family caregiving be seen

as a form of social organization that includes the interpersonal relationships and the division of practical tasks: “a truly collective action, depending upon direct and indirect contributions from a number of actors, including the cared for himself.”

It is a well-known fact that the majority of older adults who need assistance are cared for by a family member (AARP, 2003). The family transition to providing care for an older adult has become so widespread that Brody (1985, p. 25) called this phase of the life course “normative family stress.” Caregiving tasks may include direct personal care, such as bathing and grooming, and indirect care, such as cooking, cleaning, and running errands. When an older adult has an acute or chronic illness, caregiving tasks may encompass simple forms of medical treatment such as injections.

Usually, a primary caregiver—often a wife, daughter, or daughter-in-law—assumes major responsibility. The generation of mostly women with direct caregiving responsibilities for two generations is called the sandwich generation; they juggle the responsibilities of mother-caregiver, daughter-caregiver, and worker (Marks, 1998; Stephens, Franks & Townsend, 1994). In addition, other family and friends, especially male relatives, may assume instrumental caregiving responsibilities, including bill paying (Hash, 2003).

Providing care for an older frail relative is complex and often involves rewards and risks. Rewards include feelings of being useful, appreciated, and satisfied with one’s caregiving. Caregivers may also develop a sense of altruism and competence and have the opportunity to share feelings of love and empathy with the care recipient (Toseland & Smith, 2001). Risks thought to stem from the stress experienced by caregiving may include restrictions on the caregiver’s activities, social isolation, reduced paid employment, and emotional difficulties such as depression and anxiety (Toseland & Smith, 2001).

Uncertainty about the older adult’s illness or disability as well as the costs associated with such needs as special diets may also increase risks. Still another source of stress for caregivers is having to make end-of-life decisions for the care (Smerglass & Deimling, 1997).

INTERGENERATIONAL FAMILY INTERVENTIONS

Social work practice with older adults and their caregivers is based on knowledge that came to the fore in the 1970s and 1980s about intergenerational family

functioning, filial relationships, and the biopsychosocial processes of aging. Theorists who defined intergenerational family dynamics contest the idea that there is a totally isolated nuclear family. Rather, they suggest that family dynamics involve the connecting link between generations based on loyalty, reciprocity, and indebtedness (Boszormenyi-Nagy & Spark, 1973). Research studies on the topic consistently reveal the financial, physical, and emotional reciprocity across generations, taking the form of telephoning, visiting, writing, and showing respect and concern. Care was also found to vary due to cultural factors associated with race/ethnicity. Diversity dimensions may also include size of household, intergenerational contacts and family support exchanges, gender, cohort group, and socioeconomic status (Tennstedt & Chang, 1998).

Following suit, family therapists suggested that therapy is indicated when a family experiences disagreements about autonomy issues or when the family experiences hidden and unresolved conflicts between generations (Greene, 1989). Autonomy issues encompass the balance between independence and dependence within the family; unresolved conflicts include unsettled scores or arguments. Moreover, it was noted that multigenerational conflicts often arise because of challenges to the family’s long-standing interaction patterns, involving a shift in role transitions and family structure (Davey, Murphy, & Price, 2000; Newton & Lazarus, 1992).

Systems theory is frequently used to explore how people interact as a unit, particularly their structure and organization as a group. Systems theory assumes that a family is a functioning whole, with each person in constant interplay with another. Family dynamics is composed of these mutual influences and refocuses a practitioner’s concerns on the here-and-now interactions that provoke difficulties. A family systems approach to family interventions offers the social worker a number of other useful guidelines:

- Assumes the family is a system with unique and discernible structure and communication patterns.
- Defines the boundaries of the family membership and cultural forms.
- Develops a picture of family structure, power relationships, and how roles are differentiated.
- Examines communication patterns to learn about the rules and cultural patterns.
- Determines how responsive the family is to stress as well as its ability to restructure to meet caregiving demands. (Based on Greene, 2001, p. 224)

The ecological perspective is also used to better understand how a family relates with other social systems. The perspective is based on Bronfenbrenner's (1979) conceptualization of person-environment fit. The ecological perspective lends itself to multisystemic analysis of how client families function and the consideration of what resources may support their endeavors. For example, practitioners work with small-scale microsystems (such as families and peer groups), the connection between systems known as mesosystems (such as the family and health care systems), exosystems (the connections between systems that do not directly involve the person, such as Social Security and Medicare), and macrosystems, or overarching large-scale systems, such as legal, political, and value systems.

Social work practice from an ecological perspective focuses on what Gitterman and Germain (1976) termed problems of daily living. It also underscores the need for social workers to promote everyday competence among older adults (Willis, 1991). Research on environmental stress suggests that caregiving responsibilities have the potential to negatively affect the mental and physical well-being of the caregiver, be disruptive to marital and family relationships, and cause problems in meeting work and other social responsibilities (Pearlin, Aneshensel, & Leblanc, 1997). These research models make the distinction between primary and secondary stressors. Primary stressors are those associated with the necessities of the caregiving role, such as coping with the behaviors associated with dementia. Secondary stressors are more peripheral to or outside the caregiving role and may involve social or workplace issues of the sandwich generation. Such stressors in caregiving often precipitate families contacting social services agencies. From the ecological perspective, the social worker would determine how well the family fits with the environment, with a view toward ascertaining resource needs; choose intervention strategies congruent with a client's environmental and cultural context; direct interventions at any aspect of the ecosystem; and base interventions on client strengths and expertise (Greene & Barnes, 1998).

INTERVENTION MODELS

Models of geriatric health care are based on designs that promote optimal functioning among elders. At the core of this care process are comprehensive assessments used to gather a wide array of information

about the quality of an older adult's biopsychosocial functioning (McInnis-Dittrich, 2002). The social worker evaluates the client's capacity to function effectively in his or her environment and to ascertain what resources are needed to improve interpersonal functioning (Greene & Sullivan, in press). The purpose of the biopsychosocial assessment is to assess functional capacity or everyday competence: the ability of older people to care for themselves, manage their affairs, and live independent, quality lives in their communities (Willis, 1991). The assessment may also include a diagnostic workup, which is an in-depth medical and physical evaluation (McInnis-Dittrich, 2002).

MODELS OF FAMILY INTERVENTION

During the 1980s and 1990s, social workers developed models for working with older adults and their family caregivers. These included the family case management approach for Level I needs (Greene & Kropf, 2003), the auxiliary function model (Silverstone & Burack-Weiss, 1983), and the functional age model of intergenerational family treatment (Greene, 1986, 2001).

The family case management approach is a process of assisting families with multiple needs, helping them cope with stress and issues related to the use of multiple service providers (Table 69.1). "The goals of family case management are to mobilize a family's strengths, to marshal resources, and to maximize family functional capacity" (Greene & Kropf, 1995, p. 85). The social worker first engages the family in a helping relationship and then works with the family to develop and carry out a mutual care plan.

The auxiliary function model (Silverstone & Burack-Weiss, 1983) proposes that the major problems facing frail, impaired older adults are not disease or old age, but the effects these conditions may have on mental and physical functioning. The proponents of this model contended that therapy should be based on a supportive relationship and designed to counter the factors associated with depletion or loss. The major goal of the social worker in this model of intervention is to combat a family's feelings of helplessness in the face of its multiple losses, that is, to convey a sense of hope.

Another example of family-focused intervention is the functional age model of intergenerational family treatment (Greene, 1986, 2001). This model can be used to examine caregiving risk and well-being from

TABLE 69.1. Key Features of Family-Focused Social Work Case Management

Family-focused social work requires that the case manager

- Identify the family as the unit of attention.
 - Assess the frail or impaired person's biopsychosocial functioning and needs within a culturally sound family context.
 - Write a mutually agreed upon family care plan.
 - Refer client systems to services and entitlements not available in the natural support system.
 - Implement and coordinate the work that is done with the family.
 - Determine what services need to be coordinated on behalf of the family.
 - Intervene clinically to ameliorate family emotional problems and stress accompanying illness or loss of functioning.
 - Determine how the impaired person and family will interact with formal care providers.
 - Integrate formal and informal services provided by the family and other primary groups.
 - Offer or advocate for particular services that the informal support network is not able to offer.
 - Contact client networks and service providers to determine the quality of service provision.
 - Mediate conflicts between family and service providers to empower the family when it is not successful.
 - Collect information and data to augment the advocacy and evaluation efforts to ensure quality of care.
-

Source: Vourlekis and Greene (1992, p. 12).

a systems perspective; it is an approach used to promote a family's caregiving capacity. The model suggests that the social worker understand the "family as a mutually dependent unit with interdependent pasts and futures" (p. 20). As such, it employs a systems approach to intervene with families whose older relative is experiencing interference in performing activities of daily living—those skills that are called on to meet environmental demands. The model comprises assessment and intervention strategies in two domains: the functional age or biopsychosocial functioning of the older adult (Birren, 1969) and the role allocation and life course development of the family.

Functional Age

The central part of the functional age model is the social worker's assessment of the functional age or capacity of the older adult. Functional age is composed of three spheres related to adaptational capacity:

1. Biological age, referring to a client's health-related issues, such as chronic disease, medication effects, and physical concerns, such as energy levels. Decrements in memory, cognition, and judgment also are included in biological age.
2. Psychological age, encompassing affective and rational processes, such as mood, and thought processes, encompassing introspection and the meaning of events.

3. Social age, referring to the role one plays in the social structure, including norms, values, culture, and ethnicity.

Family

Along with the assessment of functional age, the social worker also develops an understanding of the family's adapting and coping capacity. The family is viewed as a social system with a high degree of interdependence and interrelatedness (however obscure) that is challenged when an older member has a crisis in functional capacity. The family is assessed from two perspectives:

1. The family as a set of reciprocal roles, including the expectations members share concerning behaviors in a certain situation, such as what a "good" older child does for his or her parent.
2. The family as a developmental unit, referring to the tasks expected of the family as a mutual aid system.

Family development emphasizes that family relationships are more than a combination of individual life cycles. Rather, family members' life stages are intertwined, with the effects of membership, including births, marriages, and deaths, introducing family change over time (Carter & McGoldrick, 1999).

Group Interventions

Because many older adults are more socially isolated than they were in their younger years, a group approach provides the therapeutic effect of group dynamics (McInnis-Dittrich, 2002). This reaffirmation of the human connection is based on the long-standing tradition of social group work with vulnerable older persons (Saul, 1983) and continues today in efforts of narrative gerontologists and others (Crimmens, 1998; Webster, 2001).

There are a variety of groups appropriate to work with older adults, using an array of theoretical frameworks, such as Yalom's (1985) existential perspective. According to McInnis-Dittrich (2002), group methods may have to be adjusted to account for elders' physical and sensory limitations. The group leader may have to take a more active role, and the pace may be slower. Group interventions may take several forms: group psychotherapy (Zarit & Knight, 1996), based on psychodynamic theory and intended to help clients gain insight; reality orientation groups (Greene, 2001), based on cognitive frameworks and designed to combat confusion and disorientation among elderly persons; support groups, based on the strengths perspective and intended to share solutions for common problems (Cox & Parsons, 1994); and reminiscing groups, based on Eriksonian life stages and aimed at recalling the past to settle past concerns.

Support Groups

Support groups are based on mutual aid and often provide information about a specific illness (Table 69.2). Support groups for caregivers take many forms and can reduce caregiver stress by providing a caregiver with respite; reducing loneliness; promoting ventilation of emotions; sharing feelings in a supportive environment; validating, universalizing, and normalizing thoughts, feelings, and experiences; instilling hope; affirming the significance of the caregiver role; educating caregivers about the aging process, resources, or health and disability topics; teaching problem-solving and coping strategies; and fostering the caregiver's capacity for problem solving (Hash, 2003, p. 223).

Reminiscing Groups

One of the most common theoretical frameworks used in group work with older adults and their caregivers is the reminiscing group format. Life review is based on Erikson's (1950) approach to the eighth stage

of development, in which the developmental tasks involve resolving the crisis of integrity versus despair. Robert Butler (1963), one of the founding group of geriatric psychiatrists, believed that Erikson's approach provided the insight necessary to frame a life cycle psychiatry to guide psychotherapy with older adults. He contended that life review is "a progressive return to consciousness of past experiences in an attempt to resolve and integrate them" as well as a means of coming to terms with past conflicts and relationships (p. 65).

Based on his research at the National Institute of Mental Health and his private practice, Butler (1963, p. 237) came to believe that the "possibilities for intrapsychic change may be greater in old age than at any other period in life." He also thought that through therapies that define and seek opportunities, older adults come to terms with life, bear witness, find reconciliation, and achieve integration and transcendence.

Since the inception of Butler's life review therapy, the intervention has been applied with individuals, families, and groups. Its use with families can create a therapeutic milieu in which members can resolve conflict that may accompany various role changes in adulthood, such as shifts in responsibility involved in caregiving (Greene, 1983). There is some evidence that the use of reminiscence therapy can enhance family coping strategies (Comana & Brown, 1998).

Reminiscing groups with older adults can produce or enhance a cohort effect. That is, older adults find their historical connection and share accomplishments, tribulations, and viewpoints. The purpose may be to support social functioning, uncover and resolve unconscious conflicts, or ascribe new meaning to old events (Greene, 2001). Groups usually consist of no more than 10 people and may be run for a short period (10 weeks or less) or for as much as a year. Review content may be prompted by using visual or artistic devices such as videos, plays, or drama (Hargrave, 1994).

CONCLUSIONS

Although a number of group and family interventions are now seen as effective, the longevity revolution presses the profession to think about the aging process and caregiving in a broader context (Corman & Kingson, 1996; Kiyak & Hooyman, 1999; Silverstone, 2000). That expanded context embraces alterations in attitudes toward aging, an increasing empirically based gerontological knowledge base, as

TABLE 69.2. Forums for Educating and Training Caregivers

Community Workshops and Forums

Provides information about community services, usually single sessions lasting an hour to a day; often sponsored by health and human services organization.

Lecture Series and Discussion

Lectures given by clinical experts on topics of interest to specific groups of caregivers.

Support Groups

Allows for mutual sharing of information, usually unstructured, and encourages reciprocal and self-help among group members.

Psychoeducational and Skills Building Groups

Educates members usually in short-term, structured groups by teaching specific problem-solving and coping skills and sharing information about caregiving resources.

Individual Counseling and Training

Focuses on the individual caregivers' needs, helping them deal with the emotional and coping skills needed to be effective in the role and to handle the stresses of caregiving.

Family Counseling

Helps the family system deal with issues related to caregiving that will allow them to sustain the care recipient and maintain family balance and cohesiveness; often connects the family with other resources in the community.

Care Coordination and Management

Educates caregivers on how to perform caregiving roles more effectively and on how to connect with formal caregivers.

Technology-Based Interventions

Uses telephone-mediated groups, computer-mediated groups, and video conferencing to educate and train caregivers.

well as changing family forms (Bengtson, Giarrusso, Silverstein, & Wang, 2000; Greene, 2000).

From a research perspective, there have been numerous studies that emphasize the role of caregiving in reducing institutional placements. There have been few studies that examine the effects of programmatic interventions such as support groups. The strongest research efforts to date have focused on caregiver burden, stress, and strain. According to Cairl and Kosberg (1993, p. 86), this research has provided information on the (1) the nature and scope of burden or stress experienced by the caregiver; (2) the variance in the experience of burden relative to the type of relationship of the caregiver to the frail elderly or the involvement in external supports; and (3) the potential consequences of the experience of burden with regard to caregiver tolerance and, more specifically, the propensity to institutionalize. Cairl and Kosberg argue that although this tradition of research offers a clear picture of caregiver stress, it does not offer an understanding of whether burden results in decreased capacity. The baby boomer generation and information about successful aging compel practitioners to consider caregiving issues differently (Noonan & Tennstedt, 1997; Rowe & Kahn, 1998; Stull, Kosloski, & Kercher, 1994). The negative emphasis on caregiver burden has led some researchers

to call for “a wholesale rethinking about caregiving experiences and outcomes to include positive aspects of caregiving and positive indicators of well-being” (Kramer, 1997, p. 218).

M. JOANNA MELLOR

Interdisciplinary Team Practices

70

Social work with older persons frequently includes interdisciplinary teamwork. An interdisciplinary team can be described variously as “a functioning unit, composed of individuals with varied and specialized training, who coordinate their activities to provide services to a client or group of clients” (Ducanis & Golin, 1979, p. 3), as “a group with a specific task or tasks, the accomplishment of which requires the interdependent and collaborative efforts of its members” (Beckhard, 1972, p. 287), and, more fully defined, as

a group of persons who are trained in the use of different tools and concepts, among whom there is an organized division of labor around a common problem with each member using his own tools, with continuous intercommunication and reexamination of postulates in terms of the limitations provided by the work of the other members and often with group responsibility for the final product. (Luszki, 1958, as cited in Given & Simmons, 1977, p. 166)

RATIONALE FOR INTERDISCIPLINARY TEAM PRACTICE

The importance of an interdisciplinary team approach in the health care of older persons has been recognized and espoused in the literature for the past 30 years. As early as 1915, health educators, physicians, and social workers were working together in teams at Massachusetts General Hospital, but it was not until the 1950s when Drs. Cherkasy and Silver advocated a team approach to the delivery of primary care service that attention began to be given to the interdisciplinary team modality. By the 1960s, interdisciplinary educational experiences were being developed for students in the health professions, and the federal government “advocated the use of health teams in its newly created Neighborhood Health Center Program” (Bernard et al., 1997, p. 155). The following decade witnessed funding of training for interdisciplinary teamwork in geriatrics by the Department of Veterans Affairs and the Bureau of Health Professions (Geriatric Education Centers) at the federal level and by the Robert Wood Johnson and W. K. Kellogg Foundation in the private foundation arena. From the early 1970s through the 1980s there were numerous presentations at professional conferences and journal articles focused on interdisciplinary team care, nearly all of which were either descriptive, highlighting inter-

disciplinary team development and activities, or prescriptive, encouraging the health care professions, including social work, to adopt such practices.

By the early 1980s, funding for interdisciplinary teams and training in interdisciplinary teamwork waned. Following this lull, interest in the team approach in the care of the older person once again came to the fore and was highlighted by the National Institutes of Health 1987 Consensus Development Conference, which issued the following statement:

This process, comprehensive geriatric assessment, is defined as a multidisciplinary evaluation in which the multiple problems of older persons are uncovered, described and explained, if possible, and in which the resources and strengths of the person are catalogued, need for services assessed, and a coordinated care plan developed to focus interventions on the person's problems. . . . Comprehensive geriatric assessment involves clinicians from the many health care professions who are necessarily involved in good geriatric care. (Solomon et al., 1988, p. 342)

The concept that underlies interdisciplinary team health care is that the patient generally presents with a multitude of interlocking needs and issues and that no one discipline is equipped with the knowledge and skills to assess and develop appropriate care plans to meet these needs. Geriatric patients are frequently beset by many health, social, and environmental needs. The same is true of other populations, such as chronically ill children and the disabled. Complicating the care of these populations is not only that the patients/clients have several needs and issues but that these several needs may overlies each other or interact in such a manner that correct assessment is compromised and attention to any one need, in isolation, is ineffective.

In many situations involving older persons, a plethora of physical, psychological, social, environmental, and financial issues need to be addressed and holistic care provided. It is this holistic care that can be provided only by an interdisciplinary team. The following case studies provide examples of the need for a team approach to health care for the elderly.

Maria Harrod

■ Maria Harrod is an 83-year-old widow who lives alone and is discovered by her daughter lying on the floor in her apartment in a weak-

ened state. Hospitalization follows, and Maria is diagnosed as suffering from malnutrition. After being stabilized and restored to health, she is discharged with the admonition to eat five small but nutritious meals each day. Maria's daughter works but manages to visit every evening and prepare a meal for her mother before returning home to care for her family. Six weeks later, Maria is again hospitalized. While in the hospital, she is visited by a social worker, who identifies Maria as depressed. Her previously undiagnosed depression and social isolation caused the initial incident and also resulted in noncompliance of the five-meals-a-day routine that the physician had recommended, contributing to ongoing malnutrition. ■

George and Peggy Wylie

■ Mr. and Mrs. Wylie are in their early 70s and recently celebrated their 50th wedding anniversary. They enjoy an active retirement which includes volunteering for several organizations, such as delivering meals to homebound neighbors once a week for the local Meals on Wheels program. Recently, the director of the Meals program, a social worker, received a complaint from one of the recipients, who declared that Mr. Wylie was unaccountably rude to her. The director, knowing George as a kind, friendly person, believed that the incident had been misinterpreted but decided to drop in on the Wylies on her way home from work. She found them drinking martinis before dinner and stayed for a brief chat. George seemed more outgoing than usual, but there seemed no cause for concern. The director wondered whether he might have a drinking problem but decided that she should watch for further signs of this before advising him to seek counseling. Two days later, both the Wylies turned up in the emergency room at their local hospital. Peggy had a deep gash on her leg and George was concussed. Apparently, Peggy discovered her husband about to leave the house wearing only shorts and a T-shirt, even though the temperature was below freezing. When she tried to stop him and told him to put on other clothing, he became violent and threw a pair of scissors at her. Peggy then pushed him and he fell to the floor, hitting his head and passing out. In

the emergency room, Peggy receives stitches for the leg injury. Meanwhile, assessment of her husband's concussion results in the finding that he has suffered a stroke, which is probably the cause of his uncharacteristic behavior. ■

Without the initial input of a social worker or psychiatrist, in the case of Maria, and the input of a physician or nurse, in the case of George Wylie, the complete pictures remained hidden. The correct diagnoses are relatively simple; even so, without the attention and teamwork of several disciplines, timely and effective care remained out of reach. For Maria, earlier involvement of a social worker or psychiatrist would have resulted in an initial assessment of depression, and for George, it was perhaps fortunate that his behavior caused him to be seen by a physician and nursing staff.

By the late 1980s, recognition of the value of interdisciplinary team care resulted in interdisciplinary team education becoming a mandatory requirement for the newly funded Geriatric Education Centers (GECs). Funded by the Bureau of Health Professions of the U.S. Health Resources and Services Administration, the GEC's goal is to increase the geriatric expertise of those who educate and train health care professionals. The inclusion of training in collaborative, interdisciplinary care remains a key element in the offerings of these centers. More recently, the John A. Hartford Foundation began funding the Geriatric Interdisciplinary Team Training (GITT) Program and its initiatives for promotion of geriatric education in the disciplines of medicine, nursing, and social work, further promoting interdisciplinary team care of older persons (Robbins & Rieder, 2002). The Institute of Medicine has issued a call for a "New Health System for the 21st Century," in which teams are identified as playing a central role in primary care (Grumbach & Bodenheimer, 2004).

INTERDISCIPLINARY TEAM MAKEUP

The core interdisciplinary team in geriatric care generally includes a physician, a nurse, and a social worker sharing their expertise in the assessment and treatment of older persons. Beyond these three core disciplines, it is recognized that many other professions may need to be included, depending on the individual circumstances. Clinic and hospital interdisciplinary teams may include representatives from

other disciplines on an ongoing basis or seek to include them as needed. Nursing facilities routinely include the disciplines of nutrition, psychiatry, and physical and occupational therapy and call on others as needed.

ADVANTAGES OF INTERDISCIPLINARY TEAM CARE

The understanding that geriatric interdisciplinary team care is beneficial to the older patient and the efforts of the Veterans Affairs Medical Centers, GECs, and the recent Hartford initiatives in training health care professionals in interdisciplinary team skills has created a growing interest in and practice of interdisciplinary team care. A number of research studies in the 1980s (Rubenstein et al., 1984; Rubenstein, Stuck, Siu, & Wieland, 1991; Williams, Williams, Zimmer, Hall, & Podgorski, 1987) reported on the beneficial impact of comprehensive geriatric assessment (i.e., team assessment) of hospitalized older patients. The more recent emphasis on evidence-based outcomes is underscoring the benefits of the interdisciplinary practice modality both for the older person in terms of improved care and quality of life and for health insurance companies in terms of cost savings. Grumbach and Bodenheimer (2004, p. 1246) conclude, "Medical settings in which physicians and nonphysician professionals work together as teams can demonstrate improved patient outcomes."

The holistic approach of the interdisciplinary geriatric health care team is more valuable than the sum of its parts. Representatives of a variety of health care professions working together promote the wellness of older persons, decrease acute care incidents, and are cost-effective.

BARRIERS TO TEAM CARE

In spite of the increasing support for interdisciplinary team care, the development of such teams is not without difficulties. Gathering together representatives of several disciplines to discuss older patients or ensuring that the various professionals communicate with each other in regard to assessment and treatment is insufficient in itself. The development of an effectively functioning interdisciplinary team, as opposed to a multidisciplinary group, itself requires interdisciplinary effort and the willingness of its members to overcome the following barriers.

Differences Between Disciplines

In developing a functioning team, as with any group developed for a purpose, one needs to overcome the differences in age, ethnicity and culture, gender, socioeconomic status, language, and personality of the members. But, beyond these factors, there are a number of differences related to the various disciplines that frequently create barriers to the formation of a smoothly functioning interdisciplinary team.

Communication Versus Jargon

Each discipline has its own professional language or jargon, enabling its members to communicate in a form of shorthand. The resulting alphabet soup and specific terminologies can be a source of confusion and give rise to charges of elitism by outsiders. Even more troubling, though frequently unrecognized, is the use of similar phrases or terms by members of different disciplines that hold different meanings for each discipline. For example, a patient's "support system" means one thing to a social worker and something altogether different to a nurse or physician. Lack of communication results, with accompanying damage to team functioning.

Culture and Philosophy

Philosophies and cultural milieus differ among the disciplines. For example, social workers are educated to value self-determination of the individual client/patient, whereas physicians are educated to cure and overcome illness. Social workers see the best interests of their clients as based on the clients' psychological and social needs; physicians view the best interests of their patients as lying in full restoration of health. This divergence in perspectives can create irreconcilable caring strategies when a patient or family is hesitant about or refusing treatment. Within the interdisciplinary team setting, these different perspectives can promote distrust between the disciplines.

Time Constraints and Schedules

Differing schedules and organization of practices result in concrete difficulties in finding time to meet or otherwise communicate between the disciplines. For instance, the availability of physicians on call or working in a community practice is often at odds with the schedules of nurses and social workers employed full time by a medical center or nursing facility. Other

health care professionals, such as nutritionists, dentists, and therapists, may be available only on a part-time basis. Student education within the disciplines also tends to be structured differently: as semesters versus 4-week rotations, integrated class and field practice versus class followed by practice internships. All these differing schedules and time constraints become a programmatic barrier in fostering interdisciplinary teams.

Levels of Training

Health care disciplines vary in the level of knowledge and educational requirements for entry into the professions. Physicians are required to spend many years in gaining their medical credentials and expertise within their selected specialty. Nursing education can range from the minimal training of a nurse's aide to a licensed certificate or master's degree level. Similarly, social workers may hold master degrees but are also employed with undergraduate degrees, as are physical therapists. A functioning interdisciplinary team must overcome these differences in educational backgrounds and levels and the potential they afford to create superiority/inferiority complexes and consequent lack of respect for each other's contribution to the team.

Turf Issues

Health care professions are set apart from each other by the nature of their specific area of knowledge and expertise. It is this special knowledge and expertise that rightly give each profession its authority and credibility but also give rise to the universally recognized turf battles. Members of each profession naturally work to protect and enhance their own area of specialty. Participation in an interdisciplinary team both enhances the feeling that the boundaries of one's own discipline are being breached by another discipline and also provides a forum to react directly, in person, in asserting one's own turf. Overcoming this barrier is perhaps the hardest and yet most important task in the development of a functioning interdisciplinary team.

To be truly effective, all members of an interdisciplinary team have to be very clear about the specific knowledge and skill areas that they contribute to the team but also be willing to allow members of the other disciplines to talk their language and venture into their realm of knowledge. The term *transdisciplinary*

team is increasingly used, especially in the field of palliative care, to identify a higher order of interdisciplinary team in which the members have earned each other's trust and learned each other's specialty so that they seamlessly carry out each other's discipline-specific tasks. However, an interesting dynamic is often experienced in interdisciplinary teams in their process of metamorphosing into transdisciplinary teams. Members of a discipline become open to other team members embracing their special knowledge, but when a member of a discipline reaches a point at which his or her use of adopted knowledge begins to equal that of members of that other discipline, the discipline-specific role is threatened, and there is a pulling back and reassertion of turf. In this sense, the task of overcoming the turf barrier may never completely be accomplished.

Administrative Issues

Leadership Support

Administrative support for interdisciplinary teamwork within a health care organization is crucial. Without such support, it is very unlikely that the various disciplines will buy in to the concept. Team participants require the support of the administration in order to justify the time that is spent in interdisciplinary teamwork at the expense of other tasks. In addition, putative teams wither away when support from the top is lacking, as a new team generally includes one or more less than enthusiastic participants. Without the acknowledged backing of the organization's leadership, there is no incentive for reluctant participants to remain involved, and the team will fail to thrive.

Financial Support

When state or federal regulations mandate interdisciplinary team assessments, as they may do in nursing facilities and Veterans Affairs medical centers, participation in an interdisciplinary team is one of the ongoing tasks of a salaried employee. For the vast majority of social and health care providers, however, whose earnings derive from fee for services or involve contractual arrangements between organizations and government or insurance companies, there is no third-party payment coverage for time spent in interdisciplinary teamwork. This lack of funding may be judged shortsighted in light of the cost effective-

ness of interdisciplinary team care, for it is clearly a barrier to the development and ongoing maintenance of teamwork.

Danger of Success

There is one final barrier to the making of the ideal interdisciplinary team, and this is peculiar in that it emerges only when a team is experiencing success. Generally this setback is found in stable teams that have been in existence for a lengthy period. The team members know each other well, respect each other's knowledge, and are comfortable with the team's decisions. The team may even be transdisciplinary in nature. The danger lies in the emergence of a "group-think" mentality: The members know how each of them is thinking about a specific patient/client, there is little or no disagreement, and decisions regarding assessment and treatment plans are reached quickly. Therein lies the danger. The team members are no longer challenging each other, and although the group determinations may prove accurate, they are equally likely to be flawed. Either insufficient thought is given to the case under discussion and vital signs and symptoms are ignored, or the team moves unquestioningly to the acceptance of a multiplicity of overlapping variables and sees complications where simplicity is the reality. To outward appearances, the interdisciplinary team is functioning smoothly, but its outcomes may well be detrimental to the patient's/client's well-being.

CHARACTERISTICS OF A WELL-FUNCTIONING TEAM

Drinka and Clark (2000) note that interdisciplinary health care teams are "not just assemblages of individuals from different professions. They are complex and paradoxical entities that often seem to defy understanding." Most interdisciplinary geriatric care teams are neither a disaster nor the ideal. Interdisciplinary teams, like organizations, are evolving, changing systems and remain fluid.

A functioning interdisciplinary team is one in which its members:

- Recognize the knowledge and skills of each of the members.
- Understand and appreciate the differences between members, whether these are personal char-

acteristics, discipline-specific ideologies, or professional cultures.

- Trust and respect each other.
- Fulfill certain roles, such as leader, facilitator, recorder, or process evaluator. Leadership can be democratic, authoritarian, vested in one individual or shared.
- Convene on a regular basis. Interdisciplinary teams need not necessarily meet in person but can interact by phone or e-mail. The important criterion is a regular time schedule maintained for sharing assessments and developing/evaluating care plans.
- Are able to think “outside the box.”
- Tolerate, and even welcome, conflict as an aid to problem solving.

SOCIAL WORKERS AS TEAM MEMBERS

Because of their relationship skills and professional training, social workers are ideally suited for interdisciplinary teamwork. Social workers’ knowledge and specific training in biopsychosocial assessment, work with families, short-term treatment modalities, and identification and referral to community services are especially helpful to the work of the interdisciplinary team. Apart from these areas of expertise, social work training in working with individuals and groups and emphasis on relationship skills means that social workers tend to be good listeners, group facilitators, managers of interpersonal conflict, and focused on collaboration. As such, social workers are valuable not only as interdisciplinary team members but for the leadership they offer in the development and maintenance of fully functioning interdisciplinary teams.

The Role of Social Work in the Interdisciplinary Team

The geriatric health care interdisciplinary team has always counted social work as a core participating discipline, along with nursing and medicine, but it is only in the past few years that the specific role and contribution of the social worker to interdisciplinary team practice has been articulated. A national interest group, emerging from the Hartford Foundation’s GITT program, spent several months in the late 1990s discussing and identifying social work’s specific role and contributions to the geriatric health

care team.¹ Mellor and Lindeman concluded that the role of the social worker as a member of an interdisciplinary team includes but is not limited to the following:

- **Diagnosis/Assessment.** The social work assessment takes into consideration how well the patient (and the family or caregiver) is functioning in six areas:
 - Physical: a brief medical history, functional abilities, appearance, and observed behavior.
 - Psychological: affect, mood, outlook, attitude, personality characteristics, cognitive functioning, self-image.
 - Social: vocation, social roles, support networks, education, and financial status.
 - Cultural: values, general rules of behavior, definition of the “sick role,” beliefs about the root causes of illness and prescribed treatments, communication patterns that encompass varied language and speech patterns as well as bilingual issues.
 - Environmental: living conditions and home surroundings, with focus on safety and maintaining functional independence.
 - Spiritual: beliefs about people’s roles and responsibilities, rules for living, belief system, diet, and acceptable medical treatments.
- **Care Management.** Also referred to as case management, this social work role includes problem identification (e.g., lack of financial resources, need for help with activities of daily living or mental health intervention) as well as linkages to and coordination of community resources to facilitate the highest practical level of functioning for the patient and family. It requires a knowledge of community resources and entitlements and skills in matching the patient/family with resources, linking resources, and serving as an interpreter and advocate for the patient/family.
- **Individual Counseling.** Psychosocial counseling includes treatment of mental health problems such as depression and anxiety through various techniques, including family therapy, relaxation, and stress management training for the patient and/or caregiver. This is intended to assist patients and families to adjust to major life stressors and transitions such as illness, disability, institutionalization, and loss as well as to empower the client. A patient’s ability to adapt to an illness has a profound impact on his or her quality of life as well as

the patient's willingness/ability to comply with the prescribed treatment and is paramount to recovery, physical and emotional healing, timely discharge from the hospital, risk management, and effective decision making. The social worker brings skills in listening, problem resolution, and negotiation with attention to community and environmental factors.

- **Group Work.** Group psychotherapy and supportive psychoeducational groups are designed to help patients and families/caregivers cope with a specific illness (e.g., depression, Alzheimer's disease, cancer, diabetes). The social worker brings skills in group development and facilitation.
- **Liaison.** The social worker can also serve as a liaison between the patient/family and the professional community, forming a vital link. This is particularly pertinent when the family lives out of the area and its input must be obtained via long-distance communication.
- **Advocacy.** Social workers' training, including a working knowledge of ethics, confidentiality, advance directives, cultural/ethnic factors, and patient/family rights, serves to help teams face the challenge of balancing patient needs with the system demands. Often, the most important service provided to patients and families by a geriatric/gerontological social worker is simply to assist in negotiating an overwhelmingly bureaucratic system, such as Medicaid, Social Security, disability, funeral arrangements, or dealing with insurance and hospital paperwork by acting on their behalf and/or teaching them to help themselves.
- **Community Resource Expertise.** Knowledge of community resources and how to access them is an invaluable piece of the social work profession. This involves high-level skill in negotiation and bargaining for appropriate resource allocation. A working knowledge of financial systems, including federal, state, and county programs, is part of this expertise. Serving as a resource referral coordinator requires negotiation and collaboration to assist patients and families in setting priorities, determining care goals, and balancing issues. (Mellor & Lindeman, 1998, pp. 5–7)

These areas are not necessarily exclusive to the discipline of social work, but they are knowledge and skill areas in which the social worker receives specific training and for which social work has particular expertise and responsibilities.

SUMMARY

Interdisciplinary health care teams are not yet universal, but the growing body of information from evidence-based studies underscores the value of this model of practice. Well-functioning interdisciplinary teams are understood to promote quality of life for the patient and family and to be cost-effective in terms of health dollars, through reduced hospital stays and more timely, holistic treatment interventions. Furthermore, baby boomers, the next cohort of older persons, identify access to interdisciplinary team care as a feature of the health care system they envisage for their future. Hence, social workers in the field of aging are increasingly likely to participate in interdisciplinary teamwork. Social work has a valuable and crucial role to fill in this growing practice model.

DENIS P. CRONIN

Psychodynamic Psychotherapy

Despite Freud's (1904/1950) dictum that older adults are not suitable for psychoanalysis because their mental processes are characterized by insufficient elasticity, psychodynamically oriented therapists now increasingly share the belief that the older adult is highly amenable to treatment. The myth that the older adult inevitably and irrevocably possesses rigid, inelastic personality structures has given way to clinical experience and empirical evidence stressing that it is the nature of the psychiatric disorder and not the age of the adult that is crucial in securing treatment (Lazarus, 1980, 1988; Muslin, 1984; Yalom, 1975, 1980a, 1980b, 1987).

Psychodynamically oriented therapists who treat the older adult all share a similar belief in the responsiveness of many older adults to psychodynamically oriented psychotherapy, along with the belief that the later part of the life cycle possesses considerable potential for self-understanding and the discovery or re-discovery of various aspects of the self (Cath, 1984; Lazarus, 1980, 1988; Muslin, 1984; Muslin & Epstein, 1980; Myers, 1984; Nemiroff & Colarusso, 1985; Sadavoy, 1994; Sadavoy, Jarvik, Grossberg, & Meyers, 2004). Older adults, in fact, are often keenly aware of their limited time left to live (Cath, 1984; Neugarten, 1979) and make productive use of psychotherapy.

IMPORTANCE OF PSYCHODYNAMIC TREATMENT OF THE ELDERLY

Psychodynamic therapy has a unique place in the treatment canon for the older adult because it is the form of treatment that is most suited to addressing the unique interplay among intrapsychic, personality, and developmental factors (Lazarus, 1984; Sadavoy, 1994; Sadavoy et al., 2004) that distinguishes an older person seeking psychotherapy from a younger adult. The older adult's formidable efforts to contend with the unique stressors of the aging process are often fraught with significant, often unprecedented tensions, challenges, and conflicts. These challenges call for an approach to treatment that will not be limited to mere alleviation of the symptoms of anxiety and depression, but one that will support the older adult in his or her efforts to reestablish a sense of inner cohesion and self-worth in the face of numerous narcissistic injuries in a culture that often denigrates the old.

According to Hyman Muslin (1984, p. 69), a psychoanalyst and practitioner of self-psychology:

Intensive psychotherapy should be the treatment of choice in those older adults who possess the

ordinary capacity for this work, depending on the nature and intensity of the problem, the psychological capacity to introspect, and the ability to form resolvable transferences.

Issues in Clinical Practice

There are many psychodynamic concerns that are especially relevant to the psychodynamic psychotherapy of the aged. Many therapists stress the critical importance of applying more psychodynamically oriented techniques systematically to the aged, both as therapy for depression and anxiety and to clarify the psychodynamic, developmental aspects of the later stages of the life cycle (Grunes, 1987).

Of all the age-specific dynamic themes, most prominent is the enormity of the sense of loss often endured by the older adult: loss of physical prowess, friends and family, and material wealth, among many others. However, the biggest losses that the older adult must endure are the profound sense of a loss of possibility (Yalom, 1975, 1980a, 1980b, 1987) and loss of a sense of self (Grunes, 1987; Guttman, Grunes, & Griffin, 1980). Some psychodynamic theorists see this lost sense of self as a process of disavowal of those aspects of the older person that he or she perceives as damaged or deteriorated in order to maintain the intactness of the personality in the face of decline. The loss accentuates the fact that a central function of the psychodynamic therapist's role with the aged adult is to "make the adult's past viable" (Grunes, 1987, p. 43).

In the absence of external buttresses for the sense of self over time, the therapist becomes a replacement for . . . the adult's historical self. . . . The psychotherapist therefore acts as a stimulator of the adult's early identifying relationships which he brings alive through his empathic mirroring. (p. 43)

Older adults are also particularly vulnerable to survivor guilt. Many investigators have reported adults' disinterest in maintaining or enhancing their life after the demise or severe disability of a spouse (Cath, 1984; Silberschatz & Curtis, 1991). Many older adults express survival guilt more subtly, often denigrating any self-affirming, worthwhile aspirations as too unrealistic for "older people" like themselves. A psychodynamic approach is likely to be the most effective approach for helping the older adult deal with

the self-deprecating feelings that often accompany survival guilt.

Important Characteristics of Older Adults for Successful Psychodynamic Therapy

As Kahana (1979, 1987) has argued, old age is best viewed on a continuum of functioning, from normative aging at one extreme to a state of significant mental and physical decline at the other extreme. Applying this functional perspective to an assessment of which older adults can benefit most from an insight-oriented form of psychotherapy, it is probably clear that such an approach would be most beneficial to older adults on the more functional, less debilitated end of the functional spectrum: those who have the capacity for introspection, insight, and who are motivated to pursue this form of therapy (Muslin, 1984; Pollock, 1987).

Crisis Situations

Neugarten (1979) and Lazarus (1984) stress that psychotherapy for the older adult is usually indicated when the individual is unable to master and adapt to the psychological impact of a crisis. As the older adult moves more and more to the debilitated end of the functional spectrum (Kahana, 1979, 1987), he or she becomes less suitable as a candidate for insight-oriented or psychodynamic therapy as the therapeutic vehicle most likely to help him or her overcome the adverse psychological effects of a crisis. More appropriate forms of treatment for this group include the less intrapsychic, more behaviorally and environmentally supportive techniques.

Long-term insight-oriented psychodynamic treatment can also be very beneficial for the older adult attempting to recover from a crisis. Because an integral component of the more ambitious, long-term clinical approach is the alteration of extant maladaptive defenses through ongoing interpretive efforts, Yesavage and Karasu (1982) stress that older adults embarking on such a challenging, albeit productive, clinical route have the resiliency to be able to replace long-standing maladaptive defenses with more adaptive ones that will support their efforts to regain self-esteem and cultivate healthy, productive self-object relationships (Kohut, 1971, 1977; Kohut & Wolf, 1978; Lazarus, 1980, 1988; Wolf, 1986).

PSYCHODYNAMIC APPROACHES TO TREATMENT

The most common forms in which psychodynamic therapy is practiced with the older adult include self-psychology (Kohut, 1971, 1977), short-term (brief) psychodynamic psychotherapy, and long-term intensive psychodynamic psychotherapy, including classical psychoanalysis. Although self psychology can be conducted either as short-term or long-term psychodynamic therapy, it is usually practiced in the long-term mode.

The cornerstone of all psychodynamic approaches is the therapeutic alliance that develops between therapist and client, with the therapist assuming responsibility for the environment in which the therapy takes place. In the context of psychodynamic treatment, this alliance, the associated transferences that emerge from it, and the insight attained by the client into the sources of his or her conflicts and distress all constitute the therapeutic medium through which the older adult experiences growth and change. The emphasis on unconscious mental life as both a contributing cause of the older adult's psychological difficulties and as a critical component of the treatment process distinguishes all forms of psychodynamic psychotherapy from the other, less insight-oriented approaches. In a psychodynamic formulation of a clinical problem, symptoms and behaviors are viewed as serving multiple functions that are determined by complex and often unconscious forces.

Long-Term Psychodynamic Therapy

A long-term psychodynamic assessment involves evaluating both the personality structure of the adult and the adult's disorder or clinical symptoms for their suitability for long-term psychodynamic therapy.

An older adult who is not interested in attaining in-depth understanding and for whom a brief course of psychotherapy and/or a particular medication can successfully treat his or her problem would not be an appropriate candidate for long-term psychodynamic psychotherapy. A long-term dynamic approach may be indicated when brief therapeutic approaches and pharmacology both fail to address the adult's problems, provided the adult has what Pollock (1987) and Muslin (1984) describe as the capacity (and probably penchant) for introspection; the stamina, motivation, and cognitive flexibility to undergo intensive, ongoing

self-scrutiny; and the capacity to experience the often unsettling affect that can accompany this process.

As Gabbard (2004) suggests, the focus of long-term psychodynamic therapy depends on the adult and on the theoretical perspective of the therapist. Therapeutic goals are shaped by the therapist's theory of how therapy works. Some practitioners of long-term therapy focus largely on symptom alleviation and removal. Others, depending on their theory of clinical practice, espouse loftier, more in-depth goals, such as a more cohesive, enhanced experience of self that is less subject to fragmentation and diminishment of self-esteem (Kohut & Wolf, 1978); improved reflective functioning; enhanced capacity to resolve interpersonal conflicts; and enhanced capacity to obtain effective self-object relationships (Gabbard, 2004).

Classical Psychoanalysis and Self Psychology

Classical psychoanalysis sees the root cause of psychological distress and dysfunction as lying in the conflict over basic drives and basic defenses. Resolution of these conflicts, the basis for psychological growth, occurs through the transference (labeled a transference neurosis) that develops between therapist and client and the insight attained into the source of these conflicts by the client. The emphasis placed on the vicissitudes resulting from the conflict between the press for basic drive gratification and the tendency of certain defenses to thwart this goal renders classical psychoanalysis less useful for the older adult than for the younger one.

Self psychology, a recent psychoanalytic paradigm of treatment, focuses on narcissistic injury to the functioning self, reflected in lack of cohesion and proneness to fragmentation and diminished self-esteem (Kohut, 1971, 1977; Kohut & Wolf, 1978; Wolf, 1986). This clinical approach has been employed successfully as an underlying model in psychodynamically based group psychotherapy and in both forms of individual (i.e., short-term and long-term) psychotherapy with the older adult (Lazarus, 1980, 1988; Muslin, 1984; Schwartzman, 1984). This approach is viewed by many theorists as generative of new psychodynamic-oriented insights that complement and supplement other theoretical models (Lazarus, 1980, 1984, 1988; Muslin, 1984). Self psychologists describe the self as a "developmental, psychological structure responsible for maintenance of one's self-image, self-

esteem, feelings, and affects related to one's physical and psychological integrity and need for others to . . . help modulate one's self-esteem" (Muslin, 1984, p. 58). The potential for diminishment of the older adult's self-esteem and self-efficacy as he or she experiences the declines of aging renders the self-psychologically oriented therapist's focus on rehabilitation of the fragmented self a felicitous theoretical model for treatment.

The focus on injury to the self undergoing fragmentation distinguishes self psychology from the conflict over drives and defenses that is central to traditional forms of psychoanalysis (Kohut, 1971, 1977; Kohut & Wolf, 1978; Wolf, 1986). In self psychology, both short term and long term, the adult is provided with an empathic, therapeutic atmosphere through which fixated aspects of the self reflected in maladaptive or inappropriate ways for maintaining self-esteem and sustenance from others can undergo rehabilitation. Progress is largely contingent on the therapist's use of empathy to facilitate the adult's resolution of a number of self-object transferences (Kohut & Wolf, 1978), each of which contributed to an impasse in the adult's healthy psychoemotional development, often reflected in lack of autonomous functioning and poor self-esteem regulation.

Brief Psychodynamic Psychotherapy

The most salient factors distinguishing brief psychodynamic treatment from the longer version are more restricted goals, the lessened intensity of therapist engagement, and the need to establish a therapeutic alliance quickly. According to Levinson, Butler, and Beitman (1997), the most critical criterion for an individual's suitability for brief as opposed to long-term dynamic therapy is the ability to rapidly attach and detach emotionally without an escalation in the severity of symptoms.

Lazarus (1980, 1988) recommends the use of brief psychodynamic therapy for the more resilient older adult whose problems, such as adjustment disorders, are both clearly defined and treatable over a manageable time frame. Lazarus stresses that by setting a time limit on therapy, brief psychodynamic therapy reinforces the older adult's confidence in his or her personal ability to resolve problems and master current stresses. Establishing a time limit not only accelerates the therapeutic process but also reduces the individual's anxiety over a prolonged therapeutic relationship and brings the prospect of termination into focus ear-

lier in the treatment process. Malan (1963, 1976, 1979) was able to demonstrate that brief psychodynamic psychotherapy for older adults alleviates symptoms, resolves conflicts, and, equally important, helps bring about fundamental characterological change usually associated only with long-term psychodynamic treatment so long as the older adult is capable of insight and is able to forge a productive working relationship with the therapist.

Lazarus (1984) has suggested that developmental issues more specific to the older adult may be a major difference between brief psychotherapy with older adults when compared with younger ones. This author contends that narcissistic issues that continually threaten the older adult's self-esteem and sense of mastery may render the older adult more receptive and responsive to the therapist's empathy in brief psychodynamic therapy (Lazarus, 1984), resulting in the attainment of a productive therapeutic alliance more quickly for the older adult.

CRITICAL ISSUES IN PSYCHODYNAMIC TREATMENT

Transference Issues

The literature on geriatric psychotherapy supports the notion of the timelessness of the unconscious and the fact that transference processes are as vital and as much a phenomenon to be reckoned with in old age as in youth (Berezin, 1972; Meerloo, 1955; Newton & Jacobowitz, 1999). Little clinical evidence supports the concept of a highly age-specific transference, although the reactions of the older adult to the therapeutic process are likely to reflect the unique array of stressors that characterize this period of life.

Eroticized transferences are possible, with the client turning unconsciously to the therapist as a wished-for replacement for a lost partner or spouse, leading the client to identify with a much more youthful, sexually appealing self-image that he or she imagines to be potentially appropriate for the therapist (Crusey, 1985). Similarly, eroticized transferences may be mobilized as the older adult becomes aware of his or her sexual decline.

"Reverse" transferences often play a major role in the older adult's resistance to psychodynamic treatment. Many older adults who are in psychodynamic treatment develop a resistance to the treatment process (Myers, 1984, 1986) that takes the form of their challenging the therapist, for example, as being too

young and inexperienced and therefore incapable of understanding an older adult. The crucial issue is that beneath the surface interaction between the older adult and therapist and at the root of all manifestations of the reverse transference, there often reside significant feelings of helplessness and inferiority on the part of the older adult for which the development of a reverse transference process can function as a defense against these painful feelings (Grotjahn, 1955; Myers, 1984, 1986).

Narcissistic Assaults

Narcissistic assaults resulting from the inevitable declines of old age (e.g., lost beauty, power, and physical prowess) often promote an idealizing or mirroring transference to the therapist on the part of the older adult (Kohut, 1971, 1977; Lazarus 1980, 1988). This transference involves older adults compensating for perceived narcissistic assaults accompanying the aging process by imagining themselves as the worthy recipient of a therapist who is unfaltering in his or her care and admiration and unrelenting in his or her approval of the adult. The tendency for older adults to develop an idealized type of transference can be extremely useful in securing their involvement in a cohesion-generating, self-esteem-enhancing (Kohut & Wolf, 1978) therapeutic process.

Conflicts Over Death

Conscious or unconscious conflicts over death and mortality may cause the older adult to view the therapist as an idealized, magical protector capable of warding off the inevitability of death. The realistic inability of the therapist to provide the much sought-after protection and reassurance may so alienate older adults that they may harbor significant angry feelings toward the therapist in his or her capacity as a disappointing transference figure.

Defense of Withdrawal From Treatment

Many older adults are inclined to use defenses of withdrawal and/or physical preoccupation to deal with intrapsychic conflicts and anxieties. They may also deploy these same defenses in their efforts to avoid therapy and resist the transference process. Inordinate use of reminiscence, a highly useful therapeutic tool if

used appropriately, and overreliance on past accomplishments as a way of avoiding the present can also feature prominently in the resistance process of the older adult (Kahana, 1987; Myers, 1984, 1986; Nemiroff & Colarusso, 1985; Sadavoy & Leszcz, 1987).

Countertransference Issues

Older adults are more likely to mobilize the therapist's unresolved conflicts about aging, including unconscious fears of illness, decline, and death (Muslin, 1984; Nemiroff & Colarusso, 1985; Yesavage & Karasu, 1982). According to Muslin:

In working with older adults . . . the analyst must be mindful of the self-needs of the adults and not to become unduly influenced by the adult's advanced age, superficial attitudes, or slowness of psychomotor functioning. These might mislead the analyst to dismiss the older adult as a potential candidate for psychoanalysis. For those analysts who work with the older adult, the self-transformations required to enable the analyst to empathize accurately with their older adults is of paramount importance. (p. 69)

Yalom (1987) suggests that the treatment of the older adult stimulates the therapist's memories of his or her relationships with parents and grandparents. Reinforcing his point, he asks, "To what extent does our sense of hopelessness or pessimism in treating the older patient reflect our personal dread of inexorable aging and death?" (p. xii).

The countertransference is a significant component of psychodynamic treatment. The therapist usually shares many psychoemotional, historical, and generational commonalities with his or her adult clients that the therapist eventually recognizes in the unique form in which his or her countertransference crystallizes. But for the younger therapist working with the older adult, lack of the experiential and affective breadth (e.g., continuous loss) that often characterizes the life of the older adult makes it more difficult to identify an appropriate range and number of parallel countertransference experiences in the treatment of the older adult. The result of this, in Grunes's (1987, p. 39) words, is that

the therapist must struggle with re-experiencing his own early relationships both to his parents and to his grandparents. . . . A further living

counter transference experience derives from the often negative stereotypes and prejudices which the therapist may have adopted from society's attitude toward aging.

The goal of establishing adequate empathic rapport or attunement with the older adult always looms as a potential problem, given the range of respective life experiences between the usually younger therapist and older adult. This empathic breach often manifests itself in the form of reverse empathy on the part of the older adult to compensate for the empathic gap between the therapist and the older adult (Grunes, 1987). Through the process of reverse empathy, the aged adult attempts to strengthen the self-object relationship to facilitate the formation of a working alliance. This process of reverse empathy (Grunes, 1987) represents an attempt on the part of the aged adult to establish a bond with the therapist so that both therapist and client can become "mutual self objects" (p. 38). "A need to know significant details of the therapist's life may be viewed as manifestations of reverse empathy" (p. 38).

A therapist expressing countertransference in the guise of anxiety over an older adult's apparent helplessness and dependency can unwittingly so overwhelm the older adult that he or she withdraws from treatment and rejects the therapist. Conversely, in the face of the older adult's decline, a therapist may act on a grandiose need to conquer the forces of aging (Myers, 1984).

Overidentification with the older adult's problems, manifested in feelings of pity and sadness communicated inappropriately to the client, can appear inauthentic and disparaging when compared to the psychological oxygen of the therapist's accurate empathy, and can stymie the process of exploration of possible avenues for growth and change (Hiatt, 1971). Conversely, the therapist who unconsciously avoids the pain that accompanies the therapeutic process of accurately empathizing with the older adult's loneliness and loss may become so overwhelmed by the client's problems that he or she may attempt to keep the older adult alive by avoiding termination of therapy (King, 1980).

The thinking of many therapists, their training notwithstanding, reflects the unfortunate influence of the dominant lay culture in their persistent view of older adults as asexual individuals (Meerlo, 1955). Persistence in this erroneous view by the therapist often functions as a defense against unresolved conflicts associated with parental sexuality or Oedipal conflicts (Myers, 1984; Nemiroff & Colarusso, 1985; Zinberg & Kaufman, 1963). Revulsion over the adult's

eroticized transference toward the therapist, or shock and disgust over the therapist's eroticized countertransference feelings, can be manifestations of deep-rooted sexual conflicts that can adversely impact the therapeutic relationship.

EMPIRICAL SUPPORT FOR THE PSYCHODYNAMIC APPROACH

Although numerous testimonials from many therapists attesting to the effectiveness of psychodynamic treatment with the older adult are encouraging, some researchers (e.g., Gallagher & Thompson, 1982, 1983; Lazarus, 1984) have expressed concern over the paucity of actual empirical research and the lack of systematic, methodologically sound studies of the effectiveness of psychodynamically oriented treatment of the older adult. Some empirical support for the effectiveness of psychodynamic therapy for the older adult exists, mostly in comparative studies comparing brief forms of psychodynamic treatment with other approaches in the treatment of older adult depression.

Thompson, Gallagher, and Breckenridge (1987), studying the differential effectiveness of behavioral, cognitive-behavioral, and insight-oriented brief therapy in the treatment of older adult depression, supported the efficacy of short-term psychodynamic therapy. They found the other modalities to be equally effective and concluded that psychotherapy, regardless of modality, can function as both a primary and an adjunctive method of treatment of the older adult, depending on the client and the presenting problem (Thompson et al., 1987).

Focusing on the maintenance of psychotherapeutic gains over a 2-year period among a sample of 91 older adults who were initially diagnosed as being in an episode of major depression, Gallagher-Thompson, Hanley-Peterson, and Thompson (1990) confirmed the earlier findings of the efficacy of short-term psychodynamic treatment of older adults by demonstrating the maintenance of therapeutic gains over time in the treatment of major depressive disorder. Gains were maintained over time for a substantial proportion of the sample who were depression-free following initial treatment. The highly significant improvement in symptoms and other measures of functioning by the older adults in these more recent studies reinforced earlier research findings highlighting the effectiveness of psychodynamic psychotherapy for older adults (Gallagher & Thompson, 1983).

Lazarus (1984) studied the process and outcome of brief psychodynamic psychotherapy in a sample of eight older outpatients (four men and four women) ranging in age from 63 to 77 years. These older adults upon entering therapy felt estranged from their historical image of themselves as competent adults. They also felt unable to cope with their current problems, and their self-esteem was diminished. Older adults treated with brief psychodynamic psychotherapy in this study tended to use the therapist to “reestablish a sense of continuity with their former, more positive self-image” (p. 27). Many older adults in this study improved in their interpersonal relationships and in their ability to resolve conflict.

After intensively studying the process and outcome of time-limited psychodynamic psychotherapy with older adults, Silberschatz and Curtis (1986, 1991) found that older outpatients entered treatment with specific conscious and unconscious goals. These same investigators also found that the most successful therapists were highly responsive to the therapeutic goals identified by the older adult and worked with the older adult to help him or her challenge and overcome distorted, maladaptive self-perceptions and beliefs.

CONCLUSION

There can be no doubt that psychodynamic psychotherapy is very suitable for the cognitively intact older adult who possesses the necessary personal qualities outlined by Pollock (1987) and Muslin (1984) for engagement in this more intense therapeutic process. This approach to therapy may well be the approach most likely to help the older adult whose therapeutic goals extend beyond alleviation of the painful feelings of depression and anxiety, to a focus on obtaining an enhanced capacity for dealing with issues of self-esteem and identity, pervasive loss and survival guilt in this “season of losses,” the fear or reality of physical decline, and the painful feelings of isolation, loneliness, and narcissistic injury that the older person may experience.

Reminiscence and Life Review

72

Reminiscence and life review are significant natural coping mechanisms, and, as treatment modalities, both can help older adults find meaning through reflection on their life experiences (Butler, 1963; Coleman, 1986). The appeal of reminiscence and life review for geriatric social workers and other mental health professionals is that the interventions are non-judgmental, nonstigmatizing, and easy to provide to older adults (Bohlmeijer, Smit, & Cuijpers, 2003; Jonsdottir, Jonsdottir, Steingrimsdottir, & Tryggvadottir, 2001).

This chapter is divided into four sections. The first section addresses the theoretical background of reminiscence and life review. The second examines the efficacy of life review and reminiscence interventions for different target groups. The third section describes successful intervention methods, and the fourth discusses implications for practice in relation to several emerging issues in reminiscence and life review research.

THEORETICAL BACKGROUND OF REMINISCENCE AND LIFE REVIEW

Reminiscence and life review as therapeutic interventions grew out of the intersection of Erik Erikson's (1964) conceptualization of later life and Robert Butler's (1963, 1974) interpretation of successful aging. For Erikson, the last stage of psychosocial development finds the older adult confronted with the crisis of ego identity versus despair. When successfully handled, ego integrity leads to a sense of dignity, fulfillment, and "emotional integration" of one's life (Erikson, 1964, p. 269). Without ego integrity, older adulthood brings a sense of disgust and despair, wherein the adult "expresses the feeling that time is now short, too short for the attempt to start another life and to try out alternate roads to integrity" (p. 269). According to this theoretical perspective, the key to successful older adulthood—and to feeling satisfied and complete as a human being—is the successful integration of all elements of one's life, both positive and negative.

Butler's (1963) conceptualization of the life review, in conjunction with Erikson's (1964) theoretical framework, normalized reminiscence during later life. Butler refuted the then common belief that reminiscence among older adults is symptomatic of an underlying pathology, asserting that it is a universal, normal occurrence in older adults who are reviewing their life experiences. Noting that life review could contribute to depression among some older adults, Butler argued

that the life review was a form of reminiscence spanning the life of the individual that could actually facilitate the successful and adaptive integration of experiences, create meaning, and offer older adults the possibility of change. He also noted that reminiscence could be especially useful during stressful life transitions and events such as the death of loved ones and when facing one's own death.

The definitions and applications of both reminiscence and life review continue to evolve as their use as interventions is refined. More recent theoretical developments stress the importance of structuring reminiscence interventions to facilitate the integration, evaluation, reframing, and potential resolution of recalled experiences. For example, Coleman (1986) further conceptualized reminiscence and life review as treatment modalities, emphasizing that difficult memories should not be hidden but unearthed and treated therapeutically, potentially leading to empowerment rather than depression for the older adult. Haight and Burnside (1993) explored how life review and reminiscence, though often used interchangeably, can be considered separate interventions. Specifically, Haight and colleagues (2003) have argued that whereas reminiscence is unfocused and nonevaluative, life review, as a structured and evaluative process, is a more effective intervention for older adults.

REMINISCENCE AND LIFE REVIEW WITH DIFFERENT TARGET GROUPS

Social workers and other mental health professionals use reminiscence and life review to address a variety of mental health problems. This section describes evidence-based findings from life review and reminiscence interventions that pertain to four groups of older people that concern geriatric social workers: depressed older adults, cognitively impaired older adults, older adults undergoing life transitions, and older adults with their caregivers. The following criteria were used for selecting relevant journal articles and books: Participants were elderly (generally age 55 and over); the research design included control and/or comparison groups; and the study used pre- and posttest measures of change.

Depressed Older Adults

Though sparse, evidence-based research on this population comparing reminiscence and life review in-

terventions with no intervention is promising. For example, in a study of depressed or anxious nursing home residents (Hyer, Sohnle, Mehan, & Ragan, 2002), those participating in a group focusing on positive memories experienced a significant decrease in depressive symptoms as compared to a control group. In another study, community-dwelling depressed elderly participated in two kinds of individual reminiscing interventions (Fry, 1983), one structured around specific negative life event topical areas, and the other unstructured, covering any aspect of negative life events. When the two treatment groups were compared with a control group, participants in both reminiscence interventions displayed significant improvements with respect to depression and ego strength, with those in the structured reminiscence intervention experiencing the most improvement.

When compared to other kinds of psychotherapy, reminiscence and life review interventions are no more effective. For example, reminiscence group therapy was compared to goal-focused group therapy for older people with major depressive disorder (Klausner et al., 1998). Both groups experienced a decrease in depression and increase in functional ability; however, the goal-focused group also improved on several other psychological dimensions. In another study of those with major depressive disorder, three conditions were compared: reminiscence group therapy, problem-solving group therapy, and a wait-list control group (Arean et al., 1993). Both intervention groups experienced decreased depression and increased life integration as compared to the control group, but only the problem-solving group evidenced improved problem-solving skills. In a third study, depressed older people who attended a senior center were assigned to one of three interventions: reminiscence, current life events discussion, and no intervention (Perrotta & Meacham, 1981). When the three interventions were compared, there were no significant changes in depression or self-esteem among the groups.

Cognitively Impaired Older Adults

The limited amount of evidence-based research on reminiscence and life review with this population shows a mixed pattern of results. The most positive findings occurred in a life review program for nursing home residents with dementia or depression with cognitive impairments (Tabourne, 1995). At the end of the program, participants in the experimental group displayed a significant decrease in disorienta-

tion and increase in social interaction as compared to the control group.

Results from other studies are more ambiguous. One study of nursing home residents with dementia concluded that reminiscence group participants showed only short-term positive effects in depressive symptomatology when compared to a support group and a no-treatment group (Goldwasser, Auerbach, & Harkins, 1987). Another study of moderately confused nursing home residents found no significant differences between three reminiscence groups and three control groups (Orten, Allen, & Cook, 1989). Findings indicated that, based on improvements in one of the reminiscence groups, skilled group facilitator leadership may be a central ingredient to improved social behavior for participants with dementia. A third study, by Baines, Saxby, and Ehlert (1987) comparing reminiscence and reality orientation to control groups for confused nursing home residents, found that the group receiving reality orientation followed by reminiscence improved the most on cognitive ability, behavior, and communication. These findings suggest that reminiscence may be more effective for those who are more cognitively oriented and/or experiencing earlier phases of dementia (Spector, Orrell, Davies, & Woods, 2004).

One of the most sophisticated studies, conducted in Hong Kong on nursing home residents with Alzheimer's disease, also found no significant differences among reminiscence, socialization, and no-intervention control groups (Lai, Chi, & Kayser-Jones, 2004). However, when examining changes over time only for those in the reminiscence intervention, participants' social engagement and well-being improved. Lai and her colleagues summarize this research on reminiscence with cognitively impaired elderly as "promising but not definitive" (p. 45).

Older Adults Undergoing Life Transitions

One of the few evidence-based studies of reminiscence and life review interventions pertaining to this group has examined the efficacy of two reminiscing approaches (general reminiscence and life challenges reminiscence) for older people undergoing stressful procedures in the hospital (Rybarczyk & Bell, 1997). When patients awaiting surgery participated in either of the two reminiscing approaches, they experienced a decrease in anxiety as compared to those who participated in a present-focus interview or no-treatment

control. When awaiting other medical procedures, the life challenges interview played an especially instrumental role in enhancing patients' feelings of self-efficacy. Another study examined life review with older people who were relocating (Haight, Michel, & Hendrix, 1998). This intervention was conducted on an individual basis with residents who had recently moved to a nursing home. When compared with a friendly-visit intervention, those who participated in the life review experienced significantly decreased depression and sense of hopelessness as well as increased life satisfaction and psychological well-being a year after the intervention.

Older Adults and Their Caregivers

One of the very few evidence-based studies examining the effectiveness of reminiscence and life review for this population was conducted in England for older people with dementia and their caregivers (Thorgrimsen, Schweitzer, & Orrell, 2002). When the reminiscence group was compared with a no-treatment control group, neither the older adults nor their caregivers experienced any significant improvements; however, positive trends occurred for the older adults (i.e., improved behaviors and activities of daily living) and the caregivers (i.e., reduced stress levels) who participated in the reminiscence group. In another study, older people with Alzheimer's disease and their caregivers received individual life review sessions with a practitioner that led to the development of a "life story book" (Haight et al., 2003). The older people with Alzheimer's disease who participated in these life review sessions experienced a significant improvement in their mood when compared with a life review intervention that was only caregiver-focused and a no-treatment control. Caregivers who participated in the life review intervention with their care recipient or in the caregiver-focused life review intervention experienced diminished burden in comparison to the no-treatment control.

REMINISCENCE AND LIFE REVIEW METHODS

Mental health professionals use a variety of approaches when conducting reminiscence and life review. In much of the literature on reminiscence and life review, the procedures have not been empirically evaluated, or, if tested, they are not described in suf-

ficient detail to be useful for practitioners. Five interventions mentioned in the previous section are highlighted here based on their effectiveness and the clarity of their intervention methods.

The Life Story Book

This intervention is designed to facilitate life review with older participants and their caregivers (Haight et al., 2003). Two practitioners meet separately but simultaneously with the care receiver and caregiver to develop a book that portrays the life of the care receiver with dementia. The caregiver contributes to this effort by locating pictures and mementoes; the person with dementia selects from these options; and the practitioner asks the person with dementia to describe the pictures and mementoes. With the care receiver's permission, these sessions are tape-recorded and transcribed. Portions of these transcriptions are then used as captions for the book. Practitioners encourage the caregivers and care receivers to reminisce about the pictures between sessions as a way of increasing communication and enhancing pleasurable interactions. When the book is completed, the older person with dementia decides whether and how to share it with others.

Structured Reminiscence

This intervention is designed for depressed older people and consists of five weekly 90-minute sessions conducted on an individual basis (Fry, 1983). During each session, the practitioner helps the older participant to reminisce about one upsetting event from the past using a structured format that focuses on eight topical areas, each of which is discussed for 10 minutes. Fry (p. 23) lists these topical areas and provides illustrative questions, some of which are included here:

1. Strong negative and positive feelings associated with the events.
2. People, objects, or other experiences related to the event.
3. Images or ruminations about the event (e.g., "Were there thoughts you couldn't get rid of although you tried very hard?").
4. Fears, anxieties, or hopes related to the event (e.g., "Do you wish certain things would happen that would make you feel better?").

5. Dreams related to the event.
6. Preferences about interactions with others in relation to the event (e.g., "Did you wish people would let you alone?").
7. Unresolved feelings (e.g., "Were there people or situations that you tried very hard to avoid?").
8. How time was spent during the event.

As participants reminisce about the event in relation to each of these topical areas, the practitioner listens empathically but avoids giving advice or providing evaluative comments.

Positive Core Memories

This 12-week group approach is designed for nursing home residents who are experiencing depression or anxiety (Hyer et al., 2002). During the initial sessions, the practitioner works with the group members to identify two or three positive core memories (i.e., challenges and obstacles that were overcome). The practitioner encourages group interaction, thereby enhancing mutual identification with and appreciation for one another's positive core memories. Later sessions are devoted to applying the lessons learned from these memories to present-day experiences. In particular, the practitioner helps the participants to identify the coping methods they have used in the past and to apply these methods to problems in daily life.

Life Review and Experiencing

This 8-week intervention is used to help older people cope with relocation to a nursing home (Haight et al., 1998). Practitioners meet with older participants individually and use a Life Review and Experiencing Form to guide the intervention. The form consists of a series of questions which are organized around several phases of life (p. 128): childhood, adolescence, family and home, and adulthood. The final portion of this form focuses on summary questions (e.g., "What was the hardest thing you had to face in your life?"; "What was the proudest moment in your life?") that are intended to help older participants assess their lives so that they can acknowledge and integrate their mistakes as well as their contributions. Taken together, the questions provide a guide from which practitioners can selectively choose as they help older people chronologically review and evaluate their lives.

Life Challenges Interview

This intervention is a 1-hour individual interview designed to help older patients cope with anxiety prior to surgery or other invasive medical procedures (Rybarczyk & Bellg, 1997). The intervention begins by asking participants to recount early memories and follows themes that emerge in a chronological framework. A unique focus of this interview is on identifying specific challenges that were successfully met (e.g., obtaining good grades in school, learning to drive, finding a job). Practitioners ask questions that help older participants to reflect on how they met life challenges and highlight the strengths and resources of the older participants. Practitioners try to help older participants describe stressful situations that were “defining moments” (p. 90) because these events can serve as vivid reminders of their competence in the face of adversity. Finally, the session concludes with a summary of the two or three strengths and resources that emerge most consistently throughout these stressful situations. Practitioners provide this summary of the older participant’s strengths or ask the participant to do so.

EMERGING ISSUES IN REMINISCENCE AND LIFE REVIEW

The literature on reminiscence and life review among the elderly has burgeoned over the past four decades since Butler’s (1963) seminal work in this area. A number of research issues have emerged as particularly salient during this time. These issues are highlighted and their practice implications discussed.

Dosage

Reminiscence and life review interventions vary greatly in length, with no consensus about the ideal treatment dosage. Some interventions are a single session (Rybarczyk & Bellg, 1997); others last for many weeks (Thorgrimsen et al., 2002). Perhaps optimal treatment dosage varies in relation to presenting problems. For those undergoing a life transition such as nursing home placement, a 6-week intervention apparently “primes the pump of introspection,” leading to a positive long-term outcome (Haight et al., 1998, p. 135). Older adults who are depressed may require higher intervention dosage; several interventions report successful outcomes after 10 to 12 sessions (Hseih & Wang, 2003).

Cognitively impaired older adults may need an even higher intervention dosage in which reminiscence and life review are part of a daily, ongoing treatment program (Spector et al., 2004).

Negative Outcomes

Both Butler (1963, 1974) and Coleman (1986) note that depression, obsession, and agitation are possible negative outcomes or concomitant factors with reminiscence and life review. Arguing that reminiscence per se is not necessarily adaptive, Watt and Wong (1991) suggest the need to identify those forms of reminiscence that may aid the older adult in adapting to aging (integrative, instrumental, transmissive, and narrative reminiscence), as well as those that may have a negative impact on the older adult (escapist and obsessive reminiscence). Interestingly, there are relatively few evidence-based approaches that address how to ameliorate the possible negative impact of reminiscing and life review. One exception is the work of Hyer and his colleagues (2002), who use a number of techniques to help reduce potential adverse effects of the reminiscence and life review process, such as providing time to experience sadness, empathizing with painful emotions, focusing on the meaning of hurtful memories, and highlighting personal strengths and resources that have resulted from painful life events.

Integrating Approaches

A number of treatment modalities are emerging that may naturally ally with reminiscence and life review because they offer tools to help older adults reinterpret and reevaluate events and experiences in a positive and functional way. For example, Watt and Cappeliez (1995) suggest that reminiscence can be integrated with cognitive approaches to address problems with depression. Similarly, Weiss (1995) asserts that the integration of life review and cognitive behavioral therapy allows older adults to first explore past events, inner strengths, and unresolved issues and conflicts, and then reexamine and reframe dysfunctional thought patterns and emotions to build a sense of positive control and self-efficacy.

Reminiscence can also be integrated with other treatment modalities. Klausner et al. (1998) outlined the treatment intervention of goal-focused group psychotherapy, which teaches older adults to reframe neg-

ative memories and use success stories rather than past failures to help individuals achieve their goals. Arean et al. (1993) found that problem-solving therapy, an intervention designed to help older adults find constructive ways of coping with current life stressors, alleviated depression significantly better than reminiscence therapy among older adults diagnosed with major depressive disorder, although reminiscence therapy was effective with individuals described as “good life integrators” (p. 1008). This study suggests that reminiscence therapy may not work as effectively with older adults characterized as “poor life integrators” (p. 1009) and that reminiscence therapy may be more effective if combined with problem-solving therapy.

Culture and Tailoring Interventions

Research on how contextual factors such as culture may influence the effectiveness of reminiscence and life review interventions is still preliminary. Atkinson, Kim, Ruelas, and Lin (1999) note that the life review of an older adult living in a collectivist culture such as those in Asia and Latin America may focus on life-long goals and achievements that subordinate individual achievements, and therefore may reminisce differently from those in Western culture, which is more individualistic and egocentric. An example of a culturally sensitive approach is described by Jonsdotir and colleagues (2001), who, when conducting a reminiscence group in an Icelandic nursing home, included stories from well-known Icelandic writers to stimulate the participants’ storytelling.

Other factors such as intervention format may also play a key role in shaping the influence of reminiscence and life review. Haight and Dias (1992) found that reminiscence and life review conducted in individual versus group contexts were differentially effective for varying outcomes. They suggest that, if the purpose of the intervention is to promote psychological integration and healing, then individual life review sessions may be more appropriate because they permit greater privacy and more practitioner attention as older clients recount past hurts and fears. However, if the purpose is to enhance social relationships, then group sessions that encourage nonevaluative reminiscence may be more appropriate because such sessions promote enjoyable social interactions about pleasurable memories.

Other factors that impinge on intervention effectiveness are characteristics of the practitioner. Rybarczyk and Auerbach (1990) discovered that the

effectiveness of different forms of reminiscence varied according to the age of the person providing the intervention. That is, participants in life challenge reminiscence interviews experienced more benefits, as compared to those in general reminiscence interviews, if they were interviewed by age peers rather than younger professionals. They reasoned that age peer interviewers shared knowledge about common cohort events (e.g., the Depression) that evoked greater trust and willingness to explore previous life challenges in greater depth. Taken together, these studies suggest that understanding the effectiveness of reminiscence and life review interventions in different cultural and social contexts enables practitioners to tailor their approaches to their clients’ needs.

CONCLUSION

Reminiscence and life review interventions offer social workers and other mental health professionals creative ways to help older people find meaning in their lives. Though evidence-based research is limited, existing studies on reminiscence and life review interventions suggest that these approaches have promise for a variety of target groups. The challenge for practitioners is to contribute to the ongoing refinement of reminiscence and life review interventions as they tailor their approaches to address the specific needs of their older clients.

The strengths perspective is a philosophical standpoint that focuses on the inherent resilience in human nature that undergirds much of social work practice. This perspective is especially applicable to work with older adults, who have a lifetime of rich experience that can be used to address current difficulty. Strengths-based and solution-focused approaches are both rooted in the belief that capacity rather than pathology should be the primary focal point of the helping process. Both the strengths perspective and the strategic approaches are discussed in this chapter. The vignette that follows provides an example of an older client with whom the approaches were initiated.

■ Celia Jones was referred to the home- and community-based services social worker by her daughter, who lived two states away and was very concerned about her mother's deteriorating mental and physical health. Celia was a 78-year-old African American woman. Her husband of 55 years, Emil, had died 2 months earlier after battling diabetes, hypertension, and heart disease. They had had a very stable marriage and loving relationship; Celia had been Emil's dedicated and sole caretaker after his leg had been amputated 5 years previously. Emil's heart condition worsened suddenly and resulted in a hospital admission. During this period, he sent Celia home one night, seeing her exhaustion from spending so much time with him. He died unexpectedly while she was at home resting. Her guilt at not being present with him when he died left her unable to work through her grief.

Emil's death compounded Celia's previous sense of loss and grief due to the death of their only son, David, 3 months earlier. David's death was attributed to the effects of Agent Orange used in the Vietnam War. David had publicly urged the military to conduct clinical treatment trials and offer compensation to veterans experiencing this syndrome after the war ended. He had received an award for his activism and had been invited to speak at congressional hearings, both of which provided affirmation for Celia of the contribution David had made in his life. David, who had never married, lived in the same town as his parents and had developed an especially strong bond with his mother.

The prolonged illnesses and subsequent loss of these two family members contributed to

Strengths-Based and Solutions-Focused Approaches to Practice

73

some of Celia's own health issues, and she experienced unremitting depression. In addition, Celia's caregiving responsibilities for her husband contributed to her becoming disconnected from her community and support systems such as friends and her church. Celia's reaction was to consider selling her small and cluttered house, move into an apartment, and withdraw from friends and family. She was refusing to answer phone calls and not eating or sleeping well.

The social worker, operating from strengths-based and solution-focused perspectives, did not assume that she understood Ms. Jones's viewpoint, even though she had encountered multiple issues of grief and loss in her prior practice experiences working with older adults. Rather, she listened carefully to her story of loss but also was alert to what had brought her joy: her strengths, her goals, her resources. She knew that only Ms. Jones was the expert on her situation and could develop the pathway for recovery and healing.

In the first visit, the social worker reinforced Ms. Jones's curiosity and willingness to let the social worker enter the house. After the social worker's visit, Ms. Jones felt more hopeful about her future than she had for the past 8 weeks and picked up the phone to call her daughter. ■

Strengths-based and solution-focused approaches to intervention with Celia Jones draw on similar assumptions about practice with older adults and form the basis for this chapter. These two approaches work well together and may serve to reinforce each other because they each contain complementary principles that constitute client-centered and holistic perspectives for social work practice.

This chapter first presents frameworks of strengths-based principles and solution-focused principles commonly used with older adult populations within a larger strengths perspective. Second, applications of these approaches in various settings are discussed to broaden comprehension of the uses of each approach. Strengths-based and solution-focused approaches can be used in community settings, such as senior centers and mental health centers, as well as support groups for caregivers and grief/loss support groups. In addition, social workers employed in home- and community-based services programs, assisted living facilities, and nursing facilities can use these approaches with older adults adjusting to decreases in

functioning, transitions to new settings, and efforts to deal with end-of-life issues. Benefits and cautionary notes about use of these perspectives are addressed, including how these perspectives contrast with a traditional problem focus in social work generalist practice. We include discussion of future research implications, focusing on the potential of the strengths-based and solution-focused approaches for improving social work practice for older adults.

STRENGTHS OVERVIEW

The strengths perspective, also referred to as the strengths-based perspective, is a philosophical view about how social workers can interact with clients to elicit positive outcomes (Cowger, 1994; Saleebey, 1997, 2002). When practiced fully, the strengths perspective is an operational stance that puts social work values into action; it is not just about providing support and motivation. It involves recognizing the inherent power that individuals can and must bring to bear on their own lives to achieve their potential and learn the life lessons that will facilitate their own distinctive journey toward aging well. It does not assume that clients are "other," but rather, in the classic stance developed by Martin Buber (1957/1970), addresses relationships as having I-Thou status, where the relationship is subject-to-subject rather than subject-to-object. Ageism is sometimes manifested in a paternalistic attitude that treats older adults as having lived past their ability to participate productively in society and acknowledges only limited options in their behavioral repertoires. By contrast, the strengths perspective engages individuals in a way that promotes the ongoing task of building a mindful and meaningful life. For instance, a social worker utilizing the strengths perspective reassures clients that he or she will not interfere with their independence and autonomy.

The strengths perspective seeks to empower people and communities. For example, as applied to an understanding of health care, the strengths perspective leads social workers to consider the multiple influences that shape health status. Social workers are urged to go beyond linear explanations for health and disease and to focus on the capacity of individuals and communities to take an active role in achieving and maintaining health (Weick, 1986). Emphasis is on removing barriers to access to formal health care, on more effective use of community resources, and on working to establish policies that support increased access. The strengths model is best understood in

comparison to the traditional medical model that socializes the client to be a passive recipient of services largely determined through professional expertise. The strengths perspective serves as an antidote to victim blaming through its focus on dialogue, collaboration, resilience, empowerment, and, ultimately, wholeness as defined by the client (Saleebey, 2002).

The strengths perspective assumes that the key to opening up critical areas of dialogue is through sharpening the skill of listening deeply to client concerns, dreams, and visions of a desired future—a future that can fundamentally change behavior and thoughts in the present. Often, the simple power of language has the capacity to elevate or denigrate. The potential for social workers to engage clients in helpful ways may be influenced by the choice of words they employ and the way those words are understood or received by the client.

The strengths perspective also fosters a sense of belonging by recognizing the reciprocity between the client and the social environment even in the most extreme stages of coping with dementia or receiving full personal care. Although these relationships may appear one-sided, there are usually benefits for clients and caregivers as well as helping professionals. The communication between the client, family and friends, and professional helpers and advocates provides insights that improve direct care, empirical research, and policy.

The conceptual underpinnings of the strengths perspective reflect a social constructionist approach to reality, which posits that our explanations of all human interactions, including social problems, are based on views of reality that are socially and personally constructed (Berger & Luckmann, 1967; Geertz, 1973; Gergen, 1999). The phrase “socially and personally constructed” suggests that personal beliefs and group consensus shape what a group of people consider to be real at a given time. Hence, in the strengths perspective, understanding the beliefs and values of the older adult is the beginning point for all further work.

Principles of the strengths perspective (Saleebey, 2002) generally include the following:

- All individuals have strengths.
- All experiences, even negative ones, may present opportunities for growth.
- Practitioner diagnosis and the assessment process in direct practice often make assumptions that limit rather than expand capacity.
- Collaboration rather than coercion leads to highly motivated and engaged clients.

- All environments have resources.
- A civil society engages in care for all of its members.

Practice based on these principles always involves a delicate dance of interpretation as one applies them to the web of difficult work with clients and sometimes the people in their environments. However, incorporation of a focus that builds on individual and community strengths and resources and on forming a collaborative relationship with clients to help them achieve their goals opens new possibilities for effective practice. A parallel perspective has emerged with the development of the positive psychology movement. Peterson and Seligman (2004) have challenged psychologists to measure and describe what is right with people in lieu of what is wrong with them; Saleebey (1997) recommends avoidance of classifying people based on a *Diagnostic and Statistical Manual of Mental Disorders* diagnosis. The social worker’s role is to skillfully create a helping relationship that empowers the client to resolve life struggles.

THE STRENGTHS-BASED APPROACH WITH OLDER ADULTS

The strengths-based approach was initially developed for use with adults served in mental health centers/agencies (Kisthardt, 1993; Rapp, 1998; Saleebey, 2002). A strengths-based perspective has also been successfully extended to social policy and direct practice with older adult populations (Chapin, 1995; Fast & Chapin, 2000, 2002; Tice & Perkins, 1996). These strengths-based approaches follow the general principles elicited by Saleebey and others, but they are particularly tailored for work with older adults:

- Discovering and building on strengths of older adults rather than problems will facilitate hope, self-reliance, and personal satisfaction.
- Acknowledging that older adults have the power to learn, grow, and change is fundamental.
- Developing the older adult–social worker relationship is essential to effectively assist the older adult.
- Participating in decisions, making choices, and determining the direction of the helping process is a primary role for the older adult.
- Acquiring resources based on active outreach to the community is a key role for the social worker.

Strengths-based social work practice with older adults requires assertively helping to acquire needed

additional resources when necessary. However, naturally occurring helping systems in the community are first carefully explored and bolstered. For example, it may be possible to identify a neighbor who would be willing to take the older adult's trash to the curb in winter, or a fellow church member who may be willing to shovel snow from the driveway or provide rides to church, in return for mending or ironing. Fostering these kinds of reciprocal relationships also strengthens informal supports and chances for social interaction that are vital to aging well.

Although many social workers are now employing strengths perspective principles in their practice with older adults, work to further specify helping strategies and to develop a model that can be the basis for careful research is yet to be done. Staudt, Howard, and Drake (2001) reviewed nine research studies that examined the use of strengths-based case management in mental health and substance abuse treatment. They recommended that future studies consider experimental designs where strengths-based case management approaches are treated as an independent variable. In addition, they recommended that research control for differences in case manager trainings and differences among case management styles. They also recommended that measurement of client outcomes be given increased attention.

PHILOSOPHICAL TENETS OF THE SOLUTION-FOCUSED APPROACH

Solution-focused therapy shares common roots with the strengths perspective. Solution-focused therapy traces its origins to work by de Shazer and colleagues (1986; for a more detailed development of theoretical underpinnings of solution-focused therapy, see Berg, 1994; de Shazer, 1988, 1991; Lipchik, 1993, 2002). Central to the solution-focused approach and all therapy models are certain assumptions, discussed below, about the nature of the person, how problems are formed and maintained, how change occurs, and the role of the individual and the social worker in the therapeutic/helping process (Bonjean, 2003; de Shazer et al., 1986).

First, the idiosyncratic nature of the person is affirmed because the solution-focused approach values the subjective experience and worldview of the individual (Bonjean, 2003). This is also an example of how the solution-focused approach shares its social constructionist epistemology with the strengths perspective. The social worker's role is to assist individuals to

create their own solutions based on experiences when the difficulty is not present. The social worker draws on the strengths of the individual and resources available to him or her as a means to overcome challenges and attain the goals that will lead to a satisfactory life (de Shazer et al., 1986).

Second, the solution-focused approach makes clear how problems are formed and maintained. All individuals experience difficulties in life; however, the difficulty becomes a complaint when attempts to resolve the problem are ineffective despite recurring attempts to resolve it (de Shazer et al., 1986; Nelson-Becker, 2004). In some cases, the individual may perceive the situation as static or not changing despite behavior that was intended to resolve the complaint. The individual requests professional social work assistance when he or she has complaints about life that are no longer acceptable to the help seeker.

A solution-focused approach avoids identifying the cause and effect. Looking for a cause and effect maintains the focus of intervention on the problem or complaint. Just as the name suggests, the solution-focused intervention revolves around constructing or identifying solutions. The approach suggests that the solution to the complaint is found in exceptions to the complaint or those times when the complaint is absent (Bonjean, 2003; de Shazer et al., 1986). The social worker's role is to help the individual identify those exceptions. Hence, the interview questions or assessment focuses on those times when life is going well and attempts to find out what was happening that made life satisfactory. In this manner, the solution is separated from the problem and can build on the strengths and positive experiences of the individual.

Third, a solution-focused approach has a unique perspective on how change occurs. Constructing or identifying solutions creates an expectation of change. The expectation of change or actual change itself does not have to be great; in fact, any expectation of change is valuable because slight changes influence the interactional pattern between the client and other individuals (Bonjean, 2003; de Shazer et al., 1986). Part of the expectation of change is based on the fact that clients will do something different from what they did in the past to resolve the complaint.

Finally, the solution-focused approach defines the role of the individual and social worker as a collaboration to establish goals that are based on client values. Solution-focused interventions are client-centered: The individual decides what his or her goals are and when enough change has occurred to end therapy or the intervention. The client-centered approach to goal

setting also de-emphasizes the social worker as the expert and develops a collaborative relationship that is respectful of the individual's life experience, worldview, and capacities (Bonjean, 2003; de Shazer et al., 1986).

Solution-focused approaches have been utilized in clinical work with older adults and their families; they illustrate how the approach can be used successfully as a clinical/psychosocial intervention in addition to case management or direct service intervention (Bonjean, 1997, 2003; Dahl, Bathel, & Carreon, 2000). A solution-focused approach includes principles that guide the social worker's action and are comparable to the strengths perspective principles (Bonjean, 2003). The focus is on the positive elements in one's life, on the solution, and on the future in order to facilitate change toward the older adult's goals:

- Goal attainment is accomplished in the older adult's own unique way, and he or she is able to resourcefully and creatively change.
- Both the older adult and the social worker are experts.
- Identifying exceptions to the problem enables the older adult and social worker to build or create solutions. An exception is any instance when the older adult does not experience the challenge.

The solution-focused approach emphasizes these principles as fundamental to intervention. Both solution-focused and strengths-based approaches have broad application to work with older adults. They may be easily utilized in many types of settings, and the fundamental principles, consistent with social work values, are quickly assimilated by social workers at any level of practice.

APPLICATIONS

In this section, we illustrate the application of strengths-based and solution-focused approaches in a variety of settings where social workers provide services to older adults. A challenge for social workers is that many settings use a traditional problem-solving model or a diagnosis is made as a basis for the intervention. The solution-focused and the strengths-based approaches avoid the traditional model's emphasis on diagnosis, pathology/deficits, or problems.

Regardless of the agency auspices or services, the strengths-based/solution-focused assessment lays the foundation for the social worker and older adult to develop goals important to the older adult and identify

intrapersonal, interpersonal, and social-environmental resources to reach these goals. The social worker's role is to help the older adult define and articulate goals and the changes that will illustrate measurable achievement of the goals. This emphasizes and supports the self-efficacy, autonomy, and self-determination that are essential to client empowerment and a sense of hope.

In the case of Celia described earlier, the home- and community-based social worker has knowledge of human development and models of change, a wealth of information about community resources, and the professional skills to assist the older adult. Social work helping skills include assisting the older adult to focus her energy on solution identification as well as providing an alternative viewpoint about the challenges faced by the older adult. The expertise the older adult brings to the relationship is her own life experience, personal strengths, and viewpoints regarding her personal circumstances.

In addition, the older adult provides the definition of the challenges she faces, potential solutions to these challenges, and a preference about how she would like to overcome them (Bonjean, 2003). The social worker can use assessment and active listening skills as a means to elicit discussion with the older adult about how she conducted her life prior to the current circumstances and events as well as to review earlier life challenges and responses. After the home- and community-based social worker and older adult identify goals, they agree on the formal and informal resources to assist the older adult.

In this example, the social worker learned that Celia was a primary caregiver for more than 5 years. Prior to taking on the caregiving role, Celia was socially active and engaged with her church and other social groups and participated in activities to promote her health and well-being. Focusing on these positive dimensions and strengths, the social worker can work with Celia to reengage her with her support system and develop new support systems, for example, a grief and loss group through the local senior center. We primarily consider senior centers as a source of congregate meals and social activities; however, they can also provide services that support the health and well-being of older adults such as caregiver support and grief and loss groups. If such groups do not yet exist in the community, it is incumbent on the social worker practicing from a strengths perspective to work with community agencies to see that such services are made available. The senior center social worker using a strengths perspective approach would

also work to expand such community support options and to enact policies to create those options.

Another resource available to address the depression experienced by Celia is the community mental health center. A mental health social worker could use a solution-focused approach to identify the exceptions to the problem (e.g., the depression) by concentrating on prior feelings when Celia felt life was going well. She could help Celia identify possible change opportunities to separate the problem from the solution (Bonjean, 1997). The social worker using the solution-focused approach will apply his or her assessment skills to find instances when the problem was not present or when feelings were less intense. This approach builds on the strengths and successes of the older adult instead of focusing on what is not working.

For instance, the mental health center social worker assessing Celia would learn about the small things that helped her feel better each day: taking walks in her garden, looking at the artwork her son had created for her, and thinking about the life her husband would want her to live. These exceptions could be used to help Celia recognize that there are brief lapses in her feelings of grief and loss when she reflects on the enjoyable times and rewarding life she had built with her husband and son. More important, Celia would recognize that there are moments and times when her grief and loss are not as painful. The mental health center social worker could encourage Celia to think about these exceptions to her emotional pain and use this process to take small, incremental steps to work through her grief and loss.

Long-term care institutions, such as assisted living and nursing care facilities, also offer many opportunities to apply the strengths and solution-focused perspectives. A social worker working in these locations may help to focus older adults' energy on those activities they found personally meaningful throughout their life and facilitate engagement in those same or similar activities in the new location. Initial anger in making the transition can also be a tool when the social worker helps direct it into building a significant future.

CAUTIONS AND BENEFITS

We believe the strengths-based and solution-focused approaches have great value particularly for older adults who encounter life challenges with diminished friendship networks, emerging health concerns, and other losses. However, there are three cautions in

using these approaches. First, although there is much anecdotal evidence that these approaches offer benefit to older adults, there has been little formal research to provide empirical evidence of the specific mechanisms by which these approaches assist older adults in leading more fulfilling lives. There has been little discrimination of what type of older adult may benefit and who may not. Future research could include better delineation of how these approaches operate in comparison to other approaches and better evaluation of specific outcomes.

Second, when needs are minimized, a novice worker may lose the sense of urgency to address these needs. There are times when needs are of a critical nature and must be immediately addressed. A social worker does well to learn to discriminate when it is appropriate to engage a strengths-based or solution-focused approach and when emergent issues, such as domestic violence or other abuse, must be addressed first.

Third, although we believe the approaches discussed here have lasting value and can be used to some extent in nearly every context, it is important to understand that in specific situations other approaches might better meet certain needs. As with any social work approach, no one size fits all. It is important for social workers who work with older adults to become adept at incorporating many models of practice.

We believe there are many merits to integrating strengths and solution-focused perspectives into work with older adult clients. Foremost is that they sharpen the focus on the capacity of older individuals rather than on pathology and disability. The strengths-based and solution-focused approaches do not ignore biological components; the social worker conducts a biopsychosocial assessment and considers biological influences in the larger context of the older adult's social environment. Thus, these perspectives work to counter the dominant paradigm alive in many disciplines today that discounts the truth that the key to healing generally resides within the individual. The strengths and solution-focused perspectives require workers to assertively look for strengths and resources in their clients as well as the clients' families and environments. Such reframing can initially be a challenge, but social workers can train themselves to see in new ways, and this becomes a skill that develops over time.

The strengths perspective particularly gives voice to populations whose views previously were ignored. Listening to older adults, particularly older adults of oppressed groups, such as people of color, women,

gays, lesbians, bisexual and transgender individuals, and people with disabilities, helps social workers understand more clearly how they managed to survive and even thrive in challenging environments. The emphasis on exploring strengths in the context of unique life experiences is beneficial across ethnic, cultural, and economic groups (Chapin, 2001).

Finally, using these perspectives can be energizing for the social worker who practices with older adults. Sometimes, when facing a long litany of challenges rehearsed by older adult clients who often find no redress in formal societal institutions, social workers can become overwhelmed and discouraged and experience compassion fatigue. The perspectives detailed in this chapter can keep social workers fully engaged as they encourage older individuals to explore their hopes, dreams, and goals and, in the process, replenish their own energy reserves.

CONCLUSION

The strengths perspective and the strengths-based and solution-focused approaches focus on client and community capacity, resilience, and goals. These distinct strategies offer social workers a practice framework that helps them put into action values such as self-determination and social justice. The strengths perspective draws on a long but sometimes neglected tradition in social work of starting where the client is and of honoring the insights into the capacity to identify their own solutions that clients possess. Because older adults bring a lifetime of experience in working out solutions, these approaches can be especially helpful for the gerontological social worker. The next step is for gerontological researchers and practitioners to further elucidate these approaches to determine how the strengths-based and solution-focused approaches can be most effectively implemented in specific settings and conditions.

Spirituality in Professional Helping Interventions

74

Older adults typically value the importance of religion and spirituality in their lives. Fifty-eight percent of older Americans reported that religion is very important, the highest rating on a 4-point scale in a recent Gallup poll (Princeton Religious Research Center, 2001). As health and mobility decline in older ages, formal religious participation tends to decrease, but private spiritual expressions (use of prayer, the Bible, and religious radio/TV) tend to increase (Levin, 2001). Because religion and spirituality are often important aspects of their lives, older adults may welcome integration of a spiritual perspective when they interact with formal helpers.

Spirituality has recently begun to be a focal point for investigation in many gerontological disciplines. For example, in social work, recent studies about elders have explored connections between cultural diversity and religiousness (Ahearn, 2001), spirituality as an important resource for well-being (Ai, 2000), use of existential psychotherapy (Lantz, 1998), collaboration between social work and churches (Tirrito, 2000), and issues related to dying and hospice programs (Lloyd, 1997; Reese, 2001; Smith, 2001). Numerous empirical studies in other fields have examined the relationship between religion or spirituality and well-being, with about 80% reporting positive correlations between religiousness and greater happiness, life satisfaction, or other measures (H. G. Koenig, McCullough, & Larson, 2001). In particular, empirical studies of the effects of religion on the health and mental health of older adults, though having mixed outcomes, generally suggest that religious and spiritual practices have salubrious effects on social support, coping, and quality of life at the end of life (Krause, 1997; Levin & Chatters, 1998; Nakashima, 2003; Nelson-Becker, 2004). These findings imply that religious and spiritual interventions may be valuable resources for social workers in maintaining life satisfaction for some older adults.

Development of a spiritually sensitive practice requires a strengths-based approach that includes listening to the profound and diverse questions clients express and demonstrating openness to hear all expressions of grief, longing, confusion, and joy that emanate from the human experience. Spiritually sensitive practice involves the ability to recognize and respond to these expressions with clients, but it does not impose a viewpoint that is contrary to the perspective of the client. It is a hearing of the heart: an ability to hear the pain and the hope in the stories clients tell and an ability to highlight for clients important themes or subtexts of which they may not be fully aware.

SPIRITUALITY: WHAT IS IT?

Spirituality is the search for meaning, purpose, and morality. It develops through relationships with self, others, the universe, and/or ultimate reality or the ground of being, however a person or group understands this (Canda & Furman, 1999; James, 1909/1982; Tillich, 1962). Because spirituality has many aspects, attempts to define the term lead to at least three interrelated conceptualizations: an essential or irreducible core element of human nature; one aspect of many (biopsychosocial-spiritual) dimensions that constitute humans; and transpersonal experiences in which consciousness expands beyond the limits of ordinary ego and physical boundaries, for example, through a sense of connection with the divine (Carroll, 1998). Transpersonal experience includes the journey within to the deepest nature of oneself as well as the process of fulfilling and transcending the individual self in the context of our connections with others and the universe (Robbins, Chatterjee, & Canda, 1998). It may also include direct mystical experiences with the divine (James, 1908/1962). Individuals and groups may express their spirituality with or without involvement in religious organizations.

Spirituality is expressed through religious involvement somewhat more commonly among older adults compared to younger cohorts (Marler & Hadaway, 2002), although some older adults do not affiliate with a religion, that is, the beliefs, values, rituals, and institutions that are concerned with spirituality, shared by a community, and transmitted through traditions. Different disciplines view spirituality in varying ways (e.g., divinity schools often conceptualize spirituality as being one component of religion); social work generally views spirituality as the overarching dimension that may or may not include religious behaviors (Bullis, 1996; Canda & Furman, 1999; Joseph, 1988). Older adults, however, in contrast to their often younger social workers, are more likely to be able to define and discuss religion or their practical philosophy of living more easily than they define spirituality, a term they may find confusing (Nelson-Becker, 2003).

For a helping professional, spiritually sensitive practice involves a focus on the older adult client's distinctive and unique spiritual beliefs, values, practices, experiences, and community support systems. It also involves understanding general theories and ideas about spirituality that may be applicable across individuals and cultures. This parallels anthropological concepts of the emic or insider approach (considering the individual's unique perspective) and the

etic or outsider approach (considering how other spiritual/religious traditions or theories would view this individual). These two points of view are complementary when trying to understand individual spiritual concerns.

AGING AND THE SPIRITUAL JOURNEY

A natural concomitant of the aging process seems to be a turn toward exploration of the meaning of existence in relation to the universe. This inner spiritual exploration coinciding with aging is an expected cultural norm across cultures and spiritual traditions (Atchley, 2001). Tornstam (1994) found that adults over 75 often exhibit an increase in transcendent attitudes, including delight in the inner world, less death anxiety, and greater sense of connection to the universe. Some older adults do seek satisfaction through humanistic philosophies by creating a life of service and altruism with a goal of generativity (Erikson & Erikson, 1997). Yet others find no appeal in religiosity or spiritual growth that are expressions of explicit spirituality, and maintain secular patterns that they established years earlier or developed in late life.

SPIRITUAL INTERVENTIONS OR SPIRITUAL HELPING ACTIVITIES

Although "interventions" is the term most often used in the social work literature to describe the activities conducted by social workers in collaboration with clients and is in fact part of the title of this chapter, the authors prefer the term "spiritually focused helping activities." This avoids the implication of the word "intervention" that helping should be imposed by professionals from an external or elite perspective. Instead, spiritually sensitive practice is a process of empathic and respectful person-centered engagement and dialogue. The remainder of this chapter identifies spiritual needs expressed by older adults and the clinical contexts where these needs may be addressed. Eleven domains of spirituality that may be addressed in the assessment process are considered, as well as sample questions that explore these domains. The need for self-reflection on the part of social workers who consider using spiritually focused activities with older adults is discussed and then types of spiritual activities that may be used under different circumstances are identified. Finally, ethical considerations for use of any type of spiritually focused helping activities are presented.

SPIRITUAL NEEDS AND CLINICAL CONTEXTS OF OLDER ADULTS

Spiritual Needs

Spiritual needs pertain to the universal desire to locate meaning and purpose in life. Among many types of spiritual needs, there are three commonly expressed by older adults: the need to create meaning and purpose, the need to become empowered through connection to a Higher Power/Transcendent Force or Nature, and the need to give and receive support through affiliation. Entering a later stage of the life course compels one to find meaning in one's life. This often includes looking beyond the immediate situation and refraining from defining oneself according to immediate circumstance. For example, one woman residing in a nursing care facility was overheard to describe herself as "wheelchair-bound with bad eyesight and a bad heart." Although that self-description was physically accurate, this individual was also proud to be a grandmother of 11 with an award-winning talent in writing children's literature.

Many older adults need to be able to find empowerment through their sense of connection to a Higher Sacred Power. A 66-year-old client of one of the authors had coped relatively well with Parkinson's disease and bipolar illness, but when she received a diagnosis of cancer in her nasal passage, her coping mechanisms were overwhelmed. A devout Catholic, she was very angry at God but felt her faith did not allow her to be angry, resulting in internal conflict that she was unable to resolve alone. The author helped her expand her view of God and, with her permission, contacted her chaplain for a visit.

Continuing old affiliations or making new ones is a way to remain connected to community and continue to make contributions. In older ages, adults typically receive many services; they need to know that they can still make significant contributions to others, whether through sharing wisdom-based stories or imparting knowledge gained as a by-product of lifelong vocational pursuits. They value the support they both receive and provide to others.

Clinical Contexts

There are numerous life challenges across settings where spirituality may be a resource for older adults who value this expression. For more information about social work practice in particular settings such as community-based services, long-term care, and

hospice, see other chapters in this volume. There are four common contexts for spiritually focused helping activities: coping with chronic or terminal illnesses, bereavement, relocation, and caregiving.

When chronic illness leads to pain or life limitation, older adults often feel discouraged. One active response is to use emotion-focused coping (Lazarus & Folkman, 1986). "Religion helps me in a lot of ways. When I feel that I'm depressed about things, it just seems that I think about how the Lord is able and He rules the world. When I get that feeling, it helps," commented one older African American female study respondent (Nelson-Becker, 2004). Social workers may support clients by engaging with the spiritual support systems, language, and symbolism that appeal in accordance with clients' orientation on the spiritual/religious continuum.

Bereavement is difficult at any age, but losses are magnified in later life when one's life companion dies and friendship networks begin to thin. The loss of spouse, close siblings, friends, and pets can be very painful. Older adults' physical and mental well-being is often compromised during the bereavement process. One's spiritual beliefs and practices may bring comfort for those who suffer from the loss of important companions and grapple with the meaning of life and the deaths of their significant others. Spiritual mentors, such as clergy or wise friends and relatives, as well as religious or nonreligious spiritual support groups can provide guidance and social healing that help the bereaved individual build a life without the physical presence of the deceased.

Older adults who transition to greater levels of care, often in new locations, find it hard to maintain contact with their faith communities. In such cases, religious television and radio programs may take on new significance. Engagement with familiar religious activities, such as prayer, meditation, scripture reading, reciting a mantra or rosary, and attending religious ceremonies, can be facilitated for interested clients. Spirituality can thus be a special resource that aids in the transition process until the older adult is able to build new supports.

Caregiver burden is becoming an increasing concern as older adults live longer with chronic conditions (Centers for Disease Control, 2004). Researchers have begun to explore the role of caregivers' spirituality as well as the role of spirituality for the older adult. Spirituality has been viewed as a resource in dealing with multiple physical, emotional, and social demands that contribute to this burden. T. Koenig (in press) found that spirituality was used by caregivers to resolve ethical dilemmas. Overall, the clinical context of the

problem an older adult encounters as well as the personal stance of the older adult may indicate whether spiritually based activities should be considered as potential resources.

SPIRITUAL ASSESSMENT

Many social work agencies now incorporate some questions on religion and spirituality as part of their formal intake process. Usually this takes the form of one or two brief questions surrounding religious affiliation and church/synagogue/spiritual group attendance. In social work and aging, Ortiz and Langer (2002) developed a short protocol for conducting spiritual assessments with older adults, and Ai and colleagues (in press) have developed a spiritual support scale. Olson and Kane (2000) conducted a broader review of ways to measure or assess spirituality in older adults, though this takes less of a clinical focus. In addition, social work has developed spiritual assessment tools to assist practitioners (Bullis, 1996; Canda & Furman, 1999; Hodge, 2001; Nelson-Becker, 2005), as have medicine and nursing (Anandarajah & Hight, 2001; Fitchett, 1993; H. G. Koenig, 2002; Puchalski & Romer, 2000; Sulmasy, 2002). The Fetzer Institute (1999) has an excellent resource for measurement of religious and spiritual dimensions that also has some possibilities for clinical application with older adults.

Spiritual assessment with older adults should form part of a comprehensive assessment that is ongoing. Some older adults consider religion and spirituality to be private matters, so they may not be forthcoming about these dimensions in the beginning. An essential starting point in spiritually sensitive practice is to create a supportive and collaborative space for older adults to freely reflect on their religious and spiritual views and experiences according to their own interests. For example, a social worker might initiate a conversation in a casual manner by mentioning the presence of a spiritual painting in the client's living room. Such an invitation creates an opportunity to make a smooth transition to conducting a spiritual assessment.

Spiritual assessment can help the social worker to determine whether the client would like to explore spirituality further by receiving counseling from the social worker or referrals to other resources. Before embarking on a detailed spiritual assessment, the social worker should ask four preliminary questions:

1. What helps you to experience a deep sense of meaning, purpose, and moral perspective in your life?

2. Are spirituality, religion, or faith important in your life? If so, please give examples. If not, please explain why they are not important.
3. If important to you, what terms for referring to spirituality, religion, or faith do you prefer?
4. Would you like to incorporate spirituality, religion, or faith in our work together? Please explain.

Posing these questions is crucial in setting an appropriate framework to customize the questions that are consistent with the client's orientation and needs. In Table 74.1, we present 11 domains of spiritual assessment that we developed from previously cited sources along with examples of questions for use as an assessment tool or guide. The goal of this guide is to obtain a comprehensive understanding of an older adult's relationship to spirituality.

In conducting an assessment, a worker needs to be ready to frame and present assessment questions in a manner that the client can easily understand and to which he or she can relate. Conducting a thorough spiritual assessment based on Table 74.1 is quite a formidable task to accomplish. We recommend that the extent of assessment and the selection and wording of questions should be determined by the issues at hand, the setting and nature of the client-worker relationship, and the social worker's clinical expertise. Spiritual assessment may be incorporated into ongoing work with the client if time allows. The simple act of asking these questions to explore the client's spiritual life together itself may generate a therapeutic effect, bringing some insights and clarification to issues that are important to the client. In some cases, simply asking the previous four preliminary questions will be sufficient.

SPIRITUALLY FOCUSED HELPING ACTIVITIES

All social work activities with older adults may be framed within a spiritually sensitive practice approach if the social worker is intentional about his or her own spiritual development and aware of the spiritual path. Thus, although the social worker may not use explicit spiritual activities with a client either because they are outside the area of focus or the older adult has no interest in spirituality or religion, the social worker may utilize implicit spiritual sensitivity in preparing for his or her own interactions throughout the day. Explicit spiritually focused helping activities are those activities that help older adults by promoting profound healing or spiritual development. These activities may be as-

TABLE 74.1. Eleven Domains to Explore During Spiritual Assessment

<i>Domains</i>	<i>Definitions</i>	<i>Relevant Questions</i>
1 Spiritual Affiliation	The formal religious or nonreligious spiritual groups with which the client closely identifies his or her orientation.	<ul style="list-style-type: none"> ✓ Do you belong to any spiritual/religious group? ✓ What does membership in this group signify to you? ✓ Do you express your spirituality outside of participation in a religious or spiritual support group?
2 Spiritual Beliefs	Perspectives and ideas related to existential issues, the divine, nature, meaning, or purpose in life.	<ul style="list-style-type: none"> ✓ What religious or spiritual beliefs give you comfort or hope? Describe. ✓ What religious or spiritual beliefs upset you? Describe. ✓ Do you believe in God, a Transcendent Power, or Sacred Source of meaning? ✓ Describe your vision of who God or this Sacred or Higher Power is. ✓ How would your beliefs influence your medical decisions if you became very ill? Would your beliefs interfere with or enhance your medical care in any way? ✓ Do you believe in an afterlife? What does this mean for you now?
3 Spiritual Behavior	The spiritual practices or actions engaged in daily or special occasions such as prayer, meditation, or worship (including both private and public, organizational and nonorganizational).	<ul style="list-style-type: none"> ✓ What religious or spiritual behaviors do you engage in? ✓ How often do you engage in these religious or spiritual behaviors? ✓ Do you engage in these privately, with family, or in spiritual groups? ✓ What about these behaviors do you find nourishing or undermining?
4 Emotional Qualities of Spirituality	Feelings associated with spiritual beliefs and/or experiences/activities (both positive and negative).	<ul style="list-style-type: none"> ✓ Have you recently experienced an emotion such as anger, sadness, guilt, joy, love, or relief in the context of religious or spiritual experiences? ✓ What significance, if any, did this have for you? ✓ What feelings did you have in response to (a specific experience)?
5 Values	Moral principles and ethical guidelines derived from spiritual beliefs.	<ul style="list-style-type: none"> ✓ What are the guiding moral principles and values in your life? ✓ How do these principles guide the way you live?
6 Spiritual Experiences	Private or shared profound transcendent experiences shaping sacred meanings, including both ordinary and altered states of consciousness.	<ul style="list-style-type: none"> ✓ Have you had any spiritual experiences that communicate special meaning to you? If so, please describe. ✓ Do you experience a connection with spiritual forces such as God, angels, spirits, or deceased loved ones?
7 Spiritual History	Developmental trajectory of spiritual beliefs, values, practices, and experiences. Includes both gradual change and pivotal points involving crisis or life enhancement.	<ul style="list-style-type: none"> ✓ Were you raised in a spiritual or religious tradition? Do you now practice in the tradition in which you were raised? Describe early experiences and parental involvement.

(continued)

TABLE 74.1. Eleven Domains to Explore During Spiritual Assessment (*continued*)

<i>Domains</i>	<i>Definitions</i>	<i>Relevant Questions</i>
		<ul style="list-style-type: none"> ✓ In what decades of your life were you involved in spiritual practices? Would you rate your involvement as low, medium, or high for each? Were there any change points? ✓ What events in your life were especially significant in shaping your spirituality? ✓ Who encouraged your spiritual or religious practices? ✓ Describe any spiritual breakthroughs that are relevant to you now.
8 Therapeutic Change Factors	Unique spiritually focused individual strengths and environmental resources available for healing, growth, and improvement of well-being.	<ul style="list-style-type: none"> ✓ What might be an object or image that symbolizes/represents your spiritual strengths? ✓ Could you tell me a story of how it helped you to cope with difficulties in the recent past? ✓ How do you see that this particular spiritual strength may help your current problems? ✓ What spiritually based strategies, rituals, or actions have helped you to cope with times of difficulty or to experience healing or growth?
9 Social Support	Assistance and support offered by other individuals and groups that promote client coping and spiritual well-being.	<ul style="list-style-type: none"> ✓ When you have religious/spiritual concerns and problems, who do you talk to? ✓ In the past, what types of supports have you received from these people?
10 Spiritual Well-Being	Client's subjective sense of happiness and satisfaction related to his or her spirituality.	<ul style="list-style-type: none"> ✓ How worthwhile do you find living your current life? Can you tell me more about it? How does this relate to your spirituality? ✓ How does your spirituality help you to find meaning in your life? ✓ How strongly do you feel connected to God/Higher Power/Spiritual/Universe?
11 Extrinsic/Intrinsic Spiritual Focus	<p>Extrinsic focus: client's spiritual identity and orientation tied to a certain group membership and conformity.</p> <p>Intrinsic focus: client's spiritual identity and orientation that may or may not be tied to a group membership, but is more flexible and relatively self-determined.</p>	<ul style="list-style-type: none"> ✓ Do you find the teachings and values of your spiritual group similar to or different from your own? Please explain. ✓ How integrated are your spiritual practices with your daily life, apart from spiritual group participation?

sociated with a religious organization or a nonreligious support group, or they may be private. A social worker may foster this type of helping indirectly through networking and/or collaboration with religious/spiritual organizations desired by the older adult or directly through exercise of spiritual activities during the session under specific conditions that are discussed below. Table 74.2 designates types of spiritually

focused practices and the conditions under which they may be considered for use.

Implicit Spiritual Activities

Spiritually sensitive practice with older adults develops when the social worker relates with the client

TABLE 74.2. Using Spiritually Focused Activities With Older Adults in Social Work

<p>1. Client has not expressed interest in spirituality. (<i>Implicit Spiritual Sensitivity</i>)</p>	<p>A. Social worker uses other types of helping activities with client, for example:</p> <ol style="list-style-type: none"> 1. Life review 2. Strengths-based interventions 3. Cognitive-behavioral techniques 4. Other therapeutic styles <p>B. Social worker prepares self for therapeutic encounter through private spiritually based activities outside of session, for example:</p> <ol style="list-style-type: none"> 1. Meditation 2. Relaxation 3. Visualization/imagery (e.g., seeing client surrounded by protective light) 4. Spiritual journaling 5. Engagement with a spiritual support group for grounding 6. Prayer for self-guidance <p>C. Social worker engages with client in spiritually sensitive relationship, for example:</p> <ol style="list-style-type: none"> 1. Relates with unconditional positive regard 2. Extends sense of hope to client until client can begin to build own 3. Listens with ears, mind, and heart to catch the meaning behind client verbalizations and nonverbalizations
<p>2. Client has expressed interest, but social worker does not have relevant expertise or permission for direct use of spiritually focused activities; or social worker–older adult relationship has not yet been deeply established. (<i>Explicit Spirituality Focused Helping</i>)</p>	<p>D. Above activities plus (with caution): Social worker refers client to outside spiritual support systems, for example:</p> <ol style="list-style-type: none"> 1. Ministers, rabbis, spiritual mentors with whom client already has relationship 2. Church/synagogue/mosque/temple leaders and spiritual teachers/healers congruent with client’s expressed religious or spiritual affiliation 3. Other systems of potential spiritual support that are consistent with client interests
<p>3. Client has expressed interest, <i>plus</i> a spiritually sensitive relationship and practice have been established. (<i>Explicit Spirituality Focused Helping</i>)</p>	<p>E. Social worker collaborates with outside spiritual support systems, for example:</p> <ol style="list-style-type: none"> 1. Social worker works directly with outside supports chosen by client (e.g., chaplain or traditional healer) unless there is a concern 2. With client approval, social worker works with outside system members generally to build greater support for client or to assist in clarifying and mediating problems <p>F. Above activities plus (with caution) direct use of spiritual helping activities by client request, for example:</p> <ol style="list-style-type: none"> 1. Use of insights from spiritual/sacred writing 2. Exploration of personal sacred objects/symbols/stories 3. Use of art, music, poetry as therapy 4. Creation of spiritual map/time line including identification of significant mentors

(continued)

TABLE 74.2. Using Spiritually Focused Activities With Older Adults in Social Work (*continued*)

<p>4. Client has expressed interest, <i>plus</i> a spiritually sensitive practice has been established, <i>plus</i> social worker has credentials or qualifications for particular activities (<i>Explicit Spiritually Focused Helping</i>)</p>	<ol style="list-style-type: none"> 5. Focused relaxation and breathing techniques 6. Exploration of forgiveness issues 7. Discussion of significant dreams 8. Development of rituals/ceremonies 9. Reading inspirational texts 10. Discussion of attitudes toward death/dying/after-life 11. Reflection on harmful/helpful aspects of spiritual group participation
<p>G. Above activities plus (with caution) direct use of technique/therapy/ritual for which social worker is formally sanctioned and client requests, for example:</p>	<ol style="list-style-type: none"> 1. Use of prayer/religious ceremony with client when social worker is also a clergy person or recognized leader in the same religious group 2. Biofeedback 3. Jungian dreamwork 4. Body-centered therapy 5. Guided visualization 6. Meditation with a spiritual focus (such as Zen mindfulness meditation or Christian centering prayer) 7. Disciplines for healing and spiritual cultivation such as Reiki, Tai Chi, or hatha yoga 8. Herbalism 9. Acupuncture

Source: Adapted from Canda & Furman (1999, p. 254).

through genuine respect, unconditional positive regard, empathy, and openness to the client's distinctive spiritual perspective. These relational qualities should be the foundation of both implicit and explicit spiritually focused activities. Spiritual sensitivity requires explicit discussion of spirituality or use of overt spiritually focused activities only when appropriate for the client's goals and interests. Section 1 of Table 74.2 indicates some spiritually focused activities that may be appropriate when the client has not expressed interest in spirituality.

Establishing a personal intention to be fully and spiritually present helps center the social worker for whatever events or situations enter his or her physical, psychological, or emotional space. This type of preparation also is effective in countering compassion fatigue: It provides the ability to be fully connected to the present moment and manage the energy dissipation that often results from empathic engagement

with older adults who may experience many forms of pain. Building a work and/or home environment with inviting spaces, artwork, and beauty provides a place where one can release the accumulation of energy that may be absorbed in all facets of direct social work practice. Listening to calming sounds or relaxing music helps build a holding or safety zone. Creating supportive networks with other professionals, friends, and family and engaging in personal renewal strategies such as taking walks in a natural setting also provide a type of inoculation against burnout when work with older adults becomes very complex or sad.

Creativity is a principle that asks social workers to develop their imagination. Where the older adult can no longer see possibility, the task of the social worker is to help open up creative solutions in the context of the current difficulty. As Baltes and Baltes (1990) suggest, selective optimization with compensation encourages frail or disabled older adults to take full

advantage of their ability level by choosing to focus on what they still can do, perhaps doing less of it or performing something differently and at a slower pace. An important task of the social worker is to reenvision the current situation and to assist older clients in reengaging their passions in innovative ways or to develop new ones.

Explicit Spiritual Activities

Spirituality can be engaged explicitly when the older adult has expressed interest in doing so. Sections 2, 3, and 4 of Table 74.2 indicate some explicitly spiritual activities that may be appropriate depending on the client's goals, the practice situation, and the qualifications of the social worker. Sections 2 to 4 represent increasingly direct levels of engaging spirituality. Greater caution to avoid inappropriate impositions of the social worker's own values and assumptions should be used as intrusiveness increases.

Basic explicit spiritually focused helping activities (section 2) are activities that do not necessarily require special training or supervision. On the first level, they may simply involve referral to outside spiritual support systems. For agents who are skilled at research and investigation, this may first involve locating the type of spiritual support system with which the older adult chooses to be affiliated and then facilitating the connection. At times, it may involve advocating for the older adult when the spiritual or religious system itself has been a source of misunderstanding, betrayal, or pain. It may involve collaboration when the older adult asks the social worker to share information or to remain in contact with the spiritual mentor or leader about some issue. As in all ethical social work practice, consents need to be signed for information sharing to occur.

If the older adult has expressed interest and a spiritually sensitive relationship is in place (Canda & Furman, 1999), the social worker may include activities directly in sessions, such as exploring personal sacred objects/stories or a spiritual time line (section 3). The activities described as possible choices should be used only if the social worker has competence or expertise in using them. Activities in section 4 require that the older adult expresses interest, a spiritually sensitive relationship has been established, and the social worker has credentials or qualifications to conduct the activity (e.g., assisting an older adult to interpret the contents of a dream through Jungian analysis).

Further Ethical Considerations

An important consideration in choosing to be engaged in any type of spiritually focused practice, whether implicit or explicit, involves thinking through ethical issues. Work with older adults involves a self-assessment process. In the context of practice, social workers often encounter situations that help them understand their own values better. They grow as they engage in self-reflection that assists in identifying limitations, biases, and negative attitudes. Achieving value clarity calls one to be open to explore personal understandings and to refine these understandings based on further evidence (Canda & Furman, 1999). Questions to ask oneself include: What types of experiences have I had that shaped my current reaction? What does this response suggest about my strengths and limits in regard to this helping situation and generally? Is there something here that I want to work on? If so, what is my plan?

Other principles that are important to consider from an ethical standpoint include respect, client-centeredness, and inclusivity (Canda & Furman, 1999; Canda, Nakashima, & Furman, 2004). Respect in work with older adults includes demonstrating respect for all secondary clients as well as the primary client. Sometimes family members have very different ideas from the older adult about what actions an older adult should take. Family members tend to privilege safety over independence and sometimes pressure their older relative to move to a more restricted environment where he or she will be safe. Respect involves recognition of the power of formal and informal support systems to provide important nurturance for clients and to listen to and address all viewpoints.

Client-centeredness involves honoring the older adult's aspirations, values, and dreams even when they are very different from our own. It means helping clients to achieve their goals, even when we might disagree that a goal is in their best interest. Related to this is the principle of inclusivity. Inclusivity concerns more than tolerance of an older adult's particular religious belief, for example, and includes honoring diverse spiritual expressions even when they are quite dissimilar from our own.

Before social workers engage in any type of spiritual helping activity with an older adult, they need to be clear that there is no motive aside from the welfare of the client. Even when the intent is only to help, the planned activity needs to be well considered. For example, if the social worker privately prays *for* a client with a petition for something that is contrary to the

older adult's self-determined goal, this raises concerns about client self-determination and informed consent. Activities need to be performed in a way that honors the older adult and the traditions of the association or organization connected to the activity. Some activities are not permitted to be conducted outside of formal affiliation and authorization with the religious tradition, such as Christian sacraments and indigenous healing ceremonies. For example, unless a social worker is also an ordained or lay minister in a faith tradition that practices administration to the sick, also known as laying on of hands, and the older adult is a member of the same faith tradition or seeks out this ritual, it should not be practiced out of context. Not only should the social worker have competency and skill in the activity, but he or she also should have permission from the client and the culture or group that is associated with the activity to conduct it.

CONCLUSION

Spiritually focused assessment and helping activities should be included among the strategies social workers use with older adults, especially as spirituality tends to be important to older cohorts. Later life is a developmental time when spiritual questions often arise, even if they were not a concern at earlier life stages. If social workers are not comfortable addressing these issues themselves, more training should be sought or a referral network should be developed.

Older adults may be particularly aware of spiritual needs when they cope with challenges related to illness, death, relocation, and caregiving contexts. One of the resources this chapter presents is examples of questions that may be used to identify whether a client is interested in addressing spirituality and, if the client is interested, additional questions (Nelson-Becker, Nakashima, & Canda, in press). Implicit spiritual helping activities (those used to prepare for social work with older adults) and explicit spiritual helping activities (those that may be used directly with older adults) have been discussed, as well as ethical considerations on which to reflect when doing work in this area. A second resource included here identifies implicit and explicit types of spiritually focused helping activities and situations when they may be appropriate based on ethical considerations.

The resources contained in this chapter are intended to be very practical applications for social workers interested either in developing a spiritual component in their work with older adults or deepening

and extending the spiritual foundation they already employ. Though there has recently been a surge of research in the areas of religion and spirituality, more specific research should be conducted related to aging studies. Gerontological social workers need to continue to explore spirituality through dialogue with other practitioners, researchers, educators, and older adults.

C. Advocacy and Empowerment Models

KEVIN J. MAHONEY
KAREN ZGODA

Approaches to Empowering Individuals and Communities

75

Jane Addams, once described by FBI director J. Edgar Hoover as the most dangerous woman in America, was born in 1860 to an upper-class family and formally educated (Specht & Courtney, 1994). Abandoning her social class and the privilege it afforded, Addams dedicated her life to serving the poor. She worked hard to promote international peace and to improve the social conditions that caused poverty. Addams became internationally known for creating Hull House, a settlement house located in a poor, working-class neighborhood in Chicago. She strongly believed the poor were victims of social and economic conditions, so she lived and worked with these neighbors, in their cultural and community contexts, to help them help themselves (Addams, 1910).

Addams is credited with laying the groundwork for what is now called empowerment-based practice in social work. Building on the work of Addams, contemporary empowerment theory grew out of the progressive social movements of the 1960s and 1970s. These social movements, including the women's movement, the Black Power movement, and the welfare rights movement, were founded to change oppressive social conditions in the United States. Acting in accordance with the principle of self-determination, empowered communities and individuals fought for the right to determine their own fates. Micro- and macrolevel interventions of empowerment were designed to better the lives and communities of oppressed peoples and thus ultimately effect a progressive transformation in society (Gutiérrez, Parsons, & Cox, 1998).

Although specific definitions of empowerment abound, it is clear that many social workers are currently examining the significance of power for their clients (Gutiérrez, DeLois, & GlenMaye, 1995). Relying on a definition supplied by Solomon (1976), the National Association of Social Workers (NASW, 2001), as part of their National Committee on Racial and Ethnic Diversity, defines empowerment as essentially an individual's ability to do for himself or herself. This involves fostering a connection between an individual and his or her own power and reaching across cultural barriers to become further empowered. Lee (1994) adds to this definition by stating that the focus of empowerment should be on members of stigmatized groups. Askheim (2003), Boehm and Staples (2002), and Adams (2003) assert that empowerment deals with the transmission of power such that the disempowered take or receive power. In this case, individuals are the experts at using their skills, competencies, and self-determination to act in their best

interest. The social worker facilitates this process. The World Bank (2002) defines empowerment in terms of poor people and their expansion of assets and capabilities such that they can assert power over the institutions that affect them.

Empowerment theory today is essentially a broad, yet fairly consistent, collection of concepts, methods, and models designed to develop power in individuals, families, groups, and communities (Gutiérrez et al., 1998). Empowerment theory asserts that there are numerous, perpetuating problems associated with an absence of power. Unequal access to resources, caused by an unequal distribution of power, prevents individuals and groups in oppressed communities from gaining the social goods they need. As a result, vulnerable persons are unable to shield themselves from the negative effects of oppression, including poor functioning in family and community systems.

The absence of power may produce intense feelings and behaviors. Pinderhughes (1994) asserts that individuals who are less powerful may feel less gratified, experience less pleasure and more pain, feel alone, fear their own anger and/or anger at the more powerful, fear abandonment, feel inferior, deprived, or incompetent, and have a strong tendency toward depression. Common behaviors among the less powerful include an inability to impact an external system or the self, projection of acceptable attributes (i.e., smart, attractive, competent) onto the power group, distrust, sensitivity to discrimination, paranoia, isolation, use of passive-aggressive behavior as a defense mechanism, rigidity in behavior to control feelings of powerlessness, striking out or becoming aggressive to avoid feeling powerless, and use of deception.

Major empowerment theorists recommend similar intervention strategies to achieve empowerment, most commonly beginning with an individual and expanding to include sociopolitical systems (Askheim, 2003; Cox & Parsons, 1993; Gutiérrez et al., 1998; Heumann, McCall, & Boldy, 2001; Lee, 1994). At an individual level, a relationship between the social worker and the client is established, linking families to needed services, raising consciousness, and empowering goals and outcomes. Individual goals may include increasing control over one's life, increasing self-confidence, and, as a result of increased knowledge and skills, better self-perception. If these elements are adequately addressed, individuals should be able to identify barriers to self-realization, increase power, and increase control over their life. At a structural level, the focus shifts to community and societal change. Social workers work with clients to gain

knowledge about sociopolitical issues and power structures, develop advocacy skills, learn methods of sociopolitical change, and engage in social action. Fundamentally, work at this level deals with the social structures and power relations that construct barriers to individual and community empowerment. As a result of these interventions, people and communities resolve disempowering situations and thus rebuild and reclaim an empowered status in society. Outcomes of empowerment-based interventions may include changes in self-efficacy, self-awareness, feeling that one has rights, self-acceptance, critical thinking, knowledge, skills, assertiveness, asking for help, problem solving, accessing resources, practicing new skills, lobbying, community organization, collaboration, and political action.

It should be noted that, under the empowerment model, the relationship between social worker and client is based on collaboration and mutual responsibility, not the traditional professional-client relationship (Cox & Parsons, 1993; Gutiérrez et al., 1998; Lee, 1994). Indeed, the success of the empowerment intervention depends heavily on the success of this relationship, also referred to as a balanced partnership or an egalitarian relationship. As problems of disempowerment are rooted in sociopolitical systems, social workers and clients should act as partners with a common interest in addressing the problem. Using dialogue and critical analysis, the social worker should both work with the client and facilitate the empowerment process of the client. Clients bring just as much valuable expertise to the problem situation as the social worker does.

EMPOWERING THE ELDERLY

The elderly face a unique set of factors that contribute to a loss of power (Cox & Parsons, 1993; Heumann et al., 2001; Thompson & Thompson, 2001; Waters & Goodman, 1990). At an individual level, the elderly cope with a decline in physical health, increase in mental stress (frequently as a result of depression, loss, and grief), and loss of social support systems, including peers and spouse. Elderly clients may view their problems as unique, personal, and theirs alone to solve. At a social level, many elderly individuals cope with economic loss from retirement, rising health care costs, poor housing, discrimination resulting from ageism, loss of status and contributory roles (i.e., from work and civic activities), political marginalization, continuing sociopolitical disadvan-

tages for members of minority populations, and a disempowering social service model. These factors can interact to produce increased dependency, oppression, learned helplessness, internalization, and powerlessness and ultimately limit elders' independence and ability to actively participate in society. Indeed, due to ageism, an assumption may exist that the elderly need to be cared for and looked after, reducing unique needs to a focus on provision of care.

Elderly people in the United States value independence and privacy as the core of empowerment (Heumann et al., 2001; Waters & Goodman, 1990). Many seniors want to age in the home they have known their entire lives; to own that home and manage that household is empowerment. Many prefer not to depend on visiting service providers who gradually usurp more and more decisions for their own convenience.

Accordingly, when the elderly need care, they want efficient outcomes and concrete results (Boehm & Staples, 2002). In terms of empowerment, the elderly tend to focus on their financial situation and ability to maintain it. They also focus on improvements in health care, social networks, living conditions, and relations with family and friends. In contrast, social workers often focus on the process of empowerment, rather than the results of the process, thus reinforcing a professional-client relationship. To be considered worthwhile and effective by consumers, the empowerment process should be cost-effective in terms of time and effort and show tangible results.

THE CASH AND COUNSELING DEMONSTRATION AND EVALUATION

One approach for capturing and describing some of the ways social workers can work to empower individuals and families is through case example. The Cash and Counseling Demonstration and Evaluation (CCDE) shows how older adults and persons with disabilities who needed Medicaid-funded home- and community-based services were given the opportunity to direct and manage those services and the positive results that ensued. We begin by describing this intervention and its positive effects and then backtrack to examine the elements and techniques that empowered individuals and families and the roles that social workers can play.

Today, in most states, whether you are an elderly individual or a younger person with disabilities, if you need Medicaid assistance to perform major activities of daily living such as bathing, dressing, toileting,

transferring (walking), or eating, you will rarely have much say over who helps you or when they come, never mind what they actually do. But, for years, persons with disabilities have been saying, "If I had more control over my services, my quality of life would improve and I could meet my needs for the same amount of money or less." The Cash and Counseling Demonstration is, at its heart, a policy-driven evaluation of this basic belief.

The CCDE, funded by the Robert Wood Johnson Foundation and the Office of the Assistant Secretary for Planning and Evaluation in the U.S. Department of Health and Human Services, is a test of one of the most unfettered forms of consumer-directed care: offering elders and younger persons with disabilities a cash allowance in place of agency-delivered services. Operating under a research and demonstration waiver granted by the Centers for Medicare and Medicaid Services, 6,700 volunteers from across Arkansas, Florida, and New Jersey participated in this large-scale test, half of whom were randomly assigned to manage individualized budgets while the other half remained with traditional agency providers.

Consumers who meet project eligibility criteria and express interest in participating in CCDE are randomly assigned to participate in the program, managing a cash allowance to purchase services, or serve as a control group and receive services through the state's existing system. The evaluation compares outcomes for consumers receiving traditional service packages with those receiving cash allowances with respect to cost, quality, and satisfaction. The evaluation also examines impacts on informal caregivers and analyzes the experiences of paid workers.

In the Arkansas Cash and Counseling Demonstration, the first to get under way and therefore the first from which results are available, consumers had the opportunity to receive a monthly allowance, which they could use to hire their choice of caregivers (except spouses) and buy other services or goods (such as assistive devices and home modifications) to meet their personal care needs. Allowances were equal to the value of the number of hours of care consumers were expected to receive under the traditional Medicaid program, averaging about \$350 per month. Consumers were required to develop written plans for managing the allowance and have them approved by counselors. In addition, virtually all consumers chose to have the program's fiscal agents write checks for their purchases and withhold payroll taxes for caregivers hired with the allowance. Consumers who were unable or unwilling to manage the allowance them-

selves could designate a representative, such as a family member, to do so for them.

The resulting analysis showed that when Arkansas Medicaid beneficiaries had the opportunity to direct their personal care services themselves, it significantly increased the proportion of consumers and (paid) caregivers who were very satisfied with their care, thinning the ranks of the dissatisfied in the process. Specifically, consumers were much more satisfied with the timing and reliability of their care, less likely to feel neglected or rudely treated by paid caregivers, and more satisfied with the way paid caregivers performed their tasks (Figure 75.1). The program also reduced some unmet needs for personal assistance services and substantially enhanced consumers' quality of life. Moreover, it produced these improvements without compromising consumer health or functioning (Foster, Brown, Phillips, Schore, & Carlson, 2003). There were no major incidents of fraud or abuse.

Both elderly and nonelderly adults had better experiences under Cash and Counseling than under agency-directed services, though impacts on most outcomes were larger for the nonelderly. In Arkansas, Cash and Counseling users of all ages were more likely than the agency-care group to receive paid care: 95%

of both elderly and working-age Cash and Counseling participants got paid care, compared with 79% of elderly and 68% of younger consumers who were supposed to get care from an agency. Even those who did receive agency care were provided only about two-thirds of the help they were eligible for, often because of agency staff shortages. In terms of Medicaid costs for their care, Cash and Counseling participants averaged about twice the cost of those assigned to agency care during the first year. However, by the second year, savings in nursing home and other long-term care costs offset nearly all of this extra cost (Dale, Brown, Phillips, Schore, & Carlson, 2003).

The effects on caregivers were equally dramatic. Caregivers for consumers managing the cash allowance experienced less financial, emotional, and physical strain. Furthermore, even though the workers hired by consumers frequently lacked formal training, they felt well-prepared for their jobs. Most were very satisfied with their pay and working conditions.

The results of the controlled experiment in Arkansas (and preliminary figures on the results in Florida and New Jersey) were so positive that the Robert Wood Johnson Foundation, the DHHS Office of the Assistant Secretary for Planning and Eval-

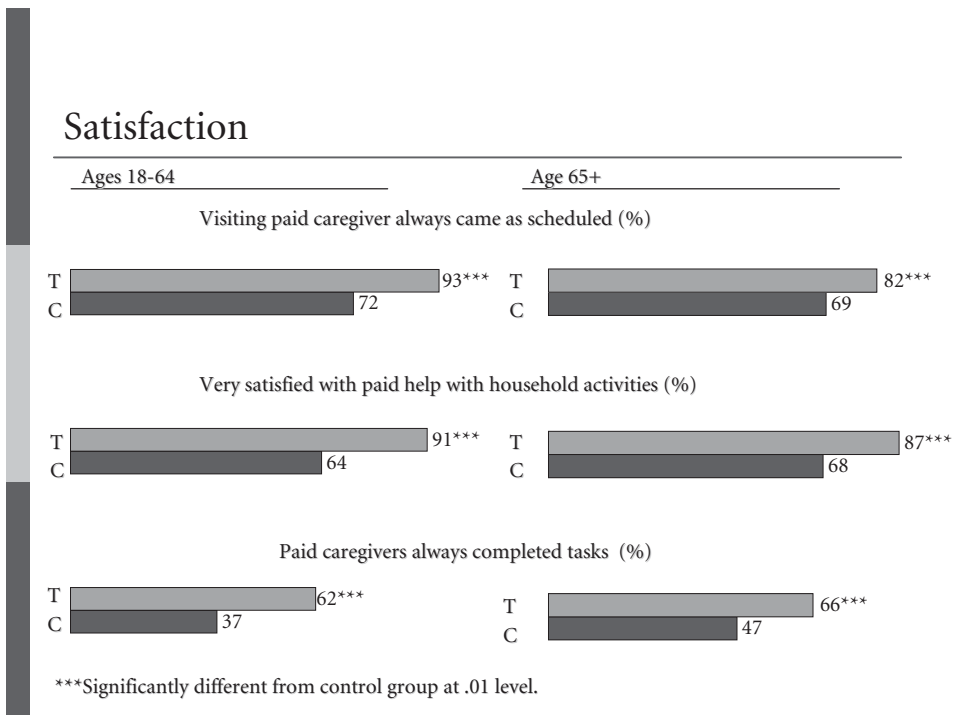

FIGURE 75.1.

uation, and the Administration on Aging have authorized funding to add 10 states to the demonstration in 2004.

HOW DOES CASH AND COUNSELING EMPOWER?

This case study gives us the opportunity to examine what the elements and activities are that empower or help to empower consumers. We can then draw lessons, on both the macro and the micro levels, suggesting ways social workers can work to enhance the power of older individuals, their families, and their communities.

We believe that the Cash and Counseling model itself empowered consumers. Some of the ways the model was operationalized formed empowerment tools in their own right, namely, providing information to facilitate informed decision making; designing the role of counselor/consultant to foster empowerment; building in opportunities for peer counseling and support; and introducing technological tools like Web-based programs for designing, approving, and revising cash plans and recording expenditures against those plans. We consider each in turn.

Consumers can be involved in directing their own home- and community-based services to varying degrees. Whereas our case example is drawn from the Medicaid world, parallel choices also exist in the private long-term care insurance arena. The levels of

consumer empowerment in home- and community-based care can be characterized as in Table 75.1.

Under the original Cash and Counseling Demonstration, consumers could chose option C (and let the fiscal intermediary handle the paperwork of book-keeping, check writing, tax paying, record keeping), or they could chose a modification of option D as long as they passed a skills test showing they understood their tax and labor law obligations and retained receipts showing they had spent the dollars to meet their personal care needs.

But remember: Cash and Counseling was a choice. The consumer could always choose to return to the traditional system. In this way, the design of the program was itself empowering. Consumers also played an active role in program design. Focus groups and surveys of representative samples of consumers provided valuable insights on who was interested in the Cash and Counseling choice and why, what features were attractive, what information consumers needed to make an informed choice, and what kind of supportive services they needed to manage their own cash allowances. Additional focus groups helped hone outreach messages and make sure program communications were understandable and efficient.

Cash and Counseling systematically involved consumers at three distinct levels: the state level, where the model was designed and monitored; the program operation level, where forms and training materials were pretested; and the individual level, where consumers were regularly asked for feedback on their sat-

TABLE 75.1. Levels of Consumer Empowerment in Home- and Community-Based Care

<i>A. Enlightened Care Management</i>	<i>B. Consumer as Employer</i>	<i>C. Flexible Consumer Budget</i>	<i>D. Cash</i>
Early forms of care management relied on a medical model where professionals made the key decisions as they were assumed to know what was best. But, under the best practice of care management, consumer preferences are elicited in the design of the care plan, and there is a regular feedback loop to ascertain consumer satisfaction.	At this level, we move from consumer involvement to consumer choice. Here the consumer is able to hire, manage, train, and even terminate his or her personal care worker.	At this level, the consumer has a choice over his or her whole service package. Instead of being limited to a personal care worker, the consumer has a budget that he or she can tailor to meet individual personal care needs. Consumers can purchase a variety of goods and services, including home modifications and assistive devices.	The ultimate form of consumer-directed care puts the dollars in the consumer’s hands and does not restrict usage.
<i>Less Empowerment</i>		<i>More Empowerment</i>	

isfaction with all aspects of the program. Accessibility guidelines were developed (with separate funding) to make sure consumers with disabilities were truly able to take part in planning activities.

The model itself was empowering, but so, too, were some of the discrete ways the program was run. To put this another way, elements of the program design independently shifted power to the people.

Information: Knowledge Is Power

What information does a consumer need and want to make an informed decision? How much information is too much? What formats works best for which consumers? What reading level should be assumed? These questions were regularly revisited as the Cash and Counseling options were developed. Focus groups were used to get initial impressions about the program and to pretest program communications. Various approaches to training were tested on a small scale before going public. All materials were available in frequently used languages and in varied formats appropriate for persons with disabilities. The questions of who, to whom, what, when, where, why, and how to share information are critical in the health care and social service decisions.

The Consultant: Institutionalizing the Role of Power Broker

The job title for the counselor/consultant/support broker could well be “empowerment agent.” Counselors interacted with consumers to (1) help consumers think expansively about their personal assistance needs and how best to meet them (this is often referred to as “person-centered planning”); (2) review initial and revised spending plans to ensure that they include only permissible goods and services; (3) assist consumers in linking up with necessary resources (e.g., how to find personal care workers or identify the best source of other goods and services); (4) help with employer functions; and (5) monitor the consumer’s condition and the uses of the allowance. The consultant’s role is described in ethnographic studies of Cash and Counseling participants in Arkansas and New Jersey (Cash and Counseling Library, available online at <http://www.cashandcounseling.org/library>). For the counselors’ own perceptions, one could also read *Consumer and Counselor Experiences in the Arkansas Independent Choices Program* (Mathematica Policy Research, 2004). Perhaps

the best hands-on guide to what counselors actually do can be found in the recently published “Guide to Quality in Consumer Directed Services” (Applebaum, Schneider, Kunkel, & Davis, 2004, pp. 35–44) in the pages devoted to consumer support strategies.

Peer Support

When the Cash and Counseling program held focus groups to secure consumer input, consumers stayed after every session and traded phone numbers and ideas on how to manage their personal assistance needs. Thus, the program’s designers learned one quick lesson: Adults like to learn from people who have real-life experiences similar to their own. Drawing on this insight, the Cash and Counseling Demonstration devoted resources to encouraging peer interaction and support.

The Increasing Importance of Technology

Technology can empower. The flexibility to use the cash allowance for a wide range of goods and services paid dividends: Non-elderly treatment group members might have received fewer hours of total care because they reduced their need for human assistance. Treatment group members were more likely to obtain equipment to help with personal activities and communications, such as specialized telephones, lifts, or emergency response systems. (Dale et al., 2003).

As Cash and Counseling expands to additional states, one of the most promising activities is the development of a Web-based tool to assist in the development, approval, and revision of cash plans and the recording of expenditures made against those plans so consumers can have an up-to-the-minute picture of how much of their cash allowance is still on hand. Focus groups showed that a sizable proportion of consumers or their representatives had access to computers and favored such a Web-based tool to expedite communication between themselves and their counselors and fiscal management agencies.

WHY DID CASH AND COUNSELING HAVE SUCH SIGNIFICANT EFFECTS?

There may be a couple of reasons why the Cash and Counseling model has such dramatic effects on both

consumers and their informal caregivers. The first centers on locus of control and the ability to affect one's environment. The second reason this model may have enjoyed such success is that the flexible budget often allowed and encouraged greater integration of the consumer into the family and the community. The flexible budget allows clients to hire family and friends (i.e., individuals with a personal caring relationship with the consumer) to be their personal care workers. It also releases the consumer from many of the restrictions typical of agency-delivered care. For example, agency workers, for liability reasons, are often not allowed to take consumers in their cars. With the flexible cash allowance, consumers could ask their worker to drive them to a grocery store so they could do their own shopping. Consumer-employed workers defined quality in terms of the relationship. Knowing that the consumer is in charge, and providing services according to his or her preferences, was a consistent theme.

Finally, the flexible cash allowance makes it possible for consumers to reciprocate and maintain some symmetry in their interpersonal relations. In line with exchange and equity theories, there is evidence to believe that individuals may be less depressed when relationships promote feelings of respect and value (Wolff & Agree, 2004).

EMPOWERING COMMUNITIES

We have seen how social workers, as program designers, can empower individuals and families, and we have seen how social work clinicians, taking on the role of counselor and consultant, can empower individuals and families. We also want to mention ways that social workers can empower communities. Again, we draw from home- and community-based services experiences. In a recent issue of *Community Living Briefs*, Lee Bezanson (2003, p. 5) describes "Beyond Incremental Change: The Challenge of Inclusion":

In the model community approach, states' resources are being committed to engaging local communities to become fully accessible and inclusive. Medicaid and the social service network of providers and advocates are at the table, but so too are citizens with disabilities, the Town Selectmen, the Superintendent of Schools, the religious institutions, the Rotary Club, Kiwanis. The dialogue is inclusive of everyone. And from these new dialogues new local initiatives emerge: ac-

cessible meetings with accessible materials, accessible voting places, city councils and task forces with members who have disabilities, public education on the need for universal design in new buildings, a Hoyer lift at the town pool . . . the list is endless.

DISCUSSION AND CONCLUSION

The Cash and Counseling Demonstration is but one example of how social workers and the elderly can work together in partnership to actualize empowerment-based practice. This program was designed to build on the assets and capabilities of elderly clients by allowing them to choose their care providers and services. Elderly clients worked with program consultants to put their monetary allowances to good use, often saving money and markedly increasing satisfaction with care in the process. In fact, so powerful were these effects that caregivers of the elderly also felt significant positive effects as a result of program participation. Giving the elderly the power of choice and the resources to make choices about their care reduces feelings and behaviors associated with disempowerment. Having consultants on hand and the future development of a technology-based allowance management system also assist in developing client capabilities. In essence, the Cash and Counseling Demonstration respects the independence and dignity of the elderly while delivering tangible results.

This case study has allowed us to see many of the principles and attributes of empowerment described in the first sections of this chapter, but it has also put meat on the bones—giving examples of discrete practices social workers can engage in at both the micro and macro levels to return power to older persons.

Some, fueled by ageism, contend that older persons are not interested in consumer-directed care. Clearly, this is not true. The Cash and Counseling model is not an option for everyone, but it is important to note that in Arkansas fully 72% of those who volunteered to participate were over age 65.

Finally, what about social workers? Some had feared that an emphasis on empowerment might undermine the professionalization of social work. In this case study, we see evidence that the most empowering assistance social workers can offer the elderly is to work with them where they are, both mentally and physically, and to start with the client's goals and preferences. Consumers are usually the experts when it

comes to their own lives and lifestyles. Our overarching goal as social workers is to help them maintain and improve their independence and dignity. In doing so, we revisit the very roots of social work. We work with the community, in their community, to help them help themselves, continuing a tradition that we hope Jane Addams would embrace today.

National Advocacy Groups for Older Adults

76

Advocacy is defined as the “pursuit of influencing outcomes—including public policy and resource allocation decisions within political, economic, and social systems and institutions—that directly affect people’s lives” (Advocacy Institute, 2004). It involves one party seeking to represent the interests of another, although it should be noted that those interests are not always congruent. The terms “advocacy” and “lobbying,” often used interchangeably, are not synonymous. Advocacy refers to a range of activities, such as mass media campaigns, community organizing, formal legal proceedings, and public policy research, undertaken in an attempt to raise awareness and change government policy. Lobbying is a specific type of advocacy activity that is focused on influencing legislation (e.g., a mass media campaign undertaken to defeat or support a proposed piece of legislation). Lobbying efforts, therefore, are directed at a legislative body (Duitch, n.d.).

As part of their everyday work, social workers deal with people’s immediate problems and concerns, often on a one-to-one basis. But individual problems are often related to larger social issues. Advocating to government agencies or lawmakers or appealing to the public for macrolevel change is essential to help communities of people and to address policy issues of importance to social workers. But change does not happen overnight. It is a long process involving research, discussions, compromise, and political maneuvering. At every stage, outside voices are making recommendations and applying pressure for particular changes (Duitch, n.d.).

This chapter focuses on national advocacy groups for older adults. Although individual advocacy in social work is important and necessary, organizational advocacy also is essential and has the advantage of potentially bringing greater and more sustained resources to advocacy efforts (McConnell, 2004). Organizational advocacy can be most powerful when combined with individual stories, thereby giving a personal face to the issues.

ORGANIZATIONAL ADVOCACY

Organizational advocacy can take a variety of forms. Steve McConnell (2004), senior vice president for policy and advocacy for the Alzheimer’s Association, delineates five distinct types. Legislative advocacy, one of the most familiar types, involves attempts by an organization to influence legislation to the benefit of a group of individuals or a cause. There is also admin-

istrative advocacy, in which the target of influence is government agencies. Government agencies should not be underestimated in terms of advocacy, for they largely determine how a law is carried out. Program advocacy, yet another type, is directed at improving services for a specific population by changing organizational practice. These efforts are typically focused either on service organizations or the trade organizations representing their interests. Issue advocacy, which frequently precedes legislative advocacy or lobbying, is designed to influence public opinion on a particular issue. A fifth type of organization advocacy, legal advocacy, relies on the courts to bring about social or policy change.

EARLY ADVOCACY EFFORTS

Early national efforts to advocate on behalf of older persons were largely undertaken by a small cadre of “policy elites located inside government itself” (Hudson, 2004, p. 18). The earliest advocacy efforts are thought to have occurred in the 1920s around pension issues (National Association of State Units on Aging [NASUA], 1985). The National Association of Retired Federal Employees, created in 1921, was one of the first advocacy organizations to appear on the national scene and sought to improve federal retirement benefits. In 1935, the Social Security Act was passed, the first piece of legislation to specifically address the needs of older persons. In 1950, the Federal Security Agency sponsored the first National Conference on Aging in Washington, DC. Shortly thereafter, advocate Ethel Percy Andrus founded the American Association of Retired Persons and the National Retired Teachers Association (AARP-NRTA) to assert the interests of retired teachers.

It was not until the 1960s that advocacy became more formalized. In 1961, the first White House Conference on Aging convened in Washington, DC, giving much-needed visibility to aging issues. Advocacy during these early years was largely rooted in activist movements: civil rights, women’s rights, and disability rights (Stone, 2004). New organizations emerged in response to major enacted legislation: Medicare and the Older Americans Act. The Older Americans Act not only established new programs and services for older adults, but also created a national administrative network on aging, the Administration on Aging and the State Units and Area Agencies on Aging (National Association of State Units on Aging [NASUA], 1985). The incremental construction of an

old-age welfare state through Social Security, Medicare, the Older Americans Act, and other measures created a latent constituency of older voters as well as a number of old-age interest groups (Binstock, 2004). “By the late 1970s,” Hudson (2004, p. 19) observes, “an imposing, bureaucratic, mass-based advocacy and policy network was in place for the aged.”

NATIONAL-LEVEL ADVOCACY

Nonprofit Organizations

Today, organizations advocating at the national level for the well-being of older persons are numerous and diverse (see Figure 76.1). They play a central role in articulating the special needs of older Americans on many important issues. Most of these groups are represented in the membership of the Leadership Council of Aging Organizations (LCAO), a coalition of national aging organizations established in 1978. The coalition was founded, in part, to defend existing benefit levels in old-age programs. At the time, President Nixon was trying to shift responsibility for the needs of older persons from the public to the private sector. Attempts were being made to abolish the Senate Special Committee on Aging. And significant cuts in human services and Social Security were being proposed in federal budgets.

The growth of the LCAO, both in terms of number of members (14 member organizations in 1978, 52 in 2004) and types of organizations represented, closely parallels the evolution of programs and services for older persons in this country over the second half of the 20th century. In 1980, LCAO had 23 member organizations; their key issues at the time included Social Security financing, universal national health insurance, senior housing, long-term care, and ageism. Over the next 20 years, LCAO more than doubled in size, encompassing many organizations representing broadly defined health-related interests (e.g., Catholic Health Association of the United States, American Public Health Association).

During this time, many organizations were creating special units or sections to address issues related to older persons. A fundamental shift in LCAO occurred when organizations that did not have the interests of older persons as their primary focus wanted to be included under the LCAO advocacy umbrella. For example, the National Association of Social Workers (NASW), the profession’s largest membership organization, reports that fewer than 5% of its

FIGURE 76.1. Leadership Council of Aging Organizations (2004), types of constituencies served.

members identify aging as their primary practice area (Barth, 2003). However, growing awareness of the aging of their client population has led NASW to become more involved and active in aging issues, as evidenced by their joining the LCAO in 2004.

Today, LCAO includes professional organizations representing a wide range of interests and constituencies in the field of aging, including retired union members (e.g., National Council of Senior Citizens,

United Auto Workers Retired Workers Department); the aging network (e.g., National Association of Area Agencies on Aging, National Association of State Units on Aging); aging service programs (e.g., National Association of Nutrition and Aging Service Programs); providers of aging services (e.g., American Association of Homes and Services for the Aging, National Academy of Elder Law Attorneys); special segments of the older population (e.g., National Cen-

ter and Caucus on Black Aged, Asociacion Nacional Pro Personas Mayores, Older Women's League, Alzheimer's Association); professionals working in the field (e.g., NASW, National Association of Professional Geriatric Care Managers); and gerontological researchers and educators (e.g., Gerontological Society of America, American Geriatrics Society).

LCAO also includes mass membership organizations of older persons that have been particularly effective in gaining the attention of policymakers and decision makers (e.g., AARP, National Committee to Preserve Social Security and Medicare). The unique political power that these groups hold over policymakers and members of Congress stems from the perception that they can influence the voting behavior of their members (Binstock, 2004). With more than 35 million members, AARP is considered the most influential old-age interest group. AARP's annual expenditures on lobbying and public policy research easily exceed those of all other old-age interest groups combined. As Robert Binstock remarks, "It is probably not too much to say that if AARP took an advocacy position that all the other members of the LCAO coalition opposed, members of Congress and their staffs would be much more influenced by AARP's stance" (p. 51). Indeed, in 2003, AARP's expenditures on lobbying and lobbying-related activities—most of which was devoted to efforts to persuade Congress to pass a Medicare prescription drug benefit—exceeded those of all interest groups in Washington, including General Electric, Microsoft, Boeing, and General Motors (Gettlin & Vaida, 2004).

As LCAO, like the older population, has grown in size and diversity of interests represented, it has faced the challenge of speaking with a unified voice. The increasing number of LCAO member organizations with narrowly focused interests limits the coalition's ability to take positions on more broadly defined issues, particularly those relating to income security and health care issues. There is also the growing problem of competing interests among organizations representing providers, professionals, and older persons, especially as resources dwindle.

Federal Agencies

In addition to the network of private nonprofit organizations who advocate on behalf of older persons, there also is an important advocate for older persons in the federal structure. The Older Americans Act (OAA) of 1965 established the Administration on Aging (AoA), the federal focal point and advocate agency for older

persons and their concerns (see Figure 76.2). In this role, it is AoA's responsibility to heighten awareness among other federal agencies, organizations, groups, and the public about the valuable contributions that older Americans make to the nation and alert them to the needs of vulnerable older people. In addition, the OAA created a national network of state units and area agencies on aging with broad responsibilities to serve as advocates on behalf of older persons and to plan for the effective development of state- and areawide service systems to best address their needs (NASUA, 1985).

CHALLENGES FOR FUTURE ADVOCACY

Advocacy efforts for older persons may face less popular support as the aging segment of the population changes. Today's older persons are no longer viewed as universally poor, frail, and socially dependent. Furthermore, knowing who is elderly is more difficult because programs for older persons created over the past century use eligibility ages ranging from 50 to 70 years. In addition, the elderly do not identify as a political group except on Social Security issues (Campbell, 2003). The emerging generation of older Americans is more diverse, is better educated, has a greater interest in personal choice and control, and is more skeptical of government than previous generations of older Americans (Rother, 2004). Future advocacy strategies will need to reflect these complexities and be open to a variety of options instead of focusing on a single solution (Rother, 2004).

Leadership is another challenge facing aging advocates. In the past decade, there has been a notable shortage of high-profile champions for aging issues. Advocates lack leaders inside government, people like statesman Arthur Flemming, who helped create the AoA and the White House Conference on Aging; Congressman and Senator Claude Pepper, who pushed health and long-term care policies for older persons and opposed mandatory retirement; and Senator John Heinz, who was an influential and effective leader in the Senate on aging issues. Leadership is lacking not only at the individual level but also at the aggregate level. There are no longer powerful advocates in Congress. The House Select Committee on Aging was abolished in 1993, and the Senate Special Committee on Aging has seen its sphere of influence diminished in recent years.

The future success of national advocacy groups, therefore, will depend on their collective ability to (1) clearly articulate the needs of America's aging

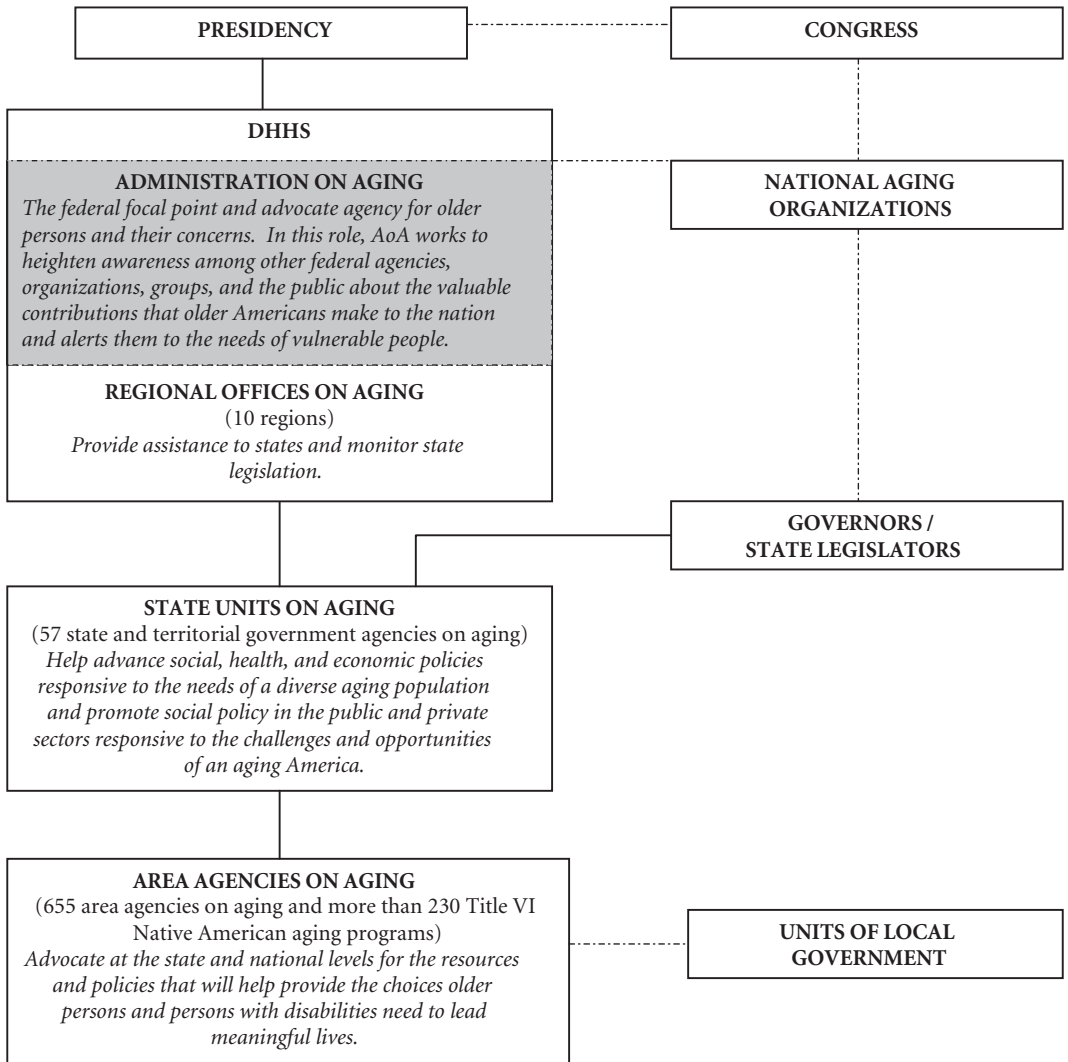

FIGURE 76.2. The National Aging Service Network.

population, (2) determine where shared interests lie on specific issues, (3) reach consensus on the most pressing issues, (4) identify a leader to champion their issues, and (5) sustain open channels of communication between the public and national leaders (NASUA, 1985).

Successfully meeting these challenges is critical to the future of aging programs. Although advocates can no longer expect to wield the influence of earlier days, their efforts are more important, and more difficult, than ever. The victories of earlier efforts resulted in programs on aging so large and successful that they have become a major focal point of national policy debates. Ironically, their very success makes them extremely vul-

nerable, as deficits continue to grow and Congress looks for ways to cut federal spending. Much is at stake. Developing new advocacy strategies and partnerships is essential if advocates are going to protect the programs so essential to the well-being of older people.

NAMKEE CHOI,
SECTION EDITOR

**Local, State, and Federal Policies/
Regulations Affecting Older Adults**

This page intentionally left blank

OVERVIEW

This part of the Handbook discusses federal, state, and local policies and regulations that most directly affect older adults and their families. Effective social work practice with diverse groups of older adults and their families requires not only extensive knowledge of policies and regulations at multiple system levels but also expert skills for evaluating their impact and policy advocacy. This part is intended to provide students and practitioners with a critical overview of various policies, regulations, and attendant programs, with the hope that it will serve as a foundation for advanced policy analysis and advocacy skills.

Specifically, the part focuses on the following 10 key areas: (a) federal income maintenance policies and programs; (b) policies related to private retirement benefits; (c) health and mental health care policies—Medicare; (d) health and mental health care policies—Medicaid; (e) policies affecting long-term care in institutions and other long-term care issues; (f) policies affecting social services, housing, and transportation; (g) policies related to competency and proxy issues; (h) end-of life policies; (i) policies affecting families of dependent older persons; and (j) policies to protect the rights of older adults. Each chapter provides a brief history of policy development; a critical evaluation of current status, gaps, and effectiveness; and future directions and recommendations. Implications for social work practice and policy advocacy are also discussed in the concluding section of each chapter.

In chapter 77, Choi discusses three important federal income maintenance programs for older persons: the Old-Age, Survivors, and Disability Insurance (OASDI) Program, or Social Security; the Supplemental Security Income (SSI) Program; and the Senior Community Service Employment Program (SCSEP). For each program, beneficiaries/participants, eligibility criteria, financing mechanisms and issues, and reform proposals or need for improvement are described and critically evaluated, with special attention to the program's effect on and implications for people of color, women, and/or low-income older persons.

Hudson begins chapter 78 with an overview of the development of private pensions and regulations governing private pensions in the United States. He then proceeds to discuss the types, roles, and functions of private pensions in the overall retirement income picture, recent trends in pension coverage, and the ade-

quacy of private pensions in helping to meet the retirement needs of vulnerable populations.

In chapter 79, Lee describes Medicare program components, coverage, and eligibility. Recent changes, expansions, and additions to Medicare (such as Part D, outpatient prescription drug program) are described, and comparative advantages and disadvantages of the original Medicare provisions and those of changes are briefly illustrated. The chapter also covers issues related to projected Medicare financing difficulties, Medicare long-term care coverage and funding, and lack of mental health parity.

In chapter 80, Galambos provides a brief description of the historical context for the establishment of Medicaid and illustrates the program's basic standards and guidelines with respect to federal regulations, state responsibilities, and the impact of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996. The author then examines programs and services available under Medicaid for older adults. In particular, dual eligibility, managed care, the freedom of choice and home- and community-based waiver programs, and Medicaid long-term care financing issues are discussed.

Given the looming issue of long-term care for the graying population, the content of chapter 81 is a timely topic. In this chapter, Chen examines the development of federal and state policies affecting institutional long-term care, especially nursing home care. She also discusses how the political, social, and economic changes have brought forth diversification in long-term care service settings where new issues of regulations, quality of care, service delivery, and financing have emerged. Future directions for this complicated and costly service are also discussed.

Chapter 82, written by Keigher, deals with a wide range of policies and programs that are designed to meet social services, housing, and transportation needs of community-dwelling older adults. Keigher provides a good overview of the provisions and/or mandates of the Older Americans Act, the *Olmstead* decision, and the Social Services Block Grant (Title XX of the Social Security Act). With respect to housing policies and programs, the author not only discusses different types of rental subsidy programs but also provides a description of other housing assistance programs, including property tax relief, home modification and home mortgage conversion programs, and home-energy assistance programs. The chapter concludes with the discussion and critical evaluation of the problems of transportation for an aging society

and the discussion of special needs transportation programs.

Issues of older persons' competency and proxy determination are intertwined with many ethical, legal, economic, and civil rights issues. In chapter 83, Wilber and Alkema discuss the complicated but fragmented legal policies governing protective services and supportive and surrogate decision-making interventions for vulnerable older adults. Using a case example, the authors illustrate the ethics and realities of guardianship and guardianship alternatives, legal procedures, and the role of social workers in surrogate decision making.

In chapter 84, Raveis provides a detailed review of issues and policies related to end-of-life care. Discussion of the Medicare, out-of-pocket, and other costs of care at the end of life is followed by discussion of trends in hospice use and the gaps and limitations in end-of-life care with respect to coverage, service delivery, and geographic and socioeconomic disparities in care. Cultural factors impacting elders' care decisions are discussed. Ethical and legal issues related to end-of-life care for the elderly are also addressed, in-

cluding advanced directives and assisted suicide. The chapter concludes with policy recommendations to improve end-of-life care.

In chapter 85, Li and Rafferty focus on two federal programs that are intended to support families of dependent older persons: the Family and Medical Leave Act (FMLA) and the National Family Caregiver Support Program (NFCSP). The authors present the history, provision, and implementation of each program and then discuss the deficits and inadequacies of each program in addressing the financial, respite care, and other needs of family caregivers.

In chapter 86, Davitt discusses legislation and policies in place to protect the rights of older adults. Specifically, the author focuses on those that prohibit discrimination due to age in employment, those that promote the civil rights of older adults by making discrimination based on disability illegal, grandparents' rights, the patient's bill of rights, and legislation to protect older adults from abuse, neglect, and exploitation. Along with the description of the intent and provisions of relevant laws, their loopholes and implementation and enforcement issues are also discussed.

NAMKEE CHOI

Federal Income Maintenance Policies and Programs

This chapter provides a brief description and discussion of three important income maintenance programs for older persons: Old-Age, Survivors, and Disability Insurance (OASDI), or Social Security; Supplemental Security Income (SSI); and the Senior Community Service Employment Program (SCSEP). For each program, beneficiaries/participants, eligibility criteria, financing mechanisms and issues, and reform proposals or need for improvement are discussed. Special attention is paid to the program's effect on and implications for people of color, women, and/or low-income older persons.

It is often said that economic security in old age is supposed to rest on a three-legged stool: savings, a public or private pension, and Social Security (Villa, Wallace, & Markides, 1997). For a large proportion of older persons, combined incomes from these three sources indeed constitute their retirement economic security. However, for many low-income older persons who have accumulated few assets and earned no or only a small amount of pension benefits, Social Security is their most important source of income, and it needs to be supplemented by SSI and/or earnings. For low-income or disabled older persons who have not accumulated enough earnings history to receive Social Security benefits, SSI may be the only source of income. Older persons who are dislocated workers and/or have a low level of education, skills, training, and work experience are likely to face difficulty finding a job or continuing to work in the rapidly changing labor market. Older job seekers may participate in a few federal employment assistance programs that serve all age groups; however, SCSEP is the only federal program specifically designed to provide employment training and education for low-income older persons.

The OASDI program, Title II of the Social Security Act, is an employment-, earnings-, and payroll-tax-contribution-based social insurance program that provides a partial replacement of lost earnings for retired and disabled workers and their dependents and survivors. SSI, Title XVI of the Social Security Act, is a public assistance safety-net program for low-income older and/or disabled persons whose eligibility is determined by strict income and resource tests and, in the case of those under age 65, by a disability determination process. The SSI program, which began disbursing benefits in January 1974, originates in the Old Age Assistance (OAA; Title I of the Social Security Act), Aid to the Blind (AB; Title X of the Social Security Act), and Aid to the (Totally and Permanently) Disabled (AD; Title XIV of the Social Security

Act) programs. Unlike its predecessors, which were state programs, SSI is the first and only federal public assistance program that applies uniform standards of eligibility and benefit calculation throughout the country. Both OASDI and SSI are administered by the Social Security Administration (SSA).

As an employment assistance program for low-income older persons, SCSEP is authorized by Title V of the Older Americans Act and funded and administered by the U.S. Department of Labor. It is the only such program that focuses on older persons; nevertheless, the level of funding is low and the number of program participants relatively small. Older job seekers also participate in programs funded by the Workforce Investment Act, which replaced the Job Training Partnership Act in 2000, and the Trade Adjustment Assistance Reform Act of 2002, which provides employment and training assistance for individuals who have lost their jobs due to the adverse effects of international trade. However, in most states these workforce development programs do not have a special allotment of positions or funds for older persons, and, as a result, the number of older job seekers enrolled in them is even smaller than that enrolled in SCSEP. Thus, only SCSEP is described in this chapter.

SOCIAL SECURITY

Who Receives Benefits?

Since the disbursement of its first retired worker benefits in January 1940, the Old Age and Survivors Insurance Program (OASI) has become the most important income maintenance program for older persons and their dependents in the United States. The Social Security program is almost universal, covering more than 95% of the working population, or 156 million workers, and paying out benefits to 47.4 million people in 2004 (Social Security Administration [SSA], 2004a). For a majority of people, old age is marked by retirement from their job(s) and receipt of Social Security benefits, which replace part of their lost earnings.

In addition to serving as a partial replacement of lost earnings for retired workers, Social Security benefits are also paid to spouses of retired workers, divorced and/or surviving spouses, dependent children and parents, and surviving dependent children and parents. Since the Disability Insurance (DI) program was added to the OASI in 1954, benefits have also become available to disabled workers under age 65 and

to their spouses and children. Of the 47.4 million Social Security beneficiaries in 2004, 63% were retired workers, 12% were disabled workers, 6% were spouses of retired or disabled workers, 11% were surviving spouses, and 8% were dependent or surviving children. In May 2004, the average monthly benefit for retired workers was \$922, and those benefits for older couples and older widow(ers) or parents alone were \$1,523 and \$740, respectively (SSA, 2004a).

Since 1975, Social Security benefits have been automatically adjusted yearly to reflect the increase in the Consumer Price Index (CPI). These cost-of-living adjustments (COLAs) have been essential for protecting the real purchasing power of the Social Security benefits. Although those who worked in low-paid jobs receive a smaller Social Security benefit in absolute dollars than those who worked in high-paid jobs, the earnings-replacement rates are higher for the low earners (about 50%) than for the high earners (about 30%) because of Social Security's progressive benefit computation formula and the program's provisions for disabled workers, spouses, children, and survivors (Gist, 1998; U.S. General Accounting Office [U.S. GAO], 2004).

Eligibility Criteria

To be eligible for Social Security retired worker benefits, most people need 40 work credits (4 credits per year, with \$900 in earnings constituting one credit in 2004). The full retirement age at which covered workers can receive full Social Security benefits (or primary insurance amount [PIA]) is 65 years for those born in 1937 or earlier, but it will be 66 years for those born between 1943 and 1954, and 67 years for those born in 1960 and later. For those born between 1938 and 1942 and those born between 1955 and 1959, the full retirement age will increase by 2 months for every successive birth year. For example, for those who were born in 1938, it will be 65 years and 2 months; for those who were born in 1939, it will be 65 years and 4 months. People can retire at any time between age 62 and the full retirement age, but the benefits of those who opt for early retirement are reduced by 5/9 of 1% per month for the first 36 months and 5/12 of 1% per month subsequently. People can also delay retirement beyond the full retirement age and receive delayed retirement credits added to their Social Security benefits. The delayed retirement credit for those born in 1943 and later will be 8% yearly.

Social Security retired beneficiaries are allowed to work, but the earnings of those between ages 62 and 64 are subjected to the Social Security earnings test. In 2004, for example, for every \$2 earned over the limit of \$11,640 annually (\$970 a month), \$1 in SSA benefits is withheld. (Disability Insurance beneficiaries can earn up to \$810 [for nonblind] or \$1,350 [for blind] per month in 2004 without having their benefits reduced. These earnings ceilings are adjusted yearly.) Attempting to remove perceived work disincentives of the earnings test among Social Security beneficiaries, the Senior Citizens Freedom to Work Act of 2000 eliminated the earnings test for beneficiaries aged 65 and older. However, a study showed no clear early evidence of increased employment among this age-group, although it found that higher earners had increased their earnings further (Song, 2003/2004).

An older spouse of a retired worker is eligible for 50% of the retired worker's benefits. Spouses who have their own earnings history and retired worker benefits can receive the higher benefit of the two—the spouse benefit or the retired worker benefit—but not both. A divorced spouse is treated the same as the current spouse if the marriage lasted 10 years or longer. Survivors benefits are paid to surviving spouses and dependent children and to dependent parents of covered workers or beneficiaries. A surviving spouse is entitled to full benefits at age 65 (if born before January 2, 1940) or to reduced benefits as early as age 60 (age 50 if disabled or earlier if taking care of a surviving dependent child). Divorced surviving spouses are treated the same as married surviving spouses if the marriage lasted 10 years or longer. Thus, Social Security survivors' benefits function as long-term life insurance.

Social Security and Low-Income Persons and Persons of Color

The poverty rates among older persons in general have been declining steadily since the mid-1970s, owing primarily to Social Security benefits. In 2000, Social Security, on average, accounted for 38.4% of income for those aged 65 and older, as compared with 17.9% of income from pensions, 17.5% from assets, and 23.1% from earnings (McDonnell, 2003; SSA, n.d.). Especially for a large proportion of older women and persons of color, Social Security benefits constitute the most significant source of retirement income, because these individuals are significantly less likely than older white men to receive income

from pensions and assets. Without Social Security benefits, the poverty rate among older women and persons of color would be more than 50% (Beedon & Wu, 2003; Rix & Beedon, 2003). In 2000, 34% of African American older married couples and 45% of Hispanic older married couples, compared with 25% of their white counterparts, received at least 80% of their income from Social Security. Among unmarried older women, 61% of African Americans and 62% of Hispanics, compared with 48% of whites, received at least 80% of their income from Social Security. Comparable figures for unmarried older men are 50% of African Americans and 62% of Hispanics, compared with 38% of whites. For 75% of all married and unmarried elderly units in the bottom quintile of income distribution, Social Security was the essential source of income, providing at least 90% (SSA, n.d.).

Despite the significance of Social Security as retirement income for women and persons of color, many low-income female workers and workers of color face some serious challenges in achieving equitable Social Security coverage. One such challenge is related to the fact that Social Security benefits are determined not only by the number of work credits but also by the amount of earnings actually reported by employers. This is particularly notable when considering the situation of domestic service workers, a career in which a disproportionate share of workers are women, especially women of color. These workers may not get full credits for all their wages because an employer is not required to report a household worker's wages less than a certain amount (\$1,400 in 2004). Thus, if a domestic service worker were employed by three employers and paid less than \$1,400 by each, there is a strong possibility that none of her (or his) wages would be reported. As a result, her (or his) Social Security benefits would be lower than they should be. Social Security wage-reporting rules need to be reconsidered to rectify this inequity for low-income household workers (Flippen & Tienda, 2002; Kijakazi, 2002).

Financing of Social Security

Social Security works as an intergenerational transfer program based on a pay-as-you-go system, under which payroll tax revenues from current workers (6.2% each from employees and employers or 12.4% from the self-employed up to a maximum taxable ceiling of \$87,900 in 2004) are used to pay the benefits of current beneficiaries. In addition, proceeds

from taxing part of the Social Security benefits of middle- and high-income recipients are added to the OASDI trust funds, but they constitute only a very small portion of the annual income of the trust funds.

The fiscal health of the pay-as-you-go system depends on a high worker-to-beneficiary ratio. In 1960, the ratio was 5 to 1, and in 2004, it was about 3 to 1. Because a majority of the baby boomers are currently in their prime working years, we have more payroll tax revenues than benefit outlays; as a result, the OASDI trust funds have been accumulating a surplus that is projected to reach \$1.1 trillion between now and 2018 (Concord Coalition, 2003). (In reality, the surplus payroll tax revenues are not deposited in the trust funds, however, because the trust funds are simply bookkeeping devices, with the special-issue U.S. Treasury bonds they contain representing promissory notes from the Treasury Department to the Social Security Administration.)

As the boomers begin receiving Social Security checks in 2010 (or earlier for those opting for early retirement), the worker-to-beneficiary ratios will decline further (to 2 to 1 in 2035), and the benefit outlays will exceed the payroll tax revenues beginning in 2019. According to the OASDI Trustees Report of 2004, despite the yearly income-to-outlay deficits that are expected to begin in 2019, the redemption of the accumulated assets of the trust funds will be sufficient to pay the full cost of benefit outlays until 2041. However, after 2041 this cumulative amount will become negative, indicating a net unfunded obligation. Through the end of 2078, the combined funds have a present-value unfunded obligation of \$3.7 trillion (Board of Trustees of the Federal OASDI Trust Funds, 2004). Another gauge of the increased burden of Social Security outlays is their share of the gross domestic product (GDP); in 2003, Social Security expenditures were about 4.4% of GDP, but in 2030, they are expected to be 6% of GDP, while the federal revenues dedicated to Social Security will remain at 5% of GDP (U.S. Congressional Budget Office [U.S. CBO], 2004).

Reform Proposals

Special presidential commissions under the Clinton and George W. Bush administrations, as well as many think-tank groups, have proposed reforms to improve Social Security's long-term fiscal health. Of these reform proposals, those that have suggested partial privatization of Social Security, which would allow

voluntary individual carve-out accounts, have received the most attention because of their potentially radical departure from the social insurance ideal of Social Security. Proponents of individual carve-out accounts have touted the possibly higher return rates individuals could realize by investing part of the money now going into payroll taxes in private securities markets; however, Wall Street's slump and the increasing budget deficit in recent years have dampened the public's support for this plan. Other serious issues could arise if voluntary individual carve-out accounts were allowed (Orszag & Greenstein, 2001; Shelton & Beedon, 2002):

- High earners are more likely to select the carve-out option, leading to reduced revenue for the Social Security Trust Funds and reducing the redistributive effect of the Social Security system;
- Complicated administrative issues (e.g., transition cost at the macro level and property issues at the micro level in situations such as a couple's divorce, survivors benefits, etc.);
- High administrative or transaction costs for individual account holders; and
- Risk of misinformation and inability of less-educated individuals to manage their own investment strategies.

In addition to the partial privatization ideas, the following Social Security reform options have been proposed. First, it would be possible to increase the payroll tax revenue through the following measures:

- Increase payroll tax rates to draw additional resources;
- Eliminate the maximum taxable ceiling so that entire earnings can be subjected to Social Security payroll taxes;
- Tax all, rather than part of, the benefits for middle- and high-income recipients.

The potential problems of these measures are as follows:

- Given the flat rate, and therefore the regressive nature, of the payroll tax system, low-income workers may be disproportionately negatively affected by increased payroll tax rates;
- Elimination of the maximum taxable ceiling and taxation of all Social Security benefits for middle- and high-income recipients, though long overdue, will not generate enough revenue to significantly shore up Social Security's long-term deficit.

A second option would be to decrease the benefit outlay by doing the following:

- Cut the benefits for future beneficiaries;
- Reduce incentives for early retirement;
- Increase the Social Security early and/or full retirement age.

These options have a number of drawbacks:

- Negative impact on low-income older persons for whom Social Security is the most significant or sole source of their retirement income;
- Negative impact on blue-collar workers and workers in physically demanding jobs who are unable to find continuing employment or extend their working careers;
- Negative impact on low-income persons of color who are unable to extend their working careers, with the resulting possibility that SSDI and the SSI costs will increase (Choi, 2004; Munnell, Meme, Jivan, & Cahill, 2004);
- Negative impact on low lifetime earners in general and persons of color in particular, given the strong relationship between lifetime incomes and life expectancy, and resulting problems of inequity for low earners who tend to have shorter life expectancies and, thus, shorter benefit-receipt periods than their well-off counterparts (see Duggan, Gillingham, & Greenlees, 1995; Gist, 1998).

A third option would be to subsidize the OASDI program with general revenues, increase federal borrowing, make Social Security coverage of state and local employees mandatory, and restructure family benefits:

- Decrease consumption of resources by other federal programs to make up the shortfall in Social Security and divert the resources to shore up Social Security;
- Increase federal borrowing to fund deficits in benefit outlays;
- Extend coverage to the approximately 30% of state and local employees (4 million workers) who are not covered under Social Security to pull resources (i.e., payroll tax revenues) from this relatively stable group of workers (Munnell, 2000);
- Restructure the current benefit formula for spouses, as well as benefits for other dependents and survivors to increase the program's efficiency and social adequacy (higher earnings replacement

rates for lower earners as an antipoverty measure) for low-income people (refer to Favreault, Sammartino, & Steuerle, 2002).

The problems with these measures are as follows:

- Given the projected fiscal problems of Medicare and Medicaid, which are even more serious than the ones just discussed, decreases in spending for these public programs are not likely;
- Increased federal borrowing will certainly burden the future generations that will have to repay the debt with interest;
- Inclusion of uncovered employees of state and local governments may incur short-term costs;
- The economic impact of restructuring family benefits will be small and will not solve the long-term fiscal crisis of Social Security.

A fourth possibility would be to combine the aforementioned options. Considering the strengths and weaknesses of the reform proposals described here, a combination of these options appears to be an ideal approach that will be able to close Social Security's long-term deficit and preserve the program's many strengths as the nation's most significant retirement income source, especially for low-income people (see Diamond & Orszag, 2004). Social Security has been one of the most efficient federal entitlement programs, if not the most, for more than 60 years, providing financial security to millions of older persons, their dependents, and their survivors. The long-term fiscal health of Social Security must be saved with careful deliberation of the micro- and macroeconomic impacts of all possible options.

SUPPLEMENTAL SECURITY INCOME

Who Receives Benefits?

Since SSI became the nation's first and only federal public assistance program in 1974, the number of its recipients has grown many times over. According to the SSA's annual report for 2004 (SSA, 2004b), an average of 6.6 million individuals received federally administered SSI benefits on a monthly basis in 2003. Of these, 1.8 million people were aged 65 years or older (1.1 million in the low-income aged category and 0.7 million in the disabled category), and 4.8 million were disabled or blind individuals under age 65. In 2004, the maximum federal benefit was \$564 and \$846 per

month for individual and couple recipients, respectively. Like Social Security benefits, SSI benefits are automatically adjusted yearly to reflect the increase in the CPI. A majority of states also provide state supplementation to the federal SSI benefits. In January 2004, the average federal SSI payment averaged \$393 for 6.9 million recipients, and 2.5 million of these also received monthly state supplementation averaging \$138.

Of the recipients who were aged 65 or older in 2003, 45.4% received both federal SSI benefits and state supplementation, 57.4% were dual beneficiaries of both SSI and Social Security, and 2.5% received both SSI and Veterans Affairs disability cash benefits (SSA, 2004b). About 85% of older recipients were aged 70 or older, and 71% and 29% were women and men, respectively, reflecting the lower income status of those aged 70 or older and of women. A majority of these older recipients were unmarried (SSA, 2003, 2004b).

Eligibility Criteria

Supplemental Security Income is a means-tested public assistance program for low-income persons aged 65 or older, persons who are blind, and persons with other disabilities, and provides assistance of last resort. A person's or a couple's resources and income are used to determine eligibility and the amount of SSI benefits available. Resources, such as the applicant's home and a car (valued \$4,500 or less), household goods and personal effects with equity not exceeding \$2,000, life insurance with total face value of \$1,500 or less, and burial funds not exceeding \$1,500 per person, are exempt from the eligibility determination process. With respect to income, earned and unearned (or general) income exclusions/disregards apply when determining an individual's benefit. Earned income exclusions include the first \$65 earned per month plus one half of the remainder plus impairment-related work expenses for the disabled or the blind and infrequently or irregularly received income of \$30 or less per quarter. Also allowed is an income set-aside under special programs (e.g., the Plan for Achieving Self-Support program, or PASS) that are aimed at promoting self-support among SSI beneficiaries. Unearned income exclusions include the first \$20 per month (e.g., Social Security benefits, pensions, and interest and dividends), food stamps, rent subsidies under the U.S. Department of Housing and Urban Development (HUD), other state or local as-

sistance based on need, and \$60 or less per quarter of infrequently or irregularly received income.

When a married individual who lives with an ineligible spouse applies for SSI, part of the spouse's income and resources are considered in determining the applicant's benefits. If an individual lives in someone else's household and receives support and maintenance from the householder, his or her SSI benefits are reduced by one third. When an individual is a resident of a medical facility (e.g., skilled nursing facilities) in which Medicaid pays half of the bill, the federal SSI payment is reduced to a \$30 personal allowance. Eligibility for SSI is also limited to U.S. citizens, noncitizens who were receiving SSI benefits on August 22, 1996, and others in certain categories of qualified noncitizens, including certain blind and other disabled persons who were lawfully residing in the United States on August 22, 1996, refugees, asylees, Cubans and Haitians with refugee-like status, and those with 40 qualified quarters of earnings and their spouses. Refugees and asylees may receive SSI benefits for only 7 years, but a proposal to extend the period has been considered in the Congress since 2004.

Underutilization of SSI Among Older Persons

Although the number of SSI recipients has grown since 1974, SSI participation rates are low, especially among eligible low-income older persons. Previous studies estimated that only 40% to 60% of SSI-eligible older persons participated in SSI and found that, compared with SSI participants, eligible nonparticipants had relatively higher incomes and a smaller amount of potential SSI benefits, higher rates of home and car ownership, and better health (Choi, 1992, 1998; Davies, 2001; McGarry, 1995). In addition, the analyses of self-reported reasons for SSI nonapplication among eligible Social Security beneficiaries show that a large proportion of eligible nonapplicants lacked accurate information on the program and believed that they did not need the benefit because they had managed to get by without the extra income (Choi, 1998). A study of underutilization of SSI among Mexican American older persons also found that the most commonly reported reasons for their nonparticipation were lack of knowledge about the program (especially among those with no or a low level of formal education) and previous feelings of discrimination or mistreatment by SSI representatives or other formal providers (Dietz, 2001).

Because of SSI's strict eligibility criteria, means test, and disability determination process, poor older persons (who are likely to have low levels of education) can be easily misinformed of and intimidated by the application process. Moreover, with the initial disqualification of noncitizens from SSI eligibility in the 1996 Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA), many poor lawful permanent residents may still be confused about their eligibility. This is true even though, in 1997, Congress restored the eligibility of those who were receiving SSI benefits on August 22, 1996. Because SSI eligibility is grounded in old age and disability, the applicants and recipients are considered "deserving." Nevertheless, there have been periods of retrenchment when SSI eligibility determination and recertification processes became overly strict, and as a result, many recipients and applicants were denied the benefits. Although an appeals process is in place for those denied the benefit, the daunting task of appealing discourages many older persons and the disabled from applying for or reclaiming their benefits.

Coordinated Benefits

In addition to the federal SSI benefits, 45 states provide some form of optional supplementation administered by state government, federal government, or both. Eligibility criteria and the amount of supplementation vary by state. In general, SSI recipients are also eligible for Medicaid; 40 states use SSI eligibility criteria to determine Medicaid eligibility, and 11 states use their own Medicaid eligibility criteria. Applicants for SSI may be eligible for food stamps (except in California, where the cash value of food stamps is included in state supplementation), and a person can apply for food stamps at the time of the SSI application. The Ticket to Work and Work Incentives Improvement Act of 1999 also helps disabled SSI beneficiaries (and Social Security Disability Insurance beneficiaries) obtain vocational rehabilitation, employment, or other support services from an approved provider of their choice to help them go to work and achieve their employment goals.

Representative Payee System

When adult SSI (and/or Social Security) recipients are incapable of managing or directing the management of their benefits and are declared legally incompetent,

the SSA appoints representative payees for them and sends their SSI benefits to the representative payees. In many cases, the representative payee is a spouse, a parent, or other close relative who will act in the recipient's best interest. In some cases, an SSA-approved organization (such as a nursing home where a beneficiary is a resident or another qualified organization) may be appointed, and SSA has authorized some organizations to collect a fee from the benefit for acting as payee. The fee may not exceed the lesser of 10 percent of the benefit amount or a specified amount (\$31 a month in 2004; SSA, 2004b). Individual representative payees may not collect a fee for their service. A representative payee should use the funds only for the current and foreseeable needs of the beneficiary and must account for all benefits received. Representative payees are also required to report to the SSA any changes that may affect SSI recipients' eligibility and payment amount (SSA, 2001).

Financing of SSI

The SSI federal benefits are financed by the federal general revenues. In fiscal year 2003, federal expenditures for SSI cash payments totaled \$32.9 billion (of that amount, a little less than \$4.0 billion went to those aged 65 and older). The SSA's administrative cost for the program was \$2.7 billion, or 7% of the total federal SSI cash payments. The cost of state supplementation payment in the same year was about \$5.0 billion. The federal SSI payments constituted 0.3% of GDP in 2003, but they are projected to decrease to 0.24% of GDP in 2028 due to the slow increase in SSI participation and SSI benefits (SSA, 2004b).

Improvements Needed to Increase the SSI's Income Security Function

The SSI program has significantly helped older and/or disabled persons with no other source of income or with limited income. However, as shown by the low utilization rate, only about half of eligible older persons participate in SSI. Since all SSI-eligible nonparticipants have low incomes and would be able to benefit not only from the federal cash benefit but also from the other benefits, such as state supplementation and Medicaid, effective outreach efforts must be implemented to help them apply for SSI benefits.

The SSI eligibility rules related to resource and income limits, as well as exclusions/disregards, should also be made less strict. The resource limits of \$2,000 for an individual and \$3,000 for a couple and the face value of life insurance and a burial fund not exceeding \$1,500 each often disqualify otherwise-eligible older persons (Choi, 1998). Moreover, the unearned (or general) income exclusion of \$20 also discourages many low-income Social Security recipients or other public or private pensioners from applying for SSI because the entire Social Security and pension benefits minus \$20 will be counted against their prospective SSI benefits. The earned income exclusion (\$65 plus one half of the remainder) should also be increased to encourage low-income older working persons to apply for SSI. The application and appeal processes per se, including the proof of income (or, rather, lack of it) and disability determination, should also be streamlined to be less complicated, demeaning, and intimidating for older persons with limited education and resources to assist their application.

Especially given that poor older unmarried women and people of color, who constitute the largest proportion of SSI aged recipients, are the ones who were poor prior to reaching age 65 (Kijakazi, 2001), they are likely to have very little, if any, income from other sources. Even a modest increase in SSI benefits will provide these and other most vulnerable older persons with extra cash to buy the basic necessities of food, clothing, and shelter and have a greater sense of security. Moreover, any future Social Security reforms that may have negative effects on low-income workers, retirees, dependents, and survivors must be accompanied by significant improvements in SSI's income subsidy and security function (Davies & Favreault, 2004).

SENIOR COMMUNITY SERVICE EMPLOYMENT PROGRAM

The SCSEP, authorized under Title V of the Older Americans Act, is the only federal employment training and educational program focusing on low-income persons aged 55 or older. The SCSEP aims at promoting part-time community service activities and fostering economic self-sufficiency through unsubsidized employment following a period of subsidized work experience and training at nonprofit and public sector agencies (U.S. GAO, 2003). The program is funded by the U.S. Department of Labor (DOL) and administered by the Employment and Training Administration, which awards grants to 10 national orga-

nizations—the AARP Foundation; Experience Works (EW; formerly Green Thumb); the National Asian Pacific Center on Aging (NAPCA); Asociación Nacional Pro Personas Mayores (ANPPM; National Association for Hispanic Elderly); the National Caucus and Center on Black Aged (NCCBA); the National Council on the Aging (NCOA); the National Indian Council on Aging (NICOA); Senior Service America; the National Urban League (NUL); and the U.S. Forest Service (USFS)—and to units of state and territorial governments. These grantees are responsible for recruiting and collaborating with the host agencies where SCSEP participants receive employment training (U.S. Department of Labor [U.S. DOL], 2004).

Participants, Eligibility Criteria, and Nature of Training

For the 2000–2001 grant year, 106,000 SCSEP participants worked in part-time subsidized community service jobs provided by nonprofit and governmental host agencies (U.S. GAO, 2003). During the grant year ending June 30, 2002, the SCSEP enrollees had the following characteristics (AARP, 2004):

- 30% male and 70% female
- 27% with less than a high school diploma
- 12% veterans and 13% disabled
- 51% white and 49% minorities
- 78% aged 60 and older

Program participants must have a family income at or below 125% of the federal poverty level, and enrollment priority is given to persons over age 60, veterans, and qualified spouses of veterans. Program participants are placed in a wide variety of community service positions at nonprofit and government agencies, but they most frequently hold positions in education and social service organizations as teacher aides, librarians/library aides, day care assistants, receptionists, and nurse's aides (U.S. DOL, 2004; U.S. GAO, 2004).

On average, participants work 20 hours a week in the assigned positions and are paid the highest of federal minimum wage, state minimum wage, or prevailing wage. The positions are assigned to provide participants with skills and experience that will enable them to obtain unsubsidized jobs. Other training may include classroom, lectures, seminars, individual instruction, and training through other employment and training programs or through community colleges. Specific kinds of training include the following (AARP, 2004):

- Skills assessment;
- Formal program orientation;
- Creation of an individual employment plan that will identify barriers to employment and will recommend assignments, training, and services to overcome these barriers;
- Assistance with setting employment goals;
- Résumé preparation;
- Referrals to employment opportunities; and
- Follow-up meetings, evaluations, and reviews to determine the participant's progress and "next steps."

Funding and Effectiveness of SCSEP

In 2001, SCSEP was funded at \$440.2 million to support 61,762 job slots nationwide. (The number of actual participants surpassed the planned number, owing to enrollees who transitioned from the program into full- or part-time jobs and other program attrition.) The DOL allotted 78% of the funds to 10 national grantees and the remaining 22% to each of the 50 states, the District of Columbia, Puerto Rico, and the other territories. The SCSEP program is required to use at least 75% of its funds to subsidize participants' wages, with the remainder available for such activities as assessments, counseling, training, and job placement assistance (U.S. GAO, 2003).

In 2001, the proportion of the SCSEP enrollees who found unsubsidized full- or part-time jobs following their unsubsidized community service exceeded the DOL's goal of 20% (AARP, 2004). The SCSEP is cost effective, returning \$1.50 for every dollar invested in empowering older adults to be productive, taxpaying citizens who provide value-added service to their communities (National Council on the Aging, 2001). Studies have also shown that employers who hired workers who had gone through the SCSEP program reported generally positive attitudes toward these older workers because of their low absenteeism, low turnover rates, and willingness to take on demanding or difficult tasks (Wagner, 1998).

Strengthening SCSEP for Development of an Older Workforce

The U.S. GAO (2003) estimated that only about 12% of 1.3 million older people who were not working and wanted a job participated in federal employment and training programs and that the majority of them

(68%) were enrolled in SCSEP. Considering its high success rates in transitioning older persons into unsubsidized employment, its cost-effectiveness, and the positive reception its clients have received by employers, SCSEP needs to be expanded to serve more low-income older persons. The funding level can be gradually increased to serve more people in years to come. As the baby boomers retire, it is projected, there may be a labor shortage of 35 million workers by 2030 (U.S. GAO, 2003). Especially because people aged 55 or older will constitute nearly a third of the population in 2030, it is imperative for low-income unemployed people in this age-group to have access to employment training and job placement programs. In addition to the badly needed additional income, a sense of involvement in the community and in society in general will greatly improve the quality of life among these low-income older persons. Investment in development of the older workforce also needs to be considered in the context of Medicare and Social Security's financing problems. By helping older persons extend their productive years, we can decrease the burden on the Medicare and Social Security systems.

CONCLUSION

Income security in old age, along with affordable and accessible health care, is a basic human right that must be met regardless of an individual's prior economic status or earnings history. The employment- and earnings-based Social Security, means-tested SSI, and SCSEP providing employment assistance to older low-income job seekers constitute a reasonably sound system of income security for older persons, but, as discussed in this chapter, they also contain many deficits and limitations affecting those who are the most vulnerable. Along with careful strategies to solve the projected long-term fiscal problems of Social Security, increased funding levels, relaxation of overly strict eligibility criteria, and expanded outreach efforts for SSI and SCSEP are needed to improve the effectiveness of these programs. Social workers should actively participate not only in ongoing debates of Social Security reforms to help preserve the program's social adequacy function but also in advocacy to make SSI and SCSEP and other employment-assistance programs more accessible and adequate for low-income older persons. Social workers should continue to work to inform low-income older persons and their families of their entitlement to SSI and SCSEP and help reduce the stigma attached to these programs.

ROBERT B. HUDSON

Private Retirement Benefits

78

The “fear of outliving one’s income” has long stood as the principal economic concern facing people in old age. From the time that “modern aging” was recognized in the middle to late 19th century, there was a protracted period in which both private and public sectors worked to augment the limited savings individuals might have amassed to cushion their later years. Yet, more recently, the growth and security of the private pension sector have faltered, just as increases in societal aging are putting new pressures on Social Security, the nation’s principal public pension system.

This chapter reviews the place of private pensions in the overall retirement income picture, recent trends in private pension coverage, and the adequacy of private pensions in helping to meet the retirement needs of vulnerable populations. The last issue is of special importance to geriatric social workers, who must be aware of and knowledgeable about the income adequacy and security challenges that their clients are facing.

PRIVATE PENSION DEVELOPMENT

The American Express Company established the first private pension plan in the United States in 1875, although most of the initial plans were concentrated in the railroad industry (Sass, 1997). The number of workers covered grew slowly over the next several decades (roughly 3 million workers covered by the time of Social Security’s enactment in 1935); grew dramatically in the years during and after World War II (coverage growing from roughly 4 million in the late 1930s to 10 million by 1950); and climbed to 31 million workers by 1975. Although in the ensuing years the number of workers covered under all types of employer-sponsored pension plans has continued to increase (reaching 52 million by 1998), the number of workers covered under so-called traditional plans (formally known as *defined benefit plans* and discussed later in this chapter) has declined from 27 million in 1975 to 23 million in 1998 (Employee Benefit Research Institute [EBRI], 2002).

The early plans, especially in the railroad industry, were justified (to shareholders) as a way of increasing workers’ loyalty and reducing strikes and high turnover, which plagued the industry in those years. Pensions proved ineffective in meeting these objectives, but they did play a role in supporting mandatory retirement provisions directed at older workers who were deemed less productive. A number of factors led

to the rapid growth of plans during and immediately after World War II:

- Wage freezes during World War II and the Korean War encouraged fringe benefit growth in lieu of wages;
- In 1949, the Supreme Court supported a National Labor Relations Board ruling that pensions were a proper issue for collective bargaining;
- There was growing recognition by unions of the inadequacy of Social Security benefits and the need for their supplementation; and
- Multiemployer pension plans were introduced in construction, transportation, and other industries (Schulz, 1988).

In addition to strong economic growth during the period, Sass (1997) argues that the last two items were critical to private pension plan growth in the postwar era; the United Mine Workers and the Congress of Industrial Organizations (CIO) pushed for industry-wide standards, pressures that led to coverage expanding from 19% to 45% of the labor force between 1949 and 1960.

Despite this growth in private pensions, by the late 1960s a number of problems had emerged involving both worker protection and plan solvency. When companies went bankrupt (e.g., Studebaker automobile company in 1963) or fraud was rampant (Teamsters union pension fund in 1964), workers were left unprotected. Long vesting periods also left many workers at risk should they be laid off or fired after years of service. These concerns led in 1974 to the passage of the nation's principal private pension legislation—the Employee Retirement Income Security Act (ERISA). Among other provisions, ERISA

- Established pension plan termination insurance through the newly created Pension Benefit Guarantee Corporation;
- Set minimum vesting standards (number of years required for pension benefits);
- Strengthened funding and fiduciary standards within plans;
- Required plans to report to participants their accrued benefits and vesting status;
- Permitted employees, upon job separation, to transfer their pension rights on a tax-free basis from one plan to another; and
- Created tax-deferred individual retirement accounts.

As Schulz (1988) points out, however, ERISA did not address all private pension problems. Employers were not required to offer a plan, only to adhere to these regulations if they did offer one. In addition, state and local government plans were excluded from coverage, survivors' provisions were weak, and—unlike Social Security—pension benefits were not indexed to increases in the cost of living.

The post-1970s period has been marked by a leveling off in the expansion of private pension coverage among workers and by a dramatic shift in the *type* of private pension coverage being offered to workers. Well into the 1970s, there was hope that coverage, which had tripled between the early 1950s and the mid-1970s, would continue to expand. Yet economic stagnation, changes in the domestic and international competitive marketplace, and employers' perceived needs for more flexible labor force policies precluded this further expansion in coverage. The growth in the number of “traditional” pension plans (defined benefit plans [DBPs]) essentially halted, and later began to decline notably, and the newly introduced defined contribution plans (DCPs), made possible by ERISA provisions, began to greatly expand. The consequences of these two trends are that roughly one half of workers continue to lack any private pension coverage, and the move in the direction of DCPs has shifted much of the risk associated with pension performance from the employer to the employee.

In a popular metaphor applied to sources of retirement income, private pensions have long been seen as one leg of a “three-legged stool,” the other two being Social Security and individual savings. Yet liberalizations in Social Security over the past 30 years, the inability of many individuals to accumulate significant retirement savings, and the leveling off in the expansion of private pension coverage have meant that the Social Security “leg” is longer than the other two, especially among moderate- and low-income retirees. Thus, whereas employer-provided pensions provided about 20% of the total wealth of individuals aged 51 to 61 in 1992, this was considerably less than the proportion provided by Social Security, and it was very unevenly distributed, with roughly one half of workers having any such coverage.

THE ROLES AND FUNCTIONS OF PRIVATE PENSIONS

The role of pensions in assuring economic well-being in old age can be viewed from a number of perspec-

tives. Most basically, pensions are tied to the advent of capitalism, wherein “family enterprises” were slowly supplanted by capitalized industry and paid labor (Sass, 1997). Well-functioning families—at least those involved in small business or family-owned farming—saved either for old age or for bestowing bequests. The supplanting of those traditional family and economic forms by the urbanized and bureaucratized world of modern industry dramatically undermined the viability of that level of economic planning.

As they have evolved, private pensions occasionally met competing and occasionally consonant needs of employers and employees. In the early years, private pension plans helped “firms get diligent service out of blue-collar workers, secure career commitments from white-collar workers, and facilitate retirement at a specific age” (Sass, 1997, p. 227). Organized labor recognized the need to protect older workers but was suspicious of companies using pension promises as a way to unjustly tie workers to a given company. Over time, unions sought both expansion of Social Security and development of union-based rather than employer-based plans. The third actor to get seriously involved in pension development and reform was the federal government. Social Security was expressly designed to be a floor, not a ceiling, for retirement income, and there have long been pressures to maintain its “adequacy” function (disproportionately of benefit to low-income workers) over its “equity” function (a private sector–type “money’s worth” approach of benefit to higher-income workers).

By the 1970s, however, the piecemeal expansion of private pensions had created problems for each of the stakeholders. Businesses worried about the long-term burdens they were saddled with in the form of DBP obligations. Workers were being repeatedly victimized by the inadequate safeguards of functioning pension plans and by the dire consequences of both company plan bankruptcies and union plan scandals and poor management. For its part, the federal government—whose role in management of the economy and of public social benefits had dramatically expanded in the wake of the Great Depression and World War II—realized that pensions had emerged as an institutional leg of old-age policy in America. It was this confluence of concerns that led to the passage of ERISA in 1974.

Changes in the economy (relative decline of old-line manufacturing firms, rise of service and technology industries) and in both labor supply and demand (need for flexible labor market policies, decline of

unions, rise of contingent workers) have led to the stagnation and decline of DBPs and their partial supplementation by DCPs. ERISA regulations helped stabilize the workings of existing DBPs, but these very regulations have dissuaded most new businesses from adopting these traditional pensions. At the same time, ERISA and the Omnibus Budget and Reconciliation Act of 1982 have provided major tax incentives for both workers and employers to switch employer-based pensions to the DCP model. Finally, today’s younger workers find DCPs appealing because of their greater portability, an attribute that outweighs the security associated with DBPs in an era where career-long work with a single employer is dramatically declining (Munnell, Sunden, & Lidstone, 2002).

In short, the historical role of pensions to provide labor force stability to the employer and retirement security to the worker has shifted to a model that increases pension portability for the worker, reduces the employer’s obligation to the worker, and places the risks of pension plan performance upon the worker.

TYPES OF PRIVATE PENSIONS

Currently, DBPs and DCPs constitute the two principal types of employer-sponsored pension plans available in the United States. These do not include two other well-known retirement vehicles: individual retirement accounts (IRAs; available generally to workers with no employer-sponsored plan) and Keogh plans (available to the self-employed or small-business owners). Public sector plans may also be categorized as DBPs (Social Security is the world’s largest DBP) or DCPs (employees of the federal government now contribute to such plans), but the discussion here is confined to private sector plans only.

In a DBP, employers promise employees a given benefit amount upon retirement in accordance with a benefit formula stated in the plan. The following are the three principal types of DBPs:

1. Flat-benefit formula. A flat dollar amount is paid for each year of service recognized under the plan.
2. Career-average formulas. Under these plans, employees earn a percentage of the pay recognized for each year they are plan participants, or the formula averages the participant’s earnings over the period of plan participation. At retirement, the benefit equals a percentage of the career-

average pay, multiplied by the participant's number of years of service.

3. Final-pay formulas. These plans base benefits on average earnings during a specified number of years at the end of a participant's career; this is presumably the period when earnings are the highest. This plan has the effect of providing pre-retirement inflation protection to the employee, but it can represent a higher cost to the employer (EBRI, 1997c).

In the case of DCPs, employers make provision for contributions to an account established for each participating employee. The final retirement benefit equals the total of employer contributions, employee contributions (if any), and investment gains and losses. Employer contributions are often based on a specific formula, such as a percentage of employee salary or company profits. Because of these features, a major difference between the DBP and the DCP is that, unlike those of the DBP, future benefits of the DCP cannot be calculated in advance (EBRI, 1997c). Indeed, there is a fundamental conceptual distinction between the two types of plan. Strictly speaking, only DBPs are "pensions" by virtue of their paying a monthly benefit that is based on a formula tied to length of service and earnings; DCPs should be understood as tax-deferred savings plans providing benefits that are based on underlying assets, interest, dividends, and capital appreciation (Friedland, 1996). There are several types of DCPs, the most common being money-purchase plans (mandatory employer contributions as a percentage of worker salary), profit-sharing plans (amount derived from company profits), a thrift or savings plan (essentially an employee savings account, often with matching contri-

butions by the employer), and 401(k) plans (a qualified deferral arrangement under this section of the tax code, which allows an employee to have a portion of compensation—otherwise payable in cash—contributed to a plan such as those described here; these contributions are most commonly treated as a pretax reduction in salary; EBRI, 1997b, 1997c).

Data from the EBRI, shown in Table 78.1, document the trend in the direction of DCPs. The number of DBPs has declined notably since the mid-1980s; the number of DCP plans has risen significantly; the number of individuals covered under DBPs has stagnated; and the number of participants covered under DCPs has grown enormously.

Within the DCP category, especially spectacular growth took place in the 401(k) plans, with assets growing by 16 times, contributions by 9 times, and benefit payments by 12 times. By 1998, assets in 401(k) plans had risen to 38% of all private retirement plan assets and 78% of all DCP plan assets. Finally, the move toward DCPs grew to the point where by 1997, DCP assets exceeded DBP assets for the first time (EBRI, 2002).

ERISA of 1974 also established IRAs to give workers who did not have employer-based pensions an opportunity to save for retirement on a tax-deferred basis. Legislation in 1981 dramatically liberalized IRA eligibility to include workers who also had employer-based coverage. In 1986, restrictions for the latter group were again imposed, limiting the tax-deferral provision to those families with relatively low incomes. Although considerable assets are held in IRA accounts (VanDerhei, 2001), much of this results from contributions made by middle- and upper-income workers in the early 1980s, when deductibility extended across both income and pension-covered

groups. In the 1990s, however, the number of active IRA participants dropped, with only 9.2% of those with employee-based coverage and, more important, only 6.3% of workers without such coverage contributing (EBRI, 1997a).

Finally, the federal tax code now encourages the self-employed to establish retirement savings vehicles. So-called Keogh plans, also known as H.R. 10 plans, were authorized in 1962 and allow “unincorporated small business owners, farmers, and those in professional practice to establish and participate in tax-qualified plans similar to those of corporate employers” (EBRI, 1997c, chap. 17, p. 1). Quite restrictive until ERISA’s passage in 1974, Keogh plans have been liberalized over the years, now allowing contributions that are the lesser of 25% of the worker’s compensation or \$30,000 per year. More than other retirement savings vehicles, Keogh plans remain the province of higher-income individuals. Table 78.2 shows the participation rates and amount of contributions into IRAs and Keoghs by adjusted gross income.

PRIVATE PENSION COVERAGE

Over more than a century, private pensions have developed unevenly, reflecting the divergent interests of many parties who might have a stake in their existence. As indicated earlier, the business community has been actively involved, although changes in the marketplace have generated new approaches to employer-based pensions. Organized labor has had a major role in pension development, but declines in union membership and changes in both labor force demand and supply have reduced its influence. The

federal government has stepped in to bring some regulatory clarity and tax advantages to the industry, but in the absence of any government mandating of the provision of pensions by employers, that role must be considered highly truncated.

Yet enormous numbers of individuals and families have had little or no involvement in the development of private pension, nor have they had any or sufficient coverage under those pension schemes. For these groups, the “second leg” of the retirement income stool is either too short or nonexistent. Not surprisingly, many of these same individuals are those toward whom social workers direct many of their service efforts: low-income individuals, women, populations of color, part-time workers, employees of small firms, and many—to use Barbara Ehrenreich’s (2001) term—in sectors where workers are “nickel and dimed.” Within these categories of vulnerability, there is some variability in pension coverage; however, in contrast to workers who are White, male, full-time, highly educated, and working in traditional mainline or emerging high-technology fields, the contrasts are stark.

Since the late 1970s, the percentage of private sector workers ages 25 to 64 who are participating in employer-based plans has remained essentially constant at about 50%. There are, however, important internal dynamics within this overall pattern of constancy. There has been a slight reduction in male pension plan participation, dropping from 55% in 1979 to 51% in 2000. This decline has held for all male income groups except the highest earnings quintile, where participation rose from 70% to 72%. At the other end of the earnings spectrum, participation by men in the bottom income quintile dropped from 21% to 19% (Munnell et al., 2002).

TABLE 78.2 Workers’ Participation in and Average Contributions to IRAs and Keogh Plans, 1997

<i>Adjusted gross income</i>	<i>Keogh plans</i>		<i>IRAs</i>	
	<i>% Workers participating</i>	<i>Average contribution (\$)</i>	<i>% Workers participating</i>	<i>Average contribution (\$)</i>
Under \$20,000	—	2,245	2	630
\$20,000 to \$40,000	—	2,665	7	1,504

Participation for women has risen over the same period, although it still remains lower than for men. Women's private plan participation increased from 38% to 42% between 1979 and 2000, with participation increases being seen in all five income quintiles. However, as with men, participation rates fall as one goes down the income quintiles, the participation rate for the highest-income women in 2000 being 71%, and the rate for the lowest-income women being 11%. Interestingly, across all worker status categories—full-year/full-time, full-year/part-time, part-time/full-year, part-year/part-time—women's participation rates exceed men's. This seeming disparity from the aggregate figures appears to result from women workers' overall lower earnings and/or lower rates of full-time work in comparison to men, categories in which participation rates are disproportionately low (EBRI, 2003b).

Despite these relative improvements in private pension coverage for women, the income women receive from these pensions remains decidedly lower than that received by men. The upper portion of Table 78.3, using constant 2001 dollars, shows (a) how the growth in pension incomes for both men and women is growing only slowly, and (b) that women's benefits continue to hover at roughly one half of men's. Because these data are for current retirees (aged 50 and older in these calculations), they reflect the earnings experience of cohorts of women older than the majority of those included in data on pension plan participation among current workers.

Data from the Survey of Income and Program Participation (SIPP), based on pension income data from 1996 for individuals aged 65 and over, also show this "50% phenomenon," with men reporting pension in-

come of \$700 and women income of \$346. These and other data also show differential patterns by education, race, and employer characteristics. Table 78.2 reveals the expected monotonic relationship between pension income and education, ranging from no high school diploma to graduate degree. SIPP data, organized slightly differently, show an essentially identical pattern (EBRI 2003a, Fig. 3). Private pension participation rates among Black and Hispanic workers are shown in data from the Current Population Survey (CPS; EBRI, 2003b) to be lower than those for White workers, although the gap narrowed somewhat at higher income levels, as shown in Table 78.4.

The more dramatic picture painted by these data shows the critical place of income and employment status in determining pension coverage. There are much greater similarities by income across race and ethnic groups than there are by race and ethnicity within income groups. Consistent with these findings is a trend reported by Snyder (1993) showing a 66% increase in the number of retired Black men receiving pension income between 1982 and 1990, and a 250% increase between 1970 and 1990. However, as with the comparison between men and women, pension incomes by race and ethnicity have not improved as much as has pension plan coverage. Thus, among retirees aged 65 or over receiving pension income, Whites receive \$560, Blacks \$507, Hispanics \$375, and "Other" \$416 (EBRI, 2003a).

Overall, there have been notable improvements in recent years in the numbers of women and people of color covered by private pension plans. The more sobering finding is that coverage declines markedly with decreasing income, and there are notably higher proportions of women and people of color earning

low wages who thus remain disproportionately underprotected. In addition, the improvements seen in pension coverage and income among the Black population for the most part have not occurred among Hispanic workers and retirees.

THE RELATIVE CONTRIBUTIONS OF PRIVATE PENSIONS

The shortcomings of America's private pension system in meeting the income needs of vulnerable populations can be seen in both relative and absolute terms. The U.S. Bureau of the Census (2002) calculates the percentage of income derived from different sources for households ranked by income quintile. Table 78.5 shows that private pensions constitute a higher proportion of income as overall income rises, thereby showing that such income is both absolutely and relatively distributed very much toward the better-off.

Other quintile breakdowns of retirement income by source show that (a) among the older population,

private pensions constitute roughly 10% of retirement income for all groups except those aged 85 and over, among whom they make up only 6.8% of such income; (b) private pensions constitute 11.3% of retirement income among older unmarried men compared with 7.5% for older unmarried women; and (c) private pension income makes up 10.5% of retirement income among Black household units, compared with 9.9% among White units, and only 6.5% among Hispanic units (U.S. Bureau of the Census, 2002).

CONCLUSION

The workings of the private pension system in the United States and the patterns of participation in these plans have significant implications for geriatric social workers. Not surprisingly, these private sector vehicles—sweetened with inversely redistributive tax benefits—work to the advantage of relatively privileged groups in American society. Whether by gender, race, income, or education, the privileged tend to prevail.

TABLE 78.5 Shares of Aggregate Income of Aged Units 65 or Older From Particular Sources by Quintiles of Total Money Income, 2000

Income quintile	1st	2nd	3rd	4th	5th

Two implications in particular emerge for geriatric social work. The first is to be cognizant of the ways in which the workings of the system—notably, which employers offer plans—work to the advantage of the better-off. It is imperative that social workers involved with low-income individuals and communities work to modify seeming inequities and, more immediately, to encourage clients—where they are able—to participate in plans to prepare for their retirement years.

The second implication is for geriatric social workers themselves. A growing body of literature is predicting that alarming numbers of Americans will be forced to rely too heavily on Social Security benefits in their retirement years. Since the maximum retirement benefit available under Social Security is about \$20,000 (and most workers will receive far less), large numbers of workers approaching retirement will find their standard of living in serious jeopardy. And, as research by Martha Ozawa (1993) has documented, social workers are less financially prepared for retirement than professionals in either nursing or education. Not only is the personal professional; here, the professional is personal.

Policies Affecting Health, Mental Health, and Caregiving: Medicare

79

This chapter provides an overview of Medicare, a program that was enacted as part of Title XVIII of the Social Security Act of 1965. It also discusses Medicare's new policy developments, projected fiscal problems, limited long-term care coverage, and lack of mental health parity. The chapter concludes with a review of social work's role in Medicare.

OVERVIEW

What Is Medicare?

Medicare is a federal health insurance program for older persons and persons with disabilities enacted under Title XVIII of the Social Security Act of 1965. It is an entitlement program that covers persons regardless of income or prior health condition. The program currently covers more than 41 million Americans, of which 35 million are older persons and 6 million are nonelderly persons with disabilities (Kaiser Family Foundation, 2004). The total program outlays were \$256.8 billion in fiscal year 2003 (Kaiser Family Foundation, 2004).

What Is the Structure of Medicare?

Medicare consists of four parts: Part A, the hospital insurance program; Part B, supplementary medical insurance; Part C, Medicare Advantage; Part D, outpatient prescription drug program (Table 79.1).

Who Is Covered Under Medicare?

Almost all persons aged 65 and over are entitled to Part A if they or their spouse is eligible for Social Security payments. Persons who are 65 and under who receive Social Security Disability Insurance payments are also generally covered after a 2-year waiting period. All persons regardless of age who have end-stage renal disease (ESRD) are entitled to Part A. Persons who are not automatically entitled to enroll in Part A can voluntarily obtain coverage by paying full actuarial cost.

Participation in Medicare Part B is voluntary. All persons aged 65 and over who are enrolled in Part A are eligible to enroll in Part B by paying a monthly premium. About 95% of Part A beneficiaries voluntarily enroll in Part B.

In general, Medicare covers a diverse population, although the distribution of beneficiaries by race/

TABLE 79.1 Summary of Medicare Parts A Through D

	<i>Description</i>	<i>Coverage (as of 2004)</i>	<i>Financing</i>
Part A	Hospital insurance program	Inpatient hospital (first 60 days of hospital stay for each benefit period with a deductible of \$876 in 2004; for 61–90 days in the same benefit period there is daily coinsurance; after 90 days in the same benefit period, one must draw upon their lifetime reserve; for anything over 150 days in the same benefit period there is no coverage; there is a lifetime reserve of 60 days), inpatient mental health/substance abuse care (for up to 190 days, lifetime limit), skilled nursing facility (up to 100 days following a hospital stay with a co-pay of \$109.50 per day for the 21st through the 100th day of care), hospice (up to 210 days of care with a co-pay of 5% of the cost for inpatient respite care up to the cost of the inpatient hospital deduction), and home health care (postinstitutional home health care for 100 visits per episode, except for those persons with Part A coverage only).	1.45% of payroll tax paid by employees and employers. The self-employed pay a single tax of 2.9% on earnings.
Part B	Supplementary medical insurance	Physician and outpatient hospital care, lab tests, medical supplies, and home health, with a deductible of \$100 in 2004.	Beneficiary premiums (25%) and federal general revenues (75%). Monthly Part B premium is \$66.60 in 2004.
Part C	Medicare Advantage, managed care plans (formerly called Medicare + Choice)	Part A and Part B benefits depending on the plan, additional benefits that are not covered by traditional Medicare (e.g., eye and foot care).	Medicare pays plans to provide Parts A and B totaling \$36.3 billion in 2003; 62% of enrollees on the basic plan pay a monthly premium in addition to the Part B premium.
Part D	Outpatient prescription drug program. Enacted under the Medicare Prescription Drug, Improvement and Modernization Act of 2003, to be implemented in 2006.	Beneficiaries pay a deductible for the first \$250 in drug costs; pay 25% of total drug costs between \$250 and \$2,250; pay 100% of total drug costs between \$2,250 and \$5,100; and pay the greater of \$2 for generics, \$5 for brand drugs, or 5% coinsurance after reaching the \$3,600 out-of-pocket limit. Medicare will provide additional assistance to beneficiaries who qualify based on low incomes and limited assets.	Beneficiary premiums (25.5%) and general revenues (74.5%). Congressional Budget Office estimates the monthly premium to be \$35 in 2006.

From Kaiser Family Foundation (2004). State Health Facts Online. Distribution of Medicare Beneficiaries by Race/Ethnicity, State data 2000–2001, U.S. 2001.

ethnicity shows that a majority are White (84%). Blacks represent 8%, Hispanics 5%, and other groups 3% (Kaiser Family Foundation, 2004). Thirty-seven percent of the beneficiaries have incomes below 150% of the federal poverty line, and about 35% report needing assistance with at least one activity of daily living. About one quarter of recipients live in rural areas (Kaiser Family Foundation, 2004).

What Types of Medicare Plans Are Available for Beneficiaries?

There are two major types of Medicare plans: original Medicare and private Medicare plans. Regardless of which type of plan a person is enrolled in, as long as one has Medicare Part A and Part B, that person has a right to the same basic benefits.

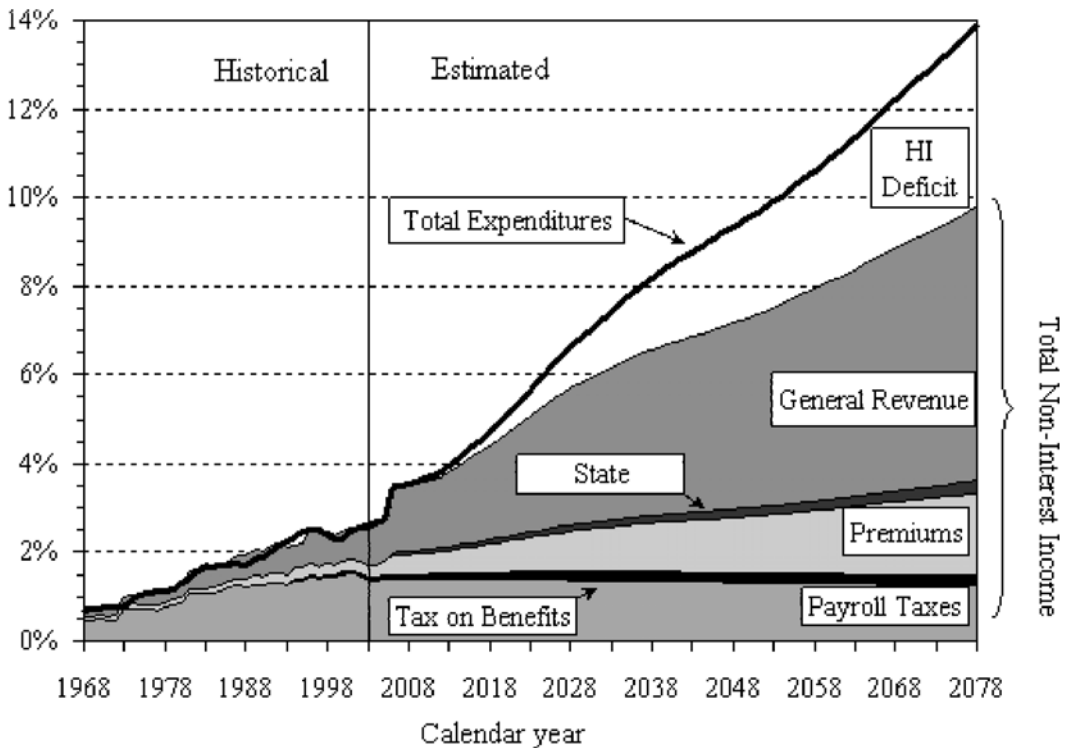

FIGURE 79.1 Medicare Expenditures and Non-Interest Income by Source as a Percentage of GDP
From Annual Report of the Trustees of Medicare HI and SMI funds (2004).

Original Medicare Plans

The Original Medicare plan is structured as a traditional fee-for-service plan offered by the federal government. A person who is eligible for Medicare will be automatically enrolled in this plan. One advantage of this plan is that the enrollee is able to choose to go to any doctor or hospital. The drawbacks include large out-of-pocket cost stemming from high hospital deductibles, annual deductible for doctor's visit, and co-payments for most outpatient medical care. In addition, there is no or limited coverage for routine dental care, hearing aids, vision care, routine foot care, or long-term care.

Private Medicare Plans

Medicare Advantage (formerly called Medicare + Choice), is offered by managed care companies, primarily health maintenance organizations (HMOs). To participate, one must have both Medicare Part A and Part B. HMOs have been an option under Medicare since the 1970s, but the role of these private plans expanded greatly under the Balanced Budget Act (BBA)

of 1997 by including other plans such as preferred provider organizations (PPOs), private fee-for-service plans (PFFS), provider-sponsored organizations (PSOs), and medical savings accounts. The Medicare Prescription Drug, Improvement and Moderation Act of 2003 created another option called regional PPOs.

The appeal of these private plans is relatively low out-of-pocket cost, which averaged from \$429 in 1999 to \$1,260 in 2003. However, these plans do not always offer savings for beneficiaries. About 31% of enrollees in Medicare Advantage programs do not have a plan that offers prescription drug benefits, which is usually a large out-of-pocket cost item. Plan participation and enrollment have varied over the years. In 2004, 11% of Medicare beneficiaries participated in these plans, down from 16% in 2000 (Kaiser Family Foundation, 2004). Enrollees are allowed to enroll in and disenroll from these plans only once, during a 6-month period beginning 2006. These plans offer a number of advantages. For example, they may be more affordable than traditional Medicare plans for persons on a fixed budget. They cover all benefits provided by traditional Medicare plans. In addition, they may provide benefits not covered by traditional

Medicare, such as limited prescription drugs, vision care, and foot care. However, the enrollee's choice of doctor and hospital may be limited to participating providers, and access to specialists and services usually is predetermined.

Supplemental Coverage

A majority of Medicare beneficiaries rely on some form of public or private supplemental insurance to fill in the gaps in Medicare's coverage. According to the Kaiser Family Foundation (2004), 34% had employer-sponsored benefits, 23% owned Medigap policies, 12% had Medicaid, and 2% had other public insurance.

- **Employer-sponsored benefits:** The pressures of rising health care costs have led to reductions in many employer-sponsored benefits. A survey by Kaiser and Health Research and Educational trust (2003) showed that between 1998 and 2003, a large percentage of employers dropped coverage to retirees from 66% to 38%. Furthermore, a 2002 survey by Kaiser Family Foundation and Hewitt Associates showed that large firms (1,000 or more employees) made changes in how they offer their benefits to retirees. About 44% increased contributions to premiums, 36% increased cost sharing for retirees, and 13% terminated benefits.
- **Medigap policies:** This form of insurance typically covers Medicare's deductible and coinsurance. It may also cover some benefits that Medicare typically does not cover. Enrollees after 1992 have a choice of 10 plans, Plans A through J. Plan A offers the most basic benefits, and the other plans offer the basic package with a combination of other benefits. Plans H through J offer prescription drug plans, all three having a \$250 deductible (Committee on Ways and Means, 2004). Three recent laws (Balanced Budget Act of 1997; Balanced Budget Refinement Act of 1999; and Medicare, Medicaid, SCHIP Benefits Improvement and Protection Act of 2000) expanded guarantee issues for enrollees. They are 6-month open enrollment and guarantee issuances of Medigap policyholders whose coverage was previously terminated. This also extends to enrollees who were trying out Medicare + Choice.
- **Medicaid:** Some low-income and disabled Medicare beneficiaries are entitled to partial or full coverage under Medicaid as dual beneficiaries. Medicare is typically the payer of first choice when both Medicare and Medicaid provide the benefits; Med-

icaid then picks up the portion not covered by Medicare (typically the long-term care benefits). Prescription drugs are covered under Medicaid. In addition, certain low-income groups, called Qualified Medicare Beneficiaries, Specified Low Income Medicare Beneficiaries, and Qualified Individuals, qualify for limited Medicaid benefits. For these groups, Medicaid typically pays for Medicare Part A deductibles and coinsurance and/or Part B premiums. However, these groups do not qualify for prescription drug benefits under Medicaid.

What Is the Projected Financial Crisis of Medicare?

Medicare's financial crisis has long been predicted. Between 1994 and 1996, the trustees of Medicare projected that the Hospital Insurance (HI) fund would become insolvent by 2001 (Kaiser Family Foundation, 2004). By 2001, however, the trustees projected a 28-year solvency for the HI fund, the longest period of solvency in Medicare's history.

Why is there such fluctuation in projecting the health of Medicare funds? There are three main factors, the first relating to how the HI fund is financed—mainly through payroll taxes. Like Social Security's OASDI fund, the HI fund is a pay-as-you-go system in which current employees pay for the HI fund for current Medicare beneficiaries. As a result, the aging of the country's population and the smaller number of workers supporting beneficiaries through their payrolls directly affect the health of the HI fund. The number of beneficiaries is expected to rise from 40 million in 2001 to 77 million in 2030 due to the graying of the baby boomers. Furthermore, the number of workers per beneficiary will fall from 4.0 in 1999 to 2.3 in 2030 (Kaiser Family Foundation, 2004). Given these parameters, theoretically, the HI fund could become insolvent. In contrast, the Supplementary Medical Insurance (SMI) fund cannot be insolvent because its revenues come from premiums paid by beneficiaries and general tax revenues. Furthermore, Medicare requires general revenues and beneficiary premiums to be automatically adjusted to cover the cost of Medicare Part B. However, SMI costs are growing faster than those of the HI fund. To keep up with rising costs, beneficiaries' premiums must be raised, and more contributions from general revenues will be needed. Therefore, the insolvency of the HI fund has become a proxy for the overall financial health of Medicare.

The second factor is the rising cost of medical care. Medicare's spending is projected to grow at a faster

TABLE 79.2 Major Legislative History of Medicare

<i>Date</i>	<i>Legislative milestones</i>
July 30, 1965	Medicare was enacted under Title XVIII of the Social Security Act.
1972	Coverage was extended to disabled and those with permanent kidney failure.
1980	Medicare supplemental insurance (Medigap) was brought under federal oversight. Coverage of home health services was broadened.
1982	Tax Equity and Fiscal Responsibility Act of 1982 made it easier and more attractive for health maintenance organizations to contract with Medicare.
1983	Prospective payment system was implemented for hospitals—developed diagnostic related groups (DRGs).
1988	Medicare Catastrophic Coverage Act was enacted to include outpatient prescription drug benefits and a cap on patient liability.
1989	Medicare Catastrophic Coverage Act was repealed.
1996	The Health Insurance Portability and Accountability Act of 1996 (HIPAA) was enacted to provide improved continuity or “portability” of group health plan coverage and group health insurance provided through employment or through individual insurance market.
1997	The Balanced Budget Act of 1997 established Part C (Medicare + Choice), developed and implemented prospective payment system for home health care, skilled nursing, rehabilitation hospitals, and ambulatory outpatient care.
2003	Medicare Prescription Drug, Improvement and Modernization Act of 2003. Provides seniors and individuals with disabilities with a prescription drug benefit, more choices under Medicare.

From U.S. Department of Health and Human Services (1999) *Mental Health: A Report of the Surgeon General*. p. 412.

rate than that of the overall economy. The health care costs per enrollee are projected to rise faster than the wages per worker on which the payroll tax is paid (Kaiser Family Foundation, 2004). In 2002, health care costs rose 5.7 percentage points faster than the overall economy, measured by the growth of the gross domestic product (GDP; Centers for Medicare and Medicaid Services [CMS], 2004). As a result, whereas Medicare’s annual costs are currently 2.7% of GDP, they will reach almost 14% of GDP by 2078 (Social Security Administration, 2004).

The third factor is related to the economy. With an improved economy, the availability of general tax revenues also improves. This potentially gives Medicare more funds to add to its trust fund.

In 2004, there were continued projections that the HI funds were headed for both near-term and longer term financial insolvency. Each year, Medicare’s trustees (the secretaries of treasury, labor, and health and human services; and two public trustees of different political parties selected by the president and confirmed by the Senate) issue a report on the current state and outlook of the HI fund and SMI fund. According to the trustees’ report (2004), the projected date of HI fund depletion has moved forward significantly to 2019, from 2026 in the previous year’s report, mainly as a result of a lower projected payroll tax in-

come and higher projected expenditures for inpatient hospital care. Annual expenditures are expected to exceed noninterest income beginning this year, and tax income deficits will grow until HI fund reserves are exhausted in 2019.

The financial outlook for SMI has changed even more dramatically since the enactment of Medicare Part D (prescription drug plan). The cost of this new plan, combined with a higher projected cost for Part B, greatly steps up the overall projected rate of growth of the SMI fund. Given these projections, the sustainability of Medicare will be difficult without greatly altering how the program is financed.

Four options are available to potentially combat the financial crisis of Medicare (Philips, 2000):

1. Reduce the number of people enrolled in the program by increasing the eligibility age. (The Old Age Insurance program under Social Security has already adopted this option.)
2. Increase beneficiary cost sharing. The current out-of-pocket cost for beneficiaries is already high, and with this option the burden will become even greater.
3. Reduce the total per-beneficiary program cost. Holding down the cost per beneficiary will be the key (e.g., reducing how much Medicare reim-

burses providers), but it will be important to consider if these reductions in program costs will be helpful in the long run and how they would affect beneficiaries and the quality of their care.

4. Find an additional source of revenue. Doing so, however, would require some kind of taxation, and with any new taxes, there are key questions that must be answered. How much can the government tax for it to be adequate? Who will pay the tax (equity)? What effects will the new tax have on the economy? Would the new tax be efficient to administer?

NEW POLICY DEVELOPMENTS

Changes in Medicare Payments: Prospective Payment System for Home Health Care and the Integration of Managed Care

The BBA of 1997 made sweeping changes in Medicare payments to postacute care (PAC) services. Since 1984, acute short hospital stays had been paid based on the prospective payment system (PPS), which provided incentives for hospitals to reduce the length of stay and discharge patients either to the patient's home or to PAC earlier than in the past. Furthermore, hospitals that provided PAC services had opportunities to earn more revenues from Medicare. These payment incentives facilitated the shift from inpatient to outpatient services, leading to massive growth in Medicare payments for PAC services. Between 1990 and 1995, home health care services grew from \$3.9 billion to \$18.3 billion (U.S. Department of Health and Human Services, 1999). The proportion of Medicare beneficiaries using home health increased from 5.8% in 1990 to 10.8% in 1997. Between 1987 and 1991, the annual average number of home health visits per patient doubled, from 23 visits to 45 visits per user. By 1997, the number of visits had risen to 73, and patients who received more than 200 visits represented about 10% of all home health users (Health Care Financing Administration [HCFA], 1999). Medicare spending also grew rapidly, reflecting the growth in utilization. Medicare home health expenditures increased at an annual rate of 21% between 1987 and 1997, with these costs representing 2% of total Medicare spending in 1987 and 9% in 1997 (HCFA, 1999).

The BBA of 1997 was introduced to curb Medicare payments to PAC services, particularly in home health care. PPS in home health care and skilled nurs-

ing facilities is Medicare's latest attempt to control costs. The idea behind PPS is not new to Medicare, whose policies reflect its integration of the principles of managed care. However, managed care has never been a vital part of providing care for Medicare beneficiaries, for two principal reasons. Competition among health plans has been an issue for Medicare. Medicare is a government program, and many private health plans do not wish to negotiate rates and benefits or accept lower rates from the government. This has led to some private managed care plans dropping out of the program and/or dropping benefits under Medicare + Choice. The other issue is related to consumer information and how consumers use these private managed care plans. Many Medicare beneficiaries saw managed care plans as limiting choice and services. Others, however, saw them as an option for reducing their out-of-pocket costs and took advantage of the liberal enrollment policies by switching between the traditional Medicare plans and managed care plans when doing so was more financially attractive to the beneficiaries.

Although managed care has not taken a strong hold of Medicare, the process and structure of managed care have continuously evolved and will continue to evolve. Medicare, the largest health insurance provider, has also followed the evolution of managed care and has changed its policies to reflect the process of managing illness and cost. According to Fairfield, Mechanic, and Rosleff (1997), there have been five generations of managed care. The first generation focused on retrospective utilization reviews and mainly contracted with preferred providers. The second generation used more proactive utilization reviews, increased the use of capitation and gatekeeping, and paid hospitals through prospective payments. The third generation used sophisticated utilization management, full capitation of risk, and clinical practice guidelines and managed high-cost cases. The fourth generation is what the United States is currently working toward achieving. The managed care system is increasingly interested in health outcomes, more health systems integration, and improved information systems. The fifth generation is the future goal of managed care, which will use anticipatory case management, targeted disease management, and outcome-based reimbursement. These generations are apparent in Medicare's history starting in the 1970s, when HMOs were first introduced to Medicare. Beginning in 1983, hospitals were reimbursed for Medicare patients on a flat-rate basis, determined by the patient's diagnosis, known as the diagnostic re-

lated groups (DRGs). Whatever the payment was for a particular condition, hospitals were expected to treat patients within the limits of that flat payment. The question of case mix became crucial regarding the types of patients that were admitted, and discharge planning conducted by social workers became central to the survival of hospitals. The concept was further expanded to nursing homes using resource utilization groups (RUGs).

Under PPS for home health care, Medicare pays home health agencies a predetermined base payment. There are six main characteristics of home health PPS. First, the unit of payment under home health PPS will be for a 60-day episode of care. Second, there will be case-mix adjustment to the payment, which adjusts payment for a beneficiary's health condition and needs. Third, outlier payments will be made for care of the costliest beneficiaries. Fourth, adjustments to payment will be made for beneficiaries whose episodes consist of four or fewer visits. These episodes will be paid by a standardized, service-specific per-visit amount multiplied by the number of visits during an episode. Fifth, adjustments to payments will be made for beneficiaries who experience a significant change in their condition. Sixth, adjustments to payments will be made for beneficiaries who change home health agencies (HCFA, 1999).

Based on these six factors, payment to home health agencies will be adjusted for the health condition, the care needs of the beneficiary, and the geographic differences in wages for home health agencies across the country. Adjustments for health conditions, clinical characteristics, and service needs are referred to as case-mix adjustment. The home health PPS will provide home health agencies with payments for each 60-day episode of care for each beneficiary. There is no limit to the number of episodes per beneficiary as long as the person remains eligible for home health benefits. Although payment for each episode is adjusted to reflect the beneficiary's health condition and needs, a special outlier provision exists to ensure appropriate payment to reflect the home health agency's cost in caring for the sickest beneficiary and to ensure access to home health services for which they are eligible (HCFA, 1999).

Today, Medicare is focusing more on health outcomes and is investing in information systems that can provide critical data to help target specific high-cost diseases and track health outcomes. Furthermore, Medicare is looking toward various managed care structures (e.g., HMO and PPOs) to provide health care for older persons and the disabled. Part C

(formerly Medicare + Choice) was created to further integrate managed care structures (providers) as a primary alternative to the traditional fee-for-service Medicare. This has been seen as a move to privatize Medicare and control its ever-increasing costs.

Prescription Drug Benefits

On December 8, 2003, the Medicare Prescription Drug, Improvement and Modernization Act of 2003 (P.L. 108-173) was enacted. This created a new drug benefit as Part D of Medicare, which will begin in January 2006. Until that new benefit begins, an interim Medicare-endorsed drug discount card and transitional assistance programs will be available.

Medicare beneficiaries have access to a transitional discount card program (from June 2004 through January 2006) that will provide them with an estimated 10% to 15% savings. For beneficiaries whose incomes are below 135% of the federal poverty level and who do not have private or Medicaid drug coverage, the federal government will provide \$600/per year for drug expenses in 2004 and 2005 and also will pay the annual enrollment fee.

In 2006, Medicare will begin to pay for outpatient prescription drugs through private plans. Under this arrangement, beneficiaries can remain on the traditional fee-for-service Medicare plan and enroll separately in a private prescription drug plan or enroll in Medicare Advantage plans for all Medicare-covered benefits plus the prescription drug coverage. Under this basic plan, in 2006 beneficiaries will be accountable for the following:

- A deductible for the first \$250 in drug costs;
- 25% of total drug costs between \$250 and \$2,250;
- 100% of total drug costs between \$2,250 and \$5,100;
- The greater of \$2 for generics, \$5 for brand-name drugs, or 5% coinsurance after reaching the \$3,600 out-of-pocket limit; and
- An estimated \$35 per month in premiums for basic drug coverage in 2006.

Medicare will provide additional assistance to beneficiaries who qualify based on low incomes and limited assets. Beneficiaries for the first time will have to meet income and asset tests to receive assistance. The Congressional Budget Office estimates that 14.1 million beneficiaries will be eligible for this type of assistance, within the following categories:

- *Dually eligible beneficiaries for Medicare and Medicaid:* Beginning in 2006, the drug benefits traditionally received under Medicaid will be provided under Medicare. These beneficiaries will pay no premiums or deductibles, and no drug costs above the out-of-pocket threshold. Below the threshold, those with incomes under 100% of poverty will pay \$1 to \$3 co-pays; those above the poverty line will pay \$2 to \$5 co-pays.
- *Beneficiaries with incomes below 135% of the poverty level and assets under \$6,000 for singles and \$9,000 for couples:* A subsidy will be provided to cover the premium for basic coverage in their region. These beneficiaries will pay \$2 to \$5 co-pays with no deductible and no cost sharing above the out-of-pocket threshold.
- *Beneficiaries with incomes below 150% of poverty level and assets under \$10,000 for singles and \$20,000 for couples:* A subsidy will be provided to pay for premiums on a sliding-scale fee. These beneficiaries will pay a \$50 deductible and 15% coinsurance up to the out-of-pocket threshold and \$2 to \$5 co-pays above the threshold.

This new prescription drug benefit will interact with other coverage, in particular, those programs that currently supplement Medicare. Medicare Advantage will have to provide prescription drug coverage beginning in 2006. Employer-sponsored plans that elect to provide prescription drug benefits comparable to Part D will receive subsidies from Medicare, which will pay 28% of the costs. In 2006, Medigap insurers will not be allowed to issue new policies that include drug coverage or supplement Part D coverage. Beneficiaries who already have Medigap policies may keep their policies (but a penalty may be faced when they choose to enroll in Part D at a later date).

According to the CMS (2004), about 7.4 million beneficiaries are expected to enroll. Savings from the discount card program are estimated to range from \$1.4 to \$1.8 billion, and savings from the transitional assistance program are projected at \$2.4 billion.

Medicare needs to consider the following issues as it manages an outpatient prescription drug benefit (Fox, 2004):

1. What should be the role of the pharmacy benefits manager who will process the claims and administer the program?
2. What drugs will be covered? (Generic drugs, brand-name drugs, quality-of-life drugs, drugs

that are expensive but have marginal effectiveness, new drugs first released to the public with limited information, over-the-counter drugs and equivalents?)

3. How broad should the pharmacy network be for the transitional discount card program when having broader networks means paying the pharmacies higher dispensing fees?
4. How can generic brands be promoted rather than more expensive brand-name drugs?
5. How can drug utilization be managed? This is an issue of quality of care and cost. Utilization reviews need to reflect the needs of older beneficiaries. Fox (2004) suggests three points for utilization reviews—prior authorization, at the time the prescription is filled, and after it is filled (retrospective review). Retrospective review can help target educational efforts for patients, physicians, and intensive disease management or case management programs.

LONG-TERM CARE AND MEDICARE

Relationship Between Medicare and Long-Term Care

Long-term care constitutes a variety of services that include medical and nonmedical care to people who have a chronic illness or a disability. Many people who need long-term care often receive support services such as help with activities of daily living (e.g., bathing, dressing, and toileting). Long-term care is provided in various settings, including but not limited to the home, the community, assisted-living facilities, and nursing homes. It is estimated that by 2005 about 9 million people aged 65 and over will need long-term care services (CMS, 2004). This number will increase to 12 million by the year 2020. It is estimated that about 40% of persons who are 65 and older have a chance of entering a nursing home and that those who enter nursing homes will remain there for 5 years or more (CMS, 2004).

Medicare was originally conceived not to provide long-term care services but to provide basic health care services to seniors. Medicare pays only for medically necessary services in skilled nursing facilities and home health care, and only on a short-term or “intermittent” basis. Most people who need long-term care, however, need more support services (nonskilled care), which help with activities of daily living. Medicare will not pay for this type of service.

Furthermore, Medicare's approach to health care is medically oriented and does not fully incorporate the psychosocial aspect of health care that can influence a patient's treatment outcomes. As a result, social work services, which can provide vital psychological and social services to older patients, have played a minimal role in providing care in skilled nursing facilities and home health care.

Given the large number of older persons potentially needing long-term care services and the high cost of care, many older persons are left financially vulnerable. They may have to pay out of pocket for long-term care services directly or through long-term care insurance. Ultimately, many older persons needing long-term care services may use up all their financial resources and qualify for Medicaid, which pays for support services and nursing home care.

Currently, there are about 7 million dually enrolled beneficiaries in Medicare and Medicaid. Of these 7 million, about 6 million receive full Medicaid benefits, and about 1 million receive Medicaid assistance with Medicare cost sharing (Kaiser Family Foundation, 2004). Dually eligible beneficiaries differ in many ways from other Medicare beneficiaries. They are the poorest, the sickest, and high users of health care services among Medicare beneficiaries. Almost 75% of dual enrollees have incomes under \$10,000 (just above the poverty level), compared with 13% of other Medicare beneficiaries (Kaiser Family Foundation, 2004). Approximately 25% of dual enrollees reside in nursing homes, compared with only 2% of other Medicare beneficiaries (Kaiser Family Foundation, 2004). They are twice as likely to have significant limitations in activities of daily living and are more likely to have chronic illnesses such as diabetes and stroke (Kaiser Family Foundation, 2004).

For these dual enrollees, coverage of services is the key to their health care. Whereas Medicare covers basic health care services, Medicaid will pay for Medicare's premiums and cost sharing and cover other benefits not covered by Medicare, such as nonskilled long-term care services. For dually eligible beneficiaries, coverage of nonskilled long-term care services such as home care and nursing home care is critical. For many older persons in the United States, being dually eligible is the only way to receive coverage for long-term care.

Lack of Parity in Mental Health

Currently in the United States, coverage for mental health is much more limited than that for physical ill-

ness. Mental health coverage can be obtained through private health insurance, Medicare, Medicaid, or private payment. However, there is a disparity between mental and physical coverage under insurance plans. Many have argued that this inequality results from a lack of knowledge about treatment options and interventions for mental illness. This policy also stigmatizes persons with a mental disorder. For the business community, parity for mental and physical health coverage has been provided through a 1996 law, which required businesses with 50 or more employees to have an annual or lifetime limit on spending that does not differentiate among types of illness. This parity law, however, does not stop companies from charging higher deductibles or co-payments for mental health benefits or not providing mental health coverage altogether. The law also permits restrictions on the number of visits to a therapist or days of hospitalization (Alliance for Health Reform, 2004).

For Medicare, the issue of parity is important, given that mental disorders such as dementia, depression, and schizophrenia all increase as the population ages. According to the National Institute of Mental Health (2004), among 35 million older persons, an estimated 2 million have depressive illness, and another 5 million may have depressive symptoms that fall short of meeting the full diagnostic criteria. But Medicare has no parity for mental and physical health. Medicare pays for a lifetime benefit of 190 days of inpatient psychiatric treatment. Although HI payment is limited to 60 days per episode for general hospital care, it does not have a lifetime limit on the number of days for such care. For outpatient mental health services, there is a 50% cost sharing rather than the 20% for other outpatient services. With the growing number of older persons with mental disorders, it is critical for policymakers to ensure parity for Medicare.

SOCIAL WORK AND MEDICARE

Social work services have been a vital part of patient care for Medicare beneficiaries, who are often in need of mental health services and other social services. Historically, before PPS was introduced in skilled nursing facilities and home health care, social work had been reimbursed independently. The BBA of 1997 changed this to include social work services under a consolidated bill. This change has unintentionally discouraged the use of social workers in these settings. Although social workers have been the primary mental health care providers in skilled nursing facilities,

psychologist and psychiatrist payments were not included in the consolidated billing and still maintain direct billing. The Clinical Social Work Medicare Equity Act of 2003 changed the reimbursement for clinical social work services and excluded these services from the consolidated billing under PPS. These changes mark an important point in Medicare, creating equity among mental health providers in direct Medicare payments.

Provisions of medical social service have been a part of Medicare home health since the beginning of the program. Medicare requires that social work services be available to patients (HCFA, 1992), but there is no requirement that social workers see patients or participate in the planning of their care (Dhooper, 1997). Under Medicare, social work services are not considered a primary service such as skilled nursing care or physical and speech therapy. Therefore, social work services cannot be the only services provided to a patient in home health care. For that reason, the traditional pathway for a patient to receive social work services under Medicare is to receive a referral from a nurse or a physical or speech therapist.

For home health agencies to get reimbursed for social work visits, Medicare requires that the visits be justified by “a clear and specific link between the social and emotional needs of the beneficiary and the beneficiary’s medical condition or rate of recovery” (HCFA, HIM 11). Medicare mostly does not limit the number of social work visits provided to a patient as long as the visits are justified (Abel-Vacula, Nathans, Phillips, & Robbins, 2000). Direct patient contact is an important aspect of reimbursement for social work services. Therefore, Medicare does not reimburse social work services that are limited to assistance with Medicaid applications, arranging transportation for dialysis patients, and assisting with advance directives and living wills (Abel-Vacula et al., 2000).

As Medicare looks toward managing care and controlling costs, reimbursement will be increasingly tied to health outcomes. To improve outcomes, providers must look toward providing care for the whole person, including the patient’s need for physical and mental health care and social services. As an individual’s social and mental health are increasingly linked to improving physical health, social work services will become vital in managing the care of the older persons. As agencies look at ways to efficiently and effectively deliver services under a set rate, they must carefully weigh the cost and benefit of each profession, including social work. Under PPS, it is critical that social workers demonstrate their efficiency

and effectiveness in improving patient outcomes that contribute to revenue for an agency.

Policies Affecting Health, Mental Health, and Caregiving: Medicaid

80

Title XIX of the Social Security Act, commonly referred to as Medicaid, became law in 1965. Prior to its enactment, health care services for persons with low incomes and assets were provided piecemeal through an arrangement of services offered by state and local programs, charities, and hospitals (Provost & Hughes, 2000). Modeled on the Kerr-Mills Act of 1960, Medical Assistance for the Aged, and the Social Security amendments of 1950, it was designed as a cooperative program, funded jointly by the federal and state governments, including the District of Columbia and the territories (Grogan & Patashnik, 2003; Provost & Hughes, 2000). Medicaid is an entitlement program that pays for medical care for certain individuals and families who demonstrate low income and limited resources (Hoffman, Klees, & Curtis, 2000; Rowland & Garfield, 2000). Originally established as a program to subsidize medical care for persons with low incomes and assets, its particular emphasis is on dependent children and their mothers, persons with disabilities, and older persons.

This chapter provides a description of the historical context for the establishment of Medicaid and explains basic standards and guidelines. It then examines programs and services available under Medicaid for older adults. In particular, dual eligibility, managed care, the freedom of choice and home and community-based waiver programs, and long-term care financing issues are discussed.

MEDICAID: STANDARDS AND GUIDELINES

Using broad national guidelines that are established by federal regulations, each state shapes and administers its own Medicaid program and develops its own standards. These standards include eligibility requirements; type, amount, duration, and scope of services; and rate of payment for services. Due to state-developed standards, there is great variability in Medicaid policies throughout the country.

Medicaid is not designed to provide medical assistance for all persons with low incomes. Low income is only one test for Medicaid eligibility. In addition, resources and assets are tested against threshold levels. These threshold levels are determined by each state, using federal guidelines. States have discretion in determining the financial criteria for Medicaid eligibility and which groups of individuals their Medicaid program will cover. States may also develop a type of program called a state-only program that pro-

vides medical assistance for designated poor persons who do not qualify for Medicaid. These state-only programs are optional, and the amount and type of assistance vary from one state to another (Hoffman et al., 2000).

As part of the cooperative venture with the federal government, states are required to provide Medicaid coverage for particular individuals who receive federally assisted income-maintenance payments and for related groups who are not receiving cash payments. Table 80.1 outlines the mandatory Medicaid categorically needy eligibility groups for which the federal government provides matching funds. In addition to these mandatory related groups, states have the option of providing Medicaid coverage for other categorically related groups. These groups fall within defined categories, but the eligibility criteria are circumscribed more liberally.

Certain provisions of these optional and mandatory categorically related groups, such as the medically needy option, have particular relevance for older people in the United States. The medically needy option contains provisions that broaden eligibility requirements to persons who are eligible for Medicaid under one of the mandatory or optional groups with the exception that their income and/or resources exceed the eligibility level set by the state in which they reside. Under these circumstances, persons may qualify immediately or may be required to spend down their resources through incurring medical expenses that reduce their income below the level set for medically needy persons as outlined by individual state requirements. Using these spend-down procedures, individuals become eligible for Medicaid coverage after their medical expenditures exceed their assets.

TABLE 80.1 Mandatory Eligibility Groups and State Options

Medically categorically needy eligibility groups: Federal matching funds are provided

Individuals are generally eligible if they meet the requirement for the Aid to Families with Dependent Children (AFDC) program in effect in their state on July 16, 1996, or, at state option, more liberal criteria.

Children under age 6 whose family income is at or below 133% of the federal poverty level (FPL).

Pregnant women whose family income is below 133% of the FPL (services limited to those related to pregnancy, complications of pregnancy, delivery, and postpartum care).

Recipients of adoption or foster care assistance under Title IV of the Social Security Act.

All children born after September 30, 1983, who are under age 19, in families with incomes at or below the FPL (this process phases in coverage, so that by the year 2002 all such poor children under age 19 will be covered).

Supplemental Security Income (SSI) recipients in most states (some use more restrictive Medicaid eligibility requirements that predate SSI).

Special protected groups (typically individuals who lose their cash assistance due to earnings from work or from increased Social Security benefits, but who may keep Medicaid for a period of time).

Certain Medicare beneficiaries.

State options: Medicaid coverage for other categorically related groups

(The broadest optional groups for which states will receive federal matching funds for coverage under the Medicaid program include those listed below.)

Infants up to age 1 and pregnant women not covered under the mandatory rules whose family income is no more than 185% of the FPL (the percentage amount is set by each state).

Children under age 21 who meet the AFDC income and resources requirements in effect in their state on July 16, 1996.

Institutionalized individuals eligible under a special income level (states set the amount—up to 300% of the SSI federal benefit rate).

Certain aged, blind, or disabled adults who have incomes above those requiring mandatory coverage, but below the FPL.

Recipients of state supplementary income payments.

TB-infected persons financially eligible for Medicaid at the SSI income level if they were within a Medicaid-covered category (limited to TB-related ambulatory services and TB drugs).

Certain aged, blind, or disabled adults who have incomes above those requiring mandatory coverage, but below the FPL.

Certain working-and-disabled persons with family income less than 250% of the FPL who would qualify for SSI if they did not work.

Optional targeted low-income children included within the State Children's Health Insurance Program (SCHIP) established by the BBA of 1997.

Medically needy (MN) persons.

From Hoffman, E. D., Klees, B. S., & Curtis, C. A. (2000). Overview of the Medicare and Medicaid programs. *Health Care Financing Review*, 22, 1, 188.

Eligibility for Medicaid and benefit provisions for the medically needy are not required to be as extensive as for the categorically needy; in fact, regulations may be fairly restrictive. Although federal matching funds are available for medically needy programs, states are expected to follow certain federal requirements, including inclusion of certain groups and services under these guidelines. In addition to these mandated service requirements, states may elect to extend the medically needy eligibility to additional groups and to provide supplementary services. As of 2000, a total of 38 states had elected a medically needy program and were providing some services within this category. In 2002, the number of states offering medically needy programs dropped slightly to 36 (Centers for Medicare and Medicaid Services, 2003a). States that have not opted for a medically needy program may use the special income level option to extend Medicaid to the near poor in medical institutional settings (Hoffman et al., 2000).

Although Title XIX of the Social Security Act allows flexibility for states to craft their own Medicaid plan, some federal requirements are mandatory for states to receive federal matching funds. The federal government requires states to offer medical assistance for basic services to the categorically needy group as outlined by the federal guidelines. Mandated services particularly germane to older adults include nursing facility services for persons aged 21 and over, home health care for persons eligible for skilled nursing services (in addition to inpatient and outpatient hospital services), rural health clinic services, physician services, and laboratory and X-ray services. In addition to these mandatory services, states also may provide some optional services for which they receive a federal match. Examples of approved optional Medicaid services include diagnostic services, clinic services, intermediate care facilities for the mentally retarded, prescription drugs, prosthetic devices, optometrist services and eyeglasses, transportation services, rehabilitation and physical therapy services, and home and community-based care to certain persons with chronic impairments.

The Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (P.L. 104-193) introduced restrictive changes to eligibility standards for Supplemental Security Income (SSI) coverage. This law had an impact on the Medicaid program, since one eligibility category is SSI recipients. The law imposed restrictions on SSI eligibility among legal resident aliens and other qualified aliens who entered the United States on or after August 22, 1996. The law requires a waiting period before these individuals can be

eligible for SSI. Individual states can exercise the option to provide Medicaid coverage for aliens who entered before that date and to provide Medicaid for alien individuals after a waiting period. Emergency services continue to be mandatory for alien groups. For those aliens who lost SSI benefits due to the new restrictions imposed by P.L. 104-193, coverage can be provided only under another eligibility status outlined within Medicaid regulations (Hoffman et al., 2000).

HISTORICAL ANTECEDENTS IN COVERAGE OF OLDER ADULTS

Within its 40-year history, Medicaid has evolved as an assistance program for older adults with low income and assets and for persons with disabilities. A 1972 amendment to the Social Security Act established a federal program for cash assistance for the aged, blind, and disabled. This program, known as Supplemental Security Income, set uniform national minimum eligibility standards and benefits (Rowland & Garfield, 2000). Within this legislation, optional benefits eligible for federal matching funds included services provided by intermediate-care facilities and intermediate-care facilities for the mentally retarded. Further legislation in the 1980s assured Medicaid coverage to some Medicare beneficiaries who had not meet the eligibility requirements for any cash assistance program. Additionally, in the 1980s, changes to the Medicaid benefits package expanded within the options for home and community-based long-term care, increasing the role these programs have for low-income older adults. These legislative changes also emphasized increased access to care, quality of care, improved outreach programs, specific benefits, and fewer limits on services (Rowland & Garfield, 2000).

The proportion of older adults receiving Medicaid has declined over time. In 1973, 19% of Medicaid beneficiaries were 65 and over (Provost & Hughes, 2000). By 1998, persons 65 and over accounted for only 11% of the Medicaid population (Provost & Hughes, 2000). In 2000, it was estimated that older persons constituted 10% of all Medicaid beneficiaries (Centers for Medicare and Medicaid Services, 2003b). However, those Medicaid beneficiaries 65 and over account for an uneven share of total Medicaid expenditures. The same 11% in 1998, or 4 million aged participants, accounted for 31% of total Medicaid expenditures, or an average per-person expenditure of about \$9,700 (Provost & Hughes, 2000; Hoffman et al., 2000). The same 10% in 2000, or 4.1 million older adults, had an average expenditure of about \$11,345 per person (Cen-

ters for Medicare and Medicaid Services, 2003b). The number of older adult participants on Medicaid has declined, in part due to policy changes in both Medicaid and Medicare. These changes pertain to both eligibility requirements and service coverage requirements.

Additionally, Medicaid's total spending on long-term care accounted for approximately 40% of its total expenditures in 1998 (Rowland & Garfield, 2000). This amount was a result of its expansion of services for older adults and the disabled. In 2002, Medicaid's spending on long-term care accounted for 37.5% of total expenditures (Kaiser Commission on Medicaid and the Uninsured, 2003). Medicaid defines long-term care to include services provided in nursing facilities, intermediate-care facilities, intermediate-care facilities for the mentally retarded, mental health, home health services, and personal care support services.

THE RELATIONSHIP BETWEEN MEDICAID AND MEDICARE: STATE BUY-INS FOR "DUAL ELIGIBLES"

For individuals with low income and limited assets who receive Medicare, dual enrollment in Medicaid is an option. "Dual-eligible" beneficiaries are Medicare beneficiaries who also qualify for Medicaid benefits as a result of their low income. For eligible persons, Medicare health care coverage is supplemented by programs and services available through the state Medicaid program. Older adults with low income and assets may be eligible for Medicaid under the following categories:

- Recipients of the federal SSI program;
- Older adults with excessive medical or long-term care expenses in proportion to their income and assets;
- Older adults whose income levels are below the federal poverty threshold, and who have limited financial assets, referred to as Qualified Medicare Beneficiaries; and
- Older adults who have incomes between 100% and 120% of the federal poverty threshold and who have limited financial assets, referred to as Specified Low-Income Medicare Beneficiaries.

Services provided under the dual-enrollment program include such items as prescription drugs, eyeglasses, hearing aids, and nursing home care that extends beyond the 100-day limit allowed by

Medicare. Assistance may also be provided in covering Medicare premiums and cost-sharing payments through the state Medicaid program. For all eligible services, Medicare is billed as the first payer, and Medicaid is considered the payer of last resort.

Since 1965, Medicaid has covered the Medicare premiums and the cost sharing of additional benefits not covered by Medicare for SSI recipients. Additionally, Medicaid's role in financing low-income Medicare beneficiaries was expanded through a series of incremental changes to the legislation. One such expansion is the development of Medicaid into a Medicare supplement.

In 1994, Medicaid covered approximately 20% of older people with incomes below 150% of the federal poverty threshold (Health Care Financing Administration, 1996a). Comparisons with recipients in other age-groups indicate that low-income older people have the highest per-user Medicaid payments. During 1997, 6.4 million dual-eligible persons represented just 19% of the Medicaid population but accounted for 35% of program expenditures (Provost & Hughes, 2000). It is estimated that Medicaid provides some level of supplemental health coverage for 6.5 million Medicare beneficiaries (Centers for Medicare and Medicaid Services, 2003b).

Another option available for dual-eligible older adults is a state option known as Programs of All-Inclusive Care for the Elderly (PACE). PACE started as a demonstration project, and Congress granted it program status in passing the Balanced Budget Act (BBA) of 1997 (Mollica, 2003). PACE is designed to provide an alternative to institutional care for persons aged 55 and older who are regarded as needing a nursing facility level of care (Mollica, 2003). This is a federal program option under both Medicare and Medicaid that allows for an integrated model of acute and long-term care services for individuals with dual eligibility (Mollica, 2003). PACE offers and manages the health, medical, and social services of participants enrolled in the program. In addition, PACE is responsible for coordinating the use of other services as indicated for rehabilitation, prevention, and psychosocial needs. Services may utilize day health centers, homes, hospitals, and nursing homes. The aim is to maintain independence, dignity, and quality of life. PACE providers receive payment for services through predeveloped PACE agreements. Providers must make available items and services covered under both Title XVIII and Title XIX. These services must be rendered without amount, duration, or scope limitations and without requiring deductibles, co-payments, or

other forms of cost sharing. PACE is one option that allows for seniors to age in place (Mollica, 2003).

MEDICAID AND MANAGED CARE

There has been a movement to develop and utilize managed care systems as an alternative to the traditional fee-for-service system. In response to rising Medicaid costs and the national recession of the 1980s, state Medicaid programs turned to managed care, which aims to provide an accessible, cost-effective approach to health care service delivery. Under the managed care system, health maintenance organizations, prepaid health plans, and other forms of managed care contract with the state to provide an agreed-upon set of services to Medicaid enrollees. In return, the provider system receives a predetermined payment per enrollee for a specific period of time. The purpose of managed care is to provide an accessible, cost-effective approach to health care service delivery.

Since the 1980s, states have continued to experiment with various managed care approaches in an attempt to contain costs, reduce redundancy of services, and strive for better coordination and continuity of care. In 1997, Congress passed the BBA, which provides states with the option of setting up Medicaid managed care programs without the prior waivers required in the past (Klemm, 2000).

The change in law may have contributed to the rise in the proportion of Medicaid enrollees in some form of managed care, which increased from 14% of enrollees in 1993 to 58% in 2002 (Centers for Medicare and Medicaid Services, 2003b; Hoffman et al., 2000). The growth in Medicaid managed care has been rapid, but penetration rates vary widely among states. For example, two states (Alaska and Wyoming) have no managed care enrollment, and 12 states have penetration rates of between 76% and 100% (Provost & Hughes, 2000).

Most state Medicaid managed care enrollees consist of children and nondisabled adults. In the past, older adults and the disabled were considered high-risk population groups for managed care arrangements due to the need to deliver comprehensive services to a high-need group while controlling costs (Provost & Hughes, 2000). However, several states are moving this population group into managed care arrangements through managed care waivers. In 1997, a total of 24 states enrolled older adult Medicaid beneficiaries into managed care programs (Mollica, 2003). Overall, the number of Medicaid beneficiaries

enrolled in managed care programs increased from 14% of enrollees in 1993 to 58% in 2002 (Centers for Medicare and Medicaid Services, 2003b).

FREEDOM OF CHOICE AND HOME- AND COMMUNITY-BASED SERVICES WAIVERS

In response to a disproportionate amount of Medicaid expenditures that were being used for institutional care (Grannemann & Pauly, 1983; Provost & Hughes, 2000), Medicaid began shifting delivery of services to home and community-based settings. Part of the inappropriate use of nursing facilities was linked to an institutional bias in the Medicaid benefit and eligibility structure (Grannemann & Pauly, 1983; Holihan, 1975). In addition, studies indicated that some people who were residing in nursing homes and receiving Medicaid funding were capable of living in the community (Fox & Clauser, 1980; Kraus et al., 1976; Pegels, 1980). Furthermore, advocates and policymakers increasingly recognized that residents in nursing and intermediate-care facilities for the mentally retarded reported a poor quality of life (Gardner 1977; Scheerenberger, 1976). In response to all these factors, the Medicaid waiver program was born.

The legislative change that allowed for the development of Medicaid waiver programs was Section 2176 of the Omnibus Reconciliation Act of 1981. Since the waiver program was established, three mechanisms have allowed states to test Medicaid program innovations: (a) Section 1915(b), or freedom of choice waivers; (b) Section 1115, research and demonstration projects; and (c) Section 1915(c), home and community-based services (HCBS).

Section 1915(b) waivers refer to programs that enroll beneficiaries in managed care programs on a mandatory basis. Additional services are provided through savings produced from managed care, and carve-out systems are provided for specialty care such as mental health. There is the option to create programs that are available in certain regions or districts (Provost & Hughes, 2000).

Section 1115 Research and Demonstration Projects provide a mechanism for states to test new ideas. Under this initiative, states investigate program innovations, such as small-scale pilots of new benefits, various financing mechanisms, and major restructuring of state Medicaid funding (Provost & Hughes, 2000).

The HCBS waiver program, or Section 1915(c), allows states to develop and implement a network of health care and social services that makes it possible

for individuals to remain in the community and avoid institutionalization (Hoffman et al., 2000; Provost & Hughes, 2000).

Under this waiver program, states may choose to provide a variety of services not otherwise covered under Medicaid as an alternative to institutionalization. Waiver services may be provided to individuals who are older and disabled, physically disabled, developmentally disabled, or mentally retarded or mentally ill. Waiver services may also be provided to persons with a specific illness or condition such as persons with AIDS.

Seven specific services outlined under the regulation may be offered as part of an HCBS waiver: case management services, homemaker services, home health aide services, personal care services, adult day health care services, habilitation services, and respite care services (Duckett & Guy, 2000; Health Care Financing Administration, 1996b). In addition, other services may be provided if they are requested by the state and approved by the Health Care Financing Administration. They must be cost effective and demonstrated to be necessary to avoid institutionalization. Examples of additional services include transportation, in-home support services, meal services, special communication services, minor home modifications, and adult day care (Duckett & Guy, 2000; Health Care Financing Administration, 1996b). In New York, for example, available services also include personal emergency response systems, housekeeping and chore services, and access to ancillary health services such as optometry, audiology, dentistry, and podiatry (Fisher & Raphael, 2003).

Under the HCBS waiver program, a capitation device allows plans to provide services that are not otherwise available through Medicaid. In capitation arrangements, providers receive from the state a monthly reimbursement rate for each Medicaid managed care enrollee. Within that reimbursement, the providers are at full risk to pay for all services covered by the managed care plan (Fisher & Raphael, 2003).

The HCBS program has experienced tremendous growth since its inception in 1981. In 1998, the estimated total Medicaid expenditures for this program reached over \$9 billion for about 606,953 participants (Duckett & Guy, 2000). As of 2002, there were 263 approved waiver programs operating in 49 states (Centers for Medicare and Medicaid Services, 2003a). Community-based long-term care spending increased from 14.9% in 1992 to 25.3% in 1998 and to 27% in 2000 (Centers for Medicare and Medicaid Services, 2003a; Provost & Hughes, 2000).

LONG-TERM CARE FINANCING ISSUES

The high cost of nursing home care may be covered under Medicaid. Medicaid is the primary source of long-term care insurance for older adults and people with disabilities. National data indicate that Medicaid finances the nursing home care of about 60% to 70% of individuals in nursing facilities (Grogan & Patashnik, 2003). Medicaid covers skilled nursing facility care, intermediate facility nursing care, intermediate care for the mentally retarded and developmentally disabled, and HCBS (Provost & Hughes, 2000). Medicaid will finance nursing home care after an individual's savings and income are depleted or spent down. It is estimated that two thirds of individuals who enter long-term care facilities spend down their assets and become eligible for Medicaid (Grogan & Patashnik, 2003), and that nearly half of the nation's nursing home bill is covered by Medicaid (Min DeParle, 2000).

Historically, there has been tremendous growth in spending on nursing home care. For example, in 1966, it accounted for just 11% of Medicaid spending. By 1999, this amount had increased to 48% (Rowland & Garfield, 2000). A large percentage of expenditures for nursing facility care is spent on a relatively small number of individuals. In 1998, only 4% (1.6 million persons) of the individuals served by Medicaid received nursing facility services, but this accounted for about 25% of total Medicaid expenditures, or \$44.1 billion (Provost & Hughes, 2000).

Recent data indicate some declines in nursing home care spending. In fiscal year 2002, a total of \$93,219 billion was spent on nursing home care, or about 37.5% of total Medicaid expenditures for 1.7 million persons (Centers for Medicare and Medicaid Services, 2003b). These decreases may reflect the growing use of less costly service delivery systems such as HCBS waiver programs and managed care to deliver services that were traditionally provided by nursing homes.

Medicaid's expanded role in the financing of long-term care services has contributed to the development of quality standards for this industry (Rowland & Garfield, 2000). Key influences include implementation of comprehensive nursing home reform that raised standards for quality nursing home care and protections offered to spouses of nursing home residents outlined in the Spousal Impoverishment Act (Rowland & Garfield, 2000). Also, the HCBS initiatives for older adults provide less costly care options while allowing individuals to remain in the least restrictive setting.

CONCLUSIONS

President Lyndon Johnson signed the Medicaid legislation into law on July 30, 1965, at the Truman Library in Independence, Missouri. Wilbur Mills, chair of the House Ways and Means Committee, crafted the legislation as a federal matching program so that states would be able to provide additional health insurance to low-income parents and dependent children, older adults, and people with disabilities. This program established the principle that the government would take responsibility for the provision of health care to low-income individuals (Min DeParle, 2000). Challenges for the future of the financing of health care services for older Americans through Medicaid center around the question of how to provide comprehensive care to a growing population of persons in the most efficient and effective manner possible. This nation is confronted with larger numbers of older adults who are living longer. Utilization of health services will increase tremendously as the baby boomers age. This increase in utilization will challenge Medicaid's ability to provide needed services to older adults. Will the United States keep pace with the changes, or will a portion of the aging population go unserved? Only time will tell.

Policies Affecting Long-Term Care and Long-Term Care Institutions

81

In recent decades, the development of the long-term care (LTC) policies in the United States has lagged behind the growing care needs of older persons with chronic illnesses and mental or physical disabilities and their families. In most industrialized societies, the responsibilities for social policy and service delivery are seen as shared by the household, the state, and the marketplace. In these societies, an assurance of government involvement to protect an individual's minimum standard of living when the market fails to do so is an important policy principle. A policy based on a balanced and complementary system between the private (market and household) and public sectors is often sought by progressive reformers. However, in the United States, LTC policies are lopsided, with the responsibility for LTC provision primarily placed on the elder's household. As life expectancy lengthens and LTC becomes increasingly expensive and complex, this imbalance creates financial and social burdens for many families.

LTC policies for older persons have also been characterized as a political, incremental process with unpredictable outcomes (DiNitto, 1999). This incremental LTC public policy process has resulted in a gap in available, accessible, affordable, and acceptable LTC services. The outgrowth of this process is the failure to meet the changing needs of the current older adult population. Despite a decline in the utilization of institutional LTC, current public sector policy remains highly biased toward the nursing home industry, contributing further to the current LTC policy crisis.

This chapter examines the development of federal and state policies affecting LTC, namely, nursing homes and other providers of such care. It presents relevant issues surrounding LTC vis-à-vis the political, social, and economic changes in U.S. society.

THE DEVELOPMENT OF LTC POLICY IN THE UNITED STATES

Understanding the history of LTC policy, particularly in recent decades, provides an important perspective for understanding the forces that shaped the development of the institutional LTC sector and possible considerations for current and future policy reforms. The development of major policies affecting LTC institutions in the United States has indisputably paralleled the growth of the nursing home industry. The earliest federal legislation impacting the growth of nursing homes can be traced to the Social Security Act of 1935

(Institute of Medicine [IOM], 1986). This act created a federal-state public assistance program for older persons called Old Age Assistance (OAA). The act was drafted in opposition to the use of public poorhouses, which in those days housed older adults along with petty criminals, alcoholics, orphans, unwed mothers, and persons with mental illnesses (Vladek, 1980).

Growth of Nursing Homes

Although the abolition of poorhouses was a favorable policy decision, early policies offered few publicly funded alternatives for LTC. This pattern set the stage for the current policy problems and barriers to providing sound policy solutions. Similar to the development of other social and health care policies, LTC was not immune to the failure of the public sector to supply such care for older adults, hence allowing the private sector to provide the mainstay of the LTC services we see to this day. In 1954, the amendment of the 1946 Hill-Burton Act (which originally promoted the construction of hospitals in underserved rural areas) resulted in the state providing funding to market-based nonprofit organizations for the construction of skilled nursing facilities. The construction boom was fueled by successive legislation in 1958 and 1959 that authorized the Small Business Administration and the Federal Housing Administration to aid proprietary nursing home construction and operation.

Other forces also led to the growth of nursing homes. The 1950 amendment to the OAA changed the federal funding for nursing home care from paying the recipient to paying the nursing home providers and other medical suppliers directly. Also, under the OAA, the federal government gave public income assistance to older adults in need but excluded payments to older adults in public institutions. This was purposely implemented to move the institutionalized older adult population from poorhouses to nursing homes. Both strategies assisted the growth of both voluntary and proprietary nursing homes. More important, these ideas helped shape the current delivery and payment structure of the welfare state and supported the idea of distinguishing the “deserving” from the “undeserving” for public assistance, social care, and various health plans in the United States.

In the 1980s, the role of nursing homes in LTC continued to expand as a direct result of the acute hospital care cost containment policies on both federal and state levels. Until 1983, Medicare hospitals were reimbursed on a cost-plus basis, a method that

encouraged long hospital stays. As Medicare moved to the prospective payment system (PPS) created under the Social Security amendment of 1983, hospitals were paid a flat fee for each admission based on either the admitting diagnosis or a specific surgical procedure code known as the diagnostic related group (DRG). The shift from cost-plus to flat-rate reimbursement for care motivated hospitals to reduce lengths of stay and to accelerate discharge of patients as soon as a discharge was medically feasible (Wood & Estes, 1988; Neu & Harrison, 1988). As a result, the average length of a Medicare hospital stay declined, and nursing homes took on another role as an important site for posthospital subacute care (Cohen & Dubay, 1990). Hospitals were also creating subacute care units to fill up their empty beds, for this emerging reimbursement opportunity added to the acute care reimbursements.

The phenomenon of “sicker and quicker” patients entering LTC facilities was actually a precursor to DRGs. Prior to PPS, the application of modern technology in older patients’ care management resulted in people living longer with greater care needs. Treatments such as renal dialysis, complex surgical procedures, coronary artery bypass grafting, and cancer chemotherapy are examples of medical interventions that result in older patients surviving previously fatal diseases, and nursing homes providing longer periods of care and rehabilitation. The DRGs just added to this demand for institutional LTC, and the private sector market responded once again.

Diversification of LTC Services

In recent years, however, there has been an increasing array of services besides nursing home care to support older adults and adults with disabilities. Current trends do indicate the slowing growth of nursing homes as most LTC is now provided outside the nursing home in the community and increasingly in group residential care settings (Bishop, 1999; Quadagno & Stahl, 2003). According to the census report (Hetzel & Smith, 2001), the proportion of people 65 years and older living in nursing homes declined from 5.1% in 1990 to 4.5% in 2000. The public demand for a less medicalized model of LTC prompted growth of alternative types of institutional care such as assisted-living facilities and personal care homes, which were marketed as providing a more homelike environment for older adults who did not require serious medical attention. The National Academy for State Health

Policy reported 32,886 licensed assisted-living residences with 795,391 units or beds nationwide in 2000 (Mollica, 2000). The cohort of individuals aged 75 and older are the most likely to use assisted living. If current demand for assisted living were to increase solely according to the increase in the 75 and older population, ignoring all other market factors, the number of assisted-living beds would increase from 987,000 in 2000 to more than 1,900,000 in 2030 (National Center of Assisted Living, 2001). Unlike nursing homes, which are subjected to extensive federal regulations, these newer forms of institutional LTC generally have considerable flexibility to determine the resident populations that they serve and the services they provide. Also, unlike in nursing homes, payment for care, especially in assisted-living facilities, is borne to an even greater extent by the household as opposed to the state (see Zimmerman et al., 2003, for a recent comparative study between nursing homes and assisted-living facilities).

Recent advances of facilities with more homelike environments and community-based services were also assisted by the Medicaid-covered home and community-based services (HCBS), a program established in 1981 through section 1915(c) of the Social Security Act. These services have become a growing component of state LTC systems, with most of the growth accounted for by substantial increases in the number of HCBS waivers and the beneficiaries served through waivers. The 1915(c) HCBS waiver programs allow eligible individuals to either remain in their own homes or live in a community setting, rather than an institutional setting such as a hospital, nursing home, or intermediate-care facility for the developmentally disabled. In a few states, Medicaid use of preadmission screening along with these waivers is beginning to divert individuals away from nursing homes as the dominant means for providing LTC to older adults under Medicaid. Every state except Arizona operates at least one such waiver for older adults (see O'Brien & Elias, 2004, for further discussion on Medicaid HCBS programs).

An HCBS-like program provided under a unique capitated managed care environment is the Program of All-Inclusive Care for the Elderly, better known as the PACE program. Authorized under the Balanced Budget Act (BBA) of 1997, PACE is financed by both Medicare and Medicaid and is provided by not-for-profit or public entities. Currently, there are 25 approved PACE program sites modeled on the system of acute and long-term care services developed by On Lok Senior Health Services in San Francisco, Califor-

nia. PACE programs feature a comprehensive medical and social service delivery system, including all Medicare and Medicaid services provided by that state. At a minimum, a PACE program must provide an additional 16 services, including social work, drugs, and nursing facility care. Minimum services that must be provided in the PACE center include primary care services, social services, restorative therapies, personal care and supportive services, nutritional counseling, recreational therapy, and meals. When an enrollee is receiving adult day care services, these services also include meals and transportation. Participants must be at least 55 years old, live in the PACE service area, and be certified as eligible for nursing home care by the appropriate state agency.

Despite the noticeable presence of alternative forms of institutional and community-based LTC, the nursing home industry continues to hold back the growth of its competitors. This is largely due to the prominent role that the government has played in nursing home construction and continues to play as the principal payer for nursing home care (a topic covered in detail later in this chapter). Current policies impacting LTC institutions, including those affecting other formal LTC services, are significantly shaped by nursing home facility providers, who have become a strong political interest group in the United States. This political and legislative influence has resulted in a nursing home-dominated LTC system in the United States. The reason for this influence is twofold: (1) because LTC is too expensive to operate without federal help and (2) because the nursing home lobby has become a strong voice in nursing home funding and other policies (Kane, Kane, & Ladd, 1998). This influence overshadows the attempts of other LTC providers and elder care advocates to weaken the influence of the strong nursing home lobby. Hence, for many years, the nursing home industry continued to hinder the growth of other types of institutional care because federal laws and regulations have favored nursing facilities over others (see Kane et al., 1998, for further discussion).

KEY ISSUES SHAPING INSTITUTIONAL LTC POLICIES

Decreasing Use of Nursing Homes

There is a general consensus regarding the definition of LTC, as captured in the report prepared by the U.S.

Senate, Special Committee on Aging (2000), which describes LTC as follows:

It [long-term care] differs from other types of health care in that the goal of long-term care is not to cure an illness, but to allow an individual to attain and maintain an optimal level of functioning. Long-term care encompasses a wide array of medical, social, personal, and supportive and specialized housing services needed by individuals who have lost some capacity for self-care because of a chronic illness or disabling condition.

The need for LTC is often measured in terms of the extent to which an older adult requires assistance or supervision in performing life tasks. These include basic *activities of daily living* (ADLs), such as bathing, dressing, toileting, or eating (Katz, Ford, Moskowitz, Jackson, & Jaffe, 1963), and *instrumental activities of daily living* (IADLs), which are activities related to independent living and include preparing meals, managing money, shopping for groceries or personal items, performing light or heavy housework, and using a telephone (Lawton & Brody, 1979). Currently, the majority (1.5 million, or 90 percent) of nursing home residents are older adults (65 years and over). The majority of these older persons are chronically ill and have difficulty in their physical and cognitive functioning, requiring dependence for an average 3.9 out of 5 ADLs (Jones, 2002; American Health Care Association, 2003).

Past studies have predicted increasing institutional LTC use by older adults as disability rates increased (Kemper & Murtaugh, 1991). Recent data, however, show that disability rates have decreased, overturning earlier predictions. Changes in the disability rates among older persons are certain to affect the demand for institutional LTC. Using data from the National Nursing Home Survey (NNHS), Redfoot and Pandya (2002) report that nursing home utilization among older persons, using age-standardized terms, declined by one fourth (26%) between the earliest wave of the NNHS (1973–1974) and 1999. In addition to the decline in disability rates, Redfoot and Pandya (2002) surmised that demographic and social changes may have influenced the substantial decline in utilization of institutional LTC among persons 75 years and older. These changes are as follows:

- Improved health and longevity outcomes due to better socioeconomic status (e.g., occupation, education, income, and wealth) and medical advances;

- Increased availability of informal caregiver support resulting when falling mortality rates narrowed the gender ratio of the number of older adults, leading to decreased widowhood and fewer older adults living alone;
- Increased ethnic diversity among older adults requiring LTC, reflecting changing patterns of LTC service utilization, since racial and ethnic minorities are more likely to use informal support than are non-Hispanic White elders; and
- Increased availability of other forms of LTC such as assisted-living facilities, personal care homes, and home health care.

Such recent trend data should not, however, decrease efforts to improve current institutional LTC policies. Institutional LTC continues to be a critical part of LTC services and serves approximately 5% of the older adult population. Many research reports surmise that in the coming decades there will be a significant increase in the demand for LTC services, particularly as the first baby boomers reach age 85 in 2030 (Applebaum & Kunkel, 1991; Knickman & Snell, 2002; U.S. Senate, Special Committee on Aging, 2002). It is projected that by 2040, growth in the over-85 population—the population most likely to need LTC services—will more than triple, from about 4 million to about 14 million (Walker, 2002). Furthermore, among the racial and ethnic minority population, data indicated that there has been a sharp increase in nursing home utilization rates among Black elders (28.2 per 1,000 in 1973–1974 to 55.6 per 1,000 in 1999; Redfoot & Pandya, 2002). Demographic trends indicate that policymakers will find themselves faced with both the traditional LTC problems and even more complex problems created by the increasingly diverse older adult population.

Cost and Financing of Institutional LTC

Despite the decrease in institutional LTC use, the costs of this form of care continue to rise. LTC expenditures (public and private) can be expected to grow significantly to meet this demand. Institutional LTC has become increasingly unaffordable for the majority of older adults without federal and/or state assistance. For example, in 2003, the average per diem rate at a nursing home was \$181 for a private room, or about \$66,000 annually (Congressional Budget Office, 2004).

It is often mistakenly believed that Medicare, the health insurance program for adults aged 65 and older

and people with certain disabilities, covers all LTC costs. Medicare, enacted in 1965 as a component of the Social Security Act (SSA), was not originally intended to cover LTC costs. From the outset, Medicare coverage has focused on acute, episodic illness rather than chronic disease management and LTC. However, with the increased need for LTC, subsequent Medicare benefit amendments were made to cover some aspects of LTC. Currently, these LTC benefits are as follows:

- Medicare nursing home coverage: The beneficiary must spend at least 3 full days in a hospital and must have a physician's order providing the medical reason for needing skilled nursing care. The beneficiary's transfer from a hospital must occur within a certain period. Payment includes 20 days of care at a skilled nursing facility at full cost, and the difference between the amount above \$109.50 per day (in 2004) and the actual cost for another 80 days.
- Medicare home health care: The beneficiary must require postacute care (such as recovery from joint replacement) and/or care for chronic conditions (such as congestive heart failure), be homebound, and require intermittent skilled nursing care, physical therapy, or speech therapy. In addition, the beneficiary must be under the care of a physician, and the home health services must be furnished under a plan of care ordered and periodically reviewed by a physician. Payment includes part-time or intermittent skilled nursing; physical, occupational, and speech therapy; medical social services; and home health aide visits. There are no annual or lifetime limits on home health care coverage as long as the beneficiary continues to meet the eligibility criteria. Under the Home Health Prospective Payment System (HHPPS), a national standardized home health episode payment, adjusted for case mix and wage index, is up to 60 days. Other types of payment adjustments are also available for episodes with four or fewer home health visits (low utilization payment adjustment, LUPA), certain intervening events that give rise to a partial episode (PEP adjustment), and significant change in condition (SCIC). In certain cases that exceed a specific cost threshold (an outlier), payment adjustment is available up to 5 percent of total home health payments (Center for Medicare and Medicaid Services [CMS], 2004).

Home health care coverage was introduced to prevent older adults needing LTC from entering costly

nursing homes. The resultant boom in home health care visits and payments by Medicare has become a national concern. To contain these rising expenditures, Congress passed the Balanced Budget Act (BBA) of 1997 and the Health Insurance Portability and Accountability Act (HIPAA) of 1996, reasserting that Medicare coverage is available only for acute-care recovering patients. In 1997, Medicare adopted the interim payment system on the projected 1999 prospective payment system (PPS), further restricting home health care eligibility and reimbursements only for homebound patients. Although containing increasing Medicare expenditures remains a major concern, there has been a rise in complaints from the home health industry that the PPS rates are not covering the actual care given. Currently, Medicare continues to struggle as it tries to be the source of help for chronic, nonimproving, and homebound LTC recipients while containing the rising costs to the taxpayer of providing services.

Today, federal financing for LTC is more available for institutional LTC rather than home health care. The current financing of institutional LTC is dominated by Medicaid, the means-tested health coverage program for low-income persons. Low income, however, is only one test for Medicaid eligibility; assets and cash-redeemable resources are also tested against established thresholds (U.S. House of Representatives, 2004). Medicaid funding comes through a general tax revenue of federal and state funds. In addition to Medicaid, other federal and state programs also supplement LTC in the United States. These programs were created under federal legislations including the Social Security Act (Medicare), the Older Americans Act, the Rehabilitation Act, and Social Services block grant, as well as, state-legislated programs. Finally, private LTC insurance is available in the private sector for those who can afford it.

Combined with Medicare policy, Medicaid-related policies contribute to nursing homes' dominance of the U.S. LTC system (51.4%) over all other providers of Medicaid-funded LTC services. This is partly because eligibility requirements for Medicaid coverage of nursing home care are more generous than those for programs covering the medically indigent. These eligibility requirements are as follows:

- Medicaid nursing home care: The recipient must not have an income above 300% of the Supplementary Security Income (SSI) standard. (Note: A spouse of a nursing home resident living at home is also allowed to reserve a large portion of avail-

able income and assets, under the “spousal impoverishment laws.”)

- Medically needy option in Medicaid: Many states allow even higher incomes for covering nursing home care under the medically needy option in Medicaid; if a person’s income is above 300% of the SSI standard (\$1,692 in 2004), but below the nursing home charges, Medicaid will pay the difference if a state has added this option to the medically needy program.

In 1997, more than half of U.S. nursing home residents were poor enough to qualify for Medicaid coverage (Congressional Budget Office, 2004), resulting in a substantial societal burden: The public share of payments rose to 64% of overall payments (\$66.1 billion), with Medicaid paying 49.3% (\$50.9 billion). Policymakers are faced with the challenge of how to reduce the public (i.e., taxpayer) burden as profound financial burden of LTC looms large with changing demographics.

Access to and Disparities in LTC Service Delivery

Existing policies fail to address the lack of coordination of LTC services, largely because of the strong presence of the nursing home industry in the policy-making process. The industry’s influence prevents other similar services from replacing nursing home care or filling in gaps in the continuum of informal and formal LTC services. In recent years, LTC policies have evolved that do impact the distribution of different types of residential care, such as assisted-living facilities, intermediate nursing homes, and life care communities servicing older adults. The conception of LTC has steadily encompassed more types of services that, alone or combined, allow older adults to live in a noninstitutionalized setting or to remain in their own home. These services include 24-hour emergency call service, home health care, homemaker services, hospice programs, respite care, home-delivered meals, transportation, adult day care, home health aides or visitors, swing beds, family patient education, referral programs, and equipment rental. The boundaries between nursing homes and other types of care remain blurred as new and improved models of care are created and fragmented reimbursement mechanisms linger.

The majority of these services are extremely expensive, especially when the increase in longevity and morbidity in older adults render service need over a

longer period of time. Insurance coverage and support toward payment for these needed services remain limited, with long-term financing and provision continuing to heavily rely on provision of care by the elders’ households. Further, federal and state funding, largely through Medicaid, is available only to those who have impoverished themselves after spending down their cash assets. Because the majority of older adults and their primary caregivers eventually can no longer pay privately for LTC, Medicaid has inevitably become the largest payer.

The uneven distribution of service delivery and inequities in LTC public and private sector coverage both contribute to the lack of care coordination, which often divides the LTC population into haves and have-nots, resulting in large disparities in LTC service delivery. Low-income older adults tend to populate licensed nursing homes, since Medicaid reimburses skilled, intermediate, and custodial (basic) nursing care. The asset requirements of Medicaid eligibility often cause extreme financial strain on older adults and their families, who inevitably spend down to become eligible for Medicaid coverage of nursing home care. This is especially so for older women, racial and ethnic minorities, and middle-income households with few resources. In contrast, older adults who can afford to pay privately for LTC are more apt to populate assisted-living facilities, where residents pay out of pocket. Assisted living is largely not affordable for moderate- and low-income persons aged 75 or older, unless they disposed of their assets and spent them down to supplement their income (Hawes, Phillips, Rose, Holan, & Sherman, 2003). Few elderly persons had incomes sufficient to cover even the basic monthly charge in the average assisted-living facility (Hawes et al., 2003). This is true with the older female population, which is contributing to the higher than proportional use of health and LTC dollars due to a combination of higher life expectancy, lower economic status, higher incidence of chronic illness, and, often, lack of spousal caregivers (Blackburn & Chilman, 1987).

Quality of Care in Institutional LTC Settings

The issue of quality of care in LTC institutions has always been one of the important foci of LTC policy. In the 1950s, horrifying news of deaths of residents due to fire in out-of-date buildings and facilities with low standards made front-page news. This prompted many national studies, such as the 1955 study by the

Council of State Governments. The nation learned that the majority of nursing homes had low standards of service and relatively untrained personnel; the first attempt to create nursing home standards by several participating states took place shortly thereafter (IOM, 1986). These prompted further standards through increased federal financial involvement in nursing home services and new construction. However, early nursing home standards were vague as to what the minimum criteria of care provision or enforcement procedures should be. This led to great variability in standards of quality and enforcement approaches across states. It did, however, result in closure of a number of nursing homes that could not meet the new standards, and some other homes demolished their old facilities and built new ones.

By the 1960s, regulatory policy affecting nursing homes had evolved from a limited focus on safety to more elaborate state and federal health standards. This change, which was an outgrowth of the shift in service focus to residents with more complex medical needs and greater disability, resulted in increased regulatory standards focusing on competency in clinical care, as well as on safety and fire regulations. Current clinical problems that require close monitoring of care include malnutrition, incontinence, infection, overmedication, dehydration, decubitus ulcers, and depression, among others. Quality of life and residents' rights (lack of privacy, lack of preferred meal choices, and impolite staff members) are also critical components to be considered in nursing home care quality and standards.

Controversy over proposed changes in nursing home regulation led Congress to commission a study, to be performed by the Institute of Medicine (IOM) Committee on Nursing Home Regulation (IOM, 1986), on how to improve the quality of care in nursing homes. Many of the recommendations for changes in the quality regulation system made by the IOM committee were passed into law as part of the Omnibus Budget Reconciliation Act of 1987 (OBRA-87) and implemented in 1990 and 1991. One of the most important recommendations was to shift the focus of nursing home regulations from assessment of process and structure to a more resident-centered and outcome-oriented approach. The committee recommended the development of a national information system on residents that would allow development of outcome norms and integration into the quality assurance process. As a result of the law, the Resident Assessment Instrument (RAI), which includes a standard assessment instrument and the Minimum Data Set (MDS, with newer versions known as MDS 2.0)

were developed (Feldman & Boulter, 1991). Completion of the MDS has been mandated for all Medicare- and Medicaid-certified nursing homes.

The federal government does not establish standards for new forms of institutional care such as assisted-living facilities. Most states license and regulate assisted-living residences, and an increasing number of states place Medicaid-eligible adults in assisted-living residences as an alternative to traditional placement in a nursing home. This trend has led many to speculate that the federal government will become increasingly involved in setting minimum standards of care in residences electing to participate in the federal-state Medicaid program. Motivated in part to delay federal oversight and regulation, national associations representing selective areas of the LTC industry have increased self-regulation efforts. According to the U.S. General Accounting Office (GAO) report (2004), assisted-living residents sometimes need help to pursue complaints against their providers, especially when faced with an involuntary discharge. LTC ombudsmen are available in all states, but nursing home residents claim most of their attention.

Although care has improved greatly from the era of poorhouses, quality of care continues to be a nursing home issue to this day (IOM, 1986, 2001; Kane, 2003; Quadagno & Stahl, 2003; Wiener, 2003). Poor care and elder abuse can result from understaffing, lack of proper training for staff members, and poor maintenance of the facilities. Consumer advocacy groups in California, Michigan, Illinois, Kansas, and other states are developing quality guides to help consumers choose nursing homes. These efforts generally rely on formal complaints and deficiency statements from the federal and state certification survey. The inclusion of outcome measures is rare, but staffing and ownership information is more common. In 1995, *Consumer Reports* ranked facilities in nursing home chains based on federal deficiency statements (Consumer Union, 2003). In addition, many state agencies publish consumer guides that include general information about nursing homes, but these do not usually include specific information about quality.

THE FUTURE OF FINANCING, ORGANIZING, AND DELIVERING INSTITUTIONAL LTC SERVICES

Current policy debates and research surrounding LTC have focused on issues related to its increasingly complex financing, organizing, and delivery of a spec-

trum of services and products over a longer period of time (Kemper, 2003; Quadagno & Stahl, 2003). Currently, both the public and private sectors play a role in financing LTC. Nursing homes are funded by private insurance, other private funds such as charitable or philanthropic funds, government (federal and state), and resident out-of-pocket payments (private pay). Financing LTC has progressively become a major policy issue as costs continue to rise; policy discussions continue on how to alleviate the burden on both public and private budgets.

Theoretically, states are required to provide LTC services to older adults. However, current economic growth rates are not likely to support public funding at the current percentage levels, much less the substantially increased ones that are projected. As the baby boomers reach old age, there will be greater fiscal pressure on the public programs (primarily Medicaid) that pay for most institutional LTC. To make matters worse, many private health insurance plans continue to have relatively limited LTC coverage, which keeps pressure on the public and household sectors to pay institutional LTC costs.

These pressures suggest that new ways of financing and delivering LTC services need to be considered today. Current debates focus on three major approaches:

- Reducing the number of people eligible for Medicaid coverage and limiting Medicare's home health care benefit.
- Altering the incentives that encourage people to substitute Medicaid for private LTC insurance. In recent years, private LTC insurance policies have become more comprehensive. Most private LTC insurers cover home health care, respite care, adult day services, assisted living, personal care, and hospice care. Some companies offer policy innovations that include reimbursement of family caregivers, payments for family caregiving training, and the option to receive a cash benefit that consumers can use for any purpose (AARP, 1999). The problem with private LTC insurance is that the majority of plans that provide meaningful coverage and appropriate consumer protections are relatively expensive and thus unaffordable for many people.
- Expanding publicly financed LTC insurance. This includes the expansion of Medicaid by broadening the eligibility criteria, creating more comprehensive LTC coverage under Medicare, or creating tax incentives.

The prospects of the first two policy changes being realized are bleak amid the current policy environment. As for the latter, the HIPAA of 1996, which amended the Internal Revenue Code, clarified the tax treatment of LTC insurance, out-of-pocket expenditures for LTC services, and "living benefits." Some of the major provisions of HIPAA include deductions for qualified LTC expenses, including LTC insurance premiums, as long as combined medical expenses and outlays for LTC services and supports exceed 7.5% of adjusted gross income. In addition, employers can offer LTC insurance as a tax-free employee benefit; qualified living benefits are no longer taxable. Additional public sector LTC incentives are found at the state level. As of 2002, a total of 24 states provide either a tax credit or a tax deduction more generous than that allowed at a federal level to purchasers of private LTC insurance (AARP, 1999). However, according to AARP (1999), almost half of older adults will not qualify for the federal tax deductibility provision because they have insufficient incomes to owe taxes. Many others may not have sufficient deductions to justify itemizing. These tax changes are, however, good examples of incremental policy change designed to redistribute the public, private, and household sector responsibilities for LTC payment.

Public-private partnerships have also sprung up in policies where Medicaid modifies its asset test for people who buy LTC insurance covering a specified amount of LTC services, such as 2 years of nursing facility coverage. People still in need of services and supports after using all their insurance benefits would be eligible for Medicaid without having to spend down a comparable amount of their assets. Some programs waive the asset requirement entirely for people who privately insure their care in a nursing home for a specified period.

Such efforts, however, often become engulfed in ideological debates about whether a social insurance or a private insurance approach is best (Meiners, 1996; Weiner & Rivlin, 1988). This debate centers on a conflict of values and beliefs about the appropriate role of the federal government in the financing and provision of social services. Documentation indicates that the baby boom generation is likely to be better educated and more financially secure than previous generations of older adults. Whether these individuals have factored financing for LTC into their retirement planning, however, is not clear. As Americans struggle to reconcile the paradoxical views of their welfare state, that is, self-sufficiency or group sufficiency, LTC will continue to be built on the basis of these cross-pres-

tures (see Hecló, 1986, for a discussion on the two views of the U.S. welfare state).

THE ROLE OF SOCIAL WORK IN POLICIES AFFECTING INSTITUTIONALLY BASED LTC

The National Association of Social Workers (NASW) advocates the availability of services within a continuum that links all levels of LTC and addresses the physical, mental, cultural, and psychosocial health needs of the individual, family, and caregivers. The NASW (2004) continues to support the enactment of a universal, comprehensive health care system that provides affordable coverage for people of all ages and relieves individuals and families of burdensome out-of-pocket expenditures.

There is another challenge for social work. LTC policies have neglected the importance of social workers in institutional LTC settings vis-à-vis other health care professions. It is important to acknowledge and advocate for what social workers contribute to the functioning of older adults in LTC settings. Professional social work services are relevant for improving the functioning and quality of life of elders in nursing homes, assisted-living facilities, group homes, board and care homes, life care communities, hospice, and other types of institutional care.

SHARON KEIGHER

Policies Affecting Community-Based Social Services, Housing, and Transportation

82

Created in a time of rising societal concern for the poor and disadvantaged, the Older Americans Act (P.L. 89-73), Medicare, and Medicaid (Titles XVIII and XIX of the Social Security Act) were all signed into law in 1965. Together their broad national principles are the bulwark of American “aging policy.” As elders’ capacities and limitations changed over the past four decades, the OAA has remained consistent with President Lyndon Johnson’s assessment that it “affirms our Nation’s sense of responsibility toward the well-being of all of our older citizens” (Administration on Aging, 2004c, p. 1).

Today, however, three strong and contesting forces threaten this bulwark. One is the subtle influence of the Americans with Disabilities Act (ADA) of 1990 (P.L. 101-336). “Aging advocates” tentatively embrace this law, while maintaining an uncertain alliance with “younger” disabled advocates in the independent living movement. As American institutions increasingly include persons with disabilities (“just another diversity group”) and claim to provide appropriate inclusive accommodation, our judiciary is still parsing out governments’ murky responsibilities for the care of persons in communities.

Juxtaposed against this commitment to appropriate care is the Bush administration’s New Freedom Initiative, which, in the name of expanding civil rights and opportunities for persons with disabilities, is aggressively privatizing services and divesting government program responsibilities. As the Reagan administration did with New Federalism, this Bush administration is consolidating categorical programs into flexible but smaller state block grants. Federal “entitlements,” implemented with fewer federal funds, now serve fewer and fewer low-income and disadvantaged people.

The third and most potent force shaping aging policy today is the fiscal and budget policy of George W. Bush’s administration. States’ budgets had increased by 5.2% in 1999, and received 4% increases from 2000 through 2002, but “beginning in fiscal 2001, states were confronted with a fiscal situation more severe than any they had dealt with during the past 60 years. State revenues . . . collapsed, declining in inflation-adjusted terms for eight straight quarters” (National Association of State Budget Officers, 2004). States were forced to make stark budget cuts, increase taxes, and drain their reserve funds. After the events of 9/11 and the subsequent recession, states’ budgets dropped on average by 2.5% in 2003. The reserves were gone, and the IOUs had come due.

With the nation deep in a recession, in 2002 the Bush administration declared war in Afghanistan and

Iraq, spending some \$200 billion by early 2005. It also granted \$45 billion in tax cuts to benefit the wealthiest 1% of taxpayers. Together these actions dramatically reversed the federal budgetary surpluses accrued in the late 1990s and created a rationale for slashing federal discretionary assistance to states for human services. The progressive Center for Budget and Policy Priorities reported in 2004 that, “by 2009 the budget proposes to cut overall funding for domestic discretionary programs outside homeland security by \$45.4 billion—or 10.4 percent—below today’s level, adjusted for inflation. To lock in cuts of this magnitude, the Administration proposed five-year binding caps on discretionary spending” (Center for Budget and Policy Priorities [CBPP], 2004a).

These cuts will cause significant hardships for low-income persons who are older, are disabled, or have families and depend on this assistance. The fiscal year 2005 cuts to Section 8 housing vouchers could remove 250,000 households from the program. Yet the amount these cuts would save pales in comparison to the revenue losses in future years from the tax cuts. Over the next 5 years, savings from all the domestic discretionary cuts combined will be substantially less than the cost of the tax cuts just for the 1% of households with the highest incomes (CBPP, 2004b).

Within this dire political context, community services for older people may seem insignificant. Take, for example, a recent AARP housing survey, which found that 83% of older Americans express a desire to stay in their current homes for the rest of their lives. They find their homes comfortable and convenient and feel secure and independent there (AARP, 2004). However, as people age, and their health or physical abilities may decline, it is sometimes impossible to remain at home without changing living arrangements and the home itself. Social services and financial assistance to compensate for functional incapacities are essential to keeping elders “at home.” Key among these since the 1960s are a range of federal programs, already heavily supplemented by state and local governments, and elders’ own pockets, for community-based social services, housing, and transportation. And more, not less, will be needed in the future by some 76 million aging baby boomers.

Given the cost and budget pressures described here, the common theme underpinning U.S. aging policies since 2000 has been less about assisting older and disabled persons to stay in their own homes and communities and more about simply barring them from institutions (and becoming public charges) as long as (politically) possible. This chapter describes the essentials of “aging policy” in community services

for older, frail, and/or disabled adults living at home independently, and interdependently, in their communities with supportive social services, housing, and transportation. The first section highlights the broad mandates of the federal Older Americans Act (OAA), the foundation of our nation’s “aging network” of state and local social services. The second section overviews federal housing policies that benefit low-income and disabled older Americans. The third section highlights federal transportation programs benefiting older adults and their local challenges. The discussion of the OAA is particularly timely, since July 14, 2005, will mark the 40th anniversary of this groundbreaking national legislation.

COMMUNITY-BASED SOCIAL SERVICES FOR OLDER PERSONS

In keeping with the traditional American concept of the inherent dignity of the individual in our democratic society, the older people of our Nation are entitled to, and it is the joint and several duty and responsibility of the governments of the United States, and of the several States and their political subdivisions to assist our older people to secure equal opportunity to the full and free enjoyment of the following . . . (Older Americans Act, 1965)

The goals and objectives of the OAA are global, idealistic, and sometimes contradictory. A product of the federal legislative process, the act embodies compromises negotiated every seven years when it is reauthorized. As is typical with most social services legislation under our federalist system, the federal government grants aid to the sovereign states, which further subcontract with local governments to administer programs. Despite the idealism of universal rights and flexible services articulated throughout the act, its \$1.1 billion appropriation to the Administration on Aging (AoA) in 2001 paled in comparison with the \$16 billion to Medicaid for home and community long-term care. By fiscal year 2005, the AoA’s total discretionary budget has grown to \$1.376 billion, a 9.9% increase over the previous 4 years.

The Older Americans Act

The OAA is the nation’s primary vehicle for organizing, coordinating, and providing services, protec-

tions, and opportunities for older Americans and their families in local communities. The original act made its services universally available to persons aged 60 and over, while requiring states to target assistance to persons with the “greatest social or economic need.” The subtle contradiction suggests the mission conflict that has dogged “the aging enterprise” ever since (Estes, 1980). Poverty among the elderly declined from 35% in 1959 to 11% in 2002 (Federal Interagency Forum on Aging-Related Statistics, 2000) due largely *not* to the OAA but to indexing Social Security’s annual cost-of-living adjustments and to Medicare’s covering most health care for virtually all elders.

The OAA is the cornerstone of our nation’s state aging networks, facilitating the provision of home care, congregate and home-delivered meals, transportation, caregiver supports, information and assistance, health promotion and disease prevention, other community activities, and advocacy to persons aged 60 and over. The act requires elders’ participation in policy making and provision of accessible, reliable information to elders and their families for making informed decisions. Every state has a comprehensive information, counseling, education, and assistance system linking consumers to resources and services needed to remain safe in their homes and communities. Thirty-six state units on aging (SUAs) administer the State Health Insurance Counseling and Assistance Program to advocate for, educate, and counsel older consumers regarding Medicare, Medicaid, Medigap supplemental insurance, long-term care insurance, and other choices.

The OAA’s programs and services are administered and coordinated through a nationwide collaboration of federal, state, and local partners known as the Aging Service Network. This network includes the federal AoA in the Department of Health and Human Services (DHHS), 56 SUAs, 655 area agencies on aging (AAAs), 244 tribal organizations, about 30,000 local community-based service providers, and more than 500,000 volunteers across the nation. SUAs play significant policy, planning, and advocacy roles in leveraging other federal, state, and local public and private funds to support its programs.

The OAA today ensures home and community-based services (HCBS) for millions of older Americans, with 51 of the nation’s 56 SUAs administering an array of state and federally funded programs that provide such services. Thirty-three SUAs are the operating agency for one or more Medicaid HCBS waivers for the elderly. Nationally, about a third of the fund-

ing provided by the states for HCBS is derived from the OAA, with the remainder from state, other federal, and private sources. In fact, today 51 SUAs administer state-funded HCBS programs for older persons and/or younger persons with physical disabilities. Some SUAs also administer waivers for traumatic brain injury, assisted living, adult foster care, medically fragile children, and other specific populations (National Association of State Units on Aging, 2004).

Reauthorized by Congress every seven years, most recently in 2000, the OAA establishes the administrative structure and funding for the federal AOA, SUAs, and local AAAs. The states, which have key planning responsibility, designate district planning and service areas (PSAs) within which AAAs coordinate and arrange for service delivery, typically through contracts with local governments and private agencies. Forty-six states have multiple substate planning areas; 10 states operate only a single PSA serving the entire state.

Each title of the OAA authorizes specific services. Title I defines the 10 objectives in the act regarding retirement, physical and mental health, suitable housing, community-based long-term care, employment, freedoms, and protections. Title II establishes administrative responsibilities for the AoA within the DHHS and mandates the duties of its chief executive, the assistant secretary for aging.

Title III, Grants for States and Community Programs on Aging, is the most extensive and important section for social workers. Through it, social and nutrition services reach 7 million citizens each year through senior centers, home-delivered meals, congregate meals, rides, case management, personal care, homemaker and adult day care services, information and referral contacts, and other supportive services. Since 2000, it has also provided respite and other services for family caregivers (Administration on Aging, 2004a).

Title IV, Training, Research, and Discretionary Projects, supports evidence-based research on program design, competency guidelines, and cooperative agreements. Alzheimer’s demonstration grants, added in 1992, assist states in developing innovative models for serving individuals with Alzheimer’s disease and their families.

Title V, the Senior Community Service Employment Program (SCSEP), provides part-time employment and training opportunities for low-income adults aged 55 and older. These programs, unlike those under the other titles, are administered by the

U.S. Department of Labor. Title VI provides grants for Native Americans (Indians, Alaska Natives, and Native Hawaiians) for supportive and nutrition services (comparable to Title III) to 241 tribal and Native organizations, and 2 organizations representing Native Hawaiians.

Title VII, created in 1992, established elder rights protection systems for the prevention of elder abuse, neglect, and exploitation. In 2000 this title incorporated the long-term care ombudsman programs and state legal assistance development, to strengthen all three legal advocacy programs. Most states have also used their own general revenue to expand these programs beyond the provisions of the OAA. For example, many states have also funded prescription drug assistance programs to offset the costs of purchasing medications. Thirty-eight have established some type of state program to provide pharmaceutical coverage or assistance to low-income elderly and disabled persons ineligible for the state's Medicaid waiver program. Most states provide information and assistance, and administer program funds and oversight. Most states are coordinating the new national pharmacy discount cards and have recently assumed additional duties for the Medicare prescription drug cards as well.

Home and Community-Based Services

In 2000 the OAA added provisions to strengthen its community-based aging programs. As part of the president's New Freedom Initiative, aging and disability resource centers have been jointly funded by the AOA and Centers for Medicare and Medicaid Systems as local collaboratives. By integrating information systems throughout different levels of government and enhancing access for individuals seeking long-term care services, these centers cross-reference information from local centers for independent living and AAAs. The AOA and the Centers for Disease Control and Prevention are also jointly funding state grants to link SUAs and state health departments in developing evidence-based state health promotion initiatives to improve the physical activity, health, and quality of life of older persons.

A new concept, consumer direction in care, evolved in the 1990s to describe programs of services offering maximum choice and control to persons needing help with daily activities, particularly those who qualify for public benefits, especially Medicaid. Offering a range of approaches permits users to choose their preferred services, when and how they will be delivered, and who, among professionals,

neighbors, friends, and family members, will provide them. A plethora of recent federal initiatives are seeking to eliminate barriers to community living by enhancing consumer choice in care planning. Since 1998, the cash and counseling demonstration projects (funded by DHHS and the Robert Wood Johnson Foundation) have been testing the use of a cash benefit for Medicaid consumers to purchase their own personal and attendant care. These quasi experiments have been successful in Arkansas, Florida, and New Jersey, and 10 new state demonstrations were being added in 2004 (Mahoney, Simone, & Simon-Rusinowitz, 2000).

Building on these agenda, the president's New Freedom Initiative is piloting a whole raft of Real Choice Systems Change demonstration grants, funding nursing home transition, personal assistance services, Money Follows the Person, quality assurance/improvement, and broader systems change grants. More than 22 states are participating in these initiatives so far. A collaborative clearinghouse Web site (www.hcbs.org) provides up-to-date information on these activities in the states with federal agencies' support.

Together these various initiatives suggest an elder care system gearing up to serve the "age wave" of baby boomers expected to need long-term care in coming decades. More private market solutions are developing and being automatically incorporated throughout the aging network. On the one hand, this may be quite appropriate, given the improved level of private resources available to older people today. On the other hand, the entrepreneurial momentum stimulated by many aspects of the president's New Freedom Initiative is privatizing the decision-making processes even within publicly funded programs. Indeed, emerging hybrid programs (public-private partnerships) are giving middle- and high-income persons more choices, without much concern raised that means-tested government services for low-income elders—the 40% who are single, not homeowners, and have only Social Security for income—do not protect them sufficiently.

The Olmstead Decision: The Supreme Court's Landmark Ruling on Community Integration of People With Disabilities

A key impetus toward consumer direction was congressional passage of the Americans with Disability Act (ADA) of 1990. But implementation of that act remained moribund on the rights of the severely dis-

abled until 1999, when the U.S. Supreme Court held in *Olmstead v. L.C.* that under the ADA, people with disabilities should be served in the most integrated settings possible—their own communities.

The case of *L.C. and E.W. v. Olmstead* was brought in 1995 by the Atlanta Legal Aid Society on behalf of two women with mental retardation and mental illness held in a state psychiatric hospital. The hospital's treating professionals all agreed that the women were appropriate for discharge into community programs, but slots were not available to them.

The state of Georgia asked the Supreme Court to decide “whether the public services portion of the federal ADA compelled the state to provide treatment and habilitation for mentally disabled persons in a community placement, when appropriate treatment and habilitation could also be provided to them in a State mental institution.” The case was significant because it hinged on the meaning of a U.S. Justice Department regulation (28 C.F.R. § 35.130(d)) enforcing Title II of the ADA that said: “A public entity shall administer services, programs, and activities in the most integrated setting appropriate to the needs of qualified individuals with disabilities.” The Justice Department had interpreted this regulation as requiring community placement of institutional residents when the state's own treating professionals have recommended such placement.

In allowing the women's right to community placement, the 11th Circuit Court held that “by definition, where, as here, the State confines an individual with a disability in an institutional setting when a community placement is appropriate, the State has violated the core principle underlying the ADA's integration mandate.” A final settlement of the case was reached on July 11, 2000. In upholding the circuit court's ruling, the Supreme Court set a very high standard for states to serve disabled persons in community and other integrated settings and made attainable a goal long sought by disability rights advocates.

Five years later, and 14 years since passage of the ADA, some believe our nation has made scant progress in this area. Ira Burnim, legal director at the Bazelon Center for Mental Health Law (one of the case's cosponsors), bemoans the meager progress made since then in mental health:

Budget pressures have closed psychiatric hospitals across the country, but few appropriate community services have been adequately funded to help people with mental illnesses live successfully in the community. Instead, states have “trans-

institutionalized” people with mental illnesses to settings as outmoded, isolating and inappropriate as the facilities they were meant to replace. Increasing numbers of people with psychiatric disabilities now find themselves in large board and care homes, “adult homes,” nursing homes, and other institution-like settings. Thousands wind up in jail or prison because chronically underfunded community mental health systems fail to provide meaningful support.

Burmin believes individual lawsuits continue to be required to combat persistent segregation of people with mental illnesses (www.bazelon.org/olmstead).

Aging advocates across the country have been increasingly supportive of the goals and work of disability rights advocates. The directors of the SUAs are working with the Bush administration to develop a more definitive focus on older adults in the New Freedom Initiative, supporting the systems change grants and implementation of the *Olmstead* decision. Dozens of national organizations are encouraging the administration to issue a new executive order directing all federal agencies to review existing policies that create barriers to community living for older adults and recommend changes. Federal policy changes that enable states to incorporate consumer direction into their HCBS programs, including efforts to integrate Medicare- and Medicaid-funded services, will continue to generate controversy as long as true expansion requires public funds.

Social Services Block Grants (Title XX of the Social Security Act)

Title XX was added to the Social Security Act in 1975, in response to runaway federal spending under Title IV of the Social Security Act during the Nixon administration. A series of political deals had allowed Republican governors in major states to spend their Title IV grants, an open-ended source of federal funds, for social services provided in state institutions as varied as prisons and public schools (Derthick, 1975). Title XX put on the brakes, creating a new capped formula grant program. It was designed to complement the federal Community Development Block Grants to low-income communities with social services. Title XX allocated \$1.8 billion to the states, enabling each to provide social services it found best suited to the needs of its residents. Services had to be directed to one of the following five goals:

1. Prevent, reduce, or eliminate dependency;
2. Achieve or maintain self-sufficiency;
3. Prevent neglect, abuse, or exploitation of children and adults;
4. Prevent or reduce inappropriate institutional care; and
5. Secure admission or referral for institutional care when other forms of care are not appropriate.

In 1981 the Reagan administration made Title XX one of the first block grants to states under its New Federalism reforms, capping the federal allocation. Congress soon tired of appropriating annual increments of general-purpose revenue for block grants that could not easily prove their national impacts.

Federal Title XX still funds states and five territories for “the proper and efficient operation of social service programs.” Each state develops its own plan, details the type of activities and individuals to be served, and files the plan with DHHS. Federal funds are allocated to states according to population, and state matching funds are no longer required. In its 30 years, Title XX funding has declined relative to inflation, with total federal expenditures currently capped at \$2.8 billion annually. While the extent to which older adults benefit from Title XX services is unknown, advocates need to monitor their state’s planning process to assure that older adults receive their “fair share” of services.

Ultimately, the most critically important community-based social services for older Americans have distinct limitations. The most vital ones, medications and in-home personal care, are the most strictly means tested. Social workers are often faced with the challenge of using social services to fill gaps in critically needed personal income and community infrastructures (Lipsky & Smith, 1989). One of these, housing, will be discussed next.

HOUSING POLICIES FOR AGING COMMUNITIES

Community planning for older individuals and families requires consideration of a wide range of needs beyond the control of individuals. Adapting community infrastructures to the needs of older users involves consideration of income disparities, geography, zoning, housing stock, transportation patterns, availability of financing sources, and other public policy concerns. Demographic data on the personal living arrangements, household configurations, incomes, wealth, and trans-

portation needs of older persons are particularly important for community planning. New housing where it can sustain social support and “naturally occurring” relationships that are often the very reason older persons choose to remain in their communities.

Currently well over two thirds of the noninstitutionalized older population own their homes, the vast majority mortgage free (U.S. Bureau of the Census, 2001). For most of these individuals, the home is their primary and sometimes only asset. Unfortunately, single women and economically disadvantaged elders are frequently forced out of their homes by rising property taxes and their inability to make repairs, afford structural modifications, or even buy special adaptive equipment when they become disabled. And renters are even more challenged, since,

the number of affordable rental units for the aged is steadily declining and has been at a crisis level for some time. Government-subsidized housing for the poor (section 202 and section 8: public housing and rental assistance, respectively) has conspicuously failed to meet growing demand. (Olson, 2003, p. 103)

The largest government housing program by far is the federal tax deduction allowed on mortgage interest and local property taxes. These “tax expenditures” allowed income deductions—taken almost entirely by middle- and upper-income homeowners—for mortgage interest of \$43 billion and local property taxes of \$42 billion in 2002, or \$85 billion uncollected by the Internal Revenue Service (Citizens for Tax Justice, n.d.) After that, federal housing policy gives priority to low-income elderly who need assistance in paying rent and elderly homeowners who have difficulty paying property taxes or maintaining their property or who need to adapt their homes to remain there safely. For some of the latter, government-insured loans can help them use the equity in their homes to finance needed services and home modifications or to develop alternative options. Similarly essential to low-income renters and homeowners are government programs that help offset the costs of home energy use and weatherizing property. As we shall see, however, these subsidies are barely discernible in the federal budget.

This section describes the range of provisions that assist elders in finding, obtaining, and maintaining suitable, accessible, affordable, and safe housing, including (a) publicly funded subsidized housing, (b) property tax relief, (c) home equity conversion pro-

grams, (d) creative alternative housing, including home modifications and assisted living, and (e) home energy assistance programs.

Subsidized Housing

The federal government addresses the housing needs of the low-income elderly, primarily through the Department of Housing and Urban Development (HUD) and, in rural areas, the Farmers Home Administration (FmHA) of the Department of Agriculture. By the end of the 1980s, more than 1.9 million households containing persons aged 65 and older were living in low-rent housing subsidized in some way by the federal government. This represented 9.6% of all elderly households and 43% of all low-rent federal housing, although the elderly constituted only 22% of all households (U.S. Congressional Budget Office, 1988; U.S. Senate, 1991). Compared with the rest of the population, the elderly were quite overrepresented in subsidized housing (Golant, 1992, p. 117), and they continue to be today.

This “overrepresentation” occurred because elders traditionally have had lower incomes than other renters. From their very inception, several federal housing programs targeted assistance to older people and retirees. Residents who moved into subsidized housing when construction was at its peak in the 1970s have been “aging in place” since then, and the needs for assistance of today’s longtime older residents of public housing have increased accordingly. This is the rationale for local demonstration partnerships between AAAs and housing authorities to upgrade facilities and create some services on-site for the first time.

The 1980s and 1990s saw a dramatic turnaround in federal housing priorities, however, away from increasing the stock of quality affordable housing through public construction toward the use of housing cost supplements in the form of certificates and Section 8 vouchers. Real expenditures resulted from the new Stewart McKinney Homelessness Assistance Act.

Low-Rent Public Housing

Established by the Housing Act of 1937, the first federal public housing program included construction for low-income elderly and nonelderly persons. Tenants must have very low incomes (50% or less of a locality’s median income) and spend 30% of their net income on rent and utilities. This housing is

owned, operated, and maintained by some 3,000 local nonprofit public housing authorities, typically governed by community members appointed by local governments.

In 1990, about 192,000 (of 482,209) public housing apartments were occupied by the elderly, or about 40% of the program’s total inventory. Today openings typically occur only when a unit is vacated, since so few new projects are being built anymore. The cap on supply reflects the federal policy change from a “production-oriented, project-based” approach to rent subsidization for private market housing. The resultant decline in construction and rehabilitation of low-rent units has produced the growing gap between increasing demand for and declining supply of affordable housing, a gap that is growing wider every year. Current priorities are to sell off public housing stock, or to perform simple maintenance and limited remodeling, but with no new construction.

This shift to rent subsidization has made it more difficult to track the actual impact of federal housing expenditures. The number of households receiving aid and the federal outlays for traditional programs decreased in the mid-1980s, and the number of households assisted “may have declined” (U.S. House of Representatives, Ways and Means Committee, 2003, p. 15-Housing-1).

Section 202 Housing

First enacted as part of the Housing Act of 1959, Section 202 is one of the few programs (along with low-income tax credits and FmHA Section 515) that finances new construction of low-rent apartment projects specifically for the elderly and the nonelderly population. This program has had “a choppy legislative existence” and was actually phased out during the early 1970s (Golant, 1992, p. 127). The number of new units produced annually peaked at more than 20,000 in the late 1970s and then declined to under 10,000 a year in 1990. By then there were 218,000 units occupied by the elderly and about 12,000 nonelderly disabled. Today there are about 300,000 housing units.

Experts have long considered Section 202 one of the more successful federal housing programs serving low-income elders (U.S. House of Representatives, Select Committee on Aging, 1989), largely because of the dedicated efforts of its nonprofit sponsors. Default and vacancy rates have been very low. By 1990 about eight applicants over age 62 were on waiting lists for every unit that became vacant, and the demand for those units remains high.

Because residents were aging in place so rapidly, the 1990 Affordable Housing Act included provisions to begin including congregate dining rooms and other common spaces in Section 202 housing to accommodate the provision of services on site. It also dropped the requirement that every project include 25% efficiency apartments, which have been more difficult to lease.

Section 521 Rental Assistance Program

The Rural Rental Assistance program (Section 515) was initiated in 1962 in the FmHA to provide rental housing units or congregate housing for elderly populations (aged 62 and older) living in small towns and rural communities (towns under 10,000 and communities as large as 20,000 if not located within a Metropolitan Statistical Area). It was expanded in 1966 to serve all low- and moderate-income families, and in 1983 priority was restricted to low-income households and those in substandard housing.

Sponsors of developments may be individuals, state and local public agencies, profit-making corporations, and nonprofit organizations. Sponsors apply for insured low-interest loans (as low as 1% for up to 50 years) to construct, purchase, rehabilitate, and operate low-rent, multifamily housing projects. Approximately 200,000 (or half) of the more than 400,000 units in the program are occupied by the elderly.

Section 8 Vouchers

The Housing and Community Development Act of 1974 created the Section 8 rental program to serve all age-groups, including the elderly. Section 8 vouchers are used by individuals to supplement their renting a variety of new, already built, public and privately owned rental units. At the end of 1989 it was estimated that 48% (1,152,000) of the 2,400,000 apartments subsidized by Section 8 vouchers were occupied by the elderly (U.S. Senate, Special Committee on Aging, 1990). In 2004 the program supplemented the rents paid for about 2 million units occupied by low-income persons, and only about a quarter of eligible households received any housing assistance at all (CBPP, 2004b).

Unfortunately, one of the Bush administration's many housing policy changes on the horizon is a budget proposal to cut \$1.6 billion from Section 8 vouchers in 2005, with larger cuts to follow annually. By 2009 the proposed budget would cut \$4.6 billion below current utilization level by turning Section 8

and a whole series of other housing programs into a block grant program giving states greater discretion to set basic standards for tenants' rents. The perverse effect of this will be to favor use by more middle-income tenants, while shrinking the program by 250,000 households in fiscal year 2005, and by 600,000 in fiscal year 2009, or 30% of present support (CBPP, 2004b).

Property Tax Relief and Deferral Programs for Older Home Owners

Many states (and some counties) have property tax deferral programs, homestead tax credits, and other forms of property tax relief for persons on low, fixed incomes. Tax deferral programs basically provide a low-interest loan to cover the property tax owed in a given year, so that an individual's available income may be used for food, needed services, and medicine instead of taxes. Such assistance can make the difference in allowing elders to remain at home, especially in areas with rapidly rising property taxes.

A major problem, however, is the low benefit "take-up" rate by persons with very low incomes. Aware that the loan must be repaid, seniors are often reluctant to apply (www.ncoa.org/content.cfm). Consequently, an important role of AAA staff is outreach to and case advocacy with potentially eligible seniors, assisting them in applying for such benefits. AAAs also do class advocacy with local elected officials to establish such programs. Friendly local elected officials are sometimes amenable to waiving or deferring property taxes on an individual case-by-case basis.

Home Equity Conversion Mortgage Programs

One option available to individuals and couples who need cash for living expenses (and do not plan to leave their home to heirs) is to borrow against their home equity. Home equity conversion mortgages are offered by many private lenders, but the federally insured Home Equity Conversion Mortgage (HECM) program allows the largest loan advances and the greatest choice in how to receive the cash. Mortgages are insured by the Federal Housing Administration (FHA) of HUD. The FHA determines how much HECM lenders may loan, based on the borrower's age and the home's value. The HECM program limits loan costs, and the FHA guarantees that lenders will

meet their obligations. The funds received from a HECM can be used for any purpose, and although they are costly, they are typically much less costly than other reverse mortgages. Generally, the only reverse mortgages that are less expensive than HECMs are those offered by state or local governments, which typically must be used for a specific purpose (to repair a home or pay property taxes) and generally are available only for homeowners with low to moderate incomes.

HECM loans are available in all 50 states, the District of Columbia, and Puerto Rico. (In Texas, HECM credit line options are not available.) Eligible, current homeowners must be aged 62 or over and must live in the home as a principal residence. The home must be a single-family residence, in a one- to four-unit dwelling, a condominium, or part of a planned unit development. (Some manufactured housing is eligible, but cooperatives and most mobile homes are not.) The home must be at least a year old and meet HUD's minimum property standards, but the HECM can be used to pay for needed repairs. The owner must discuss the program with a HUD-approved counselor.

HECM loans must be paid in full when the last surviving borrower dies or sells the home, but they may also become due if any of the following occurs:

- The property deteriorates and the problem is not corrected;
- All the borrowers permanently move to a new principal residence;
- The last surviving borrower fails to live in the home for 12 consecutive months because of physical or mental illness; or
- The owner(s) fails to pay property taxes or hazard insurance, or violates any other borrower obligation.

Options for Assisted Living and Day Care Services

Most older adults today have incomes “too high” to qualify for subsidized housing; consequently, the private housing market provides options for alternative housing and housing adaptation. There remains, however, a great need for more affordable, imaginative, attractive, and functional designs. Such housing and transportation alternatives are addressed by a panoply of consumer-oriented Web sites listed at the end of this chapter, which include user-friendly hous-

ing designs and adaptations. Topics include safety, lighting, universal design, and uses for specific areas of the home. Two of the most recognized long-term care settings include traditional continuing care retirement communities and the newer form, assisted-living facilities. An overview of the types and characteristics of various kinds of supportive housing options is shown in Table 82.1.

Assisted living and other forms of supportive housing are specifically designed for those who need extra help in their day-to-day lives but who do not require the 24-hour skilled nursing care found in traditional nursing homes.

Fortunately, the trend over the past two decades has been to create a wider variety of living options that are much more homelike than the institutional facilities of the past. The Los Angeles Caregiver Resource Center provides fact sheets that provide an overview of these options and guidance in finding information and referrals. Its goal is to help find facilities that are comfortable, safe, appropriate, and affordable.

What's in a Name?

Supportive housing options vary widely in terms of size, cost, services, and facilities. The terms used to describe these options vary from state to state. Table 82.1 outlines the most common terms and the differences among them.

The list in Table 82.1 is only a general guide, since the names of housing options available in different communities vary by state. Practitioners may familiarize themselves with their own state's options by contacting their state unit on aging.

Continuing Care Retirement Communities

Continuing care retirement communities (CCRCs) are sometimes called life care communities. Entering one is usually a onetime decision, and that is the appeal. Many have large campuses with separate housing for those who live very independently, assisted-living facilities that offer more support, and nursing homes for those needing skilled nursing care. With all these types of housing on the same grounds, people who are relatively active, as well as those who have serious physical and mental disabilities, all live nearby. Residents then move from one housing choice to another as their needs change.

TABLE 82.1 Between Home and Nursing Home

<i>Names/types of facilities</i>	<i>Characteristics</i>
Personal care homes	Facilities using these names tend to be smaller (fewer than 10 individuals) and less expensive. Many are in traditional homes in residential neighborhoods. Shared bathrooms, bedrooms, and living spaces are the norm.
Sheltered housing	
Homes for adults	
Board and care	
Domiciliary care	
Adult foster care	These facilities tend to be larger, more expensive, and specifically designed for the frail elderly or persons with disabilities, emphasizing independence and privacy. Most offer private rooms or apartments and large common areas for activities and meals.
Senior group home	
Residential care facilities	
Assisted-living facilities	
Adult congregate living	These are usually large complexes that offer a variety of options ranging from independent living to skilled-nursing home care. These facilities are specifically designed to provide lifetime care within one community. Facilities within this category tend to be the most expensive option.
Continuing care retirement communities	
Life care facilities	

From Los Angeles Caregiver Resource Center.

Although usually very expensive, CCRCs have traditionally guaranteed lifetime shelter and care with long-term contracts that detail the housing and care obligations of the CCRC, as well as its costs. A wide variety of independent living units may be available: large and small apartments, cottages, cluster homes, or single-family homes. In addition to usual features, they may provide grab bars, a monitored emergency call system, and other safety features. Residents of these units are usually active older people.

Assisted-living units may be small studio or one-bedroom apartments with scaled-down kitchens. These facilities may have group dining areas and common areas for social and recreational activities. Residents typically need some assistance in daily living activities but also want some independence. Nursing home accommodations are usually furnished one-room units for two or more persons with an attached bathroom. Residents require skilled nursing care (short- or long-term) and may benefit from rehabilitative therapy to maintain or improve their abilities.

Because CCRCs are expensive, they generally are beyond the means of low- or moderate-income seniors. Most communities require an entrance fee, which can range from \$20,000 to \$400,000, and monthly payments, which can range from \$200 to \$2,500. In some places, residents own their living space; in others, the space is rented. In some communities, the entrance fee may be partially refundable within the first year or two, if a resident moves out.

Typically three different fee schedules are available, depending on how much long-term nursing care is anticipated:

1. *Extensive contracts*: unlimited nursing care and little or no increase in the monthly fee;
2. *Modified contracts*: a specified amount of nursing care, with the user responsible for payments beyond that amount; or
3. *Fee-for-service contracts*: user pays full daily rates for long-term nursing care.

Some CCRCs have specific ethnic, religious, or fraternal order affiliations and may require membership. Most require potential residents to have a medical examination, and selected preexisting conditions may cause a CCRC to deny admission. Some CCRCs require residents to have both Medicare Part A and Part B. Residents must have the resources to meet the entrance fee and monthly payments (Los Angeles Caregiver Resource Center, 2004).

Assisted-Living Facilities

Assisted living is a relatively new residential care option for individuals needing long-term assistance. It and a plethora of care options are increasingly available as substitutes for traditional care in nursing homes for individuals needing assistance with activities of daily living. Currently about 33,000 assisted-living facilities

operate in the United States, with more than 90% of the care privately funded. Although most states have Medicaid waivers that could pay for health care within assisted-living facilities, fewer than 60,000 Medicaid recipients currently reside in them. These facilities are regulated by and within states, and these regulations vary greatly (U.S. Senate, Special Committee on Aging, 2002, p. 14). Even definitions of “assisted living” vary significantly by state, sometimes including “board and care” homes or group homes (see Table 82.1).

In 2003 the Senate Special Committee on Aging asked the assisted-living industry, consumer advocates, providers, and others to work together to make recommendations about best ways to assure quality in assisted living. More than 30 organizations collaborated in producing a consensus report and recommendations (Assisted Living Work Group, 2003). Their report is now available through the American Association of Homes and Services for the Aging (Assisted Living Work Group, 2003, <http://www.aahsa-store.org/Product/Display.asp>).

A good assisted-living facility helps residents be as independent as possible while providing assistance when needed. The AARP’s checklist can assist consumers and families in selecting an appropriate assisted-living facility by facilitating comparisons among facilities. It urges consumers not to make visits and decisions alone but to talk with family and friends about this major life decision (AARP, 2004).

Adult Day Care and Services

Day care services for older adults are viable, cost-effective community-based programs that serve individuals throughout the day to help keep them living at home. There are 3,493 adult day centers in the United States serving individuals of all ages with a variety of chronic conditions such as dementia, mental retardation, developmental disabilities, mental illness, HIV/AIDS, brain injury, and physical disabilities. Twenty-one percent of these centers operate on a medical model, 37% on a social model, and 42% as a combination providing a vast array of services. Growth in the day services industry has been rapid, with 26% of current centers opened within the past 5 years. There remains a need for 5,444 new centers nationwide (U.S. Senate, Committee on Aging, 2002, p. 15).

Creative Alternative Housing, Home Modifications, and Other Resources

Frequently, widowed persons find themselves “house poor,” owning a home that is too large and costly to

maintain. Because of pressure to cover property taxes or a mortgage, or to modify the home to meet new needs, this may be the time to sell.

But if one has good reasons for staying put, a more desirable option might be creating an accessory apartment to rent out. Even without modification, when zoning permits, such housing may be ideal for either sharing a house, having boarders, or taking in older adults under foster care. AARP offers helpful guidelines for doing this, as does Jane Porcino’s popular book (1991) on creating alternative community housing. Another option is creating an accessory apartment in the home of an adult child, or an ECHO cottage, a separate housing unit in the side or backyard of the relative’s property, again if zoning allows. Either option facilitates provision of daily assistance. Home equity conversion loans can often make this arrangement quite affordable, and some ECHO cottage designs are actually portable (National Resource Center on Supportive Housing and Home Modification, 2004).

Low-Income Home Energy and Weatherization Assistance

The Low-Income Home Energy Assistance Program (LIHEAP, P.L. 105-185) allocates federal block grants to states, territories, and Indian tribal organizations to operate home energy assistance programs for low-income households. Established in 1981 and reauthorized and amended several times, the program will be reauthorized in 2005. It is administered by the Division of Energy Assistance in the Office of Community Services, Administration for Children and Families within DHHS and may be operated by any of several agencies within the states.

Funds are allocated to states according to a complex three-tier formula taking account of energy costs and state poverty levels; in fiscal year 2003 the federal appropriation was approximately \$1.8 billion (U.S. House of Representatives, Ways and Means Committee, 2003, p. 15-LIHEAP-1). States may use the funds for assistance in paying heating and cooling bills, low-cost weatherization projects, services to reduce the need for energy assistance, assistance with energy-related emergencies, and developments to leverage the funds to attract matching funds from other sources. Administration/planning costs are limited to 10% of the state’s total allotment. States may make payments directly to consumers or to home energy suppliers. Households with incomes

up to 150% of the federal poverty level may be eligible, as are persons receiving SSI, TANF, food stamps, and other means-tested assistance. DHHS performance goals currently seek to increase the percentage of recipients aged 60 and over, as well as those in the lowest-income households. Because funding for this program may derive from several federal, as well as state, sources, the state agencies responsible for it may be human services, community development, and/or housing. States are required to hold public hearings and seek public participation in developing state plans, so advocates for older adults have a special role in monitoring its implementation.

TRANSPORTATION FOR AN AGING SOCIETY

Transportation availability is intimately tied to social welfare policy and is readily seen in the competition for government dollars between mass transit systems and highway construction. Expanding or improving mass transit favors city dwellers, individuals who do not own cars, and the less well-off, whereas highway construction benefits car owners, the auto industry (and rubber and steel industries), suburbanites, and more affluent communities (Blau, 2004, p. 27). This same competition heavily influences transportation policies and provisions for older adults in local communities, and, not surprisingly, automobiles are the undisputed winners.

A recent AARP telephone survey that interviewed a national, stratified sample of 2,422 adults aged 50 and older on their transportation preferences found that 4 out of 5 usually drive, but those aged 85 and older and those with poor health or disabling conditions were substantially less likely to drive. Thirteen percent of persons aged 50 and older rely on ride sharing most of the time, and fewer than 5% rely on walking, public transportation, taxis, and community or senior vans. Fewer than one in eight respondents felt that transportation problems interfered with their ability to do necessary errands, get to appointments, or engage with others, although 5% of those aged 75 and older said they often experienced such problems (AARP, 2002).

With older adults so reliant on automobiles, it is not surprising that the AOA's first priority is to ensure that older Americans can "drive as long and as safely as possible and that alternatives are available to individuals who no longer drive." As we anticipate the largest ever group of older drivers in U.S. history, the

AoA reports that research is showing that "older persons are successfully adjusting for these changes and are driving safely well into their 70s, 80s, and 90s" (Administration on Aging, 2004b, p. 1). One explanation for this is that state driving authorities have become more flexible, as well as vigilant, requiring more frequent driving exams after certain ages and issuing more licenses with restrictions to certain geographic areas, road types, or driving conditions.

When older individuals are no longer able to drive safely, families and sometimes physicians are needed to make alternative arrangements. Suburban areas may include senior van services, taxi vouchers, medical vans, and ride-share programs. In rural areas, individuals typically have little choice but to rely on relatives and friends for rides. Public mass transportation and paratransit are typically available only in urban areas.

Since 2001, the Bush administration's New Freedom Initiative has focused some attention on improving the coordination of transportation alternatives for all special-needs populations (children, elderly, and disabled persons) at the local level. A 2003 memorandum of understanding between AOA and the Federal Transit Administration (FTA) of the U.S. Department of Transportation commits each agency to assist its respective networks in coordinating transportation services and facilitating access to them by older adults. In 2004 the FTA issued grants to help localities assess their level of coordination and develop action plans, including leveraging local funding sources, technical assistance to enhance partnerships, enhancing technologies to improve scheduling and billing, and providing consumer education. A glimpse of the FTA's "road map" for "United We Ride" can be found online in the FTA administrator's presentation to the Community Transportation Association of America (Dorn, 2004).

Capital Assistance Programs (Section 5310)

Special-needs transportation is largely funded through the FTA Capital Assistance Program for Elderly Persons and Persons with Disabilities. This program provides financial assistance to states for meeting the transportation needs of special populations where public transportation is unavailable, insufficient, or inappropriate. The Section 5310 program supplements FTA's other capital assistance programs, funding transportation projects in

urban, small urban, and rural areas. Only designated states may apply, and eligible subrecipients include private nonprofit organizations, public bodies approved by the state to coordinate services for elderly and disabled persons, and public bodies that certify to the governor that no nonprofit corporations or associations are available in an area to provide service. A typical project provides \$1 million to a state to purchase 35 accessible vehicles for use by 30 local recipient organizations throughout the state. If states do not spend their allocation in the year it is given, funds are redistributed to other states in the subsequent year.

Funds are allocated to states by a formula based on the population of elderly and disabled persons, and may cover up to 80% of the eligible project costs. This special program assistance began in 1975, distributing \$20 million to more than 1,000 private nonprofit organizations to purchase vehicles. In fiscal year 2004 the federal allocation of \$98 million funded nearly 4,000 local subrecipients, enabling thousands of persons to achieve greater mobility and independence. Unfortunately the fiscal year 2005 allocation dropped to \$88 million.

CONCLUSION

This chapter has used the federal funding framework to highlight the array of social service, housing, and transportation programs serving older adults in local communities. “Following the money” from the federal agencies through and within different levels of state and local government reveals where services come from and is essential to being an effective advocate for this age-group.

Following precedents set by Presidents Nixon and Reagan, the George W. Bush administration is striving to reduce the size of government by limiting and eliminating its responsibilities for basic human needs of disadvantaged persons. President Bush’s New Freedom Initiative is hollow rhetoric compared with his administration’s reductions in social services, housing benefits, and public infrastructure. In the name of “opportunity” and “free choice,” the New Freedom Initiative is a proxy for what was once the security of basic subsistence provision for in-home services, adequate shelter, and transportation assistance. Privatization of services, increasing user co-payments, and preference for corporate welfare are the real policy goals. This, coupled with the recession of 2001–2004 and the continuing state fiscal crises, has made social

work advocacy for basic services for the aging an urgent imperative at all levels of government today.

This chapter discusses a number of decision-making policies and proxy issues that affect the lives of older adults. The topic is a challenging one because there is little in the way of national policy on guardianship or the variety of related approaches sometimes referred to as guardianship alternatives. Each state develops its own protective service policies, and these policies are carried out by professionals at the local level, including probate judges, adult protective service workers, and health and social service providers. Given the lack of overarching national policy, we begin at the other end of the spectrum with an older adult who needs decision-making support. We use the following case example to discuss concepts that underlie protective services policies and to examine the various policy and program approaches available to social workers to meet the needs of vulnerable adults:

■ Mrs. C. is a recent widow in her early 80s. In addition to being physically frail, she has been previously diagnosed with diabetes and congestive heart failure. A concerned neighbor calls the Area Agency on Aging, and an adult protective service worker is sent to the home. The home visit reveals that Mrs. C. is unable to accurately answer questions about her age, birth date, or where she lives. Since the death of her husband she has been unable to pay her bills, keep her apartment clean, or adequately prepare food. She appears to have little in the way of assets, but she reports that she is related to the king of England and had a grandfather in Montana who willed her money. She alleges that this money, which she kept in a suitcase, has been stolen from her by the building manager along with her furniture, dishes, and personal belongings. Mrs. C. does not have a working phone. Her refrigerator has been disconnected, there is no food in her house, and she remembers eating little in recent days. Her companions are two uncaged birds and a small dog. ■

Mrs. C.'s situation illustrates a number of challenges that may involve social workers and other gerontological professionals. Given the present information, Mrs. C. appears to have little social support, few if any links to the formal service delivery system, and several complex medical and mental health problems that compromise her daily functioning and safety. It is unclear whether her apparent confusion

Policies Related to Competency and Proxy Issues

83

stems from an immediately treatable condition such as dehydration, unstable blood sugar, or a urinary tract infection, or whether she has a progressive dementing illness. Regardless of the etiology, she appears to need urgent and probably long-term assistance. A social worker may be called upon to help Mrs. C. if she is hospitalized, at discharge, or after she has returned home.

CORE VALUES GUIDING SERVICE DELIVERY TO OLDER ADULTS

One of the major challenges of developing and applying policies that both protect Mrs. C. and safeguard her civil liberties is providing the appropriate level of support without inappropriately restricting her rights of autonomy and self-determination. A fundamental approach to keep the important goal of safety from incorrectly trumping individual freedom is to apply core values that guide how protective service policies are legislated and applied (Wilber, 2000). These core values include (a) striving to offer the least restrictive appropriate alternative, (b) marshaling services to support aging in place whenever possible, (c) centering decisions to the greatest extent possible around client preferences and expressed needs, (d) drawing from the repertoire of available interventions to develop an individualized plan of treatment, (e) supporting informal caregivers, and (f) interdisciplinary communication to clinically integrate medical, social, and housing services. Ideally these policies are operationalized in the context of self-determination and person-environment fit, offering social workers appropriate tools to balance respect for the client's personal freedom with legitimate concerns about personal safety.

Protective services and decision-making interventions are designed to assist people who are unable to manage their daily affairs (i.e., unable to provide for basic necessities such as food, shelter, and clothing) and/or for those who are at high risk of physical and/or fiduciary harm. Several approaches are available depending on the individual's needs, availability of a support system, and physical and mental capacity. Sometimes this range of services is referred to as *daily money management (DMM)*, a term coined by Jack McKay, a pioneer in the field who referred to financial and decision-making services offered by social service agencies for lower- and middle-income clients. Table 83.1 provides a general outline of these interventions based on capacity requirements, appro-

priateness for the service, and complexity of problems that each can address. Before describing these approaches, we briefly explore the legal and clinical definitions of capacity.

WHAT IS CAPACITY?

In the United States, those aged 18 and older are considered to be adults and, as such, are trusted to have independent decision-making capacity. This principle means they are allowed to engage in the world using their own cognitive power and accepting responsibility for their choices. Adult decision making includes "the right to folly," which is the right to make poor choices coupled with the responsibility to live with the consequences of those choices. Sometimes, however, poor choices stem from cognitive impairment, which affects the individual's ability to make a reasoned decision. When this is a concern, capacity can be challenged in court.

The legal determination of capacity is quite specific; a court of law determines whether or not someone has capacity or competence to make "reasoned decisions." Applebaum and Grisso (1988) identified four domains to evaluate capacity: (a) to communicate relatively consistent or stable choices, (b) to understand basic information about choices, (c) to evaluate reasonable implications or consequences of available choices, and (d) to use a reasoned process to rationally weigh risks and benefits of choices. As these domains suggest, examination of capacity should focus on the process of decision making, not the decisions themselves. For example, Mrs. C.'s decision making would be questionable if she did not seek help because she believed that her relationship to the "king of England" would protect her. She might have reached the same decision not to seek help because her neighbor threatened to harm her if she called anyone. In this instance, however, her decision shows evidence of a reasoned if not altogether appropriate approach.

In contrast to a legal determination, capacity is also a psychological construct. From this perspective, the term becomes much more ambiguous than its codified legal definition. Although an extensive body of research has developed to examine standards for determining capacity (e.g., Appelbaum & Grisso, 1988; Collopy, 1988; Kapp & Mossman, 1996; Sabatino, 1996), definitive guidelines remain elusive. The problem with developing a practical definition is that capacity may be fluctuating, intermittent, and deci-

TABLE 83.1 Characteristics of Financial and Health-Related Services Available to Older Persons

Service	Capacity		Appropriateness to address risk of older person			Complexity
	Required for execution	Survives incapacity	Personal risk: high, medium, low	Financial risk: high, medium, low	Oversight / recourse	Ability to address complex financial / medical issues
Power of attorney	Yes	No	Low	Medium	Oversight by family; legal action	Medium
Bill-paying services	Yes	Not usually	Low	Medium	Agency audit; legal action	Low
Joint accounts/ joint tenancy	Yes	Yes	Low	Medium	Virtually none; legal action	Low
Durable power of attorney	Yes	Yes	Low	High	Oversight by family; legal action	Medium
Durable power of attorney for health care	Yes	Yes	Medium	Low	Oversight by family; legal action	Medium
Representative payee	No	Yes	Medium	Medium	Virtually none by federal governmental agency	Low
Personal trusts	Yes	Yes, if drawn properly	Medium	High	Internal audit, banking commissioner, legal action	High
Limited guardianship	No	Yes	High	High	Court; legal action	High
Plenary guardianship	No	Yes	High	High	Court; legal action	High

Note: These criteria assume the availability of an appropriate social support network.
 From Wilber, K. H., & Reynolds, S. L. (1995). Rethinking alternatives to guardianship. *Gerontologist*, 35, 248–257.

sion specific (Buchanan & Brock, 1986). For example, Mrs. C. might be able to make decisions about her living arrangements but not her finances. She may be clear about her affairs one day yet confused the next.

Local courts determine capacity based on state statutes, focusing their capacity determinations on one of three areas: disabling condition tests, functional behavior tests linked to disability, or a risk model based on an “essential needs” test (Sabatino, 1996). The disabling conditions test indicates that a person could be deemed incapacitated by virtue of a specific diagnosis related to cognitive impairment, such as Alzheimer’s disease. The problem with this definition alone is that it does not take into account the duration, extent, and/or severity of the illness or condition. Most states have moved away from this exclusive criterion and have added the functional behavior test to the measuring stick. The functional behavior test includes looking at a person’s functional capacity related to self-care and the management of his or her own estate. Arkansas, for example, specifies

that the appointment of a guardian is appropriate when a person has a disabling condition (physical, mental, substance abuse) to the extent that he or she lacks sufficient understanding to make or communicate decisions to meet essential requirements for health, safety, or management of his or her estate (Social Security Administration, 2004a). However, the functional test could be interpreted broadly to include activities and responsibilities that may not be within the individual’s purview (e.g., grocery shopping and meal preparation for a cognitively impaired older adult living in a retirement facility that includes these services). In this instance the third approach, the “essential needs” test, represents the most flexible interpretation of incapacity determination criteria. The essential needs test, which basically is a risk model tailored for a specific individual, focuses primarily on activities and behaviors that the individual will reasonably engage in and evaluating whether or not he or she can continue to make these decisions and/or execute these tasks. States laws in California,

Illinois, and Nebraska are based on this perspective. It is important to note, however, that the interpretation and execution of guardianship laws reside with the presiding judge, who typically serves in county probate court.

APPLYING SUPPORTIVE AND SURROGATE POLICIES AND PROGRAMS

Social workers and other professionals must understand the relevant policies in their states. They must also assess how these policies apply to each client's specific needs. Identification of Mrs. C.'s specific needs involves assessing what types of decisions she needs to make, what type of support is appropriate and available, and how and by whom decisions will be carried out. Collopy (1988) and Smyer (1993) distinguish between decisional capacity, the ability to *make* a reasoned choice, and executional capacity, the capacity to *act* on the choice. This distinction is important for choosing the appropriate level of intervention—supportive decision making or surrogate decision making. Individuals who retain decisional capacity but need support to act on their decisions can be served through *supportive decision-making* interventions. In contrast, *surrogate decision-making* support is most appropriate for those who have lost the capacity to make reasoned decision based on legal criteria and need a proxy to make decisions on their behalf.

Supportive Decision Making

Supportive decision-making services allow Mrs. C. to make decisions with help from another party to carry out her decisions through assistance with banking, bill paying, and budgeting. For example, after she is medically stable, Mrs. C. may be capable of making decisions about how to use her resources and where to live, but she may need help implementing these choices. She might not be able to organize her bills or understand medical claim forms, but she can agree on the amount she wants to pay for each item, sign checks, and mail paid bills. To illustrate, let us assume that Mrs. C. is treated in the hospital and her condition greatly improves so that she is able to return home. Hospital social workers link Mrs. C. to a community case management agency that offers DMM services to help her manage household finances. It becomes clear that Mrs. C.'s husband had managed the finances throughout their marriage, and Mrs. C. has

no experience or knowledge in financial matters. Within the realm of supportive decision-making services, DMM includes (a) offering education and advice to Mrs. C. so that she can learn how to manage her financial affairs; (b) ensuring that she receives benefits to which she is entitled, using tools such as the National Council on the Aging's Benefits Checkup (<http://www.benefitscheckup.org/>); and (c) providing hands-on assistance—helping her to create an overall budget, identify the bills that need to be paid, determine how much to pay, assist with making out checks, and enter transactions into her checkbook register. DMM services can also help Mrs. C. with setting up direct deposits for incoming funds, arranging for automatic deductions for bill payment, and identifying unknown assets such as retirement investments. Paperwork and processing forms after a hospital stay can be overwhelming, so DMM services can help Mrs. C. complete medical claim forms and follow up with insurance carriers. Finally, DMM services include future planning, such as help setting up a durable power of attorney (described later in this chapter) to name a decision maker if Mrs. C. should lose capacity and help with funeral planning. The process is *supportive* in that Mrs. C. herself makes the decisions about future plans, who to choose as surrogate decision makers, and under what conditions they would assist her.

DMM is the formal provider's response to supportive decision making in the event that Mrs. C. does not have a trusted family member or friend. Although some communities are fortunate enough to have DMM services, many do not. Another approach to providing services is for Mrs. C. to identify a loved one or trusted friend who can assist her, such as her niece Betty, who was located by the hospital chaplaincy service, to carry out these same tasks. In this circumstance, Mrs. C. could ask Betty to directly assist her as a DMM case manager would. She could also add Betty to her bank accounts, nonretirement investments, and property as a joint tenant. Using the services of an attorney, she could develop a trust to include all these assets and name Betty as a trustee so that she could act directly on Mrs. C.'s behalf (for more information on various financial planning transactions, see Quinn, 1997).

Social Worker's Role in Supportive Decision Making

Social workers and other gerontological professionals can function in a variety of roles through the sup-

portive decision-making process. If Mrs. C. planned for future help from a family member by arranging for joint tenancy on her accounts, a social worker could facilitate communication between Mrs. C. and her niece Betty to explain Mrs. C.'s current physical and cognitive state, detail current and future needs upon discharge from the hospital, and help Betty assume responsibility of her aunt's financial matters. The social worker could also act as a community liaison by assisting Betty with locating needed services that would generally not be covered by insured services, such as attendant care or home modification equipment. Additionally, a social worker could provide psychosocial support to both Betty and Mrs. C. during this transition period. If Mrs. C. had not planned for incapacity, a social worker could assist her by a referral to a community agency for DMM or by providing DMM to her under the auspices of a community agency's defined protocols. Later we will describe how professionals can fulfill this role while maintaining appropriate boundaries for Mrs. C.'s safety and their own.

Surrogate Decision Making

Rather than recovering from a tractable health problem, Mrs. C. might be suffering from a progressive degenerative disease that has caused significant cognitive impairment such that she can no longer make necessary decisions about her care and her finances. In this case, activating surrogate decision-making tools on her behalf may be a social worker's most appropriate intervention. Surrogate decision-making tools include various powers of attorney that are preplanned and triggered by incapacity, as well as representative payeeship and legal guardianship, in which decisions facing Mrs. C. are formally transferred to another party.

Powers of Attorney

Powers of attorney (POAs) are mechanisms to delineate surrogate decision-making arrangements ahead of time so that if Mrs. C. loses capacity, her wishes about daily living and preferences for end-of-life care can be effectively carried out (Mrs. C. must still create a will to disperse her assets upon death, but testamentary decision making is beyond the scope of this chapter; see Quinn, 1997). A POA delegates authority to an "agent" to carry out specific or general tasks. Typically, because of this delegated authority, a POA

is in effect only as long as the person who is delegating the authority, the "principal," has capacity. However, durable powers of attorney (DPA) may be developed to allow the agent to make decisions for the principal (Mrs. C.) if she has lost decision-making capacity. The two important types of DPA are durable power of attorney for health care (DPAHC) and a DPA for finances. Using a DPAHC, Mrs. C. can make her health care wishes known in a "living will" and then designate an agent to carry out those wishes if she loses capacity. For example, she might specify that she wants to have a "do not resuscitate order" in the event that her heart stops. Likewise, Mrs. C. can spell out how she wants her finances managed through a DPA for finances if she is no longer able and designate an agent to administer her affairs. Although a DPA is a surrogate decision-making mechanism, it is developed by the principal to execute his or her wishes prior to an incapacitating event. In this way it offers a less restrictive alternative to other surrogate decision-making approaches. However, this method of decision making has been criticized because it is a private arrangement with little external oversight to protect against fraud and/or abuse (Dessin, 2003). Although the basic underlying principles are the same, advance directives are based on state policies, so again we stress the importance of understanding policies and regulations where one practices. Additionally, the service auspice is important in that different institutions have different requirements for managing POAs. Some banks may not honor a financial DPA unless coupled with the bank's own proxy forms. In health care, it is crucial to inform and involve physicians in the DPAHC process because they will have a critical role in carrying out decisions that the proxy makes if the DPAHC is activated.

Representative Payee

Representative payeeship, a tool targeted to manage public benefits such as Social Security, Social Security Disability Insurance (SSDI), and Supplemental Security Income (SSI), is the only nationally based surrogate decision-making policy. The Social Security Administration authorizes "rep payees" for beneficiaries who lack the capacity to manage their money based on physician certification reporting physical and/or mental impairment (Social Security Administration, 2004b). Rep payees are responsible for providing for basic necessities (food, clothing, and shelter) using the client's own money and maintaining separate accounting receipts for expenses in-

curred. Rep payees can be individuals or previously authorized organizations that agree to accept this responsibility. Beneficiaries can request this service on their own by naming a friend or family member to become the rep payee. The Social Security Administration may determine upon granting benefits that the beneficiary lacks capacity and will automatically require a rep payee before disbursement without his or her previously expressed consent.

The constraint of rep payee status is that the designee can manage only public benefits. Therefore, if Mrs. C. received Social Security and a pension, the rep payee would specifically oversee the Social Security payment, and Mrs. C. would still need to have completed a DPA for finances to manage her pension. To encourage family members, friends, or agencies to accept this limited financial responsibility, the Social Security Administration recently authorized the payee to receive up to \$35 per month for their services. However, if Mrs. C. had few resources or received only SSI, even this small amount could significantly reduce the amount available to pay for her care.

Guardianship

If Mrs. C. lacks capacity, and alternatives are not in place or do not adequately meet her needs, guardianship may become the only option. Guardianship is intended to protect vulnerable, dependent persons who are at high risk of personal injury or financial loss, or those who require a legal decision maker to make treatment decisions and/or to authorize financial transactions. Considered the “court of last resort” (Schmidt, 1995), guardianship is best exercised in a judicious manner because it is a highly intrusive and restrictive intervention. Called conservatorship or committeehip in some states, guardianship is a legal arrangement in which a guardian—an individual or legal entity—is appointed by the court to manage the affairs of an adult who becomes a “ward.” Sometimes there is confusion about adult guardianship in that guardianship is also used for placing children under the age of 18 with nonparental adults. If Mrs. C. was placed under legal guardianship, she would effectively lose *all* civil liberties, reducing her legal status to that of a minor (Alexander, 1990; Horstman, 1975; Kapp, 1999; Rein, 1992).

Guardianship is initiated when a petitioner makes a formal request to the court. Legal guardianship requires a court hearing involving a judge, the petitioner who requests the hearing, and the respondent—Mrs. C. in this case. The petitioner, who may or may not be

come the guardian, could be a family member or friend, a public guardian, or a private professional (a private agency or individual such as an attorney or accountant). Not all states have a public guardian program, but for those that do, this entity typically serves as the last alternative of protective care for wards who lack willing or qualified caregivers and do not have resources to pay for a private guardian (Schmidt, Miller, Bell, & New, 1981). Family members are most likely to act as petitioners and subsequent guardians, taking such action after a specific triggering event or critical incident in their loved one’s life, such as physical health emergency, acute mental health problem, financial mismanagement, or the need for nursing home placement (Keith & Wacker, 1994). If the court finds that Mrs. C. lacks the capacity to manage her affairs, a guardian is appointed. Most hearings are brief, with the vast majority—more than 90%—resulting in guardianship (Lisi & Barinaga-Burch, 1995). Once guardianship is granted, the decision is essentially permanent because the ward, now having no legal rights, cannot contest its validity or appropriateness.

Although guardianships may be either full (plenary) or partial (limited), most are plenary. Under a plenary guardianship, the guardian is given responsibility for all aspects of the ward’s life, including determining living arrangements, medical treatment, and financial expenditures and managing all assets (Keith & Wacker, 1994; Lisi & Barinaga-Burch, 1995). Sometimes this is referred to as guardianship of both the “person” and the “estate.” In some instances, the court may limit the guardian’s authority to specific areas. For example, if Mrs. C. has a rep payee and no other assets to be managed, she might need a guardian only for health care decisions. In this situation, the court might appoint a limited guardianship for health care decision making. Or if Mrs. C. had a complex estate but was able to make decisions about her personal affairs, the court may appoint a guardian of the estate to manage financial matters only.

Ethics and Realities of Guardianship

The guardian is expected to manage the ward’s affairs with care and diligence based on the ward’s best interests (Friedman & Savage, 1988). To effectively fulfill this mission, guardianship removes constitutionally guaranteed liberties and decision-making authority from wards, most of whom were previously autonomous and self-reliant. Guardianship operates under the state’s *parens patriae* authority, which obligates government to safeguard individuals who lack

the capacity to protect themselves even when they do not consent to the intervention. Although such paternalistic interventions are intended to be benevolent and ultimately to protect the individual's best interest (Hommel, 1996), guardianship has been criticized for a number of shortcomings, including inadequate supervision and monitoring of guardians by the court, lack of due process in guardianship proceedings, inappropriate use of guardianship when less restrictive approaches could be used, and inadequate care by guardians (Keith & Wacker, 1994; Wilber & Reynolds, 1995).

Currently, the entities responsible for creating and enforcing guardianship laws and regulations are states and U.S. territories, not the federal government. In the absence of a mandated national policy on guardianship, each state's laws and regulations determine the legal processes, the duties and responsibilities of the court and legal guardians, and the terminology used. In 1997, the National Conference of Commissioners on Uniform State Laws, a nonpartisan group of legal experts that develops uniform legislative templates for states to frame their own laws, adopted an updated version of the Uniform Guardianship and Protective Proceedings Act (UGPPA). Yet since the act's adoption, only 4 states (Alabama, Colorado, Minnesota, and Montana) have enacted statutes that are based on it. Additionally, only 26 states have a public guardianship program that provides low-income wards without available social support a court-appointed guardian. Public guardianship programs are generally implemented at the county level and are housed in a variety of administrative units, including aging, adult services, mental health, developmental disabilities, and district attorneys' offices. This lack of uniformity across the states and municipalities further contributes to a disjointed and fragmented service delivery system attempting to address the guardianship needs of vulnerable adults with limited resources.

Recently some states, including Colorado, Delaware, and New York, have stipulated that the appointment of a guardian does not necessarily constitute a finding of legal incompetence, which suggests a movement to a broader use of limited guardianships for specific tasks on behalf of the ward and a more nuanced definition of capacity. Although a number of states have built on the guardianship reform literature of the last several decades to enact more enlightened guardianship laws, the immediate impact of these reforms appears to be small (Keith & Wacker, 1994).

Although media exposés and government hearings have identified serious problems in guardian-

ship, the few empirical studies on the quality of care and estate management have indicated that most guardians provide adequate services (AARP, 1990). In direct interviews with wards, Wilber, Reiser, and Harter (2001) found that the most frequently expressed problems were feelings of loneliness and isolation rather than concerns about guardianship. This research suggests the need to enhance quality of life by encouraging the ward's involvement in "everyday" decision making and opportunities for socialization. If Mrs. C. were placed under guardianship, she should still be encouraged to make and participate in all decisions that are practically possible. For example, the guardian should strive to honor her preference to live in her home with her pets if at all feasible.

The Role of Social Workers in Surrogate Decision Making

As interventions become more restrictive, so too does the importance of practitioners' clinical effectiveness in dealing with older adults with profoundly diminished capacity. Surrogate decision making is the most intrusive step toward the removal of personal liberties. Therefore, social workers possess two major responsibilities toward their older adult clients: to discuss planning tools for surrogate decision making such as the DPA, and/or to intervene cautiously and judiciously with older adults who need unplanned surrogate decision-making assistance via rep payee or guardianship. Both of these roles require fundamental social work skills of direct counseling, client education, and advocacy to ensure that a client's rights and best interests are appropriately safeguarded (National Association of Social Workers, 1999).

THE MISCHIEF FACTOR

Older adults engaged in any decision-making arrangements that transfer some level of authority to informal or formal service providers are vulnerable to mistreatment, malfeasance, and exploitation. Part of this dilemma is due to the limited external oversight for most alternatives to guardianship (Wilber & Reynolds, 1995). As with the areas discussed earlier, states rather than the federal government carry the responsibility of legislating and regulating policies related to elder abuse. This could change if Congress passes legislation such as the Elder Justice Act, which would establish a national Office of Adult Protective Services (<http://www.elderabusecenter.org/default.cfm?p=elderjustice.cfm>).

Currently all states have procedures in place to report elder abuse, and many states have mandatory reporting laws that require social workers and other professionals to report abuse. Because the range of behaviors constituting elder and/or dependent adult abuse vary from state to state (Wilber & McNeilly, 2001), social workers must know their state's elder abuse operational definitions and reporting guidelines. In applying state elder abuse statutes, social workers must carefully distinguish between family tensions or control issues involving a dependent older adult and his or her caregivers and legitimate complaints about financial mismanagement or abuse. This differential diagnosis of a challenging person-in-environment situation requires astute clinical judgment, patience, and often teamwork from other invested professionals.

Social workers are ethically bound to work in the best interests of their clients, and preventing role conflicts through appropriate professional boundaries is a key component of this principle. One potential conflict that might arise is when a social worker acting as the client's care provider is asked to assume either a supportive or a surrogate decision-making role. This is a common request given that many communities lack formal DMM services. For example, Mrs. C. might report "feeling comfortable" with her community social worker, John, and ask him to be her agent on a DPA for finance because "he's like the son I never had." This request may not be out of the question if John's community agency regularly provides DMM to older adults who have no other options. However, it is important that DMM services are performed as part of a formal program with written protocols and procedures and clearly defined limits of responsibility; it is fallacious to think that without a formal program, the agency holds no risk. John would furthermore have an ethical duty to inform Mrs. C. of how their therapeutic relationship would change in the event that the DPA was activated. Prior to this discussion, it is suggested that John garner the support of his supervisor and management on the appropriateness of this arrangement based on Mrs. C.'s current situation, her mental capacity to make this decision, and agency policies and protocols. Whatever the outcome, John and his agency must use appropriate and clear documentation of all transactions to shield against the potential for abuse or, perhaps equally important, the accusation of impropriety by Mrs. C., distant family members, or external regulatory agencies.

CONCLUSION

As this discussion has illustrated, social workers have a repertoire of decisional services to choose from when supporting older adults with diminished cognitive and/or execution capacity. These services are guided by state policies and operational definitions of capacity. Choosing the right blend of services may be difficult and may vary over time as circumstances change. A set of core values provides ethical tools to assist social workers when choices are not clear. In addition to understanding practice issues and applying these tools, it is imperative that social workers know and operate from the relevant state statutes and regulations where they practice.

The elderly, those aged 65 or older, represented 74.2% of the deaths that occurred in the United States in 2002 (Kochanek & Smith, 2004). With the aging of the population, this percentage will continue to increase dramatically in the coming years. This basic fact underscores that the elderly are major stakeholders in policies affecting the dying. A number of key policy events over the last 20 years have shaped in important ways the current situation in end-of-life care for the elderly. These developments, detailed below, include Congress's 1982 act authorizing Medicare to provide end-of-life care to beneficiaries with a terminal illness. This led to the selection of hospice as the standard for end-of-life care in the United States. Another significant legislative event, the Patient Self-Determination Act of 1990, reaffirmed an individual's right to self-determination. The act has promoted the use of advance directives and sparked a still ongoing legal and ethical debate about euthanasia and physician-assisted suicide. Ultimately, this social movement led to Oregon's landmark policy legalizing physician-assisted suicide.

Legislative Events Impacting the End of Life

- 1982 Congress authorizes Medicare to provide end-of-life care to terminally ill beneficiaries. Medicare hospice benefit included in Part A in 1983.
- 1990 Congress passes the Patient Self-Determination Act (PSDA). Instituted in 1991, this act requires health care agencies receiving Medicare and Medicaid reimbursement to recognize the living will and power of attorney for health care as advance directives, inform patients about advance directives, and incorporate any advance directive into patients' medical records.
- 1994 Oregon voters approve the Oregon Death With Dignity Act. When this act goes into effect in October 1997, Oregon becomes the first state in the nation to legalize physician-assisted suicide (PAS).
- 2003 Congress approves the Medicare Prescription Drug, Improvement, and Modernization Act of 2003. This act authorizes the Part D prescription drug plan, providing prescription drug benefits to all enrollees by 2006, and covers consultation with hospice physicians to discuss hospice care options and referrals.

VICTORIA H. RAVEIS

Policies Related to End-of-Life Care

84

This chapter provides a detailed review of issues related to end-of-life care. Specific attention is focused on financing the care of dying elders, including information on how care is paid for, the gaps and limitations in coverage, and relevant regulations and policies impacting end-of-life care options. Disparities in care at the end of life are examined. Attention is also focused on cultural factors that influence elders' care decisions. Ethical and legal issues related to end-of-life care for the elderly are addressed, including advanced directives and assisted suicide. The chapter concludes with policy recommendations to improve care at the end of life.

COST OF CARE AT THE END OF LIFE

Medicare Expenditures

Health care expenditures are often high at the end of life. Analyses of Medicare spending patterns have found that, on average, health care costs are about six times higher in the last year of a beneficiary's life than they are for beneficiaries who did not die, a spending ratio that has remained unchanged over the last two decades (Hogan, Lunney, Gabel, & Lynn, 2001; Medicare Payment Advisory Committee [MedPAC], 2004e). In calendar year 2002, 18% of the total Medicare program payments were attributed to benefits provided to the 5% of program participants who died (MedPAC, 2004e; Hogan et al., 2001). The high costs of health care at the end of life are attributed to the increased number of multiple, significant medical problems elderly decedents typically experience in the last year of life (Hogan et al., 2001).

Medicare, as the primary source of health insurance for persons 65 and older in the United States, is the main payer of the costs of end-of-life health care for the elderly. From 1993 through 1998, Medicare covered 61% of the health care expenses of elderly decedents in the year before their death, with multiple payers bearing the remaining portion of these expenses. Out-of-pocket expenses represented 18% of these end-of-life care costs, other payers covered 12%, and Medicaid paid 10% (Hogan et al., 2001).

The end-of-life out-of-pocket expenses of Medicare beneficiaries are determined by the type of Medicare plan in which they are enrolled. Covered benefits, premium fees, deductibles, and co-pay expenses vary across plans. Supplemental insurance plans, such as Medigap (Medicare supplement insurance), offset some Medicare coverage gaps and reduce deductibles

and co-pay fees, but beneficiaries must pay the additional premiums. Some beneficiaries also have access to employer-sponsored retirement health plans that provide assistance with Medicare's cost-sharing requirements, as well as offering additional benefits (Kaiser Family Foundation & Hewitt, 2004). Private long-term care policies provide expanded coverage for home care, skilled nursing, and institutional care at the end of life. However, these premiums tend to be expensive, and elders holding such policies tend to be wealthier and have significantly greater housing assets than those without this type of private insurance coverage (LifePlans, 1999).

For those Medicare beneficiaries whose income and financial assets are sufficiently low to qualify for Medicaid coverage, additional benefits are available. Medicaid covers Medicare beneficiaries' cost-sharing charges and provides a number of other assistance benefits, such as covering the costs of institutional residence. However, program eligibility requirements and service benefits vary by state.

Out-of-Pocket Expenses

The health-related out-of-pocket expenses the elderly can experience at the end of life may present a substantial economic challenge. The likelihood of being below the poverty level increases with age, with the highest rates found among those 85 and older (Kaiser Family Foundation, 2001). Medicare beneficiaries spend, on average, about 20% of their income on health care services (MedPAC, 2004d). Out-of-pocket spending levels for beneficiaries with supplemental coverage are similar to those for individuals without such coverage (MedPAC, 2004d). With declining health and advancing age, these expenses increase substantially. Medicare beneficiaries in poor health have 50% more out-of-pocket health expenses than those in good health (Kaiser Family Foundation, 2001). Similarly, those 85 and older have almost twice the out-of-pocket expenditures of those ages 65 to 74. Use of a residential facility increases with advancing age and adds substantially to the out-of-pocket expenses incurred by the oldest age-groups (Hoover, Crystal, Kumar, Sambamoorthi, & Cantor, 2002). It is estimated that about 90% of elderly nursing home residents spend down their assets sufficiently after one year in a nursing home to qualify for Medicaid (Zerzan, Stearns, & Hanson, 2000). Hoover et al. (2002) have estimated the mean out-of-pocket expenditures for persons 65 and older in the last year of life at \$5,211 (in 1996

dollars). Recent Census Bureau estimates, adjusted for expected out-of-pocket medical expenses, classified 13.4% to 17.7% of persons 65 or older as below the poverty level in 2002 (MedPAC, 2004d).

Cost of Family Caregiving

Families are integral to care at the end of life. Most elderly persons prefer to age in place and express preference for dying at home (Burge, 2004; Higginson & Sen-Gupta, 2000; SUPPORT Principal Investigators, 1995). Families are intensively involved in the care and support of ill and dependent family members, and this commitment continues throughout the dying trajectory (Emanuel et al., 1999). Even with comprehensive end-of-life care programs, such as those available through Medicare's hospice benefit, family involvement is needed. The delivery of palliative services and comfort care is organized around family and friends being present to provide ongoing, routine care. For terminally ill elders residing in the community, the absence of readily available family caregivers can be a barrier to hospice. In some instances, it has necessitated a relocation at the end of life to an institutional setting (General Accounting Office [GAO], 2000; MedPAC, 20004e).

Estimates of the economic capital represented by families' role in informal care illustrate the substantial financial contribution that families provide in care at the end of life. Arno, Levine, and Memmott (1999) estimated the 1997 national market value of care provided by unpaid family members and friends to ill and disabled adults as \$196 billion. This contribution eclipsed the \$32 billion spent on formal home health care and \$83 billion spent on nursing home care in 1997. Because this study did not include the expenses to the familial caregivers of unreimbursed health care fees and the loss of caregiver income and associated employment benefits, the total financial cost to families is likely to be even higher.

Cost of Hospice Versus Other Health Care

When the hospice benefit was added to the Medicare program, some proponents of the benefit argued that hospice would reduce program spending by eliminating unnecessary medical treatments and services. This predicted cost saving has not been realized. Current analysis of the costs in the last year of life has docu-

mented that mean expenditures for elderly Medicare beneficiaries were 4.0% higher overall among hospice enrollees than among non-enrollees (i.e., those with fee-for-service coverage; Campbell, Lynn, Louis, & Shugarman, 2004). This analysis revealed further that the higher hospice costs were incurred by enrollees with diagnoses other than cancer. Specifically, Medicare program expenditures were lower among cancer patients enrolled in hospice than among non-enrollees (\$27,917 vs. \$29,905). However, the reverse pattern occurred for enrollees with noncancer diagnoses. For them, hospice charges were higher (\$26,751 vs. \$22,879). Thus, although hospice may generate some savings by reducing curative treatment expenses, these expenditure reductions are somewhat offset by the cost of palliative services and the expanded supportive care the hospice benefit provides (MedPAC, 2004d; see Table 84.1 for a detailed description of the Medicare hospice benefit). Medicare reimburses hospice providers a per diem rate, adjusted for regional differences, for each day a beneficiary is enrolled in hospice. Payment levels are based on one of four levels of care: routine home care, continuous home care, inpatient respite care, and general inpatient care. Per diem payment is constant, even if no services are provided on a given day (MedPAC, 2004e). Ninety-five percent of the hospice care, across all service settings, is provided at the routine home care level (MedPAC, 2004a). The per diem rate for routine home care, on average, was \$120 per day in 2004 (MedPAC, 20004b).

TRENDS IN HOSPICE USE

Growth in Hospice Care

Since the addition of the hospice benefit to the Medicare program in 1983, an increasing number of terminally ill elders have selected this care option. In 1998, 19% of those who died had used hospice in the year before their death. By 2002, this percentage had increased to 26% (MedPAC, 2004a). Medicare spending patterns reflect this growth. Hospice expenditures increased from \$1.9 billion in 1995 to an estimated \$5.9 billion in 2003 (MedPAC, 2004a).

Length of Stay

Changes have also occurred in the length of hospice stay. For the subset of hospice enrollees in the 90th

TABLE 84.1 Overview of Medicare's Hospice Benefit

Eligibility

- Beneficiary is eligible for Medicare Part A (hospital insurance)
- Beneficiary's physician and hospice medical director certify 6-month life expectancy
- Beneficiary agrees to forgo all Medicare-covered, nonhospice benefits for the terminal illness

Hospice care team

- Physician
- Nurse
- Mental health counselors (e.g., psychologists, pastoral counselors)
- Social worker
- Home health aides
- Volunteers

Services provided

- Physician services
- Nursing care
- Durable medical equipment (e.g., wheelchairs, walkers)
- Medical supplies
- Drugs and biologicals for symptom management and pain control
- Home health aide and homemaker services
- Physical and occupational therapy
- Speech therapy
- Social worker service
- Nutrition and dietary counseling
- Grief and loss counseling to beneficiary and family
- Inpatient respite care in a Medicare-approved hospital or nursing home, up to 5 days per episode
- Physician and nurse on call 24/7

Other key features

- Hospice care must be provided by a Medicare-approved hospice program
- Beneficiary can change hospice provider only once during each 90- or 60-day certification period
- Beneficiary can be recertified indefinitely, initially two 90-day periods, then every 60 days
- Beneficiary can elect to leave hospice, reselect prior Medicare health plan's nonhospice coverage for his/her condition, and at some future time reselect the hospice benefit
- Beneficiary can use Medicare health plan to receive care for unrelated conditions

Costs to beneficiary: Gaps and limitations in care

- Beneficiary pays part of the cost for outpatient drugs—\$5 per prescription in 2004
- Beneficiary pays part of inpatient respite care—5% of the Medicare payment amount in 2004
- Medicare does not cover costs of room and board; exception is inpatient or respite care
- Hospice in the home requires informal/familial caregiving
- Hospice programs vary in range of palliative care services provided

For further information see Centers for Medicare and Medicaid Services, *Medicare hospice benefits*, retrieved August 2, 2004, from <http://www.medicare.gov/>.

percentile for length of stay, mean length of stay increased from 123 days in 1998 to 147 days in 2002 (MedPAC, 2002). This increase has been attributed to the expanded use in recent years of the hospice benefit among nursing home residents and a more diversified case mix. For the majority of hospice enrollees, though, length of stay is still relatively brief. The median length of stay remained at 16 days in 2002, with more than a quarter of the enrollees receiving hospice services for less than 1 week (MedPAC, 2004a). A disadvantage to having had a brief time in hospice is that it precludes beneficiaries and their family members from fully benefiting from hospice's special services, such as the respite care and grief counseling available to family members (Raveis, 2004). Brief hospice stays also represent a financial disadvantage to the hospice provider because there is a shorter time frame over which the costs associated with intake and setting up an individualized care plan, as well as the expenses associated with intense services that typically characterize the days preceding death, can be spread out (GAO, 2000; MedPAC, 2002). Hospice providers report that the hours a patient requires from social work, nursing, and administration in the first and last weeks of hospice enrollment are typically twice those required during the intervening period (GAO, 2000).

Trends in Use by Coverage Plan

There is evidence of beneficiaries' differential use of the hospice benefit by type of Medicare plan. There has been a consistently higher use of hospice by managed care enrollees than by fee-for-service enrollees (MedPAC, 2004e). In 2002, 34% of decedents in managed care used hospice, compared with 25% of those in fee-for-service (MedPAC, 2004a). Elderly cancer patients in managed care not only had higher rates of hospice use but also had significantly longer hospice stays than those enrolled in the fee-for-service plan (McCarthy, Burns, Ngo-Metzger, Davis, & Phillips, 2003).

The care setting where hospice is provided has also changed over time. Although the majority of hospice enrollees still dwell in the community, there has been an increase in the delivery of hospice to nursing home residents. Between 1992 and 2000, the percentage of hospice enrollees in nursing homes expanded from 11% to 36% (MedPAC, 2004a). For those enrollees in nursing homes, institutional staff are available to provide the routine care and monitoring that families are required in the home to provide, to complement hos-

pice's specialized support services (GAO, 2000; MedPAC, 2004c).

Geographic Differences

There have also been geographic differences in the growth of hospice use. The most rapid growth has been in the percentage of rural (as opposed to urban) beneficiaries electing hospice between 1992 and 2000 (MedPAC, 2002). Rates of hospice use, though, are still lower in rural areas than in urban environments. The lowest rates of hospice use are observed in rural areas not adjacent to urban areas (15.2% of all deaths), and the highest rates of use are in urban areas (22.2% of all deaths; Virnig, Moscovice, Durham, & Casey, 2004).

Case Mix

The case mix among hospice users has also changed and become more varied. Historically, elderly cancer patients have been the most common users. Although patients with a cancer diagnosis still represent the majority of hospice enrollees, the percentage has dropped from 75% in 1992 to 60% in 2002 (MedPAC, 2002, 2004a). The most common noncancer diagnoses among hospice decedents are congestive heart failure, dementia, and pulmonary disease (MedPAC, 2004a).

Sociodemographic Diversity

Recent growth in hospice use has been greatest among the oldest Medicare beneficiaries (MedPAC, 2004a). Consistent with the increased use of the hospice benefit among nursing home residents, the percentage of decedents 85 and older who used hospice has almost doubled between 1998 and 2002. Growth in hospice use has continued across all racial groups, but longstanding racial differences remain in who selects the hospice benefit. In 2002, hospice use was still highest among White Medicare decedents, with Asian American decedents having the lowest rates, followed by African Americans (MedPAC, 2004e). These patterns are consistent with the cultural precepts regarding end-of-life care and differential preferences for aggressive and life-sustaining treatments expressed by minority populations (Blackall et al., 1999; Yeo, 1995). Several investigations have documented White patients' tendency to select treatment options that limit

or forgo care at the end of life, in contrast to decisions made by Black patients that focus on prolonging life by all possible treatment means (Berger, 1998; Caralis, Davis, Wright, & Marcial, 1993; Hopp & Duffy, 2000; McKinley, Garrett, Evans, & Danis, 1996; Steinhauser et al., 2001; Teno et al., 1990). Suspicions about the motives of health care institutions and clinicians, as well as the historical legacy of the Tuskegee Institute syphilis experiments and evidence of long-standing uneven access to care, may also account for the desire of minority patients to have all available treatment, especially at the end of life (Blackhall et al., 1999; Caralis et al., 1993; Dula, 1994; Garrett, Harris, Norburn, Patrick, & Danis, 1993; Gramespacher, Zhou, Hanna, & Tierney, 1997; Hauser, Kleefield, Brennan, & Fischbach, 1997; McKinley et al., 1996; Siegel & Raveis, 1997; Steinhauser et al., 2001).

GAPS AND LIMITATIONS IN END-OF-LIFE CARE

Features of the Hospice Benefit Impact Usage

The incentive to select Medicare's hospice benefit may be impacted by the benefits covered and the savings in out-of-pocket expenses enrollees may realize with the hospice benefit. The prescription drug benefit for hospice enrollees is a compelling plan feature. Medication for symptom control can represent a considerable expense for beneficiaries, particularly the cost of pain medications. Outside of the hospice benefit, prescription drug coverage is a benefit that is primarily available through employer-sponsored health plans (Kaiser Family Foundation & Hewitt, 2004). However, by 2006, as a consequence of the Medicare Prescription Drug, Improvement, and Modernization Act of 2003, prescription drug coverage will become available to all Medicare beneficiaries who enroll in Medicare's Part D, a prescription drug plan (PDP) (MedPAC, 2004e). This coverage change will render the hospice benefit less significant. Policy analysts have expressed concern that PDP will adversely impact employer coverage of retiree health benefits (Kaiser Family Foundation & Hewitt, 2004). Dually eligible (Medicare and Medicaid) beneficiaries may also have less of a financial incentive to select the hospice benefit. Medicaid provides a range of assistive services and benefits that duplicate many of the features of hospice without the constraints that the

Medicare hospice benefit imposes on coverage of services and forgoing of curative care (see list on p. 906).

Hospice Providers Control Delivery of End-of-Life Care

Analysts and advocates for appropriate care at the end of life have expressed concern that Medicare's hospice payment schedule compels providers to use cost considerations in deciding who should be enrolled, when to initiate enrollment, and what services should be provided (Buntin & Huskamp, 2002; Huskamp, Buntin, Wang, & Newhouse, 2001; Gage et al., 2000). They cite the higher use of hospice (and longer stays) by managed care enrollees as an example of efforts to maximize revenue by managed care organizations and hospice providers. Hospice providers are not mandated to accept all enrollees. Some providers have not accepted enrollees who have high-cost needs or require services that are not routinely provided, such as chemotherapy for palliation. The difficulty these beneficiaries have in finding a hospice provider has been cited as further evidence of how cost considerations determine access to end-of-life care (Huskamp et al., 2001; Lorenz, Asch, Rosenfield, Liu, & Ettner, 2004; MedPAC, 2004b, 2004c).

Although hospice providers are mandated to offer a comprehensive package of palliative care services, they are not required to provide all possible palliative treatments. Changes in the practice of palliative medicine have led to the introduction of more higher cost services, such as the delivery of chemotherapy or radiation for pain and symptom management. Similarly, other advances in symptom control, such as transdermal administration of narcotic pain medication, are costlier than traditional pain management techniques (GAO, 2000). Hospices are not routinely making these treatments or medications available because of the expense involved, even though these services or approaches might better meet patients' needs. Providers have argued that such cost considerations are necessary, given the current Medicaid reimbursement system. However, hospices are not required to monitor quality of care or quality-of-life outcomes. In the absence of any evaluation effort, it remains uncertain to what extent, and/or for which patient groups, hospice providers are adhering to the precepts of palliative care, that is, delivering person-centered care that maximizes quality of life, reduces suffering, and respects patient rights (Task Force on Palliative Care, 1998).

Different Dying Trajectories Exist

A review of the causes of death among the elderly suggests that most deaths are likely to occur following a period of care and management. The four leading causes of death for persons 65 and older in 2002 were diseases of the heart, malignant neoplasms, cerebrovascular disease, and chronic lower respiratory disease. Alzheimer's disease, diabetes, and kidney disorders ranked among the top 10 (Kochanek & Smith, 2004). However, different fatal conditions present distinct dying trajectories (Lunney, Lynn, & Hogan, 2002). Some conditions, such as cancer, have a distinct terminal phase. Other conditions, such as congestive heart failure or chronic obstructive pulmonary disease, are characterized by gradual decline with periodic exacerbations of the illness and a survival period that is difficult to predict. Conditions associated with frailty or dementia have an even slower decline, and death may occur from complications associated with the condition. These variations in the dying process suggest that appropriate care for the elderly at the end of life is care that fits these different dying trajectories. An analysis of elderly Medicare decedents indicated that 47% met the criteria for frailty, 22% had a condition with a distinct terminal phase, and 16% had died of organ system failure (Lunney et al., 2002).

ETHICAL AND LEGAL ISSUES AT THE END OF LIFE

Advanced Directives

A national effort to promote the use of advanced directives was initiated in 1991 with the Patient Self-Determination Act (PSDA). However, the impact of advanced directives on end-of-life care has been mixed. The purpose of advance directives is to guide decision making after a patient has lost decision-making capacity. Many of the diseases and conditions the elderly are living with at the end of life may generate situations in which advanced directives would be helpful to guide the delivery of appropriate care. In the absence of clearly expressed preferences for care, investigations have shown that family, friends, and health care providers do not necessarily make an accurate judgment regarding a patient's care preference at the end of life (Sulmasy et al., 1998; Diamond, Jernigan, Moseley, Messina, & McKeown, 1989; Gerety, Chiodo, Kantan, Tuley, & Cornell, 1993; Seckler,

Meier, Mulvihill, & Paris, 1991; Steinhauser et al., 2001; Zweibel & Cassel, 1989). One investigation determined that the patient treatment options surrogate decision makers tended to select were ones they would choose for themselves (Covinsky et al., 2000).

An advance directive can include a "living will," specifying a patient's treatment preferences, including the conditions under which life-sustaining treatments (i.e., antibiotics, artificial feeding, ventilators, defibrillation, and cardiopulmonary resuscitation) would be withdrawn or withheld. It may also include a health care power of attorney, identifying a health care proxy authorized to act as the patient's agent. Advance directives can also include other instructions, such as organ donation and preferred care setting. Typically, advanced directives are written, but oral instructions are also possible. The PSDA requires health care institutions that receive Medicare and Medicaid funds to provide patients with a written summary of their health care decision-making rights (which vary somewhat by state) and the facility's policies regarding recognizing advanced directives. Institutions are also required to document in the patient's medical records that an advance directive exists, although patients are responsible for providing the copy of their advance directive to the institution (MedPAC, 1999).

Ideally, a patient's completion of an advance directive should be based on full understanding of his or her overall medical condition and probable illness course. Even though an advance directive would be a logical product of an advance care discussion with a physician, only 12% of patients completing an advance directive reported physician input (Teno et al., 1997). Although Medicare does reimburse physicians for advance care planning if it constitutes more than 50% of the visit (MedPAC, 1999), this finding suggests that this option is not widely exercised.

Advanced directives do not always ensure that family members (Ditto et al., 2001) or clinicians (Coppola, Ditto, Danks, & Smucker, 2001; Covinsky et al., 2000) will comply with the patient's end-of-life treatment preferences. Despite PSDA regulations, gaps in documentation also occur. One investigation documented that patient preferences for not receiving cardiopulmonary resuscitation were not reflected in do not resuscitate orders (Covinsky et al., 2000). It has also been found that discrepancies exist in perceptions by patients, family, and clinicians regarding whether discussions of end-of-life care preferences have been held (Curtis et al., 1999; SUPPORT Principal Investigators, 1995).

Racial and Cultural Prescriptions Impact End-of-Life Care Planning

End-of-life care needs to take into account culturally mandated patterns of communication and decision making. There are cultural preferences regarding whether a patient should be told of a terminal diagnosis or if this information should be provided only to the patient's family. As a matter of compassion and to permit a peaceful death, members of Pakistani families do not burden terminally ill patients with information about their diagnoses (Moazam, 2000). Korean Americans and Mexican Americans have been found less likely than European Americans and African Americans to support full disclosure to relatives of their diagnoses and prognoses (Blackhall et al., 1995).

Cultural and racial prescriptions also exist regarding the appropriateness of discussing and engaging in treatment decision making about end-of-life care. In the Navajo culture, for example, the very discussion of future illness or end-of-life care is considered harmful and, therefore, unacceptable, making it very difficult for health providers to determine patient care wishes or family understanding of them (Carrese & Rhodes, 1995, 2000). A similar prohibition has been found in some Chinese populations (Caralis et al., 1993). In many Hispanic groups, especially those of lower socioeconomic status and with limited education, discussions of death and planning for death are discouraged, for they are seen as tempting fate. African Americans are less likely to discuss and complete advance directives than are Whites (Shepardson, Gordon, Ibrahim, Harper, & Rosenthal, 1999). Decision making about life support is also considered the responsibility of Mexican American families as opposed to the patient autonomy model favored in European American cultures (Blackhall et al., 1995; Murphy et al., 1996).

Euthanasia and Physician-Assisted Suicide

Euthanasia and physician-assisted suicide (PAS) represent the ultimate option for the terminally ill. Oregon's legalization of PAS, with the passing of the Oregon Death With Dignity Act, permits terminally ill patients to receive lethal prescriptions from physicians to end their lives only after the physician fully informs the patient of any feasible alternatives to PAS, including comfort care, hospice, and pain control. Reports of assisted suicide cases indicate that this

choice was exercised primarily by terminally ill patients who were in severe pain or physical discomfort and dependent on others for care (Roscoe, Malphurs, Dragovic, & Cohen, 2001; Back, Wallace, Starks, & Pearlman, 1996; Meier et al., 1998). Terminally ill African Americans and patients who were more religious were significantly less likely to regard euthanasia or PAS as an acceptable choice (Emanuel, Fairclough, & Emanuel, 2000; Emanuel et al., 1999). Although terminally ill patients who were feeling depressed or hopeless were found to be more likely to consider PAS or euthanasia, such considerations did not persist over time (Emanuel et al., 2000; Breitbart et al., 2000). These findings highlight the vulnerability of the dying individual and underscore the importance of ensuring that care at the end of life is person-centered care, organized to provide optimal support and medical management.

POLICY RECOMMENDATIONS TO IMPROVE CARE AT THE END OF LIFE

The introduction of the Medicare hospice benefit has initiated a transformation of end-of-life care for the elderly in the United States. Recent years have seen an expanded use of hospice in different delivery settings and among different groups, although notable service deficiencies and disparities remain. The addition of Medicare coverage for prescription drugs (Medicare Part D), which will be fully initiated in 2006, will continue to redefine end-of-life care options for the elderly. Access to low-cost drugs may enhance symptom management by reducing some of the economic burden the elderly now experience from the high cost of medications.

However, as summarized in Table 84.2, additional reform to policy and financing for end-of-life care is still merited. It is important to recognize that there are different dying trajectories. Although hospice is appropriate for some end-of-life conditions, more comprehensive benefits and flexible coverage regulations that would permit the integration of palliative care with active treatment would ensure care options that accommodate diversity at the end of life. Revisions to the Medicare hospice provider reimbursement schedule to address the higher program delivery costs at the initiation and end of stay and the expenses incurred by a broader case mix (e.g., patients requiring more expensive palliative therapies) would improve hospice access and enhance service options (MedPAC, 2004b).

TABLE 84.2 Policy and Finance Recommendations to Improve Care at the End of Life for the Elderly

-
- Revise Medicare's hospice provider reimbursement policy to address short stays and high costs of intake and last days of life
 - Expand eligibility and benefits coverage to incorporate diversity in dying trajectories
 - Recognize advances in palliative medicine and revise benefit coverage to include approaches that were previously used only for curative purposes
 - Provide sufficient reimbursement to support access to the most appropriate and effective symptom management options
 - Incorporate cultural sensitivity in the advance care planning, decision making, and service delivery at the end of life
 - Institute monitoring and evaluation of hospice service delivery
 - Support efforts to assess service needs at the end of life that incorporate patient and family perspectives, disease factors, and service settings treatment
 - Provide sufficient reimbursement to support access to the most appropriate and effective symptom management
-

Medicare regulations do not require hospices to assess or monitor quality of care or services provided to program participants. Monitoring and evaluation efforts are needed to ensure that the elderly's care needs and preferences are appropriately met (MedPAC, 2004b). Practitioners and activists in the field are advocating for quality assurance efforts to be a part of the reimbursement procedures for hospice providers (MedPAC, 2004b).

Ensuring appropriate care for all individuals at the end of life needs to be informed by the evidence base. Gaps in knowledge exist. Comprehensive understanding of unmet needs and services required at the end of life across different service settings, disease conditions, and patient populations is lacking. Support for systematic efforts to inform these knowledge gaps is needed to ensure that services and programs are culturally sensitive and appropriately tailored to meet diverse patient groups.

Policies Affecting Families of Older Adults With Care Needs

85

The growth of the elderly population in the United States and the increased likelihood of chronic illness and disability with age have made elder care one of the major challenges faced by Americans and the U.S. government. As in the past, currently the bulk of elder care is unpaid assistance provided by families and friends of older persons, referred to as informal or family caregivers in the literature. It was estimated that approximately 66% of noninstitutionalized persons with limitations in activities of daily living (ADLs; e.g., bathing, dressing, eating) rely on informal caregivers exclusively for help; 25% supplement that with paid help; and only 5% rely solely on formal services (Liu, Manton, & Aragon, 2000). The unpaid assistance provided by family caregivers, if paid, would amount to \$45 to \$94 billion a year (Assistant Secretary for Planning and Evaluation & Administration on Aging, 1998).

Caregiving takes a toll on the physical, psychological, social, and financial well-being of caregivers. For instance, research has shown that wives who care for their husbands have higher levels of depressive symptoms and lower levels of social involvement than wives whose husbands do not need care (Seltzer & Li, 2000). About 21% of caregivers reported that caregiving has a negative effect on their health (Donelan et al., 2002). Employed caregivers often have to rearrange their work schedules, reduce work hours, or take unpaid leave, which, in the long term, can result in a substantial financial loss (Thompson, 2004).

In addition to the stress associated with caregiving, there is a growing concern about the availability of family caregivers, given the trend of women's labor force participation, marital dissolution due to separation and divorce, geographic mobility, and smaller family size (Tennstedt, Crawford, & McKinlay, 1993). Policymakers have begun to realize that family caregiving cannot be taken for granted and that informal caregivers play a vital role in our long-term care system. In this chapter, we describe two federal programs that aim to support families of elderly persons with care needs: the Family and Medical Leave Act and the National Family Caregiver Support Program. We first present the history, provision, and implementation of each program, then discuss their loopholes in addressing the needs of family caregivers and the implications for social work.

THE FAMILY AND MEDICAL LEAVE ACT

History

The Family and Medical Leave Act (FMLA) was signed into law by President Bill Clinton in February

1993, two weeks after he took office. The early version of the FMLA, called the Parental and Disability Leave Act, was introduced to the floor of the House of Representatives in 1985. This original leave bill did not include elder care because it was designed to address the issue of child care. In fact, during the formulation of a leave bill, the question of whether it should have a “parental” or “family” focus was a source of tension among its supporters (Wisensale, 2001). The latter, obviously, prevailed, and the FMLA was reintroduced to the House in 1987.

The FMLA passed both houses twice, first in 1990 and again in 1992. Both times it was vetoed by President George H. W. Bush. Wisensale (2003) argued that if Clinton had not been elected in 1992, we would not have the FMLA today.

Provision

The FMLA requires companies with 50 or more employees and all public sector employers regardless of the number of employees at a given work site to provide eligible employees with up to 12 weeks of unpaid leave per year, for the following reasons: care of a child, spouse, or parent with a serious health problem; care of a newborn, newly adopted, or foster child; or care for a serious health condition of the employee (Commission on Leave, 1996). Eligible employees are those who have worked for the company for at least 1 year and for 1,250 hours over the previous 12 months. The unpaid leave comes with two protections: job security and maintenance of health benefits. An employee is entitled to return to the same or an equivalent position after the leave and to receive the same health benefits as when working while on leave. Employees are required to notify their employers prior to taking leave, and employers can request medical certifications to justify the absence. A company can deny a leave request if the employee falls into the top 10% of the company’s payroll and his or her absence would substantially hamper the functioning of the workplace.

Implementation

The FMLA took effect in August 1993; since then, the Department of Labor has commissioned two studies, one in 1995 and another in 2000, to evaluate its implementation (Commission on Leave, 1996; U.S. Department of Labor, 2000). Each study involved a survey of employers and a survey of employees. In the

following we highlight the findings from the 2000 study that are relevant to families of dependent older persons, and note the difference between the 1995 and 2000 study findings, if any.

Coverage

About two thirds of the U.S. labor force work for employers covered by the FMLA. Among the covered companies, not all employees are eligible because of the act’s requirement for length of employment and hours worked. Combining employees in both public and private sectors, about 54.9% are both covered and eligible. Workers who cannot benefit from the FMLA were more likely to be young (less than 25 years old) or old (more than 64 years old), never married, low-educated (less than a high school education), hourly paid, and have lower family income than covered and eligible workers.

Employees’ Use of Leave

About 16.5% of all employees (regardless of whether their employers are covered by the act and their eligibility) took leave for a reason covered by the FMLA, but only a minority took the leave under the FMLA (1.9% of all employees, which was an increase from 1.2% in 1995; the majority of leave takers used other mechanisms such as sick leave and vacation days). Most of the leaves were short, with a median length of 10 days. The primary reason for taking leave was for one’s own health, followed by caring for a newborn, adopted, or foster child. About 20% of all leaves were for reasons related to caring for a parent or spouse. There was a shift in the reason for taking leave between the 1995 and 2000 studies, with more employees taking leave for reasons related to caring for a parent or spouse, caring for a new child, or maternity-disability in 2000.

The 2000 study found that 2.4% of all employees needed but did not take leave, which was down from the 3.1% found in the 1995 study. Compared with other employees, these individuals were more likely to be separated, divorced, or widowed, to have children living at home, and to receive hourly pay.

About half of those needing a leave said that it was for their own health, and 22.6% reported caring for an ill parent as a reason for the needed leave. The majority (77.6%) did not take the leave they needed for financial reasons (could not afford to take the leave), and most (87.8%) said they would have taken the leave if it was paid.

Impact on Well-Being

Employees who have taken leave for an FMLA reason generally view the leave quite positively. For example, a majority indicated that taking the leave had a positive effect on their ability to care for a family member (78.7%), on the emotional well-being of their family members or themselves (70.1%), and on the physical health of their family members or themselves (63.0%).

Overall, the two reports issued by the Department of Labor (Commission on Leave, 1996; U.S. Department of Labor, 2000) depict a positive picture of the FMLA. Both reached the conclusion that the act had positive effects on employees, especially easing their conflict between family and work responsibilities. The two studies also found that the act was a minimal burden to employers. Studies by academic researchers concurred that the FMLA has had little negative impact, although academics are more critical of its limitations, including limited coverage and the leave being unpaid (Wisensale, 2001).

Since the passage of the FMLA in 1993, many initiatives have been put forth by members of Congress to expand the law. These initiatives included lowering company size to be covered by the act, expanding allowable reasons for taking leave, and inclusion of domestic partners, parents-in-law, and grandparents in the coverage (Wisensale, 2003). All expanding proposals, however, failed. In 1999, President Clinton issued an executive memorandum and ordered the secretary of labor to propose regulations that allow states to tap into unemployment insurance funds to provide paid leave. Many states responded to Clinton's initiative, and 26 states introduced legislation that involved some type of paid family leave in 2001 (Wisensale, 2003). But it was not until late 2002 that California—the first and only state to date (July 2004)—succeeded in passing a paid family leave law that allows workers to receive 55% to 60% of their salary (up to a cap of \$728 per week) during 6 weeks of leave to care for a seriously ill child, spouse, domestic partner, or parent or to care for a new child by birth, adoption, or foster care (California Employment Development Department, 2004).

THE NATIONAL FAMILY CAREGIVER SUPPORT PROGRAM

History

The National Family Caregiver Support Program (NFCSP) was authorized under the Older Americans

Act (OAA) amendments of 2000. In operation, the program comprises both the NFCSP, authorized under Title III-E of the OAA, and the Native American Caregiver Support Program, authorized under Title VI-C. The NFCSP is administered by the Administration on Aging within the Department of Health and Human Services. It is the first national program for which the family caregiver rather than the older adult is the focus, and it is the first major initiative under the OAA since the 1970s.

Provision

The NFCSP calls for all states, in partnership with area agencies on aging (AAAs) and local community service providers, to provide direct support services to meet the range of family caregiver needs. Five categories of services are specified as basic (Administration on Aging, 2004):

1. Information to caregivers about available services;
2. Assistance to caregivers in gaining access to supportive services;
3. Individual counseling, support groups, and caregiver training to assist caregivers in making decisions and solving problems relating to their roles;
4. Respite care to temporarily relieve caregivers from their responsibilities; and
5. Supplemental services, on a limited basis, to complement the care provided by caregivers.

Federal grants are allocated to states, based on a proportionate rate of the population 70 years of age or older, to implement the program. Eligible service recipients include family caregivers, defined as an adult family member or an individual who provides informal care to an elderly person, and grandparents or other relative caregivers of children under 18. States are asked to give priority consideration to those with greatest social and economic needs, and those caring for persons with mental retardation or developmental disabilities.

Implementation

Congress appropriated \$125 million in 2001, \$141.5 million in 2002, and \$155.2 million in 2003 for the NFCSP. In fiscal year 2001, \$6 million of the \$125 million was used to fund innovative programs, projects of national significance, and conferences and training

to foster the development and testing of new approaches to sustain the efforts of family caregivers. An executive summary issued by the Administration on Aging in September 2003 reports that significant progress across the country has been made in implementing the NFCSP. For instance, the program has reached more than 3.8 million individuals with information about caregiver programs and services; provided assistance to 436,000 caregivers in accessing services; served almost 180,000 caregivers with counseling and training; provided respite to more than 70,000 caregivers; and provided supplemental services to more than 50,000 caregivers.

A report of 10 states' experience in implementing caregiver support services since the passage of the NFCSP identified two major challenges in implementing the NFCSP at the state and local levels (Family Caregiver Alliance, 2002). The first is insufficient funding. States varied greatly in the amount of funding received, ranging from \$12.6 million in California to \$639,540 in Hawaii in fiscal year 2002. But all states report that the funding level of the NFCSP is too low to meet the multifaceted needs of family caregivers. In particular, many states report a need for additional respite care and supplemental services (e.g., assistive devices, home modifications). A second challenge is a shortage of direct care workers. Many state representatives indicate that the labor shortage is a crisis that seriously hampers the delivery of quality services to caregiving families, especially those in rural areas.

In addition, the report notes that administrative fragmentation, balance between flexibility and standardization of service options, and quality assurance and evaluation are some of the issues to be addressed in further implementation of the NFCSP. First, administratively, coordinating and integrating caregiver support services and other community long-term care services (e.g., Medicaid waivers, state-funded home and community-based services) are essential but difficult, due to multiple funding sources, divergent eligibility criteria, and spreading of responsibility across numerous state agencies. Administrative fragmentation of long-term care services at the state and local levels makes it difficult for family caregivers and older persons to access the services they need. Second, the NFCSP's emphasis on local flexibility in designing and implementing its caregiver support services results in great variations in service options across and within states. Such variations, paradoxically, limit the choice for family caregivers and could be confusing and frustrating to those who attempt to access services. For instance, caregivers living in dif-

ferent parts of the same state may not be able to access the same package of caregiver support services under the NFCSP. Third, the lack of uniform assessment on caregivers across states, particularly with no standardized requirement on the collection of outcome data, makes it difficult to assess the impact of the services and to assure quality.

The experience of some states suggests that a consumer-directed approach has promise to deliver caregiver support services more effectively (Family Caregiver Alliance, 2002). The range of consumer-directed options is quite varied; for instance, some states (e.g., Pennsylvania) give cash to family caregivers, who then decide what services to use, when, and who provides the services; other states (e.g., Alabama) provide a menu of service options to family caregivers. The executive summary of Administration on Aging in 2003 identifies expanding consumer- and family-directed care as the next step in strengthening caregiver support services and a solution to the direct care workforce shortage.

The NFCSP represents a formal recognition of the importance to support family caregivers through direct services; however, resources devoted to this effort still lag, as indicated by the modest level of NFCSP funding. Thus far, no study has been conducted to evaluate the impact of the NFCSP on caregiver stress and burden, or whether the program helps to sustain family caregiving.

SUPPORT FOR CAREGIVING FAMILIES: IMPLICATIONS FOR SOCIAL WORK

Although the FMLA and the NFCSP both intend to support family caregivers, their current provisions have limitations. In the following we discuss who may be underserved, what needs may be unmet under the two programs, and the implications for social work.

Underserved Family Caregivers

Working caregivers are the potential beneficiary of the FMLA. Some working caregivers, however, cannot take advantage of the act, such as those working for smaller companies and those who are hired as part-time, seasonal, or temporary workers. Socioeconomically disadvantaged groups, such as ethnic minorities, women, and those with low education, are more likely to be in such employment conditions. These non-eligible workers are as likely as eligible

workers to need leave for a health problem of their family members or themselves. Social workers, therefore, should push for expanding the FMLA to cover smaller companies, as well as part-time, seasonal, and temporary workers.

In addition, the definition of *family* under the current provision of the FMLA is too narrow. It should be expanded to include domestic partners, parents-in-law, grandparents, siblings, aunts, and uncles. Research has shown that a substantial proportion of informal caregivers are neither spouses nor adult children of the care recipients (Alecxih, Zeruld, & Olearczyk, 2002). Social workers may have to educate lawmakers about the diversity of family caregivers and urge them to recognize the function of family rather than its form.

It is difficult to assess who is underserved by the NFCSP, due to lack of data. However, the emphasis on integrating caregiver support services and other home and community-based services in many states may reduce the opportunity for vulnerable family caregivers to access caregiver support services. For instance, research has shown that older adults cared for by their wives only are less likely to use any home and community-based services (Li, in press). Consequently, these wife caregivers may be less likely to receive caregiver support services because they are not linked to the formal care system. Yet these caregivers may be quite isolated and in great need of support. To use the limited resources more effectively and to serve family caregivers who may need support services the most, it is necessary to find out who is using the NFCSP services and who is not. Collecting data about service users should be a requirement of the NFCSP funding and can be built into the current reporting system. Collecting data about the characteristics of family caregivers who do not use caregiver support services and the reasons for not using services is more challenging. However, such data will help to identify barriers for service use and to design targeted intervention for the hard-to-reach populations. Both social work researchers and practitioners should contribute to such data collection and outreach intervention efforts.

Unmet Needs

Some needs of family caregivers, including financial need, respite and supplemental services, and community-based long-term care services, are clearly unmet or undermet within the current provisions of the two federal programs.

Financial Need

The FMLA allows workers to take unpaid leave for health reasons of their family or themselves. Taking unpaid leave, however, can create financial hardship for some families, especially during the time when extra expenses for medication or hospital stays already may be causing a financial strain. Low-income families are more likely to be affected negatively by taking unpaid leave. The two studies by the Department of Labor (Commission on Leave, 1996; U.S. Department of Labor, 2000) consistently show that financial constraint is the primary reason for not taking leave among those eligible for leaves. The use rates of the FMLA have been low and are likely to remain so if paid leave is not available, which undermines the act's intention of promoting a healthier balance between employees' work and family responsibilities (Scharlach & Grosswald, 1997). Therefore, expanding the FMLA to paid leave should be a priority that not only offers substantive help to families of dependent older persons but also is a recognition of caregiving responsibility as work (Wisensale, 2001).

By the same token, the caregiving responsibility of family caregivers who are not or choose not to be in the labor force because of caregiving also should be recognized as work. Some states have allowed relatives and other informal caregivers to receive payment for performing homemaking, chores, and personal care services (Linsk, Keigher, Simon-Rusinowitz, & England, 1992). This may also be a way to deal with the shortage of direct care workers. Recent studies of consumer-directed programs involving payment to family caregivers, such as cash and counseling, show that these programs increase satisfaction, reduce unmet needs, and enhance quality of life of elderly persons (Phillips et al., 2003).

If family caregiving is recognized as work, then the time when the caregiver provides assistance should be included and accumulated in calculating Social Security benefits (Stone, 2000). Although not ideal, this is a way to protect the long-term financial well-being of informal caregivers, most of whom are women, and to ensure that those who assume caregiving roles are not penalized financially. Social workers should be in the forefront to advocate for paid leave, consumer-directed options, and Social Security benefits for family caregivers.

Respite Care and Supplemental Services

Respite care and supplemental services seem to be a demand of family caregivers that is far from being sat-

ified under the current funding level of the NFCSP (Family Caregiver Alliance, 2002). In addition, because states vary considerably in how they spend the funding in the five basic services (information, assistance, counseling and training, respite care, and supplemental services), it may be necessary to make these services a standard provision under the OAA and to increase their funding. In this way, family caregivers, regardless of where they live, would have the opportunity to get respite care and supplemental services. Social workers' knowledge about the need of family caregivers puts them in a good position to advocate for these services.

Community-Based Long-Term Care

A more substantial support for family caregivers, nevertheless, is to provide a wide range of home and community-based services, such as adult day care, home health aides, and homemaking services, to support older persons with disability to live in the community. This would reduce the demand on family caregivers and enable older persons to choose who (e.g., family or formal agency) provides what type of care. The current funding for community-based long-term care is inadequate and severely circumscribed (Olson, 2003). For instance, only impoverished older persons who are "at risk" of institutionalization are eligible for publicly funded community-based long-term care programs through Medicaid waivers. The majority of disabled older adults are not eligible for publicly funded programs, and few can afford to purchase services to meet their long-term care needs.

Proponents of community-based long-term care often face two questions: Would formal services substitute for informal caregiving, and would community-based care save money compared with institutional care? Mounting evidence has shown that informal caregivers do not withdraw from caregiving even if formal services are available (Penning, 2002). Community-based long-term care, if provided on a limited scale, may not save money relative to institutional care. But there is evidence to suggest that a large-scale operation of community-based long-term care programs reduces overall care costs in the long run (Kane, Kane, & Ladd, 1998). Community-based care is also strongly preferred by older persons (Weissert & Hedrich, 1994). To truly support families of elderly persons, publicly funded home and community-based long-term care programs should be accessible to all persons with disability, and before their disability levels become severe. Research has shown that early home

and community-based service intervention improves subjective well-being and delays institutionalization for moderately impaired older adults (Shapiro & Taylor, 2002). Financing is an issue in any discussion of expanding social programs. Some developed countries, such as Germany and Japan, have implemented national long-term care insurance programs. Their models provide a reference for the United States to develop a long-term care system that provides options of care to disabled older persons and their families. Social workers should demand, and empower the current and future cohorts of older persons to demand, a better long-term care system for Americans.

CONCLUSION

The vast majority of older persons who require long-term care rely on family to meet their basic needs. Providing assistance to elderly relatives, however, engenders financial and personal costs for family caregivers. Policymakers thus far have taken modest actions to support families of older adults with care needs. The FMLA, while helping workers to deal with conflicts between work and caregiving responsibility, needs to expand to cover a broader workforce (e.g., workers in smaller companies and workers in part-time, seasonal, or temporary positions) and allowable reasons for taking leave (e.g., caring for domestic partners, parents-in-law, and grandparents). More important, paid leave has to be offered because most low-income families cannot afford to take unpaid leave. The NFCSP is important because it is the first national program that focuses on family caregivers. However, its low level of funding does not match its ambitious goal—to "develop multifaceted systems of support services for family caregivers" (Lewin Group, 2004, p. 1-3). To prevent the NFCSP from being perceived as merely rhetoric, the funding level must be raised. In addition, caregiver support services need to reach vulnerable groups, such as more socially isolated caregivers. Finally, a more substantial support for families of disabled older persons would be to expand home and community-based long-term care. This would reduce the demand on family caregivers and provide options of care to older persons with disability.

Policy to Protect the Rights of Older Adults

86

The Older Americans Act provides a useful framework for reviewing policy to protect the rights of older adults. Under Title I the act lays out the duties of the federal, state, and local governments and of Native American tribes to “assist our older people to secure equal opportunity to the full and free enjoyment of the following objectives”:

- (1) An adequate income in retirement . . .
- (2) The best possible physical and mental health which science can make available and without regard to economic status.
- (3) Obtaining and maintaining suitable housing, independently selected, designed and located with reference to special needs and available at costs which older citizens can afford.
- (4) Full restorative services for those who require institutional care, and a comprehensive array of community-based, long-term care services adequate to appropriately sustain older people in their communities and in their homes . . .
- (5) Opportunity for employment with no discriminatory practices because of age.
- (6) Retirement in health, honor, dignity . . .
- (7) Participating in and contributing to meaningful activity within . . . civic, cultural, educational, training and recreational opportunities.
- (8) Efficient community services . . . with emphasis on maintaining a continuum of care for vulnerable older individuals.
- (9) Immediate benefit from proven research knowledge . . .
- (10) Freedom, independence and the free exercise of individual initiative in . . . managing their own lives . . . and protection from abuse, neglect and exploitation. (Older Americans Act [OAA], P.L. 89-73, 42 U.S.C. § 3001 *et seq.*; Department of Health and Human Services, 1979, p. 2)

This chapter focuses on explicating select policies that protect the rights of older adults in relation to many of the above objectives. I begin by discussing those policies that prohibit employment discrimination due to age. I also address various policies that indirectly promote the civil rights of older adults by making discrimination based on disability illegal. In addition, the chapter addresses grandparents’ rights, the patient’s bill of rights, and the right to be free from abuse, neglect, or exploitation.

DISCRIMINATION BASED ON AGE: EMPLOYMENT

Age Discrimination in Employment Act: Purpose and Scope

Ageism is defined as “the process of systematic stereotyping of and discrimination against people because they are old” (Butler, 1969, p. 243). The key to ageism is that older adults are judged not as individuals but as members of a social category with certain traits (Quadagno, 2002). The secretary of labor reported in 1965 that there was widespread age discrimination in employment (U.S. Department of Labor, 1965). Such discrimination is based on negative stereotypes about older workers’ productivity levels and abilities rather than on dislike of or intolerance toward older workers (Querry, 1995–1996). Congress thus enacted the Age Discrimination in Employment Act (ADEA, P.L. 90-202, 29 U.S.C. §§ 621–634, regulations at 29 C.F.R. § 1625), in 1967 to prohibit arbitrary age discrimination in hiring, termination, promotion, compensation, terms/conditions, and privileges (Querry, 1995–1996). The ADEA makes it illegal to discriminate in employment practices against employees aged 40 and older (Tichy, 1991). Private employers with more than 20 employees, employment agencies, and labor unions, as well as federal employers, are covered under this act (Kapp, 2001).

Employers can assert the following exemptions against an age discrimination claim: (a) where age is a bona fide occupational qualification (BFOQ) reasonably necessary to the normal operation of a particular business, (b) where the action is based on reasonable factors other than age (RFOA), (c) to observe the terms of a bona fide seniority system, (d) to observe the terms of a bona fide employee benefit plan, or (e) to discharge or otherwise discipline an individual for good cause (29 U.S.C. at 623 (f)) (Koff & Park 1999; Tichy, 1991). In some cases age may be a factor in one’s ability to safely perform a job, such as police officer or firefighter, and can thus be used as a qualifying criterion for government employees (Kapp, 2001). In addition, employers can require medical exams for applicants over age 40 but only when they are directly related to the specific work to be performed and when exams are required for all applicants regardless of age (Tichy, 1991). Likewise, employers can promote a younger employee over an older employee due to greater seniority of the younger employee. Further, the employer cannot establish a mandatory retirement system but can legally

offer a retirement incentive as long as it is voluntary (Kapp, 2001; Tichy, 1991). An employer is allowed to fire or refuse to hire or promote based on an individual’s qualifications or actual job performance but cannot use chronological age as a proxy for job performance.

A plaintiff presents a prima facie case of age discrimination to the Equal Employment Opportunity Commission (EEOC) by showing that the plaintiff was a member of the protected group (e.g., over age 40), the plaintiff was qualified for the job, the plaintiff was adversely affected, and the employer hired or promoted someone else for the same position (Tichy, 1991). The alleged aggrieved employee does not have to provide direct evidence of the employer’s unlawful intent; rather, he or she merely has to provide evidence to refute any legitimate reasons for rejecting an applicant (for hire, promotion, etc.) put forward by the employer (Kapp, 2001).¹²

Concerns With the Law

Problems with ADEA abound. First, the act does not clarify the term *arbitrary* (Querry, 1995–1996). Second, ADEA has had little effect on hiring decisions, because such discrimination can be very difficult to prove (Jolls, 1996). Third, Harper (1993) contends that ADEA and the Older Worker’s Benefit Protection Act (OWBPA) do little to protect workers in relation to retirement incentives. Employers offer retirement incentives as a way to reduce the workforce through attrition rather than forced layoffs. Older workers in most cases cost employers more for a variety of reasons (service time, higher health care costs, etc.). Thus, it benefits the company more to reduce the number of older workers (regardless of productivity levels) than to reduce the number of younger workers (Frolik, 1999; Harper, 1993). “Conditional age-based exit incentives can be used to achieve precisely what the ADEA seeks to eradicate: the age-based elimination of productive older workers who would prefer continued employment to retirement” (Harper, p. 69).

Finally, recent case law in this area has made it difficult for older workers to win a claim around the use of age proxies (e.g., years of service; Bailey, 2001; see *Hazen Paper Co. v. Biggins*, 507 U.S. 604 (1993)). In the *Biggins* case the Supreme Court held that age and years of service are “analytically distinct” and thus years of service cannot necessarily be considered age based. This decision has also enabled employers to use reduction in force or downsizing strategies to elimi-

nate older (and generally more costly) workers from their payrolls. According to Minda (1997), these strategies are largely immune to ADEA litigation because they are generally couched in economic necessity for the employer and thus are considered “reasonable factors other than age.” Such case law developments have made it increasingly difficult for older adults to sustain an age discrimination complaint in the face of downsizing and cost-reduction strategies.³

AMERICANS WITH DISABILITIES ACT AND EMPLOYMENT DISCRIMINATION

Until 1990, older employees who had adverse action taken against them (firing, failure to promote, etc.) due to RFOAs had little recourse (Hood, 1998). In 1990, however, Congress passed the Americans With Disabilities Act (ADA, P.L. 101-336, 104 Stat. 327 (1990), 42 U.S.C. 12101–12213 (1994)), which may help those older workers who are terminated for health reasons (Kapp, 2001).

The ADA (specifically Title I) prohibits public and private employers with 25 or more employees from discriminating “against a qualified individual with a disability because of the disability of such individual in regard to job application procedures, the hiring, advancement or discharge of employees, employee compensation, job training, and other terms, conditions, and privileges of employment” (42 U.S.C. § 12112 (a)). A disabled person is defined under the act as one who either: “1) has an actual physical or mental impairment that substantially limits one or more major life activities; 2) has a record or past history of an impairment. . . ; 3) is regarded as having an impairment . . .” (42 U.S.C. § 12102(2)(A, B, C)). A qualified individual with a disability is defined as a person “who can perform the essential functions of the job with or without reasonable accommodations” (42 U.S.C. § 12111(8)). Such accommodations can include reassignment or restructuring of the job, providing special aids or training, and access to employer-provided facilities such as cafeterias, lounges, and fitness centers (42 U.S.C. § 12111(8)). The employer must provide these accommodations unless it can show that doing so would “impose an undue hardship on the employer” (Hood, 1998; Kapp, 2001).

According to Kapp (2001) and Hood (1998), prior to ADA, an older worker with arthritis could be terminated under the “reasonable factors other than age” exemption of the ADEA. “Now, however, that

same employer may be liable under the ADA if it could reasonably accommodate her arthritis on the job” (Hood, 1998, p. 8). (See www.eeoc.gov/docs/accommodation for further guidelines on the ADA.)

DISCRIMINATION IN PUBLIC SERVICES: THE ADA AND OLDER ADULTS

Title II of the ADA also protects individuals with disabilities in relation to discrimination by public services. Title II states that “no qualified individual with a disability shall by reason of such disability, be excluded from participation in or be denied the benefits of the services, programs, or activities of a public entity or be subjected to discrimination by such an entity” (42 U.S.C. § 12131(1)). A qualified individual is defined as

an individual with a disability who, with or without reasonable modifications to rules, policies, or practices, the removal of architectural, communication, or transportation barriers, or the provision of auxiliary aids and services, meets the essential eligibility requirements for the receipt of services or the participation in programs or activities provided by a public entity. (42 U.S.C. § 12131 (2))

The Supreme Court decision in *Olmstead v. L.C.* (119 S. Ct. 2176 (1999)) further interpreted Title II of the ADA. The court held that “unjustified isolation . . . is properly regarded as discrimination based on disability.” The court noted that

institutional placement of persons who can handle and benefit from community settings perpetuates unwarranted assumptions that persons so isolated are incapable or unworthy of participating in community life [and] confinement in an institution severely diminishes the everyday life activities of individuals, including family relations, social contacts, work options, economic independence, educational advancement, and cultural enrichment. (*Olmstead v. L.C.*, 1999 at 2176)

Under this decision, states are now required to provide community-based services or less restrictive service settings when a professional determination indicates that such placement is appropriate, the affected person does not oppose the placement, and the

placement can be reasonably accommodated (Fried, 2001; Kapp, 2001).

DISCRIMINATION IN HOUSING: THE ADA AND FAIR HOUSING AMENDMENTS

The housing rights of persons with disabilities are protected via the ADA (Title II, public services, and Title III, public accommodations); Section 504 of the Rehabilitation Act (29 U.S.C. § 794); and the Fair Housing Act Amendments of 1988 (FHAA, P.L. 100-430, 102 Stat.1619 (1988) 42 U.S.C. § 3601–3619).⁴ The FHAA make it illegal to discriminate in the sale, rental, or terms, conditions, or privileges of sale/rental or in the provision of services or facilities because of a handicap of the buyer/renter, someone intending to live in the property, or someone connected with that buyer/renter (Kapp, 2001).⁵

Recent statistics show that 52.5% of the elderly have at least one disability as defined by the ADA (AARP, 1997). Of note is the fact that the act covers renters and buyers who live with or are associated with a person with a disability. Thus, families wishing to take in an elderly, disabled relative, or older adults caring for mentally or physically disabled adult children, or grandparents caring for a disabled grandchild would fall under these protections. The FHAA also may be applicable in cases where independent living complexes or communities refuse to rent to seniors in a wheelchair or with other disabilities (Ziaja, 2001). Providers may be exempt from this policy if they can show that the discriminatory policy is fundamental to the nature of the facility and such a change would instill an undue burden related to accommodation on the facility. Finally, the FHAA may prohibit certain state or local regulations (e.g., zoning and fire safety codes) that restrict certain types of housing operators from admitting residents with certain disabilities (*Cason v. Rochester Housing Authority*, 748 F. Supp. 1002 (W.D.N.Y. 1990)).

GRANDPARENT RIGHTS

Increasingly our society is seeing grandparents play a much larger role in the upbringing of children, in many cases as the sole caregiver. “More than three million children in the U.S. live with older relatives, and in at least one million homes a grandparent is the sole or primary caregiver” (American Bar Association [ABA], 1998b, p. 15). There are two key areas in relation to the rights of grandparents: visitation between

grandparents and grandchildren who are still with their parents or other primary caregivers, and kinship care, when grandparents become the primary caregivers (ABA, 1998a).

Visitation Rights

Originally common law did not grant grandparents the right to see their grandchildren while in the custody of their biological or adoptive parents (ABA, 1998b). Since the mid-1960s, however, all 50 states and the District of Columbia have enacted legislation giving grandparents the right to petition the court for visitation. This results in two important problematics. First, grandparent visitation rights are governed by state law, which can make things confusing for both grandparents and advocates for older adults. Second, most state law simply grants the right to petition the courts for a visitation order (ABA, 1998b). This requires a detailed court process that can be adversarial, thus creating much disruption in the children’s lives (ABA, 1998b).

In determining whether to grant visitation rights, most courts consider what would be in the “best interests of the child,” but also they may look at any prior relationship with the person petitioning, the mental and physical health of those involved, and the child’s preference (if the child is old enough to express such; ABA, 1998b). Most commonly, state laws allow for such petitions upon the death of a parent or in the case of divorce. Some states also include such situations as parental incarceration, out-of-wedlock birth, or “when the child previously lived with the grandparent” (ABA, 1998b, p. 13). In the case of adoption, most courts have found that the grandparents’ rights are terminated, as are those of the biological parents. However, in cases where the child is adopted by a stepparent or other close relative, grandparent rights are not automatically terminated (ABA, 1998). Although some state statutes are broad enough to allow a grandparent to petition the court when the nuclear family is intact (the children reside with both parents), most courts frown upon granting visitation rights in these cases, deferring to the authority of the parents (ABA, 1998b). Finally, federal law requires states to honor visitation orders granted in another state (ABA, 1998b; see also Kapp, 2001, for a list of state statutes on visitation rights).

Kinship Care

Kinship care refers to a situation in which parents are unable to care for their children, and relatives (in

many cases older relatives) step in to provide such care. Frequently, grandparents become kinship care providers on an informal basis. However, problems can arise if grandparents do not have legal custody or guardianship over the child. Thus they may have difficulty when enrolling the child in school, consenting to medical treatment, or applying for public benefits.

To formalize the arrangement, the grandparent must look to state law for guidance. However, there are generally three options available: custody, guardianship, or permanent adoption. Guardianships can be permanent or temporary (including standby) depending on the state law. In addition, some states allow for open adoption. Other states have enacted consent legislation to allow parents to grant authority for medical and other decisions to another adult without limiting the rights of the parents (ABA, 1998b; Kapp, 2001). Standby guardianship laws enable parents to designate a guardian in advance (similar to a springing power of attorney) if they have a chronic, debilitating, or terminal illness. In some cases, if the state has removed the child from the parent's custody, it may place the child with a grandparent while the state retains legal custody (generally referred to as foster care; ABA, 1998b).

One important reason for formalizing the kinship care arrangement is to obtain necessary financial support. In many cases grandparents may be on fixed incomes, not designed to support a family. Grandparents can become foster care parents and receive payment under Title IV-E of the Social Security Act. However, in this situation the state retains custody of the child, and the grandparent must be evaluated based on state licensing requirements. This may be difficult, especially if the older adult resides in subsidized housing or senior housing. A grandparent or grandchild may be eligible for several types of benefits, including TANF, Social Security Dependent Benefits, SSI, Medicaid, CHIP, food stamps, EITC, and guardianship subsidies. Many of these programs are administered at the state level; thus, eligibility would need to be determined case by case.

Another area of concern for grandparent caregivers involves their place of residence. Amendments to the Fair Housing Act⁶ provided an exemption from FHAA rules regarding familial status for senior housing complexes. This exemption and the four-prong test to establish it may unintentionally reopen the door for "adult-only" apartment complexes (Panjwani, 1995). This may prove problematic for older adult grandparents who need to house their grandchildren while residing in such a complex. Unfortunately, this is more likely to affect African American and Hispanic

older adults. Data from the U.S. Census show that 4.2% of White children under age 18 lived with a grandparent, whereas 13% of African American children and 7.5% of Hispanic children lived with a grandparent (U.S. Census, 2000, as cited in Nelson, 2003).

PROTECTION FROM ABUSE, NEGLECT, AND EXPLOITATION

The OAA defines abuse in the following way:

Abuse is the willful infliction of injury, unreasonable confinement, intimidation, or cruel punishment with resulting physical harm, pain, or mental anguish; or deprivation by . . . a caregiver of goods or services . . . necessary to avoid physical harm, mental anguish, or mental illness. (42 U.S.C. § 3002(13)(A-B))

Neglect is the failure to provide for oneself goods or services necessary to avoid physical harm, mental anguish or mental illness . . . [or] failure of a caretaker to provide such goods or services. (42 U.S.C. § 3002(37)(A-B))

Exploitation means the illegal or improper act or process of an individual, including a caregiver, using the resources of an older individual for monetary or personal benefit, profit, or gain. (42 U.S.C. § 3002 (26))

These definitions provide guidelines for the states; however, the OAA does not stipulate penalties for the commission of abuse or neglect.

Every state has enacted elder abuse legislation that defines abuse. Most states have the equivalent of an adult protective services unit, which is responsible for investigating and substantiating cases of abuse or neglect, as well as providing protection from further mistreatment.⁷ Most state statutes provide for criminal liability for willful acts or omissions which result in elder mistreatment (Kapp, 2001). Most statutes include both family and formal care providers under the definition of caregiver. Finally, some statutes mandate certain professionals to report elder abuse, and other statutes provide for voluntary reporting of abuse (Colorado, Illinois, New Jersey, New York, North Dakota, Pennsylvania, and South Dakota; see Kapp, 1999). All states protect individuals who report abuse; as long as they have made a report in good faith, they are immune from subsequent charges of harm or defamation (Kapp, 1999; see Exhibit C for other relevant legislation).

PATIENT'S BILL OF RIGHTS

In 1997 President Clinton appointed the Advisory Commission on Consumer Protection and Quality in the Health Care Industry to advise the president on issues related to changes in health care delivery, to assure quality health care, and to protect consumers and staff in health care systems. The commission was also asked to develop a bill of rights for health care consumers. The Consumer Bill of Rights and Responsibilities was intended to accomplish three major goals:

First, to strengthen consumer confidence by assuring the health care system is fair and responsive to consumers' needs, provides consumers with credible and effective mechanisms to address their concerns, and encourages consumers to take an active role in improving and assuring their health.

Second, to reaffirm the importance of a strong relationship between patients and their health care professionals.

Third, to reaffirm the critical role consumers play in safeguarding their own health by establishing both rights and responsibilities for all participants in improving health status. (Office of Personnel Management, 2002, p. 10)

On February 20, 1998, President Clinton signed an executive order that extended the provisions of the patient's bill of rights to more than 85 million Americans with health care coverage under Medicare, Medicaid, and all other federally sponsored health care programs (U.S. Senate, 2001). The bill of rights specifies eight sets of rights and responsibilities for consumers of health care. These include the right to information, a choice of providers, access to emergency services, full participation in their medical care, respectful care, confidentiality, a fair and efficient process for filing appeals and complaints, and the responsibility to be active participants in their care (Department of Health and Human Services, 1999; for further details on the patient's bill of rights, see www.opm.gov/insure/health/billrights.htm, www.democrats.senate.gov/pbr/history.html, www.os.dhhs.gov/news/press/1999press/990412.html).

Congress has pursued passage of legislation in this area since 1997 to ensure similar protections for all health care consumers, particularly those in managed care systems. A recent Supreme Court decision in this area makes the need for a patient's bill of rights all the more crucial. *Cigna Healthcare of Texas, Inc. v. Calad*,

No. 03-83 and *Aetna Health Inc. v. Davila*, No. 02-1845, 004 consolidated and were heard as one case. See also *Rush Prudential HMO, Inc. v. Moran*, 536 U.S. 355 (2002), which held that a state-level independent medical review statute was not preempted by ERISA. The holding in these two cases states that employer-sponsored health insurance plans are regulated by the Employee Retirement Income Security Act of 1974 (ERISA), which preempts any state law in this area. Thus, beneficiaries who are denied treatment coverage by an employer-sponsored health maintenance organization (HMO) can no longer sue for damages. Under ERISA rules, the beneficiary can sue only for reimbursement of the cost of providing the procedure. This virtually eliminates consumers' ability to pressure an HMO into providing essential, physician-prescribed care and opens the door for severe limits to be placed on access to care by managed care plans. "If a health plan makes a bad decision on coverage and you are harmed by it, you now have very little redress if the decision is negligent, in bad faith or even intentional" (*Christian Science Monitor*, 2004, p. 3). In response to this decision, Representative John Dingell has introduced a new version of the Patient Bill of Rights Act of 2004 (H.R. 4628, 108th Congress). The bill provides for utilization review, internal and external review of claims denials, consumer choice, access to emergency care and specialists, access to information, protection of the doctor-patient relationship, availability of civil remedies (amending ERISA), and tax incentives for small business.

CONCLUSION

The rights of older adults are protected by a hodgepodge of policies generated by case law, executive order, or legislative initiative. This chapter simply touches the tip of the proverbial iceberg in relation to these areas. The appendix provides several lists of related legislation or case law, as well as a list of organizations with expertise in many of these areas. Legislation is important, but equally important are court decisions interpreting these laws and the regulations that guide implementation. Thus older adults and their advocates not only need to be informed about new legislation but also must be aware of changes made in all areas of policy creation. The objectives of the OAA provide guidelines for those key areas that we, as a society, have identified as crucial to the health and well-being of older adults. However, as advocates we must go beyond these guidelines to continue to enhance and expand the rights of older adults.

Appendices

Exhibit A: Age Discrimination in Employment: Policy History

<i>Policy</i>	<i>Impact</i>
Social Security Act of 1935 (P.L. 271-74)	Decommodification of older workers from labor force, may have reinforced negative stereotypes regarding older workers. The original Social Security Act did not cover all workers (e.g., domestic workers, many professional groups were excluded at the beginning). Thus economic security in retirement in the early days of social insurance was not assured for all.
Executive Order No. 11,141, 3 C.F.R. 1811 (1964–1965), February 12, 1964, Lyndon B. Johnson	Established federal policy against age discrimination in employment for federal contractors and subcontractors. No enforcement provided or cause for action.
Civil Rights Act of 1964 (P.L. 88-352, 78 Stat. 265, 42 U.S.C. §§ 2000e–2000e-17 (1994))	Title VII of this act made it illegal to discriminate in employment decisions based on race, color, religion, national origin, or sex (Eglit, 1997; Koff & Park, 1999).
U.S. Department of Labor (1965) The Older American Worker: Age Discrimination in Employment	Reported to Congress widespread age discrimination in employment that was arbitrarily based on assumptions about older workers' productivity, etc.
ADEA of 1967, P.L. 90-202, 29 U.S.C. §§ 621–634, 29 C.F.R. § 1625	See full description in this chapter.
The Fair Labor Standards Act of 1974 (P.L. 93-259)	Expanded coverage of ADEA by including employers with 20 or more employees as well as federal, state, and local government employers.
ADEA amendments of 1978 (P.L. 95-256)	The original law set the age limit at 40–65. This was amended via the 1978 amendments to ADEA to age 70 for private sector, state and local governments, and removed age ceiling for federal employees. Raised compulsory retirement age for executives and tenured faculty to age 70.
Tax Equity and Fiscal Responsibility Act of 1982 (TEFRA, P.L. 97-248)	Required employers to keep the “working aged” on their health plans (offered to younger workers) rather than shifting them to Medicare (Koff & Park, 1999).
The Deficit Reduction Act of 1984 (DEFRA, P.L. 98-369)	Required employers to “offer employees under age sixty-five the same family group health coverage” (Koff & Park, 1999, p. 260). It also lifted the Medicare Part B premium penalty for workers who stayed on the private plan.
The 1984 Older Americans Act Reauthorization (P.L. 98-459)	Extended coverage of ADEA to U.S. citizens employed by U.S. employers in foreign countries (Koff & Park, 1999).
ADEA amendments of 1986 (P.L. 99-592)	Removed the upper age limit for all employers with 20 or more employees and eliminated mandatory retirement for both public and private sectors. Mandatory retirement for tenured faculty in institutes of higher education was allowed to expire in 1993. Also in 1986 employers were required to offer the same group health insurance to workers aged 69 and over as was provided to younger workers.
Older Workers Benefit Protection Act of 1990 (P.L. 101-433)	Clarified that ERISA benefit plans are subject to ADEA and created further protections to ensure that “older workers are not compelled or pressured into waiving their rights under the ADEA in relation to early retirement incentive plans” (Koff & Park, 1999, p. 263). These waivers of claims must be in writing, must specifically refer to claims under ADEA, must advise the employee to consult an attorney, must give the employee 21 days to consider the waiver, and 7 days to revoke after signed (29 U.S.C. § 626 (f)(1)(A)-(G)).

Exhibit B: ADEA Case Law History

<i>Case</i>	<i>Holding</i>
<i>McDonnell Douglas Corp. v. Green</i> , 411 U.S. 792 (1973)	“The fact that one person in the protected class has lost out to another person in the protected class is thus irrelevant, so long as he has lost out because of his age . . .” @ 802. Also found that if prima facie case established by plaintiff, then burden shifts to employer to present a legitimate nondiscriminatory reason for action taken.
<i>Texas Dept. of Community Affairs v. Burdine</i> , 450 U.S. 248 (1981)	“Burden of persuasion, proving discrimination, rests at all times with the plaintiff.” @ 256. “Also discrimination can be proven by the plaintiff either directly by persuading a court that a discriminatory reason more likely motivated the employer or indirectly by showing that the employer’s proffered explanation is unworthy of credence.” @ 256.
<i>Aikens</i> , 460 U.S. at 7111 (1983)	Established the 4-point formula for presenting a prima facie case without direct evidence of employer’s intent.
<i>Griggs v. Duke Power Co.</i> , 401 U.S. 424 (1991)	In a race discrimination case, the court held that “Title VII proscribes not only overt discrimination but also practices that are fair in form, but discriminatory in operation.” @ 431. Established the model of disparate impact discrimination, which relies on statistics to show disparate impact on protected class.
<i>Hazen Paper Co. v. Biggins</i> , 507 U.S. 604 (1993)	“Age and years of service are analytically distinct, [thus it is] incorrect to say that a decision based on years of service is necessarily age-based.” @ 611 Case where employer fired a 62-year-old worker who was close to vesting in pension plan.
<i>St. Mary’s Honor Center v. Hicks</i> , 509 U.S. 502 (1993)	Plaintiff must demonstrate both that the proffered reason was false and that discrimination was the real reason, commonly referred to as pretext only v. pretext-plus. @ 519.
<i>Oubre v. Energy, Inc.</i> , 118 S. Ct. 838 (1998)	The Supreme Court found that employer’s failure to comply with OWBPA on these waivers gives the aggrieved employee the right to sue under ADEA.
<i>Reeves v. Sanderson Plumbing Products, Inc.</i> , 530 U.S. 133 (2000)	A prima facie case of discrimination and sufficient evidence which allows the jury to reject the employer’s explanation for the adverse employment action may permit a finding of liability. @ 147.
<i>Kimel v. Florida Board of Regents</i> , 120 S. Ct. 631 (2000)	Under judicial review, the Supreme Court ruled in 2000 that the ADEA does not apply to state or local governments as it “is not a valid exercise of Congress’ power under § 5 of the Fourteenth Amendment. The ADEA’s purported abrogation of the States’ sovereign immunity is accordingly invalid.”
<i>Erie County Retirees Ass. v. County of Erie</i> , 220 F.3d 193 (3d Cir. 2000).	Employer violated ADEA by providing Medicare-eligible retirees health benefits that were inferior to the benefits offered to retirees who were not eligible for Medicare; Medicare eligibility is a direct proxy for age. @ 211. Use of disparate impact theory.

Exhibit C: Legislation to Protect Older Adults From Abuse

<i>Legislation</i>	<i>Impact</i>
Title XX amendments to the Social Security Act of 1975 (42 U.S.C. §1397, Title XX, 45 C.F.R. 222.73)	Provided protective services for all adults aged 18 or over.
Health Care Quality Improvement Act of 1986 (P.L. 99-660)	Requires health care providers to report adverse actions involving medical staff, such as revocation of license or malpractice claims.
Nursing Home Reform Act of 1987 (as part of OBRA 87, 100-203, 42 C.F.R. § 483.156)	Requires states to establish a registry of nurse aides and any finding of abuse, neglect, or exploitation by an aide.
Older Americans Act amendments of 1987 (P.L. 100-175)	Added prevention of abuse, neglect, and exploitation to OAA objectives.
OAA Amendments of 1992 (P.L. 102-375)	Added definition of elder abuse, neglect, and exploitation to OAA.
Violent Crime Control and Law Enforcement Act of 1994 (P.L. 103-222)	Ordered the attorney general to develop guidelines for protecting children, older adults, or persons with a disability from abuse; also to evaluate the effectiveness, availability, and cost of criminal background checks. Many states have enacted legislation to require criminal background checks.
Safe Medical Devices Act (P.L. 101-629)	Required to report when a restraint may have caused or contributed to the death of a resident/patient or staff.

NOTES

1. Courts follow the precedent set in the *McDonnell Douglas v. Green* case (411 U.S. 792 (1973)) establishing a three-part test of burdens and proof for cases lacking direct evidence (North, 1997). See also *Reeves v. Sandersen Plumbing Products, Inc.*, 120 S.Ct. 2097 (2000), and *Texas Dept. of Community Affairs v. Burdine*, 450 U.S. 248 (1981).

2. According to Kapp (2001) most states have their own version of the ADEA, some of which may provide broader protections. Thus older workers can also file suit in many state courts via the respective state statute. (See Kapp for a detailed list of state statutes (pp. 10-11) and Exhibit A for a policy history of age discrimination in employment.)

3. However, where the proxy has a direct connection to age, as in the case of Medicare eligibility, courts have found that this cannot be allowed as a reasonable factor other than age (RFOA). (See *Erie County Retirees Ass. V. County of Erie*, 220 F.3d 193 (3d Cir. 2000)). (See Exhibit C for ADEA case law history and Minda (1997) for a detailed discussion of reduction in force strategies and interpretation of case law in this area.)

4. The Fair Housing Act of 1968 was originally Title VIII of the Civil Rights Act of that year which prohibited discrimination in the sale, rental, or financing of housing on the basis of race, color, religion, or national origin. FAA was also amended in 1974 to include sex as a protected class (Nelson, 2003).

5. The FHAA also made it illegal to discriminate on the basis of family status, thereby invalidating the “adults only” restrictions of many housing complexes. “Congress included familial status as a protected class because of evidence that housing discrimination against families was pervasive and often affected minority families disproportionately” (Nelson, 2003, p. 4).

6. FHAA of 1988, P.L. 100-430, 102 Stat. 1619 (1988) 42 U.S.C. § 3601-3619 and Housing for Older Persons Act of 1995, P.L. 104-76.

7. Title XX amendments to the Social Security Act in 1975 provided protective services for all adults age 18 or over (42 U.S.C. §1397, Title XX, 45 C.F.R. 222.73). After these amendments states began passing laws to establish and implement their protective service plans.

JAMES LUBBEN,
SECTION EDITOR

**International Social Work
and Care of Older Adults**

This page intentionally left blank

OVERVIEW

Population aging was very much a blessing of the 20th century, and it has had major ramifications for the practice of social work throughout the world. This part of the Handbook examines social work with older adults and their families throughout the world. The part begins with an overview chapter by James Lubben and JoAnn Damron-Rodriguez that highlights the major demographic changes taking place in aging societies. A remarkable statistic quoted in that chapter is the tripling of the world's population 65 years of age and older over the next 50 years. As the authors state, the implications of this rapid aging will profoundly shape the 21st century.

The other chapters of this part feature social work practice in selected regions of the world. Both developing and developed nations are represented. Elizabeth Ozanne provides an extensive overview of some of the policies that have evolved as Australia has oscillated between conservative and liberal governments. Iris Chi provides an overview of social work in China, presenting both a historical and a political context for the tremendous aging of the world's most populous nation that is simultaneously experiencing rapid economic development. Japan is another country in the same region that has experienced rapid aging, although it had the benefit of securing economic development prior to the aging of its population. Thus, Japan was able to consider policies and programs that most countries could not. In particular, Japan has instituted one of the most comprehensive forms of long-term care insurance in the world. Judith Phillips offers an overview of social work practice with older adults and families in Europe. She compares and contrasts countries that share common cultural and political histories but have adopted slightly different forms of care. It would be useful to also compare this chapter with that offered by Ozanne, who writes about social work with older adults in Australia.

Osei Darkwa's chapter focuses on developing nations, with a special look at Africa. Sub-Saharan Africa has been hard hit with major health crises that

have devastated large segments of its population. Darkwa discusses this crisis and considers ramifications for social work practice with older adults in such countries. Martha Ozawa and Shingo Nakayama provide an overview description of this novel system of care. They also provide an excellent description of the historical and political forces that lead to the adoption of this social program.

The paramount issue of economic security in old age is beyond the purview of this part, but it deserves some notice. Indeed, there is grave concern about the viability of public pensions in many developed countries. Political turmoil also has severe consequences for aging populations, as illustrated by the collapse of the Soviet Union. People who had built trust in one social system to care for them in old age were especially hard hit when those political and social systems suddenly changed. Whereas younger adults could readily adapt and build savings for eventual retirement in the new social system, older adults did not have that luxury and often were left impoverished.

A number of organizations can provide more information on income security in old age. One is the Foundation for International Studies on Social Security, a nonprofit organization that promotes international, multidisciplinary research on social security (its Web page is found at <http://web.inter.nl.net/users/fiss/>). Another international organization that facilitates sharing of information regarding social security is the International Social Security Association (ISSA; www.issa.int). The U.S. Social Security Administration also has useful data regarding social security programs in other countries (www.ssa.gov/international/). The Organization for Economic Cooperation and Development (OECD), which tracks the economic ramifications of aging societies, has a special Web site that provides access to numerous reports regarding the fiscal, financial, and labor market implications of aging. In addition, the OECD offers many special reports on pensions, social benefits, and systems of health and long-term care. Its Web site is found at <http://www.oecd.org/home/>.

JOANN DAMRON-RODRIGUEZ

World Population Aging

87

Longevity was one of the great achievements of the 20th century, and its implications for the 21st century will be profound. From 1999 to 2050, the world population aged 65 and over is expected to triple (U.S. Bureau of the Census, 1996; U.S. National Institute on Aging, 1996). By the year 2030, more than 60 countries of the world will have 2 million or more people who are 65 years of age or older (Kinsella & Velkoff, 2001). Europe and North America presently have the oldest populations in the world and are expected to do so by the year 2030. What is remarkable is how rapidly other regions of the world are aging. As shown in Table 87.1, Oceania, Asia, and Latin America will double the percentage of older people in their populations. The only exception to this pattern of rapid aging societies is sub-Saharan Africa, where serious health problems, most notably the AIDS epidemic, are suppressing the progression toward an aged society.

Developing countries have smaller proportions and smaller absolute numbers of older persons in their societies, but the rate of growth in the aging population is vastly higher in developing countries. For instance, the number of Africans 60 years and older is expected to grow by 146% over the next 25 years. In the Muslim world, stretching from West Africa to Indonesia, the number of older people is expected to grow by an unprecedented 200% to 400% in this same time frame. Even in Nepal, where the elderly constitute only 4% of the population, their annual rate of growth is higher than for the overall population. The rapidity of these demographic shifts creates an extra social burden on developing nations.

An additional demographic shift is in the aging of the older population throughout the world. It is projected that 7% of Europe's population will be 80 years of age or older by the year 2030. The population 80 years and older in the United States was 25 times larger in 2000 than it was in 1900. By 2030, individuals who are octogenarians or older are projected to account for almost 5% of the total U.S. population and more than 25% of the total older adult (65+) population. Among all countries of the world, Japan stands out for the rapid aging of its aged population. In 1975, only 1.1% of Japan's population was 80 years or older. In 2000, almost 4% of its population was 80 years or older, and that percentage is expected to rise to more than 11% by 2030. Among other nations, only Italy and Sweden approach this figure; both of these European countries are expected to have around 9% of their population that is 80 years or older in 2030.

This remarkable population aging has generally taken place in two main stages (Rowe & Kahn, 1999).

TABLE 87.1 Percent Elderly by Age, 2000 and 2030

Region	Year	65 Years and Over	75 Years and Over	80 Years and Over
Europe	2000	15.5	6.6	3.3
	2030	24.3	11.8	7.1
North America	2000	12.6	6.0	3.3
	2030	20.3	9.4	5.4
Oceania	2000	10.2	4.4	2.3
	2030	16.3	7.5	4.4
Asia	2000	6.0	1.9	0.8
	2030	12.0	4.6	2.2
Latin America and Caribbean	2000	5.5	1.9	0.9
	2030	11.6	4.6	2.4
Near East and North Africa	2000	4.3	1.4	0.6
	2030	8.1	2.8	1.3
Sub-Saharan Africa	2000	2.9	0.8	0.3
	2030	3.7	1.3	0.6

From U.S. Bureau of the Census, *An Aging World 2001*.

The first stage was a dramatic reduction in infant mortality and early childhood death rates, accomplished largely through improved public health. As a result, more members of any given birth cohort have a chance to age. The second stage of population aging, which is more recent and ongoing, is characterized by a significant decrease in death rates among middle-aged and older people, attributable largely to improved self-care and medical science. These more recent developments enable more members of any given cohort of older adults to reach very old age.

The astonishing growth in the number of centenarians throughout the world provides an illustration of these phenomena. Kinsella and Velkoff (2001, p. 22) state, "Over the course of history, the odds of living from birth to age 100 may have risen from 1 in 20 million to 1 in 50 for females in low-mortality countries such as Japan and Sweden." The relatively small numbers of centenarians who are currently present in the population make future projections difficult, but it is highly likely that there may be well over 1 million centenarians in the United States citizens by 2050. Some demographers project that the United States might reach this plateau as early as 2030 (Krach & Velkoff, 1999).

North America, Europe, Japan, Australia, and New Zealand are regions or countries whose citizens gained 25 years of life expectancy during the last century alone. This gain in life expectancy was double

that in all of prior human history. Developing countries are also experiencing rapid growth in their older populations due in part to increased life expectancies. These countries continued to contend with significant threats to childhood survival and major public health challenges during much of the 20th century, and so there continues to be a gap in life expectancies between developed nations and developing nations. However, as shown in Table 87.2, this gap has narrowed, and life expectancies in most countries currently are projected to be over 70 years of age. This contrasts with the situation in the 1970s, when life expectancy in developing nations was less than 56 years.

At the same time that people are living longer, fertility rates are plummeting in most regions of the world, as a result of either deliberate public policy (e.g., China) or personal choice (e.g., Italy). Table 87.3

TABLE 87.2 Average Life Expectancies (in Years)

	1970–1975	1997	2025
More developed countries	71.0	74.5	79.2
Less developed countries	55.5	63.6	71.1
World	59.5	65.8	72.4

From WHO Kobe Centre for Health Development, *World Atlas of Ageing, 1998*.

TABLE 87.3 Total Fertility Rates (per Woman)

	1970–1975	2000–2005
More developed countries (OECD countries)	2.5	1.8
Less developed countries	5.4	2.8
World	4.5	2.7

From United Nations Human Population Report 2003, p. 253.

illustrates this rapid transformation in both economically developed and less developed countries. Most of the more economically developed nations now have about equal numbers of children under 25 years of age and adults 55 years of age and older. Fertility declines in the future of developing countries are occurring over a much shorter period than what occurred in the more developed countries. Population aging is the direct result of moving from a demographic state in which both mortality and fertility are relatively high into a world in which both mortality and fertility rates become relatively low (Higuchi, 1997). An increasing number of Asian and Latin American countries have nearly completed the change from high to low mortality and fertility rates.

Many economic factors are related to these demographic shifts. The dynamics of intergenerational economic exchange may be measured in terms of age cohort ratios, which are a gross measure of dependency within a population and thus are sometimes referred to as *dependency ratios*. These ratios make the gross assumption that people 20 to 64 years of age, supposedly in their prime working years, provide the most essential support for those either too young or too old to be actively participating in the workforce. Obviously, there are some difficulties with such gross assumptions. However, such demographic indices do offer an opportunity to compare and contrast the dramatic age cohort shifts occurring throughout different regions of the world. To illustrate these trends, Table 87.4 provides data on eight countries. The proportional size of the youth cohort in most countries of the world will experience a significant decline. Although the youth cohort will continue to be larger than the aged cohort in most countries in the developing world, the aged cohort will soon surpass the youth cohort in size in most of the economically developed countries. The United States stands out as an exception to the other developed nations in this regard. In the United States, the youth dependency ratio

TABLE 87.4 Age Cohort Ratios, 2000 and 2030 (Number of Young and/or Older Persons per 100 People 20–64 Years of Age)

		Total (young+old)	Youth (0–19)	Elderly (65+)
Chile	2000	77	64	13
	2030	70	42	28
China	2000	67	56	12
	2030	65	39	26
Kenya	2000	139	133	7
	2030	70	61	9
Italy	2000	60	31	29
	2030	75	26	49
Malaysia	2000	96	88	8
	2030	79	62	17
Mexico	2000	95	87	8
	2030	67	50	17
United Kingdom	2000	69	43	27
	2030	80	37	42
United States	2000	70	48	21
	2030	87	49	37

From U.S. Bureau of the Census, *An Aging World 2001*.

will be relatively stable over the next 30 years, and so the youth cohort will continue to be larger than the aged cohort. Kenya, typical of sub-Saharan Africa, is the exception to the overall tendency for most countries, whether economically developed or developing, to experience significant increases in aged dependency ratios. Again, this is a symptom of the seriousness of the AIDS epidemic in that part of the world.

Generations in the middle will have dual responsibilities for both younger and older dependent populations, with the number of elderly dependents increasing rapidly. Other factors include a diminution of the cascade of capital between generations. Although some have predicted vast transfers of wealth from one generation to the next, these projections may have failed to adequately account for all the consequences of extreme longevity. As older persons live considerably longer, they use up their assets in late life and have less left as inheritance or for support of younger generations (Lubben & Damron-Rodriguez, 2003; Damron-Rodriguez & Lubben, 2001).

Diversity must also be recognized as an important factor in aging societies. In terms of gender, for example, internationally, women can expect to live

longer than men. Women make up 55% of all people over age 65. Although female life expectancy continued to rise into the new century, male life expectancy slowed down or stabilized (United Nations, 1999). The majority of the former Soviet Socialist Republics have a 12-year difference between the life expectancies of women and men. Less-developed countries have a smaller differential, of approximately 2 to 3 years. In developed countries, the gender gap in life expectancy is between 5 and 8 years. The female advantage in life expectancy is partially offset by the higher rates of disability in women. Women live proportionately fewer disability-free years. Internationally, women are more likely to be widowed, to live longer alone and with functional limitations, and to be poor. A major gender issue is the caregiving role of women in the intergenerational family and its subsequent costs physically and economically.

Urban and rural differences must also be considered. Urbanization is progressing rapidly. In 1975 just over one third of the world population was urban; by the year 2000, more than 60% of the population will be living in cities. The migration to cities predominantly involves a younger population, leaving more elderly in rural areas, though there are marked exceptions (Australia, New Zealand, and several Latin American countries). Elderly men are more likely than women to live in rural areas.

The majority of aging societies have groups of persons who have minority status and are marginalized or otherwise socially excluded. In 1990, ethnic minorities made up only 14% of the older U.S. population, with African Americans, Hispanics, and American Indians having markedly lower life expectancies. However, beginning in the early part of the 21st century, the percentage of growth of minority groups will be higher than for majority adults. U.S. ethnic minorities are at greater risk of economic insecurity, poorer health status, and social isolation in late life. Social exclusion due to gender and race over the life course is a major reason that older minority women who live alone are the poorest group in the United States (Wallace, Shneider, Walker, & Ingman, 1992; Wallace, Levy-Stroms, Kington, & Andersen, 1998; Quinn and Smeeding, 1994; Lubben, Weiler, & Chi, 1989). Though relative cultural homogeneity is found in some countries, many countries are multicultural and multiethnic and thus must consider this diversity in designing care systems.

The demographic revolution has a profound impact on the structure of the family. Longevity has created an unprecedented opportunity for inter-

generational interaction and an unprecedented level of familial responsibility for elder care. The complex web of kin relationships in many countries creates ties with multiple elders (Bengtson, Rosenthal, & Burton, 1996). In 1900, in the United States, only 21% had a living grandparent, but by 2000, 76% will. Over this same period, the chance of a person over 60 having a parent alive increased from 18% to 44% (Quadagno, 1999). The divorce rate, now 50% of all marriages as compared with 10% at the end of the 19th century, adds to the complexity of the contemporary family.

The dramatic aging of the population, added to other social and demographic factors, has transformed the contemporary family (Pearlin, Aneshenel, & Whitlatch, 1996; Penrod, Kane, & Finch, 1995). As never before, families may contain four or five generations, with fewer members in each generation. This contrasts with the former more intense horizontal linkage with multiple members of a single generation. For example, in the United States only 21% of adults had a living grandparent in 1900, whereas 76% of adults currently do (Quadagno, 1999). Similarly, the chances of a 60-year-old adult having at least one parent still living increased from 8% in 1900 to 44% currently (Quadagno, 1999). Today, many families have multiple elders, parents, parents-in-law, stepparents, aunts, and uncles, for whom they may have some level of responsibility. Overall, families are smaller today but include more generations; this is referred to as the verticalization of the family system and is described as the beanpole family structure. Increasingly families have as many as five living generations (Bengtson et al., 1996).

Because the proportion of adult children in relation to older persons is decreasing, the level of support required from adult children for aging parents is increasing. A measure of family dependency is indicated by the parent support ratio (PSR), which divides the population over age 80 by the population aged 50 to 64 years. In 1997, more than 40 countries had a PSR of more than 40, in comparison with only 3 countries in 1975. Table 87.5 illustrates the PSR trends in four representative regions of the world. These ratios clearly show an upward trend among all four regions but also wide variation in both the actual support ratios and the rate of increase. Western Europe will face the greatest increase in these PSRs.

Increased longevity and smaller family size have resulted in potential gaps in an older person's traditional social support network. In some extreme cases, older persons may face the prospect of aging without

From U.S. Bureau of the Census, *An Aging World 2001*.

having a son or daughter on whom they may depend for care. For example, Gironde, Lubben, and Atchison (1998) state that currently one fifth of elderly Americans do not have children, and that in the next cohort to reach 65 almost one third will be childless. Traditional norms in Korea call for oldest sons to provide for aging parents. However, approximately 15% of elderly women in Korea have no surviving son, and this figure is expected to rise to 30% by the year 2025 (Kinsella & Velkoff, 2001). Increasing structural gaps in the potential for kinship care will require more attention by policymakers and community health and welfare service providers.

Old-age pensions and health care are two areas that will be especially affected throughout the world as a result of rapid population aging. Widening public pension deficits could soon consume the economic savings of most developed countries (Peterson, 1999). Accordingly, economic security in old age must be an essential element in program and policy planning for aging societies around the world. Similarly, costs associated with providing health care in aging societies are expected to rise dramatically. A recent report from the Organization for Economic Cooperation and Development (OECD) countries indicated that the growth rate for the share of the gross national product (GDP) given over to publicly financed long-term care was likely to rise precipitously in most countries (Jacobzone, 1999). For example, the increase between 2000 and 2020 of Japan's GDP going to long-term care is estimated to be anywhere from 70% to 100%. Many other countries also expected to experience at least a 30% increase during this same 20-year period (World Health Organization Kobe Centre for Health Development, 1998).

There are also some interesting differences in disability rates around the world. In some countries, including Japan and Germany, the growth rate for the disabled is larger than the overall growth rate for older

persons. However, some developed countries are reporting drops in disability rates for the elderly. Disability rates for older persons in the United States have dropped by 1% to 2% annually since 1982. In Canada, the proportion of older persons who reported no disabilities rose from 60% in 1978 to 75% in 1991. In France, older men added 15 months to their disability-free expectancy between 1978 and 1991, and older women added 27 months (World Health Organization Kobe Centre for Health Development, 1999).

In summary, longevity was one of the great achievements of the 20th century, and with proper planning it will continue to be celebrated well into the 21st century. This can be realized if all levels of government work together to create a society for all ages as called for by the United Nations International Year of Older Persons in 1999. A society for all ages would embrace multigenerational equity and meaningful involvement at all life stages and would acknowledge the interdependence of the individual and society. The Active Ageing policy framework put forth by WHO Ageing and Life Course Programme (2002) provides policy strategies for achieving a society for all ages.

Another international beacon for health and welfare planning for aging societies has been the WHO Kobe Centre (WKC), a research center that has published numerous special reports on aging societies and held a number of international planning conferences. In typical public health care philosophy, the WKC approach has promoted older person's self-care capacity through enhanced home and community environments seeking to delay the onset of disability in older persons or prevent it from happening altogether. A unique aspect of the WKC has been its strong focus on the older person within the context of family and community.

Such approaches are likely to be more practical and less costly for economically developing nations than the large medical institution-based programs being promulgated in many economically developed nations (Lubben & Damron-Rodriguez, 2003; Damron-Rodriguez & Lubben, 2001; World Health Organization Kobe Centre for Health Development, 2002). It has been suggested that the nations of the developed world first experienced economic development and then the aging of their societies. In developing nations, these two phenomena are occurring simultaneously, which undoubtedly will alter the options available for health and welfare systems development appropriate for aging societies. Ironically, such community health care approaches may also become at-

tractive models for more economically developed nations that are fast discovering that expensive institution-based programming is not sustainable within the context of rapid aging populations.

ELIZABETH OZANNE

Older Adults in Australia

88

Gerontological social work is not well articulated and defined as a distinctive area of practice in Australia despite some centers of innovation around the country. This lack of definition relates to the small size of the professionally trained workforce in Australia, the absence of strong professional and educational leadership, and the failure to articulate social work's distinctive contribution relative to other professional groups. Opportunities for change in the current period come from recent proactive federal government policy initiatives in relation to population aging, the leadership of a relatively small group of professional gerontologists from a range of disciplines, and emergent pressures from a service system and frontline social work practitioners confronting increasing demands from aging baby boomers encountering the new challenges of parent care.

There have always been some notable individual pioneers in different areas of social work practice with the elderly. What is different in the current period is the need for a broader institutional approach. Responses from schools of social work and the organized profession to population aging have been slow to develop, but there have been, over the last decade, several major initiatives in teaching, research, and practice from individual schools and agencies, often in partnership with broader interdisciplinary gerontological consortia and coalitions.

THE DEMOGRAPHICS OF POPULATION AGING IN AUSTRALIA

The Australian population is aging numerically, in that the number of older people is increasing, and structurally, in that the proportion of people who are aged 65 and over is rising. At the date of the last census in 2002, people aged 65 years and over represented approximately 12.7% of Australia's total population, or 2.5 million people (Australian Institute of Health and Welfare [AIHW], 2002), with 54% aged 65–74 years, 35% aged 75–84, and 11% aged 85 and over. Thus, whereas half of all older people were aged between 65 and 74, there was a significant minority (more than 280,000) aged 85 and over. Fifty-six percent of older people (65+) were women. One in four people over 65 in Australia were born in a non-English-speaking country, and the ethnic diversity of the population is increasing with recent migration waves. Australian aboriginal life expectancy represent approximately 1% of the total population. The aborigines' life expectancy is, however, considerably lower than that of the gen-

eral population, and by and large they have not participated in the demographic longevity revolution.

POLICY RESPONSES TO POPULATION AGING IN AUSTRALIA

Since the mid-1980s, Australia has taken a strategic and planned approach to population aging with a series of policy initiatives from successive governments of both social democratic and conservative persuasion (Gibson, 1998; Borowski, Encel, & Ozanne, 1997; Kendig & Duckett, 2001). Under the Labor (social democratic) government of Hawke/Keating, 1972–1996, services for the aged were reviewed and restructured with a major expansion of community care services and the introduction of new accreditation requirements to regulate quality in long-term residential care (Commonwealth Department of Health, Housing and Community Services, 1991; Ozanne, 2000, 2001).

Under the Howard Liberal (Conservative) government, 1996–2004, which has just won a fourth term with an increased majority, policy focus has shifted from an initial cost-cutting preoccupation (National Commission of Audit, 1996) to a more intergenerational and future social investment orientation (Costello, 2002; Bishop, 2004). This shift in thinking was first articulated by the commonwealth treasurer Peter Costello in his Intergenerational Report in 2002 and in a later paper delivered in 2004 in which he spelled out the key demographic challenges he perceived Australia to be confronting (Costello, 2004). Under the Howard government the service range has continued to expand, but there has also been more focus on fiscal efficiency and a much greater shift to consumers carrying more of the financial burden of their care. Several reviews of residential and community care have been undertaken, leading to the integration of high (nursing home) and low (hostel) care, the introduction of a new accreditation and certification system requiring three yearly audits, major expansion of home-based service delivery, and the continued exploration of new funding mechanisms (Hogan, 2004; Bishop, 2004a, 2004b).

THE SOCIAL WORK WORKFORCE IN AUSTRALIA: ITS SIZE AND DISTRIBUTION

The total social work workforce in Australia is relatively small, compared, say, with that of nursing, and

is estimated to be approximately 12,000 persons (Australian Association of Social Workers, 2004). Australian social workers do not have registration of title, so it is often difficult to distinguish professionally accredited and nonaccredited degrees in official government statistics. The most recent official ABS data (Australian Bureau of Statistics, 1997) indicate that there were 9,111 persons calling themselves social workers. This was a 27% increase between 1996 and 2001, with the substantial part of this increase occurring in the nongovernment sector (52%) as opposed to the government sector (12%). The biggest sector increases were in the category of welfare workers (without professional qualification), which grew 45%, from 6,204 to 8,987, in same period. Community workers are the numerically largest group in the community services sector, with a total of 17,101 workers in 2001 (Healy, 2004; AIHW, 2001).

Work with the aged has historically been a traditional area of social work practice in Australia, particularly during the period when the situation of the aged was more synonymous with poverty than it is today (Harding, King, & Kelly, 2002). In more recent decades the emergence of specializations in health, mental health, and child welfare has to some degree stolen the limelight, though with shifting demographics a focus on the aged is reemerging.

There is very little accurate information on the proportion of social workers who identify their primary field of practice as work with older persons. Relatively few members of the Australian Association of Social Workers (AASW) identify gerontology as their primary field of practice. However, it is estimated that approximately one third of clients in health and welfare agencies are 65 years and over, so that people over 65 constitute a significant focus for most social work practitioners.

THE PLACE OF AGING IN THE SOCIAL WORK CURRICULUM

The primary qualification for accreditation by the AASW is the bachelor of social work, which is a 2-year degree following completion of a first degree in the behavioral and social sciences. The master's qualification in Australia is primarily taken as an advanced practice coursework degree or as a research thesis. The Ph.D. is primarily a research qualification. There are 22 schools of social work in Australia, which graduate approximately 700 students annually.

Despite social work's historical commitment to the aged, specialization in aging has been slow to develop in social work courses (Ozanne, 1989; Heycox, 1989; Hugman, 2000; Wiles, 2001), with only approximately 50% of social work schools offering aged-specific content and electives. Those schools, however, that have had a long commitment to aging studies have integrated material on aging across their curriculum, as well as offering a number of elective studies at the bachelor's and master's levels (Rosenman, 1988; Lubben, Damron-Rodriguez, & Beck, 1992). Several have also developed research centers on gerontology or are affiliated with multidisciplinary university centers, for example, Melbourne, Queensland, and Curtin Universities.

In the last half decade, external pressures on the tertiary education sector from government and national research councils to address population aging as a national priority have led to the development of university-wide gerontological consortia in which social work schools have variously participated. The sectors that employ the majority of workers in aged care are health, mental health, and community care services across the federal, state, and local government and nongovernment sectors (AIHW 2001).

Since the late 1980s there have been several special editions of the journal *Australian Social Work* published on aged care and several editorials calling on social workers to respond to the challenge of population aging (Jacques, 1989; Rosenman, 1988; Ozanne, 1998; Squires, 1998), the last occurring in the International Year of Older Persons. Social workers have also contributed to the *Australasian Journal on Ageing*, a publication of the Australian Association of Gerontology (Tilse, Wilson, & Setterlund, 2003; Hugman, 2001) and to international journals and collections on social work practice with the elderly (Setterlund, Tilse, Worrall, Wilson, & Hickson, 2002; Brennan, 1988; George, 1997).

WORKFORCE ANALYSIS IN RELATION TO POPULATION AGING

There is still a failure in Australia to identify the social and relational impact of an aging society. Workforce issues so far have been defined fairly narrowly as primarily health related, with a focus on nursing and personal care or direct care issues. An increasing number of reports, however, have been commissioned by government at various levels. Similarly, different industry sectors, philanthropic funds, and

some nongovernment organizations have addressed various subpopulations of the aged care workforce. These include studies of residential care workers (Richardson & Martin, 2004), personal care workers (Angle & Newman, 2002), nurses (Australian Health Ministers' Conference, 2004), and community care workers (Healy, 2004), as well as the aged care workforce more generally (Wheeler, 2002).

There has been virtually no explicit work done in Australia on likely future demand of an aging population for human service professionals in general or social workers in particular, though several research theses are under way in this area. There is, however, evidence of a considerable shortfall emerging in case manager and policy planning positions in aged-related work in community care services, health and mental health, and family services, based on the present difficulty in filling these positions with suitably qualified persons. These professional workforce issues have yet to be seriously addressed.

CORE TASKS AND COMPETENCIES IN SOCIAL WORK PRACTICE WITH OLDER ADULTS

The debate about core competencies in relation to practice with an older population in Australia has been informed by several government statements about basic training competencies in aged care for various levels in the community services sector (Health, 2002), as well as more recent statements from the National Strategy for an Ageing Australia (Bishop, 2000) in terms of how the country might achieve "world-class" aged care practice standards. The AASW special portfolio group on aging has recently released for comment on their national Web site a three-page statement of Competent Practice for Professional Social Workers Working in Aged Care (2004; <http://www.aasw.asn.au>).

THE CONTEXT AND SETTINGS FOR SOCIAL WORK PRACTICE WITH OLDER ADULTS

The primary fields in which social workers work with older adults in Australia are health, mental health, community care, and family support services. The majority of social workers tend to be involved in direct service delivery as caseworkers or care managers, with approximately one third in program management or more senior policy and planning roles (AIHW, 2001).

Individual counseling family and intergenerational casework occurs primarily in family support services, community health and mental health centers, local government services, postacute rehabilitation services, and nongovernment aged and disability services and in private practice. Intergenerational family casework and group work are also practiced in these settings.

There has been a major expansion of community care services in Australia since the mid-1980s, from a small and fairly basic set of home support-type services to a broad mix of service types and a range of more and less intensive home support packages requiring active brokering and care coordination. Under new Extended Care at Home Packages (EACH), older persons can now be maintained at home even with very high levels of disability. Local governments employ social workers as assessment officers, care managers, and directors of aged and disability services. Social workers are also part of core staff groups in not-for-profit intensive home care agencies as care managers.

The most common form of social work practice with older adults is in acute and postacute care in hospitals and rehabilitation centers as program coordinators, discharge planners, case managers, and direct care workers. Social workers are key members of aged care assessment teams, which serve as gatekeepers to long-term care facilities and have a strategic role in relation to family support in interdisciplinary acute and postacute rehabilitation teams.

Social workers have key roles in psychogeriatric assessment teams and services, such as the Cognitive Dementia Assessment and Management Services (CADMS), which are focused on early diagnosis of dementia and appropriate referral for family members. They are also active in Alzheimer's advocacy organizations across Australia and in running the Living With Dementia group work program nationally.

Social work roles in long-term residential care are less well developed in Australia than in some other countries where social workers take more key roles in managing long-term care facilities. Managers of these facilities in Australia tend to be nurses (if they have qualifications at all), and social workers are employed primarily in direct care manager and service delivery roles in public high-level care facilities as caseworkers, family workers, group workers, and discharge planners.

Social work has had a long-term commitment to end-of-life care across a range of settings from the acute hospital to hospice to coronial services. There has been a major review and restructuring of end-of-life services over recent decades to keep pace with the

demands of population aging and to ensure a timely, high, and equitable standard of response across all service types. Social workers, in partnership with other professional groups, have taken a strategic role in several of these developments.

Case management has seen steady development as a mode of practice in Australia over the last couple of decades in health, mental health, child welfare, vocational rehabilitation disability, and gerontology (Ozanne, 1996). The National Case Management Society, which was formed in Australia in 1998, holds an annual conference and produces a quarterly journal. Social workers have been active in this development both in broadening the approach to case management from a primarily health to more psychosocially focused activity and in introducing a diversity of practice populations. Two texts on case management practice in Australia have been published by social workers in concert with others (Gursansky, Harvey, & Kennedy, 2003; Ozanne, Howe, & Selby-Smith, 1990).

Australia has a universal health care system, Medicare, funded from taxation and a small population co-payment. Health care is thus still largely a public system, and Australia has so far not seen the development of large-scale managed care providers. New forms of public regional coordinated and integrated health care delivery systems are, however, being trialed, and these schemes increasingly mandate some form of case or care management as the preferred mode of practice (Fine, 1999; O'Looney, 1993; Silagy et al., 1999; Scotton, 1998; Lubben & Damron-Rodriquez, 2003).

Increasingly, private practice social workers have encountered the impact of population aging on individuals and families. Private practitioners are involved in intergenerational family counseling in nuclear and reconstituted families. In addition, social workers in private practice have encountered increased instances of having to assist families in a much longer-lived society with major life course transitions around divorce, widowhood, retrenchment, and retirement.

In the last decade numerous new social work roles have been created in the aged and community care service system as existing services have expanded and new service types have been created. Social workers have taken up new roles on guardianship and administration tribunals, as members, investigators, and guardians. They have assumed roles as complaints officers and ombudsmen in new quality assurance arrangements in health care. They have also become key players in aged care assessment teams, cognitive assessment and dementia management services, and

care coordinators in rapidly expanding home care services implementing a range of new flexible and innovative home care packages.

WORK WITH UNDERSERVED AT-RISK POPULATIONS

In the Australian context, older populations identified as at particular risk are Aboriginal and Torres Strait Islanders, culturally and linguistically diverse populations, dementia sufferers and their caretakers, low-income and homeless aged, and rural and remote dwellers. Social workers are active in the targeted delivery of services to these groups, which are explicitly recognized in current government policy and program initiatives. There are also several underrecognized and underserved populations, for instance, older gay, lesbian, intersex, and transgender populations, the older disabled and older prisoners. Individual social workers have highlighted the plight of these populations and advocated for more explicit attention to their needs (Harrison, 1999; Bigby, Gordon, & Ozanne, 2002).

AGED ADVOCACY AND THE POLITICS OF AGING IN AUSTRALIA

Social workers have taken a prominent role in heading up some of the major aged advocacy organizations and peak bodies in Australia in both CEO and policy officer positions. Through these activities, several have also taken leadership positions in the International Federation of Ageing and regional Asia Pacific aged policy forums (George, 1997). Social workers have been active in the establishment of various self-help and advocacy organizations, like the Alzheimer's Society and the Carers Association, and hold roles as policy officers and researchers in these organizations.

As government has taken a more proactive role in the last decade in restructuring the service system in relation to an older population, so also key aged advocacy bodies and national councils have formed new coalitions and engaged in partnering discussions and mergers to increase their power and influence on government. Social workers have been active in these negotiations and in many instances have taken a leading role in pressing both industry and consumer claims (National Aged Care Alliance, 2004; Ozanne & Keogh, 2003).

VISIONING THE FUTURE

Recently in Australia the Myer Foundation, a philanthropic fund, sponsored the 2020 Vision project (Myer Foundation, 2003) to take an independent look at the present and future impact of population aging on health, income security, community services, housing, technology, and workforce development. Several reports were commissioned and forums held around the country, many in partnership with government and other interest groups, to promote debate on population aging and to push various contemporary campaigns related to aged housing, caregiver support, and expansion of community care (www.agedcare.org.au/coalition/). A recent independent evaluation of the project (Muller, 2004) concluded that it had had a major impact on promoting debate and acted as a significant stimulus to both government and the sector to engage in more proactive leadership in relation to population aging. The principal project officer driving this project was a social worker with a long history in aged care.

AN AGENDA FOR FUTURE ACTION

It is timely for social work in Australia to move ahead on a number of fronts:

1. *Defining the social work contribution to the quality of life of older persons:* There is perhaps a need in Australian social work circles and beyond to define more explicitly the social work contribution by ratifying a core national statement of knowledge, values and skills and articulating more explicitly to external publics what is unique about social work's focus in this area of practice.
2. *Mobilizing more effectively existing practitioner resources:* Frontline workers are presently mediating demands from aging baby boomers, often without specific training in gerontology or any continuing and further education backup from their professional organization or social work schools. There needs to be a two-way process whereby their frontline experience is mined (Epstein & Blumenfield, 2001) but also supported by appropriate developmental opportunities so practitioners might hone their skills in advanced provider sectors and research with older persons.
3. *Development of innovative field practicums:* Service reform has been an active part of govern-

ment restructuring in Australian aged services over the last decade and a half. In this period quite a lot of new service settings and practice models have been developed, pioneered by on-the-ground practitioners working collaboratively with other disciplines. These services are often also a part of larger regional service systems and networks. They represent the front line of change and are valuable primary training sites for social work students. Designing, supporting, and resourcing innovative field units in these settings is critical for the future training of students.

4. *National training institutes for faculty/postgraduate students*: Achieving funding support from some of the government aging workforce initiatives or a philanthropic body to support national social work training institutes for faculty and/or postgraduate students in gerontology would be one way to foster and develop teaching and research capacity in schools of social work. This might also be undertaken collaboratively with the new national Healthy Ageing Research Network.
5. *Emerging researcher forums*: Given the relatively small critical mass of gerontologists and social workers around the country, support for this type of event would appear essential to reinforce emergent research capacity.
6. *Funding for postgraduate scholarships*: There has virtually been no development of dedicated gerontological social work scholarships in Australia. The only scholarships presently available for master's, doctoral, and postdoctoral studies rely on individual faculty building in such scholarships to their individual grant applications. Philanthropic and government funding of dedicated scholarships is an option that would be timely to explore.
7. *Collaborating on joint research projects*: In order to increase their strike rate in gerontological research, social workers probably need to take maximum advantage of the ARC/MHNRC Ageing Well Research Network initiative to partner with colleagues from other disciplines on topics relevant to social work's core concerns website is www.ageingwell.edu.au. International collaborative research with Pacific Rim countries and gerontological centers in the United States, the United Kingdom, and Europe would help further this agenda.
8. *Visiting scholars exchange program*: Social work should perhaps take more advantage than it presently does of the R.M. Gibson Traveling

Scholarship in Gerontology sponsored by the Australian Association of Gerontology in bringing key overseas social work gerontologists to Australia. Australian faculty would also greatly benefit from the opportunity for exchange with some of the key gerontological centers in the United States and Europe.

Older Adults in China

89

China, the world's most populous country, has been experiencing continued low fertility since adopting its one-child policy in 1979. All demographic indicators suggest that China is already an aging society. More than 10% of the total population is aged 60 years and older (China Population Information and Research Center, 2003). According to China's fifth national census in 2000, the nation has a population of nearly 1.3 billion, with an annual growth rate of 1.07% (National Bureau of Statistics of China, 2001). In addition, the population aged 60 and over was increasing at an annual rate of 3%, and the oldest elderly population (aged 80 and above) was increasing at an annual rate of 5% (National Bureau of Statistics of China, 2001). By the year 2040, a predicted 397 million people, or more than 28% of China's population, will be aged 60 or over (United Nations, 2003), more than the current population of France, Germany, Italy, Japan, and the United Kingdom combined (Jackson & Howe, 2004). China's total fertility rate dropped from about 7.5 in 1963 (Poston & Duan, 2000) to 1.8 in 2002 (China Population Information and Research Center, 2003). This rapid transition from a relatively young to a relatively old population is unprecedented.

Chinese population experts believe there will be four periods of population aging, beginning with an initial acceleration around 2000, a rapid increase in 2010, a peak in 2040, and a slowdown that will finally stabilize around 2060. Population aging can affect the broader socioeconomic system. In China, the total dependency ratio, which is a ratio of the nonworking population (people under age 15 and those 65 and over) to the working population (people aged 15 to 64), will increase from 59 per 100 in 2000 to 77 per 100 in 2050 (China Population Information and Research Center, 2003). The general trend is for the youth dependency ratio to decrease while the old-age dependency ratio rapidly increases. Projections show that by 2025, an average of 14 Chinese elderly will have to be supported by every 100 working-age people, compared with only 6 in 1990. This rapid increase in the number of elderly may hinder future economic growth as expenditures related to social security and other related social services experience parallel increases (Jackson & Howe, 2004; Zhang, 2002). This demographic change will affect not only the labor supply but also retirement policies and social norms.

The emerging issue of who will care for the elderly in China has attracted considerable attention from common people, demographers, and government officials. No clear solution to these problems has yet been found. It is both urgent and necessary for China to find

the solutions to meet the challenges of its aging population. Some economists and sociologists believe that the way to deal with the negative effects of an aging population is to maintain a high rate of economic growth (Zhang, 2002). The relationship between the two is extremely complex, however, warranting much continued study. Whether China could find a strategic move to simultaneously solve the emerging aging issue and maintain economic growth is a question of great interest for gerontologists all over the world.

SOCIAL WORK IN CHINA

Social work has experienced three stages in China since the 1920s: introduction, abolishment, and reinstatement (Xia & Guo, 2002). Social work was introduced to China in 1922 by missionaries. Various types of social services were developed by religious organizations for disadvantaged people such as poor, sick, and disabled groups. Only a few faith-based universities and colleges located in east coast cities had teaching programs at that time to train a handful of social workers, for instance, Jinan University in Shandong and Ginling Women's College in Nanjing. Like many other universities, these colleges were forced to either close their programs or move to western or southern villages during a series of wars: the Japanese Invasion/World War II and civil war. After the Communist Party seized governmental control in 1949, both social work education and missionary activities were prohibited. Not until 40 years later, in 1988, was the first social work education meeting held in Beijing. The Chinese Association of Social Work Education was established in 1994 with only 20 social work programs. Nonetheless, currently there are more than 150 registered programs teaching social work in various Chinese universities and colleges. On average, these programs train more than 4,000 social work graduates per year. These graduates may or may not work in social work practice settings or social service programs.

Most of the social services in mainland China are subsumed under government organizations such as the Ministry of Civil Affairs, Youth League, Women's Federation, work units, street organizations, and the Rehabilitative Federation. These organizations used to hire individuals without social work training, usually high school or college graduates, to deliver services to their clients. Some of these organizations have their own training institutes, which provide both pre-service and in-service training to their staff members. In mid-1970s, the concept of social work and its prac-

tice were introduced to China from Hong Kong and other countries. Many of these training institutes began to develop social work programs in the late 1970s for their cadres.

In more recent years, the Chinese government has adopted a different approach in delivering welfare services. Instead of being a service provider, the government now focuses more on policy and planning, specifically on establishing the social security system under the market economy. Current policy encourages civil society and nongovernment organizations (NGOs) to take up the role of providing direct services. The work units now operate under the market economy, which requires self-sufficiency or making a profit. Many of these work units, which used to provide welfare services to their employees, are no longer taking up this responsibility. Therefore, more and more NGOs are being developed in various parts of mainland China and are now running various social services, ranging from child welfare to care for the aged. Therefore, social work in China has a tremendous market in the public, nonprofit, and private sectors. As with the development of the social security system, institutional social work in China is expected to make great progress in the near future (Xia & Guo, 2002).

On the other hand, social work professional development in Chinese societies outside mainland China, such as Hong Kong, Macau, Singapore, and Taiwan, has followed a different path. For instance, Hong Kong was a colony of Britain until 1997, and social work there has followed a British model. Five out of seven publicly funded universities and one private college provide social work training at various levels, including diploma, bachelor, master's, and doctorate, and more than 500 NGOs provide various kinds of social services. The Hong Kong government has been the primary funding source for both social work training and social service programs. In recent years, due to the aging population, the government has devoted more attention and resources to developing elderly programs. Taiwan, Singapore, and Macau have followed different social work development paths from that in Hong Kong. Nonetheless, there is an increasing emphasis on old-age social policies and program development in the last decade in these places, all of which are facing the challenges of a rapidly aging population.

FILIAL PIETY, FAMILY, AND CAREGIVING

In comparison with other cultures, more gerontology papers about Chinese older adults are related to fam-

ily and filial piety (Chow, 1999; Chi & Chui, 1999), mainly because of the strong family influences on the quality of later life for Chinese older adults (Chou & Chi, 2001; Zimmer, 2002). Chinese family structures traditionally cluster around relatives who assist one another, and blood tie relationships are very important within each family. According to Chinese tradition, old age is a golden time of life, when one can harvest the rewards of lifelong efforts at establishing a family (Cooney & Shi, 1999). Successful aging in China is often measured by how well one's family is doing rather than by one's own achievements. A yardstick used to measure successful aging among the Chinese is whether one can enjoy filial treatment from one's offspring (Ho, 1994; Woo, Ho, & Lau, 1998). Over the past 2,000 years, virtually every dynasty has adopted Confucian philosophy as state orthodoxy. As such, the virtue of filial piety became the cornerstone of Chinese social structure (Chai & Chai, 1965). Confucius believed there was no greater crime than failing to practice filial piety. This social norm has been deeply rooted in Chinese societies, with most adult children and grandchildren still practicing some degree of filial piety (Holroyd, 2003; Patterson & Semple, 1998; Shyu & Chen, 2004; Zhan, 2001). Therefore, many policy debates surrounding this topic try to determine if the state should take up aged care responsibility (Pei & Pillai, 1999; Chi & Chui, 1999). Many Chinese policymakers believe that the state should not intervene in old-age issues because this will discourage families from supporting and caring for older family members. It is not uncommon to find family law or legislation on family care of older parents in Chinese societies such as mainland China and Singapore (Leung & Lam, 2000).

Riley and Riley (1995) linked individual aging with changes in social structure and suggested that structural lags occur when people's lives change dramatically and social norms, institutions, and laws fail to keep pace. For instance, the one-child policy has been enforced throughout China for the past 26 years and has greatly changed Chinese family structure. Old kinship patterns have diminished, and the 4-2-1 (four grandparents, two parents, and one child) family structure has emerged as the new dominant form. The "sandwich generation" of one-child couples will face the reality of having to care for four parents and their own child as well. In recent years, some researchers have suggested revisiting the concept of filial piety and its acceptable behaviors in contemporary society (Cheng, 1988; Li & Rogers, 1999; Sun, 2002; Yeh & Bedford, 2003). This is very important because without a

new understanding of this concept, adult children who are no longer able to support their parents will have many guilt feelings and may be reluctant to seek professional help (Ng, Phillips, & Lee, 2002). At the same time, some older Chinese adults are extremely disappointed or unhappy and even have a strong sense of failure if their offspring cannot support or care for them (Lee, 1999; Lee, Woo, & MacKenzie 2002).

PHYSICAL AND MENTAL HEALTH

Nowhere is the mental and physical well-being of an aging society a more pressing issue than in China. China will have nearly 400 million elders at a time when its one-child policy will play havoc with traditional caregiving practices (Jackson & Howe, 2004). The impending intersection of increasing longevity, coupled with few social and economic supports for elders, suggests that maintaining independence in late life through good mental and physical health is imperative. This presents unusual challenges to the coping and adaptive skills of Chinese elders who have lived the majority of their lives immersed in, and adhering to, traditions that formed their worldview and ways of coping. Most of the current cohort of Chinese elders has no or little educational attainment, and many of them are illiterate. Without retirement pension schemes, Chinese elders have fewer resources than young people and thus are less able to live a dignified life in the rapidly changing market economic society (Raymo & Xie, 2000; Chi & Chui, 1999). They are aging in a society that is transitioning from an ancient culture, and as China becomes more industrialized and open to external cultural influences, they are losing their traditional ways and familiar supports (Chow, 1999; Kleinman & Kleinman, 1999; Li, 2002). This situation represents a major loss and can contribute to a variety of negative consequences.

Although almost all objective health indicators show that older Chinese adults are as healthy as their Western counterparts, subjective measures indicate otherwise (Lai, Lee, & Lee, 2000; Tang, Wang, Meng, Wu, Ericsson, Winblad, et al. 1999; Nevitt et al. 2002; Ho et al., 1997; Berkanovic, Chi, Lubben, & Kitano, 1994). In addition, older Chinese adults seem to have less sense of control over their physical health and functional capabilities (Chi & Lee, 1991). Social workers could play a significant role in Chinese health care settings if social work training were to adopt a focus on healthy, active aging. More emphasis should be placed on developing proactive and innovative health promotion and disease prevention programs and ac-

tivities for Chinese older adults, who have special needs such as illiteracy, lack of financial resources, and different health beliefs and practices (Ma & Chi, 1995; Chi & Leung, 1999; Foreman et al., 1998; Cheng, Chi, Boey, Ko, & Chou, 2002). Numerous scientific papers have been published on the effectiveness of health intervention that adopts Chinese medicine, diets, and exercises, such as acupressure, Qigong, and Tai Chi (Chen, Lin, Wu, & Lin, 1999; Ng & Tan, 2004; Tsang et al., 2003; Bent et al., 2003; Chou et al., 2005).

Studies of the prevalence of depression in Chinese elders in China and Hong Kong (Chen, Copeland, & Wei, 1999; Chi et al., 2005) reported finding a low pooled prevalence of depression and depressive mood. The analysis also revealed patterns of risk factors that were similar to those in Western countries. Nonetheless, somatization is a particular concern for Chinese elders. For some time, it has been suggested that Chinese are more likely to somatize depression and to manifest physical complaints and health problems (Kleinman, 1982). In an extensive review of the literature on depression among the Chinese, Parker, Gladstone, and Chee (2001) conclude that the existing evidence supports the hypothesis that the Chinese tend to deny depression or express it somatically. This presents a scenario in which misdiagnosis is probable, with little hope for improvement. Untreated depression creates ongoing hardship for the affected individual and is of concern to a society that is struggling to provide care to an ever-increasing number of elders. There is some relatively new evidence on the far-reaching effects of depression. One such example is reported by Chi and Chou (2000) in their study of Chinese elders in Hong Kong in which depression at baseline was negatively associated with cognitive functioning 3 years later, even after controlling for health, social support, exercise, education, and finances.

Suicide, on the other hand, is a major public health problem in China. It is the fifth-leading cause of death overall, and the elderly suicide rate is three times higher than the average rate (Yip, Chi, & Yu, 1998). China, in contrast to Western countries, experiences much higher rates of suicide among women, as well as rates in rural regions and among elders that far exceed those in the United States and other countries. The reasons for such striking epidemiological contrasts are insufficiently studied. Unlike among women in the United States, where suicide declines in the latter half of life, it rises sharply with aging for women in China, similar to the rise in rates for elder men living in rural China and in other parts of the world. It has been pointed out that indigenized social work practice with Chinese women should pay special attention to their self-concept and

attitudes toward death (Cheung & Liu, 2004; Chong & Lang, 1998).

Social workers have taken strong advocate roles in developing research, policies, and services for the most disadvantaged older persons in Chinese societies, such as suicide prevention initiatives in Hong Kong. The Hong Kong government first recognized that elder suicide was a serious problem in 1998 after the first suicide study was published (Chi, Yip, & Yu, 1997); the Working Group on Elderly Suicide was established in 1999 to examine the causes of the problem and to recommend potential solutions. One of this group's recommendations was that more local research studies were needed to understand the factors associated with elderly suicide in Hong Kong. With government support, a series of elderly suicide research studies were commissioned by the government to carry out an elderly suicide, including a psychoautopsy study of elders, a community study to examine suicidal ideation in elder women, and epidemiological studies. This work has led to a number of publications (Yip, Chi, Chiu, & Kwan, 2003; Chiu et al., 2004; Chi et al., 2005), and ultimately these projects spawned the development of new aging and mental health services for elders and consequently these projects seemed to have an effect on lower suicide rates in recent years in Hong Kong.

CONCLUSION

Gerontological social work is urgently needed in China and other Chinese societies, and social workers should practice in a variety of settings along the aging wellness and long-term care continuum in order to make an impact on these rapidly aging societies. The role of social worker in these settings is often unique because social worker's primary focus is the psychosocial well-being of elders and their families, which are directly related among older Chinese adults. Social workers should review their own attitudes toward social norms, including family and filial piety, sharpen their skills in family work, and increase their knowledge of indigenous evidence-based interventions. Furthermore, social workers understand the interaction between elders' needs and how to change the environment to meet those needs. According to the 2000 census in China, only 1% of the Chinese elderly population was living in institutions (National Bureau of Statistics, 2001), and most social workers were working in community-based settings such as senior centers, senior housing, day care centers, health clinics, and home care programs. It is anticipated that many social workers in China would practice in nontraditional settings. This may be a

healthier trend or solution for the challenges of the aging population in China because older adults would be less excluded from society. To achieve this objective, an interdisciplinary training approach for Chinese gerontological social workers is crucial. After all, physically or psychologically healthy Chinese elders can be resources rather than a burden to each other, to the family, and to the community.

Older Adults in Europe

90

An analysis of social work with older adults in Europe raises a number of definitional and conceptual problems. Difficulties arise when we consider what can be defined as “Europe.” Shardlow and Walliss (2003) argue it is less a geographic location (such as that bounded by European Union [EU] member states) than an “ever-shifting idea or ideal” (p. 922) that is continually in a state of flux, socially, economically, and culturally. Additionally, there is no universal understanding of what constitutes “social work” in Europe, and the term is often used synonymously with “social services,” “social care,” “care management” (United Kingdom), and “social professions” or “social pedagogy” (Denmark, France). The boundaries of social work are also unclear, with different professions in different countries carrying out social work functions, based on history, culture, influence of occupational groups, and the role of the state (Shardlow & Payne, 1998). The definition of older adults also varies between European states, with “old age” being determined by state legislation on retirement age and pension entitlement, for example, in the United Kingdom, or linked with a “loss of power” in some European cultures (Bosnia) rather than being based on chronological age or external appearance (Vincent, 2003). Such diversity and the associated difficulties of researchers from “outside” studying another culture have led to a dearth of comparative empirical work on social work with older people across Europe. In a European study by Shardlow and Cooper (2000), no empirical studies were found in the topic area of social work with older people. Most literature reviews consider the wider social policy context, the organization of social services and health and social care systems, with little commentary on the role, function, and approaches of social work.

Despite not being able to compare “like with like,” together with a lack of consensus regarding what should be included in a definition, social work in Europe can be defined by its diversity, in terms of policy and conceptual frameworks as well as practice traditions. This chapter will explore such diversity, drawing examples from countries illustrating different social policy traditions and welfare responses to older people.

Demographic factors are a unifying factor across Europe and have led to older people being recognized in the EU agenda for action. In responding to the challenges of an aging society across Europe, there have been a number of similar policy responses, such as the move from institutional to community care, changes in the management of care with the growth

of managerialism in services, and the integration of health and social care. In addition, there have been a number of common ongoing difficulties, for example, the funding of long-term care, the reconciliation of work and family life, and the supply of social care workers to care for older people.

The consequences of an increasing older population provide the context and purpose for social work intervention, with the focus on increasing dependency needs of people in late old age and the concomitant support required, through intergenerational caregiving issues and through transitions in later life such as bereavement and loss of social support. Viewing older people as “dependent” and “in need,” however, narrowly concentrates the social work response on practical and social support (Hugman, 1994). Focusing on what older people can contribute in terms of skills, knowledge, and experience will be of increasing importance. The social policy framework is changing across Europe, and further challenges are emerging. Consequently, new areas of social work are opening up, based on citizenship and social inclusion—a greater focus being placed on ethnic elders and asylum seekers and on challenging ageism and racism—emerging issues that will impact on social work with older adults in the future.

THE SOCIAL POLICY CONTEXT

There are a number of ways of defining “Europe.” This analysis will focus mainly on welfare states in the EU, including recent states such as Greece and Poland, and will also include Israel. Because it is impossible to do justice to all countries falling within this definition, the concentration will be on states that typically illustrate the “welfare state regime” developed by Esping-Andersen (1990, 1999), who suggested three distinct clusters based on social protection systems. Social care and social work approaches can also be added to this typology (Lorenz, 1994), although caution must be exercised in taking the typology further because it does not address gender, race, and age, which do affect how people experience social welfare. The Esping-Andersen models include the following:

1. *The market liberal (residual) welfare state*: The United Kingdom is an example of this model. Social insurance plans predominate; benefits are targeted on the poor; families and charities have a primary role. Social work tends to concentrate

on the poor and deviant. The social worker is a rationer and a gatekeeper of resources.

2. *The conservative corporatist state*: Germany is an example of this model. The state is predominant, with the market having only a marginal role; the church has an important role in shaping such regimes, and the emphasis is on family care. For example, German families are obliged to support their elderly relatives, and social services have a residual role.
3. *The social democratic welfare state*: The Scandinavian countries are examples of this model. The welfare state hinges on principles of equity, and the state pursues services of the highest standard. Benefits are high. The market has little role. The state takes direct responsibility for dependents, women are supported in their choice to be in paid work or in the household, and the home help service is the mainstay of care for older people. Social workers, employed by state agencies, enjoy a high status in society.

The Esping-Andersen framework does not adequately describe all European countries. Indeed, it might be appropriate to suggest an additional model when considering countries such as Spain and Israel. Thus, we identify a *Mediterranean welfare state* model in which there is a high level of public pensions but underdevelopment of family support. Social work is a recent development since World War II in most states that fall within this type. Church-run establishments are prominent, along with the Red Cross; in Greece, for example, social workers are involved in assessment and direct service provision to older people and their caregivers; they are also involved in the administration of public assistance and self-help organizations (Cannan, Berry, & Lyons, 1992).

Further developments in the conceptualization of “care” are also leading to changes in policies for older people in each of the preceding typologies. For example, in the Scandinavian countries there is increasing emphasis on the marketization of public provision and private social work (Denmark); the United Kingdom is undergoing reorganization of community care programs, and in Germany there is reform of long-term care insurance to establish more integrated care (Lowenstein & Ogg, 2003). The spread of democratic liberal governments across Europe has led to the enlargement of the EU, resulting in harmonization of civic and legal frameworks (Warnes, Friedrich, Kellaher, & Torres, 2004).

DEMOGRAPHIC CHALLENGES

Older people have moved to center stage on the European social policy and social work agendas in all welfare states through demographic, attitudinal, and legislative changes (Phillipson, 2002) and also through “grassroots” action by users and caregivers groups, such as the European Older People’s Platform. In 2001 there were 62 million elderly people aged 65 and over in the EU, representing 16% of the total population. By 2010, the number of very old people aged 80 and over will rise by almost 50% (European Commission, 2003), with countries such as Belgium, Greece, Luxembourg, France, and Italy expecting to experience the largest increases in the next decade (Anderson, 2003). Coupled with an aging population are low fertility trends and increasing divorce, meaning smaller families with fewer members in the family available to care for older people. Many older people, particularly older women, also live alone. Increases in female labor market participation and the difficulties of juggling work and care add to the issue of who provides care and the costs of so doing.

At the EU level the debate has focused on the economic pressures of an aging Europe—intergenerational equity and the social and economic integration of nonworking populations, the main emphasis being on pension provision. The emphasis in the debate on the sustainability of current levels of economic, health, and social care provision has cast the aging agenda in a negative light, failing to acknowledge the rich potential older people bring to all aspects of life (Langebaek, 2003).

FAMILY CARE

“The family is the cornerstone for care in Europe” (Anderson, 2003, p. 4). The changing nature of the family in all states, however, has implications for the care for older people. One of the key issues is whether there is a legal obligation to give economic support to older members of the family. The guiding principle behind many states (particularly the conservative corporatist) is “subsidiarity,” meaning that social action should be taken at the lowest level, that is, at the level of the individual or the family before the state is asked to intervene (Austria, Germany, Greece, and Luxembourg). Thus families have a legal responsibility to pay for the care of their elderly members. Mediterranean countries place a legal obligation on relatives to pay for the care of their elderly member, and in

Italy even in-laws and half siblings are obliged to provide support in proportion to income (Hantrais, 2000). It is in such countries that coresident care is common, with only around 4% of care provided to older people outside the household (Anderson, 2003). However, even in countries wedded to this principle, there is some mellowing as other ways of funding care, such as long-term care insurance, are introduced and there is evidence that older citizens are willing to shoulder the costs of care themselves (Krieger, 2004). However, social work in Germany, for example, can only be understood in the context of “subsidiarity,” with little activity at the national level (Giarchi, 1996).

Filial norms and preferences for care also do not necessarily conform to the Esping-Anderson typology presented here. In a five-country study, Daatland and Herlofson (2003) highlight the north-south dimension in the support for filial norms, with the highest in Spain and Israel and the lowest support in Norway, England, and Germany. However, they note that “filial solidarity is not incompatible with generous welfare state arrangements, nor do filial obligations necessarily imply that the family is seen as the ‘natural care provider’ ” (p. 537). Additionally, in all countries there was a call for more state responsibility. However, the role of the state is that of complementing rather than substituting between services and families, with the role of services not discouraging family help (Lowenstein & Ogg, 2003). In the same study of five countries (Norway, Germany, England, Spain, and Israel), services represented a source of autonomy and independence for both older and younger family members (Lowenstein & Ogg, 2003).

SOCIAL WORK AND OLDER PEOPLE

Only a minority of older people and their caregivers, even those who draw on social services, will encounter a social worker. Apart from Greece, Portugal, and Luxembourg, the 1992 Eurobarometer study indicated that fewer than 30% of older people received care, and fewer came in touch with a social worker. The role and function of social workers across Europe differ. In some countries they are state agents (Finland, Norway, Sweden, the United Kingdom, and Ireland) and in others they are nongovernmental (the Netherlands), although these organizations may be state funded; yet in no European state has social work become entirely a state service. Private social work as an alternative has not emerged as a trend. Social work in such contexts has elements of social control (particularly in Italy) as

well as advocacy (the United Kingdom). In some countries a generic service is offered, whereas other states operate more specialist provision, with social workers specializing in work with adults and older people. In the Netherlands, for example, social work operates generically, and bureaus are open to all citizens without the need to be defined in a particular age category. Information and advice, material help, mediation and advocacy, as well as counselling and group work, are offered (Munday, 1996).

Apart from ideological differences in the organization of the welfare state and consequently social work, there are also differing academic discourses across Europe. In some countries (Germany, France, and Italy) the notion of “social pedagogy” is apparent. This is education and lifelong learning in its broadest sense aimed to help the poor in society “to realise their full potential and active membership of a society” (Lorenz, 2000, 92). In relation to older people the emphasis has been on providing people with means to manage their own lives and make changes in their circumstances (Hamalainen, 1989). There are some arguments that social work and social pedagogy in this sense are “unified in the modern concept of social work” (Hamalainen, 2003, p. 76).

Many commentators have noted the trend toward convergence in European social care systems with increasing welfare pluralism (Munday, 1996; Giarchi, 1996). Consequently, there are a number of common issues in social work practice across Europe. For example, there is consensus that community care is the best policy for older people.

Increasingly the agenda across Europe has been to develop community care, enabling older people to remain at home for as long as possible, preventing and deferring their entry to residential and nursing care. Support for community care is widespread across Europe and among different age-groups (Walker & Maltby, 1997). One of the primary roles of the social worker is to enable people to live at home, with the focus on home care. Coordinating care for older people and their caregivers in the community, however, is complex because different countries have distinctions between health and social care (apart from Denmark, the Netherlands and Italy). In addition, there are a multiplicity of providers—both for-profit and nonprofit private sector suppliers, as in the United Kingdom, voluntary nonprofit sectors such as in Germany and Belgium, and a range of religious and voluntary organizations in countries such as Greece, Portugal, and Spain (Walker & Maltby, 1997).

In the pursuit of community care in the United Kingdom and Sweden, the social worker has become a care manager increasingly taking on a managerialist and purchasing/assessing function and having less direct contact with service users providing a social work/counselling service (Weinberg, Williamson, Challis, & Hughes, 2003; Giarchi, 1996). Shortages of qualified social workers and social care workers have meant that in many situations social workers are unable to realize their full potential in their attempts to prevent dependency and are forced to take a reactionary rather than a preventative role, with increased targeting and rationing (Pijl, 1991). The United Kingdom fits this description, despite its emphasis on person-centered care (one of the standards of the National Service Framework for Older People developed by the Department of Health in 2001), whereas other countries, such as the Netherlands, as mentioned earlier, attempt a more preventative approach.

A further role for social workers in many countries is to coordinate care between formal and informal sectors and hence to support caregivers. This role is much more developed in some states, such as the United Kingdom, than in others, such as Greece, where there is less infrastructure of service provision to fully realize this aim (Walker & Maltby, 1997). The demand for residential care appears to be increasing across Europe as demography, family mobility, and long-term health care needs increase. Social workers may have a vital role to play in such a transition (European Foundation, 2004a).

A second common issue is the fragmentation of health and social care. Coordinating community care services, particularly between health, social care, and housing, for the benefit of users and caregivers is a problem throughout Europe (Jani-Le Bris, 1993; Walker, 1996). In Germany the institutional structures and funding arrangements that characterize health and social care systems contradict policy emphasis on community care (Scharf, 1998).

On a more positive note, however, more integrated and interprofessional approaches are being developed, with social workers acting with other professionals in the health care field, for example, psychiatric nurses, or in the housing arena in the promotion of the strengths and position of older people. Such an example can be found in a number of countries such as the Netherlands (Klein Beernink, 1994), where generalist social work is practiced (concentrating mainly on a therapeutic approach), or France, where social workers work in holistic and multidisciplinary teams and there is little division between social and health ser-

vices (Munday, 1996), with many social workers based in sociomedical centers (Tester, 1996). Israel partially overcame service fragmentation through lower case-loads and adequate training and supervision (Lowenstein, 2000). In Greece, services for older people are concentrated mainly in hospitals, with little social work activity in the community other than indirect social services provided by the Greek Orthodox Church and the Red Cross, although families have primary responsibility to care for older members as in most Mediterranean states. Health and social care services are provided by voluntary centers (KAPIs), which form an important part of the community care system providing health and social care.

In Italy social work has located a “new occupational space” (Shardlow & Payne, 1998, p. 65) in relation to “integrated domiciliary care, covering health and social care needs through the provision of domiciliary hospital care; day care fostering for isolated older people; new forms of residential health care; group living; day centers; self-help groups and various other forms of voluntary help” (p. 65).

A multiprofessional first-contact team conducts assessment, and it is the social worker’s role to transform that assessment into the planning, delivery, and coordination of care. One of the interesting aspects of the role in Italy is the support to active older people, as well as those who are frail, through the encouragement of activity with younger generations and assistance with initiating self-help groups, in an attempt at harnessing them as a resource. In Denmark, illustrating the Scandinavian liberal model, domiciliary care has high priority in the attempt to promote community care, with an emphasis on quality of life of both service users and caregivers (Cannan et al., 1992), and social care is seen as a right equal to medical care.

Despite the introduction of cash for care incentives introduced, for example, in the United Kingdom, Austria, Germany, Finland, the Netherlands, and Italy, the role of the family remains key to the whole development of community care, particularly in rural areas (Evers & Leichsenring, 1994), where there is little service provision. Regional inequality is another issue to be tackled in all countries.

Another common issue facing social workers in Europe is tackling ageism and racism. One of the major areas of social work practice in Europe in the 21st century is the focus on different ethnic groups with heterogeneous cultural and spiritual backgrounds. The challenge to social work is to address the values, norms, and traditions of such diverse groups (Guttmann & Lowenstein, 1991). New social challenges in relation to

this issue can be found in Israel. In Germany large private welfare organizations have taken on this role; in Italy special social services take on this role.

The in-migration of non-Europeans (from former colonies and asylum seekers) will grow in importance for the cultural diversity of older people within the coming decades in Europe. These immigrants are concentrated in the main metropolitan centers in Europe and are among the most deprived and vulnerable to social segregation and social exclusion (Phillipson, Bernard, Phillips, & Ogg, 2001; Scharf, Phillipson, Smith, & Kingston, 2002). Most countries (Netherlands, Spain, Greece, Italy, Denmark, Germany, France, Israel, and the United Kingdom) have services in place, with an emergency response and also more developed services, although many of these do not accommodate for older people to the same extent as younger people and suffer from institutional racism. The rise in the number of illegal immigrants and asylum seekers from within as well as outside the EU has led to unsympathetic responses. One of the difficulties is the lack of knowledge and experience transfer between countries on the role of social work with older people in this respect.

A further consequence of migration is that many areas are left depleted of a younger population, and population decline has disadvantaged older people who have remained and “aged in place.” A related area is the welfare of increasing numbers of migrants who move from northern Europe, Scandinavia, Britain, and Germany, for example, to Spain and Portugal. Problems in health and social care develop particularly for those who cannot speak the language and where services are less well developed (King, Warnes, & Williams, 2000). Retirement migration into relatively isolated rural settlements can also be a source of problems requiring social work assistance, particularly if family support is at a distance.

A fourth common issue is working with users and caregivers. Increasingly social workers work with people who are physically disabled and cognitively frail or who have dementia and often a multiplicity of problems. Working with individuals who care for such older people also forms a major part of social work. Across Europe it is estimated that 1 in 10 Europeans over the age of 15 provide care (as a result of long-term illness, disability, or old age) within the household, and 1 in 7 do so outside the household (Walker, 1999); the majority of these caregivers are women. The empowerment and participation of users and caregivers is a primary objective of the social worker. Many caretakers juggle work with family life, which includes

looking after children and older parents (Fagan, 2001; Phillips, Bernard, & Chittenden, 2002), with workers with elder care responsibilities more numerous in Greece, Italy, Portugal, and Spain than in Denmark, the Netherlands, and the United Kingdom (Anderson, 2003). The stress of these demands may lead to social work assessment and help, yet in only a few countries, for example, the United Kingdom, is there a right to a caregiver's assessment. This is an increasingly recognized issue due to the demographic impact on employment (fewer younger people in the workforce to replace those retiring), and the reconciliation of work and family life is a high priority on the European agenda.

How should social work in Europe respond to the care of older people? Should there be an aim for a consensus/convergence approach to strengthen the profession and lift its status? There can be no definitive interpretation of social work in Europe. Although it would be difficult to envisage a common model for practice across Europe, elements of knowledge-based best practice form a basis; among them are engaging with service users and caregivers on a more equal and effective footing. Social workers will have to engage with the notion of citizenship, even in areas where they have to evoke authority through legislation. Rights around citizenship are more common in Scandinavian countries (Munday, 1996). Empowerment and advocacy based on these principles have led some analysts to suggest that social workers act as ethnographers, searching for multiple views and narratives of the problem (Schindler, 1999).

Based on the preceding commentary, there is a case to be made for the development of a critical gerontological social work perspective across Europe. Ray and Phillips (forthcoming) argue that there is a lack of synergy between knowledge derived from critical gerontological research and social work knowledge and practice; they propose a model of critical gerontological practice that draws on key elements from the field of critical gerontology, the existing social work knowledge base, and critical practice theories. In Israel, gerontology has become much more professionalized and linked to social work (Lowenstein, 2001).

ROLE OF THE EUROPEAN UNION

The European Commission has been granted competence in areas of good practice in care for older people. This has mainly focused on transfer of knowledge

through research programs and training programs. New states joining the EU, such as Romania, will increase the diversity of European social work because such states have nonexistent services for older people outside of major urban centers, yet issues around the social exclusion of ethnic groups such as travelers will be of increasing importance for all European states as labor market opportunities allow transnational migration. A future challenge will be to develop social work in states that have scant resources and no social security systems yet that place themselves in a European context. Bosnia-Herzegovina, for example, cannot offer local-based care to those who need residential or nursing care. The significant material gaps between new and potential member states and the 15 existing states in the EU are a challenge across Europe (European Foundation, 2004b).

CONCLUSION

Since the early 1990s, the emphasis across Europe has been on the costs and associated long-term funding of care of an increasing aging population. Cost containment and efficiency have been the overriding trends in policy and practice. A process of "substitution" has taken place between community and institution in the location of care. Community home-based care rather than institutional care has been favored as one response; another has been to broaden the welfare mix. Private markets were introduced in social and health service and housing provision. Social work, however, has remained within the state remit in all countries in Europe. Consequently, social work has shifted its focus from an emphasis on interpersonal skills, methods, and processes of social work to the role of a state agent in rationing and prioritizing care. New opportunities are provided to all states through the role of older people as caregivers across the generations, and their resources are being harnessed in self-help groups and volunteering. The notions of citizenship, empowerment, and participation even for dependent older people are at the forefront of European social work development, in both practice and training. Yet some states are more advanced than others, with the Esping-Anderson typology providing a convenient framework to look at this. Aging is characterized by its diversity, and this factor must not be ignored in our discussion. Not only structural and cultural diversity through age, race, ethnicity, and gender but also differences among older people with particular problems such as dementia, learning disability, and mental illness have to be ac-

knowledge. Such older people face stigma and ageism in extreme ways. The trend is to place importance on person-centered care, which necessitates good communication between agencies. Consequently, the boundaries of social work are becoming increasingly blurred. Social work values and practices are widespread across Europe but they are “outside” of the social work profession as interagency working increases. Social work therefore has to grapple with its core identity across Europe in a time of uncertainty of future social policy provision.

Older Adults in Developing Nations

91

Population aging has emerged as one of the most significant demographic processes of the 21st century. The phenomenon is progressing rapidly in both developed and developing countries. Due to the impact of population aging, the elderly population in developing countries has outpaced those in the developed world. Current estimates are that more than 248 million of the roughly 418 million persons aged 65 and older in the world (59%) are living in the developing world. The projected population data demonstrate similar trends; a growing proportion of elderly persons are predicted to live in developing countries, 67% by 2020.

In Africa, for example, it is projected that the elderly population will increase from 3.3% in 2000 to 6.9% in 2050. Within the African continent, the southern region has the highest percentage of older inhabitants; 6.2% of the population in 1997 was estimated to be 60 years of age or older, slightly more than in the northern African region (Kinsella & Ferreira, 1997). The northern region follows closely with an estimated elderly population (60 and over) of 5.9%, compared with 4.6% in eastern Africa and 4.4% in western Africa during the same period (United Nations, 1980). Even though the variation in the elderly population may not be substantial, it has implications for contemporary welfare policies and programs for older persons. In Latin America and the Caribbean, the increase is from 5.4% in 2000 to 16.9% in 2050, higher than the current European average.

Asia is estimated to have the greatest number of elderly persons: 217 million, with China alone having about 87 million persons (6.8% of its population) aged 65 and older. This figure is projected to increase to 167 million (11.5%) by 2020. Also, India's elderly population is projected to increase from 51 million (5.0%) to 93 million (7.3%) by 2020.

GENDER

As in the developed world, women are overrepresented among the elderly population in the developing world, a phenomenon that demographers describe as the feminization of the aged. According to the U.S. Bureau of the Census (1997), by 2010, of a population of 820 million African people, 14.2 million will be females aged 65 and older; 10.8 million will be elderly males. In the 75 and older age-group, there will be 4.3 million females and 3.1 million males. For example, by 2020, the total population of the sub-Saharan region will be just over 1 billion, with 19 million females aged 65 and older and 13.5 million males within the

same age-group. By 2025 this population will increase to 21.8 million females and 15.3 million males aged 65 years and older. In the same year there will be more than 4 million women aged and 4.6 million men aged 75 years and older (U.S. Bureau of the Census, 1997).

The population structure of specific African countries depicts a similar trend. For example, in Kenya women who reach 60 years are expected to live another 17 years, whereas men of the same age can look forward to an additional 15.5 years of life (Kinsella, 1992). In Zimbabwe, women will outnumber men in all age-groups by year 2005, and, as in most parts of the world, the rate of widowhood among women will increase (U.S. Department of Commerce, 1990). In Ghana, population indicators show that the elderly male population will rise from 262,000 in 1996 to 293,000 by 2000, and the elderly female population from 287,000 to 328,000 over the same period (Adlakha, 1996). In Morocco, the elderly male population was 554,000 in 1992 and is estimated to be 680,000 by 2000; the elderly female population was 570,000 in 1992 and is estimated to be 794,000 by 2000.

In addition to the gender difference in life expectancy, other gender differences have been documented in social roles and economic and health status (Pratt & Kethley, 1988). In most parts of Africa and Asia, consistent with cultural expectations, older women are likely to provide caregiving to their husbands, which may cause additional strains in their social functioning.

The economic status of women in developing nations is generally more negatively affected in old age than that of men. Even though both older men and older women continue to work well beyond official retirement age, older men tend to have more opportunities to earn income than older women. Retired older African males, due to their greater prior attachment to the formal labor market, tend to have greater access to statutory insurance schemes (e.g., social security) than do older women. Because older women in the developing world tend to operate within the informal sector, they generally have no retirement insurance in old age. Some women engage in petty trading to supplement income from farming activities, but they are less likely than men to have many opportunities to generate income. Additionally, older men tend to exercise control over valuable community resources (such as land), serve as spiritual leaders, and perform numerous community rituals. Some receive income (in the form of cash, in-kind, or token compensation) for their services, thus enhancing their economic position.

Accordingly, the feminization of the older adult population and significant gender differences in social and economic status present a special challenge in developing nations. Gender-specific policies and programs will have to be enacted. It is also worth noting that women live longer than men, and they tend to spend more of their older years in a disabled state (Colvez, 1996). Life expectancy of women is now about 10% greater than that of men. Any insurance programs targeting the needs of elderly women should take this factor into consideration. The implications of this gender imbalance for social support and public planning can be great, since older women are more likely to be widowed.

HEALTH CARE ISSUES

Most developing countries have a pluralistic medical system, with traditional and Western healers operating side by side. Because most elderly persons reside in rural areas, they tend to rely on traditional medicine to meet their health care needs. Empirical evidence on access to health services in a number of developing countries indicates that rural dwellers have less access than their urban counterparts (Apt, 1992; Banga, 1992, 1993). This is due to the limited number of health providers in rural areas and the disproportionate amount of public funds allocated to urban health care (Ebrahim, 1993). Since practicing in urban areas is more financially and professionally rewarding than operating in a rural environment, most doctors work in urban settings. A major barrier to obtaining access to health care is poverty, with most elderly people unable to afford the most basic health care (World Bank, 1993). In general, resource constraints have prevented health policymakers from extending health care services to rural areas equivalent to those in urban areas. Thus, access to health care for elderly rural people is more problematic than for elderly urban dwellers. The lack of guaranteed health care for older persons has contributed to poor access and utilization of formal health services, and poor older persons in the developing world continue to bear the greatest burden. The challenge today is to develop a health care system that offers equitable access to all elderly people on the continent. Suggestions in this regard are made later in the chapter.

One factor that is likely to affect population aging in the developing world is the incidence and prevalence of AIDS/HIV. Without question, the world in general and the developing world in particular have

been severely impacted by the AIDS pandemic, with men, women, and children suffering equally. For example, although Africa's sub-Saharan regions contain only 12% of the global adult population, the vast majority of people living with AIDS or HIV infection are located in Africa. Of the 33.4 million adults and children estimated to be living with HIV or AIDS at the end of 1998, 22.5 million are in sub-Saharan Africa (UNAIDS, 1999). Further, in 1998, of the 2.5 million deaths from AIDS-related illnesses worldwide, 2 million of the casualties were in sub-Saharan Africa (UNAIDS, 1996).

Even though most of the attention on the continent is focused on younger populations (commercial sex workers, pregnant women, young girls, etc.), the HIV/AIDS problem should be of great concern to the older adult population as well. The United Nations AIDS Programme (2004) fact sheet notes that many girls are getting infected through sex with older men because older men provide the girls with gifts, money, or other favors. What is more, condom use among older men may be lower than in the population in general.

AIDS/HIV is expected to affect life expectancy the world over, as a result of increases in mortality in the young and adult ages. For example, in East Africa and southern Africa, the regions most affected by the AIDS pandemic in Africa, infant mortality rates are nearly 70% higher than what they might have been without AIDS (World Population Profile, 1998). The impact of the HIV/AIDS epidemic raises a number of critical social questions regarding social work practice with older people in the developing world. With many people dying at a younger age, many older persons are left without family caregivers. Some governments in the developing world are increasingly showing sensitivity to these problems, but there is more to be done to address the multiple challenges posed by the problem.

Although family ties are strong and the family remains the primary source of support for older Africans, modern social changes (e.g., industrialization, urbanization) are changing the traditional family structure and its ability to support its elderly family members (Ingstad, Bruun, Sandberg, & Tlou, 1992). Some older persons no longer receive adequate physical and social support due to out-migration (Peil, Bamisaiye, & Ekpenyong, 1989). Whereas the industrialized countries of Europe and North America have provided statutory insurance programs such as social security, health care, education, and a number of state-mandated social services, very limited statutory pro-

grams have been enacted in most developing countries to address the challenges of population aging.

IMPLICATIONS OF POPULATION AGING

The rapid increase projected in the number of older persons globally has significant implications for many areas such as health care, financing of social services, social protection, housing, and the role of the elderly population in a rapidly changing and urbanizing society. Social insurance programs are needed to address emerging challenges created by population aging. It is feared that, as the population ages, the economically active age-groups will not be able to support the dependent age-groups, mainly children and older persons who are traditionally cared for by the family.

The incidence of disease and disability also increases with advancing age. Moreover, there are special problems of diagnosis, assessment, management, and care of people in the older age-groups. In many countries, governments have accepted the responsibility of supporting the needs of older persons. Therefore, in cases like Ghana, where the present supply of human resources and facilities for health care is inadequate, these services will be even further strained.

It is clear that the increasing numbers and proportion of older persons will mean that more facilities and services will be required to meet their specific needs. In response, it is necessary for governments in developing countries to instigate appropriate policies.

IMPLICATIONS FOR SOCIAL WORK PRACTICE

A number of institutional and community-based services have been developed to meet the changing needs of older adults. Among these are multipurpose senior centers, adult day care, respite care services, congregate living, and assisted living centers. Such programs provide a setting for older people to socialize, reduce the effect of isolation, and offer an opportunity to partake in life-enhancing activities. As much as programs of this nature contribute to the quality of life of seniors, they are limited in that they provide few avenues for seniors to use their talents to benefit other people who may need their services and expertise. One challenge confronting an aging society is how to utilize the talents and experience of older adults to help other age cohorts that might need their services.

FAMILY CAREGIVING

In most parts of the developing world today, the demographic transition is negatively affecting the social fabric and communal arrangements that made it a joyful moral obligation to care for older persons (Apt & Grieco, 1994; Peil et al., 1989). One important consequence of fertility decline is a progressive reduction in the availability of kin to whom future generations of older persons may turn for support. This process may have a significant impact on the well-being of older persons, especially in the less developed regions, where social support for the older person is largely provided by the immediate family (Hoyert, 1991; Wolf, 1994). At the same time, improved chances of surviving to the oldest ages are likely to spur efforts to improve the health status of the older population and lead to reforms in the pension and health systems.

Today, the family is undergoing changes in terms of form, proximity, roles and functions, relationships, power, and decision-making hierarchies. Given the demands placed on members of the family who could sell their labor within the new economic system, the traditional role of caring for older persons has been affected in both rural and urban Africa. Families are no longer in a position to fulfill the economic, cultural, and social functions that they did before colonization and industrialization. Today, due to the change in the social role of women (the traditional caregivers) and increased migration of youth from rural to urban centers, the family is undergoing a very rapid transformation (Peil, 1991). For example, an increasing number of women work outside the home for pay, and this new role has affected their ability to provide informal caregiving. The increasing migration of the youth to urban centers in search of a better life deprives older individuals of the physical support and services that they may need from them (Peil, 1989). In spite of these changes, policies should be geared toward supporting and encouraging family members to enable them to continue their caregiving role. Ultimately, professional effort will be needed to complement family caregiving.

STATUTORY PROGRAMS IN THE DEVELOPING WORLD

As more people live longer, retirement, pensions, and other social benefits tend to extend over longer periods of time, making it necessary for social security systems to change substantially to remain effective (Creedy,

1998; Bravo, 1999). But the features and scope of statutory programs in developing countries vary in terms of the programs provided, the basis of eligibility, and funding and administrative mechanisms. Social security appears to be the primary statutory program provided in most countries. It operates as either a provident fund (e.g., Nigeria and Kenya) or a pension scheme (e.g., Ghana and Cote d'Ivoire; Kludze, 1988). Some countries (e.g., Botswana, Malawi, Sierra Leone, and Somalia) provide only workers' compensation. Others (e.g., Algeria, Cape Verde, Egypt, Guinea, Morocco, South Africa, and Tunisia) provide four statutory programs (e.g., unemployment benefits, workers' compensation, social security, and family allowance). In the majority of the countries (e.g., Benin, Central Africa Republic, Ethiopia, Gambia, Ghana, Kenya, Libya, Madagascar, Nigeria, Sudan, Zambia, Zimbabwe), about 68% of the population have at least two types of social insurance programs.

In contrast to the Africa situation, there is largely universal coverage of the populations in most Asian countries. For example, the pension and provident fund systems of countries such as Korea, Malaysia, Singapore, and Taiwan Province of China have near-universal coverage. However, in other countries, coverage is very limited to those in the formal sector (Heller, 1998). The social insurance programs in most countries do not have universal coverage. Persons who are not part of the formal labor force or not employed in the civil service sector are not included. Also, most rural populations are excluded, since most workers are involved in the informal labor market. Social security systems, like the Beveridge model, were designed around a traditional male working life concerned with a man's ability to earn and provide (Pascall, 1986).

NONSTATUTORY INSURANCE PROGRAMS

Informal welfare programs exist in most developing countries, to provide protection against the unforeseen contingencies of life. Prior to the advent of modern social insurance programs in most developing countries, such informal structures were based on family and an elaborate network of filial obligation. The structures provided social protection to address the needs of people within the informal sectors. In spite of the advent of the modern welfare state in some developing countries, nonstatutory welfare programs continue to be the only source of security to a sizable percentage of older people in such countries.

Cultural and religious societies, rotating credit societies, funeral societies, and informal saving societies exist throughout the continent (Midgeley, 1997).

An Array of Social Services

A fair mix of government and community-based social services could be created to meet the needs of older persons. Core services such as health care, social housing, food and nutrition, and transportation could be addressed under a comprehensive service model for older persons. For example, a percentage of social security funds could be invested in low-income social housing programs for older persons with prior attachment to the labor market and who have earned sufficient social security credit. The balance could be paid under a flexible social loan program over a period of time. Also, transportation services could be provided under contract with private social service agencies to transport older people to meet specific needs. For example, reduced fares could be offered to older consumers on all government-operated transportation services. Another service is adult day care centers. They would offer an avenue for elderly persons to meet their peers to exchange notes and engage in life-enhancing activities. South Africa is one of the few countries beginning to experiment with this idea.

Reinforcing Traditional Security/Welfare Programs

It is necessary to reexamine traditional forms of social protection with the view to strengthening them. A double-decker social insurance system, one for those in the rural areas operating in the informal sector and another for those in urban areas operating in the formal sector, may be the best way to address the needs of both rural and urban elderly persons (Darkwa, 1997). Non-waged-based protective programs such as crop and animal insurance may be needed to provide additional protection to the sizable majority of elderly persons who rely on these sources for their livelihood.

Redistribution of Caregiving

In addition to state-sponsored insurance programs, the private sector should play an instrumental role in providing welfare services to address the needs of older persons. Religious organizations and business

groups should consider a comprehensive array of church-based and employee assistance programs (fringe benefits, adult day care services, etc.) to supplement the limited governmental effort. This will go a long way toward relieving employees from the caregiving tasks during working hours. To date, businesses are beginning to respond in sharing in elder caregiving, but there is still much to be done, given changing demographics. A matching fund program could be instituted by religious organizations and business groups. Under a scheme of this nature, churches and businesses could match financial resources raised by community groups in support of elderly services. Given the magnitude of resources controlled by businesses and religious institutions, their involvement in the provision of social services to older persons will be a fine and befitting gesture.

CONCLUSION

Older persons in the developing world are being affected to varying degrees by the demographic transition. With an increase in the elderly population, the need to provide pre- and postretirement social protection programs is greater than ever before. Migration, urbanization, education, and wage labor are the main factors bringing about changes in the structure and support systems of the family. Thus, any policies, programs, and services that are enacted to address the needs of older persons should take those factors into consideration. Furthermore, an array of social services should address issues such as caregiving, postretirement adjustment, generational equity, health care, housing, and institutional and community-based social services. Addressing the needs of older persons should be a shared responsibility among governments, family members, nonprofit organizations, religious and faith communities, and the business community. Such a redistribution of responsibilities would ensure that identifiable sectors of the society are involved in addressing the needs of older persons. In sum, we need to redesign our social insurance and welfare system to fit the realities of our current situation. As times change, we should be able to adopt the current scheme to new realities and emerging changes.

MARTHA N. OZAWA
SHINGO NAKAYAMA

Long-Term Care Insurance in Japan

92

At the U.S.-Japan Conference on the National and International Implications of Population Aging in Oiso, Japan, in 1986, Henry Aaron, a prominent scholar of social security, stated that Japan and the United States would have to reckon with the looming public spending on long-term care for their seniors (Conference on the Societal Impact of Population Aging in the United States and Japan, 1986). That prediction has become a reality. Starting in the early 1990s, the Japanese government opened the debate on long-term care, which led to the passage of the Long-Term Care Insurance Law of 1997, which went into effect in April 2000. Because of the comprehensiveness of its coverage and provisions, the act has been hailed as the most important legislation since the National Pension Law (Kokumin nenkin ho) of 1961. The total expenditures for the Long-Term Care Insurance program, including administrative costs but excluding co-payments, for fiscal year 2003 (ended March 31, 2003) are estimated to be ¥5.4 trillion (or \$45 billion [dollar equivalents of yen values are calculated on the basis of the \$1 = ¥120 exchange rate]; Dai 1 kai shakaihosho shingikai kaigo hoken bukai, 2003) and are projected to increase as the program is fully implemented and the aging of the population accelerates (Ministry of Health and Welfare, 1995). It is estimated that the expenditures for this program will reach ¥20 trillion (or \$167 billion) in 2025 (“Kaigo hoken,” 2003). Japan’s Long-Term Care Insurance program was the third program in the world that took the social insurance approach; the first was implemented in the Netherlands in 1967, and the second in Germany in 1995 (Ikegami, 1997).

This chapter examines the following questions: What were the forces that led Japan to establish a long-term care program for elderly people? What are the law’s provisions? Finally, what are the aspects of policymaking in developing this program that are unique to Japan?

FORCES BEHIND THE LEGISLATION

Multiple forces led the Japanese government to develop a public program for long-term care for the elderly: demographic imperatives, changing public attitudes toward the care of elderly people, misuse of hospitals for nonmedical purposes, and the obsolescence of the previous long-term care system. In addition to these forces, a new ideology of “socialization of care of the elderly” emerged that changed the tenet of Japan’s welfare state. We will discuss each force in turn.

Demographic Imperatives

Japan's population is aging rapidly. In 2000, life expectancy at birth was 84.62 years for women and 77.64 years for men. The proportion of the elderly (aged 65 and older), 17.4% in 2000, is projected to reach 28.7% in 2025 and 35.7% in 2050 (National Institute of Population and Social Security Research, 2002, Table 1, p. 12). These demographic changes will take place in the context of a shrinking population: Japan's population is projected to decline from 128 million in 2007 to 101 million in 2050 (National Institute of Population and Social Security Research, 2002, Table 1, p. 12).

Because of these demographic changes, the living arrangements of the elderly have changed dramatically. From 1980 to 1992, the proportion of the elderly who lived alone increased from 8.5% to 11.7%, and the proportion of the elderly who lived only with their spouses increased from 19.6% to 27.6%. Conversely, the elderly who lived with their adult children declined from 69.0% to 57.1% during the same period (Ministry of Health and Welfare, 1995, p. 81).

Even if elderly people live with their adult children, the availability of women (the traditional caregivers) who can care for elderly relatives has declined, because of their increasing rate of labor force participation. From 1975 to 1992, the percentage of married women who worked increased from 42.6% to 52.2%, and the percentage of married women who worked outside their homes increased from 8.1% to 35.5%. Despite these changes, women still constitute 85.9% of the caregivers, and 54.2% of the caregivers are aged 50 to 69 (Ministry of Health and Welfare, 1995, pp. 59–60).

In the meantime, the number of elderly people who are in need of care has been increasing at a relentless speed. In 2000, a total of 1.5 million elderly people were bedridden, excluding those with dementia; 200,000 had dementia; and 1.2 million were frail. Thus, 2.8 million elderly people (or 12.7% of the elderly population) were bedridden, suffering from dementia, or frail (Ministry of Health, Labor, and Welfare, 2002b, p. 7; National Institute of Population and Social Security Research, 2002, p. 12).

It is projected that by 2025, a total of 5.2 million elderly people (or 15.0% of the projected elderly population) will be at risk of needing long-term care, of whom 2.8 million will be bedridden, 400,000 will have dementia, and 2 million will be frail (Ministry of Health, Labor, and Welfare, 2002b, p. 7; National Institute of Population and Social Security Research, 2002, p. 12). The probability of being bedridden and/or suffering from dementia increases from 1.5% for those

aged 65 to 69, to 3.5% for those aged 70 to 74, to 6.3% for those aged 75 to 79, to 11.5% for those aged 80 to 84, and to 33.5% for those aged 85 and older (Ministry of Health, Labor, and Welfare, 2002b, p. 58). It is estimated that 50% of those aged 65 and over will need long-term care in their lifetimes (Katsunuma Cho Yakuba, 2003). Furthermore, the time that the elderly need long-term care has increased because these elderly people live longer. In 1992, 47.3% of bedridden people were in that condition for more than 3 years (Ministry of Health and Welfare, 1995, pp. 58–59).

Changing Public Attitudes

In spite of the Japanese traditional value that compels adult children to care for their ailing parents, more and more Japanese have come to accept the need to provide support and care for elderly people through a publicly provided long-term care program. Public opinion polls, conducted from 1994 to 1996 by three major newspapers, indicated that between 60% and 87% of the respondents favored some type of publicly financed and publicly provided long-term care system (Nagase, 2001; Ministry of Health and Welfare, 1995). A 1995 government survey indicated that 82% of the public supported long-term care insurance based on a social insurance scheme (see Masuda, 2001). In addition, the younger generations support publicly provided long-term care for their own parents more strongly than do the parents themselves. The Survey on Long-Term Care and Health Care in Old Age, conducted by the Ministry of Health and Welfare (1992), asked the respondents aged 45 to 64 where they want their parents to receive long-term care and asked respondents aged 65 or older where they wanted to be cared for. Only 31.3% of the younger generation versus 43.3% of the older generation stated that home was the desirable place to be cared for. Nonetheless, these figures indicate that a sizable proportion of both young and old generations accept the fact that the majority of the elderly should be cared for outside their homes.

Increasing Health Care Spending and Its Misuse

As in the United States, Japan's total health care expenditures have been increasing at a faster rate than the growth of its economy. It is expected that Japan's national expenditures for health care will increase at an

annual rate of 5.6%, from ¥27 trillion (\$225 billion) in 1995 to ¥54 trillion (\$450 billion) in 2010, and at annual rate of 4.5%, from ¥54 trillion in 2010 to ¥104 trillion (\$866 billion) in 2025, all in constant yen. For each period, the rate of increase in health care expenditures for the elderly is expected to be even greater. As a result, the share of national health care expenditures for the elderly is expected to grow from 39% in 1995, to 42% in 2010, and to 54% in 2025. These numbers indicate that at least in the aggregate, the health care expenditures for the elderly will grow disproportionately, relative to the increase in total health care expenditures in Japan. As of 1999, per capita health care expenditures for the elderly population were ¥782,000 (or \$6,409), 2.8 times the amount for nonelderly people (Ministry of Health and Welfare, 1999a).

To confound the health care financing problem, many elderly people are hospitalized in general hospitals not because they need medical care but because they have no place to go—a phenomenon the Japanese call “social hospitalization.” In 1999, 25% of hospitalized patients aged 75 and older could have been discharged if they had places to go (Ministry of Health and Welfare, 1999b). To decrease health care expenditures, policymakers were convinced that they had to provide long-term care to those who do not need to be hospitalized, under a separate long-term care program, because it would be more economically efficient to do so.

Macroeconomic Issue

Japanese policymakers recognized that without a comprehensive long-term care program, many prime-age women would be forced to curtail, or even terminate, their employment to care for their aging parents or in-laws. It is estimated that for each 10 persons who need long-term care, 1 person terminates his or her employment to care for an elderly person (Iwamoto, 2001). The result, policymakers believed, would be slower economic growth. Moreover, because policymakers wanted to see faster growth in the service-related and high-tech industries, maintaining well-educated women in the labor force was critical. Furthermore, they wanted the elderly—who were saving money at twice the rate of the non-aged and had a median of ¥6,500,000 (or \$54,200) in bank savings accounts—to spend money for current consumption (Yusei Shou, 1999). The elderly were saving this much money because they were afraid of becoming in need of long-term care (Kyogoku, 1998).

Obsolescence of the Income-Tested Program

The previous long-term care program, which was instituted under the Social Welfare Law for the Elderly in 1963, became obsolete, both ideologically and programmatically, for meeting the long-term care needs of current and future generations. That program was generally targeted to low-income elderly people and those without other family members at home and was subsidized by the three levels of governments (national, prefectural, and municipal). Thus, high-income elderly people who live with other family members are effectively excluded. Under this program, a low-income elderly person pays almost nothing to stay in a nursing home, whereas a high-income elderly person, if admitted to a nursing home, pays as much as ¥240,000 (\$2,000) a month. Those who did not meet the eligibility criteria had to find services in the marketplace and purchase both home-based and institutional care services and pay for them out of their own pocket.

Such a selection process created dissatisfaction among the public; even if elderly people who needed care lived with other family members, it had become difficult for family members to provide adequate care. Moreover, unreasonably high payments that were imposed on high-income residents of nursing homes were another source of contention (Ito, 2000).

Furthermore, the health and welfare systems were uncoordinated, so that elderly people had to apply to government agencies to receive home care or institutional care and deal separately with health providers (physicians and nurses) to receive medical care (Masuda, 2001). In spite of all these difficulties in the previous system and a relatively limited number of elderly people who were eligible for nursing home care because of stringent eligibility criteria, there were waiting lists for nursing home placements of 2 to 3 years in many localities (Ito, 2000).

A New Ideology in Japan's Welfare State

Perhaps more influential than any other force that led Japan to launch comprehensive long-term care insurance was the emergence of an ideology that adopted the notion of socialized care for the elderly. Since the end of World War II, the Japanese government concentrated, first, on the amelioration and prevention of poverty; second, on income security for retired work-

ers, disabled workers, survivors of deceased workers, and dependents of retired or disabled workers; and, third, on the perfecting of universal health care insurance. In the 1980s, policymakers and the public started addressing the public provision of care services for the elderly. This new initiative represented a departure from the earlier assumption that only families were to be responsible for providing care for the elderly. Such an initiative signified the public acceptance of the governmental responsibility to finance and provide care services for the elderly. The public responsibility in this area was the start of a new ideology in Japan's welfare state, under which the central focus was to ensure adequate and effective support and care for elderly people so that they could continue to be productive members of society with the maximum possible vigor. Government leadership in developing such a new ideology is characteristic of Japan's policy making because the Japanese public has a high level of trust in and reliance on government.

Several pieces of legislation that ensued are the manifestation of the new ideology. The 1989 Gold Plan (formally called the Ten-Year Strategy to Promote Health and Welfare for the Aged) was the manifestation of this new ideology. It set specific targets for doubling the number of nursing home beds, tripling the number of home helpers, and achieving 10 times the number of adult day care centers, as well as establishing local agencies whose job was to coordinate home-based care services for the elderly (Ministry of Health and Welfare, 1996). Under the 1990 amendments to the Social Welfare Law for the Elderly, municipal governments were made legally responsible for developing a variety of home-based and institutional long-term care services. In 1994, in a governmental document entitled *21st Century Social Welfare Vision: Toward Establishing Shoshi-Korei Society*, the national government changed the weight of public social welfare expenditures from 5:4:1 (pensions, health, and social services) to 5:3:2 as a goal (Health and Welfare Statistics Association, 2001b, p. 190). The 1994 Gold Plan (which basically was the upgraded version of the 1989 Gold Plan) raised the already ambitious targets set in the 1989 Gold Plan on all fronts (Campbell, 2000; Campbell & Ikegami, 2000). In this way, Japan's welfare state started to make support and care for the elderly its centerpiece.

After the enactment of the Long-Term Care Insurance Law, the quest to develop infrastructures for long-term care provisions continued unabated. The Gold Plan 21st Century accelerated the quantitative targets for personnel, services, facilities, and manage-

ment technologies, as well as the development of a movement to improve the image of the elderly, the encouragement of independent living with dignity, and the establishment of mutually supportive local communities (Masuda, 2001; Ministry of Health, Labor, and Welfare, 2002b).

In summary, the Long-Term Care Insurance program was developed because of various external forces, such as demographic imperatives, changing public attitudes toward the care of elderly people, the misuse of hospitals for nonmedical purposes, and the obsolescence of the previous long-term care system. But the primary catalyst for establishing such insurance was the new ideology in Japan's welfare state. Anticipating the accelerating changes in demographics, family structure, and living arrangements of the elderly, the Japanese government and the public responded to the need for long-term care of the elderly aggressively and positively, however costly this program may be.

BASIC PROVISIONS OF LONG-TERM CARE INSURANCE

From the beginning of the policy debate in the mid-1990s, the planners of long-term care insurance set forth clear goals. Furthermore, they decided that the municipal governments were to be the insurers. Their goals were as follows:

- To spread the burden for paying for long-term care for the elderly throughout the society;
- To establish a clear link between contributions and benefits and to clarify the sources of funding for the program;
- To introduce a system under which health care services and long-term care services are integrated but funded separately;
- To adopt a social insurance scheme in developing a long-term care program; and
- To eliminate hospitalization for social purposes (Ministry of Health, Labor, and Welfare, 2002b).

The decision to designate municipal governments as the insurers came naturally (although some mayors resisted the idea; Ito, 1998) because, as provided under the 1990 Amendments to the Social Welfare Law for the Elderly and amendments to seven other laws related to social welfare (Kyogoku, 1998), municipal governments had played the primary role in developing various types of social welfare services, as well as "community plans" for health and social services for

the elderly. That is, the planners of the Long-Term Care Insurance program conceived of long-term care as an extension of social welfare services, instead of an extension of health care services, and thought that municipal governments had enough experience to become the insurers of the Long-Term Care Insurance program (Kyogoku, 1998); moreover, municipal governments had been the insurers for the national health insurance plan for self-employed and nonemployed persons.

The consensus on adopting a social insurance scheme for a long-term care program was developed early in the policy debate—around 1994—and specific policies were developed later. The planners of the program dealt with basic principles in the following areas:

- The share of aggregate expenditures to be met by the national, prefectural, and municipal governments and the insured;
- Certification and classification of recipients of long-term care;
- Separate treatment of two age-groups of the insured with regard to contributions and eligibility to receive care;
- Types of benefits provided, the maximum payments to be met by the insurance, and the co-payments that are to be paid by the insured;
- Special, financial protection for low-income insured people; and
- Permission for for-profit organizations to participate in the insurance program as providers of home-based services (Ministry of Health, Labor, and Welfare, 2002b).

Shares of the Financial Burden

An extensive infusion of general revenue is involved in financing the Long-Term Care Insurance program. This is reflected by the proportion of the financial burden to be met by the three levels of government and the insured: 25% by the national government, 12.5% by the prefectural governments, 12.5% by the municipal governments, 17% (changed to 18% in 2003) by the insured aged 65 and over, and 33% (changed to 32% in 2003) by the insured aged 40 to 64.

Of the national government's contributions, 5 percentage points are to be set aside to assist municipalities that are facing financial difficulties because they have a high proportion of low-income elderly people, a large proportion of those aged 75 and older who are at high risk of becoming bedridden or having dementia, or many waivers of premiums because of

natural disasters experienced by insured people (insured people who encounter natural disasters do not have to pay premiums). In addition, the national government is to pay 50% of the administrative costs incurred by municipal governments.

The proportions of the financial burden placed on people aged 65 and over (17%, changed to 18% in 2003) and on people aged 40 to 65 (33%, changed to 32% in 2003) are directly related to the ratios of the populations in these age-groups: There are about twice as many people aged 40 to 64 (43 million) as people aged 65 and over (22 million; Nagase, 2001). Thus, the program was designed to impose the same financial burden on the two age-groups.

Premiums Levied on Two Age-Groups

People Aged 65 and Over

The premiums to be paid by elderly people depend on their incomes. For calculating premiums, elderly people are categorized into five groups according to five economic conditions: (a) elderly individuals who receive public assistance or old-age pensions and whose other household members do not pay municipal taxes; (b) elderly individuals in households in which no members pay municipal taxes; (c) elderly individuals who do not pay municipal taxes but whose other household members do; (d) elderly individuals who have annual incomes of less than ¥2,000,000 (\$16,667); and (e) elderly individuals who have annual incomes of ¥2,000,000 or more, as of April 2003.

The program considers Group 3 the baseline group and requires people in that group to pay a set premium. Premiums for Groups 1, 2, 4, and 5 are derived from the baseline premium that is paid by Group 3. Table 92.1, which applies to the city of Aioi (2003), illustrates the point. Elderly individuals in Group 3 pay premiums of ¥34,800 (or \$290) a year, Group 2 pays 25% less, Group 1 pays 50% less, Group 4 pays 25% more, and Group 5 pays 50% more. It is estimated that 72% of the elderly belong to Groups 2 or 3 (Ministry of Health, Labor, and Welfare, 2002b). The national average annual premium in 2003 is ¥39,516 (\$329; "Kaigo hoken ryo," 2003). The baseline premium is set by municipal governments and can be changed every 3 years.

Premiums from elderly individuals are collected in two ways. For those who receive social security benefits of ¥180,000 (\$1,500) or more a year (about 80% of the elderly), their contributions are deducted from

TABLE 92.1 Annual Premiums for Elderly Persons Aged 65 and Over, by Level of Income Status 2003–2005: The Case of Aioi City

<i>Economic Status</i>	<i>Relative Premiums</i>	<i>Absolute Premiums</i>
Group 1	0.50	¥17,400 (US\$145)
Group 2	0.75	¥26,100 (US\$218)
Group 3	1.00	¥34,800 (US\$290)
Group 4	1.25	¥43,500 (US\$363)
Group 5	1.50	¥52,200 (US\$435)

Note: Group 1 = those who are on public assistance or receive old-age pensions; Group 2 = elderly people who do not pay municipal taxes, and neither does the rest of their household; Group 3 = elderly people who do not pay municipal taxes, but some of their household members do; Group 4 = elderly people with annual income less than ¥2,000,000; Group 5 = elderly people with annual income more than ¥2,000,000.

From City of Aioi, *Kaogo hoken ryo ni tsuite* (Aioi City: Author, 2003), retrieved from http://www.city.aioi.hyogo.jp/sections/c/if/if_about.html.

their social security benefits and sent to the municipal governments. Those whose social security benefits are less than ¥180,000 a year send their premiums directly to their municipal governments (Ministry of Health, Labor, and Welfare, 2002b; Nagase, 2001). In the aggregate, the contributions by those aged 65 and over are supposed to meet 18% (in 2003) of the total benefit expenditures in particular municipalities.

People Aged 40 to 64

Employed persons in this age-group must be insured for health care to be insured for the Long-Term Care Insurance program. (Ostensibly, the objective of not covering persons without health care insurance coverage is to prevent the use of long-term care insurance for meeting the cost of medical care.) Employed persons become insured by paying a premium in the form of payroll taxes on top of payroll taxes for health care insurance. The payroll tax rate for health insurance is 8.2% (in 2003), and the payroll tax rate for the Long-Term Care Insurance program is 0.89%. Because employers pay half the payroll taxes, the tax rate levied on employees for the Long-Term Care Insurance program is 0.445% of taxable earnings. For health care insurance and the Long-Term Insurance combined, employees pay 4.549% of their taxable earnings up to ¥11,760,000 (\$98,000; Mitsui Seimei, 1998). The rates of payroll taxes for the two programs

can be changed annually. The payroll taxes for the Long-Term Care Insurance program are transferred to the Long-Term Care Insurance Trust Fund.

Self-employed or nonemployed persons, who also must be covered by health insurance before they can be covered by the Long-Term Care Insurance program, pay their premiums for both types of insurance directly to their municipal governments. Their premiums are based primarily on household income, with half the premiums paid by the national government. The premiums for the Long-Term Care Insurance paid by these persons are transferred to the Long-Term Care Insurance Trust Fund.

The Long-Term Care Insurance Trust Fund, which collects and pools the contributions from those aged 40 to 64 nationwide, transfers to each municipal government the amount equal to 32% (as of 2003) of the total benefits expenditures incurred by that municipal government. This proportion reflects the program design under which this age-group is to bear 32% of the total benefit expenditures.

The collection and distribution, by the Trust Fund, of premiums paid by those aged 40 to 64 has a built-in redistributive function. That is, because the distribution of funds reflects the budgetary needs—32% (as of 2003) of the total benefit expenditures in particular municipalities—and the collection of premiums reflects the economic capabilities of workers in such municipalities, some municipalities with greater financial needs will receive more from the Trust Fund than the premiums that are sent to the fund, and vice versa.

Certification and Classification of People in Need of Long-Term Care

The Long-Term Care Insurance program has an elaborate system for classifying insured people according to the level of care they need and certifying the existence of such need. This system is intended to treat insured people uniformly, fairly, and efficiently and to avoid fraud and abuse of the program. The law requires each municipal government to develop a Board for Certifying the Need for Long-Term Care composed of people with proper credentials in the fields of medicine, nursing, and social welfare. (If desired, two or more municipal governments are allowed to establish such a board together.) The first step in certifying the need for care involves a home visit by a municipal government official, who investigates an applicant's physical (i.e., functional) and mental conditions using an 85-item questionnaire

that was developed by the national government and is used throughout the country. Indicators of physical and mental conditions are processed by computer to arrive at the overall scores. The investigator brings the computerized results to the board, which, together with input from the family physician, certifies the applicant's need for and level of care.

Applicants for long-term care are then notified whether they need just *support* or *care*. Those who are certified as in need of support receive only home-based care services. Applicants who are certified as in need of care are classified into five groups, depending on the level of care needed. The level of need is measured by the number of minutes per day of care and services that applicants need for daily living (Health and Welfare Statistics Association, 2001b, p. 188). Those certified in need of care are eligible to receive both home-based and institutional care.

After certification by the Board for Certifying the Need for Long-Term Care and final authorization by the municipal government, applicants are ready to receive services. The insurance program encourages them to hire professionals to develop a "care plan"—a package of services that they can receive most effectively and efficiently. To be a professional in this field, a person must pass a national examination that assesses one's knowledge about long-term care. Upon passing the exam, the person must complete a practicum of specified duration. After the successful completion of the practicum, the applicant receives a certificate, which enables him or her to be a care planner and/or care manager (see Kizaki, Masuda, Inagawa, & Hirata, 2001, p. 95).

Fees for care planners are paid for outside the maximum payment constraints (explained later) by the insurance program. The insured may establish their own care plans within the budgetary constraints. The insured can choose not to have a care plan, but, in that case, they must pay the entire cost of services and then claim reimbursements from the insurance program, which is impractical in most cases. Thus, the thrust of the law is to encourage the insured to hire professionals to develop care plans.

In addition, a professional "care manager" can be hired to monitor and coordinate the services that the insured will receive. Again, the cost of hiring such a professional will be paid for by the Long-Term Care Insurance program in the same way that the cost of hiring a professional to develop a care plan is paid. The care plan developer and the care manager can come from a qualified, service-provider organization

that participates in the Long-Term Care Insurance program.

To be eligible for any type of services, those aged 40 to 64 must prove that their incapacities are the result of 1 of 15 recognized age-related diseases and illnesses, such as nervous disorders caused by diabetes, stroke, or Parkinson's disease. Thus, if one's incapacity was caused by an auto accident, for example, he or she is deemed ineligible. Other than this restriction, insured people aged 40 to 64 are treated the same as insured people aged 65 and over.

Those who successfully complete the certification are required to repeat the assessment every 6 months thereafter (Shakai Hoken Techo Henshubu, 2002).

Types of Services Provided and Co-payments

The insurance program provides two types of services: (a) home-based services and (b) institutional services. The insurance program recognizes 15 types of home-based provisions and 3 types of long-term care institutions in which insured persons can be placed. The maximum payments that the insurance program provides differ depending on the level of care needed, the type of facility, and the index of value of long-term care services (explained later).

Home-based care services include home helpers, bathing and toileting services, nursing services, rehabilitation services, and counseling on home care management. Under the law, short stays in various types of facilities and services provided in group homes (especially for people with dementia) are defined as home-based services. The provision of home-based care also includes the cost of renting or buying special devices and equipment. The program also pays for the cost of renovating homes, which is authorized by the Board for Certifying the Need for Long-Term Care, on a case-by-case basis.

Three types of institutions are recognized: (a) nursing homes for people who do not have severe medical or mental problems, (b) skilled nursing homes for people who need medical attention), and (c) sanatorium-type nursing homes for people with dementia and other chronic illnesses).

The amount of services (valued in yen) that the insured will receive depends on whether they need support or care; among those who need care, the amount of services depends on the degree of care needed, on whether they need home-based services or institutional services, and the type of nursing homes they are

placed in. The monthly maximum payment allowed for home-based services for those who just need support is ¥61,500 (or \$513) in 2003. Table 92.2 shows the maximum payments for home-based and institutional services in the same year for those who need care according to the classification of the insured, just described, and according to the types of nursing homes they are placed in. These payments are sent directly to the service providers, and the municipal gov-

ernments collect co-payments and other payments from the insured (explained later).

As Table 92.2 indicates, the maximum spending for home-based services is not necessarily low. For example, the level of maximum spending for home-based services for people in Group 5 is higher than for those in comparable groups who are placed in general nursing homes or skilled nursing homes. These standards reflect the high priority that is placed on home-based services to prevent institutionalization (Kyogoku, 1998).

The Ministry of Health, Labor, and Welfare evaluates the value of specific services on the basis of complexity and duration, using a unit system. For example, as of 2003, a physical care service for less than 30 minutes is valued as 210 units; the same service for .5 to 1 hour is valued as 402 units. A home-making service up to 1 hour is valued as 208 units; the same service between 1 and 1.5 hours is valued as 291 units (see Ministry of Health, Labor, and Welfare, 2003). Then, the sum of the units derived from various kinds of services for specific amounts of time is multiplied by ¥10. The product of the total units and ¥10 is the amount of maximum payments. In arriving at the maximum payments, the ministry took into account nine types of services that the insured who need support are assumed to need for daily living at home and the types of care that the insured in Groups 1, 2, 3, 4, and 5 (who all need care) are assumed to need at home or in a particular type of institution. The authority to change the yen value of a unit of service rests with the national government.

The co-payment by the insured is uniformly set at 10% of the cost of services received. In addition, while being institutionalized, the insured will pay a flat amount for meals and meet the cost of incidentals. However, a lower flat amount for meals will be charged to those in lower economic statuses, namely, Groups 1 and 2 (see Table 92.1). Specifically, the insured in Group 1 pay ¥300 per day, those in Group 2 pay ¥500/day, and the rest pay the normal rate of ¥780 per day (\$6.50; Ministry of Health, Labor, and Welfare, 2002b). Generally, out-of-pocket expenditures equal a 10% co-payment and, for those who are institutionalized, charges for meals and incidentals.

Protection Against Financial Hardship

The Long-Term Care Insurance program has a safety net to protect low-income people from undue financial hardship. First, the insurer (municipal govern-

TABLE 92.2 Maximum Monthly Payments for Home-Based Services and Institutional Services, by Type of Facility and Level of Need, 2003

<i>Level of Care Needed</i>	<i>Maximum Payments Per Month</i>
<i>Home-Based Services</i>	
Group 1	¥165,800 (US\$1,381)
Group 2	¥194,800 (US\$1,623)
Group 3	¥267,500 (US\$2,229)
Group 4	¥306,000 (US\$2,550)
Group 5 (high)	¥358,300 (US\$2,986)
<i>Institutional Services</i>	
<i>General nursing homes</i>	
Group 1	¥205,808 (US\$1,715)
Group 2	¥227,392 (US\$1,895)
Group 3	¥248,672 (US\$2,072)
Group 4	¥270,256 (US\$2,252)
Group 5 (high)	¥291,536 (US\$2,429)
<i>Nursing homes for those needing medical care</i>	
Group 1	¥248,976 (US\$2,075)
Group 2	¥263,872 (US\$2,199)
Group 3	¥279,984 (US\$2,333)

ments) can waive the 10% co-payment. Second, the cost of meals provided in nursing homes and the insurance premium can be paid for by the public assistance program, which is financed entirely by the national government. The municipal governments make the determination on these matters on a case-by-case basis (Nagase, 2001).

Participation of For-Profit Organizations

The Long-Term Care Insurance program allows for-profit organizations to participate as providers of home-based services as long as the prefectural governments certify them. To receive certification, these organizations must meet the minimum standards for staffing and credentials of staff. The objectives of allowing for-profit organizations to participate in the program are to create competition, innovation, and, as a result, higher quality, and to ensure that enough services are available in the community to meet the need for services (Nagase, 2001). It is estimated that 45% of the total expenditures for home visits in 2003 was attributable to the services provided by for-profit organizations (“Kenshou kaigo hoken 3 nen,” 2003).

DISCUSSION

Several aspects of the Long-Term Care Insurance program are unique to Japan’s policy development.

Infusion of General Revenues

The first aspect is the heavy infusion of general revenue in this program. As was mentioned earlier, this program is financed 50% by general revenues of the three levels of government. However, such a practice is not unusual in Japan because other social insurance programs are financed in a similar way. For example, general revenues are used to finance half the spending on first-tier social security benefits (the Japanese social security program uses a two-tier approach to calculating benefits). As a result, general revenues finance about one third of the entire social security expenditures (Ozawa, 1985).

Japan’s use of general revenues for financing social insurance programs, such as the Long-Term Care Insurance program and the social security program, reflects the country’s collectivist orientation for financing such programs. One effect of this orienta-

tion is that the financing side of these programs becomes more progressive than it would if the programs relied solely on payroll taxes. Another effect is that decision making tends to be shared more broadly by the old and the young populations, and, as a result, relatively radical changes in a social insurance program become possible.

Coverage of Those Aged 40 to 64

The second aspect is the inclusion of people aged 40 to 64. The Ministry of Health, Labor, and Welfare (2002a) reported that in 2001, only 0.2% of those aged 40 to 64 were certified as being eligible to receive support or care under the new Long-Term Care Insurance program, which indicates that the probability of this age-group receiving any type of long-term care services is small. Thus, the primary objective of covering this age-group was to transfer financial resources from this group to the elderly population. Policymakers knew that without contributions by this age-group, it would be difficult to develop an adequate system of long-term care for the elderly. In addition, from the beginning the Japanese government publicized that the entire society would bear the financial burden of providing long-term care for the elderly.

Coverage of the Entire Elderly Population

The third aspect is that all elderly people—rich or poor, Japanese citizens or foreigners—are covered (Kyogoku, 1998). This policy objective is reflected in the Japanese government’s attempt to collect premiums from the elderly according to economic class and to subsidize the out-of-pocket expenses of low-income elderly persons, as discussed earlier. The inclusion of all elderly people in this program reflects Japan’s way of policy making in general. In Japan’s social security program, for example, policymakers made it possible for those who were too old to establish eligibility for social security benefits to receive flat-amount “old-age pensions,” thus obviating the need for a program like Supplemental Security Income in the United States.

Japanese Version of Income Testing

The fourth aspect is how an income test is used in the program. As was shown earlier, to arrive at the pre-

mium amount, the Long-Term Care Insurance program classifies elderly people into five economic groups, such as those on welfare or receiving old-age pensions and those who do not pay any municipal taxes, and then develops the premium for each economic class; this is called *bracket income testing* or *categorical income testing*. Likewise, lower meal charges are used in nursing homes for lower economic groups. In both cases, the program does not use an income test that reduces benefits at a specified rate, as income level goes up, as is widely practiced in the United States with programs such as Temporary Assistance to Needy Families (TANF) and food stamps. Also, a similar bracket income test is used in the administration of Japan's children's allowances program (Ozawa, 1991). At any rate, Japan's method of income testing results in a simpler administration of income testing, as well as in less stigma.

American policy analysts may argue that the Japanese way of income testing creates a notch problem (i.e., at certain points of income, a one-dollar increase in income results in more than a one-dollar decline in net income). In the case of the Long-Term Care Insurance premiums, at some points of income levels, a one-yen increase in income results in more than a one-yen increase in premiums. Such an income test may create not only unfairness but also pervasive work disincentives. The Japanese public seems unconcerned about such a notch problem (Ozawa, 1991). Here, we see a clear cultural difference.

In the eyes of Japan's policymakers, the Long-Term Insurance program is not a finished product. The expenditures may grow faster than expected. The issue of transforming the program from the age-based one to a disability-based one is already being debated among policymakers. Given the flexible attitudes that Japan's policymakers have in developing a social insurance program, we believe they will face these challenges successfully and make changes in the Long-Term Care Insurance program as economic and demographic conditions change.

Social Work Research in Aging

This page intentionally left blank

OVERVIEW

New significant trends impacting access to and use of health and mental health services find social workers taking on new roles and new models of practice. Social work's biopsychosocial and multidisciplinary approach to care positions practitioners to have important responsibilities within emerging health delivery systems. As earlier chapters in this volume attest, social workers are critical in maintaining older individuals in their communities and reducing the cost of health services. Similarly, in collaborative work with other disciplines on behavioral and psychosocial processes, social work researchers are addressing the emerging issues in gerontology. Interdisciplinary research in behavioral and psychosocial processes is fundamental to the understanding of disease etiology, as well as to the promotion of health and well-being.

The incredible growth and diversity of this older population pose both opportunities and challenges for gerontological research. Social and behavioral research will have the opportunity to help improve health and functioning and contribute to reduced rates of disability for older people. But there is also a challenge. In the years to come, unprecedented numbers of elders will face risks of frailty and loss of independence. Social work research is challenged to understand and study issues related to practice with older adults and their caregivers. We need a strong social work research agenda in aging that can help improve the quality of life for older people and their caregivers. This part of the *Handbook* focuses on issues that social workers face in conducting research in aging; it concludes with a report on the current status of social work research and suggests future directions for our research agenda.

Amy Horowitz, in chapter 93, offers a comprehensive review of significant methodological issues in conducting research with older adults. There are research issues applicable to all age-groups, but this chapter raises the special considerations that apply to research in aging in general and focuses on many of the complicated areas in which social workers conduct research. The chapter covers many of these areas, such as design problems in cross-sectional and longi-

tudinal research and interventions studies. In addition, sampling, recruitment, and retention of participants, data collection, and measurement problems are addressed. Horowitz pays attention to qualitative and quantitative methods and is particularly sensitive to the special issues in research with minority and other special populations. In addition, she addresses the complex informed consent and ethical concerns that frequently must be considered in human subjects research with older adults and their families.

Terry Lum, in chapter 94, challenges us to understand the value of research utilizing secondary analysis, introducing researchers to the rapidly expanding resource of public large data sets. During the last two decades, this resource has become increasingly accessible to geriatric social work researchers. This chapter elucidates the benefits and limitations of utilizing data sets, as well as offering valuable technical advice.

Chang-ming Hsieh and Elizabeth Essex, in chapter 95, present the critical program evaluation issues in measuring client satisfaction with care. Although client satisfaction is only one aspect of quality of care, it is an important indicator of service quality. The authors propose a clear methodological approach that can be readily adapted for agency use in assessing client satisfaction with services. Social work evaluators can follow the steps outlined to develop client satisfaction measures that directly relate to the goals of the specific agency.

In the final chapter of this part, Denise Burnette and Nancy Morrow-Howell provide an overview of the state of social work research in aging and offer directions for the future. They note that social work researchers in aging are beginning to establish a national presence in social work schools, but the extent to which they are conducting research is not yet clear. Furthermore, they find that social work researchers are contributing to the multidisciplinary knowledge base in aging but "barely have a foothold in federally funded research." However, the authors include findings from their studies on a social work gerontological research agenda, and they conclude with their belief that social work is "well positioned to . . . assume a true leadership role in research on aging."

AMY HOROWITZ

Issues in Conducting Social Work Research in Aging

93

This chapter addresses issues in social work research in aging. The intent is not to provide a methodological discourse or tutorial. Rather, the primary purpose is to introduce the reader to the major issues that need to be considered in designing and/or evaluating research in aging. Obviously, all aspects of the scientific method that are relevant to any age-group are also relevant to research on older adults. However, there are special considerations that apply to research in aging in general, and social work research in aging in particular, that are the focus of this chapter. These include issues relevant to design, informed consent and ethical considerations, sample recruitment and retention (especially in terms of ethnic elders), and data collection and measurement, including the use of proxy data. The chapter will conclude with a brief discussion of the current and future role of the social work profession in contributing to the knowledge base in gerontology.

GENERAL DESIGN CONSIDERATIONS

Cross-Sectional Versus Longitudinal Designs

Gerontological research has significantly broadened its reach over the past several decades, going beyond a relatively narrow focus on the study of older people to the study of the processes of aging. As follows, the study of *change* has become the hallmark of gerontological research, and longitudinal designs the preferred means to reach the objective. Whereas cross-sectional designs can and do continue to make important contributions to the field in several ways (e.g., identifying key processes for further study, examining rare populations, highlighting cross-cultural and cross-national comparisons), they remain limited by their inability to separate *age effects* (i.e., the actual effects of chronological aging), *period or time of measurement effects* (i.e., the effects of the environment at the time the data are collected), and *cohort effects* (i.e., the consequences of being born at a particular point in history in terms of subsequent life experiences; Ferraro & Kelley-Moore, 2003). In contrast, longitudinal data allow the investigator to examine dynamic processes, to make inferences about the cause and consequences of those processes (Alwin & Campbell, 2001), and to address the primary question underlying most aging research, that is, why and how do individuals change (or not) as they age (Hertzog & Nesselroade, 2003)?

There are several types of longitudinal designs. Longitudinal panel designs are the most common and follow a single group of individuals (typically a single cohort) over time. In cohort sequential designs, several cohorts are followed during an identical time period (Collins, 1996), adding to the ability to distinguish between age changes and age differences, but also adding significantly to the cost of the research. Both, however, are subject to the primary limitation of longitudinal designs, that is, bias due to nonrandom attrition. Attrition is a problem in longitudinal research with any age-group, but differential attrition is especially problematic in aging research due to selective mortality, morbidity, cognitive decline, and institutionalization (Ferraro & Kelley-Moore, 2003). Drawing conclusions based solely on the hearty individuals who survive in a longitudinal study can lead to seriously biased findings, especially since much of the research in aging, as well as research of special interest to social workers, focuses on the physical and mental health and well-being of aging individuals. An alternative approach is the cross-sequential design, which involves the collection of cross-sectional data from two independent samples of the same cohort at different points in time. Although this design results in assessment of change within an identified cohort, rather than individual change, it does avoid the problem of attrition (Collins, 1996). Fortunately, recent advances in statistical methods for the analyses of longitudinal data offer techniques that can account for nonrandom attrition (i.e., multiple imputation, full-information maximum likelihood methods, and multigroup estimation), as well as ones that can examine intraindividual change and interindividual trajectories. The interested reader is encouraged to explore the numerous resources, both print and instructional, that are now available (see, for review, Ferraro & Kelley-Moore, 2003; Hertzog & Nesselroade, 2003).

Use of Secondary Data

The increasing availability of longitudinal data sets for secondary analyses has been a major development in the field and one that has advanced, as well as benefited from the advances in, statistical methods for longitudinal data (Cutler, 1995; George, 1995). These data sets are often available on the Web and include, to name just a few, the National Health and Nutrition Examination Survey (HANES) I—Epidemiologic Follow-up (<http://www.cdc.gov/nchs/>

<http://www.cdc.gov/nchs/soa/han1/>); the Established Populations for Epidemiologic Studies of the Elderly (EPESE; www.icpsr.umich.edu/NACDA/archive.html); the Longitudinal Study on Aging (LSOA; www.cdc.gov/nchs/lsao.htm); the National Long-Term Care Surveys (NLTCs; <http://nltc.cds.duke.edu/data.htm>); the Assets and Health Dynamics of the Oldest Old (AHEAD; <http://www.pop.psu.edu/dataarchive/daman/ahead1.htm>); and the Health and Retirement Study (www.umich.edu/~hrswwww). They offer the researcher a range of rich and cost-effective options to explore research questions related to the health and well-being of aging individuals. In addition to serving as the primary data resource, public data sets are often used to provide external comparison groups for a study sample (e.g., comparing health status of a locally recruited older sample with representative national samples) or can also be used to provide outcome data for study participants (e.g., health care utilization data from Medicare and Medicaid records or mortality data from the National Death Index; Fredman, Hawkes, Zimmerman, Hebel, & Magaziner, 2001). However, Kasl (1995) warns against reliance on these data sets for “opportunistic analyses” to answer more complex questions regarding the social and psychological influences on the health of older adults. He argues that these data are seldom collected with the purposes of new investigators’ questions in mind and that measurement of key variables is often limited because of the original broad scope of these studies. Both the advantages and the disadvantages of using available data sets further highlight that good research of any type is that in which the research question drives the research method.

Intervention Research

Of special relevance to social workers is the significant increase over the past decade in intervention research focusing on aging issues. Social workers are traditional change agents, and much of our research interest calls for the evaluation of treatment programs that are intended to assist consumers of social work services. Intervention research can be defined as involving “actions that alter, or are intended to alter, relationships between observable phenomena” (Schulz & Martire, 1999, p. 2). Intervention research may utilize observational or quasi-experimental designs, but the design of choice is the randomized clinical trial. When participants are randomly assigned to treatment and control conditions, one can assume (but

should always verify) that characteristics that might influence outcomes, or interact with treatment, will be equally represented in each group. Thus, the only difference should be the planned intervention. However, intervention studies in the health and human services seldom take place in laboratories. It is often unrealistic to expect that participants in the no-treatment group will not seek alternate services. Therefore, it is critical that measurement of related services be incorporated in the design (Arean, Cook, et al., 2003).

Intervention studies are also subject to bias due to attrition. As with longitudinal surveys, participants with the poorest physical and mental health status are overrepresented among the dropouts. However, there is also treatment-related participant attrition (Schulz & Martire, 1998), that is, participants dropping out because of the nature of the treatment (e.g., too burdensome, or not receiving the desired treatment). Thus, to address this bias resulting from retention of the most committed participants, most randomized intervention studies base their analyses on the principle of “intent to treat”—that is, including all original participants assigned to treatment in the analysis regardless of how much or for how long service was actually received. Newer approaches such as mixed-effects modeling and survival models are also being used to identify treatment effects (Lebowitz, 2004).

There are numerous other considerations in the design of intervention research. Most important, there must be a conceptual link between the treatment and the outcome (Arean, Cook, et al., 2003). This means that the treatment should be reasonably expected to affect the outcome, and to manifest this effect within the time frame of the study. Further, although seemingly an obvious consideration, the target population must evidence need for the treatment. To provide an example of how these conditions were not met, one can consider the early caregiver intervention studies, most of which failed to report significant treatment effects for social support or psychoeducational group programs with the short-term outcome of reducing caregiver stress and depression. However, these programs were often not targeted to depressed or stressed caregivers (Toseland & McCallion, 1997) and, in fact, recruited volunteers who were likely to be more effective problem solvers. Thus, there was little room for improvement in stated outcomes. Similarly, the early case management interventions were supposedly designed to reduce institutionalization. However, even if they were successful, the follow-up period was typically insufficient for program effects on placement rates to

emerge among populations that were not initially on the path to nursing home placement. Thus, working with clearly defined target populations and distinguishing between primary and secondary outcomes, as well as between short-term and long-term outcomes, is critical in intervention research. Further, as Schulz and colleagues have stressed (Schulz et al., 2002), the challenge to intervention researchers is to produce outcomes that are clinically meaningful, as well as statistically significant.

Qualitative Versus Quantitative Research: The Nondebate

We have hopefully gone beyond the stage where proponents of qualitative or quantitative research methodology advocate the virtues of one method to the exclusion of the other. As noted earlier, the research question must drive the methodology, not the reverse. Qualitative methods are being used more frequently, and more fruitfully, in gerontological research, as their contributions are being better understood and their methodologies for data collection and analyses have become more sophisticated. Qualitative research can offer an in-depth view of complex social processes associated with aging and can be defined as an “approach to the study of human behavior that relies on the analysis of narrative data to create an interpretation of the meaning of these behaviors from the perspective of the participants themselves, with their own social context” (Cobb & Forbes, 2002, p. M197). Qualitative research in gerontology can be especially useful, for example, when the research question addresses a phenomenon that is not well understood, to identify key variables for study, to generate research questions or hypotheses for future study, or to collect information that is needed for the development of quantitative measures. Qualitative methods, however, are not always a precursor to quantitative research. These methods can also be especially useful in identifying explanations for unexpected or anomalous findings (Barbour, 1999), as would be the case, for example, in examining why caregiver intervention studies often fail to produce significant quantitative treatment effects although caregivers typically self-report receiving many benefits of these programs. More recently, there has been an emphasis on combining qualitative and quantitative methods within studies, using “mixed-methods” approaches (Morgan, 1998), which offers opportunities to integrate the inherent strengths of both while

minimizing their limitations (Bechtel, Davidhizar, & Bunting, 2000). The interested reader is referred to the many excellent textbooks available on qualitative sampling, data collection, and analyses (see, for example, Denzin & Lincoln, 2000; Gubrium & Sankar, 1993; Padgett, 1998, 2004).

RESEARCH ETHICS/INFORMED CONSENT

Research in aging presents ethical challenges, some of which are unique to the study of older adults and some of which are not (AGS Ethics and Research Committees, 2001). At the heart of any discussion of ethics in research is the process of securing informed consent from potential participants and/or their surrogates. The basic elements of consent are that it is voluntary, informed, and provided by someone who is competent to provide consent and who comprehends what he or she is consenting to (High, 1992). Being an older adult does not, in and of itself, constitute vulnerability in terms of research participation. However, even where participants are fully cognitively capable of providing informed consent, there are still issues to consider in securing informed consent from older adults. In general, older adults may need more time to understand the information completely (AGS Ethics and Research Committees, 2001). Sensory impairments are common among older adults and may interfere with the consent process. Large print and clear color contrast in informed consent documents are helpful even for those who are simply experiencing normal aging vision changes. For participants with vision problems, the informed consent should be read aloud by the researcher. For older adults with hearing problems, communication regarding questions about the study can be facilitated by the use of assistive listening devices, which consist of a microphone and headset and are easily available in retail stores to help with two-person conversations. Ironically, because of these special considerations for older adults with vision and/or hearing impairments, they are often excluded from general research studies, which, in turn, creates an ethical issue in terms of limiting their rights to research participation and underrepresenting their perspectives in research findings.

Another problem in securing consent is that older adults, although fully informed and willing to participate in a study, are often reluctant to sign documents at all, or would like someone in their family to review the consent before they sign it (Berkman, Leipzig,

Greenberg, & Inouye, 2001; Boulton, Boulton, Morishita, & Pirie, 1998; Cohen-Mansfield, 2003). In these cases, accommodations can be made for verbal consent, which is then independently witnessed, and adaptations made to the consent process so that it proceeds in two stages.

Conducting research with older adults with dementia and other cognitive impairments can raise questions about the appropriateness of proxy consent and whether such individuals should be participants in research studies even when there is no possible immediate benefit for them. However, the Alzheimer's Association has affirmed that persons with Alzheimer's disease should not be deprived of the potential benefits of participating in research, and U.S. federal regulations have endorsed proxy consent, as long as extra attention is given to monitoring the participant in terms of potential harm or discomfort (Post, 2003). Many older adults in the early stages of Alzheimer's disease and/or with mild cognitive impairment can contribute to the decision-making process (Sachs et al., 1994). Interestingly, a study of proxy decision making found that proxies commonly reported that the decisions were shared with the older patient, although whether this was true shared decision making or the proxy's attempt to involve the older adult was unclear (Sugarman, Cain, Wallace, & Welsh-Bohmer, 2001). In addition, Sugarman et al. (2001) found that caregivers often felt the "burden" of making the decision for the older person with dementia, suggesting that researchers need to be sensitive to this concern when soliciting consent. Some have argued that regardless of proxy consent, ethical standards would call for the participant themselves to show willingness to participate (Good, 2001). However, there is currently no requirement in federal regulations that assent be obtained from patients with dementia.

Another ethical consideration, especially for social workers, involves the sometimes dual roles of the practitioner-scientist (AGS Ethics and Research Committees, 2001). A clear conflict of interest can arise, or be perceived, if the social worker as researcher is also involved in the treatment of the research participant (Good, 2001). Even recruitment efforts by the social work or medical professional who is treating the older adult can be perceived as coercive (Cohen-Mansfield, 2003). At the very least, special care must be taken in the informed consent process so that expectations of the two roles are not confused by the research participant. However, the better solution is to avoid these situations entirely.

As is the case for all research studies, regardless of age-group, approval and monitoring of all human subject concerns, including recruitment and consent procedures, are the responsibility of the organization's institutional review board (IRB). IRBs can differ somewhat in their requirements from institution to institution, but they all follow the Code of Federal Regulations, known as the Common Rule. These regulations clearly spell out the required elements of the informed consent document (e.g., risks and benefits; how data will be stored and used; limits, if any, to confidentiality), as well as other aspects of human subject recruitment and protection. Detailed information on required procedures can be accessed through the Office of Human Research Protections (OHRP; <http://www.hhs.gov/ohrp/>). Furthermore, the Health Insurance Portability and Accountability Act (HIPAA) of 1996 included regulations about the use and confidentiality of individually identifiable patient health data known as the Privacy Rule and applies to covered entities, including health care providers as individuals or organizations. This is a complex set of rules that can apply when the social worker is conducting research within a covered entity in which he or she is employed or is seeking data from a covered entity. Additional patient authorizations may be required to release information, data may have to be de-identified before release, and/or the researcher may have to enter into a business associate agreement. Many IRBs now require documentation of compliance with HIPAA regulations. The final HIPAA Privacy Rule is available at <http://www.hhs.gov/ocr/hipaa>. Furthermore, most government agencies have developed educational materials for researchers about the Privacy Rule; see <http://privacyruleandresearch.nih.gov> for a series of helpful booklets for researchers and IRBs.

RECRUITMENT AND RETENTION OF RESEARCH PARTICIPANTS

The time, effort, and cost of recruiting and retaining participants in research studies should not be underestimated, and building in strategies for recruitment and retention is a key component of any research design. In this section, general issues and strategies for recruitment and retention will be reviewed, followed by a more detailed discussion of one of the critical problems in aging research today—the recruitment of ethnic minority elders in research studies.

Recruitment methods for nonprobability samples and intervention research vary significantly across

studies and can include radio ads, newspaper ads, referrals by social and health care professionals, referrals by current research participants, presentations at public forums or senior organizations, mailings, flyers, and, more recently, notices on Web sites. As in all aspects of the research design, the nature of the study and the nature of the population drive the recruitment process (Cassidy, Baird, & Sheikh, 2001).

Understanding why older adults and their family members do or do not agree to participate in research is important in addressing concerns and developing strategies to maximize recruitment and retention. On the one hand, older people often report wanting to help others or wanting to share their story as reasons for research participation. Participation in clinical trials is often motivated by the desire for the treatment, receiving feedback about their current status, and receiving support from research staff (Connell, Shaw, Holmes, & Foster, 2001).

On the other hand, barriers to research participation include a distrust of research, preferences for treatment rather than randomization in clinical trials, problems with transportation, lack of time, and problems understanding the informed consent (Connell et al., 2001; Lovato, Hill, Hertert, Hunninghake, & Probstfield, 1997; Stahl & Vasquez, 2004). When research is conducted in residential centers, concerns about privacy and lack of perceived benefits, as well as problems with fatigue, can affect recruitment (Cohn-Mansfield, 2003).

Most studies, if possible, try to compare participants with nonparticipants on some key characteristics to identify potential biases. Common characteristics associated with refusal to participate in research include older age, lower education, and poorer health status (Ganguli, Mendelsohn, Lytle, & Dodge, 1998; Norton, Breitner, Welsh, & Wyse, 1994). However, one study found that even though refusers and participants had similar ages and health status at baseline, 3-year follow-up data indicated that the former had a significantly higher risk of nursing home placement and mortality than did the latter (Minder, Muller, Gillmann, Beck, & Stuck, 2002). This finding underscores the truism that research participants will always be different than those who choose not to participate, but we can never totally be sure in what ways.

In selecting recruitment strategies for any study, there are often trade-offs between cost and effectiveness. Patrick, Pruchno, and Rose (1998) compared five recruitment strategies for a study of older parents of disabled adults: agency referrals, support groups,

participant referrals, media, and mass mailings. Overall, they found that the least time- and resource-intensive strategies were those that involved existing groups (i.e., agencies, support groups, and referrals from participants). Yet these strategies consistently underrepresented minorities, those with low incomes, and those who are more socially isolated.

There have been many suggested strategies to maximize recruitment that have varying levels of success depending on the target population. These include enclosing an incentive or gift (e.g., a dollar bill or a pen) in mailed questionnaires and including local newspaper articles or press releases about the study to support its legitimacy (Boult et al., 1998). All printed recruitment materials should be written in clear, non-technical, and jargon-free language and composed at no more than an eighth-grade reading level (Warren-Findlow, Prohaska, & Freedman, 2003). Researchers will need to deal with the logistic barriers to research participation, which may involve providing or covering the cost of transportation, as well as providing respite care if the potential participant is responsible for the care of another family member. Providing access to a research staff on a regular basis and providing periodic feedback via written materials such as study newsletters (that will not bias future data collection) have been recommended to maximize retention (Connell et al., 2001), as has providing incentives in terms of small monetary payments for each session or interview (Cassidy et al., 2001). I have used techniques such as sending a thank-you letter after each interview with a reminder about the next wave, as well as reminder letters a few weeks before the next interview to maximize retention. Interestingly, a randomized trial of advance notice letters, versus no letters, mailed 2 weeks before a mailed survey found that the letter increased participation by Whites but not by African Americans (Napolis-Springer, Fongwa, Stewart, Gildengorin, & Perez-Stable, 2004). In a study of bereavement-related depression, one of the successful strategies, in addition to media announcements, was writing personal letters to bereaved spouses found through newspaper obituaries (Schlernitzauer et al., 1998), which again underscores that recruitment strategies need to be study specific.

The serious underrepresentation of ethnic minority elders in survey and clinical research has been given increased attention in recent years, with three journals devoting special issues to the subject (*Gerontologist*, 2003, 43(1); *Journal of Aging and Health*, 2004, 16(Suppl. 5); and *Journal of Mental Health and Aging*, 2000, 6(1)). Although the National Institutes of

Health Revitalization Act of 1993 mandates the inclusion of ethnic minorities in research, problems with recruitment of ethnic minority elders persist. However, recent federal initiatives, such as the creation of Resource Centers on Minority Aging by the National Institute on Aging (Stahl & Vasquez, 2004), have contributed to a growing knowledge base about issues and strategies relevant to the recruitment of ethnic minorities in research studies.

In addition to the numerous attitudinal and logistic barriers to research participation noted earlier, additional forces are at play when addressing ethnic older populations. The mistrust of medical research and the scientific community, based on a history of mistreatment, is cited consistently as the primary barrier to recruiting older African Americans for research studies, even those studies that address psychosocial rather than medical issues or treatments (Connell et al., 2001; Curry & Jackson, 2003; Moreno-John et al., 2004; Stahl & Vasquez, 2004). Furthermore, the stigma regarding mental illness and help seeking is a particularly strong force that deters involvement in clinical research by Latinos (Gallagher-Thompson, Solano, Coon, & Arean, 2003), as well as by Chinese elders and their families (Guo, Ley, Hinton, Weitzman, & Levkoff, 2000). On the other hand, it has also been suggested that failure to involve family members can also hinder recruitment of Latinos (Arean & Gallagher-Thompson, 1996). At the same time, the sense of fatalism regarding chronic illness in general that is prevalent in ethnic communities (Connell et al., 2001) and the belief that the health problem is a private issue for the family to deal with (Curry & Jackson, 2003) also contribute to lower participation rates among minority elders. The complexity of forms and procedures is often a barrier to those with low literacy (Curry & Jackson, 2003), and the lack of culturally sensitive protocols often leads to high dropout rates (Connell et al., 2001). Finally, failure to communicate the relevance of the research to the community has been a major factor in decreasing acceptance (Curry & Jackson, 2003).

Specific strategies have been suggested to increase recruitment of ethnic elders. In one study of African American caregivers, they themselves recommended that future research participants be contacted by those currently involved in the research (Connell et al., 2001). Dilworth-Anderson and Williams (2004) found that assigning the same interviewer to interview participants in a study of African American caregivers was a successful strategy. However, given the logistics of data collection and staff turnover, this is not always

possible in a longitudinal study. Some researchers have recommended having interviewers ethnically matched with participants (Arean, Alvidrez, et al., 2003; Armstrong, Crum, Rieger, Bennett, & Edward, 1999). Curry and Jackson (2003), however, note that the data on matching research interviewer to participant on race are still very mixed, but still emphasize the importance of ethnic and racial minority researchers at all levels of research staff.

Regardless of the specific strategies, involving members of the ethnic community in the research process and forming research partnerships with them through a participatory research process has clearly emerged as the primary recommendation for increasing participation in research by ethnic elders (Arean, Alvidrez, et al., 2003; Burnette, 1998; Curry & Jackson, 2003; Gallagher-Thompson et al., 2004; Olin, Dagerman, Fox, Bowers, & Schneider, 2002; Reed, Foley, Hatch, & Mutran, 2003; Vesey, 2003). Targeting community opinion leaders and church leaders and partnering with local physicians represent important strategies for community involvement (Curry & Jackson, 2003). Levkoff and Sanchez (2003) also emphasize the importance of understanding the history between the academic or health institutions sponsoring the research and the community because this will affect initial relationships.

Although the importance of community involvement at all levels and phases of the research process cannot be overstated, it must also be recognized that community- and consumer-oriented approaches require additional staff, money, and time (Arean, Alvidrez, et al., 2003; Curry & Jackson, 2003). In addition, each culture and community will have its own unique history and concerns about research participation, and there is no one set of rules that will apply to all communities (Burnette, 1998; Stahl & Vasquez, 2004). Still, given the social and health disparities that permeate our society, the imperative to include ethnic minority older adults in research studies that can help address these disparities has never been stronger.

DATA COLLECTION

General Considerations

The primary methods of direct data collection with individuals include observations, self-administered questionnaires, telephone interviews, and in-person interviews, all of which have been successfully used with older adults. Each has its benefits and drawbacks.

Some suggest that there is a greater likelihood of answering sensitive questions on a self-administered questionnaire, but that the response rates are generally lower, and “don’t know” responses are higher than for either telephone or in-person interviews (Pruchno & Hayden, 2000). Telephone interviews are less costly than in-person interviews and also have the advantage of increased interviewer safety and decreased interviewer effects. However, telephone interviews often elicit less-detailed responses to open-ended questions than do in-person interviews and have greater missing values (Wilson & Roe, 1998). Telephone interview are also more likely to recruit healthier older adults (Carter, Elward, Malmgren, Martin, & Larson, 1991).

The unique issues faced in collecting data directly from older adults have mostly to do with the effects of normal aging changes and age-related diseases on the ability to understand the questions and respond to them. More time may be required for the questionnaire or interview to be completed due to normal age changes in cognition. Some conditions, such as Parkinson’s disease and stroke, can seriously affect both oral and written communication ability. As noted earlier, vision and hearing impairments can also affect the way data are collected. Self-administered questionnaires will be impossible for the many older adults with age-related vision impairments and can be difficult even for those with normal aging vision unless print is large and legible and has good contrast. In-person interviews often depend on visual aids, such as response category cue cards. These cannot be used with visually impaired elders, and alternatives, such as unfolding techniques when asking Likert-type scales, can be used without compromising the validity of the data. Obviously, persons with serious hearing impairments will have difficulty with either interview format, although some with mild or moderate impairments can function better face-to-face than they can on the telephone. Again, assistive listening devices should be part of every interviewer’s supplies. When interviewing the very old, fatigue can be a factor. Thus, flexibility in scheduling and procedures to conduct the interview in multiple sessions need to be in place. Interviews of older adults are often conducted in the home, but this brings with it the potential for distractions from phone calls and household members, as well as concerns about privacy (Reed et al., 2003). Often family members or formal caregivers will want to stay in the room when the interview is taking place either because of curiosity or out of safety concerns. Our research group has found

that a firm statement in the beginning about the importance of confidentiality is often required and successful. When it is not, the family member often leaves after only a few minutes. In any case, it is important to document the presence of another person during the interview and the perceived effect on the participant's responses so that the validity of interview can be assessed.

Use of Proxies

When an older adult cannot directly participate in a research study because of cognitive impairments or other health problems, a family member or other significant individual is often called upon to act as a proxy respondent. This raises the question of proxy reliability, that is, the extent to which a proxy can accurately report the elder's status. A great deal of research has addressed this question, much of it focused on assessing congruence in assessments of functional ability (i.e., activities of daily living [ADL]). Most studies find relatively good agreement among elders and caregivers in terms of ADL capability but also find that the family members tend to assess the elder as more disabled than does the elder him- or herself (Lyons, Zarit, Sayer, & Whitlatch, 2002; Magaziner, Bassett, Hebel, & Gruber-Baldini, 1996; Matthew, Adamek, & Dunkle, 1993; Neumann, Araki, & Gutterman, 2000; Todorov & Kirchner, 2000; Yip, Wilber, Myrtle, & Grazman, 2001; Zanetti, Geroldi, Frisoni, Bianchetti, & Trabucchi, 1999). There is less overall agreement between elders and caregivers when assessing mental health (Neumann et al., 2000). The direction of difference, however, is similar, with caregivers reporting the elder as experiencing significantly greater depression and poorer psychological well-being than do elders in their self-ratings (Bassett, Magaziner, & Hebel, 1990; Burke et al., 1990). Given this known bias in how proxies evaluate their older relatives, it is very important to interpret findings based on proxy respondents accordingly. This bias can be more problematic in research where both proxies and older adults are respondents. In these cases, proxy status is often incorporated in the analyses as a covariate.

MEASUREMENT

Aging research, as an interdisciplinary field, encompasses measurement in a number of domains, including, but not limited to, health, functional ability,

cognitive functioning, mental health, social relationships and social support, leisure and activity participation, personality, life events, psychosocial well-being, and caregiver functioning and well-being. There has been a great deal of psychometric work over the past several decades in the development of measures specifically for older adults and in the validation of existing measures for use with older people. As a result, there is an increasing potential for comparability across studies using similar measures (Cutler, 1995). There is, however, much more work to be done in determining the appropriateness of many existing measures for use with various ethnic minorities. This is a critical need, since many concepts that we measure (e.g., family, depression, pain) have culture-specific meanings. In fact, Burnette (1998) cautions against making cross-cultural comparisons based on participants' self-ratings, since these are made in the context of their own reference group, which will differ across cultures.

Twenty years ago, the first resource for measures in aging was published (Mangen & Peterson, 1982). Today, the researcher in aging has a number of excellent resources available, which present and discuss various options for measurement in domains of interest and their psychometric properties relative to application in various groups of older adults (see, e.g., Andersen, Rothenberg, & Zimmer, 1997; Lawton & Teresi, 1994; Lichtenberg, 1999; Skinner, Teresi, Holmes, Stahl, & Stewart, 2002; Teresi, Lawton, Holmes, & Ory, 1997).

CONCLUSION

Gerontology has traditionally been a multidisciplinary field, with a growing emphasis on using this strength to build interdisciplinary research collaborations. There has also been a tradition in gerontology of communication and collaboration between the scientific and practice communities, although in practice there is still much work to be done to translate research findings into applications that will benefit older adults (Pillemer, Czaja, Schulz, & Stahl, 2003). To facilitate this connection, the National Institute on Aging has funded an initiative to establish the Edward R. Roybal Centers in Applied Gerontology. The goal of these centers is to improve the process of applying findings from behavioral and social science research to programs that directly affect older adults.

Within this scientific environment, the social work perspective, with its dual emphasis on theory

and service and its expertise in the health and social services, has much to offer the study of aging. A study of research priorities in social work research in aging identified several high-priority topics that were consistent with the current federal research agenda (Burnette, Morrow-Howell, & Chen, 2003). These included, for example, improving outcomes for ethnically diverse elders and intervention research that directly informs practice and policy. Yet a recent review of the research literature found that social workers are not well represented as contributors to the knowledge base in aging (Morrow-Howell & Burnette, 2001). Further, these investigators estimate that only 4% of all social work faculty have an interest in aging. Clearly, there is important work to be done in the field to develop the potential of social work researchers to contribute their unique perspective to the field of aging. To facilitate this process, the John A. Hartford Foundation has implemented a major initiative to increase the research capacity of the social work profession, through support and research training provided to both social work faculty and doctoral candidates in aging. This initiative has been a significant force in the field, as more than 50 faculty scholars have already been in the program. The impact of this program, along with other federal initiatives, can be expected to increase the contribution of social work to the research literature in aging.

Using Large Datasets for Research on Older Adults and Families

94

Researchers in the fields of health and social sciences are increasingly interested in using large survey data sets for their research. Collecting data from thousands of respondents is expensive and time consuming, but researchers now have many opportunities to conduct research through secondary analysis of large data sets that they were not involved in collecting. *Secondary analysis* refers to “any further analysis of survey or social dataset that presents interpretations, conclusions or knowledge additional to, or different from, those presented in the first report on the inquiry as a whole and its main results” (Hakim, 1982, 12). The trend toward using secondary analysis of existing data sets in research on older adults and their families has been fueled by the increasing availability of public-use survey data containing information collected from older adults and their families, advancement in computer technology that allows researchers to analyze very large data sets on personal computers, the availability of commercial statistical software that can account for potential biases from complex sampling designs, and the Internet and data archives that make these existing data sets more accessible.

The use of secondary data analysis in the field of social work is still relatively uncommon for several reasons. First, many social work researchers do not have the skills to understand complex survey designs, complete preliminary data processing, and carry out the advanced statistical techniques required to take advantage of these available resources. Many social work doctoral programs do not teach secondary analysis of large data sets in their research curriculum. Further, some social work researchers still see secondary analysis of existing data sets as an inferior cousin to primary data collection. The goals of this chapter are to introduce geriatric social work researchers to the rapidly expanding resource of public-use large data sets and to describe the steps that geriatric social work researchers should take to benefit from these resources. Throughout the chapter, I will use the Study of Assets and Health Dynamics Among the Oldest Old (AHEAD) as an example to illustrate my discussion.

Study of Assets and Health Dynamics Among the Oldest Old (AHEAD)

- The AHEAD is an ongoing longitudinal study of the joint dynamics among health (physical, cognitive, and functional), dementia, economic and family resources, and care

arrangements. It provides data to address a broad range of scientific questions focused on the interplay of resources and late-life health transitions. The population of AHEAD includes all adults in the contiguous United States who were born in 1923 or earlier and reside in households. More detailed information about the AHEAD data can be obtained from its Web site at <http://hrsonline.isr.umich.edu/>. ■

BENEFITS AND LIMITATIONS OF USING LARGE SURVEY DATA SETS IN RESEARCH

Large survey data are collected to provide information for funding and policy decisions, to monitor program or policy implementation, or to address specific social and scientific research questions. Federal government agencies in the United States, such as the U.S. Census Bureau and the National Center for Health Statistics, routinely collect large amounts of survey data from nationally representative samples to meet the information needs of the government. Examples of these national surveys include the U.S. Census, the Current Population Survey (CPS), the National Health Interview Survey (NHIS), and the Survey of Income and Program Participation (SIPP). Many of these survey data sets contain information on demographics, socioeconomic status, living arrangements, health, mental health, physical and cognitive functioning, and program participation from thousands of older people and their families. Federal governmental agencies regularly report aggregated data from these surveys, but the potential of these data for further analytical study is immense. Researchers can analyze individual-level information from these survey data sets to shed new light on many aspects of the health and well-being of older people and their families.

Many researchers outside of the government also collect survey data to address specific research questions. Examples of these surveys include the National Long-Term Care Survey (NLTC), the Americans' Changing Lives (ACL) Survey, and the Health and Retirement Study (HRS). Many of these survey data sets are not fully analyzed and may have potential utility beyond the specific research questions for which a particular study was designed. They provide an opportunity for testing specific hypotheses that have not yet been examined.

There are many benefits of using large existing survey data sets in researching issues related to older adults and families. First, it is an expeditious means of answering some types of research questions. Primary data collection is time consuming; using data sets collected by the government, services providers, or other researchers is a time-saving alternative. Second, secondary analysis of existing data makes economic sense in the current tight budget environment. Most of these data sets can be obtained free of charge, whereas primary data collection is very costly. Third, users of large survey data may benefit from the work of experts who are involved in survey design and data collection. Fourth, many of these large survey data files are collected from a nationally representative sample, thus allowing researchers to generalize their findings to a national level, an ability that is particularly important for policy research and program development. Fifth, many large surveys oversample certain subgroups of the population. This allows researchers to estimate reliable population parameters for some specific subpopulations, such as older people of color, lower-income older people and families, or the oldest old (Korn & Graubard, 1999). Sixth, the large sample sizes also give researchers enough statistical power to estimate the existence of weak to moderate associations between variables of interest, which is not possible using smaller sample sizes (Korn & Graubard, 1999). Finally, since researchers using existing survey data are not involved in research design and data collection, the concern of reactivity in the data is eliminated.

There are also some serious limitations in using existing data sets for research on older adults and families. First, secondary analysis of large survey data sets is not appropriate for answering all types of research questions. Some questions may require collection of preliminary data to test specific hypotheses or to get more in-depth responses from subjects. Other types of research questions may require an experimental design. Second, researchers may not be able to find any existing survey data sets that have variables and samples that are needed to answer their research questions. Third, even though they may find an existing data set that has variables related to their research questions, these variables may not be the most appropriate measurements for their constructs of interest. Since secondary researchers were not involved in deciding which measures were included in the original research, they can only use what is available. Fourth, researchers have no control over the survey design and data collection, and therefore no control

over the quality of the data. Fifth, the learning curve of using large data sets can be very steep, and inexperienced researchers usually require extensive work and time to learn survey designs, primary data processing, and specific statistical methods needed to conduct data analyses. Many social work researchers find these tasks formidable.

Despite these potential limitations, with some training and education, most geriatric social work researchers would be able to expand their research capability by learning how to conduct secondary analysis of the rapidly expanding library of existing survey data.

UNDERSTANDING LARGE SURVEY DATA SETS

The main difference between survey and nonsurvey data (such as clinical and administrative data) is in sampling. Sampling lets researchers collect information from a relatively small number of individuals to provide accurate information about a much larger population. Most large survey data are collected from respondents selected through a complex sampling design that involves multistage sampling, stratification, clustering, and differential selection probabilities (i.e., weighting). In multistage sampling, individuals are first organized into small groups or clusters, such as geographic areas, counties, or city blocks. These clusters are sampled in the first stage of sampling. Individuals within the selected clusters are sampled in the subsequent stage. Several stages of cluster sampling (e.g., from counties to city blocks and then to households) may also be conducted before individuals are sampled. The first cluster to be sampled is known as the primary sampling unit (PSU). Cluster sampling is mainly used to improve logistics and to reduce the travel costs of data collection as interviewers only need to travel to a smaller number of clusters (e.g., counties) instead of traveling all over the country to collect data. Cluster sampling may lead to a correlation among sample units because individuals within the same cluster, such as household and neighborhood, are more homogeneous than individuals in different clusters. This correlation violates the assumption of independent observations in most statistical procedures and, if unaccounted for, leads to losses in precision in population estimates. Statistical analysis that does not take into account this potential correlation would potentially underestimate the standard errors of population estimates (Korn & Graubard, 1999; Lee, Forthofer, & Lorimor, 1989).

Stratification is the process of organizing individuals in the population into relatively homogeneous subgroups before sampling. The population may be stratified by income, race, geographic area, or other factors that are crucial to the analysis. Once these strata have been defined, sampling can be conducted independently within each stratum. For example, if the population is stratified by race, individuals in the population are first organized into Whites, Blacks, and other racial groups. Random sampling may then be conducted independently within each stratum. Individuals in different strata can have different probabilities of being selected into the sample. Unlike clusters, strata themselves are not being sampled in multistage sampling, and all strata are used in the sampling process. Stratification and cluster sampling can both be used at the same time in multistage sampling. Because individuals within a stratum are more homogeneous than individuals across strata, stratification may produce smaller estimates of variance and thus underestimate the standard errors of population estimates (Korn & Graubard, 1999; Lee et al., 1989). Researchers need to account for the effects of stratification in analysis of large survey data.

AHEAD Sampling Design

■ AHEAD is based on a stratified multistage area probability sampling design with dual sampling frames. AHEAD households were assigned to one of two groups (those who were born after 1913 and those who were born prior to 1914) based on the age of the oldest person in the household. Households in the “born after 1913” group were selected exclusively from the area probability frame component. Households in the “born prior to 1914” group were selected using roughly a 50% sample from the areas probability frame and the remaining 50% through a stratified sampling from a list frame of Medicare enrollees. Households were organized into clusters of metropolitan statistical areas (MSAs), single large non-MSA counties, or groups of small non-MSA counties. Detailed information of sampling in AHEAD can be found in Soldo, Hurd, Rodgers, and Wallace (1997) and on the AHEAD Web site. Sample design variables were created in the public use data files for AHEAD users to adjust for features of the complex multiage design. ■

In many large surveys, members of certain subgroups of the population, such as people of color or the oldest old, are sampled at higher rates relative to members in other subgroups of the population. Oversampling produces a larger sample size sufficient to allow separate inferences to be made for each of the subpopulations (Korn & Graubard, 1999). If uncompensated, however, oversampling may lead to bias in population estimates as the oversampled subpopulation has a greater influence on population estimates than it should have in the population. Many large survey data sets provide oversampling data in a base weight variable, which equals the inverse of the probability of selection into the sample. This base weight variable is used in statistical analysis to account for the differential probabilities of sample selection.

Nonresponse is another concern in analysis of large survey data, especially when the response rates differ across subgroups of the population. To account for the potential bias of differential response rates across subgroups of the population, researchers incorporate a nonresponse adjustment weight into the final analytical weight. The PSU and the sample subgroup are cross-classified to create weighting adjustment cells, and response rates in these cells are calculated. The nonresponse adjustment weights equal the inverse of the sample response rate within each of these cells. The analytical weight appropriate for estimating population characteristics is the product of the nonresponse adjustment weight and the base weight.

In spite of adjustments for differential sample selection rates and differential response rates, the weighted sample distributions of major demographic and geographic characteristics may still not correspond exactly to those for the population that are available from a source external to the survey data. The problem arises from the inherent inadequacies of the sample frame—individuals who should have been selected into the sample are not selected because they are not in the sample frame. To bring weighted sample distributions for important demographic and geographic subgroups in line with corresponding known population totals, researchers incorporate a small poststratification factor to analyze weights. They create poststratification adjustment cells by cross-classified sampling strata and the subgroups. The sum of the provisional sample weights (before poststratification adjustment) of all sampled individuals in each cell is calculated and is compared with a known census figure for the same cell. Assuming that the census figures are more accurate, the provision

sample weights are multiplied by a constant factor so that the sum exactly matches the census figures. These constants are used for poststratification adjustment (Korn & Graubard, 1999).

Oversampling and Weights Adjustment for AHEAD

■ AHEAD oversamples Hispanics, Blacks, and households in the state of Florida. Household selection weight (i.e., base weight) is created to account for unequal selection probabilities of the three subpopulations. Weights are also created to adjust for geographic and race group differences in response rates and for the subsampling of households in a small number of locked buildings or dangerous areas. Poststratification adjustments are made at both the household and the person level to control sample demographic distributions to known 1990 census totals. Weights are also created for household analysis, as well as for individual analysis. ■

SECONDARY ANALYSIS OF LARGE SURVEY DATA

Similar to other types of research, secondary analysis of large survey data starts with research questions and hypotheses. Once researchers have specified their questions and hypotheses, the next step is to find a data set that may contain the needed data to test the hypotheses. Several major data archives preserve and make available existing survey data for public use. Among them, the National Archive of Computerized Data on Aging (NACDA) is the best starting place for researchers who are interested in exploring the possibility of using secondary analysis of existing survey data for research of older adults and families. NACDA is funded by the National Institute on Aging and is located in the Inter-University Consortium for Political and Social Research (ICPSR). Since its inception about 25 years ago, the NACDA has preserved and made available the largest library of electronic data on aging in the United States. As of 2004, it had approximately 2,500 unique studies on aging and health with approximately 20,000 files (data, codebooks, documentation, and data definition statements). Researchers can search the library by keywords, specific

variables, or subjects. Once they have identified one or more data sets that may be used to answer their research questions, they can download the codebooks and other documents of these data sets from the site. Researchers can also download most data sets directly from NACDA or through the official ICPSR representatives in their institutes. Table 94.1 shows some examples of large survey data sets that contain information related to geriatric social work. Researchers should evaluate all possible data sets by the quality of the measurements available, as well as by the sampling frame. The key question to answer is whether the survey data contain the needed information and sample at a reasonable quality to answer the research questions.

It is very important that researchers obtain and carefully read the codebooks and other documents of data sets before conducting any data analysis. These documents usually give researchers information about the sampling frame, sampling designs, oversampling, and response rates, as well as preliminary data processing such as coding for missing data, imputation, and creation of composite variables. They also give detailed information about the format of the data, the variable names, and the location. Many large data sets are stored in several smaller data files. These documents also provide detailed information about the content of each data file, the system of identification numbers, and how they can be merged. Some codebooks even give basic descriptive statistics, such as frequency and mean, for each variable in the data set.

SELECTION OF VARIABLES AND OBSERVATIONS INTO AN ANALYTICAL DATA FILE

Researchers typically use only a small group of variables in a large survey data set in their research. It is a good idea for researchers to select only those variables and observations that are relevant to their research questions into a new analytical data set. Recoding and other data manipulations should be performed on this analytical data set rather than on the original data set obtained from data archive. Most large data sets are in American Standard Code for Information Interchange (ASCII) data format and have a rectangular shape (sample units arranged in rows and variables arranged in columns). Researchers need to use their database or statistical software, such as SPSS or SAS, to extract variables from data files using column

numbers and to save the extracted variables in a data format for their statistical program. Some newer data sets, such as AHEAD, come with computer programs that can convert their ASCII rectangular data files into specific statistical data files (such as SPSS or SAS data files), and researchers can directly extract variables using their statistical software.

Researchers may also find that only a subset of sample units, such as the oldest old or the working poor, is relevant to their study. It is therefore essential that researchers develop clear and objective criteria for case selection and exclusion. For survey data, case selection and exclusion affects the number of observations available across PSUs, and researchers must pay attention to the effects of case selection and exclusion on sampling designs.

PRELIMINARY DATA ANALYSIS

Prior to any substantive analysis, researchers should obtain unweighted tabulations on the distribution of sample units across PSUs to check whether enough sample units are available in each PSU to allow for meaningful analysis. If there are too few sample units in a particular PSU, researchers should consider combining it with adjacent PSUs in the same strata.

The second step of preliminary data analysis is exploring the univariate distribution of each variable used in the study. Recoding, such as log transformation, may be needed for variables that violate basic statistical assumptions. Recoding may also be needed to combine categories of variables or to change the ways that responses were coded. For example, in the AHEAD data, most negative responses are coded by the number 5, and positive responses are coded by the number 1. Researchers need to recode the negative responses from 5 to 0 to create indicator variables for further data analysis. Very often, researchers may need to create their own scales or indexes from existing variables in the data set. For example, the HRS survey asked each respondent several questions on education, including the number of years the respondent had attended school and the highest diploma achieved. Researchers may need to use this information to create their own variables for education.

The third step of preliminary data analysis is to decide how to incorporate the sample weights and account for stratification and clustering in the analysis. The decision to use weighted or unweighted estimators in survey data analysis is not always straightforward. Because use of weights in data analysis

TABLE 94.1 Examples of Large Survey Data Sets That Can Be Used by Geriatric Social Work Researchers for Secondary Data Analysis

<i>Data name</i>	<i>Sample size and sampling</i>	<i>Survey design</i>	<i>Oversample</i>	<i>Remarks</i>
Assets and Health Dynamics Among the Oldest Old (AHEAD)	8,222 respondents who were born before 1923. Multistage area probability sampling design with two sampling frames.	Ongoing longitudinal household interview survey.	Blacks, Hispanics, and residents of Florida.	Ongoing longitudinal survey. First wave of interview in 1993.
Americans' Changing Lives	3,617 respondents in first wave from a multistage stratified area probability sample.	Longitudinal study. Data were collected in 1986, 1989, and 1994.	Blacks and those 60 years of age and older.	
Census public use microdata files	1% or 5% of total U.S. population in 2000. Stratified systematic sample.	Cross-sectional self-administered questionnaire survey.	No	These data are from the national censuses taken every 10 years.
Current Population Survey	Ongoing monthly survey of civilian noninstitutionalized U.S. population aged 15 years and older. Sample size is about 60,000 households.	Ongoing rotation panel design. New households panel are brought into the sample every month. New households are interviewed monthly for 4 months, skipped for 8 months, and then interviewed for 4 months before being removed from the survey.	No	Ongoing survey since 1937.
Health and Retirement Study (HRS)	12,521 respondents in the 1931–1941 birth cohort from a multistage area probability sampling design.	Ongoing longitudinal survey. First wave of interviews was conducted in 1992.	Blacks, Hispanics, and residents of Florida.	The HRS and AHEAD were merged into one survey in 1998 with additional birth cohorts added to the sample.
Longitudinal Study on Aging	7,541 individuals who participated in Supplement on Aging to the 1984 NHIS and who were 70 years of age or older at that time.	Longitudinal study of a cohort of older people who were 70 years of age or older in 1984. They were reinterviewed by telephone in 1986, 1988, and 1990.	No	
National Health Interview Survey	Approximately 43,000 households including about 106,000 persons. Multistage area probability sample design.	Cross-sectional household interview survey.	No	An ongoing annual survey since 1957.
National Long-Term Care Survey, 1982–1989	6,393 persons who were disabled and community-dwelling in 1982 and their informal caregivers; a multistage probability sample.	Longitudinal study. Data were collected in 1982, 1984, and 1989.	No	

produces approximately unbiased population estimators, researchers should use weights, stratum identifiers, and sampling unit identifiers in their descriptive statistics to account for the effects of oversampling, nonresponse, clustering, and stratification (Korn & Graubard, 1999; Lee et al., 1989; Lepkowski & Bowles, 1996). However, use of sample weights when unnecessary may lead to larger standard errors and thus statistical inefficiency. Therefore, researchers should first check for the degree of inefficiency before any analytical statistical procedures are conducted. The degree of inefficiency is given by the following equation (Korn & Graubard, 1999):

$$\text{Inefficiency} = (1 - (\text{Variance of unweighted estimators} / \text{variance of weighted estimators}))$$

If the inefficiency is small relative to the estimator, sample weights should also be used in completing analytical statistics, such as regression analysis. However, if the inefficiency is relatively large compared with the estimators, researchers should augment the weighted model with unweighted models or other alternative approaches that incorporate the design variables into the model (Korn & Graubard, 1999).

VARIANCE ESTIMATES IN LARGE SURVEY DATA

Many researchers are surprised to learn that the standard statistical software (such as SPSS) does not

account for this lost precision due to complex sample designs (Brogan, 1998; Carlson, 1998; Lepkowski & Bowles, 1996). A number of statistical programs that implement these complex sample variance estimation methods are available to analyze large survey data. Two common approaches for estimating correct variance from survey data with complex sampling design are the replication approach and the Taylor series linearization approach (Brogan, 1998; Carlson, 1998; Korn & Graubard, 1999; Lee et al., 1989; Lepkowski & Bowles, 1996). The replication approaches, such as Balanced Repeated Replication, Jackknife Repeated Replication, and Bootstrap methods, use repeated subsamples from the whole sample to calculate the point estimates of the population parameters. The standard errors are then obtained using the variability of these subsample statistics. The linearization approach rewrites the population estimates in the form of a Taylor’s series expansion with the assumption that all higher-order terms are negligible. The standard errors are obtained by applying a standard formula for the mean-square error to the first-order portion of the expanded estimates (Brogan, 1998; Carlson, 1998; Korn & Graubard, 1999; Lee et al., 1989; Lepkowski & Bowles, 1996; StataCorp, 2001). The detailed techniques of these two approaches are beyond the scope of this chapter. Table 94.2 summarizes several major statistical programs that can account for the imprecision from sampling designs. Researchers should learn to use one of these programs for secondary analysis of large survey data.

TABLE 94.2 Summary of Statistical Program for Survey Data Analysis

<i>Program</i>	<i>Account for sampling design effect</i>	<i>Statistical procedures</i>	<i>Ease of use</i>
Stata	Can handle most sampling designs, except two-state cluster sampling, probability-proportional-to-size sampling, poststratification, and certainty PSUs.	Has the most statistical procedures for survey data.	Relatively easy to use.
SUDAAN	Can handle all sampling designs.	Limited statistical procedure.	More difficult to use.
WesVar	Can handle all sampling designs except two-state cluster sampling.	Limited statistical procedure.	Easy to use.
SAS	Can handle all sampling designs except poststratification and two-stage cluster sampling.	Very limited statistical procedure.	Difficult to use.

CONCLUSION

Large existing survey data sets are valuable resources for researchers in the fields of social and health sciences. During the last two decades, these resources have become increasingly accessible to geriatric social work researchers. However, most geriatric social work researchers are challenged by the complex sampling designs and specific statistical techniques that are required to take advantage of these data sets. Some researchers who are already using large survey data sets do so incorrectly by ignoring the need to adjust for the complex sampling designs. This chapter addresses the benefits and limitations of using secondary analysis of existing large survey data in research on older adults and families. It shows steps that geriatric social work researchers should take to start using these data sets to answer some of their research questions. More and more resources are available either in print or on the Internet that geriatric social work researchers should consult to develop their expertise in secondary analysis of survey data.

Measuring Client Satisfaction Among Older Adults and Families

95

Client satisfaction has long been an important part of program evaluation (e.g., Eckert, 1994; Kane, Bartlett, & Potthoff, 1995; Rossi, Freeman, & Lipsey, 1999; Royse, Thyer, Padgett, & Logan, 2001). Although the quality of care or services cannot be represented by client satisfaction alone, client satisfaction is generally accepted as an important indicator of care or service quality (Ingram & Chung, 1997; Royse et al., 2001). In measuring satisfaction with care or services for older adults, the clients may be the older adults themselves and/or caregiving family members (e.g., Atherly, Kane, & Smith, 2004; Tornatore & Grant, 2004).

There are, however, a number of limitations regarding client satisfaction studies. First, such studies have been criticized for using measures that are not contextually specific (Schneider, 1991). Popular generic satisfaction instruments, such as the Client Satisfaction Questionnaire (CSQ-8; Nguyen, Attkisson & Stegner, 1983) and the Reid-Gundlach Social Service Satisfaction Scale (R-GSSSS; Reid & Gundlach, 1983), may not provide helpful information for care or service providers because different settings usually have different service components (Chou, Boldy, & Lee, 2001).

Second, in general, most respondents of client satisfaction surveys indicate satisfaction with services received (e.g., Ingram & Chung, 1997; Royse et al., 2001). Older adults are particularly likely to indicate satisfaction with services, perhaps because of their dependence on service provision and fear of repercussions if they give negative responses. Or perhaps they have low expectations related to their own health outcomes (Atherly et al., 2004). Given the predominantly positive responses from client satisfaction studies, it is difficult for service providers to make sense of the data without comparing the results with other agencies or conducting multiple surveys longitudinally (Ingram & Chung, 1997).

Third, researchers have long argued that client satisfaction is multidimensional (e.g., Ruggeri & Greenfield, 1995). Although many published client satisfaction instruments provide information on various domains or dimensions of the instruments, these domains or dimensions are usually obtained through factor analysis and are often too abstract to make direct inferences for service provision. Users of these instruments generally end up obtaining only global/overall satisfaction scores.

Finally, many studies measure satisfaction by summing or averaging satisfaction scores across survey items to represent client satisfaction, assuming that all survey items carry equal weights (e.g., Chou et

al., 2001; Kruzich, Clinton, & Kelber, 1992). This assumption is somewhat problematic because individual clients may perceive certain survey items to be more important, or to carry more weight, than others (Chou et al., 2001).

In this chapter, we propose an approach to measuring client satisfaction that can overcome the limitations just outlined. We first describe the main steps that go into this approach and provide a concrete example, using a community-based case management program for older adults. Readers can follow these steps and apply the approach to their own care or service settings. We then provide a theoretical perspective for this approach and discuss methodological issues of validity, reliability, and scoring.

PROPOSED MEASUREMENT APPROACH

Our approach to measuring client satisfaction can be applied to client satisfaction surveys in all service settings. For those who are interested in developing survey questionnaires that are administered by interviewers, the approach involves four major steps outlined in the following. For those who are interested in developing self-administered survey questionnaires, step 3 can be skipped, and therefore only three steps (1, 2, and 4) are required.

1. *Identify major aspects of care or services provided within the specific setting.* This step directly addresses the issue of contextual relevance. Major service aspects can be identified through combining literature review and discussions with care or service providers and clients. We recommend that these aspects be concrete so service providers can make sense of the results. We also suggest that the number of aspects not be too large to avoid a lengthy instrument that can be difficult for older adults to complete. It is also important to make sure that clients can easily recognize and distinguish between service aspects.
2. *Construct a Likert-type satisfaction rating item for each of the service aspects.* A typical item can be phrased “how satisfied are you,” with each of the respective service aspects identified in step 1. We recommend the use of either a 5-point or 7-point response format, ranging from “completely satisfied” to “completely dissatisfied,” to be consistent with most existing satisfaction measures.
3. *Construct a Likert-type importance rating item for each of the service aspects.* Clients are asked to in-

dicating the importance of each of the major service aspects to themselves, using a 5-point response format (e.g., 1 = “Extremely important” to 5 = “Not at all important”). This information will be used in step 4. For self-administered questionnaires, it is most straightforward to skip this step.

4. *Construct a mechanism to obtain an importance hierarchy for the service aspects.* The limitation in step 3, used for interviewer-administered questionnaires, is that clients may give two or more service aspects the same importance rating. To further distinguish the importance of service aspects to the clients, interviewers should, in this final step, ask respondents to rank order in importance those items for which they gave the same rating so a hierarchy of importance can be obtained. For self-administered survey questions, simply have the respondents provide the rank ordering of importance. The resulting importance hierarchy is used to calculate weighted satisfaction scores.

To illustrate the major steps, we now describe their use in developing a measure for client satisfaction with services provided by a community-based case management program for frail older adults. The program, located in a large midwestern city, provides case management services to about 4,000 adults 60 years of age and older. The case management agency wants to collect client satisfaction data and use the data to help improve its services. However, using popular generic instruments, such as the CSQ-8 (Nguyen et al., 1983) and the R-GSSSS (Reid & Gundlach, 1983), may not fit the purpose of the survey because these instruments are not specific to case management settings. Other instruments, like the Home Care Satisfaction Measure: Case Management Service (HCSM-CM13; Geron et al., 2000), are designed specifically for case management settings. The primary limitation with this type of instrument, however, is that it only produces global satisfaction scores. Without collecting the data longitudinally or comparing the data with that from other agencies, service providers often have difficulty interpreting the results.

To overcome these limitations, we follow the four major steps described earlier to develop an interviewer-administered client satisfaction measure for this case management service setting. We decided against a self-administered survey because of the population the agency serves. Many of the clients had very

little education and therefore have minimal literacy skills. In addition, a number of clients have visual impairments. Although our intention is to illustrate the four major steps to develop an interviewer-administered survey questionnaire, we also provide sample wording for a self-administered survey questionnaire (in Appendix C) for those who are interested. Our steps in questionnaire development include the following:

1. From a review of the literature on elderly case management services (e.g., Geron et al., 2000; Robinson, 2000; White, 1986) and discussions with service providers and clients, five major aspects of service provision are identified: assessment of clients' needs, plan of care development, case manager's knowledge regarding available services, case manager's ability to get services for clients, and case manager's availability.
2. A Likert-type satisfaction rating item for each of the five major service aspects is constructed (see Appendix A, S1–S5).
3. A Likert-type importance rating item for each of the five major service aspects is constructed (see Appendix A, I1–I5).
4. We construct a two-step procedure to obtain the importance hierarchy. Interviewers are instructed to (a) rank the importance based on the results from the importance rating in step 3, and then (b) ask the respondent to rank order those items for which he or she gave the same ratings (see Appendix B).

THEORETICAL PERSPECTIVE

The theoretical perspective underlying our proposed approach is an extension of the first author's earlier work on life satisfaction (Hsieh, 2003, 2004). There are a number of similarities between client satisfaction and life satisfaction regarding measurement and conceptualization. First, client satisfaction, like life satisfaction, involves subjective evaluations of objective conditions (e.g., Reid & Gundlach, 1983). Second, client satisfaction is a multidimensional construct (Chou et al., 2001; Ruggeri & Greenfield, 1995), and so is life satisfaction (e.g., Cummins, 1995, 1996; Diener, 1984). Third, client satisfaction, like life satisfaction, can be measured by either a single-item global satisfaction or a composite of satisfactions with various domains (e.g., Nguyen et al., 1983). Given these similarities, the theoretical perspective that has been used

to address the measurement and conceptualization issues in life satisfaction literature can serve as a foundation to study client satisfaction.

Reflective Approach Versus Formative Approach

Besides using single-item global satisfaction measures, researchers who construct multi-item measurements of life satisfaction generally follow either a “top-down” or a “bottom-up” approach (Diener, 1984). The top-down approach assumes that global life satisfaction is a predispositional trait or personality that influences one's evaluation of satisfaction in multiple domains, whereas the bottom-up approach maintains that global life satisfaction can be regarded as the composite of satisfaction in various domains (Diener, 1984). Similar to the case of client satisfaction, the multidimensional nature of life satisfaction limits the utility of single-item global life satisfaction measures, since an individual can be satisfied with his or her overall life but dissatisfied with certain aspects of life (Cummins, 1996). In fact, the use of top-down and bottom-up approaches to measuring life satisfaction coincides with the use of reflective indicators (or effect variables) versus formative indicators (or causal variables) in measurement in general (e.g., Bollen & Lennox, 1991; Chin & Newsted, 1999; Cohen, Cohen, Teresi, Marchi, & Velez, 1990; Fayers & Hand, 1997; Fayers & Machin, 2000). In a formative indicators model, indicators are viewed as determining or causing the latent construct, which is similar to the bottom-up approach. In a reflective indicators model, indicators are viewed as determined by the latent construct, which is similar to a top-down approach (Bollen & Lennox, 1991; Chin & Newsted, 1999; Cohen et al., 1991).

Since the landmark study by Campbell, Converse, and Rogers (1976), it has become common to measure global life satisfaction by simply summing across satisfactions in various discrete life domains, such as health, finance, and friendships (e.g., Beatty & Tuch, 1997; Mookherjee, 1992). This so-called bottom-up approach (Diener, 1984) to measuring global life satisfaction can be applied to the measurement of global client satisfaction. That is, Campbell et al.'s (1976) conceptual model of life satisfaction can be adapted for client satisfaction (Figure 95.1). As portrayed in Figure 95.1, global client satisfaction is determined by satisfactions with various service aspects.

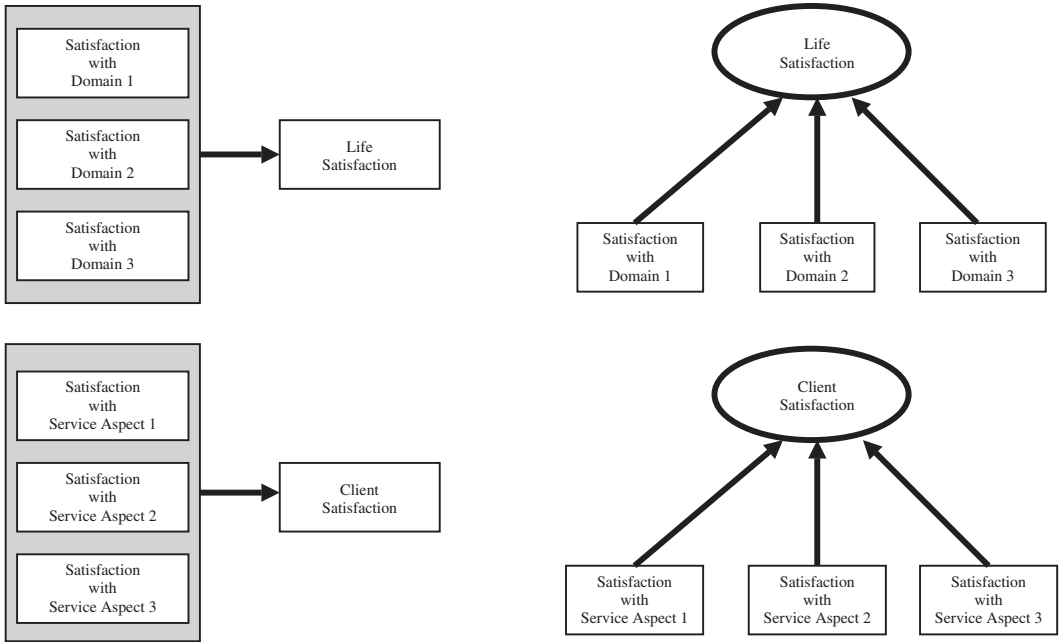

FIGURE 95.1 Parallel between Life Satisfaction and Client Satisfaction.

Weighting by Perceived Importance of Various Service Aspects

As many have observed (e.g., Cummins, 1995, 1996; Diener, Lucas, Oishi, & Suh, 2002; Diener, Napa Scollon, Oishi, Dzokoto, & Suh, 2000; Hsieh, 2003; Oishi & Diener, 2001), the correlation between the global life satisfaction outcomes produced by the different approaches (top-down vs. bottom-up) is usually not very high. A factor that might contribute to the low correlation is the possibility that individual satisfaction items do not carry equal weights (Hsieh, 2003, 2004). That is, simply summing satisfaction scores across various items, without considering the potential unequal weights of these items, may not provide a good indication of an individual’s global satisfaction. In fact, researchers (e.g., Campbell et al., 1976; Inglehart, 1978) have long noted the possibility of unequally weighted individual life domains in the overall picture of life satisfaction. Despite different terms used to discuss this (e.g., domain importance by Campbell et al. in 1976; value priority by Inglehart in 1978; and psychological centrality by Ryff and Essex in 1992), researchers generally agree that global life satisfaction is a weighted composite, not a simple sum, of domain satisfactions, and the relative importance of each discrete life domain should act as a weighting mechanism.

Based on the findings in life satisfaction literature, it is very likely that simply summing client satisfaction scores across various service aspects may not be a good indication of a client’s global satisfaction. Instead, client satisfaction measures can incorporate clients’ perceived importance of service aspects as a weighting mechanism, linking satisfaction with various service aspects to global satisfaction.

METHODOLOGICAL ISSUES

As shown in the conceptual model (see Figure 95.1), we define and conceptualize client satisfaction as the client’s sense of service quality that stems from satisfaction or dissatisfaction with the service aspects that are important to him or her.

Validity

Although our approach to measuring client satisfaction appears to have face validity, we recommend that any new measures using this approach still be cross-validated with existing measures to obtain concurrent validity. This can be done by using a correlation analysis between total scores (see later explanation of

scoring for calculating total scores) for the new measure and those of existing measures. Using the example we provided, we suggest the new case management client satisfaction measure be validated with both generic client satisfaction measures, such as the CSQ-8 (Nguyen et al., 1983), and contextually specific measures, such as the HCSCM-CM13 (Geron et al., 2000). In addition, a single-item global satisfaction measure can be included (see Appendix A, S6) as an existing measure to serve the purpose of cross-validation (see Hsieh, 2003, for an example).

Reliability

It should be noted that given the formative indicators model this proposed client satisfaction measure is based on, applying conventional guidelines for measurement construction may not be adequate. As Bollen and Lennox (1991) suggested, the concept of reliability based on internal consistency is only appropriate for a reflective indicators model. In other words, for a formative indicators model, using internal consistency as an indication of reliability is problematic (Bollen & Lennox, 1991). Therefore, reliability of the measures constructed using our proposed approach should be assessed through the test-retest method.

Scoring

Because we propose to construct measures using Likert-type rating items, it is unlikely that ratio level measurement data can be obtained. It is therefore difficult to justify why the assigned values of a 7-point scale should take 1 to 7 and not 2 to 8 or some other range of values. In fact, the issue of scoring is further confounded by the lack of conceptual or theoretical development regarding how importance should be incorporated into client satisfaction measures. It seems reasonable to assume that more important service aspects should weigh more. Without guidance from any conceptual framework, however, it is not clear if satisfaction with a service aspect that is “not important at all” should carry zero weight in one’s global satisfaction, nor is it clear how much more weight should be given for each 1-point increase in a 5-point (or 7-point) importance rating scale.

The issue of weighting also exists in life satisfaction literature (Hsieh, 2004). A common way of obtaining weighted score is to use multiplicative scores:

multiplying satisfaction and importance ratings (e.g., Ferrans & Powers, 1985). As Trauer and Mackinnon (2001) pointed out, multiplicative scores can be problematic. The primary drawback of multiplicative scores is the difficulty in interpreting the meaning of the score, given that the same score can be obtained by the combination of a high satisfaction rating with a low importance rating or a low satisfaction rating with a high importance rating (Trauer & Mackinnon, 2001). To overcome the conceptual ambiguity produced by multiplicative scores, we suggest the use of the following general formula to produce weighted global client satisfaction scores (see Hsieh, 2003, 2004):

$$\frac{\sum(S_i \times I_i)}{\sum I_i}$$

where S_i is the satisfaction score for service aspect i , and I_i is the importance score for service aspect i . In other words, an individual’s weighted global satisfaction score is calculated by summing the products of the satisfaction score and the importance score across all service aspects and then dividing by the sum of importance scores.

As pointed out by Trauer and Mackinnon (2001), multiplying two scores (satisfaction and importance) that do not have ratio level measurement properties is problematic. As a beginning step to deal with the issue of measurement properties, sensitivity analysis can be employed to check the dependence of the results on the score choices made in weighting schemes (e.g., Agresti & Finlay, 1997). Following Hsieh’s earlier work on life satisfaction (2003), a few sensible score choices can be employed to see if any pattern emerges from the results. In addition to assuming that the weight of importance increases or decreases as a linear function, weighting mechanisms can be constructed on the assumption that the weight follows nonlinear functions, taking into account the nature of an ordinal scale (see Hsieh, 2003, for a more detailed discussion).

Unlike multiplicative scores, which may be difficult to interpret, the score obtained by our proposed weighting scheme clearly indicates an individual’s weighted (by importance of various service aspects) satisfactions. A hypothetical example can be used to illustrate the case. An instrument obtains satisfaction scores and importance scores for two service aspects. Person A has a low satisfaction score of 1 and a high importance score of 5 for one service aspect and has a low satisfaction score of 2 and high importance score of 5 for the other aspect. To calculate person A’s multiplicative score, which is 15, we multiply the satisfac-

tion score by the importance score for each service aspect ($1 \times 5 = 5$, and $2 \times 5 = 10$) and then take the sum of these products ($5 + 10 = 15$). It will be impossible to distinguish person A from person B, who has a high satisfaction score of 5 for both service aspects and a low importance score of 1 for one service aspect and a low importance score of 2 for the other aspect, if a multiplicative score approach is used, since person B's multiplicative score will be 15 ($5 \times 1 + 5 \times 2 = 15$) as well. However, there will be a clear difference in the scores for person A and for person B using the weighting formula proposed here. To calculate each person's weighted global satisfaction score, the multiplicative score (15) is divided by the sum of the importance scores, resulting in a score of 1.5 ($15/10$) for person A and 5 ($15/3$) for person B. Table 95.1 shows these score values.

Another issue is the way importance should be measured. A common approach to measuring domain importance in life satisfaction literature is to ask respondents to rate the importance of each individual domain (e.g., Campbell et al., 1976; Ferrans & Powers, 1985). This approach is limited because it cannot provide direct comparisons across domains. For example, if both domains receive the same importance rating, can we conclude that they have equal importance? Building on the first author's earlier work (Hsieh, 2003), different service aspects can be ranked by asking the respondents to place these major service aspects into a hierarchy, based on their perceived importance of the service aspects. Using ranking is advantageous for two reasons. First, it not only shows the importance of each service aspect but also provides direct comparisons of importance across service aspects. Second, findings in life satisfaction literature

suggest that the weighted composite (using ranking) of various satisfaction items is a better indicator of global life satisfaction than the simple sum of satisfaction items (Hsieh, 2003).

Proposed Scoring Method

To illustrate how to obtain a client's weighted satisfaction score, we again use the case management example. Assume a client gives respective satisfaction ratings of 3, 5, 5, 7, and 6 for the five satisfaction items in Appendix A (S1–S5); the client's importance hierarchy corresponding to the items (from first to last) in Appendix B is 3, 5, 4, 1, and 2. We first reverse the rank number of the importance hierarchy to give more important items higher numbers (weights). Thus, the most important item (ranked number 1) will become 5, and what ranked number 2 will become 4, and so on. Next, we follow the scoring formula to obtain the weighted global satisfaction score. For each service aspect, the satisfaction score is multiplied by the importance score, and these products are summed ($3 \times 3 + 5 \times 1 + 5 \times 2 + 7 \times 5 + 6 \times 4 = 83$). We then divide this number (83) by the sum of the importance rankings ($3 + 1 + 2 + 5 + 4 = 15$), resulting in a weighted global satisfaction score of 5.53. We recommend the use of this straightforward weighting method. For those who are interested in other types of scoring, see Hsieh (2003) for a discussion.

CONCLUSION

The method of measuring client satisfaction proposed here is designed to overcome the limitations of past client satisfaction studies. By asking the clients to rate their satisfaction with all major service aspects within a specific care or service setting, our approach addresses the issues of contextual relevance and the multidimensional nature of client satisfaction. In addition, this measurement approach addresses the possibility of unequal weights among the different service aspects by incorporating perceived importance into the measurement of client satisfaction. That is, the measure takes into account the potential interpersonal differences in perceived importance of various service elements. It is, therefore, a true client-centered satisfaction measure. Our example of this client-centered method of measuring client satisfaction can be easily adapted by other case management service agencies. Gerontological social workers in other prac-

TABLE 95.1 Score Values for Two-Person Hypothetical Example

	<i>Person A</i>	<i>Person B</i>
Domain 1 score		
Satisfaction	1	5
Importance	5	1
Domain 2 score		
Satisfaction	2	5
Importance	5	2
Weighted global score		
Multiplicative weighting	15	15
Proposed weighting	1.5	5

tice settings can also follow the steps outlined in this chapter to develop client satisfaction measures that can pinpoint the exact sources of clients' satisfaction and dissatisfaction. Service providers can continue to maintain the service elements with high client satisfaction scores and make improvements on the sources of dissatisfaction. In addition, because most gerontological social workers face the issue of limited resources, this approach can help them set priorities for service improvement based on clients' perceived importance and ultimately benefit their clients.

APPENDIX 95.A

Satisfaction Items

The following questions ask how satisfied you are with different services provided by the Central West Case Management. Please use a number from 1 to 7 to indicate your satisfaction where 7 means "Completely satisfied" and 1 means "Completely dissatisfied." If you are neither completely satisfied nor completely dissatisfied, you would put yourself somewhere from 2 to 6; for example, 4 means neutral, or just as satisfied as dissatisfied.

- S1. How satisfied are you with your case manager's assessment of your needs? _____
- S2. How satisfied are you with the plan of care your case manager developed? _____
- S3. How satisfied are you with your case manager's knowledge regarding the services that are available? _____
- S4. How satisfied are you with your case manager's ability to get services for you? _____
- S5. How satisfied are you with the availability of your case manager? _____
- S6. All together, how satisfied are you with the services you receive from the Central West Case Management? _____

Importance Items

Some people may feel some areas of the case management services are more important than others. What areas of case management services do you consider extremely important or not at all important to you? Please use a number to indicate the importance of the services from 1 through 5, where 5 means "Extremely important" and 1 means "Not at all important."

- 1. Case manager's assessment of your needs _____
- 2. Your plan of care _____
- 3. Case manager's knowledge regarding available services _____
- 4. Case manager's ability to get services for you _____
- 5. Availability of your case manager _____

APPENDIX 95.B

Constructing the Importance Hierarchy

Directions to interviewer:

Based on responses to the importance items, please rank the five areas of case management services from 1 (the most important) to 5 (the least important) below. For items with same importance ratings, ask the respondent to rank order their importance. Use the same ranking number for any areas the respondent believes are equally important.

- _____ Case manager's assessment of your needs
- _____ Your plan of care
- _____ Case manager's knowledge regarding available services
- _____ Case manager's ability to get services for you
- _____ Availability of your case manager

APPENDIX 95.C

Constructing the Importance Hierarchy

(Sample wording for self-administered survey questionnaire)

Based on importance, please rank the following five areas of case management services from 1 (the most important) to 5 (the least important). Use the same number for any areas you believe are equally important.

- _____ Case manager's assessment of your needs
- _____ Your plan of care
- _____ Case manager's knowledge regarding available services
- _____ Case manager's ability to get services for you
- _____ Availability of your case manager

All societies, political or academic, must choose; these choices can be good, or bad. The worst choice may be looking for answers before there is consensus, or at least a debate, on what the real questions should be. (Munger, 2000, p. 1)

In advocating for an integrated social science research agenda, political scientist Michael Munger observes that academic research has become diffuse, and the enterprise of accumulating social science knowledge unfocused. Current scholarship, he argues, is busily coming up with answers, yet most have lost sight of the questions. Increasingly, research agendas built on some form of consensus provide both a vehicle and a focus for taming the unruly process of determining important questions and establishing guidelines for the development, dissemination, and use of new knowledge about these questions. The National Institutes of Health, for example, routinely use mechanisms such as expert consensus conferences and lay consumer panels to inform the development of research agendas and to encourage and legitimate the appropriation of resources to act on established priorities.

The National Institute of Mental Health (NIMH) Task Force on Social Work Research (1991) provided a critical impetus for refining the focus of social work research. By the mid-1990s, research agendas began to appear, for example, in social welfare (Coulton, 1996), health care (Ell, 1996; Jansson & Dodd, 1998), and social work organizations (Auslander, 1996). As chair of the NIMH Task Force, David Austin (1998) spurred these efforts in calling for a strategic approach to social work research that is based on specific domains of expertise. He recommended that each domain assess the state of its own knowledge, identify critical knowledge gaps, and establish research needs and priorities to address these gaps.

Drawing on multiple data sources and using several critical indicators, several years ago we initiated an assessment of the current status of social work research in the field of aging. In the next section, we highlight findings from that review. In addition, findings from a national Delphi project we conducted to further articulate research priorities for gerontological social work are discussed. Finally, in light of this review of social work research in aging to date and findings from the Delphi study, we consider future research directions for the field of gerontological social work.

Current Status of Social Work Research in Aging and Future Directions

96

CURRENT STATUS OF SOCIAL WORK RESEARCH IN AGING

In an effort to assess the current status of gerontological social work research (Morrow-Howell & Burnette, 2001), we used reports from professional associations, that is, the Association for Gerontology Education in Social Work (AGE-SW), the Council on Social Work Education (CSWE); published reports on research (Austin, 1998); public and private funding databases; and our own surveys of published literature to explore four specific questions: To what extent are social work faculty members identifying research interests in gerontology? To what extent are social work researchers contributing to the multidisciplinary knowledge base of gerontology? What topics are gerontological social workers investigating? To what extent are social workers being funded for their research?

Based on membership in AGE-SW and the Strengthening Aging and Gerontology Education for Social Work (SAGE-SW) interest list, we estimated that 296 social work faculty nationwide (4% of all social work faculty enumerated by CSWE) have a significant interest in aging. It is important to note that not all these individuals are actively engaged in research. Compared with faculty interest in other social work domains, gerontology ranked fourth as a domain of current or future research interest, after children, mental health, and health, respectively (Austin, 1998). These data suggest that a relatively small proportion of the nation's social work faculty is interested in gerontology, particularly as compared with interest in other substantive domains. Necessary first steps in advancing the field are thus to increase the number of social work faculty interested in aging, and then to increase the subset of these faculty who actively engage in research.

We next assessed social workers' contributions as lead authors or coauthors of articles published in the *Gerontologist* from 1995 through 2001. Social workers were lead authors of 12% ($n = 50$) of the 415 articles reviewed and coauthors of another 8% ($n = 38$). Twenty percent of articles published in the *Gerontologist* during this period thus involved social work. We interpreted this as a moderately successful achievement, although it is certainly underrepresentative of the level of involvement of social workers in gerontological practice.

In our review of topics of social work–authored articles in the *Gerontologist*, the largest category of interest was family caregiving, constituting nearly one

third of all articles. Fourteen percent of articles focused on ethnicity, addressing such topics as ethnicity and disability, ethnic elders' participation in research protocols and Alzheimer's disease centers, and ethnicity as it relates to grandparenting, postacute care, depressive symptoms, and issues of morbidity and comorbidity. Another 12% of articles addressed formal service use, comparing users and nonusers and examining high users, extended users, and formal and informal care mixes.

In a parallel review of the *Journal of Gerontological Social Work* during the same 5-year period, about 17% of articles focused on caregiving and about 10% addressed ethnicity. Most articles on ethnicity described the service needs of subgroups of ethnic elders, and a few focused on service use and ethnic-sensitive practice. Another 7% of articles examined international aging and addressed issues in countries such as China, Hong Kong, Israel, Sweden, Britain, Canada, Japan, and Puerto Rico. About one quarter of articles (6% each) addressed four broad topics—adjustment to new settings or situations; volunteerism and work; professional gerontological social work training; and changing families. About 5% focused on development and testing of psychosocial interventions, including strengths-based approaches, solution-focused treatment for problem behaviors, a personal advocacy model, and a model of community-based mental health services. Other topics that received limited attention were formal service use and delivery, income and insurance, elder maltreatment, end-of-life care, mental health, and interdisciplinary practice. It is important to note here that social workers may be publishing on these topics in interdisciplinary or more specialized journals.

Our review of publications in these two major journals over a 5-year period suggests that social work researchers are indeed investigating a broad range of critical issues in our field. However, nearly 40% of the articles reviewed in the *Gerontologist* and 30% of those in the *Journal of Gerontological Social Work* focused on family caregiving or ethnic diversity. Although these are core topics for professional social work, other important topics appeared to be neglected. There was very little attention, for example, to developing and testing interventions that could directly inform the development of guidelines for practice and policy.

Finally, we sought information on the number of gerontological social worker researchers supported by external funding. Reliable estimates of these counts are not readily available, so we offer tentative findings.

We found that social workers are grossly underrepresented among funded investigators funded by the National Institute on Aging (NIA). Based on a review of several key private funding agencies, we concluded that social workers fare better with foundation funding but are still underrepresented.

To summarize the data we examined, social work researchers in aging appear to have established a small national presence in social work schools, but the extent to which they are conducting research is unclear. Social work researchers are contributing to the multidisciplinary knowledge base in aging, as indicated by manuscripts in the *Gerontologist*, but contributions to this literature are incommensurate with involvement in interdisciplinary practice. And, although gerontological social workers are investigating topics that are important to their field, attention to these topics varies, and a number of critical areas remain underexamined. Finally, social workers barely have a foothold in federally funded research in aging but seem to be faring better with some, but not all, private foundations.

We have thus made progress on some fronts, but we still have far to go. The absence of a disciplined, integrated research agenda has impeded our work, and continued advancement will depend on decisions about substantive priorities in social work and in gerontology, and on the multiple, mutable contexts in which social science research occurs. We will return to issues of context momentarily. With respect to substantive priorities, gerontological social workers must identify the most pressing gaps in basic and applied knowledge on older adults, their families, and communities. They should take an independent lead in developing social work research agendas that can be used to guide rigorous, systematic investigations on these topics. In addition, they should assume a key collaborative role in developing and participating in interdisciplinary agendas.

IDENTIFYING SUBSTANTIVE TOPICS: HIGHLIGHTS FROM A NATIONAL DELPHI STUDY

Based on our assessment of the status of social work research in aging, we initiated an effort to identify key substantive priorities for gerontological social work research through a national Delphi study (see Adler & Ziglio, 1996, for a review of Delphi methodology) of two expert gerontological panels—one of 46 academic social work researchers (Burnette, Morrow,

Howell, & Chen, 2003) and another of 52 social work practitioners (Morrow-Howell, Burnette, & Chen, under review). Each panel completed three successive questionnaires that were designed to ultimately delimit a set of high-priority, high-consensus research topics for the field.

To be included, a topic had to achieve a threshold of priority and consensus ratings (see Burnette et al., 2003, for details on calculations of these ratings). Coincidentally, each panel identified 16 top research priorities. Table 96.1 presents these data, with correspondent topics listed opposite each other to facilitate comparison. In some cases, topics that are conceptually similar, though not identical, are grouped under the same broad rubric. There is considerable overlap in substantive topics identified as priorities by the researcher and practitioner panels, but each panel also identified unique topics.

The academic researcher panel's top priority was developing and testing psychosocial interventions across specific populations and conditions, and they identified three other priority topics on intervention. The practitioner panel identified three of the same intervention topics as priorities: family interventions, ethnic-sensitive interventions, and management of dementia. The two panels also agreed on the need for research on workforce issues for an aging society. The researchers called for knowledge development on recruitment and retention of professionals more generally, whereas practitioners saw gerontological social work education as a top priority. Both panels also identified family caregiving, mental health problems, and transitions in living arrangements as high-priority areas for knowledge development.

Differences in these two stakeholder groups are also noteworthy. The researcher panel endorsed the need for research on interventions and on the service delivery system with greater specificity and breadth. They endorsed four topics related to use, coordination, and quality of services, plus a separate topic on services to family caregivers. Practitioners named only one topic on service delivery—outreach and service delivery to underserved populations. Other priorities unique to the researcher panel included psychosocial outcome measures, housing and living arrangements, and chronic physical health conditions and health-related quality of life.

The practitioner panel endorsed seven unique topics. Two topics, income security and long-term care policy, concern social policy, an area in which social work has yet to establish itself (Morrow-

TABLE 96.1 Comparison of Priorities of Researcher and Practitioner Panels

<i>Researcher panel</i>	<i>Practitioner panel</i>
Intervention research	
1. Developing and testing psychosocial interventions across populations and conditions	1. Family interventions
2. Developing and testing ethnic-sensitive assessment and interventions	2. Ethnic-sensitive interventions
3. Developing psychosocial outcome measures	
4. Developing/testing psychosocial and ecological interventions for cognitive and mental disorders	3. Management of dementia
Housing and living arrangements	
5. Maximizing housing/living arrangement options for aging in place	
6. Transitions and adjustments across care settings and environments	4. Transitions in living environments
Service delivery	
7. Coordination and integration of health, mental health, and social service systems	
8. Utilization and barriers to health, mental health, and social services	
9. Interface between informal and formal care	
10. Service use by ethnic elders	5. Outreach and service planning/delivery for underserved elders
Detection and assessment	
11. Determining needs of ethnically diverse elders	
Family caregiving	
12. Effective services to family caregivers	
13. Understanding specific caregiver population	6. Family caregiving, including grandparent caregiving and caregiving to developmentally disabled
Health/mental health	
14. Chronic illness, disability, and rehabilitation: Quality of life and psychosocial well-being	7. Quality of life in long-term care
15. Detection, assessment, and treatment of late-life depression	8. Depression assessment and treatment
	9. Mental health assessment and treatment
Workforce	
16. Recruitment and education of professional workforce for an aging population	10. Gerontology education in social work
Social policy	
	11. Income security
	12. Long-term care policy
Capacity building	
	13. Self-determination, decision making, and autonomy
	14. Empowerment strategies
	15. Planning for later life: Individuals and families
	16. Normal and successful aging

Howell & Burnette, 2001). Four other unique topics, which we term *capacity building*, concern issues practitioners typically encounter in their daily work: ethical issues of self-determination, decision making, and autonomy; client empowerment strategies; long-range planning with individuals and families for later life; and issues of normal and successful aging.

The research priorities identified by these expert panelists represent critical knowledge needs for social work in aging. Moreover, they overlap and complement the current research agendas of the NIA Strategic Plan (2001–2005) and the National Research Council's (NRC) report on the NIH Committee on Future Directions for Behavioral and Social Science Research (Singer & Ryff, 2001; see Burnette et al., 2003, for a discussion of this overlap). As such, these priorities can serve as a useful guide for the development and prioritization of social work and interdisciplinary research to improve professional practices and public policies that affect the well-being of older adults.

Finally, after comparing topics identified by the two expert panels and establishing their fit with major national research agendas, we suggest that these priorities be further organized in a tighter framework. We propose a combination of the four core substantive topics (housing and transitions in living arrangements; family caregiving; health and mental health; and workforce for an aging society) with four cross-cutting themes (intervention research, social policy, service delivery, and capacity building). A first step in a refined agenda would then be to review and summarize the current state of knowledge on each of 16 topics in a hypothetical four-by-four grid. Such reviews would help highlight critical knowledge gaps, inform the development of key research questions, and eventually lead to a body of evidence-based knowledge and guidelines for gerontological social work practice and policy.

CONTEXTS OF SOCIAL WORK RESEARCH IN AGING

The process of assessing the state of research, identifying substantive priorities, and organizing topics in a theoretically meaningful and practically useful framework is necessary but not sufficient to ensure successful implementation of a research agenda. Research priorities are fundamentally context-dependent, meaning that social, political, and economic

forces constantly influence preferences, options, and outcomes. To build and sustain a viable infrastructure for a program of research, gerontological social workers must garner sufficient professional and public awareness, create new and enhance existing opportunities for educating and cultivating potential funding sources, and credibly conduct, disseminate, and apply our knowledge and skills within and beyond social work.

Increasing Awareness and Support

Gerontological social workers must work actively to increase the level of awareness and understanding among colleagues in social work and other disciplines and the general public about the social, health, and economic needs of older adults and aging societies. With respect to gerontological associations and interest groups, who already understand the needs of our aging society, educational efforts should focus on the social work profession's vital role in meeting those needs. Within and beyond these organizations, gerontological social workers must educate widely about the role of social work research in addressing these needs. They should collaborate with professional organizations whose mission is to advance social work research to effectively convey this message to public media and to advocate for funding for basic and applied research on high-priority interventions, services, and policies.

Gerontological social workers currently have several strong venues through which to organize and promote their research. Founded in 1993, the Institute for the Advancement of Social Work Research (IASWR) aims

to advance the scientific knowledge base of social work practice by enhancing the research capacity of the profession; to promote use of research to improve practice, program development and policy; and to strengthen the voice of the profession in public education and public policy determinations by ensuring that social work is represented within the national scientific community. (Institute for the Advancement of Social Work Research [IASWR], 2001, at <http://www.iaswresearch.org>)

Gerontologists are highly visible among IASWR leadership. In 2000, the organization sponsored an invitational meeting with NIA staff to discuss strategies to

forge stronger links with social work researchers. The IASWR listserv also regularly distributes information on aging-related conferences and funding opportunities to its membership.

Other important resources are the Society for Social Work and Research (SSWR) and the Association for Gerontological Education in Social Work (AGE-SW). SSWR, a strong force in evidence-based practice, was established in 1994 to create a network for social workers involved in research, encourage social workers to engage in research, and advocate for research funding and research training programs. Gerontological social workers are also prominent among SSWR membership, leadership, and conference participants. Plans to establish a special aging interest group within SSWR are under discussion.

AGE-SW has existed in a variety of forms for several decades, and its membership has grown steadily in recent years. The group sponsors a number of research activities, including a gerontology symposium at the CSWE annual program meeting, initiated in the mid-1990s, and a mentoring program to assist junior faculty and doctoral students with research and teaching in aging. AGE-SW also has a long-standing research committee, but its organization and activities have vacillated over the years. Rejuvenation of this committee could provide a useful forum for advancing a unified gerontological social work research agenda.

Developing and Leveraging Funding Sources

The John A. Hartford Foundation's Faculty Scholars and Doctoral Fellows programs offer an unprecedented opportunity to increase the number and reach of geriatric social work researchers (Berkman, Silverstone, Simmons, Volland, & Howe, 2000; Lubben & Harootyan, 2002). To ensure that scholars supported by these initiatives realize their long-term potential, parallel investments in institutional infrastructure for social work research in aging are needed. As we have noted (Morrow-Howell & Burnette, 2001), such programs might focus exclusively on aging, or they could build gerontological research into existing programs and structures. The latter approach might include nesting aging research within existing program initiatives such as the Social Work Research Development Centers funded by the NIMH during the 1990s, those currently funded by the National Institute on Drug

Abuse, and other existing centers and projects. This strategy could help maximize resources, increase awareness of aging issues and the number of social work faculty involved in aging research, and promote knowledge development on aging across substantive areas within the profession.

In addition to building on existing institutional resources, the long-range impact of current initiatives that aim to focus and advance the field will depend on social workers' ability to successfully develop new and strengthen existing links to federal, state, and local funding agencies, philanthropic foundations, and other internal resources of academic institutions. As noted, social work ties with the NIA have been tenuous. Improving this linkage could have a major impact on research funding, interdisciplinary collaboration, and training and career development for social work researchers. The recent NIA-funded Institute on Aging and Social Work (Berkman & Mehrotra, 2003) is an example of what is possible. Efforts to strengthen ties with the NIMH should also be stepped up, particularly given the surgeon general's report on mental health (U.S. Department of Health and Human Services, 1999) and the institute's recent initiative to expand its research portfolio relating to aging (National Institute of Mental Health, 2001).

Also at the federal level, we would do well to explore opportunities for collaborative research with the Office of the Assistant Secretary for Aging, Administration on Aging, Center for Medicare and Medicaid Services, Social Security Administration, Agency for Healthcare Research and Quality, Department of Veterans Affairs, and Substance Abuse and Mental Health Services Administration (see Austin, 1998, p. 36; Council on Social Work Education [CSWE], 2001, p. 5).

Private monies also offer opportunities for expanding and enhancing gerontological social work research. An example is the recently established Institute for Geriatric Social Work (IGSW), funded by Atlantic Philanthropies and located at Boston University School of Social Work (Geron, 2002). IGSW is dedicated to improving the workforce of social workers to serve our aging society by offering continuing education to BSW and MSW practitioners. IGSW recognizes the need to document the effectiveness of social work interventions to support the expansion of reimbursement options for social work practitioners. Thus, a priority of the institute is promoting intervention research that builds an evidence base for geriatric social work practice.

FUTURE DIRECTIONS FOR SOCIAL WORK RESEARCH IN AGING

Nearly a decade ago, Ewalt (1996) noted that an ongoing decline in federal responsibility for social work-related problems has heightened the imperative for the profession to proactively establish directions for its practice, policy, and research agendas. The urgency of this mandate continues to grow, even as the aging of U.S. and other world populations becomes a more visible social and economic force in the 21st century. This demographic shift alone should ensure a topmost place for aging in any social research agenda. But gerontological social workers must use their collective experience, knowledge, and influence to systematically define and advance their own priorities. We conclude this chapter with a brief discussion of key areas of inquiry for social work researchers in aging and some of the changing contexts in which that research will likely take place.

Establishing a research agenda may help focus gerontological social work researchers' attention on important neglected areas of the profession. Three particularly critical areas of deficiency are social policy, psychosocial interventions and outcomes, and services research. Our review of social work-authored publications showed scant attention to policy development or policy analysis. Social workers' firsthand experience with the impact of social policy on older clients and their families should enable social workers to play a major role in the formulation, implementation, and evaluation of policy (Fahey, 1996), yet a seeming lack of interest and/or expertise has largely excluded them from public policy dialogue. Rigorous investigations of all phases of public policy processes are needed, and social work researchers should bring this knowledge to public debates through skillfully planned, coordinated dissemination activities.

There is also a clear need for increased attention to developing psychosocial outcomes measures, testing psychosocial interventions, and improving services at all levels of practice. These deficiencies are particularly troubling given the increased emphasis on research that directly informs practice. As Austin (1998) notes, "The most important issue for the immediate future is to bring the practice effectiveness concerns of social work practitioners together with the resources represented by social work researchers" (p. 27). Likewise, the SAGE-SW blueprint for improving quality of life for older adults and their families recommends two foci for gerontological social work research—increased opportunities and support for research and increased em-

phasis on practice-based, measurable research (CSWE, 2001, pp. 4–5). This report further calls for researchers to develop strategic outreach and incentives to faculty and field supervisors to conduct practice-based research and to assist in developing practice protocols.

Finally, with respect to the contexts of future research, there is a growing appreciation of the complexities of generating and applying knowledge in real-world settings. Social work's commitment to intervention and services research, including evidence-based practice, practice guidelines, and service effectiveness, will doubtless continue (Proctor, 2002; Rosen & Proctor, 2003). These lines of inquiry will require the development of measurable outcomes—a process that will entail concerted efforts over time (see Kane, 2003). Meanwhile, novel priorities will arise, along with new contingences and resources, including more sophisticated methodologies, innovative technologies, changing values, and evolving political and economic climates.

It will be important to maintain sufficient focus while remaining vigilant to developing social, economic, and political contexts of social work research. Research agendas will need to be reviewed and revised periodically, and an effective balance preserved between long-range investments in high-priority areas with shorter-range and evolving issues. The latter tend to be initially localized and typically receive widespread attention only after a period of accumulating evidence. Social work researchers should thus remain in close touch with practitioners, whose work provides a peerless window into the world of newly developing issues. Similarly, the research process should be informed by the views of a variety of stakeholders. In addition to practitioners, the perspectives and interests of policymakers, consumers, and social work researchers in substantive areas such as health, mental health, disabilities, and families will also be valuable.

Interdisciplinary approaches to knowledge development and dissemination are also on the rise. The collaboration of biological and environmental scientists and social scientists on issues of aging, for example, permits the expansion of research questions and findings beyond a single social, biological, or physical issue. Research that informs practice guidelines and social policies may thus need to address a wider range of aging experiences and incorporate multiple sources of knowledge within and beyond conventional disciplinary and geographic boundaries. Collaborations with researchers in other domains of social work, other disciplines, and various stakeholder groups should enrich the experience, outcomes, and applica-

tion of research about and with older adults. Important first steps will be to determine which topics are appropriate, which disciplines are key, which stakeholders are essential, and which funding sources are available.

It is also important to note that neither consensus nor resources guarantee the effective implementation of even the most carefully articulated research agenda. Focus and commitment are also essential. To maximize our ability to effectively address the psychosocial needs of older people and aging societies, social work must increase the production and dissemination of scientifically sound practice- and policy-relevant research. More highly skilled gerontological social work researchers will be needed to accomplish this goal, and their investigations of high-priority topics will require adequate short-term and long-range support. We are well positioned to create and take advantage of existing opportunities to assume a true leadership role in research on aging—to make unique, significant contributions to national research agendas, interdisciplinary research teams, and the profession's own knowledge base.

Social Work Education and Careers in Aging

This page intentionally left blank

OVERVIEW

The four chapters in this closing section, *Social Work Education and Careers in Aging*, signal the dramatic progress in gerontological social work education that has occurred since the first stage of the gerontological social work movement (1965–1994), which JoAnn Damron-Rodriguez describes in her chapter. In the second stage (1995–2004), highly visible national leadership and external support replaced concerns about student disinterest and faculty resistance to gerontological social work; for example, the Bureau of Health Professions 1995 recommendations for geriatric social work education, the Geriatric Social Work Initiative funded by the John A. Hartford Foundation, the National Association of Deans and Directors 2002 report, *Promoting Social Work for All Ages*, and the annual National Conference for Gerontological Social Work in conjunction with the Council on Social Work Education's (CSWE) annual program meeting all were initiated during the second stage. Building on these two stages, gerontological social work education appears to be moving into a third stage, illustrated in part by these four chapters.

As identified by James R. Reinardy and Sara Zoff and Nancy L. Wilson, greater recognition now exists that organizational and curricular changes are needed to embed and sustain gerontological content within social work education programs. Accordingly, the dissemination of high-quality teaching resources is a necessary but not sufficient condition for curriculum transformation. Instead, the time-consuming, sometimes incremental process of change—assessing organizational barriers and enablers; obtaining the buy-in of faculty, student, and community stakeholders, and collaboration and partnerships—is essential to ensure that such teaching materials are utilized and institutionalized within social work curricula, not gathering dust on office shelves. Both Reinardy and Zoff and Wilson provide the reader with guidelines for sustainable curricular and organizational change, primarily oriented to the infusion of gerontological content in foundation curricula, but also to the development of advanced or specialized practicum options. Strikingly, their recommendations draw largely on the accomplishments of social work programs throughout the country—large/small, BSW/MSW, urban/rural—rather than on national directives or expert white papers.

Because of the national leadership and funding that characterized the second stage, the exciting work of the third stage is occurring at the program level,

sometimes without external funding, among faculty, practitioners, and students committed to disseminating their lessons learned and best practices. The national geriatric social work movement is no longer abstract, distant, or confined to only resource-rich programs; instead, it is a campaign of relationship building, collaboration, and partnership at the local level. Hundreds of social work educators are not only drawing on models stimulated by foundation funding, such as Geriatric Enrichment in Social Work Education (GeroRich), Strengthening Aging and Gerontology Education for Social Work (SAGE-SW), and the Practicum Partnership Program, but are also generating their own transformative approaches, congruent with their programs' distinctive mission and goals. Perhaps the third stage will come to an end when gerontological social work education is no longer regarded as a new way of doing things, but as the way we do things, the rule rather than the exception (Bland et al., 2002).

Another distinguishing characteristic of the third stage is the development, implementation, and evaluation of gerontological social work competencies. Social work education has long struggled with whether and how to define competencies that can be measured. As documented by JoAnn Damron-Rodriguez, both the CSWE/SAGE-SW project and the Practicum Partnership Program have contributed to the field through their development of geriatric social competencies. In addition, some GeroRich projects drew on the generalist SAGE-SW competencies. Although further refinement and testing of generalist versus advanced competencies are needed, the groundwork has been laid for competency-based gerontological social work education and identification of best practices. Classroom- and agency-based educators must continue to address the challenge of evaluating the outcomes of a competency-based approach.

As suggested by Wilson, greater attention needs to be given in the third stage to improving the public image of gerontological social work and clarifying the geriatric social worker's distinctive roles and contributions, particularly on multidisciplinary teams. Continuing education and credentialing, which are congruent with the specialization model referred to by Wilson, are related to both of these goals. Robyn Golden and Monica White highlight social work's strengths in working with older adults and clarify the rationale for and benefits of credentialing for social work case managers in aging. Social workers are central to case management with older adults but are

often less visible than other professions in the medical and rehabilitation fields. Certifying the knowledge and skills distinctive to social work case management with elders may enhance public and multidisciplinary awareness of geriatric social work.

In sum, these chapters document educational changes at the local level that are preparing graduates for working effectively with older adults, although not necessarily as a career in the sense of advanced specialization in gerontological skills. For those who do choose to specialize, however, the issue of credentialing

and improving the public image of gerontological social work is critical not only to their careers but to the quality of services to older adults and their families.

Strategies for Implementing and Sustaining Gerontological Curricular Change in Social Work Education

97

This chapter addresses the comprehensive strategies that are needed to implement sustainable gerontological curricular change on a program level. What steps, actions, and considerations do social work programs need to make to develop a curriculum that prepares students to meet the growing challenges of an aging society? We begin with a brief review of select literature on organizational and curricular change, including strategies for changing gerontological curricula. Then, after drawing from the literature on principles for change, we outline and illustrate the major considerations that should inform the change process: planning, implementing, and institutionalizing an aging-rich curriculum.

ORGANIZATIONAL AND CURRICULAR CHANGE

The major steps that typically make up the organizational change process are determining the need, developing and communicating a vision, identifying barriers, building a consensus, creating the change strategy, and then implementing and evaluating the change (Knorr, 1993). This process has its roots in the pioneering work of Kurt Lewin (1957), whose notion of force field analysis was grounded in systems theory and who depicted organizational change as a process of unfreezing, changing, and then refreezing. The key was to introduce a state of disequilibrium into the system where driving forces overcame restraining forces. In this view, often applied to business, top management must be strongly committed to the process. There is often a change champion with a compelling and consistent vision. Teams are involved in the process, attempts are made to reach all corners of the organization, and, especially important, organizations must modify their policies and procedures if change is to be sustained (refrozen) (McNamara, 1999).

A second arm of change literature, while incorporating much of the above, places more emphasis on elements such as cultural change, vision, power, and social control. Less emphasis is on top-down leadership and more on visionary leadership and bottom-up strategies (Wons, 2002). This approach is evident in the work of Nichols-Casebolt, Figueroa-McDonough, and Netting (2000), who propose change strategies to integrate women's knowledge into social work curricula. They argue that a major transformation is needed given the marginalization of such content. Their analysis includes the type of

culture characterizing the school, the kind of leaders available, opportunities for effective leadership, and other organizational characteristics that affect choice of strategy. Bottom-up change is also a theme in Brager and Holloway's (1983) classic model for changing organizations from within. They propose a detailed framework of questions, beginning with initial assessment (e.g., What are the forces for and against? Does the change represent the agency's values?) and preinitiation (e.g., How do you develop legitimacy? Increase agency stress?) through initiation (strategies of who, what, when) and institutionalization (building the change into policies and procedures).

Although these principles of organizational change apply to educational institutions, change leaders have to balance and build on the tensions specific to each university's threefold cultural mix of scholarship, teaching, and service (Hanley, 2001). Given tenure and the university reward system, faculty buy-in also becomes essential. Hagner and Schneebeck (2001) emphasize the need, when seeking faculty engagement, to assess the mix of the faculty and the different rewards to which each of its members will respond. Building on constituencies' and stakeholders' interests becomes even more imperative for achieving change as universities and colleges increasingly become open systems and respond to learning as both a social and a market-driven good (Graves, 2001).

Successful approaches to curricular change need to be comprehensive, multifaceted, and systems-based. This is demonstrated by Bland and colleagues (2000) in a recent review of the literature to determine the major strategies needed for curricular reform in medical schools. They identified reappearing themes that suggested 13 characteristics of successful curricular change: leadership, the institution's mission and history of change, politics (internal networking, resource allocation, external relations), organizational structure, need for change, complexity of change, cooperative climate, participation, communication, human resource development, rewards, performance dip, and evaluation.

GERONTOLOGICAL CURRICULAR CHANGE IN THE SOCIAL WORK LITERATURE

Most of the published social work literature in gerontological education addresses curricular frameworks, educational models, and pedagogy. Other articles

have investigated conditions affecting curricular change, such as barriers and enablers. Barriers include ageist attitudes, lack of organizational commitment, lack of training, few incentives, limited resources, and faculty and student disinterest (Browne, Braun, Mokuau, & McLaughlin, 2002; Kropf, 2002; Rosen, Levy, & Singer, 2002; Scharlach, Damron-Rodriguez, Robinson, & Feldman, 2000). Examples of enablers are linkages to a gerontology center, a multidisciplinary approach, and the presence of a medical school (Damron-Rodriguez & Lubben, 1994; Damron-Rodriguez, Villa, Tseng, & Lubben, 1997). A few authors, however, have described comprehensive change projects or models. Meredith and Watt (1994) present a comprehensive change project that links faculty professional growth with institutional development and curriculum development. Beginning with the social work dictum "Start where the client is," they conclude that *curriculum shift* and *sustainability* depend on the benefit perceived by faculty members. They were able to tailor seed grants, film discussions, resource kits, and conference opportunities to individual faculty member's perceived needs. They credited the success of curricular change to the involvement of those affected by the change as well as to a focus on enriching rather than replacing the curriculum.

A second project of interest applies Lewin's (1957) normative change model to integrating gerontology into the curriculum (O'Reilly & Kazanowski, 1993). Although applied to a nursing program, the principles transfer to social work education programs. The authors discarded a rational change model (i.e., that a group will change when given convincing information about the need for change, etc.) as not taking into account the emotions, culture, needs, attitudes, and values of the target system. Employing a respected champion, the project emphasized planning, group work, and consensus building in the change process. In the beginning, the leaders assessed both the driving forces (e.g., grant availability, employment opportunities, accreditation standards, demographic changes, patient needs) and restraining forces (time constraints, lack of interest and/or knowledge about gerontology, full curricula, few opportunities for publishing) that worked for and against the plan. In Lewin's model, part of the process of unfreezing involves introducing discomfort (e.g., leaders focus on a school/department's performance gap, or faculty are led to discover that they have ageist attitudes) and safety (group support, reward opportunities) at the same time. This change process placed emphasis on

group work and consensus building and applied many of the strategies used by Meredith and Watt (1994). The authors emphasize that the process takes time—up to 2 years to integrate content into the curriculum—and that toward the end, at the refreeze phase, change energies tend to decline (a performance dip). Leadership and motivation are important at this point to maintain the process, and evaluation should be ongoing.

In addition to the literature cited, there are a handful of articles on specific strategies, such as student recruitment and collaborative field projects. These are incorporated in the following section, which applies change strategies to gerontological curricular change. Project reports and lessons learned from the Geriatric Enrichment in Social Work Education (GeroRich) Program (Hooyman & St. Peter, in press) are also applied. The program completed its third and final year on June 30, 2004, and surely will add much to the literature on aging and curricular change (see Hartford Geriatric Enrichment Social Work Program, n.d.).

GERONTOLOGICAL CHANGE STRATEGIES IN THE SOCIAL WORK CURRICULUM

As the models described earlier illustrate, curricular change entails multiple efforts to achieve faculty buy-in. But the curriculum is embedded within a program, which in turn is embedded in a department/school, university/college, and community. Thus, strategies for lasting change not only address the faculty but, as the organizational literature suggests, must target in a comprehensive, multidimensional manner all internal and external stakeholders that make up the system. They incorporate into the change process the mission, nature, and culture of the school/department, and they recognize that change is a transformative process that includes recognition of need, tension, vision and leadership, communication and consensus, a plan to follow, ongoing support and development, and rewards.

Change as Vision and Sustainability

Sustainability happens not only at the end or institutionalization phase of the change process, where changes are incorporated into program objectives and syllabi. It is just as important that it be related to vision, which guides the change process prior to its

inception and throughout. A key question is: To what extent and how will gerontological content be incorporated into the curriculum? Is the curriculum envisioned as a specialization, or as being integrated and infused with aging content (Singer, 2000)? Is it seen as transformed (Hooyman & St. Peter, in press)? Integration adds content to the curriculum, albeit in strategic places; specialization, at least at a minimum, adds a series of courses at the advanced level. Infusion attempts to fill the curriculum throughout with content related to aging across foundation courses: in exercises and assignments and course objectives. The more profound the vision, the more sustainable (if accomplished!) in that it will not only call for the addition of a course or an objective here and there, but will challenge the faculty and school to rethink the curriculum, the program's organizational goals, and its supports and linkages with the community. Hooyman and St. Peter encourage programs to work toward a curricular transformation to achieve long-term change.

Given these alternatives, change agents need to assess at the point of planning prior to initiation what is feasible in their program, including factors such as the program's mission, history of change, culture, resources on aging (in both the faculty and the community), possible resources for faculty development, and potential allies and pressures for change/resistance from within and outside of the program. Of all of the options, integration of content guarantees little sustainability. Content is easily lost with changes in personnel. More important, the faculty as a whole has not grappled with the question of how the educational experience leads to desired outcomes for their graduates.

Vision is of critical importance because it drives the change process. It requires that faculty members have both private and public conversations about the program's goals and values and about what they see as the learning outcomes for their students. This takes hold when leaders frame questions to enlarge debate, avoid premature closures, and act as proponents, not judges (Brown & Jackson, 2001). A central challenge to enlarging the debate is developing an integrating theme that builds on faculty interests as well as transforms the curriculum. The strategy is not simply to add on content, for several reasons. Infusion or transformation will not be achieved. Faculty members will grumble at having to add content to an already full curriculum. In addition, not only is there a natural resistance to change, but change often entails a loss (Bridges, 1991). Faculty members have

worked hard to develop course and curricular content—they are going to be much more open to the transformation of their work rather than its replacement. Examples of crosscutting themes include use of the notion of aging across the life span to organize courses, the organizing theme of multigenerational practice, and the incorporation of aging as a dimension in a strengths-based perspective. The University at Albany, for example, has adopted an integrated framework of intergenerational and multicultural practice to incorporate into its curriculum both multiple generations and racial, ethnic, and gender identities. The University of Washington uses a multigenerational perspective to infuse content on aging. The curriculum incorporates interactions among generations, not only between them (see www.gerorich.org).

As discussed in the sections that follow, making the vision a reality involves a collaborative, multifaceted approach. It requires the involvement of faculty, administration, students, and stakeholders from the community, and it should draw from several potential process tools. These include design teams, curricular audits and assessments, individual interviews, focus groups, task forces, alumni partnerships, practitioner advisory boards, and faculty retreats. The vision also must respect the mission of the social work program and university. Although university and program missions appear all-encompassing, they take on a specific life in reality, and social work programs are more and more becoming open systems, responsive to a competitive environment where strategic planning is important (Mudrick, Steiner, & Pollard, 1992). If a program does engage in strategic planning, change leaders have an important opportunity to move the faculty to adopt a vision on aging content. Council on Social Work Education (CSWE) reaffirmation may also present such an opportunity, although the focus of the change effort can be lost in the complexities of the reaffirmation process.

Change as Collaborative Effort

Accomplished change leaders perceive all stakeholders to be both targets and advocates/forces for change. For example, students who are moved to embrace a career in social work with older persons also become advocates who seek change in the curriculum. A practitioner advisory board that begins recommending practice competencies to the curriculum committee

also becomes a gentle pressure on the faculty to undertake curricular reform. Potential stakeholders that are both targets and forces for change include faculty and staff, students, field instructors and practitioners in the community, gerontology centers, faculty and departments of related disciplines, professional associations, and other schools or departments of social work.

Faculty members, both as individuals and as forming the program's policy body, are a central focus of the change effort. Obtaining their buy-in and collaboration in a transformative change process demands a thoughtful assessment of their needs, motivations, and reasons for resistance to change. Hagner and Schnebeck (2001) recommend that change leaders assess the mix of their faculty. Some faculty members tend to be *entrepreneurs* or *lone rangers*. They are quick to take a project and run with it on their own. They have a high level of commitment but may require more attention to engage in a collaborative effort. Others are *reward seekers* whose motivational structures are closely tied to the university's reward system. Others are *risk averters*. They are committed to quality learning but may be afraid that their current success in teaching and service may be jeopardized by the new vision. Risk averters may need significant levels of institutional support; they may also profit from success stories told by peers who have incorporated aging content into their pedagogy.

The mix of change strategies depends on the type of faculty and culture of the department or school. Change leaders in a large program with a heavy research agenda may place more emphasis on individual faculty consultations and mini-grants for syllabi changes, whereas those in a smaller program may build more group processes into their change effort. Regardless of the number of strategies employed—brown-bags, focus groups, one-to-one meetings, faculty development workshops, faculty retreats, strategic planning, outside consultants, funded travel to workshops and institutes—the faculty as a whole must, in the end, own the new curriculum. This requires dialogue and decision making in faculty meetings and throughout formal policymaking bodies, such as curriculum committees. It also necessitates opportunities for faculty members to examine attitudes toward aging, their own as well as those of others. Videos, presentations to the faculty by outside consultants and older persons on life's challenges and rewards may be helpful. Many faculty members, often senior members in leadership positions, find themselves in the role of

caregiver for their parents. This may be an opportunity to begin a dialogue.

Studies show that the number of students interested in working specifically with older adults is very low, around 5% (Kosberg & Kaufman, 2002; Kropf, Schneider, & Stahllman, 1993). Although this is a concern, it is easy to forget that a vision for transforming the curriculum must include all students, regardless of their career interests. A brown-bag on geriatric social work in the marketplace or the development of a gerontological student interest group will provide supports for students interested in aging careers. A brown-bag on end-of-life issues, on the other hand, or a presentation on kinship care may attract entirely different groups, helping these students link aging issues to their lives and careers. Nevertheless, a strong contingent of students interested in geriatric social work will be a force for change as well as a model to other students for interest in aging issues.

The GeroRich Web site provides examples of numerous strategies used by projects to recruit as well as stimulate and maintain students' interests in aging. These include focus groups and surveys to assess reasons for student disinterest as well as programs in service learning, stipends, simulation games, brown-bags, special conferences and job fairs, alumni mentors, and student interest groups. As an example, the University of Minnesota–Twin Cities sponsored an all-day workshop for its students in the field. The planners chose legislation on vulnerable adults and presented it as relevant to many practice settings, not just those serving older persons. Another strategy, one that directly feeds into the curricular change process, is to appoint students with interests in aging to key curricular and events committees.

Collaboration with stakeholders outside of the school, particularly in the community, is an especially important dimension of curricular change. Social work programs prepare their graduates for work in the community, and much of the learning experience takes place in the community through the practicum. An advisory committee made up of key stakeholders, including geriatric practitioners, field instructors, and older persons, can be of immeasurable help to the change effort, providing expertise in the development of the curriculum. For example, change agents may lead the advisory board in a series of structured group processes to develop and recommend knowledge and skill competencies for the curriculum. By building communication channels between the board and the faculty through

newsletters, a Web site, e-mail, and representative positions on important committees such as curriculum policy, the board may also exert a political influence on the transformation. Finally, advisory boards can help bring the change vision to the community, where the development of practice opportunities in working with older adults is critical. The GeroRich Web site highlights several strategies that build linkages with the community. Suggestions include a speaker's bureau of experts on aging available for guest lectures and role-plays, a Web site to feature alumni who are working with older adults, community focus groups for input into the curriculum, and mentor programs to link students with practitioners (www.gerorich.org).

The literature demonstrates the value of collaboration with other academic units. There is an association, for example, between aging content in the curriculum and multidisciplinary approaches to research and teaching. Also, the presence of a gerontological center at the university is associated with aging content (Damron-Rodriguez & Lubben, 1994; Damron-Rodriguez et al., 1997). Browne and colleagues (2002) at the University of Hawaii describe how a university-community collaboration formed and maintained two councils for guidance: an advisory council of community leaders and a consortium council of practicum instructors. With their guidance, the change project standardized competencies for the curriculum, initiated a "train the trainers" project to provide training in cultural competence and interdisciplinary practice for community practicum supervisors, developed a formative summative strategy to evaluate the curriculum, and implemented student recruitment strategies.

Change as a Multifaceted Campaign

Netting and colleagues (Netting, Hash, & Miller, 2002) describe the development of their Geriatric Rotational Education and Training Project as a collaboration *and* a campaign. Both characteristics speak to the multifaceted nature of change. Collaborative strategies involve working with stakeholders as allies in a change effort; campaign strategies are used to persuade. Both imply multiple processes at multiple levels to develop and implement a shared vision. Two important characteristics of this multifaceted approach are the importance of staging (Brager & Holloway, 1983) and the quality of leadership (Bland et al., 2000).

Although phases or stages of an organizational change effort run together, it is helpful for planning and organizing purposes to view the process in phases. Meredith and Watt (1994) describe their Gerontology Development Project in three phases: baseline curriculum needs assessment, resource development, and evaluation. The phases that are typically identified in the change literature are planning, initiation/implementation, and institutionalization (Glaser, Abelson, & Garrison, 1983). Planning involves an initial assessment of who the key stakeholders are and whether they will support or resist the change. Who are the allies on the faculty who will promote the infusion of aging into the curriculum? Change agents need to assess the change effort in terms of the school/department's values, the amount of resources required, and the complexity of the change. Also, what is the culture of the social work program? Constructive cultures are those that encourage achievement and self-actualization of faculty and students and that nurture teamwork; defensive cultures are associated with authoritarian administration (Nichols-Casebolt et al., 2000). A defensive culture, for example, will require a change effort that is closely tied to the dean's or director's support.

At the planning stage, change agents assess the feasibility of the vision, as discussed earlier. Will the vision engage the stakeholders? How can the change process spread that vision beyond a core group to all stakeholders? Faculty members with an interest in aging are a given, but what about those with other teaching and research interests? How can the project attract junior members who are pressured to prepare for promotion and tenure? What positive driving forces can be used to overcome resistance? In preparing to initiate or implement the change, it is also important to understand that lasting change comes from a process of building relationships (Simmons, 2003). Relationship building takes time: The literature suggests that a curricular change effort will take at least 2 years, preceded by several months planning. When should implementation begin? Projects that begin in the middle of the academic year risk losing momentum during the summer.

Because campaigns are about persuasion and persuasion requires several avenues to the heart and mind, the change initiative will need to implement several of the strategies discussed earlier. A major challenge throughout the campaign will be to link stakeholders together and to communicate the vision and the change process in a consistent, com-

pellent manner. GeroRich Projects used multiple strategies to communicate their message, including Web sites, focus groups, newsletters, weekly dialogues, videos, and bimonthly curriculum development dinners. Leaders need to monitor and assess progress throughout the project and be willing to adopt new strategies when current ones are not working. The final phase, institutionalization, sometimes called refreezing, is the time when stakeholders no longer refer to curricular changes as *new ways of doing things* but as *the way we do things* (Bland et al., 2000). The change has been incorporated in the objectives of curriculum and syllabi and in the program's policies and evaluation standards. Most important, the teaching and values of faculty members reflect in their habits and actions the new but sustainable vision.

If there is to be sustainable change, particular attention must be given to the selection of the change leader, as his or her activities are vital to successful innovation (Fullan & Stiegelbauer, 1991). Although much of the change literature describes single leaders and change champions, leaders need not work alone; two of the models described in this chapter were based on a team or coleader approach (Meredith & Watt, 1994; O'Reilly & Kazanowski, 1993). Indeed, one of the first tasks for the leader of the change process is to build allies and form an innovation nucleus (Nichols-Casebolt et al., 2000). Many of the projects described in the GeroRich Program describe leaders who formed teams or boards or constituent bodies with which to work. Depending on the program's culture, administrative or senior status in a leader may be important (i.e., in a defensive culture); in other schools, the administration may welcome bottom-up initiatives. Several other characteristics are essential for the leader or champion. In their review of curricular change process, Bland and colleagues (2000) found that a key characteristic associated with success was the leader's ability to remain a leader throughout the project, communicating a consistent and engaging vision of change. Other characteristics include the leader's effectiveness in using organizational authority, building coalitions or empowering others to build coalitions, actively seeking input and participation from stakeholders, and articulating stories and symbols that represent the underlying mission of the organization. In keeping with earlier comments on engendering a sustainable vision, the most successful leaders use participative and value-influencing behaviors more than organizational power (Bland et al., 2000).

CONCLUSION

Sustainable gerontological curricular change requires far more than the notion of a faculty committee reviewing the curriculum and recommending additional content on aging. Sustainable change is transformative; it requires a comprehensive, multifaceted, and systems-based effort. In sum, it is a process—nurtured through leadership, campaign, and collaboration—whereby the stakeholders of a social work program become their vision.

NANCY L. WILSON

Educating Social Workers for an Aging Society: Needs and Approaches

98

This chapter has three primary aims: (1) to review the need for a knowledgeable cadre of social workers prepared to fulfill many roles in a rapidly aging society, (2) to present alternative models and approaches to the education of “aging-savvy” social workers, and (3) to highlight best practices and resources to support educational innovation focused on improving the quality of life for aging individuals, families, and communities.

Academic leaders in gerontological social work have endorsed important principles in social work education to address the global challenges of population aging. The Task Force on Aging (Keigher et al., 2002) of the National Association of Deans and Directors authored a 2002 report: *Promoting Social Work for All Ages in Social Work Education: A Guide for Deans and Directors*. Recommending an approach to aging based on “human development across the lifespan,” the report urges use of the “United Nations Principles for Older Persons” addressed in the United Nations (1991) statement *Toward a Society for All Ages: Independence, Participation, Care, Self-Fulfillment, and Dignity*. These principles, highlighted in Table 98.1, underscore “the importance, challenge, and vitality of the latter half of life, and the exciting intergenerational learning opportunities that lie ahead for the social work profession and academic community” (Keigher et al., 2002, p. 10). Given the broad, multidimensional mission of social work as a profession and the aging of the population, social workers in a wide range of settings are likely to have one or more practice roles that require education for effective practice across the life span.

ROLES FOR SOCIAL WORKERS IN AGING

There are consistent indications of a growing need for social workers capable of working with older adults and family members. An estimate by the National Institute on Aging in 1997 projected a need for 60,000 to 70,000 social workers by 2010 (Council on Social Work Education Strengthening Aging in Gerontology Education Program [CSWE/SAGE-SW], 2001, p. 1). Career forecasts published by *US News and World Report* as well as the Bureau of Labor Statistics (BLS) identify geriatric social work as a field of growing demand, with the BLS predicting particularly rapid job growth among gerontological social workers (21% to 35% between 2002 and 2012; Avery & Charski, 1998; U.S. Department of Labor, 2004). For decades, publications outlining the need for a gerontologically pre-

TABLE 98.1. Guiding Principles in the Design and Delivery of Social Work and Aging Education

Independence: People have a right to remain independent in later life. To be independent, people need access to the basic resources vital to living decently, including nutritional food, clean water, adequate housing, income, and health care. Older people need opportunities to earn money, to sustain a decent standard of living, to retire when they feel ready, to receive training, and to remain a vital part of the fabric of society. They need to live in safe environments that can adapt to their changing needs so that they may age without becoming unable to meet other needs.

Settings where social workers address independence: employee assistance, workplace, housing, community education, home modification programs.

Participation: Older people must be empowered to maintain vital social roles, to make contributions to society, and to have their contributions valued. This principle highlights the importance of social inclusion, seeing retirees as volunteers providing services and organizing social movements, but also their interpersonal strengths as familial agents whose connectedness with others promotes interdependence and social cohesion and builds social capital.

Settings where social workers support participation: family service agencies, neighborhood centers, community ministries, volunteer programs.

Care: Elders have a right to be cared for. Care includes health and social care, as well as elders' legal rights to receive and control how care is delivered. Social work involves advocating social justice and fairness in the allocation of services, providing competent, culturally appropriate social services, and facilitating the delivery of appropriately expert health or mental health care.

Settings where social workers ensure that care is provided: child welfare or aging service programs, home health agencies/clinics, hospitals, hospice programs, long-term care facilities.

Self-Fulfillment: Even with physical limitations, older people still need stimulation, challenges, and opportunities to enjoy the growth, caring, and sharing that enrich life. Social workers are concerned with the caring work done by many elders, and although it is unevenly distributed across demographic characteristics, it is full of meaning and power to those doing it. Additionally, learning from and teaching younger people is important.

Settings where social workers support self-fulfillment: case management, respite, support groups, counseling, and community support.

Dignity: People have a right to dignity in old age and in death. Older people should be able to live free from abuse, to be respected and treated fairly, and to be allowed control and dignity in dying. Regardless of impairments, people should have choices in where they live and how to structure their daily lives and should be helped to remain in familiar surroundings if they so choose. Elders are entitled to privacy and property, medical care, and medical decision making.

Settings where social workers enable dignity: health care, residential long-term care, protective services, and hospice.

Source: Abbreviated from Keigher et al. (2002).

pared workforce have identified several central roles for social workers: (1) serving as leaders in the creation of health, housing, human service, and economic policies responsive to population aging; (2) contributing to the health and well-being of older adults through leadership, scholarship, and advocacy; (3) providing high-quality direct services to older adults and families through outreach, preventive education, clinical practice, and case management; (4) developing and managing health and social service programs; and (5) serving as effective members and, as appropriate, leaders of interdisciplinary teams (Berkman, Damron-Rodriguez, Dobrof, & Harry, 1996; Berkman & Harootyan, 2003; Scharlach, Simon, & Dal Santo, 2000; Takamura, 2001).

Social work professionals and educators alike recognize that although specialists identified as geriatric or gerontological social workers will fulfill some of these roles, it is critical for all social workers to acquire

fundamental gerontological knowledge and skills (Berkman, et al., 1996; CSWE/SAGE-SW, 2001; Hooyman & St. Peter, in press; Rosen & Zlotnik, 2001; Scharlach, Damron-Rodriguez, Robinson, & Feldman, 2000). Proponents of quality care for older adults advocate that social workers prepared as geriatric or gerontological social workers work in the settings and systems identified in Table 98.2. This Older Adult Service Matrix is organized along two dimensions: service delivery systems and functional level of older adults.

There are other settings that are not identified in Table 98.2, however, where social workers with older clients could utilize the "United Nations Principles for Older Persons." A recent study of the public's understanding of the social work profession reported that 90% of the respondents envisioned a social worker's primary role as helping children and families (LeCroy & Stinson, 2004); accordingly, many so-

cial work students plan to work with children and families (CSWE/SAGE-SW, 2001). Both the popular media and many prospective social workers fail to recognize that practice with children and families often involves work with older individuals. For example, given the dramatic rise in the number of grandparents raising grandchildren, future social work graduates will more frequently encounter older adults in schools, pediatric clinics, substance abuse programs, public child welfare agencies, the juvenile justice system, and family service agencies (Kropf & Wilks, 2003). Likewise, younger family caregivers, often an employed daughter who is also a partner/wife and mother, provide the majority of care for older adults with disabilities. Caregiver stress may manifest in the workplace and produce health or mental health problems requiring social work services through an agency, clinic, or faith-based program. Furthermore, many of the problems being addressed in the systems noted in Table 98.2 are strongly linked to an older person's economic status and personal circumstances across the life course, which calls for social work intervention earlier in the life span of older individuals or within the systems structuring their lives.

Several independent surveys corroborate the importance of preparing all social workers to work effectively with older adults and their families. In a survey of the members of the National Association of Social Workers (NASW), over 60% of respondents, regardless of specialty, reported that they needed knowledge about aging (Peterson & Wendt, 1990). In a recent study of 138 MSW program graduates, a majority (77.2%) of those not employed in aging-related work noted that they had contact with older adults, and 63.4% reported a need for gerontological knowledge. A national survey conducted by the CSWE/SAGE-SW (2001) asked practitioners and academics (regardless of their interest in gerontology) to identify competencies needed in social work practice. Of the 65 age-related competencies included in the survey, respondents indicated that over half were needed by all social workers, not just those individuals specializing in aging.

However, most social work students are not prepared with such competencies, in part because of the lack of specialized aging content in their coursework at the BSW or MSW level (CSWE/SAGE-SW, 2001; Damron-Rodriguez & Lubben, 1997). In 1996, only 3% of all MSW graduates identified an aging or gerontology specialization, and only 2% of all MSW students not in an aging concentration had taken any graduate courses in aging (Scharlach et al., 2000).

Furthermore, a recent survey of accredited graduate programs in social work by Cummings and DeCoster (2003) reports that only 40 MSW programs (27%) currently offer specialized aging training (i.e., a gerontological concentration, specialization, or certificate program). Although growing numbers of social workers with aging training are needed, only a small number of current students complete specialized training in aging. As a result, many social workers enter work in aging after graduation (CSWE, 2003; Greene, 1988; Peterson & Wendt, 1990). The existing barriers to successful training of an adequate supply of social workers prepared to work across the spectrum of settings with aging issues are well documented. A summary of key barriers, along with some of the responses proposed to address these barriers, is included in Table 98.3 (CSWE/SAGE-SW, 2001; Damron-Rodriguez & Lubben, 1997; Kropf, 2002; Kropf, Schneider, & Stahlman, 1993; Rosen & Zlotnik, 2001; Scharlach et al., 2000).

LEADERSHIP, RESOURCES, AND MODELS FOR AGING IN SOCIAL WORK EDUCATION

Many of the barriers identified in Table 98.3, as well as some of the suggested solutions, are not new or unique to social work. The most important need in "gerontologizing" the field is to produce a cadre of faculty who have basic gerontological competencies. As described by Reinardy and Zoff (this volume), leaders and champions are needed to institute change within social work programs. To ensure the adequate gerontological preparation of social work students, two types of faculty expertise are needed: foundation gerontological knowledge and skills for effectively teaching life span content and skills across all areas of foundation curriculum and specialized gerontological knowledge and skills for teaching in the advanced curriculum, scholarship that informs practice and policy, and academic leadership to advance the field. Due to the investment of the John A. Hartford Foundation and the committed leadership of the Association for Gerontological Education for Social Work (AGE-SW; <http://www.agesocialwork.org/>), a number of faculty development models have been implemented to begin addressing this need.

In 1998, the John A. Hartford Foundation began funding a multifaceted Geriatric Social Work Initiative (GSWI), and as of September 2004, it has provided \$35.52 million in support of five distinct programs headquartered at leadership organizations

TABLE 98.3. Barriers to Adequate Preparation and Programmatic Responses

<i>Barriers to Training of Social Workers in Aging</i>	<i>Programmatic Responses</i>
Lack of faculty with gerontological expertise to provide academic leadership and mentoring to prepare future leaders, scholars, and practitioners in gerontological social work.	<ul style="list-style-type: none"> • Faculty development • Academic mentoring • Financial support for development
Inadequate preparation and engagement of BSW and MSW faculty responsible for foundation courses, advanced courses in other fields of practice.	<ul style="list-style-type: none"> • Faculty development • Academic mentoring • Institutional leadership • Curriculum resources
Negative views and limited understanding of students, faculty, and broader society toward older adults.	<ul style="list-style-type: none"> • Increased exposure to diverse populations, range of positions, and settings available for work in aging • Financial aid, such as scholarships, stipends, or loan forgiveness
Lack of adequately compensated positions in aging services.	<ul style="list-style-type: none"> • Advocacy for legislation • Public education
Limited institutional resources and time for special curricula in aging	<ul style="list-style-type: none"> • Leverage resources of other disciplines • Partnerships across departments, agencies, and institutions

in aging and social work (consult the programwide Web site, <http://www.gswi.org/>, for further information and links to resources from each program). The GSWI has developed a clear framework for the professional education of BSW and MSW students of the future. Along with generating additional leaders and expanding faculty expertise, the framework involves the production of needed curricular resources, defined competencies in aging, models for field education, teaching resources, and evaluation tools. The mission of each major GSWI component is as follows:

1. Faculty Scholars Program: To support the career development and research of talented faculty.
2. Doctoral Fellows Program: To provide dissertation funding for promising doctoral students committed to gerontology.
3. Practicum Partnership Program: To develop and test innovative aging-rich field experiences for graduate students that connect communities and schools of social work.
4. Faculty Development Program: To strengthen social work faculty's ability to develop, integrate, and teach aging content in BSW and MSW foundation courses via training, resource exchange, and dissemination.
5. Geriatric Enrichment Program: To expand the number and quality of courses and learning ex-

periences focused on aging at both the undergraduate and graduate levels.

As of July 1, 2004, the Faculty Development and Geriatric Enrichment Programs are no longer funded, but they provide the foundation for a new CSWE National Center for Gerontological Social Work Education.

ALTERNATIVE MODELS

Leaders and faculty in any social work program must choose a vision for incorporating gerontological content into the curriculum. They must also evaluate the institution's mission, resources, and educational culture to determine the optimum approach to curriculum change: integration, infusion, specialization, or transformation (Hooyman & St. Peter, in press; Reinardy & Zoff, this volume; Singer, 2000). Two decades ago, Lowy (1983), a pioneer in social work and aging, proposed five major organizational models for the inclusion of aging content in social work curriculum. These models addressed the ongoing debate of specialization versus foundation curriculum and the best strategies for specialization, either within social work or through a multidisciplinary gerontology certificate program/dual degree program with another discipline. To meet workforce needs and prepare for

the future, increased understanding has been developed about the relationships between the foundation and advanced curriculum approaches. For example, a recent study of factors that predict MSW employment in aging produced findings supportive of what many gerontological educators have claimed for years: More contact with older adults and more rewarding interactions with older clients were the most significant predictors of aging-related work among program graduates (Cummings & Galambos, 2003). Furthermore, there is increased appreciation for the role of continuing education for social work graduates, which enables the large numbers of currently practicing BSW and MSW social workers without prior geriatric training to acquire skills and tools to meet the needs of older adults and their family members (www.igsw.bu.edu).

PROGRAM EXAMPLES: MODELS IN ACTION

The remainder of this chapter describes two programs of the GSWI that have generated significant resources and lessons for organizational approaches to social work education in aging: the Geriatric Enrichment in Social Work Education Program (GeroRich), which emphasizes foundation competencies, and the Practicum Partnership Program, which focuses on specialization. Examples from these two GSWI components illustrate all that is possible in the field.

GeroRich: Foundation Competencies

The GeroRich framework requires that social work programs and their community partners engage in a process of curricular and organizational change to incorporate gerontological learning experiences into the preparation of all BSW and MSW students (Hooyman & St. Peter, in press; Reinardy & Zoff, this volume). Some of the 67 social work programs (BSW, MSW, and joint BSW/MSW) involved in GeroRich have relied on close collaborations with other departments or disciplines within a broader university environment, such as gerontology centers or service learning programs (Dorfman, Murty, Ingram, & Evans, 2002). Other programs have formed strong partnerships with community agencies and created classroom assignments and field practicum experiences, which provide students the real-world contact with older adults that is often lacking in their personal

lives or learning experiences. Each GeroRich program determined how to involve and support foundation faculty (most of whom are nonspecialists) in addressing aging competencies as learning outcomes in required courses in human behavior, policy, values, and ethics in practice. Extensive information from these programs—including materials to support aging-related instruction in classroom, practicum/field, and service learning—is available through the GeroRich Program Web site (www.gerorich.org) and also through CSWE-SAGE Social Work Toolkits (<http://www.cswe.org/sage-sw/index.htm>).

We turn now to a few examples of the infusion approach. As illustrated by Kropf and Wilks (2003), the issue of custodial parenting by grandparents is one example of the many intergenerational practice and policy issues that can be raised in different foundation classes. The infusion efforts of several GeroRich programs used an intergenerational framework and included one or more of the following themes within foundation courses: custodial grandparents as a social culture (culture diversity), kinship care and diversity of family forms (human behavior and social environment), and income maintenance for alternative families (social policy). Programs may begin with infusion of these issues into some courses and then expand to include others with further faculty development. For example, BSW students at George Mason University, who are required to complete an Intergenerational Advocacy Project, have addressed topics such as “Women and Social Security Across the Life Span” and “Grandparent Caregiving.” The infusion approach at the Fordham University Graduate School of Social Work also illustrates a model for placing aging issues into the larger contexts of families and communities, which parallels the practice environment encountered by most social workers. Fordham GeroRich leaders worked with foundation faculty in each of the three first-year practice courses to produce a casebook of carefully crafted cases, avoiding negative stereotypes of older adults and incorporating “generalist competencies viewed from a gerontological lens” (Gutheil & Chernesky, 2003). For example, students learned care management, crisis intervention, and community assessment skills by working with the different cases, including an aging family and a community emergency care system.

In addition to preparing students to work effectively with older persons in all practice settings, the infusion approaches have other benefits reported by GeroRich programs. Having the opportunity for students to connect content on aging with their other in-

terests in children, women, mental health, or substance abuse is an effective means of generating interest in gerontological social work as well (Hooyma & St. Peter, in press). In general, the emphasis in GeroRich has been not to

view older adults as a 'specialized interest group' needing curriculum time because of their many problems, but rather to use a life course perspective throughout foundation courses and consider how race, class, gender, age and sexual orientation can be discussed in the broader contexts of person-environment, the strengths perspective and empowerment. (Hooyma & St. Peter, in press)

Models and Resources for Specialization

Another component of the Hartford GSWI, the Practicum Partnership Program (PPP), has been coordinated by the New York Academy of Medicine (www.nyam.org). It focused on field education and specialization at the graduate level. Developed and refined through six demonstration projects (comprising 11 MSW programs) over a 4-year period (1999–2003),

the model is composed of five essential elements, which are identified in Table 98.4. All six of the PPP projects focused on training social workers who would ultimately pursue careers in aging, either in practice or academia, to use leadership and practice skills in the settings identified in Table 98.2. By way of illustrating the model, Table 98.4 also provides further background about how one of the projects, the Geriatric Social Work Education Consortium (GSWEC), has individualized the PPP program to fit the learning environment, culture, and resources of the greater Los Angeles metropolitan area. Some of the PPP elements described in Table 98.4, in particular those addressing student recruitment and formalizing community partnerships, were also identified as important factors for success and sustainability in the GeroRich program.

The evaluated outcomes of this model have been highly favorable, and program support has come from other foundations to sustain the stipends provided to students as well as support for the expanded field instructor roles. Program graduates report a high degree of confidence in their skills as well as strong commitment to the field (see http://www.gswi.org/programs_services/Ripples_2.htm).

TABLE 98.4. Essential Elements of Geriatric Social Work Practicum Partnership Program, as Implemented by the Geriatric Social Work Education Consortium

University-Community Partnerships

Administered by the Partners in Care Foundation, four graduate social work programs worked with 21 agencies to develop, deliver, and evaluate training to 32 second-year students in geriatric social work with an emphasis on leadership for the students and the agencies and experiences across the continuum of care.

Competency-Driven Education for Geriatric Social Work

GSWEC used the Social Work in Aging Skill Competency Scale (Damron-Rodriguez, this volume) to organize student-directed classroom and field learning and to measure students' skills before and after completion of fieldwork experiences in two or more GSWEC agencies.

Integrated Field Education Across Multiple Programs, Populations, Interventions, and Disciplines Through Rotations

Four agencies have served as Centers of Excellence for training students using a *biopsychosocial model* and *adult learning theory* with a focus on *diversity* issues and *leadership* skills. In addition to their site rotations in these four multiservice centers, student interns participate in task rotations in other settings that take into account the broader roles social workers play in their agencies in team building and in interdisciplinary practice.

Expanded Field Instructor Role

In each Center of Excellence a GSWEC field instruction coordinator had expanded duties beyond the traditional roles of student orientation and supervision, mentoring, modeling, and evaluation. They coordinated additional instruction for students across settings or agencies, served as teachers in seminars or classrooms, and participated on GSWEC committees.

Focused Recruitment of Students to Geriatric Social Work

GSWEC academic and field agency partners were all engaged in increasing first-year student awareness of the range, diversity, and creativity of opportunities to work with older adults as well as the rewards of geriatric social work. Other recognition and support strategies used were stipends, employment listings, and preferential career support at Centers of Excellence.

CONCLUSION

Regardless of their field of practice or work setting, social workers have important roles to fulfill so that, as life expectancy is extended, life quality is not compromised. Social work educators and practitioners must collaborate in providing current and future social workers with the basic gerontological knowledge and skills needed in all sectors of an aging society, including government, industry, business, health care, education, housing, and human services. As the demand for social workers with specialized knowledge and expertise in aging will only grow, the need to educate all students in all fields is of paramount importance. Although many barriers to gerontologizing social work education remain, there are now a growing number of knowledgeable faculty leaders, curriculum models, and teaching resources. Through undergoing a curriculum transformation process, social work programs can hope to produce graduates who have had opportunities to learn about enabling independence, participation, care, self-fulfillment, and dignity throughout the life span of all individuals of our increasingly diverse society.

BACKGROUND OF MOVEMENT TO GERIATRIC SOCIAL WORK

Recognizing the Need for Movement

By the mid-21st century, 1 in 5 persons will be over 65 years of age, creating a shift in demand for social work service to older persons and their families. Yet the need for gerontological social workers goes beyond meeting the demographic imperative. Although many professions are called to respond to the growing aging population (Hudson, 2003), the demand for gerontologically prepared social workers is grounded in the conviction that the profession's values, theoretical perspectives, and skills are essential to enhancing the well-being of older adults and their families (Berkman, Dobrof, Harry, & Damron-Rodriguez, 1997). The diversity of the older population in race/ethnicity, functional level, and cognitive capacity requires psychosocial assessment and intervention planning (Torres-Gil & Bikson-Moga, 2001). The profession is also garnering evidence of the value added by social work interventions to older adults' quality of life (Grimier & Gorey, 1998; Morrow-Howell & Burnette, 2001). Further, the development of gerontological social work acknowledges a burgeoning body of knowledge in the field of aging directly relevant to social work practice. The profession is moving toward the identification of social work competencies for effectively serving older persons (Damron-Rodriguez, Lawrence, Barnette, & Simmons, n.d.; Greene & Galambos, 2002).

JOANN DAMRON-RODRIGUEZ

Moving Forward: Developing Geriatric Social Work Competencies

99

Gerontological Social Work Movement Stage 1 (1965–1994)

Recognition of the need for specific gerontological or geriatric knowledge and skill was not present until the mid-20th century. Early leaders such as Louis Lowy (1979, p. 9) acknowledged, "Prior to 1945, not much had been happening in social work with the aging." In fact, older persons were not a targeted population in social work until the late 1960s and early 1970s, when many professions began to recognize that specialized knowledge and training were required to serve older persons.

From 1965 to 1980, federally funded educational programs in aging supported gerontological and geriatric education for a variety of professions, including social work (Berkman et al., 1997; Hudson, Gonyea, & Curley, 2003). These included the Administration on Aging (AoA) Title IV of the Older American's Act; Veterans Health Administration (VHA) Geriatric Research Education Clinical Centers (GRECC); and

Health Resources and Services Administration, Bureau of Health Professions Geriatric Education Centers (GEC). The GRECCs and GECs have grown in number and continue to support geriatric education, with the VHA providing the longest continuous stipend support for social work students. In contrast, AoA support for education has dwindled. The National Institute of Mental Health (NIMH) has not targeted older persons but has aimed to increase social work research through the establishment in 1991 of the NIMH Task Force on Social Work Research. The National Institute on Aging (NIA) support for aging research has not specifically targeted social work studies.

In the 1980s, the social work profession began to examine the relationship of its curricula to the longevity revolution. Early national surveys emphasized the need to increase aging content (Schneider, 1984). In 1988, the California GEC first surveyed all baccalaureate and graduate social work programs; they found practically no course work at the baccalaureate level and that only 3% of graduate students took an aging class (Damron-Rodriguez & Lubben, 1994; Lubben, Damron-Rodriguez, & Beck, 1992).

Gerontological Social Work Movement Stage 2 (1995–2005)

From 1995 to 2005, the profession moved forward with an agenda for social work in the field of aging. The Bureau of Health Professions (BHP) in 1995 held a National Forum for Geriatric Education, which developed 12 recommendations for the social work profession and identified actions and responsible stakeholders, public and private, to accomplish the goals (Table 99.1). The BHP is measuring accomplishment of these goals over the past decade. Several of these goals relate to the need to specify and develop geriatric social work skills or competencies.

In the late 1990s, the John A. Hartford Foundation, whose goal is to improve the care of older persons by strengthening geriatrics in the health professions, focused attention on social work. Through forums with social work leaders and a series of White Papers (Berkman, Dobrof, Harry, & Damron-Rodriguez, 1997; Scharlach, Damron-Rodriguez, Robinson, & Feldman, 2000), the Geriatric Social Work Initiative (www.jhartfound.org) was crafted. The long-range and multifaceted Hartford Initiative has had a major impact on the field, as described in other chapters of this volume (see also Robbins & Rieder, 2002).

Other private foundations have joined this effort, including Atlantic Philanthropies for the Institute for

Gerontological Social Work at Boston University. State and regional foundations, such as the Archstone Foundation in California, have also provided support. Thus, in the second stage of the social work movement, the major shift toward a geriatric-prepared workforce resulted from private foundations targeting social work, joining existing federal support that was not specifically social work-focused.

Stage 3: Working From a Multidimensional Definition of Social Work in Aging

Central to this next stage of geriatric workforce preparation is the delineation of competencies, beginning with a definition of the field of social work and aging. The BHP White Paper definition of geriatric social work is based on the generic description of the field in the NASW (1981) *Standards for the Classification of Social Work Practice*. Terms for professional practice with older adults are “gerontological” (knowledge of the aging process) and “geriatric” (interventions with

older persons with health-related issues), sometimes used interchangeably. Although the following definition was originally developed for geriatric social work, it is related here to social work practice broadly in the field of aging. Social work in the field of aging is professionally responsible intervention to:

1. Enhance the developmental, problem solving, and coping capacities of older people and their families.
2. Promote the effective and humane operating of systems that provide resources and services to older people and their families.
3. Link older people with systems that provide them with resources, services, and opportunities.
4. Contribute to the development and improvement of social policies that support persons throughout the life span. (Berkman et al., 1997)

This definition encompasses both direct or micro practice with older adults and their families and macro interventions involving programs and policies. It also acknowledges that social work is a strengths-based approach, identifying personal resources as well as problems (Chapin & Cox, 2001). The social work perspective is oriented toward family, social and community-based models of care, and public policy (Chapin & Cox, 2001). The major theoretical perspectives for gerontological social work bring a distinctive contribution to interdisciplinary geriatrics (Damron-Rodriguez & Corley, 2002; see Table 99.2).

DELINEATING COMPETENCIES

Competency-Based (Education) Evaluation

Competency-based education and evaluation (CBE) is an approach to producing a skilled workforce and ensuring that graduates can perform expected behaviors at a professionally acceptable level (Hackett, 2001). The evaluation of education inherent in CBE consists of two components (Bogo, Regehr, Hughes, Power, & Globerman, 2002): identification and development of educational goals in clear, measurable terms with indicators to judge varying levels of performance, and assessment of student skill acquisition measured through evidence-based criteria.

Graduates and employers recognize the field practicum as the primary locus for skill acquisition in social work (Fortune, 1994). Accordingly, Bogo, Regehr, and colleagues (2002) urge field educators to

TABLE 99.2. Theoretical Perspectives for Gerontological Social Work

-
- 1) *Life cycle developmental approach* with a focus on normal or healthy growth, development, and adaptation in late life
 - 2) *Biopsychosocial framework* with an emphasis on persons-in-sociocultural-context as they relate to transitions in the life course, physical functioning, and illness
 - 3) *Family systems approach* for intervention, recognizing the interdependence of family members
 - 4) *Life course perspective*, which recognizes the impact of sociohistorical context on cohorts and individuals based on class, race/ethnicity, and gender
-

move toward direct measures of competence from direct practice observation.

Social work entered the dialogue around issues related to CBE in the 1970s (Arkava & Brennan, 1976). Proponents argued that CBE offered an objective, comprehensive approach to hold universities accountable for producing social workers that were adequately skilled. Other educators cautioned that reductionism is inherent in this model (Field, 2000) and that some important professional competencies are more difficult to measure, such as critical thinking and interpersonal skills for patient interactions (Carraccio, Wolfsthal, Englander, Ferentz, & Martin, 2002). Two decades of social work literature reflect the need for clear descriptions of required competencies and standardized measures for skill outcomes in social work (Bogo, Raskin, & Wayne, 2002).

The measurement of competence is to demonstrate the effectiveness not only of education but, more importantly, of interventions in improving the lives of older people. As examples, geriatric social work practice has been found to be effective in reducing the risk of institutionalization and caregiver burden (Mittelman et al., 1993), minimizing risk factors through multidisciplinary home evaluations (Stuck et al., 2002), and improving care through geriatric clinical care management (Rizzo & Rowe, 2005).

Competencies in Aging for Other Professionals

Competencies for work with older adults have been identified generally (Bennet[[AU: Bennett in refs; pls correct throughout]] & Sneed, 1999) and for specific

professions: medicine (American Geriatrics Society, 2000); nursing (American Association of Colleges of Nursing and the John A. Hartford Foundation Institute for Geriatric Nursing, 2000); and mental health professionals (Molinari, Kier, & Kunik, 2002). Medical and other health professional education uses standardized patients and objective structured clinical evaluations. Age-specific assessment and intervention is an element in evaluation of health care systems by the Joint Commission on Accreditation in Healthcare Organizations (JCAHO, 2001).

Social Work Competencies

The identification of both micro and macro social work skills is ongoing (Dore, Epstein, & Herrerias, 1992; O'Hare & Collins, 1997; Vass, 1996). The Council on Social Work Education (CSWE) developed a competency-based generalist curriculum for baccalaureate social work (Gardella, 1997), and Dalton and Wright (1999) identified knowledge, skills, and attitudes most desired in social work graduates.

The Hartford-funded CSWE Strengthening Aging and Gerontological Education in Social Work (CSWE/SAGE-SW, 2000) initiated identification of aging-specific social work competencies. Phase I of this project included identifying competencies through the gerontological social work literature and consultation with national experts. This generated 65 competencies, which were organized into three major competency domains: knowledge about older people and their families, professional skills, and professional practice (Rosen, Zlotnik, Curl, & Green, 2000). In Phase II, a survey of the identified skills was mailed to 945 practitioners and faculty, asking them to rate 10 competencies related to generalist practice or 10 skills related to aging needed for all social workers and specialist practice in aging (Rosen, Zlotnik, & Singer, 2002).

The Geriatric Social Work Education Consortium (GSWEC), one of the Hartford Practicum Partnership Programs (PPP), conducted focus groups of employers and recent social work graduates in the field of aging and older persons and their caregivers (Partners in Care Foundation, 2000). Both employers and graduates identified the most important geriatric social work competencies to be conducting geriatric assessments, demonstrating self-awareness, practicing cultural competence, and recognizing the special needs of older adults and their families. Both groups also mentioned, albeit less frequently, skills in communication, networking, and providing emotional support and

competencies involving knowledge about the impact of ageism (Naito-Chan, Damron-Rodriguez, & Simmons, 2004).

GSWEC utilized the Geriatric Social Work White Papers, focus groups, and the pioneering work of the SAGE-SW Comprehensive Competency Survey (Rosen et al., 2000, 2002). In developing competencies to be used nationally for the field education project, a systematic effort was made to cross-reference all competencies identified separately and collaboratively with the SAGE-SW competencies. PPP focuses on specialty practice in aging; thus, the advanced practice competencies identified by SAGE-SW were included in the PPP skill scale.

Evaluation and Measurement of Competencies

Evaluation and measurement is another dimension of competency development. Studies have investigated the valid assessment of research competencies utilizing self-efficacy theory (Holden, Meenaghan, Anastas, & Metry, 2002) and of student field performance has been examined (Bogo, Regehr, Hughes, Power, & Globerman, 2002). Specialty-specific competency tools have also been developed to assess, for example, social work students' interviewing skills (Koroloff & Rhyne, 1989). Further, the reliability and validity of a measure to evaluate social work student performance has been examined (Bogo, Regehr, Hughes, Power, & Globerman, 2002). Competency standard development has been conducted in other professions to evaluate practitioners in nursing and medicine (Gordon, 1991; McKinley, Fraser, & Baker, 2000). In the health field, however, the focus on measuring student competencies tends to be on professional competencies, a focus primarily motivated by professional associations and licensure requirements and standards (JCAHO, 2001).

Self-Efficacy in Measuring Competence

Self-efficacy is defined by Bandura (1997) as the "belief in one's capabilities to perform actions required to produce given attainments." Self-efficacy has been established as a reliable and valid construct for predicting behavior and performance variation in a variety of health disciplines. Self-efficacy is thought to be task- or domain-specific and is concerned not with the number of skills acquired, but with the level of confidence felt necessary to meet specific goals. It en-

tails having the confidence to organize many subskills including ones that are cognitive, social, emotional, and behavioral to meet specific goal-directed outcomes (Bandura, 1997). A positive and significant relationship was found among self-efficacy beliefs, academic performance, and persistence outcomes across subjects and designs in Multon, Brown, and Lent's (1991) meta-analysis.

However, few studies utilize the construct to evaluate the efficacy of an intervention to increase social work competency (Cuzzi, Holden, Chernack, Rutter, & Rossenberg, 1997; Holden, Meenaghan, Anastas, & Metrey, 2002), and none addresses geriatric social work student competency based on self-efficacy theory.

MEASURING GERIATRIC SOCIAL WORK COMPETENCIES

Practicum Partnership Program Description

The Hartford PPP's primary goal was to increase the number of master's-level social workers well qualified to work with older adults and their families by developing aging-rich field practicum sites. In 2000, 3-year implementation grants were awarded through a competitive grant process to six demonstration sites (11 graduate social work education programs/academic institutions). Four sites developed programs for their second-year MSW students, and two sites developed 2-year programs. Each PPP encompassed the following elements: a university-community partnership or consortium; competency-driven field education; rotations for experience across multiple programs, populations, interventions, and disciplines; an expanded role for field instructors; and focused recruitment to geriatric social work. The use of a competency-driven educational process was central to the PPP, as field education by its very nature is skill-based (Fortune, 1994). Demonstration sites based their programs on skill competencies for working with older adults and their families at multiple intervention levels (Hadden, Damron-Rodriguez, Lawrence, Dankle, & Barnett, n.d.; Fortune, 2002).

Evaluation Design: A Focus on Competency

The New York Academy of Medicine Coordinating Center for the PPP provided leadership in collabora-

tively evaluating outcomes across the six demonstration sites. The items are based largely on sets of professional competencies for social work practice in aging developed simultaneously by GSWEC and the CSWE through different consensus-building processes. These sets were reviewed and synthesized for content relevant to the PPP's educational design. They were then matched against sets of competencies developed by the five other PPP sites, and additional competencies were identified; all were converted into statements of skills. These skill statements and new items with macro, interdisciplinary, and research and evaluation content were then grouped into domains. Members of the PPP Evaluation Committee, who are experts in social work and aging, then reviewed items for clarity and validity. As a result of these reviews and pilot testing, some items were modified, others deleted, and new items developed to form the Social Work with Aging Skill Competency Scale.

The scale measures respondents' perceptions of their perceived level of self-assessed skill in aging practice as compared to a competent MSW geriatric social worker. Respondents rate each item on a 0 to 10 scale (0 = not skilled at all; 10 = very skilled). Students were asked to compare their skill with that of an effective geriatric social worker in practice. Each domain may be subscored by adding responses of individual items. A section for respondents to comment on their skill in each domain provides the opportunity to clarify their ratings, as some items are complex.

The remainder of this chapter describes one component of the collaborative PPP evaluation research that focused on competency self-assessment before and after the PPP field experience. Other aspects of the evaluation concentrated on measuring outcomes in student's knowledge, career paths, and institutional-level changes in aging programs at each site. Students completed a pre- and postsurvey of knowledge, career interest, and assessment of competency using the instrument described earlier.

Practicum Partnership Program Student Sample

As presented in Table 99.3, no significant differences were found on the demographic and academic characteristics of PPP students in different years of the program, except in age; the YR3 cohort represented a broader age range with more younger and older students. The average or mean age over the three years was 32.9. Approximately half of the PPP participants were students of color.

Most PPP programs target second-year students; the majority of these students had been social work majors and were in the enhanced field education for 1 year even though 80% of the programs offered a 2-year experience (see Table 99.4).

Table 99.5 presents the significant difference between pre- and posttests of student competencies, with the improvement highly significant in each domain ($p = <.000$). Each domain and each item received a wide range of responses, with significantly higher responses postintervention (PPP), and Values and Ethics having the highest scores (7.1 and 8.6, respectively) and Evaluation and Research the lowest (4.3 and 7, respectively). The combined means for all domains pretest (5.4) and posttest (7.9) are displayed in Figure 99.1.

The Competency Scale has a different number of items in each domain; the possible score (10 on each item within a domain) is converted to a percentage of the maximum. Table 99.6 provides another view of the high and low competency areas as well as the improvement before and after training.

Age, gender, enrollment status, current concentration, and prior employment with older adults were not significantly related to skill competency at pre- or posttest. However, educational level at pretest was significantly related to skill competency ($p = .002$) at pretest, with second-year MSW students scoring

higher on skill competencies than students at earlier points in their educational program. Students who took classes in aging had higher skill competencies.

The first version of the competency instrument proved useful in student's self- assessment of their geriatric skills. It provided a eudiometric tool for learning

contracts with students and for assessing changes based on self-efficacy evaluations. The first version was revised because of length and problems in item construction (i.e., double-barreled and/or ambiguous questions).

GERIATRIC SOCIAL WORK COMPETENCY SCALE, VERSION II

The revision process consisted of several steps. First, the descriptive statistics of each of the original 58 item were examined. Those items with very small range and very high mode and mean ratings at pretest were examined for similar items that displayed a greater dispersion of ratings. Similarly, items that evoked little differences in skill were examined. The Cronbach alpha, a measure of internal consistency, was used to assess the degree to which the item related to the do-

FIGURE 99.1 Mean Competencies

TOTAL COMPETENCY	53%	78%

main and the overall measurement of geriatric social work competency as defined by the scale as a whole. Items with low Cronbach alpha (under .70) were identified and scrutinized for more consistent measures.

The original instrument was then given to a small, nonrandom group of expert clinicians in the field of aging, the GSWEC field instruction coordinators, who rated themselves and provided feedback on each item’s clarity. The tracking of their suggestions plus revision based on the statistical analysis was sent to the Principal Investigators of the Hartford PPPs for consensus. A statistician specializing in instrument design for geriatric competency development provided further technical assistance.

The resulting revised version of the instrument, PPP Geriatric Social Work (GSW) Competency Scale, has 38 items versus 58 items. Four domains have approximately equal numbers of items, in contrast to Version I, which had five domains with vastly different numbers of items in each (range from 33 to 4 items). The request to evaluate oneself against the standard of a “competent geriatric social worker” is replaced with a more detailed description of the skill level rating. The time in completing the self-assessment was reduced by half.

The new instrument was piloted with a convenience sample from social workers taking continuing education unit seminars with the Boston University Institute for Geriatric Social Work. See Tables 99.7

and 99.8 for the demographic and academic descriptors of the pilot sample.

As shown in Table 99.9, the mean overall competency score is high (3.2 on a scale from 1 to 5): “This skill is done with confidence and is an integral part of my practice.” There was not a ceiling effect; few items were rated with a 4 or expert skill even for practitioners with aging experience. The high (Values, Ethics, and Theoretical Perspectives) and the low (Aging Services, Programs, and Policies) domains of skills for the practicing social workers were the same as for the students. Table 99.10 converts the ratings into percentages and by doing this conveys the low overall skill assessment of practitioners participating in the training.

When the scores were converted to possible points in each domain, there was no ceiling effect and the relative highs and lows were the same as for the previous scale. The research and evaluation questions were incorporated into domain IV. The instrument is provided as Appendix 99.1; this second version of the PPP Geriatric Social Work Competency Scale is identical to the version piloted except for two changes: (1) The scale was reduced to a 0 to 4 instead of a 1 to 5 measurement, with 0 (previously 1) described as “Not skilled at all”; (2) the second change came from a review of the PPP Geriatric Social Work Competency Scale in relationship to the CSWE SAGE-SW competencies by the National Center for Gerontological Social Work Education, resulting in the addition of two competencies and a 40-item instrument.

DISCUSSION AND IMPLICATIONS

Competency-based evaluation of educational outcomes is one aspect of the movement toward best practices in geriatrics. CSWE/SAGE-SW identified competencies that have been related to social work curricula (Greene & Galambos, 2002; Rosen, Zlotnik, & Singer, 2002). PPP has measured self-efficacy with regard to specific geriatric social work skills relevant to the field (Damron-Rodriguez et al., n.d.). The PPP Geriatric Social Work Competency Scale was designed as a pre-posttest to measure the effect of the PPP’s innovative field education on the skills of graduate students who specialize in aging. It can also be used for educational planning after pretest administration for setting educational goals and has been adopted by the National Center for Gerontological Social Work Education for this purpose. Both scales are able to reflect variation in skill level.

A limitation of this CBE research is the small sample size, even for a pooled national evaluation. In addition, the evaluation was of graduate students with a stated interest in aging and in an enriched field placement. Use of the instrument with a group of students at different educational levels or generalist versus specialist in orientation has not been systematically studied. However, some sites in the CSWE Geriatric Enrichment in Social Work Education project have used the instrument for measuring outcomes from aging infusion projects (Browne, Braun, Mokuau, & McLaughlin, 2002). They found a significantly positive relationship between taking courses in aging and skill level.

In terms of next steps, collaboration with and learning from other professions as they move toward geriatric competency measurement will be beneficial (American Geriatrics Society, 2000). In addition to developing more behaviorally oriented competence measurement methods (Bogo, 2002), future work

will involve linking knowledge, conceptual thinking, and theory from the classroom with skill development in the field and in practice (Reishch & Jarman-Rhode, 2000).

- 1 = Beginning skill (I have to consciously work at this skill)
- 2 = Moderate skill (This skill is becoming more integrated in my practice)
- 3 = Advanced skill (This skill is done with confidence and is an integral part of my practice)
- 4 = Expert skill (I complete this skill with sufficient mastery to teach others)

APPENDIX

**HARTFORD PRACTICUM
PARTNERSHIP PROGRAM
GERIATRIC SOCIAL WORK
COMPETENCY SCALE**

0	1	2	3	4
→				
Not skilled at all	Beginning skill	Moderate skill	Advanced skill	Expert skill

The following is a listing of *skills* recognized by gerontological social workers as important to MSW graduates effectively working with and on behalf of older adults and their families. Please use the scale below to thoughtfully rate your current skill:

0 = Not skilled at all (I have no experience with this skill)

Please add any comments and/or suggestions regarding the skills in each section.

NOTE

Research and program models described in this chapter were funded by a grant from The John A. Hartford Foundation of New York City. The author wishes to acknowl-

I. Values, Ethics, and Theoretical Perspectives (Knowledge and value base, which is applied through skills/competencies)

Skill Level (0–4)

1. Assess and address values and biases regarding aging.	_____
2. Respect and promote older adult clients' right to dignity and self-determination.	_____
3. Apply ethical principles to <i>decisions</i> on behalf of all older clients with special attention to those who have limited decisional capacity.	_____
4. Respect diversity among older adult clients, families, and professionals (e.g., class, race, ethnicity, gender, and sexual orientation).	_____
5. Address the cultural, spiritual, and ethnic values and beliefs of older adults and families.	_____
6. Relate concepts and theories of aging to social work practice (e.g., cohorts, normal aging, life course perspective).	_____
7. Relate social work perspectives and related theories to practice with older adults (e.g., person-in-environment, social justice).	_____
8. Identify issues related to losses, changes, and transitions over their life cycle in designing interventions.	_____
9. Support persons and families dealing with end-of-life issues related to dying, death, and bereavement.	_____
10. Understand the perspective and values of social work in relation to working effectively with other disciplines in geriatric interdisciplinary practice.	_____

Comments _____

(continued)

<i>II. Assessment</i>	<i>Skill Level (0–4)</i>
1. Use empathy and sensitive interviewing skills to engage older clients in identifying their strengths and problems.	_____
2. Adapt interviewing methods to potential sensory, language, and cognitive limitations of the older adult.	_____
3. Conduct a comprehensive geriatric assessment (biopsychosocial evaluation).	_____
4. Ascertain health status and assess physical functioning (e.g., ADLs and IADLs) of older clients.	_____
5. Assess cognitive functioning and mental health status of older clients (e.g., depression, dementia).	_____
6. Assess social functioning (e.g., social skills, social activity level) and social support of older clients.	_____
7. Assess caregivers' needs and level of stress.	_____
8. Administer and interpret standardized assessment and diagnostic tools that are appropriate for use with older adults (e.g., depression scale, Mini-Mental Status Exam).	_____
9. Develop clear, timely, and appropriate service plans with measurable objectives for older adults.	_____
10. Reevaluate and adjust service plans for older adults on a continuing basis.	_____
Comments _____	

<i>III. Intervention</i>	<i>Skill Level (0–4)</i>
1. Establish rapport and maintain an effective working relationship with older adults and family members.	_____
2. Enhance the coping capacities and mental health of older persons through a variety of therapy modalities (e.g., supportive, psychodynamic).	_____
3. Utilize group interventions with older adults and their families (e.g., bereavement groups, reminiscence groups).	_____
4. Mediate situations with angry or hostile older adults and/or family members.	_____
5. Assist caregivers to reduce their stress levels and maintain their own mental and physical health.	_____
6. Provide social work case management to link elders and their families to resources and services.	_____
7. Use educational strategies to provide older persons and their families with information related to wellness and disease management (e.g., Alzheimer's disease, end-of-life care).	_____
8. Apply skills in termination in work with older adults and their families.	_____
9. Advocate on behalf of clients with agencies and other professionals to help elders obtain quality services.	_____
10. Adhere to laws and public policies related to older adults (e.g., elder abuse reporting, legal guardianship, advance directives).	_____
Comments _____	

<i>IV. Aging Services, Programs, and Policies</i>	<i>Skill Level (0–4)</i>
1. Provide outreach to older adults and their families to ensure appropriate use of the service continuum.	_____
2. Adapt organizational policy, procedures, and resources to facilitate the provision of services to diverse older adults and their family caregivers.	_____
3. Identify and develop strategies to address service gaps, fragmentation, discrimination, and barriers that impact older persons.	_____

(continued)

<i>IV. Aging Services, Programs, and Policies (continued)</i>	<i>Skill Level (0–4)</i>
4. Include older adults in planning and designing programs.	_____
5. Develop program budgets that take into account diverse sources of financial support for the older population.	_____
6. Evaluate the effectiveness of practice and programs in achieving intended outcomes for older adults.	_____
7. Apply evaluation and research findings to improve practice and program outcomes.	_____
8. Advocate and organize with the service providers, community organizations, policymakers, and the public to meet the needs and issues of a growing aging population.	_____
9. Identify the availability of resources and resource systems for older adults and their families.	_____
10. Assess and address any negative impacts of social and health care policies on practice with historically disadvantaged populations.	_____
Comments _____

Credentialing Opportunities for Social Workers in Aging

100

This chapter discusses credentialing for social workers with older adults, with an emphasis on care management, as it is the only possible current credentialing opportunity addressing social work with older adults and their families. Following an overview of credentialing is a discussion of the case management knowledge and skills needed to provide services for a growing number of older persons and their families. Social work with older adults, especially with those who are frail and at risk, has become more complex in recent years because of fragmented health and social welfare policies, programs, and services, problematic legal and financial structures, and shrinking public resources. Given this, effective case management skills are critical.

Social workers who work with older adults are present in virtually every long-term care and human services setting and sector and often act as, or call themselves, case or care managers. There is no universal consensus about the definition or distinction between these terms. Many variations and models have evolved over the years to target specific purposes, groups, and settings utilizing the core tasks of case management: assessment care planning, implementation, and monitoring. It is because of the variations in practice and the imprecise use of the terms and their meanings that the question of credentialing surfaces.

Outside of the public sector, social work and nursing are the predominant disciplines among professional case managers working with older adults, yet many who hold these positions have little or no training related to either aging or case management. Accordingly, social workers with training, experience, and certification in case management with older adults are at a premium. Given the generalist training and perspective provided by social work education, a question addressed in this chapter is whether social workers need to be specifically trained and certified to serve the aging population.

CREDENTIALING

Credentialing of human services professionals through licensing or certification is not new. Laws regulating licensing, registration, or statutory credentialing for social work practice have existed since 1964 in every state in the United States as well as the District of Columbia, Puerto Rico, and the U.S. Virgin Islands. These laws control who can practice social work, what services social workers can provide, and which titles social workers can present to the public. A credential

is evidence that a practitioner has met minimum standards to provide services to the public.

Another type of credentialing in social work is not a regulation established by law but voluntary certification programs developed by professional organizations. They typically require the applicant to meet the legal regulation requirements of the state as a condition of certification in a specialty area of social work. Licensing or registration establishes the minimum criteria for entry into professional practice, whereas voluntary certification regulates specialty areas of practice.

The development of licensing and other forms of credentialing is relatively recent in social work compared to other professions. At the same time that legal regulation for social work was being debated in California and other states, the newly formed National Association for Social Work (NASW; <http://www.naswdc.org/credentials/specialty/c-swcm.asp>) proposed a certification program for social work practice called the Academy of Certified Social Workers (ACSW). Adopted in 1960, the ACSW became the benchmark of practice certification for practitioners with a master's degree in social work.

NASW SPECIALTY CERTIFICATION

In 1998, NASW conducted a survey of its membership on the subject of certification. Respondents clearly identified the need for—and a strong level of interest in—the establishment of a national certification program in areas of social work specialization. The implementation of NASW's certification program is based on the assumption that certification provides the following benefits for members in today's competitive workplace:

- Enhanced professional and public recognition.
- Increased visibility as specialized social workers.
- Association with a select group of specialized social workers who have attained national distinction.

NASW's credentialing center has more than 20 years of experience developing credentials and certifications for social workers. Its specialty certifications, available to degreed social workers only, provide a vehicle for recognizing social workers who have met national standards and have specialized knowledge, skills, and experience. The NASW is committed to assisting with the process of certifying social workers and working to emphasize the importance of em-

ploying social workers who have specialized training and experience. Although these specialty certifications provide recognition to those who have met national standards for higher levels of experience and knowledge, they are not substitutes for state licenses.

Over the years, the number of credentials to certify specializations has increased and focus on a particular population or a specific type of practice approach or program. Certifications currently available through NASW are in health care; children, youth, and family; alcohol, tobacco, and drugs; school; and case management. The case manager certification, designated C-SWCM (Certified Social Work Case Manager), is of special interest to this chapter. NASW also offers an advanced certificate in case management, the C-ASWCM. To acquire the C-SWCM, social workers must provide evidence of the following:

- Current NASW membership.
- A BSW degree from an institution accredited by the Council on Social Work Education.
- One year and 1,500 hours of paid, supervised, post-BSW work experience.
- An evaluation from an approved supervisor.
- A reference from a BSW or MSW colleague.
- A current BSW-level license or credential.

In addition, candidates must agree to adhere to the NASW Code of Ethics, the NASW Standards for Social Work Case Management, and the NASW Standards for Continuing Professional Education, which are subject to the NASW adjudication process.

Why did NASW create a certification in case management when other sources of certification already exist? NASW members report that many social workers are being required by their employers to become certified in case management by a national professional association. Various settings that are establishing these requirements include large hospital systems, branches of the military, and managed care companies. Because a number of the case management tasks and functions have historically been at the core of social work practice, many NASW members prefer to hold a certification from their own national professional social work association instead of applying for a multidisciplinary case management certification that is not based in social work.

SOCIAL WORK CASE MANAGEMENT

As early as 1992, NASW developed standards for social work case management. As part of the standards,

the following definition of social work case management was formulated:

Social work case management is defined as a method of providing services whereby a professional social worker assesses the needs of the client and the client's family when appropriate. The case manager arranges, coordinates, monitors, evaluates, and advocates for a package of multiple services to meet the specific client's complex needs. Distinct from other forms of case management, social work case management addresses the individual client's biopsychosocial status as well as the program or system in which case management operates. Intervention occurs at both the client and systems levels. (NASW, 1992, p. 5)

Social work case management requires the social worker to develop and maintain a multifaceted relationship with the client. This may include linking the client with systems that provide him or her with needed services, resources, and opportunities and providing the emotional support to enable and facilitate utilization of these services. The social work case manager has the ability to coordinate these different needs with solutions, provide the therapeutic environment to facilitate acceptance of support and assistance, and follow up with monitoring and reassessment activities. Social work case management services may be located in a single agency or across several agencies and settings.

Social work training is especially well suited to case management. The understanding of relationships, family dynamics, human growth and development, as well as broader policy and service systems is fundamental to social work tasks and activities. The combination of macro and micro perspectives distinctive to social work education also supports a case management orientation. Austin and McClelland (1996, p. 258) note the compatibility of social work and case management, stating that "the roles and skills represented in case management clearly represent the *in vivo* application of many long-standing conceptualizations of social work practice: the person-in-environment perspective, the social-interactionist orientation, the systems basis of generalist practice and the social ecological framework."

To date, case management is not considered a profession; it is, instead, a method or approach that is utilized throughout the entire continuum of care, crossing settings, disciplines, populations, providers, communities, and funding streams. Not surprisingly,

every human services profession claims a role in inventing it (White, 2005, p. 202). Social workers often argue that they have been "doing case management" for more than 100 years. Although many of the tasks are, indeed, similar to social work, there are a few distinguishing characteristics. These include an emphasis on coordinating rather than providing direct services and, as noted by Dill (2001, p. 5), "the focus on service episodes and changes in client needs." Dill also points to the multiple objectives case managers attempt to achieve for both the client and the service system (pp. 5–6). Woodside and McClam (2003, p. 293) discuss the themes and challenges case managers face, including "large caseloads, clients with multiple needs, and scarce resources. In addition, they often work with clients who are silent, reluctant, or resistant in a bureaucracy that requires detailed documentation for each interaction."

Case managers must also attend to administrative goals such as utilization and costs of services (Scharlach, Guinta, & Mills-Dick, 2001, p. 8). They often work in restrictive circumstances, without adequate information or resources. To this point, Weissert, Hirth, Chernew, Diwan, and Kim (2003, p. 803) state, "Case managers face a daunting task: They . . . must make up for all the failing of the policies and systems within which they work. They must compensate for inadequate information and work within a variety of limitations."

OTHER CASE MANAGEMENT CERTIFICATION OPTIONS

In addition to the NASW Social Work Case Management Certification, credentialing can be obtained through some 20 other professional case management sources. This section highlights the development of two such opportunities, through the National Academy of Certified Case Managers and the Commission for Case Manager Certification.

An important project set the stage for development of a certification effort and the establishment of the National Academy of Certified Care Managers. This was an attempt to develop national standards for case management. Instead, the 1-year project, funded by a Robert Wood Johnson Foundation grant, resulted in *Guidelines for Case Management Practice Across the Long-Term Care Continuum* (Geron & Chassler, 1994). The guidelines were formulated by a group of 11 case management experts, including social workers, nurses, and researchers. Although now more than 10

years old, the *Guidelines* continue to serve as a foundation for practice, training, and service development in community-based and long-term care case management. Five principles of case management serve as a framework for the development of these guidelines. It is important to note their compatibility and congruence with social work tenets and practice:

1. Respects consumers' rights, values, and preferences.
2. Coordinates all and any type of assistance to meet identified consumer needs.
3. Requires clinical skills and competencies.
4. Promotes the quality of services provided.
5. Strives to use resources efficiently.

The same year these principles were published, the newly established National Academy of Certified Care Managers (NACCM; www.naccm.net) utilized them as the foundation for the development of a certification exam that focused on the primary functions of case management as testing domains:

- Assess and identify consumer strengths, needs, concerns, and preferences.
- Establish goals and a plan of care.
- Coordinate and link formal and informal services and resources.
- Manage and monitor the ongoing provision of and need for care.
- Attend to legal, professional, and ethical issues.

The exam was developed under a strict process that involved several hundred professional case managers across the country and a professional testing company. The exam has since been administered to hundreds of experienced case managers from various disciplines, including social workers. NACCM's founding board consisted primarily of social workers and nurses working with older adults. Although not strictly geriatric, the emphasis of the exam questions is on older adults.

The establishment of NACCM was based on several felt needs (Bartelstone, 1999):

- Consumer protection: With the rapid proliferation of case managers, certification can assist consumers and service providers in making a choice when seeking qualified practitioners.
- Multiple parent professions: Case management is not a profession and is performed by individuals from many disciplines. Certification of experience

in, and knowledge of, core functions, tasks, and activities define the case manager.

- Need to establish standards: Exam development for certification purposes requires agreement on tasks, activities, and competency that form at least minimal standards.
- Advance the approach: As more individuals become interested in credentialing, the need for a body of knowledge, education and training, and research will increase.
- Self-regulation: There is no licensing or regulation of case management practice outside of specific professions (e.g., licensed clinical social worker). Certification promotes accountability and provides validation.
- Insurance and liability issues: An increasing number of insurance companies now require some form of case management credentialing for professional liability coverage.

Although a number of case management credentials were already available in the 1990s, they were heavily focused on licensed medical and health care professionals. Both social workers and nurses working with older adults in community-based and long-term care settings recognized the need for certification for professionals with a biopsychosocial background. NASW had not yet developed its case management credential; thus, NACCM offered an opportunity for this type of credential. NACCM offers the Care Manager Certified (CMC) to those qualified individuals who pass the examination. Eligibility requirements include a bachelor's or master's degree with 2 or 4 years, respectively, of full-time supervised care management work as defined by the Academy. This certification validates the core knowledge and skills of the experienced care manager (see www.naccm.net). Individuals from a variety of disciplines and settings have earned their CMC and work in diverse community-based, long-term care, and private practice settings.

COMMISSION FOR CASE MANAGER CERTIFICATION

The Commission for Case Manager Certification (CCMC; <http://www.ccmcertification.org/download/Application.pdf>) oversees the administration of the CCM designation to individuals who meet their requirements and pass their examination. The CCMC has the largest number of certified case managers in the country, primarily in nursing, rehabilitation, and

health care but also in social work. According to the Commission’s Web site, an applicant must be able to perform all six essential activities of case management: assessment, coordination, planning, monitoring, implementation, and evaluation in multiple environments in five of six core components:

1. Processes and relationships.
2. Health care management.
3. Community resources and support.
4. Services delivery.
5. Psychosocial interventions.
6. Rehabilitation case management.

Candidates must have a master’s degree, be licensed in their area of educational specialization, and meet practice standards (see www.ccmcertification.org; Table 100.1). CCMs work in a variety of settings and serve all populations. The certification is increasingly recognized and preferred by health care and rehabilitation organizations.

CASE MANAGEMENT WITH OLDER ADULTS

In the early 1990s, a number of professional associations and organizations developed standards for the practice of case management specifically in health and aging. These include the American Nursing Association, the National Council on Aging, the National Association for Professional Geriatric Care Managers, and the NASW (Bartelstone & White, 2001). As noted, efforts to hold case managers to those standards through a variety of credentialing activities and organizations emerged, including the Case Management Society of America and the NACCM. In the late 1990s, NASW established its own case management credential for social workers. To date, more than 20 organi-

zations confer certification in case management, most of them in the medical and rehabilitation fields.

Case management, a formal, systematic approach to serving older adults, encompasses identifying problems, developing plans to address them, coordinating the planned services, and following up to ensure effectiveness. It became popular in the late 1970s with the rise of publicly funded, community-based programs for older adults and other populations with long-term disabilities. This movement was not unique to the United States; case management models were developing in other parts of the world as well (Geron, 2000).

In the United States, case management with elders grew dramatically during the 1980s when, in an effort to decrease nursing home costs, states were given the opportunity to apply for waivers from Medicaid to provide alternatives to institutionalization for low-income individuals 65 and over eligible for placement. The private practice and nonprofit sectors broadened the scope of case management by providing the service for a set fee or on a sliding-scale basis.

Credentialing of Social Work Case Management With Older Adults

The authors contend that social workers should have special expertise to perform specific functions such as case management with older adults. The fact that social workers are typically educated to work with the continuum of individual life stages, family dynamics, community organizations, and larger systems may or may not qualify them as geriatric care/case managers. Hackstaff, Davis, and Katz (2004), in their description of a Kaiser Permanente project that integrates behavior change theory into their care management program, emphasize both the level and importance of social work skills in working with a geriatric popula-

TABLE 100.1. Examples of Minimum Requirements for Case Management Certification

Bachelor’s Degree	BSW	No	Yes
Master’s Degree	No	Yes	No
Professional License	No	Yes	No
Experience	1 yr/1,500 hrs	Not stated	4 yrs full-time
Case Management Focus	Social work rehabilitation	Health/medical/long-term care	Community

tion, especially frail, at-risk elders. The theoretical grounding of social work combined with the broader case management functions has proven to be particularly effective in developing an intervention with this vulnerable patient group (Hackstaff et al., 2004).

On the other hand, an AARP study found that “many [care managers] are licensed . . . social workers, but these licenses do not necessarily guarantee an ability to address a client’s financial or legal questions or provide comprehensive knowledge of all service options” (Stone, 2002, n.p.). As the number and proportion of older adults explodes, many social workers are finding themselves without adequate training to deal effectively and professionally with an aging society. Scharlach, Damron-Rodriguez, Robinson, and Feldman (2000, p. 525) have described the need for social workers with gerontological knowledge and skills as “desperate.” The need for specialized geriatric training is not unique to social work. A recent study of psychologists whose practice includes at least some older adults found that fewer than 30% had any training in geropsychology and fewer than 20% had participated in an internship or practicum including older adults (American Psychological Association, 2004).

Several other indicators point to the importance of knowledge specific to working with the geriatric population. The California Board of Behavioral Science Examiners, for instance, now requires aging content for continuing education credits. The University of Florida has developed an online geriatric case management program. Other universities are considering similar offerings. Opportunities for dual degrees between programs in social work and gerontology are increasing. Sessions on case management are featured at most health, aging, and social work national meetings and conferences. NASW has also developed an Aging Specialty Practice Section designed to provide content expertise and inform members about current trends and policy issues that impact social work practice and service delivery in the field of aging.

Given these developments, the authors conclude that there is a case for social work certification with an aging emphasis, especially utilizing case management process and functions with the most vulnerable segment of the older population. There are a number of reasons that credentialing as an aging specialist is beneficial:

- The complexity of issues for aging individuals, family, and other caregivers.
- A growing preference by employers.
- Consumer demand.

- Insurance company liability requirements.
- Competition with other disciplines.

Two case examples are used to illustrate social work’s case management role in addressing complex client situations.

A case manager in a community senior services settings is working with Mrs. M.

■ Mrs. M is an 83-year-old, widowed female who lives alone. At the suggestion of Mrs. M’s doctor, her daughter contacted me. Mrs. M has early-stage dementia. The physician has notified the Department of Motor Vehicles, so Mrs. M is no longer driving.

The physician and the daughter were concerned about Mrs. M’s ability to care for herself. The daughter arranged for Mrs. M to move to an assisted living facility near her, but the day of the move, Mrs. M refused to go. Mrs. M’s daughter visited her mother weekly to provide marketing, meal preparation, transportation, and house cleaning, but this arrangement was clearly overwhelming and the daughter’s upcoming surgery would make her unavailable to her mother.

It became clear that Mrs. M was not taking her medication and was not eating regularly. After several failed attempts to schedule an in-home visit with Mrs. M, I contacted Adult Protective Service to intervene. Working closely with the APS worker and the daughter, I developed an intervention. The APS worker notified Mrs. M that she was not safe living alone and needed to move to a designated assisted living facility for a 1-week period and would then be reassessed. Mrs. M reluctantly agreed to the temporary move and her daughter transported her that day. In a follow-up telephone call to the daughter, Mrs. M had made a remarkable adjustment to the facility. She is involved in a number of activities and, according to her daughter, is “a new woman.” (From J. Rosenblum, Center for Healthy Aging, Santa Monica, CA) ■

Another example comes from a social work case manager in a physician’s office:

■ The phone rings and Mr. D wants to see me immediately. When he arrives, he gives me a

stack of medical bills and explanation of benefits and says, "Help. What do I do with all these bills?" Mr. D's wife, who had been the one that managed the household and the bills, died 1 year ago. Now Mr. D must try to figure out the medical bills for his mentally disabled daughter, and he is struggling. He became so upset that he cancelled her supplemental insurance and is now not sure he should have done so.

We go through the bills one by one and I divide them up. When he leaves, he will need to call the providers of the service and give them the correct insurance information. I talk to him about having help paying the bills and dealing with the insurance. He is agreeable. I make a referral to get him the help and to get together some financial information to see if his daughter might qualify for QMB (a federal program that pays his daughter's Medicare premium and also functions as supplemental insurance). In the interval, I suggest he try to get his daughter back on the HMO he just cancelled. (From R. Felder, Council for Jewish Elderly, Chicago) ■

Both cases illustrate the need for a wide range of skills and knowledge, including working with family members, physicians, and other providers such as adult protective services; understanding dementia and associated issues of care, insurance, and medical issues; knowledge of local resources such as residential facilities and money management services; and support for and problem solving with family members.

Based on interest, aging will be the next certification to be developed by NASW. This will occur by convening a national work group of seven experts from across the country who will look at criteria that the group feels is essential. They will send these recommendations to the NASW Competence and Certification Commission, which will then develop written criteria for eligibility.

CONCLUSION

Social workers with training and expertise working with older adults and their families are critical in institutional, health care, and home- and community-based settings. Empirical evidence from the social work literature shows that social workers who practice along the continuum of care are effective in ad-

ressing many problems related to aging, such as relieving depression and stress, increasing well-being and effective coping, and coordinating or providing support networks for both older adults and caregivers. In addition, there is some indication that interventions by social workers help delay or prevent nursing home admissions and reduce health care costs (Rizzo, 2003).

As the population ages, the demand for social workers who have the knowledge and skills to serve older adults effectively will increase. Credentialing and/or certification will be a critical factor in demonstrating the viability of social work's role in service delivery and quality of care. It is not a simple solution or conclusion, but like everything else in this complicated yet meaningful arena of social work and aging, credentialing and certification need to be reevaluated over time. The authors look forward to the profession's attempt to address these issues.
