In the 1960s, the temporary employment industry flourished, as the benefits accorded to companies utilizing interim help dovetailed with favorable market conditions on the whole to exponentially increase the industry's revenues. Aside from the personnel flexibility that temporary employees provided, client companies also profited from reductions in unemployment compensation costs, the creation of investment tax credits, and an increase in consumer spending. Although hiring a temporary worker generally cost more per hour than hiring a permanent employee, savings were realized by not having to pay for fringe benefits, which typically averaged 30 percent of an employee's total wage. Also, the use of temporary labor could dramatically reduce the amount of unemployment tax a particular company was forced to pay. Companies are taxed a certain percentage of their total payroll for unemployment compensation, the amount of which is determined by the layoff record of a particular company. For example, if a company hires additional staff to meet increased production demands and subsequently releases those employees, then the company's compensation percentage is increased. By using temporary employees, however, companies can still respond to various business cycles, but their unemployment compensation percentage is not affected, because temporary employees are not considered part of the regular workforce.

Benefiting from these advantages that temporary employment gave to businesses of all types, the industry's participants thrived during the 1960s. The bulk of the industry's growth, however, occurred after 1963 into the late 1960s. The industry's ascension was attributable, in part, to the diminished labor force of the nation as a whole. Unemployment dropped during the middle of the decade due to the overall health of the nation's business

community and government programs specifically designed to winnow unemployment levels. Additionally, the Vietnam War began to drain an appreciable portion of the country's workforce while at the same time infusing more money into the economy. The effect of these circumstances tightened the nation's labor supply, which improved the temporary employment industry's position. Growing at a 25 to 30 percent annual rate, the industry's leading companies, those founded in the early 1950s, helped push the industry's revenues to \$500 million by 1967, more than twice the amount recorded four years earlier.

By the beginning of the 1970s, however, the industry's growth had slowed. Geographic expansion had fueled, in large part, the growth of the industry, with small, independent companies sprouting up in cities bereft of temporary employment companies and the larger, national companies opening offices at a rapid rate. Concurrent with the near saturation of the sundry temporary employment markets, the nation's economy soured in late 1969, causing the temporary employment industry, for the first time, to falter. Lacking new markets to move into, companies involved in the industry were left with no way to offset the slackening demand for their services, and the industry, consequently, suffered a decline in revenues.

The damage to the industry, however, was only short-lived and the effects negligible, as temporary employment companies in their recovery demonstrated a characteristic unique to the industry—as general economic conditions worsened, the temporary employment industry's position improved. When the economic downturn of 1969 and 1970 developed into a full-fledged recession in the early and mid-1970s, businesses began to lay off workers to combat soaring inflation and depressed business activity. While personnel managers reexamined staffing needs, sometimes discharging too many workers, or discovering certain positions did not warrant full-time employment, temporary employees were often sought to fill particular employment gaps, which helped mitigate the awkward process of arriving at an efficient number of employees. Moreover, the difficult financial conditions forced individuals that voluntarily excluded themselves from the nation's workforce, housewives in particular, to seek part-time, temporary employment. Buoyed by these depressed economic conditions, temporary employment companies began to focus on broadening the range of services they provided to other industries. Because geographic expansion could no longer be relied on to stimulate sales, companies began concentrating on recruiting professional temporaries and specially trained laborers.

The result of these changes, both outside and within the industry, protected, to a large extent, temporary employment companies from the pernicious economic con-

ditions affecting the rest of the nation. In 1974, while many industries struggled to generate profits, the approximately 2,000 companies involved in the temporary employment industry recorded more than \$1 billion in revenues. However, the deleterious financial conditions did take their toll on the industry; total temporary payroll, for example, dropped 18.3 percent in 1975, but the industry demonstrated an ability to quickly recover from a downturn. The industry by this time supplied nearly 3 percent of the nation's total labor force, with Manpower alone drawing from a reservoir of 500,000 temporary workers.

Throughout the remainder of the decade, the industry's sales growth rate was somewhat less than the prolific pace enjoyed during the 1960s, but it was still an enviable 10 to 15 percent. By 1978, the industry employed roughly 2.5 million temporary employees for 500,000 customers and had annual revenues in excess of \$1.5 billion. By the late 1970s, 8 of 10 American companies used temporary employees to fill an assortment of positions, including such markets as health care, corporate management, marketing, and science—although secretarial and clerical business still accounted for 70 percent of the industry's placements. The movement away from using temporary workers only in emergency situations had gained momentum since the late 1950s, accounting for 40 percent of the industry's business in the late 1970s compared to the 90 percent figure that once represented the use of temporary employees in earlier panic situations.

By the early 1980s, the temporary employment industry was the third-fastest growing industry in the country. Revenues eclipsed \$5.1 billion in 1982, while more than 90 percent of American companies used temporary workers on a regular basis. Despite, or perhaps due to, this pervasive presence in the nation's business community, recessive conditions struck the industry once again in the early 1980s. However, at this time the industry was insulated by the diversity of services it offered, and temporary payroll fell by only 1 percent.

By the mid-1980s, temporary employees filled more than 700,000 jobs a week, considerably more than the 470,000 per week recorded in 1983. According to the National Association of Temporary and Staffing Services (NATSS, later renamed the American Staffing Association), the number of temporary employees on any given day in 1995 was over two million. Low initial investment coupled with the tremendous success the industry had enjoyed over the past 40 years continued to attract more and more competition, raising the specter of market overcapacity, but the bulk of the recent additions to the industry consisted of small, one-office operations, only serving customers in close proximity. By 1985, there were 2,300 companies engaged in the industry, operating nearly 7,500 offices, up from the 2,000 companies and

5,000 offices in existence three years earlier. Ten years later, in 1995, more than 16,000 help supply offices were operating in this industry nationwide.

Revenues mushroomed throughout the mid-1980s, nearly tripling from 1982's volume to more than \$15 billion in 1987, as other industries increased their use of temporary employees with specialized skills. This trend led not only to significant increases in sales, but also widened the profit margin earned by temporary employment companies. From 1986 to 1989, the industry recorded an annual growth rate of 18 percent and stood, by the beginning of the 1990s, as an industry inseparably woven into the employment structures of an overwhelming majority of American businesses. Between 1990 and 1993, the industry experienced a 25 percent increase in growth. And, in the one-year period between 1994 and 1995, temporary help receipts rose by 12.9 percent.

According to the observations of one economist, a rise or decline of 50,000 temporary employees usually augurs a parallel shift of roughly one million permanent, or payroll, employees a month or two later. This portentous characteristic of the industry became apparent once again in the late 1980s and early 1990s as a global recession quaked the foundations of a majority of industries. Temporary employee placements peaked in 1988 at slightly over one million, remaining flat through 1989, then rebounded in 1990, becoming for client companies an effective way to combat vacillating production demands. During the ensuing months of the recession, while other industries floundered, the industry fared comparatively well. The industrial component of the industry demonstrated particularly strong growth, with daily temporary placements for manufacturing positions rising from 224,000 in early 1992 to 348,000 by the end of the year.

As temporary employment companies charted their course toward the mid-1990s, the dynamics of the industry were changing, echoing the changing relationship between employers and employees in general that was prompted by mounting global competition and the concerted push for more efficiency in the American workplace. Increased pressures on American businesses to assiduously monitor expenditures persuaded many companies to reexamine their personnel needs in the wake of the recession of the early 1990s. As a result of this introspection, business operations were streamlined nationwide, leaving a considerable number of companies with reduced payrolls and convincing some observers of the national economy to prognosticate that the focus on efficiency and trend toward smaller staffs may not be just a temporary answer for depressed economic conditions but may reflect a permanent shift in management philosophy. Manufacturers, for example, once produced an excess of goods, holding the surplus in storage or building

up sizeable inventories, but after the deleterious economic climate of the early 1990s, they preferred to manufacture products only when quantifiable demand could be measured.

In 1998 the help supply industry generated more than \$80 billion in revenues, according to Census Bureau statistics. Quarterly agency surveys by the American Staffing Association suggest that of that amount, about \$58.7 billion, or 73 percent, came from temporary staffing services. The rest came from employee leasing services, which involve longer-term co-employer contracts and other minor staffing-related activities. In 1999 the temporary segment was estimated at \$64.3 billion, a 9.5 percent gain over the year before, and temporary staffing revenue was expected to climb another 8 percent in 2000.

Looking further ahead, a number of observers expected continued, albeit slower, growth for the industry in the early 2000s. In its 10-year projections published in 1999, the Bureau of Labor Statistics predicted the broader personnel supply services industry, which includes help supply as well as executive recruitment and other forms of employment agencies, to expand by 43 percent between 1998 and 2008. By the end of the period, the industry group is expected to employ a total of 4.62 million people, up from 3.23 million in 1998.

In the late 1990s the industry went through a spell of significant consolidation. Mergers and acquisitions were fueled in part by slowing growth in the overall market, but also by two strategic trends. For one, large clients seek single-vendor relationships with comprehensive service providers that can fill niches that formerly several different agencies might have. Second, with labor in tight supply and companies increasingly doing business across international borders, large international temp agencies can better meet the needs of multinational firms by having access to labor pools in many different places.

Part of the shift toward providing integrated, comprehensive services has been the growth of so-called vendor-on-premises (VOP) services. Under these arrangements, staffing agencies provide management or coordination staff and other resources at the customer's worksite. Used primarily in large contracts, VOP services ease the administrative burden of using temps for the customer and can make the agency more responsive to the client's needs—the agency assumes some of the risk in the deal. Although the practice is not necessarily more profitable for staffing agencies, it is part of the industry's strategic thrust toward providing more value-added and comprehensive solutions to customers' needs. It also makes staffing agencies more important when the job market is tight, as it was in the late 1990s, because they are serving additional functions besides simply finding enough bodies to meet the customer's quota. Customer reactions have been largely favorable.

VOP services have been around for a while, but they became much more prevalent from the mid-1990s on. From 1994 to 1999, the number of U.S. workplaces using VOP programs more than quadrupled, reaching 4,500 in 1999. Revenues associated with such sites using VOP rose accordingly, from \$2 billion to approximately \$8.8 billion (those figures include the salaries of all the temps placed at a VOP site). At that level, VOP programs were linked to about 13.5 percent of total U.S. temporary staffing revenues as of 1999.

CURRENT CONDITIONS

In 2001, revenues in the temporary help services industry totaled \$56 billion, down 12 percent from \$64 billion in 2000. Permanent place revenues declined some 25 percent to nearly \$10 billion in 2001. All told, staffing industry annual revenues in 2001 dropped 14 percent from the previous year to \$66 billion. Temporary staffing agencies employed 9.6 million people in 2001, with an average of 2.18 million temporary and contract employees working on an average day that year. Average daily employment dropped 14 percent from 2000—when a record 2.54 million temporary employees worked on an average day—and the lowest number since 1996. Some agencies estimated job placement requests have declined up to 25 percent. Turnover among temporary employees decreased in 2001 to 341 percent from 418 percent in 2000, with temporary workers finding increased competition for a smaller number of full-time positions. The average length of employment in 2001 was 11.8 weeks, up from 10 weeks the previous year.

The temporary help services industry was faced with the worst market it had seen in years. With massive layoffs and a recession in the early 2000s, there were fewer positions and more qualified workers looking for jobs. In such a climate, employers had the luxury of waiting to find an ideal candidate, rather than just a qualified, available one. Employers also contacted several agencies looking for the best candidate at the lowest price. The increasing competition among agencies for fewer positions caused many temp firms to cut costs, including lowering markup rates on employees. The focus also shifted from recruiting new employees to attracting and maintaining clients.

INDUSTRY LEADERS

Two of the industry's founders, Manpower Inc. and Kelly Services Inc., helped spark interest in the use of temporary employees by businesses both domestic and foreign. These companies pioneered many of the industry's developments in service and maintained consistent growth throughout the industry's history.

Manpower. Initially more aggressive than Kelly, Manpower rapidly expanded during the 1950s through

company-owned offices and through its franchise program. Manpower set the tone for the industry's future by supplying industrial temporaries in its first year of operation and then diversifying its services later to include salespeople. By the early 1960s, Manpower had established a technical division to provide architects, engineers, and draftsmen to its clients and operated more than 300 offices. At this point in the company's history, three of every four offices were franchise operations, bringing total revenues to \$56.8 million in 1963, with 159,500 temporary workers on its payroll serving 105,000 customers.

Four years later, Manpower opened its 500th office and served 160,000 customers with 270,000 temporary employees. Its international presence by this time had greatly increased, and now included 100 offices located in Europe, Asia, South America, Australia, Mexico, and Canada. To further capitalize on its foreign involvement, Manpower created its "Push Button Global Service" program that enabled traveling businesspersons to be met by a secretary or interpreter on arrival in a foreign city.

By the early 1970s, Manpower had established a considerable lead in the industry, with temporary employment offices in 31 countries. The company's Paris office was the largest of its offices and the heart of its total global presence. Domestically, Manpower had created an assortment of programs to train temporary employees for particular jobs and catered to a diverse clientele, supplying workers trained in marketing, data processing, and a variety of other skilled and unskilled occupations.

Toward the end of the 1970s, Manpower created a petroleum division to supply gas-pumping attendants for approximately 700 service stations in the United States. Through its 750 worldwide offices, the company generated \$383 million in revenues in 1977, more than twice as much as its nearest competitor, Kelly Services. By the mid-1980s, with revenues totaling \$1.5 billion, Manpower continued to increase its presence domestically and internationally, operating 650 offices in the United States and 450 offices abroad. In 2002, Manpower operated 3,900 offices in more than 60 countries. As of that year, the company recorded a 1.2 percent annual gain in revenue, making \$10.6 billion worldwide. Net income fell 9.4 percent that year, with \$113 million.

Kelly Services. Slower to diversify its services than Manpower, Kelly Services initially supplied only one type of temporary employee—female office workers. By the early 1960s, however, Kelly Services, originally Kelly Girl Service Inc., had begun a pilot program of providing male temporaries for industrial jobs. The company was also slower in establishing additional offices, especially in international markets, taking until the early 1960s to even consider foreign expansion, and then did so only on a limited scale in Canada. Despite these differ-

ences, Kelly Services' revenues roughly approximated Manpower's revenues throughout the 1950s and 1960s, the first full decades both companies were in operation. By the close of the 1960s, Kelly Services had nearly 300 offices in operation, a majority of which were franchises like Manpower, and had annual revenues of nearly \$80 million.

The company eventually broadened its line of temporary employees, establishing marketing, labor, and technical divisions within its operations during the 1960s; and by the early 1970s, Kelly supplied a selection of temporary workers as diverse as Manpower's. Its clerical workers, still the company's specialty, were trained in 125 skill classifications, blanketing the full spectrum of office and clerical temporary needs, one of which was supplying businesses with data processing workers.

In the late 1970s, Kelly Services, with annual revenues hovering around \$160 million, branched out into the health care field, supplying licensed practical nurses and hospital orderlies on a temporary basis. This foray into providing temporary health care workers proved to be a lucrative and prudent move by Kelly Services, enabling the company to carve a niche in a market that would become a boon for temporary employment companies in the 1980s and early 1990s. The company continued acquiring smaller providers throughout the 1990s, including a number in Europe, where it also aggressively opened its own branches in the late 1990s. By 2002 Kelly supported 2,400 offices in 26 countries. Kelly Services had revenues of \$4.3 billion in 2002, marking a 1.6 percent rise, while net income grew 12.7 percent to \$18.6 million.

WORKFORCE

In 2001 the temporary employment industry employed an average of 2.18 million people on any given day. According to U.S. Bureau of Labor statistics from the mid-1990s, secretaries and general office clerks were the most widely employed temporary workers at that time, with each representing 8.7 percent of the total temporary employment labor force. Typists and word processors trailed closely, composing 8.4 percent of the industry total, whereas the fourth largest category of temporary employees were industrial workers classified as helpers, laborers, and material movers, which accounted for 7.9 percent.

Wages were generally lower for temporary employees than for permanent workers. In 1996, the median weekly earnings for temporary employees were \$295 compared to \$416 for permanent workers. Benefits were offered less frequently to temporary employees. Only 20 percent of temporary workers had employer-provided health insurance, whereas more than 60 percent of permanent workers enjoyed this benefit. In 1995, however,

between 33 percent and 41 percent of all companies including help supply firms offered access to some form of benefits. Temporary employees, on the whole, are most likely to be female, African American, young, and enrolled in school.

AMERICA AND THE WORLD

Since the genesis of the modern temporary employment industry following World War II, American temporary employment companies have maintained a strong presence in international markets. Manpower Inc., the first U.S. company to aggressively pursue foreign business, paved the way for other industry participants to follow, leading to a broad global representation of American temporary employment companies in the 1990s.

The business today is thoroughly internationalized. All the major U.S. firms have extensive operations in other countries, particularly Europe, which is the second-largest regional market for staffing services behind the United States.

Particularly in the wake of mergers in the mid- and late 1990s, European firms rank alongside U.S. agencies in terms of size and global reach. Indeed, the world's largest staffing agency as of the late 1990s was Switzerland-based Adecco S.A., which was the product of several key mergers and acquisitions. In the late 1990s Adecco obtained 30 percent of its revenue from North America, and that proportion was expected to rise because of its purchase of some U.S.-based Olsten Corp. staffing units in 2000.

In 2001, Kelly Services and Nissokosan of Japan partnered, exchanging marketing and sales staff. The companies plan to implement internships for Japanese students at U.S. companies as Kelly provides Japanese companies with U.S. engineers and researchers.

SIC 7371

COMPUTER PROGRAMMING SERVICES

This industry consists of establishments primarily engaged in providing computer programming services on a contract or fee basis. Establishments of this industry perform a variety of additional services, such as computer software design and analysis; modification of software; and training in the use of custom software. Mass-produced software development is discussed under **SIC 7372: Prepackaged Software**.

NAICS CODE(S)

541511 (Custom Computer Programming Services)

INDUSTRY SNAPSHOT

According to the U.S. Census Bureau, the custom programming services industry achieved revenues of more than \$69 billion in 2000, making it one of the largest segments of the broader information technology (IT) services sector. Though it receives much less attention than the packaged software segment, custom software development is usually somewhat larger in terms of annual revenues.

The industry grew rapidly during the 1990s, as businesses upgraded and expanded their computer systems. Although annual growth was uneven from 1990 to 1998, ranging from as low as 6.8 percent in 1992 to more than 28 percent in 1998, the industry’s gross receipts climbed during the period at a compound average of 13.6 percent a year, based on U.S. Census Bureau data. However, the surge in the late 1990s was fueled in part by one-time Year 2000 (Y2K) compliance services, Web-enabled applications, e-commerce, and the overall dot-com craze.

Although U.S. Census Bureau figures for 2001 were not yet available in early 2003, preventing specific year-to-year comparisons, a number of reports indicate that the custom software design industry was struggling in the early 2000s, along with the larger IT industry. These difficult times were due to a slack economy and a decrease in technology spending within the corporate sector. According to estimates from research firm IDC, after a record 2.3 percent drop in 2002, overall technology spending was expected to improve in 2003, rising nearly 6 percent. IDC revealed that the IT services cate-

gory was hit especially hard in 2002, and that weak spending in the software category would likely continue into 2003. Other research organizations, including the Aberdeen Group, forecast more modest worldwide IT spending increases (4 percent).

ORGANIZATION AND STRUCTURE

Among the industry’s top players, such as IBM and EDS, custom programming services are only one of a multitude of IT services offered, ranging from consulting and training to systems integration and facilities management. Indeed, the broader IT services industry has increasingly evolved toward a one-stop solution model, where a single contractor provides a comprehensive set of computer services to its clients. As such, many non-government statistical sources, and often the companies themselves, do not separate custom programming from these other activities.

Custom programming services are used primarily as an alternative to using packaged software unmodified and hiring in-house programming staff to write custom software. The first use is noteworthy as a reminder that packaged software is often modified by third-party vendors for specific businesses; not all custom software work begins from scratch. The second use highlights that the industry is closely associated with outsourcing technical functions. In fact, it is sometimes described as the IT outsourcing industry.

A separate and popular way for companies to obtain programming services without committing to maintaining an in-house staff of programmers is to contract for leased or temporary programmers and consultants. Several large national agencies have special units devoted to placing experienced technical workers. However, unless the contracting firm is itself a programming services provider, such activities are considered outside the scope of this industry.

A variety of trade and professional organizations represent the industry. Among others, the National Association of Computer Consultant Businesses (NACCB) and Independent Computer Consultants Association (ICCA) have members involved in contract programming. These trade associations represent their members in different ways. NACCB, headquartered in Washington, D.C., lobbies government officials on behalf of member businesses. ICCA is based in St. Louis and offers certification exams. Successful completion of a computerized test allows a member to be designated a Certified Computing Professional.

BACKGROUND AND DEVELOPMENT

As computer systems became commonplace in businesses and other organizations, the need for custom programming and other computer programming services

increased. From the 1950s through the 1980s technology made huge leaps forward. Computer programmers were difficult to find in the early years, so many companies did not bother to hire them. By the late 1980s and early 1990s, very sophisticated computer equipment needed equally sophisticated code to handle growing amounts of information at rapidly increasing speeds.

Computer service companies were originally hired to automate record-keeping tasks, such as payroll. Later, they expanded into customer-related areas, such as fund transfer systems, just-in-time inventory systems, and customer information systems. Many companies could only hire these service firms in the best of financial times—given the high cost of the services. Early programming was highly customized, but the needs of businesses by the 1990s necessitated more standardization.

Computer programming companies grew in part by presenting themselves as a cost-saving alternative to in-house programming departments. According to the prevailing logic, they were specialists and could save corporations money by programming systems and software on a contract basis. Although there has been the occasional backlash against service firms when their clients are not satisfied with the outside service's performance—sometimes spurring the disgruntled customer to bring the project back in-house—custom programming services are still widely seen as being more cost-efficient than internal development.

Revenues from custom programming and related services grew swiftly during the late 1990s, as businesses sought higher levels of automation and efficiency, greater control over internal and external information, and the ability to conduct business transactions electronically, particularly over the Internet. From 1990 to 1998, industry revenues more than tripled from \$21 billion to \$64 billion, according to government statistics, yielding a 13.6 percent compound annual growth rate.

The Census Bureau estimated that in the late 1990s more than 32,000 U.S. establishments provided custom programming services as their primary line of business. The lion's share—more than 95 percent—had fewer than 50 employees. Those figures did not include firms that offer custom programming as secondary activities.

In the late 1990s, the industry enjoyed a surge in business related to Year 2000 (Y2K) computer conversion. The entire process, which involved checking and modifying software to ensure it would work properly after the date change, cost businesses worldwide anywhere from \$280 billion to \$600 billion by various estimates. Only part of that money went for programming, though, as a great deal was also spent on other preparedness measures, such as keeping extra staff and special supplies on hand in the event of a major crash. Although

January 1, 2000, proved an uneventful day for most computer systems—provoking sharp criticism of computer consultants who some believe overstated the risks—residual spending on Y2K problems was expected to total another \$20 billion during 2000.

CURRENT CONDITIONS

Census Bureau data suggests that the industry's revenues increased more than 16 percent between 1999 and 2000, reaching \$69.4 billion. However, as the economy weakened, these overall numbers likely decreased considerably in 2001 and 2002. Despite an overall decline, it is worth noting that industry players fared differently depending on their area of programming specialty. For example, according to *Weekly Corporate Growth Report*, research firm Gartner indicated that some portions of the custom software industry, including companies concentrating on Internet software, suffered declines of up to 30 percent. Those in the database management field fared much better, with decreases closer to 2 percent. Other firms, such as those offering security software, actually were able to achieve growth in a difficult economic climate, with revenue increases of more than 12 percent.

Information released in the June 2002 *IT Services Business Report* indicates that U.S. IT service revenues in the system integration category, which included firms engaged in application development and management, were expected to increase 3 percent in 2002 to \$116 billion, and 9 percent in 2003 to \$126 billion. Although these figures include more than just custom programming service revenues, they serve to illustrate the industry's expected recovery in the early 2000s.

By 2000 the Census Bureau reported that industry firms typically brought in around 58 percent of their gross revenues from programming services; the rest came from activities classified under other industries. This percentage was somewhat lower in comparison to late 1990s levels, which were closer to 75 percent.

Traditional custom-developed applications and utilities continue to face rising competition from packaged software, which has grown more powerful, flexible, and cost-efficient, particularly since the mid-1990s. Indeed, some package vendors, including SAP and Oracle, have increasingly tooled their high-end applications like enterprise resource planning (ERP) suites to enable relatively fast customization. Such packages come with a range of standard functions, as well as a development environment that allows individual businesses—usually mid- to large-sized ones—to adapt the software to their own needs and existing systems. SAP, for example, has been at the forefront of working with customers to build hybrid applications that are in large part custom, but then are generalized and resold to other customers with similar needs. In effect, customers enjoy benefits of custom-

ization without as many costs and uncertainties as with all-out custom development.

Some believe the emerging application service provider (ASP) model, where businesses rent software applications over the Internet instead of installing and running them on their own machines, will further change the competitive dynamic in the custom software business. Under this scenario, ASPs may well go beyond hosting and maintaining software, and actually perform customization for individual clients. Depending how this plays out, it could spell either an opportunity or a threat to the conventional custom programming industry. By 2002 ASPs were achieving much success with Web native applications. IDC indicated that e-marketplaces represented an especially lucrative market for ASPs. The company forecast spending on Web native ASPs would reach \$1.5 billion by 2006, increasing significantly from \$200 million in 2001.

In 2003 so-called "Web services" were an especially hot area of the custom software market. In this scenario, programmers used a number of standards to enable communication between different Web-based applications. The ultimate goal of Web services was to enable universal system communications within or between organizations. In an article by Roy Schulte, research firm Gartner predicted that the emergence of Web services would "affect application design, many types of software products and even the nature of business-to-business value-added networks."

INDUSTRY LEADERS

Custom programming services are furnished by a diverse group of companies, including several multinational firms that provide a comprehensive set of IT services to large businesses and government agencies. Some of the biggest include IBM Corp., Electronic Data Systems Corp., and Computer Sciences Corp.

On the second tier is a collection of service vendors that focus on national or regional customers, and often on a more limited range of systems and technologies. Examples of companies in this group include American Management Systems, Inc.; Accenture, Ltd.; Analysts International Corp.; Ciber, Inc.; Keane, Inc.; and MPS Group, Inc.

WORKFORCE

In recent years the U.S. labor market for programmers and others with IT skills has been exceptionally tight. Acute demand for high-tech employees has led to worker shortages, aggressive recruitment of foreign workers, and rising salaries for individuals with highly sought skills. Software engineers (or programmers) represent a major occupational group within the industry. In 2001 approximately 361,660 application software engineers were employed in the United States, making an

average of \$72,370 per year. Working in systems software were 261,520 engineers, earning an average annual salary of \$74,490.

Professionals employed by computer programming firms often receive ongoing education and training in new technologies. More programmers are needed in software maintenance than in software development, and these maintenance programmers must be familiar with many types of hardware and software. They need to understand Internet and networking technology, and to be flexible enough to work as development programmers. Many employers are interested in technical staff that not only has a strong understanding of prevailing languages and technologies in their field, but also are willing to quickly develop new skills, as corporate needs change. Programmers with broad training and in-depth knowledge of several fields have the greatest potential for success.

Computer services jobs are predominately white-collar positions. Unlike workers in telecommunications equipment, who are more likely to find jobs as precision workers, computer services workers are more likely to work as professionals, technicians, or managers.

AMERICA AND THE WORLD

The United States is a leader in computer programming, as well as in other computer professional services. Because of the U.S. high-tech worker shortage, however, the U.S. industry has grown more dependent on skilled contract workers overseas to keep pace with the steep demand for IT services. (The shortage has also spurred U.S.-based IT services companies to lobby for higher immigration rates of technically skilled workers into the United States.) Non-U.S. programmers often earn somewhat less than their U.S. counterparts and, according to some studies, are more productive, making international labor at times more cost-efficient. Important international labor markets for U.S. firms include India, Ireland, and Israel.

Computer professional services such as programming were encouraged by the passage of the North American Free Trade Agreement (NAFTA) and the expansion of the General Agreement on Tariffs and Trade (GATT). The U.S.-Canada Free Trade Agreement of 1989 led some U.S. computer services companies to expand into other markets by buying Canadian firms. Some U.S. companies also had subsidiaries in South America and Europe.

Custom programming remains an area of vigorous cross-border trade. Most international trade in computer services is realized through affiliate organizations based in the target market. Despite their historically lopsided market advantage, U.S. firms face stiff competition from foreign companies, particularly those located in Western Europe and Japan.

SIC 7372

PREPACKAGED SOFTWARE

This industry classification covers establishments primarily engaged in the design, development, and production of prepackaged computer software. Important products include operating, utility, and application programs. Establishments of this industry may also engage in services such as preparation of software documentation, installation of software, and training users in the use of software. Businesses primarily engaged in preparing software documentation or installing software on a contract or fee basis are classified under **SIC 7379: Com-**

puter Related Services, Not Elsewhere Classified. Businesses primarily engaged in training users in the use of computer software are classified in **SIC 8243: Data Processing Schools.** Those primarily engaged in buying and selling prepackaged software are classified in trade industries; those offering custom computer programming services are classified under **SIC 7371: Computer Programming Services;** those developing custom computer integrated systems are classified in **SIC 7373: Computer Integrated Systems Design.**

INDUSTRY SNAPSHOT

The packaged software industry is a key growth engine in the information economy—and the U.S. economy in general. After roaring through the latter half of the 1990s with annual growth rates of 15 percent, this rapid pace began to slow down in late 2000. In 2001 a worsening economy was exacerbated by the terrorist attacks of September 11, 2001. Together these conditions translated into an environment of uncertainty and reduced technology spending in the corporate sector that continued through 2002, at which time industry revenues were approximately \$150 billion. Although International Data Corp. (IDC) expected a more favorable overall information technology (IT) climate in 2003, the company forecast weak spending on software. However, Value Line predicted that spending on software and services would rise 7 percent in 2003, followed by slightly stronger growth during the following three years.

Factors Influencing Growth. Software demand has risen steadily, as computer hardware and software innovations have improved business productivity and information management. Sales of desktop computers and higher-end hardware directly fuel new demand for packaged software. Strong PC shipments, for instance, create a fertile market for standard desktop software packages like operating systems and productivity suites.

New product categories, especially ones aimed at the business market, can also stimulate brisk growth. Emerging business software categories include Web-based service applications companies can customize to meet their individual needs, as well as supply chain management, customer relationship management (CRM), sales force automation, knowledge management, security, and e-commerce suites.

Meanwhile, version upgrades drive repeat sales. Microsoft's release of Windows 2000, the most comprehensive overhaul of the operating system since 1995, ushered in a new wave of upgrade sales, particularly by corporate users. In addition, Microsoft changed the way it

markets volume licenses (a significant source of its revenue) to companies in 2001 in an effort to simplify the upgrade process and generate more sales in this area.

New Delivery and Pricing Options. The most fundamental changes in the software industry, however, will be how and when end users obtain new software—and under what pricing terms.

Software for rent, delivered by so-called application service providers (ASPs) over the Internet, poses a serious challenge to conventional software distribution and pricing. Instead of buying a static version of a program to run on their own computers, users log onto network-based applications that reside on the ASP's hardware. This means the current version is always on tap, and users are not saddled with installation and maintenance chores. What's more, rather than paying a fixed license cost, users pay either a flat monthly fee or a per-use fee. By some estimates, renting can save 20 percent or more over conventional licensing. These savings can be found not only in less money and time put into owning the software itself, but also in reduced or eliminated costs of buying and maintaining servers to run network applications. By 2002 the ASP market had still not blossomed, as some analysts had expected. However, according to Standard & Poor's, IDC predicted revenues in this sector would climb from a mere \$1 billion in 2000 to an estimated \$24 billion by 2005.

ORGANIZATION AND STRUCTURE

Software Categories. Packaged software is a major segment of the broader software industry, which also includes custom software development and systems integration services. The term "packaged" is thus in contrast to customized software. It is typically mass-produced with standard functionalities that are expected to work across a given class of computers, such as PCs running Windows XP or network servers running Unix. Some high-end business software straddles the packaged and custom classifications; it comes with standard functions and interfaces, but requires customization for a particular company's needs.

From a functional standpoint, there are three basic types of software:

- operating systems software, which controls how a computer operates;
- applications software, such as word processing or spreadsheet programs; and
- utility software, designed to perform support tasks for operating systems or applications.

Many software companies sell products in each of these categories.

Software Markets. In broadest terms, the software industry serves two markets, consumers and businesses.

There's some overlap, though, particularly between consumers and small, home-based businesses. Productivity suites and operating systems, for example, are common to both homes and businesses.

The U.S. consumer market represents less than 10 percent of industry sales. Important subcategories within it include operating systems, financial and tax applications, games (including ones for game consoles like Microsoft's Xbox, Nintendo's GameBoy, and Sony's Playstation), educational software, and virus detection utilities.

Much larger and more fragmented, the business market is the software industry's bread and butter. Aside from the ubiquitous desktop operating systems and productivity packages, business software includes categories such as:

- application development software
- systems management utilities
- network operating systems and utilities
- database management systems
- storage management systems
- workgroup applications (groupware)
- function-oriented applications for areas such as finance, sales, manufacturing, logistics, and human resources

Leading vendors in these areas include BMC Software, Computer Associates, IBM, Oracle, PeopleSoft, and SAP.

BACKGROUND AND DEVELOPMENT

The packaged software industry has its origins in a 1969 U.S. Justice Department settlement that forced IBM to sell software for its mainframe computers separately from the hardware. IBM had included basic software with the computer, and additional programming was generally done in-house. With this decision, individual entrepreneurs were finally able to compete with IBM. Small software companies sprang up, usually to offer a single program or utility. Most mainframe software was leased, however, rather than sold.

Early Products Flourish. The rise of the packaged software industry was a direct result of the appetite for software for personal computers. PCs got off the ground in the late 1970s, as computer enthusiasts bought machines by Apple Computer, Inc., Tandy Corporation, Atari, and Commodore. Software publishers such as Microsoft emerged to write programming languages for them, and soon these languages were being sold to the public through retail outlets. By the end of 1979, Microsoft had already sold one million copies of its version of the BASIC programming language. Primitive spreadsheets and other applications began to appear as well, all of them created by small, relatively unknown companies.

At this stage packaged software was something of a cottage industry, with programs often written by individuals at home in their spare time. Because authoring software requires little equipment, people who wrote software programs risked only their own time and stood to gain \$200,000 to \$1 million if the program proved successful, as perhaps 1 percent were, as *Forbes* reported in 1983. These small companies were encouraged by hardware manufacturers, particularly Apple, because software innovations helped sell hardware.

Considered revolutionary, Visicalc, the first spreadsheet for microcomputers, was introduced in 1979. Visicalc's popularity sold many Apple computers and raised the public awareness level of PCs in general.

In 1981 IBM introduced its version of the personal computer and chose Microsoft's DOS as its standard operating system. Other hardware manufacturers, with the notable exception of Apple, began making their hardware compatible with the IBM system, providing standardization for the industry. Standardization meant that software running on one manufacturer's equipment would run on all with minimal modification.

IBM's prestige also changed the image of the PC in the business world from that of a toy to that of serious equipment, and sales of software and hardware rose accordingly. In 1980 some 300,000 people owned microcomputers; by 1983 nearly ten times that number did.

More than 21,000 PC software packages were available by 1983. Packaged software had garnered about \$2.7 billion worth of retail sales a year as early as 1981, and the industry grew at a rate of nearly 50 percent a year. Given this record of tremendous growth, the packaged software industry and PCs began to attract a great deal of attention from the press and investors, and a number of successful software firms soon went public. Over \$180 million in venture capital was raised by about 90 software firms in 1983, and 20 firms went public. As the computer hardware business became less profitable, many investors switched to software companies.

By the end of 1983, some 500,000 copies of MS-DOS had been sold, carrying Microsoft's annual sales to \$69 million. Other software publishers picked up steam as well. Lotus Development Corporation introduced its 1-2-3 spreadsheet in 1983 and was immediately successful; some businesses even bought computer hardware just so they could run the Lotus software. Software houses that had been tiny entities only a few years earlier racked up huge sales.

One of the most frequent complaints about early software was that it was too hard to use. Making software easier to use became an important goal. A defining advance came in 1984, when Apple introduced the Macintosh. It was the first popular system to employ a graphical

user interface (GUI), a computing environment that relies heavily on images and visual tasks rather than text-based commands and keywords to control the computer. Apple also issued rules for companies writing Macintosh software to ensure all software for Apple systems would look and behave similarly.

Microsoft followed in 1985 with its first release of Windows, a GUI that ran on top of MS-DOS. Early versions were slow and cumbersome; sales were poor. Microsoft worked to upgrade Windows, but it and IBM also began work on an operating system to replace the aging DOS. Called OS/2, the new operating system was envisioned as a more powerful graphical interface than Windows. Other software developers began adapting their applications for OS/2, but few of these versions were ready by the time OS/2 was released at the end of 1987. Initial reviews and sales of OS/2 were disappointing. By the mid-1990s IBM all but abandoned OS/2, as Windows grew firmly entrenched as the dominant PC operating system, commanding as much as 90 percent market share.

Competition Mounts. With sales of PC software booming, software developers quickly branched into new markets and ratcheted up competition. It became much harder to launch new companies on a shoestring. Prices fell wherever similar programs existed, while the cost of marketing new software rose dramatically. VisiCorp, which had introduced Visicalc in 1978 on a \$500 budget, spent more than \$10 million by 1984 developing its VisiOn computing environment.

Meanwhile, competition mounted as software packages for spreadsheets, word processing, databases, and graphics proliferated. Software companies escalated the competitive frenzy by offering discounts as well as upgrade and trade-in deals. To make switching brands easier, software publishers introduced conversion utilities that could read competitors' file formats. Some even offered on-screen tutorials specifically aimed at migrating users from a competitor's program, as when Microsoft Word added special help screens tailored for WordPerfect users.

Competition also led to a price war—the first in an industry that had been largely immune to serious pricing battles. Some observers groused that prices of individual productivity applications, which could easily reach \$500 per user, were exorbitant. Packaged software prices were also hard to justify given the falling prices of computer hardware; no one wanted to spend \$500 on an application for a \$1,000 computer. Discounting, often tied to attempts to win over customers from competitors' programs, resulted in savings of as much as 80 percent off a package's list price. Larger publishers like Lotus and Microsoft also introduced collections of three or four

programs, known as suites, at a much lower per-unit price. Some industry analysts took the price war as a sign that the packaged software business was beginning to mature.

Businesses Connect. As corporations invested in personal computers instead of mainframes and minicomputers, methods for linking computers to share information became increasingly important. Packaged software could often be shared only when the computers all ran the same operating system, but businesses often wanted to link computers that used different operating systems. This forced software companies to make heavy use of consultants and, sometimes, to design custom solutions. Networking forced software firms accustomed to mass production of software to pay increasing attention to service. As market growth for PC software slowed to 15 percent by 1990, down from 40 percent in 1988, network applications, which run on network servers and facilitate sharing of storage space and resources such as network printers, also provided a new and lucrative niche for software publishers.

Until the mid-1990s, Novell, Inc.'s NetWare dominated the PC networking market without close rival. However, as elsewhere, Microsoft began edging market share away from Novell with its 1993 launch of Windows NT. Windows NT gained ground quickly by having the power of Microsoft's immense marketing engine behind it, by integrating easily with other Microsoft products, and by embracing innovations and new technologies. For example, Microsoft beat Novell by almost a year in adding Internet technology and a World Wide Web server to its network platform.

Alternatives to Windows. Tight integration with its ubiquitous DOS and Windows operating systems, and aggressive marketing and distribution tactics enabled Microsoft to dominate the applications and operating-system market, but other firms cast about for ways to break that hold.

IBM tried with OS/2 and failed. In a separate effort, Apple and IBM announced in 1991 an alliance to create the next-generation operating system, running on newer, more powerful hardware. Dubbed the PowerPC, the move was an attempt to win market share from Microsoft, but also had potential to finally unite the IBM and Apple platforms. IBM floundered, however, and delayed promoting the product and developing software for it. This left its future almost entirely in Apple's hands. By the time the PowerPC was released in the mid-1990s, Apple was far too weak to compete head-on against Windows. Instead of becoming the next-generation PC, it quietly became the next-generation Macintosh.

In the meantime, Unix had proven a more viable alternative to Windows in some contexts. Originally de-

signed in the 1960s by AT&T for telecommunications networks, Unix gradually became the standard for high-powered scientific and technical computers working on networks. As workstations from Sun Microsystems and Silicon Graphics caught on in the 1980s, Unix slowly entered the mainstream. Among its strengths was the ability to run several programs simultaneously and display them on large monitors with crisp graphics. Indeed, few operating systems matched Unix's power and stability.

One disadvantage of Unix, though, was a lack of standardization. Many companies had released variations on it, and often applications written for one version did not work on another. Moreover, while a great deal of Unix software existed for science and engineering applications, few packages were available for the wider market.

In 1991 AT&T created Unix Systems Laboratories (USL) to manage the Unix operating system. The following year Novell bought USL from AT&T in a bid to take control of Unix. Another salvo in Novell's growing battle with Microsoft, the acquisition gave Novell an operating system of its own. Novell quickly moved to widen the program's appeal, trying to standardize its competing versions and link it with NetWare.

Fearing Microsoft's impending release of NT, a half dozen major Unix companies—IBM, Hewlett-Packard, Sun Microsystems, Santa Cruz Operation, USL, and Univel—agreed in 1993 on a standardization scheme. The alliance released specifications for the Unix interface and other key elements of the operating system, while allowing companies to pursue their own variations. In the months leading up to Windows NT's debut, many of these companies released new versions of Unix.

Despite such countermeasures, Windows NT enjoyed qualified success. It failed to displace Unix and other networking platforms, but developed a user base on small and medium-sized networks. The workstation version likewise generated modest sales as a more robust and stable flavor of Windows for desktop machines. By 1998 some market watchers estimated that NT was the operating system of choice on more than a third of new servers. Still, worldwide it was believed to hold less than 14 percent of the server market, where Unix versions continued to prevail.

Internet Changes Industry. While Windows NT made headway in corporate information technology (IT) departments in the mid-1990s, a vastly more visible contest emerged over the Internet. The public computer network stemmed from a 1969 project of the U.S. Defense Department, and had been used by scientists and researchers for years. The Internet gained popularity with its ease of exchanging text messages and files, and more impor-

tantly, with its expansive collection of linked graphical pages known as the World Wide Web.

It all required software. In 1994 Netscape Navigator was released as the first commercial Web browser. Developed by Marc Andreessen, a computer science undergraduate who masterminded the noncommercial Mosaic browser, Netscape was distributed mostly as a free download. This proved a shrewd tactic to gain market share and draw attention to the fledgling company's Web server products. Within a year, Netscape controlled some 80 percent of the burgeoning browser market. Other firms, including many start-ups, released software for Internet tasks like managing e-mail, browsing news groups, and authoring Web pages.

Microsoft countered Netscape in 1995 with the launch of its Internet Explorer, based primarily on licensed Mosaic code. Like Netscape, Internet Explorer was given away online and bundled free with other Microsoft programs. Widely seen as an inferior product, Explorer caught on slowly at first. Six months into its release, it held just 7 percent of the market.

Then, in a stunning feat, Microsoft reached an accord in 1996 with America Online, the largest online consumer service, to feature Internet Explorer as AOL's preferred browser. The deal surprised most observers because AOL already had an alliance with Netscape. AOL's collaboration and Microsoft's clout with PC makers helped the software giant pry its way into the browser market, claiming 20 percent at the end of 1996. It went on to capture more than 40 percent by late 1998, when, in another unexpected turn, AOL agreed to buy Netscape.

Elsewhere in the industry, Internet functions were increasingly integrated into many types of applications. On the simplest level, developers made common programs like word processors and spreadsheets more Internet friendly by allowing Web content to be imported and exported. More profoundly, heavy-duty corporate packages like databases and enterprise applications were infused with e-commerce capabilities.

In the late 1990s, enterprise resource planning (ERP) software—used by large companies to integrate diverse business functions like finance, logistics, and human resources, under a common, powerful, Internet-enabled interface—was one of the fastest-growing industry categories. These packages improved corporate information management and provided timely, high-level, organization-wide information for top management. However, in 1999 ERP sales faltered. Growth that year slipped to 12.5 percent, an otherwise healthy level for many industries, while individual companies' revenues and profits sank well below expectation. Some observers pronounced ERP dead. That was premature, but ERP, despite its promise, was notorious for long, problematic implemen-

tation cycles before executives could bask in the real-time corporate intelligence these systems were supposed to deliver. Fears about computer glitches in the change-over to the year 2000 only aggravated ERP's problems. By the early 2000s, this category was still relatively strong, especially in the manufacturing sector. However, ERP's woes demonstrated the software market's rising aversion to uncertainty and imperfection.

CURRENT CONDITIONS

Technological advances and changing market sensibilities continue to recast this ever-changing industry. For consumer and business market alike, software publishers increasingly strive to deliver smart, integrated solutions that protect and empower users, and make them more productive—while minimizing or eliminating the hassles associated with ramping up new software applications.

Among the leading software categories in the early 2000s were security software and middleware.

Security Software. By summer 2001 revenues in the security software sector already were experiencing strong growth. According to IDC, the worldwide market for security software totaled approximately \$5 billion in 2000, a 33 percent increase from the previous year. By late 2002 security was an extremely hot topic across many industries. In the wake of the terrorist attacks that took place on September 11, 2001, and a number of subsequent, undefined threats, companies were implementing various measures to protect their electronic data and systems. IDC predicts revenues for this category could reach \$14 billion by 2005, with more than half attributed to North America. In addition to firewall applications, security software also includes encryption and antivirus programs. With more than 7,000 new viruses, Trojan horses, and worms found in 2002, these types of applications remain a necessity for computer users who share files or use the Internet.

Middleware. Middleware was an emerging software category in the early 2000s that enabled communication between a company's disparate network of computer systems. For example, some firms use middleware to enable older legacy systems for Web use, especially in the e-commerce arena. In many ways middleware works as a translator in these situations. As business processes become more and more Web centric, corporate clients turn to solutions like middleware instead of scrapping systems in which they have made significant investments over the years. Some analysts are predicting explosive growth in this category by 2005.

Application Service Providers. The Internet continues to have a major influence on the software industry. A growing number of applications being distributed via the Internet instead of through older, more traditional distri-

bution channels, impacting the industry's business model. Application service providers (ASPs) continue to represent a major shift for software buyers and sellers alike. ASPs are expected to upset the software industry's status quo by pushing software distribution and hosting to the Internet and by overturning pricing conventions. The end result: software applications, especially for business, will likely be cheaper and easier to manage.

Under the traditional model, users buy software licenses at a set price per user and install the programs, typically from CD-ROM, on their machines. Usually licenses cover only the current version; when a new version comes out, the cycle begins anew.

The shift toward ASPs is happening gradually. Microsoft, which previously derided the ASP model, served as a catalyst of sorts in 1999 when it announced guarded intentions to offer its market-leading Office suite for rent. The software giant has favored electronic distribution of conventional licenses. By 2002 ASPs were achieving much success with Web native applications, especially so-called Web services software, which companies use to facilitate communication among disparate Web-based applications. According to IDC, e-marketplaces represented an especially lucrative market for ASPs. The company forecast spending on Web native ASPs would reach \$1.5 billion by 2006, increasing significantly from \$200 million in 2001.

Linux. Beginning in the mid-1990s a swell of attention was given to the Linux operating system. It has achieved much of its popularity simply by being an alternative to Microsoft's operating systems—an alternative that undermined Microsoft's traditional closed-code licensing paradigm. Inspired by Unix, Linux is an open-source (public domain) operating system for individual PCs and network servers. As such, different Linux packages are offered by a number of vendors, and the software is inexpensive or even free. This means Linux generally is not subject to the same kinds of licensing restrictions as most commercial programs.

Although the idea of a Linux-Windows horse race may be compelling, in business settings Linux is not likely to be a full replacement for Windows. According to a study conducted by Zona Research, by the early 2000s the operating system was still being harnessed for lightweight jobs like departmental networking and low-volume Web serving. Linux performs well in these settings and can save thousands of dollars even in a small deployment. Corporate IT departments in fact have grown used to running multiple operating systems for different functions. Just as NT often proved to supplement, rather than supplant, NetWare and Unix systems, so too is Linux likely to find a place alongside one or more other operating systems in a typical company net-

work. By late 2002 a report from OneStat revealed that Linux accounted for a mere 0.26 percent of operating systems worldwide, compared to Apple (1.43 percent) and Microsoft Windows (97.46 percent).

INDUSTRY LEADERS

Although monopoly allegations have captured countless headlines, the industry as a whole is nonetheless fairly fragmented. In one of the most comprehensive studies of its kind, each year *Software Magazine* ranks the world's leading 500 software producers by their estimated software revenues (thereby excluding sales of hardware, integration services, and other nonsoftware products and services). Based on the 2002 results (calendar 2001 sales), several figures illustrate the industry's competitive breadth. Of the top 25 firms:

- Three boasted more than \$20 billion in annual software sales
- Three boasted sales between \$10 billion and \$13.3 billion
- Nineteen reported sales between \$2 billion and \$7.7 billion In addition, about 62 percent of the 500 companies listed had revenues less than \$100 million, and more than one-third reported a decline in revenue from 2000.

According to *Software Magazine*'s report, among the five largest software vendors were Microsoft Corp., IBM Corp., Electronic Data Systems Corp., Accenture Ltd., and Oracle Corp. In 2001 these producers collectively sold more than \$118 billion in software worldwide.

Below are profiles of some of these and other companies that have led various segments of the U.S. software industry either in sales or in influence.

Microsoft. The world's largest software company, Microsoft was founded in 1975 by Bill Gates and Paul Allen. The software leviathan got its first major break in 1981, when IBM chose it to supply an operating system (MS-DOS) for IBM's pathbreaking first PC. As IBM's desktop computer became accepted as the industry standard, so did Microsoft's operating system. Microsoft quickly began offering application packages as well, and became a major player in the Macintosh software market during the 1980s. Microsoft's Windows graphical interface, which partly emulated the Macintosh interface, became another standard in the IBM-compatible market, lifting the firm's sales to \$1 billion by 1990. As Microsoft shored up its applications software line, which would eventually be united under its flagship Office productivity suite, the firm grew increasingly aggressive with hardware manufacturers about licensing its software according to its exacting terms. This later became fodder for the antitrust litigation that dogged Microsoft.

Microsoft's aggressive tactics and phenomenal profit margins during the early and mid-1990s kept it lumbering forward in the software markets. The company developed a knack for neutralizing competitors through a combination of product innovations, application integration and bundling, strategic alliances, and marketing prowess.

By 1998 Microsoft had unseated IBM as the world's largest software maker and held a commanding lead in the markets for PC operating systems, desktop productivity applications, and Internet browsers, and was zeroing in on categories like software development applications, e-mail applications, and business diagramming applications. In calendar 1998 it recorded an estimated \$16.3 billion in software sales, which included a tantalizing 31 percent profit margin. For its fiscal year ending June 2002, Microsoft's corporate revenues topped \$28.4 billion, with the vast majority coming from applications and operating systems.

In spite of its being declared a de facto monopoly by the judge in its antitrust case and despite widespread rumors it would be broken up, Microsoft lunged ahead in 2000 with ambitious plans to release new versions of a few of its most popular programs, most notably its Windows 2000 upgrade, in a bid to unify its divergent Windows NT and 95/98 operating systems and stave off new competition from Linux. By late 2002, the future looked very bright for the company. In addition to a host of new products, including Windows XP, the Xbox game system, and mobile computing platforms like the Tablet PC, Microsoft finally settled its antitrust suit in November, although the company still faced government scrutiny abroad.

IBM. Historically the world's largest packaged software producer, venerable IBM fell to second place in 1998, as it redirected its strategic focus and as Microsoft's sales steamed ahead full throttle. In 2001 software represented about 15 percent, or \$12.9 billion, of the computer giant's \$85.9 billion in global revenues. Big Blue's main packaged software offerings include operating systems for its popular S/390 mainframes and AS/400 midrange systems; DB2 and IMS database management systems and other packages for transaction processing and system management (including Tivoli Systems); and groupware and desktop applications from its Lotus division, including Lotus Notes and Domino.

Oracle. Oracle Corporation, incorporated in 1977, is among the world's largest vendors of database management systems software, which is used to run high-end corporate data systems. Oracle recorded sales of \$9.7 billion in 2002, at which time its database applications were growing at an annual rate of approximately 15 percent. In this area of the software industry, IBM and Microsoft are among its database software competitors.

Oracle's products also include customer relationship management software and other large enterprise-oriented packages, where it competes with vendors such as SAP and PeopleSoft. The firm is also noteworthy for its outspoken CEO, Larry Ellison, a sharp-tongued critic of Microsoft.

Computer Associates International Inc. Computer Associates International Inc. began offering utilities for mainframes in 1976 and grew by buying programs from other software firms. In the mid-1980s it pushed into the market for PC applications software. At the beginning of the 1990s, the firm, best known for its Unicenter system management package, beefed up customer support and began implementing a plan to link different types of computer systems and allow all its programs to communicate with each other. By 2002 the company was especially focused on e-business applications. That year sales totaled almost \$3 billion, 75 percent of which was attributable to software sales.

Sun Microsystems. Best-known for its speedy workstations and low-end servers, Sun is both a sizable producer of packaged software and, since the mid-1990s, a rising force for change in the industry. Headed by Chief Executive Scott McNealy, another would-be Microsoft slayer, Sun has embarked on a multi-tiered attack on conventional industry practices.

In 1996 it introduced the Java programming language, geared toward delivering platform-independent programs and functions over the Internet. In theory this would make operating systems and even Web browsers irrelevant details because Java programs would be compatible with all kinds of systems and devices, including non-computing devices.

In a bolder foray, Sun bought Star Division in 1999, a relatively minor business productivity software vendor. The significance was this: Sun planned to distribute the Star Office suite freely over the Internet—broadside the pricing and distribution paradigm Microsoft thrived on. In the early 2000s, software represented about 20 percent of Sun's annual revenue, which totaled \$12.5 billion in 2002.

PeopleSoft. PeopleSoft is one of the top three major enterprise resource planning (ERP) vendors. ERP packages like PeopleSoft's, which came into vogue in the latter half of the 1990s, automate and integrate diverse organizational functions at large companies under a common software umbrella. Such functions might include finance and human resources, operations, and supply chain management. As corporate interest in ERP systems surged in the mid- to late 1990s, PeopleSoft's revenue more than doubled. By the early 2000s many of PeopleSoft's applications were Web based. At this time, the company was developing some applications for clients in

specific industries like education and health care. In 2001 PeopleSoft's annual revenues exceeded \$2 billion.

Compuware. Software testing and implementation are Compuware's specialty, as it offers applications to assist developers of high-end applications in mainframe and client/server environments. Compuware's core products help software developers identify errors and debug software, but it also provides software for high-end file and data management. The firm has capitalized on recent trends in the high-end corporate market by positioning its products as complements to large companies' deployment of ERP and e-commerce applications. The company's revenues more than doubled between fiscal years 1996 and 1998, and by 2002 totaled \$1.73 billion.

Adobe Systems Inc. Adobe Systems Inc. is a leading provider of desktop graphics and document publishing software. Among its best-known titles are Illustrator, PhotoShop, and PageMaker, which supported overall 2001 sales of \$1.2 billion. Adobe is also known for its ubiquitous Acrobat Reader, which displays and prints highly formatted documents, and its PageMill Web authoring suite. In 1999 Adobe launched a major new desktop publishing title, In Design, aimed squarely at the high-end market dominated by Quark Inc.'s QuarkXpress.

WORKFORCE

The packaged software industry's vibrant growth has demanded a steady influx of new employees. Indeed, industry employment nearly tripled during the 1990s. On average, according to government figures, the industry boosted its labor ranks by about 12 percent each year from 1990 to 1999.

Software engineers (or programmers) represent a major occupational group within the industry. In 2001 approximately 361,660 application software engineers were employed in the United States, making an average of \$72,370 per year. Working in systems software were 261,520 engineers, earning an average annual salary of \$74,490. Other major occupational groups in the software industry include project/product managers, graphic designers, technical writers and editors, and technical support staff. In addition to its regular employees, the industry also relies heavily on contract programmers and technical consultants, whose work may be classified under other industries for statistical purposes.

The industry's fast expansion, coupled with a tight labor market, has also yielded above average compensation for many of its workers, who tend to be highly skilled and educated. Still, pay varies considerably by workers' experience and skills, as well as by what kind of company they work for.

In addition to financial compensation, employees at publicly traded software companies, especially small

firms, may also receive shares of company stock or stock options as compensation. This practice is famous for making young and relatively low-level employees wealthy, if the firm does well in the stock market. Well-funded start-ups may likewise offer more generous salaries to attract top talent from established outfits, whereas large companies tend to splurge more on benefits packages, on-site amenities, and other kinds of perks.

Working conditions for programmers and other industry employees are generally good. Because they require concentration do to their jobs, most programmers work in quiet office settings and work alone. However, as in other professions, programmers are working increasingly out of their homes. The hours at some firms are the traditional nine-to-five, but from its earliest days, the software industry has been known for its long hours.

SIC 7373

COMPUTER INTEGRATED SYSTEMS DESIGN

Establishments in this industry are primarily engaged in developing or modifying computer software and packaging or bundling the software with purchased computer hardware—computers and computer peripheral equipment—to create and market an integrated system for a specific application. Establishments in this industry must provide each of the following services: the development or modification of the computer software; the marketing of purchased computer hardware; and involvement in all phases of systems development from design through installation. Establishments primarily engaged in selling computer hardware are classified in **SIC 5045: Computers and Computer Peripheral Equipment and Software**, and **SIC 5734: Computer and Computer Software Stores**; those manufacturing computers and computer peripheral equipment are classified in **SIC 3570: Computer and Office Equipment**.

NAICS CODE(S)

541512 (Computer Systems Design Services)

INDUSTRY SNAPSHOT

Spurred by e-commerce development and other trends, systems integration revenues grew more than 13 percent each year during the late 1990s. According to the latest data available from the U.S. Census Bureau in early 2003, revenues totaled \$87.8 billion in 2000. However, in 2001 and 2002 systems integrators were victims of a weak economy and related reductions in corporate spending that affected virtually every sector of the information technology (IT) industry—especially service providers. Although IDC, a world leader in IT industry analysis, estimated that overall technology spending would improve in 2003 by some 6 percent—following an unpre-

cedented fall (2.3 percent) in 2002. The research firm predicted a somewhat slower recovery for software spending, which affects the integration industry.

Roughly 48 percent of the industry's revenues in 2000 were specifically attributable to integrated systems design services, while the remainder came from things like computer programming and systems management services. E-commerce integration, which involves linking Internet-based data and applications with corporate databases and other non-Internet applications, has been one of the fastest-growing segments of the systems integration industry. Other growth drivers in recent years have included corporate migration to large enterprise application environments like enterprise resource planning (ERP) and supply-chain management (SCM) systems, mergers and acquisitions that require marrying the separate data systems of the merged entity, and the ongoing need to share business data and applications across diverse platforms and software environments.

ORGANIZATION AND STRUCTURE

Once a company identifies the specific design, operational, or management functions it wants its information system to perform—and the level of that performance—a systems integrator creates a system to meet those objectives. Systems integration services combine expertise in hardware, software, and communications to deliver complete information systems, including their design and development, the management of vendor contracts, the purchase of equipment and its technical integration, the implementation of the system, and any training necessary for the company to run its new or modified system.

The Information Technology Association of America, a trade group for the computer hardware and services industries, used the following analogy to explain systems integration: "In construction industry terms, the systems integrator would compare to the general contractor who interfaces with the electrician, the plumber, the mason, and any other trades that are necessary for the job, and who may undertake part of the task (for example, the role of architect). In systems integration, this general or 'prime' contractor responsibility may be assumed by an outside vendor or by the user, who may also wish to provide some of the core skills."

Integration services are, in practice, commonly offered as part of a broader package of services, many of which are not considered integration. These activities range from consulting to application development to system management. Indeed, few, if any, large systems integrators practice integration exclusively.

Companies wishing to establish or upgrade an information system turn to systems integrators for a variety of reasons. In an industry where knowledge about computers is not central to the business—such as health care,

insurance, automobile manufacturing, and numerous others—engaging the services of a systems integrator gives companies access to cutting-edge skills and technologies. Having a single contract with a systems integrator, rather than separate contracts with numerous separate vendors, gives companies a fixed price and delivery date for an entire system and assurance that the system will meet their stated needs. In addition, the integrator protects the user from problems that are typical when engaging multiple vendors—including incompatible platforms, interfacing difficulties, and contract loopholes.

Like most computer service industries, systems integration has attracted many entrepreneurs. In the past, relatively little capital was needed, compared to the computer hardware industry. Agreements with equipment manufacturers for the products to be placed in the system are made on a current-period basis. Cash outlays increase as contracts increase; there is no need to manufacture anything in anticipation of growth. The majority of the investment is made in highly specialized staff with experience in several complex fields—systems and applications software, hardware, telecommunications products, and networks. In addition, experts are needed to oversee the entire process and work with customers. When selling a service, marketing also proves an important component in the structure of the business.

Systems integration companies generally grow geographically at first, simply providing their service to a wider range of customers. Because profits do not need to be invested in increased manufacturing or in research and development, systems integration companies generate a positive cash flow more easily than manufacturers. Cash flow makes acquisitions a common method of expansion, particularly into new service fields. Many systems integration companies have expanded into other computer or business services in order to avoid becoming overly dependent on one service, which might allow a competitor to undercut them or new products or regulations to jeopardize their business.

Like most computer service industries, systems integration is offered by many small, entrepreneurial companies. The majority are privately owned. Still, larger integrators account for much of the industry's revenue. With the increased popularity of systems integration in the 1990s, a strong middle tier of companies with revenues between \$50 and \$100 million developed. A few companies offering systems integration generated \$500 million to more than \$1 billion in revenues.

Systems integration companies generally cater to either federal customers or commercial customers. Large systems integration firms maintain separate departments for the two types of customers. This division was common because soliciting contracts differs markedly be-

tween the two sectors, and the projects themselves were often fulfilled differently.

Federal regulations dictated the bidding process for government agencies. Government contracts are generally longer term, whereas commercial ones might be either long or short term and tend to be more dynamic. Government agencies frequently contract with systems integrators in order to avoid lengthy procurement cycles and still keep up with technological advances. A systems integrator may be hired to design and buy a whole system, so that no competitive bidding is required for each separate component of the network or system. The contract might also stipulate that the systems integrator will update the system as necessary to meet the agency's functional specifications. Recent revisions in federal procurement policies, however, have made government contracts more like commercial ones in some respects.

Commercial companies contract with systems integrators because they see a competitive advantage. For instance, incorporating new technologies could improve their efficiency, save them money in the long run, or help them match their competitors.

BACKGROUND AND DEVELOPMENT

Systems integration was traditionally dominated by original equipment manufacturers, which bought equipment, components, and software from various suppliers to produce a complete computer system that it then sold to end-users. In the early 1980s, the industry boomed, and computer service firms began to compete in this area. Industry revenues in 1980 were \$2.2 billion; in one year they rose 36 percent to \$2.9 billion.

The federal sector contributed significantly to the growing popularity of systems integration in the 1980s. Government agencies previously approached the development of their information systems in a technical manner, prescribing the individual technical components to be included in the vendor's bid. Because the federal procurement process was lengthy, an overly technical approach meant that technical specifications could become outdated even before the bidding process was over. To keep up with the rapidly changing computer industry, agencies began using functional specifications rather than technical ones, and systems integrators to simplify the procurement process. Several large federal contracts in the early 1980s caught the commercial world's attention and helped popularize systems integration services. For example, EDS won a contract in 1982 to computerize administrative functions in 47 U.S. Army bases, generating revenues of \$1 billion over 10 years. Around the same time, the Planning Research Corporation won a similar contract from the U.S. Patent Office.

The advances in mini- and microcomputers in the late 1980s opened up the market for systems integration.

Smaller companies, for whom mainframe systems were unfeasible, began establishing in-house computer systems and turned to systems integrators for assistance. In addition, larger companies continued to need help integrating new technologies.

Revenues in the systems integration industry grew at a healthy rate through the late 1980s and early 1990s, averaging 7.5 percent per year. However, a survey conducted by the Information Technology Association of America of predominantly public systems integration companies showed that their average net profit margin fell from 6.1 percent in 1988 to an average net loss of 0.09 percent in 1992. According to the U.S. Department of Commerce, revenues rose 8.7 percent between 1993 and 1994, and were expected to continue to rise between 1994 and 1997 at an annual rate of 8.1 percent.

The steady rise in revenues despite a general economic downturn in the early 1990s was spurred by various factors. Industry downsizing helped value-added resellers, who once handled predominantly low-cost products from small companies. Many began handling sophisticated, expensive design automation products from manufacturers who reduced or eliminated their dedicated sales forces in an effort to cut costs. Approximately 1,800 companies provided systems integration services in the United States in 1993. Their revenues totaled an estimated \$19.3 billion that year and were expected to reach \$20.9 billion in 1994.

Networking services were a strong portion of the systems integration industry's growth in the early 1990s. Centralized mainframe computing, once the mainstay in the business world, was gradually supplemented, sometimes even replaced, by distributed networks of minicomputers, workstations, and personal computers. The many options available and the constant introduction of new products discouraged companies from designing systems themselves. Analysts expected this trend toward open system architectures to affect the systems integration industry through the 1990s. Rapid advances in telecommunications technology also contributed to the increasing reliance on systems integrators. The advantages of remote connectivity to geographically dispersed companies was only partly realized by the mid-1990s, creating strong demand for network integration services.

Services for computer-aided design (CAD), computer-aided manufacturing (CAM), and computer-aided engineering (CAE) were not growing as quickly as the systems integration services industry as a whole in the early 1990s, as the incorporation of these technologies slowed. Despite the already high installed base, the ever-increasing complexity of designs and the advantages of automation for the mechanical, architectural, engineering, construction, and mapping industries was expected to sustain the growth of CAD/CAM/CAE technology and

services. Growth from 1992 to 1995 was languid, averaging 3 to 7 percent a year. By 1996 annual growth shot up to almost 16 percent, and in 1997 it approached a frenzied 30 percent.

The industry ended the 1990s at a healthy pace. Amid strong demand, in 1998 industry revenue approached \$32 billion, according to the U.S. Census Bureau; this was up from just \$20 billion as of 1996 and about \$13 billion in 1990.

CURRENT CONDITIONS

By the late 1990s annual growth had slowed down, amounting to 22 percent in 1998 and about 13 percent in 1999 and 2000, when industry revenue nearly totaled \$88 billion. Although more current Census Bureau data was not available in early 2003, it is likely that growth slowed in 2001 and 2002 amidst a weak economic climate and reduced IT spending in the corporate sector. While traditionally higher than government figures, private sector data indicate the industry's growth rate did slow down in the early 2000s. For example, the June 2002 *IT Services Business Report* found that U.S. IT service revenues in the system integration category were expected to increase 3 percent in 2002 to \$116 billion, and 9 percent in 2003 to \$126 billion. According to some reports, many companies were forced to table all but the most critical systems integration projects in 2002 due to budgetary restrictions.

Competitive Environment. The competitive landscape for integrators has changed in recent years. Some smaller firms, for instance, have had an advantage in the market for rapid e-commerce integration, where they may be seen as more flexible, more responsive, possibly more knowledgeable, and better able to meet tight deadlines. Meanwhile, large integrators like EDS and IBM Global Services bring tremendous resources and bargaining power to the table, and have been able to win larger, more complex contracts through their name recognition and stable brand image—even though they sometimes subcontract the actual work to smaller, less-well-known firms. The industry has also seen a wave of mergers and acquisitions, as companies seek the right mix of competencies and market access to best meet new demand.

E-Commerce Integration. Web and e-commerce integration continued to be a major focal point for the industry in the early 2000s. Brisk demand for these services first emerged in the mid- and late 1990s, as companies embraced the Internet as a sales and marketing channel. Typical e-commerce integration projects include linking a Web site and its supporting applications to existing corporate systems for storing product information, recording orders, managing transactions, and storing customer information. Because e-commerce initiatives are seen increasingly as vital to a company's competitive strategy, the market for e-commerce integration can be

particularly demanding, requiring fast turnaround and extensive knowledge of different systems—new and old.

Enterprise Application Integration. Another important growth driver, especially in the large corporate market, has been the widespread adoption of enterprise applications aimed at unifying data storage and management across broad swaths of corporate activities—from human resources and payroll to manufacturing and logistics. Many also have industry-specific components intended for, say, telecommunications providers or financial services. These applications, offered by vendors like Oracle, PeopleSoft, and SAP, come with many preconfigured functions and tools, but generally require customization and integration for specific users. Thus, systems integrators often sell, install, and customize them for individual clients. In a corporate survey conducted by Accenture Ltd.'s Institute for Strategic Change and reported in the December 2, 2002, issue of *Computerworld*, 46 percent of respondents acknowledged the use of enterprise application integration (EAI) systems, and 9 percent indicated that they planned to use EAI software within two years.

Web Services. Just as basic point-to-point integration, in which the focus was on enabling communication between two specific systems, gave way to broader EAI frameworks that enabled communication among multiple applications, a simpler, more cost-effective means of systems integration known as Web services was making major waves in the early 2000s. Simply put, Web services involve programming standards like Extensible Markup Language (XML) that allow communication between newer applications and legacy systems—within or between organizations—that were not designed to be co-operable.

Web services will likely impact the systems integration industry in several ways. One impact is potentially negative, since companies can use Web services in-house to achieve integration that once required trained application integrators. This is good news for the corporate sector, given that for every \$1 spent on software, companies spend anywhere from \$3 to \$20 on integration services, based on different estimates.

Given circumstances such as these, many feel that the role of system integrators is changing from a technical one to more of a consultative one, in which the integration of business processes is the primary focus. However, some industry players argued that in the early 2000s Web services still were no match for traditional EAI adaptations, and that the demise of the system integrator was not yet in sight. Indeed, along with security, systems integration was a top priority for many organizations in 2002 and 2003.

Exactly how this will play out remains to be seen. For example, in 2002 some EAI vendors were making the

switch from their own systems to those based on Web services, indicating that the two elements may coexist in harmony to some degree. One thing seems certain—Web services are of great interest within the corporate world. According to the Accenture survey cited in *Computerworld*, 87 percent of respondents revealed that they planned to “experiment with Web services technology for possible application integration uses.”

INDUSTRY LEADERS

By revenue size the two largest firms in the industry, both in the United States and the world, are New York-based IBM Global Services and Electronic Data Systems of Texas. Both are massive service organizations that provide a complete range of computer services like outsourced management and consulting in addition to systems integration. In 2001 IBM Global Services recorded almost \$35 billion in revenues, or nearly 41 percent of IBM's overall sales of \$85.9 billion. EDS posted \$21.5 in total revenue, of which services were a sizable percentage. IBM's figures include nonintegration revenue because the firm does not report systems integration separately.

Another important group of systems integrators is the large accounting and consulting firms. These include Deloitte & Touche, Ernst & Young, KPMG, and PricewaterhouseCoopers. Increasingly these firms distance their consulting functions from their accounting business, for fear of conflicts of interest. One leading consulting firm, Accenture Ltd., was formerly part of the now-defunct Andersen Consulting. Nonetheless, leading consulting firms all have vibrant computer services arms, which include integration services. All five of the aforementioned consultants have revenues in the billions.

Additional players that rank in the industry's top 10 include the integrated hardware-services providers Hewlett-Packard Co. (HP) and Unisys Corp. Each of these has a thriving hardware business (although less so for Unisys, which has focused mainly on services) in addition to offering professional services. HP reported 2001 service revenues of \$7.6 billion (which includes more than just systems integration), representing almost 17 percent of its overall revenues of \$45.2 billion. Unisys had overall revenues of \$6 billion, \$1.2 billion of which came specifically from systems integration services. Both companies provide a full array of services, including consulting and applications development. Other major systems integrators include Computer Sciences Corp.; American Management Systems, Inc.; Computer Associates International, Inc.; and Perot Systems Corp.; all of which had 2001 revenues of more than \$1 billion.

WORKFORCE

The majority of jobs in the systems integration industry were white collar, and many required specialized

knowledge. Functional area specialists had considerable expertise in a particular industry, such as financial services or health care, and used that knowledge to help the systems integration team tailor solutions to the specific needs of a company. Project managers coordinated entire projects, including planning, budgeting, training, the initial operation of new systems, and selecting products, services, and vendors. The transmission of information between people, computers, and locations was handled by communications specialists who analyzed and designed networks that carried data, voice, and video traffic.

Software specialists analyzed software requirements and designed software to meet client needs, created “blueprints” for systems integration projects, and were often involved in the development and implementation cycles. Hardware specialists designed optimal hardware configurations and managed the operation of hardware for systems in use. Supporting staff marketed and sold services, negotiated contracts, or worked in finance or accounting.

By the mid- to late 1990s, a great demand for systems integrators emerged, especially those with a strong understanding of the Internet, intranet, and Web-based application design. The demand was for people with skills in Java programming, security and firewall experts, and people who could connect presentation-level interfaces with databases and legacy systems.

SIC 7374

COMPUTER PROCESSING AND DATA PREPARATION AND PROCESSING SERVICES

This category encompasses establishments primarily engaged in providing computer processing and data preparation services. The service may consist of complete processing and preparation of reports from data supplied by the customer or a specialized service, such as data entry or making data processing equipment available on an hourly or time-sharing basis. Subgroups within this entry include computer calculating services, computer service bureaus, computer tabulating services, computer time-sharing, data entry services, data processing services, data verification services, keypunch services, leasing of computer time, optical scanning data services, and rental of computer time.

NAICS CODE(S)

514210 (Data Processing Services)

INDUSTRY SNAPSHOT

Serving a diverse array of industries, data processing services allow companies to outsource some or all of a data management process, be it payroll, electronic transaction processing, or some other task. Data processing firms offer specialized knowledge and technologies, as well as economies of scale, making them efficient and often cost-effective alternatives to handling such data in-house. As a result, demand for data processing services rose sharply in the 1990s. From just 1994 to 1998, according to government statistics, industry revenue swelled 50 percent.

A significant portion of the industry's rapid growth in the mid-to-late 1990s was fueled by the rise of the Internet and year 2000 (Y2K) related issues. By the early 2000s, growth began to level off. According to U.S. Census Bureau data, industry revenues climbed 14 percent in 1999 and 13 percent in 2000, reaching \$42.9 billion. In 2001 and 2002, the industry was impacted by weak economic conditions characterized by reduced levels of corporate spending. Although government figures for these years were not available in early 2003, there were indications that the data processing industry had fared better than others. For example, from 2001 to 2002 the majority of the industry's leading players either saw their revenues increase or decrease by less than 1 percent. In fact, some companies saw their sales rise as much as 13 percent. It is worth noting that Automatic Data Processing, Inc., the world's largest payroll processor, was able to achieve double-digit earnings growth for 41 years until 2003, when its growth was expected to be in the single-digit range. This is one indication of the industry's relative stability.

The largest segments of the industry include payroll processing, employer tax reporting and filing, credit card transaction processing, billing services, insurance claims processing, and general data-center services. Many of these functions have been outsourced for a decade or more, but market penetration is still relatively low for some, leaving considerable room for growth. Small companies, for example, have been a target for payroll-processing firms because that market is the least saturated for such services. However, recent advances in payroll software have slowed growth in this area somewhat, making it more cost effective for small- and medium-sized companies to handle payroll themselves.

One of the most important growth trends affecting the industry has been a shift toward Internet-based bill payment and presentment. Under these services, a third-party processor packages billing information for another company, say, an electric utility or a long-distance carrier, and presents it to the customer, often a consumer or small business, in a unified environment. A service might also allow users to pay bills electronically. In the late 1990s, the field was wide open for competitors and had attracted both traditional data processing firms, as well as many nontraditional players. Revenues from online bill payment and presentment services were growing in the early 2000s.

BACKGROUND AND DEVELOPMENT

The data processing services industry has evolved greatly since the 1950s, when computers became more prevalent in business. The computer services industry developed when companies purchased systems and needed assistance to effectively use them. Other niches

developed, as other firms saw the benefits of computerizing certain business functions but could not afford to install and operate systems. Computer time-sharing developed as an alternative to purchasing and maintaining an expensive system, and allowed clients to purchase time on a computer as needed, avoiding personnel and equipment costs. Calculating, keypunch, optical scanning, and tabulating services were used by corporations that saw the value of automating large batch jobs but could not maintain these systems in-house.

Many computer service companies became successful because they could offer useful services at lower prices than it would cost companies to install and maintain similar systems. The costs were divided among all users, making data processing services an attractive option. Often costs were determined by the number of transactions, instead of simply a flat rate.

Many of the segments of the industry, such as keypunch service and computer time-sharing, have decreased substantially since the 1970s. Keypunch services became outmoded for general applications when computer disks and magnetic tape were developed. Disks and magnetic tapes, the storage materials of choice, are less sensitive than cards and contain thousands of bytes of memory capacity. Computer time-sharing decreased as an industry segment when hardware prices decreased in the 1970s and 1980s, and software became more adaptable. Many corporations have invested in computer hardware and have hired in-house staffs to maintain and program their computer systems.

As computer capabilities increased, companies looked to the computer service industry to provide either more sophisticated services or to reduce their record-keeping costs. Data entry services that have typically been maintained in-house became candidates for outsourcing, as employee benefit costs increased. Access to the most sophisticated computer systems may become important for specific tasks, which would be prohibitively expensive if companies had to purchase a computer and customize the software.

Outsourcing represents the segment of this industry with the greatest growth potential. Outsourcing is the practice of turning over a portion of the company's data processing to an outside vendor. Eastman Kodak was the first major corporation to sign a 10-year contract with International Business Machines (IBM) in 1989. Other companies soon followed Kodak's lead, and outsourcing was projected to expand by 25 percent annually to become a \$21-billion business by 1996.

Economic conditions in the early 1990s forced companies to reexamine the resources devoted to data processing. Competition intensified in business, placing an additional burden on information systems. Many compa-

nies opted to use outside computer service firms for various tasks in order to tap into the most precise and timely information. By using computer service firms, companies could reserve expensive personnel and capital resources for other portions of their business.

Time-sharing and transaction processing are the two main categories within processing services. Time-sharing involves purchasing time on a large computer that otherwise would not be accessible to the company. Few companies use time-sharing any longer because most basic corporate processes can be performed in-house with the abundance of inexpensive hardware and sophisticated software. Companies that do use time-sharing do so because they can access accelerated computer power that would otherwise be too expensive; the purchase makes a computer upgrade transition period more smooth; and a company's computer resources are taxed beyond their capacities during certain seasons.

Back-office tasks, or routine, high-volume clerical tasks such as payroll processing, have long been completed by computer service vendors. Payroll duties include generation of checks and journals, employee earnings statements, departmental earnings summaries, and withholding tax reports, as well as pension fund and profit-sharing reports. The future of payroll processing is tied to the economy: when unemployment increases, the number of paychecks decreases, as does the number of small businesses, because some fail during an economic downturn. While payroll processing remains the largest single application, the industry is evolving and being utilized for more sophisticated applications in banking, finance, insurance, and medical industries.

Transaction processing vendors process routine, high-volume applications. Computer services have primarily automated back-office functions. Because most companies have completed this automation, many data processing services are focusing on areas that enable companies to win business from customers, or front office functions. Computerization can aid in automating customer information systems, providing electronic funds transfer systems, and other decision support tools. These applications rely on real-time, or immediate, activities and cannot be batch processed, unlike credit card or medical claims. The future growth in this area will be slower than previous outsourcing revenue.

Traditionally, companies providing data processing services have utilized their own extensive computer facilities and proprietary software. This practice enables them to divide the cost among many users, which makes the services more affordable for each company. Trends are developing, however, that include placing the contractor's hardware in the client's site or utilizing existing client hardware. This practice reduces the vendor's costs, as well as their revenues, while placing an increased

burden on the client. The contractors generally welcome the chance to exclude hardware costs and to make their clients responsible for computer maintenance and upkeep. Instead of focusing on hardware, the vendors are able to provide software applications to industries such as health care or insurance. Duplicating such sophisticated information applications in-house would be technologically and financially impossible. The data processing services industry is adapting to technological advances by seeking ways to assist computer owners to more efficiently utilize their resources.

In 1998 data processing service revenues were valued at \$33.2 billion in the United States, according to U.S. Census Bureau data. Around this time, some segments of the industry were expanding faster than others. Payroll processing services, for one, were poised for strong growth in the early 2000s, driven by broader market penetration. Among businesses with 100 or fewer employees, for example, payroll outsourcing services had at most a 20 percent penetration rate in the United States during the late 1990s. Even among companies with more than 100 employees, the penetration rate was barely over 50 percent. Electronic bill payment and presentment was another emerging growth area for many industry firms in the late 1990s and early 2000s. However, they faced competition from a more diverse swath of other companies that were positioning themselves in that business.

CURRENT CONDITIONS

In 2000 revenues for the data processing industry totaled almost \$43 billion, according to the U.S. Census Bureau. More than 59 percent of sales were attributable to transaction processing and data exchange. More than 13 percent came from other forms of data processing, while things like data capture and imaging as well as computer timesharing services accounted for the remainder.

Consistent with past trends, by 2003 electronic bill payment and presentment services continued to catch on with both consumers and businesses. According to a study conducted by Jupiter Research Inc. and reported in the October 17, 2002, issue of *American Banker*, some 18 million households in the United States viewed at least one bill online in 2001. Jupiter forecast this amount would increase at a compound annual rate of 23 percent through 2006, reaching 52 million households.

It was widely accepted that, in order for electronic bill payment and presentment services to take off en masse in the consumer sector, consumers would need to be able to conveniently receive and pay their bills through one entity, such as a bank. By 2003 many banks had not yet embraced these services. According to the July 2002 issue of *U.S. Banker*, research firm Gartner revealed that 60 percent of people who used e-billing did so in accord-

ance with the so-called “biller-direct model,” whereby they dealt directly with the billing party as opposed to a third party that consolidated their bills for them. Jupiter’s study found the biller-direct rate to be higher (more than 80 percent), but expected this number to fall to 40 percent by 2006, as consolidators made additional progress.

One major roadblock for consolidators like banks was the fact that many bill-issuing organizations did not want to give information away to outside parties, thereby foregoing regular communication opportunities—such as monthly e-mail reminders or Web site visits—with their own customers. In addition, many banks and payment providers charged monthly fees that, for many customers, amounted to more than what they already paid in postage to send payments the traditional way. However, some banks were eliminating such charges for customers who maintained a minimum account balance. In the early 2000s, firms like CheckFree were continuing to make inroads in the e-billing arena, and even the U.S. Postal Service was getting into the game. Facing significant drops in postal activity due to the rising use of e-mail, the agency formed a partnership with consolidator CheckFree.

By 2003 electronic bill payment and presentment services also were taking hold in the business sector. Surprisingly, large enterprises were demonstrating strong interest, according to Citigroup, Inc. The financial company found such services to be especially suitable in the business-to-business realm, since electronic bill payment and presentment shorten the invoicing and payment process. This was helpful in the event of billing disputes. According to the July 8, 2002, issue of *American Banker*, in the business sector “dollar amounts are typically much larger and relationships much more complex, frequently involving goods and services delivered to different departments in different locations. When a dispute arises, the buyer may render partial payment or may withhold the whole payment, and in conventional paper billing it may not be clear to the biller what is being paid, what is being withheld, and why.”

INDUSTRY LEADERS

One of the largest firms in the business, Automatic Data Processing, Inc. (ADP) is the biggest independent payroll processor in the United States. With more than 450,000 business customers, the publicly traded firm had sales in fiscal 2002 of \$7 billion. In addition to payroll processing, ADP provides government and tax filing services, benefits management, automotive insurance claims processing, automotive dealer services, and securities transaction processing.

Electronic Data Systems Corp. (EDS) is a major integrated technology services firm and a major processor of medical insurance claims and financial data. EDS

signed its first long-term contract in the medical area in 1966, when legislation establishing Medicare was passed. EDS organized claims processing support across the country, and by 1968 Medicaid and Medicare contracts represented 25 percent of Electronic Data Systems’ revenues. Data processing today, however, represents only a small part of EDS’s revenue. In 2001 its business process management unit reported sales of \$3 billion, almost 14 percent of the company’s \$21.5 billion in total revenue.

Catering to the small business market, Paychex, Inc. is considered the second-biggest U.S. payroll service, with 440,000 customers and \$955 million in sales as of 2002. Like ADP, Paychex offers a package of related human resource services like benefits management and tax filing.

Ceridian Corp. is another leading contender in payroll processing and human resource services. In 2001 the company recorded \$1.2 billion in sales, most of which (\$866 million) came from human resources services. In addition to being a major player in the U.S. market, Ceridian also has a leadership position in Canada and the United Kingdom. In 2003 the firm served about 18 percent of the workforce in the United States, or 20 million people.

First Data Corp. tops the credit-card transaction processing side of the business, with \$6.5 billion in 2001 sales. First Data operates the Western Union cash transfer network and is involved with merchant credit-card processing services and check authorization. In 2001 First Data’s revenues fell more than 13 percent, although its workforce increased more than 7 percent.

WORKFORCE

According to *Monthly Labor Review*, in the early 2000s employment growth in the computer and data processing sector had slowed in comparison to past years, due in part to a sluggish economy. In the first three quarters of 2001, growth was occurring at an annual rate of about 2 percent. Some industry segments, such as data entry and keypunch services, did not require a college or university education, but could be filled by high school or technical school graduates. Most segments preferred workers with a college education despite the training that they provided; in-house education at specific companies enabled workers to learn their duties. An interest and background in computer science was typically desirable for this industry.

SIC 7375

INFORMATION RETRIEVAL SERVICES

Companies in this industry are primarily engaged in providing online information retrieval services on a contract or fee basis. The information generally involves a range of subjects and is taken from other primary sources, such as the original publishers of the materials. Establishments primarily engaged in performing activities, such as credit reporting, direct mail advertising, and stock quotation services, and who also create databases are classified according to their primary activity. Establishments primarily engaged in collecting databases from primary sources and reformatting or editing them for distribution through information retrieval services are classified in **SIC 7379: Computer Related Services, Not Elsewhere Classified**.

NAICS CODE(S)

514191 (On-Line Information Services)

INDUSTRY SNAPSHOT

Demand for electronic information has skyrocketed with the growth of the Internet, but the resulting low-cost competition has wreaked havoc with traditional subscrip-

tion information services. The information retrieval business, which usually charges customers either by the amount of information retrieved or at a flat subscription rate, has traditionally served corporate and academic researchers and librarians—audiences that were used to paying a premium for professional-quality information. This stable market has been undermined, however, as similar information has come available on the Internet, often for free.

With newspaper and magazine articles routinely available for free on the Internet, old-line full-text database services like LexisNexis and Dialog have witnessed customer flight to cheaper services. As a result, competition has gotten tougher and, in many cases, revenues at traditional providers have stagnated or fallen. Mergers, acquisitions, and partnerships were frequent in the late 1990s and early 2000s, as information providers adapted to the new marketplace. Nearly all have likewise embraced the Internet in some form, as demand has weakened for proprietary software, dial-up database connections, and CD-ROM subscriptions.

In spite of some providers’ woes, however, government statistics show that the industry had an influx of new revenue in the mid- and late 1990s. In 1998 industry revenue totaled approximately \$11.4 billion, up roughly 100 percent from 1995. According to the U.S. Census Bureau, by 2000 the industry had continued to achieve considerable growth. Revenues increased 64 percent between 1998 and 1999, and more than 47 percent between 1999 and 2000, reaching \$27.7 billion. Although more recent government figures were not available in early 2003, by that time the information retrieval industry had been affected by a sluggish economy. Budget cuts at key customers like libraries and businesses had created a more challenging climate in the industry.

ORGANIZATION AND STRUCTURE

Online information services, increasingly over the Web, are the leading means of delivering electronic information. Other methods include CD-ROM, diskette, and magnetic tape. Online services are trademarked services that may or may not bear the same name as the companies that own and operate the services.

Online service companies may be considered the vendors, distributors, resellers, or retailers of informational databases that are often developed by third-party database publishers. The database publishers, often considered part of the broader “information services industry,” are not part of the online services industry, however, and are usually classified by the type of publishing they perform. The data in the databases may be numeric (such as financial statistics), bibliographic (citations to periodical literature), full-text documents, directory or dictionary entries, patents, images, or even digital audio

and video recordings. Most online services provide multiple databases. Specialized online services may also produce one of the databases themselves. Increasingly, there are online services that provide a combination of databases that they have developed along with others that they have licensed to redistribute.

Online services can be categorized as either business/professional research services or personal online services. Business/professional online services may be highly specialized by offering only a single set of related databases to a niche market. They may be somewhat specialized but offer multiple databases from different sources on a similar broad subject, such as the legal online services LexisNexis and Westlaw or the scientific service STN International. Finally, professional online services may be very general and offer up to hundreds of databases on all different subjects, such as Dialog or LexisNexis. Such distributors of multiple databases are most often referred to as “database vendors,” and their clients are usually corporate librarians.

The largest business segments are legal and investment. Marketing, intellectual property, scientific, and credit information service needs also comprise a large portion of this market. The remainder of the industry serves a variety of niche markets. For instance, many databases are tailored specifically to one industry or profession, such as chemical, health care, civil engineering, agricultural, banking, insurance, or food service. In addition, many niche services are managed by nonprofit industry service organizations.

While the business/professional services encompass both the specialized online services and the general-subject online services, consumer information services tend to be general, offering a wide variety of databases in order to appeal to a wider market. With the emergence of the Internet, however, consumer information services have largely become indistinct from other businesses, such as electronic publishing, Internet access services, and search engines.

Indeed, by far the most pervasive form of information retrieval system, both for businesses and consumers, is the Internet search engine. Far different from the traditional information service revenue model, popular search engines are completely free to users. They instead earn money through selling advertising on the site and through electronic commerce partnerships with other firms.

Although parts of the information retrieval industry are relatively young, and therefore entrepreneurial in nature, each segment of the market tends to be dominated by one or two large firms that pose formidable barriers to smaller competitors. For instance, the market for legal information is dominated by just two competitors, LexisNexis and Westlaw—and even they have been

struggling. Even niche markets tend to favor the single competitor that is first to establish a presence and to acquire ongoing access to essential copyrighted information. As a result, firms in the industry typically diversify and grow through mergers, acquisitions, or joint ventures with other companies.

Online services allow customers using computers or computer terminals to access a remote, central computer storing databases, by connecting through a telephone/telecommunications network. If the customer is using regular analog phone lines—historically the most common method and still the most common means for home and small office customers—the customer’s computer is then connected to the phone line with a modem, a device that converts between digital computer signals and analog phone signals. Business customers are increasingly using digital phone lines, such as ISDN, for online service access, because they enable higher speed and quality of data transfer. Customers access a central data bank of information by calling a local, or sometimes long-distance, telephone number, and information is then transferred to the user over the phone lines. Online services can offer local dial-up numbers throughout the country to a faraway data bank by making use of any one of various data communications networks. An alternative way to connect to the online service’s computer is via the Internet, especially the Web. If a customer’s organization has a host computer directly on the Internet, then its users can connect to the Internet through a local area network, and no modems are needed.

Online services, which manage the databases, may charge the customer a flat monthly rate for unlimited access to the data bank. In other cases, customers pay according to the length of time they access the databases, the amount of information that they access and print, and/or the type of information that they use. Professional online services may charge as much as \$300 per hour to access certain databases—and additional fees for printing records—because collecting timely information, paying copyright royalties, providing telecommunication connections, and supporting sophisticated data storage equipment generate immense overhead. Customers who access large amounts of tax and legal information may pay tens of thousands of dollars per month in online charges. In comparison to business information services, personal systems are typically inexpensive because the data is less costly, and the volume of users in the market is large.

The advantage that online systems have over other forms of electronic information services is timeliness. The medium is especially appropriate for customers who require up-to-the-minute information. Database managers can continually update information related to stock quotes and other financial data, legal rulings and court

proceedings, sporting events, world news, and other timely matters. Online systems are also advantageous because they allow access to massive amounts of information that is cumbersome for customers to access via print or other media. In fact, the most popular online services offer simultaneous searching of multiple databases.

BACKGROUND AND DEVELOPMENT

The electronic information services industry was born during the post-World War II information explosion. The advent of computers during this period formed the basis for channeling large amounts of data to scientists, engineers, businesses, and government agencies. Government investment in new information technologies in the 1950s and 1960s was supplemented by increased private sector spending on research and higher education. The result was that, for the first time, skilled professionals could create, store, and quickly access large amounts of data.

The purpose of the earliest retrieval systems was simply to store and print information—mostly for technical endeavors. As the number and size of the databases grew, however, systems engineers began to focus on searching capabilities that could filter out unneeded data. Eventually, users were able to type commands into a computer that would search and display information containing specific keywords or phrases.

The first computerized bibliographic databases stemmed from the federal government's need for the efficient application of research dollars and the desire to eliminate duplicate analyses. Some of the more popular databases developed in this period included MEDLINE and ERIC. The government also subsidized nonprofit efforts, such as the American Chemical Society's Chemical Abstracts database.

In addition to supporting nonprofit services, government investment in the 1960s initiated many of the private information retrieval services that dominated the market in the 1980s and early 1990s. For instance, Dialog sprung from a venture between the National Aeronautics and Space Administration (NASA) and Lockheed Corporation called Project RECON. ORBIT Online was developed as a result of System Development Corporation's work with the National Library of Medicine. Industry giant Mead Data Central (now called LexisNexis) got its start from seed money provided by U.S. Air Force projects.

The federal government also played a vital role in developing telecommunications networks that made online services possible. Networks that essentially provided affordable access for database online users through local telephone lines stemmed from Department of Defense

efforts. The network of all networks, the Internet, also began as a Department of Defense project.

As more efficient telecommunications networks arose, and computer technology advanced in the late 1960s and 1970s, the market for online information services began to proliferate. Companies and libraries were increasingly relying on technical and legal information to provide a competitive edge in the marketplace or to make their research efforts more efficient. Furthermore, many users were finding electronic information access to be an important tool for increasing productivity.

As electronic markets began to grow, many publishing houses began to experiment with electronic publishing as a means of delivering their information. H. W. Wilson and Company, for instance, began offering access to Wilson indexes and abstracts online through WILSONLINE. Likewise, McGraw-Hill and other periodical publishers began offering their publications online. One of the greatest commercial uses of electronic information retrieval was for legal publications.

By the end of the 1970s, the emerging information retrieval industry was beginning to establish itself in many sectors of government, academia, and industry. Because of technical limitations, however, retrieval systems remained extremely costly. Furthermore, most systems were complicated and required professional research skills for effective use. As a result, estimated industry revenues were still well under \$500 million by 1980.

Technological breakthroughs in personal computer and data storage devices fueled rapid industry growth through the 1980s and early 1990s. At the same time that microcomputers were becoming faster and less expensive, users were becoming accustomed to working with modems, networks, and other communications devices, allowing large numbers of people to gain access to reservoirs of data. For the first time, information retrieval companies were able to expand their services to the end-user, or the person that would actually use the information, rather than professional researchers.

As end-users increasingly became the market for information providers, companies began to emphasize user-friendly system interfaces that allowed easier data searching and access, such as providing menus instead of requiring the user to memorize arcane commands. Firms were also quick to take advantage of retrieval technologies. For instance, online services were able to make use of faster modem communication speeds, including high-speed, always-on network connections that are now common in businesses and, increasingly, in homes.

As new markets emerged, companies began to expand their offerings. Online information "supermarkets" such as Dialog evolved, where users could access hun-

dreds of specialized databases covering thousands of publications. Information “boutiques” that offered simultaneous online access to multiple databases and services for one particular industry or profession also resulted. Individual niche services flourished as well. Between 1987 and 1992 the number of electronic databases available in the industry leapt nearly 300 percent, from 3,369 to more than 10,000.

In the late 1980s, the emergence of CD-ROM technology, for storing and accessing large amounts of data by a personal computer, appeared as a competitive threat to online aggregators. Many database publishers who had previously been distributing their electronic databases exclusively through online services began to publish and distribute that same data themselves on CD-ROM. By the early 1990s, however, it became clear that the information market was growing fast enough to accommodate both online and CD-ROM media, and that the two could exist side by side serving different customer needs.

Legislative issues related to copyright infringement came to the forefront of the industry during the 1990s. By 1996 the U.S. Congress debated whether online services should be held fully responsible for copyright infringement by their customers, and infringement suits based on online content were already circulating in the U.S. court system. To fulfill copyright law obligations, online services were required to monitor the distribution and customer access of each copyrighted database record to ensure that proper royalty fees were paid. Thus, the computer systems of online services automatically tallied how many times a specific record was accessed to determine how great the licensing fees should be that were paid to the database producer. Database producers, in turn, paid royalty fees based on this tally information to the original publishers.

For the fairest, most accurate payment of royalties, end-user customers also were charged for each record accessed, sometimes at a different rate for different kinds of records. This system worked well for certain professional and business customers, but the home consumer market preferred flat-fee pricing. Through careful historical analysis of database access statistics, database producers and online services were in many cases able to derive revenue projections that enabled them to begin charging flat fees for customers and still honor royalty agreements.

During the late 1990s and early 2000s, the proliferation of free information on the Internet put severe pressures on old-style subscription services, and some organizations cracked under the strain. Dialog, one of the oldest and most revered subscription databases for professionals, was one casualty. In 1997 the troubled service was purchased from Knight Ridder, a newspaper publisher, by an obscure British concern known as Market Analysis Information Database (MAID). Renamed Dia-

log Corporation plc, the service continued to flounder with flat revenues and fleeing customers. In a controversial move, the company ratcheted up its search fees drastically, when it learned many users were identifying information sources (newspapers, periodicals) with its powerful search engine but then retrieving the articles more cheaply from the sources' Web sites. This alienated more users. Although the company managed to turn a slim profit in 1998, it was strapped with debt and faced an uncertain market. Finally, in 2000 the Dialog service and trade name was sold to Thomson Corp. of Canada.

Demand for information services grew rapidly in the 1990s. Based on the Census Bureau's revenue estimates, the industry grew at an average of nearly 18 percent a year between 1992 and 1998, when the industry took in \$12.3 billion in sales. That growth was heavily weighted toward the end of the period, when industry sales surged 30 percent or more each year.

CURRENT CONDITIONS

Market Conditions. In 2000, according to Census Bureau figures, the information retrieval industry took in \$27.7 billion in sales. The total market for electronic information services is tricky to gauge, however, because it depends on how they are defined. Private-sector estimates are usually quite a bit higher. For example, Veronis Suhler Stevenson, a communications market research firm, estimated that the market for business information services alone reached \$28.3 billion in 2001.

Although the business information market is but one industry subsector, it is an important one, along with the library market. By the early 2000s, the information retrieval industry was recovering from a challenging economic climate, which had led to lower levels of business and library spending. The negative downturn on the corporate side is evident in the findings of the *Veronis Suhler Stevenson Communications Industry Report*, released in late 2002. The report found that adjusted revenues for more than 70 of the industry's major publicly traded organizations—including Reed Elsevier, Reuters, and Thomson—increased almost 8 percent in 2001. This was much lower than the compound annual growth rate of more than 11 percent that these firms achieved between 1997 and 2001.

A separate publication, the *Veronis Suhler Stevenson Communications Industry Forecast*, indicated that businesses reduced their spending on information services by 0.3 percent in 2001. The forecast indicated that some segments, especially financial and economic information, achieved less significant losses than other business information segments. It predicted that conditions would improve nearly 6 percent in 2002 and then grow to more than \$65 billion by 2006, fueled by a compound annual growth rate of nearly 7 percent.

The Internet's Impact. In many ways the Internet has turned the traditional information retrieval business model on its head. In a few short years, consumer-oriented indexes/search engines like Yahoo! provided competition for subscription-based services. Although this was challenging for information retrieval companies, it does not spell doom for traditional fee-based providers. According to an estimate by LexisNexis, in 2000 the Web contained just 40 million unique documents, compared to LexisNexis' 2.5 billion documents. For professional researchers, the power of such retrieval systems also far exceeds that of a Web search engine, allowing more versatile search options and often more efficient indexing and classification. A database like LexisNexis or Dialog is also usually more stable than many Web pages, an important feature for historical research.

As of 2003 many researchers believed there was still a vital need for both free and low-end subscription services over the Internet, as well as proprietary database systems, whether accessed through the Web or other means. The main problems for vendors of traditional services will be pricing and market share, as some of their business is lost or relocated because of newer Internet sources. In the early 2000s, information retrieval companies were taking a number of measures to deliver more value to end-users in the professional and consumer sectors, and provide them with content that could not be obtained freely on the Internet. For example, most were rolling out new products for targeted audiences like public relations professionals, lawyers, students, and genealogists. Some were adding high-quality content from peer-reviewed academic journals. Still other companies, including ProQuest and the Gale Group, were in the process of digitizing old books and news articles, providing users with searchable historical content (text and images) dating back as far as the early 1700s.

Legislation and Legal Issues. The main type of legislation that affects the information services industry is copyright law. Most of the information contained in databases distributed by online services is copyrighted, yet because it is in electronic form, it can be easily reproduced. Online services have not felt any need to challenge existing copyright law, but challenges from others have touched their industry. Original authors of published articles and artists of creative works have sued database producers and vendors for electronically distributing their articles without permission.

Copyright-related issues were making waves in the industry in 2002 and 2003. At that time, a number of magazine and newspaper publishers, including news giant Gannett, were removing literally millions of freelance-written articles from electronic databases. This was happening in the wake of *Tasini v New York Times*, a U.S. Supreme Court decision that found that electronic

rights to articles default to authors and not publishers. This had the greatest impact on digital content published prior to 1999. After that year, most publications required freelance writers to consent to the electronic publication of their articles. Some publications were removing all of their electronic content published before 1999, rather than taking the time to selectively identify and remove individual articles, according to *Library Journal*.

INDUSTRY LEADERS

General Professional Database Services. The Thomson Corp., Toronto, Canada, is parent to scores of general and industry-specific information retrieval services and is a major information provider worldwide. One of its main offerings is a general-purpose database called Dialog. The Dialog service was the pioneer in online retrieval services when it was founded in 1972. It was sold in 1988 for \$353 million by its parent, Lockheed Corp., to the newspaper publishing and news service company Knight Ridder Inc. Under Knight Ridder Information Services, Dialog was also linked in the mid-1990s with DataStar, a European information service. However, amid sluggish sales, Knight Ridder sold its information services in 1997 to U.K.-based Market Analysis Information Database (MAID) for a steep \$420 million. The new company, called Dialog Corporation plc, failed to effect a turnaround; sales languished, as the company was slow to embrace the Internet paradigm. MAID sold Dialog to Thomson Corp. in 2000 for \$275 million. In addition to Dialog, Thomson's other major electronic retrieval systems include Infotrac, a periodical index and full-text database provided by the Gale Group (publisher of this encyclopedia), and Westlaw, a legal database provided by the West Group. In 2001 Thomson recorded revenues of \$7.2 billion.

The LexisNexis Group is a division of UK-based publishing company Reed Elsevier. In 2001 the information service recorded revenues of \$1.9 billion. It is among the largest general-purpose databases for professionals. The company, founded in 1970 and based in Dayton, Ohio, was known as Mead Data Central, until its parent, the Mead Corporation, sold it to the European publishing joint venture Reed Elsevier plc in 1994. The company's services include Lexis and Nexis. Started in 1973, Lexis offers access to legal databases. Nexis is the largest news and business information service, which began in 1979. LexisNexis offers its information services electronically via dial-up or the World Wide Web, as well as in print and CD-ROM formats. The company's electronic solutions allow users to search more than three billion documents.

Business and Finance. Among the online services that serve specialized business markets, the largest companies are those that provide real-time securities and other finan-

cial information services. The largest companies, which have been in the business for some time, not only provide information services, but some also continue the practice of leasing proprietary computer terminals to access the information.

Reuters Group PLC of London is a major player in financial and news information services. It has long been the biggest provider of financial news to businesses. By the early 2000s, the company had bolstered its position by acquiring competitor Bridge Information Systems, which in the late 1990s was one of the top three financial information vendors. The company also operates a massive global news wire and news gathering business, and since 1999 it has run an information retrieval joint venture with Dow Jones Interactive called Factiva (formerly Dow Jones Reuters Business Interactive) that features a full-text newspaper and journal database. In 2001 the Reuters Group recorded approximately \$5.7 billion in revenue.

The other leading competitor is Bloomberg L.P. of New York. Like Reuters, it provides an extensive line of financial and news information products, including information terminal service to the financial industry. Bloomberg also has media and publishing ventures. The company's revenue in 2001 was estimated at \$2.6 billion, and it has more than 160,000 information terminals installed worldwide.

Internet Search Engines. Web-based universal search engines have had profound impact on the rest of the information retrieval business. Unlike other services, they rely on advertising almost exclusively for revenue.

Yahoo! Inc. is the world's largest Web search engine based on number of users. From its inception Yahoo! has taken a value-added approach to collecting Web site information: it classifies all sites in a hierarchy for ease of searching. While this has meant that Yahoo! does not always list as many sites as competing search engines, users have been pleased with its approach. In 2002 Yahoo! was the Internet's most widely used search engine. The company's 2001 revenues totaled \$717.4 million. Its earnings were fueled by advertising and services like Yahoo! Auctions and Yahoo! Bill Pay. In addition to acquiring HotJobs in late 2001, Yahoo! entered the traditional information retrieval market the following year, when it launched the Premium Document Search service. This offering provided users with access to more than 70 million full-text documents from more than 7,000 different sources. However, the service was short-lived, and by early 2003 it had been discontinued. At that time, Yahoo! continued to offer access to articles from the *New York Times*, as well as investment-related information through its Yahoo! Finance service.

Terra Lycos, S.A., was formed in 2000 when the leading independent Web search engine Lycos was ac-

quired by Telefonica, a Spanish telecommunications firm. By 2003 the company had emerged as the world's largest Internet network. In late 2002 it launched a new version of the popular search engine HotBot. According to the company, the new HotBot enabled users to search four of the leading Internet search engines—FAST, Google, Inktomi, and TeomaSM—from one convenient interface. In 2001 Terra Lycos recorded sales of approximately \$618 million.

WORKFORCE

According to the U.S. Bureau of Labor Statistics' *2002-2003 Career Guide to Industries*, the information retrieval industry has achieved strong growth since the late 1980s. Between 1990 and 2000, this growth led to the creation of some 196,000 jobs. Positions in the information retrieval services industry include: computer programmers; system analysts; information processing and delivery professionals; sales representatives; management; clerical and office management; writers and editors; and research analysts.

Occupations that will likely experience the greatest growth in the next decade are related to computer programming and system development. Jobs for sales professionals in all computer and data processing fields are projected to grow at a healthy clip as well, while significant increases in the number of writers, editors, and technical writers employed in the industry are also anticipated.

AMERICA AND THE WORLD

The U.S. electronic information retrieval industry is the largest and most advanced of any nation in the world. It is also acknowledged by foreign markets as the provider of the most comprehensive and highest quality information services. Acceptance of the English language as the standard for information services has helped U.S. companies compete abroad. As a result of these factors, U.S. firms have found major growth opportunities in overseas information markets. The fact that online services specialize in transferring data over long distances has made the expansion into international markets a logical step.

The largest market for online services outside of the United States is Western Europe. Both the major U.S. business and consumer online services have subscribers in Europe. The liberalization and privatization of telecommunications services in Europe was also expected to lower the telecom rates paid by businesses and consumers, and consequently encourage the use of online services. The Asia/Pacific region, and Japan in particular, is another fast growing market. Strong opportunities for growth also exist in Latin America and Eastern Europe. Foreign investors from all countries are seeking informa-

tion about these markets, and these countries and regions will all demand increasing amounts of business, legal, and financial information about the United States and other developed markets.

Another aspect of the globalization of the online services industry is not merely the export of the services, but also the internationalization of the databases being offered. U.S. database vendors are increasingly contracting database providers in Europe and Japan to provide the content for databases on their respective industries, which in turn are offered back to the European and Japanese markets in addition to the U.S. market. For example, NEXIS began offering BizEkon, a Russian business directory, and Comline Corporate Directory, which contains profiles of Japanese firms. DataTimes, a full-text online newspaper service, started delivering "China Daily" and several other Chinese publications. Similarly, U.S. database producers are licensing their databases to foreign database vendors for distribution abroad.

RESEARCH AND TECHNOLOGY

The electronic information retrieval industry is heavily influenced by technological advances and is, in effect, a corollary of recent advances in computer and telecommunications technology.

Developments in the computer industry have made more powerful computers and database management software available at lower costs. This has permitted online services to expand their database offerings without technical limitations and has lowered the entry barrier to smaller companies to get into the business of online services.

Computer software developments have led to the growing use of graphical user interfaces for accessing online services. The software then permits users to organize the data on their own computer hard drives without spending additional costly time being connected to the online service. The most recent trends in software have made access to external data appear as a seamless part of working on one's own computer desktop. This is particularly the case for computer users whose computers are directly linked to the Internet through an organization's local area network. Lotus Notes groupware software and Microsoft Office software offer features of integrating online accessed data with desktop applications.

The development of telecommunications technologies are of particular importance to online services, which rely upon phone lines to transmit data to their customers. Even though modems may enable data transmission speeds of up to 433,600 bps, whether such speeds are actually attained depends on the bandwidth of phone lines—and usually the optimal speeds cannot be reached. While telephone networks are being improved with fiber-

optic lines, the capabilities of a phone line are only as good as its weakest link, typically the final connection to the individual office or residence. Businesses are investing in their own high-bandwidth dedicated lines, leased lines, and wide-area networks. Residences, too, now have the opportunity to use high-bandwidth lines for additional charges. Wireless communications technologies, such as cellular modems for portable computers, allow users to access online services in remote locations. By the early 2000s, direct broadcast satellites were another way that business and consumer audiences were gaining high-speed access to the Internet.

Finally, the combined developments in computer hardware, software, and telecommunications services are enabling the transmission of more complex kinds of data through online services. The rise of broadband Internet connections and advancements in data compression technologies have enabled transmission of full-motion video and accompanied sound through online services. At this point the distinction between online information services and interactive cable television broadcasters becomes blurred. The difference may merely depend on whether the data is defined as information or entertainment, or whether it is viewed through a computer monitor or television screen.

SIC 7376

COMPUTER FACILITIES MANAGEMENT SERVICES

This category includes establishments primarily engaged in providing on-site management and operation of computer and data processing facilities on a contract or fee basis. Establishments primarily engaged in providing computer processing services at their own facility are classified in **SIC 7374: Computer Processing and Data Preparation and Processing Services**.

NAICS CODE(S)

541513 (Computer Facilities Management Services)

INDUSTRY SNAPSHOT

One of the oldest of the computer services industries, facilities management includes interactive and batch data processing, data storage and retrieval, system diagnostics and maintenance, and network management. Customers hire facilities management companies to perform any or all of these services at computer facilities located on their own premises, much as they would hire a concessionaire to run a company cafeteria. Because relatively little capital is needed for equipment or buildings, facilities management initially attracted many entrepreneurs, the vast majority of who were small, privately owned enterprises.

Once a mainstay of the computer services industry in its own right, in the 1990s and 2000s facilities management evolved into just one of many services offered by companies specializing in "outsourcing." Although companies whose primary offering was facilities management still do a substantial amount of business, many companies arrange complex service agreements to include combinations of facilities management, remote

computing (doing the client's data processing off-site), contract software programming, systems integration, communications network management, and software maintenance.

Because the profit margin for facilities management fell slowly but steadily over the years, its combination with more lucrative services had a growing appeal to companies in that industry. In addition, corporations with large in-house computing facilities began looking for service companies who not only could handle day-to-day processing but could also update aging computer systems. In the late 1980s, several large corporations arranged long-term contracts for computer services valued at more than \$100 million. By the early 1990s, such megacontracts exceeded \$1 billion. For an increasing number of computer services companies, facilities management became just a single component of complex service agreements.

Strategic outsourcing had become the trend of the 2000s. Besides smaller corporations that hired contractors to manage their facilities and information technology (IT) needs, even the larger corporations hired contracting firms to manage their information systems. Strategic outsourcing consists of placing a company's computer budget and operations in the hands of another company in return for the assurance that operational savings and other improvements would result.

ORGANIZATION AND STRUCTURE

Many companies have found that their data centers, distributed networks, and related facilities can be handled more efficiently by others than by themselves. Programmers and experienced staff are difficult and expensive to hire. For this reason—particularly in industries where wages are generally low and data processing needs high, such as the insurance industry—facilities management services are frequently used. In addition, running computers is often outside the realm of expertise of a particular company. Managing the operations of complex computer systems tends to distract management from the primary focus of the business, whether it is banking, utilities, or health care. To eliminate this distraction and to cut costs, many companies hire a facilities management company to run their computer facilities on a contract or fee basis.

Facilities management companies generally charge a fixed annual amount to maintain a data center, then add fees based on processing volume. An in-house operation entails a large fixed cost; with facilities management, data processing became a variable cost. Data processing costs increase when the company's business activities increase and decrease when business slows. This pricing schedule allows more efficient use of the company's funds.

A facilities management company needs little capital to begin operations. Unlike a company specializing in

remote data processing, which requires sizable data centers and extensive communications capabilities, a facilities management company has few equipment and building requirements.

Specialized personnel, however, are a crucial component for facilities management firms, not only for the obvious technical areas, but in marketing as well. Knowledge and skill are needed to sell an intangible service to repeat customers. Facilities management companies compete not only with others who offer the same service, but also with those who offer remote processing and with the customers themselves, who could revert to in-house handling of their computer facilities. This need to constantly cost-justify their service in the face of increasing numbers of competitors led to a steady erosion of profit margins in this industry.

Facilities management companies generally began by specializing in one field of business, such as banking, health care, or government agencies. They developed an expertise in the particular needs of that industry and drew new customers from within that niche. The division between companies providing facilities management to commercial customers and those catering to the government was especially strong. A company required extensive knowledge of the bidding process for government contracts and needed to meet particular government regulations to qualify as a vendor.

Companies that began by providing specialized service in a niche market first expanded geographically, providing that same service over a wider area. Many then expanded into new service areas, gaining new expertise through mergers or acquisitions of companies in different fields. In an industry that changed as rapidly as the computer industry, it was often risky for companies to provide only one service. Such specialization made them vulnerable to price cuts by competitors and to new products, laws, or regulations that made services obsolete or difficult to provide. The leading service vendors then expanded into multiple fields. They combined multiple services into a package tailored to individual company needs.

This increased packaging of services led to the trend of outsourcing, in which facilities management played a significant role. The most basic definition of outsourcing in the computer industry is simply the purchase of outside IT services, such as hiring a firm to handle payroll processing or manage a network; however, it often refers to the reduction or dismantling of in-house operations and the sale of fixed assets—like a data center or a telecommunications network—to a company specializing in information technology. The IT company then agrees to provide the services connected to those assets back to the client. Frequently, outsourcing deals of this sort also involve the transfer of personnel to the IT company. In addition to

relieving themselves of the burden of running and maintaining their computer facilities, companies gain access to significant cash resources that were previously tied up in their computer equipment. Other companies enter outsourcing agreements without selling their facilities because they want an escape in case they regret the decision, because it is easier to rebuild in-house operations if the company still owns its computer facilities.

Facilities management was also integral in the development of transformational outsourcing. Companies that purchased mainframe computers and established their computer operations in the 1970s faced updating aged and outmoded computer facilities. Many companies saw advantages in open architectures that incorporated client/server computing and local area networks (LANs), but did not have the expertise to design new systems for themselves and coordinate the shift from the old system to the new. Transformational outsourcing placed the responsibility on others' shoulders. An IT company agreed to take over the client's existing system, design a new one, and handle all operations during the transition, be it gradual or abrupt. Such a contract involved facilities management, systems integration, and perhaps off-site data processing and other services.

BACKGROUND AND DEVELOPMENT

Facilities management services began to be offered not long after mainframe computers and data centers became more common in the 1960s. At first, computers and the in-house operations associated with them were a matter of pride for companies profitable enough to afford this cutting-edge technology. However, it soon became apparent that specialists who could bring economies of scale to the activity could often operate these facilities more efficiently than those who owned them.

From its infancy, the facilities management industry was composed of small, entrepreneurial companies. Even after more than a decade of growth, 47 percent of data processing firms had revenues of less than \$1 million, and 47 percent had revenues between \$1 and \$10 million. Of the remaining 6 percent, only half had revenues of more than \$25 million.

By the late 1970s, it was already increasingly difficult to distinguish among companies that offered remote computing, software services, and facilities management. Major vendors offered several services that blended in various ways, depending on the needs of the customers.

From the late 1960s to the early 1980s, the data processing industry, including facilities management, fluctuated with the economy. The annual rate of revenue growth declined by approximately 10 percent during periods of recession in the early 1970s and 1980s. The following periods of economic acceleration produced a corresponding increase in the growth rate. Although the

data processing industry was affected by the general health of the economy, it maintained a healthy growth rate throughout the 1970s and early 1980s. The lowest growth rate in that period was in 1982, when the industry grew by only 11 percent—a rate that nevertheless compared favorably to other industries at that time. Although facilities management individually had the smallest share of data processing revenue in the early 1980s, its annual growth rate at times exceeded the average for the industry. Revenues were \$989 million in 1980 and grew an average of 13 percent annually to reach \$1.4 billion in 1983.

In 1981, the market researcher INPUT projected a 21 percent compounded growth rate for the facilities management industry over the next five years. However, in the early 1980s, several developments in the hardware and software industries threatened the strong growth of the facilities management industry. International Business Machines Corporation (IBM) software became increasingly standardized, making computers easier to use and leading more companies to manage their facilities themselves. In addition, cheaper, more user-friendly minicomputers became common, adding to the do-it-yourself trend. However, declining prices and the need to keep up with competitors who had computerized led many more companies to buy computers, enlarging the overall market for computer services. Although the facilities management industry did not meet that 21 percent growth rate, it continued to grow steadily.

By 1992, revenues in the facilities management industry reached \$3.8 billion, almost double the revenues of 1988. The rate of growth was approximately 18 percent per year between 1990 and 1992. Firms also became increasingly productive—average sales per employee rose from \$110,000 in 1990 to \$135,000 in 1992. By 1997, the facilities management industry's revenues had nearly quadrupled from its 1992 level to \$15.1 billion.

Facilities management remained a strongly entrepreneurial industry throughout the 1990s. The vast majority of facilities management companies were privately owned and had revenues under \$2 million. Private companies composed 99.3 percent of the computer services industry in 1992, though the remaining publicly held companies dominated the higher end of the revenue scale. Large information technology services firms, such as Electronic Data Systems (EDS) and Computer Sciences Corporation, continued to make inroads in the desktop technologies and networking markets in 1995, whereas companies' internal IT departments continued to feel more secure in their ability to build client/server applications. As a result, smaller and more specialized client/server integrators were forced to respond by thinking up new value-added services. The facilities management industry also remained a highly fragmented one, with companies specializing in

providing services to a particular industry. According to *Business Week*, specializing often acted to a company's advantage, as long as the services it provided to a particular industry were comprehensive enough: "Profit margins are tightening in the generic outsourcing field, where they simply run existing systems for less money than customers can. But to broaden their scope, those giants will have to invest heavily in industry-specific software—or buy established specialty outsourcers. Either way, it seems, the specialists can win."

According to data from the U.S. Census Bureau, computer facilities management was a \$15.1 billion business in 1997, and it showed little sign of slowing down as the new millennium approached. Census figures showed that more than 1,400 establishments with a total of nearly 72,000 employees were actively engaged in this business in the United States in 1997. The industry's annual payroll totaled almost \$3.4 billion in 1997. Although facilities management companies had incentive to develop into full-service outsourcers, given the growing market and the improved profit margin involved, only a few had the resources necessary to offer that extended range of services. In addition to expertise in facilities management, an outsourcing vendor needed to understand systems integration, network operations, communications, and software development. Capital requirements were also higher. Frequently, a remote data center for off-site processing was required, along with an extensive communications network to transfer the data to the remote site. Additional capital might be needed to purchase the customer's existing computers or data center facilities and hire their information systems personnel. Only the larger IT service companies possessed the resources to accept such contracts. In an industry traditionally composed of small, entrepreneurial companies, only a minority were expected to take full advantage of this trend.

For those companies that did evolve into outsourcing vendors, many are turning to "enterprise resource planning" (ERP) applications and e-commerce. A major new growth area in outsourcing—applications-rental—was expected to be a \$6 billion business by 2002, according to Forrester Research, a consultancy in the information technology field. Some of the large software companies that specialize in ERP applications are creating dynamic new business opportunities from the ground up. Working with Internet service providers (ISPs) and major hardware manufacturers, these outsourcing vendors want to make the latest business software applications available on a subscription basis. They are targeting companies with annual revenues of less than \$500 million.

In perhaps an extreme example of outsourcing, the U.S. Chamber of Commerce in 1998 struck a deal with Cap Gemini America to handle its information systems, Internet access, telephone switches, Web site, virtual pri-

vate network, as well as its data and voice wide-area network services. The 10-year agreement carried a price tag of \$75 million, according to a spokesman for the Washington-based Chamber. Prior to striking its agreement with Cap Gemini, the Chamber had an annual information systems (IS) budget of nearly \$7 million and an IS staff of 60.

CURRENT CONDITIONS

Despite a poor economy, this sector of the industry was enjoying large increases in revenue into the new millennium. Computer facilities management generated an estimated \$19.1 billion in 2001, up 16.5 percent from \$16.4 billion in 2000, according to the U.S. Census Bureau. Revenue had grown 7.5 percent in 2000, and enjoyed an impressive 28.1 percent jump in 1999, when revenue totaled \$15.2 billion. IT outsourcing as a whole had \$120 billion in revenue in 2001 and was expected to grow 15 to 20 percent a year. However, despite large deals and rosy forecasts, some industry executives warned earnings were shrinking in late 2002 and that the industry was feeling the negative impact of the recession.

Meanwhile, more companies continued to outsource their IT operations, and several large deals were made in the early 2000s. American Express will give IBM Global Services \$4 billion to run its global IT infrastructure over the next seven years, which was expected to save Amex millions in costs. Nextel Communications signed several IT outsourcing agreements in 2002, including a five-year, \$234 million deal with EDS and a \$1.2 billion deal with IBM Global Services and TeleTech Holdings. The deals were expected to save Nextel more than \$1.1 billion in an eight-year period. Outsourcing, companies say, frees them to focus on their products, services, and clients rather than IT management.

INDUSTRY LEADERS

No one particular company dominates the facilities management industry. As they grew, most facilities management companies added services outside of the industry. EDS, headquartered in Plano, Texas, is a major player with 2002 revenues of \$21.5 billion, down 0.2 percent for the year. Besides computer facilities management for businesses and government, EDS is involved in consulting services, data processing, and computer network systems integration. EDS, which had about 137,000 employees in 2002, was founded in 1962.

Parent company IBM expanded its IBM Global Services in 2002 with the acquisition of PwC Consulting and has grown into a leader in this segment. IBM Global Services handles strategic outsourcing, business consulting, and integrated technology. IBM Global Services had total 2002 sales of \$36.36 billion, up 4 percent from 2001.

Computer Sciences Corporation, with 67,000 employees and fiscal 2002 revenue of \$11.4 billion, was founded in 1959 and is headquartered in El Segundo, California. The company began by working in a niche market, like many facilities management companies, and gradually became one of the largest of the IT services companies. Computer Sciences derived the majority of its business from state, local, and federal government work—much of it involving facilities management—and developed long-standing relationships with NASA, the Navy, and other defense contractors. Although it is considered one of the primary outsourcing firms, it no longer lists facilities management as one of its primary activities.

WORKFORCE

The growth in outsourcing at the turn of the century was phenomenal, and the demand for skilled workers was very high. The industry was booming, and many jobs such as programmers and systems analysts were available with very few skilled workers to fill these positions.

Although the nation's workforce of computer operators declined throughout the 1990s and was expected to continue to shrink well into the new millennium, all other occupations in this industry continued to grow at impressive rates. Data from the U.S. Bureau of Labor Statistics (BLS) showed that computer operators numbered 291,000 in 1996 and were expected to decline sharply through 2006. Jobs in computer programming, which totaled 568,000 in 1996, were expected to increase between 21 percent and 35 percent by 2006, according to BLS projections. Employment in the ranks of computer scientists, computer engineers, and systems analysts, numbering 933,000 in 1996, was expected to increase 36 percent or more by 2006, according to BLS. Of the 933,000 jobs in this category, 506,000 were held by systems analysts, 216,000 by computer engineers, and 211,000 by other computer scientists, including database administrators and computer support specialists. More than three-quarters of the jobs in the computer services industry were classified as white collar.

SIC 7377

COMPUTER RENTAL AND LEASING

This industry consists of establishments primarily engaged in renting or leasing computers and related data processing equipment on the customers' site, whether or not also providing maintenance or support services. This industry does not include establishments engaged in both manufacturing and leasing computers and related data processing equipment. Establishments primarily engaged in finance leasing of computers and related data processing equipment are classified in **SIC 6159: Miscellaneous Business Credit Institutions**. Establishments primarily engaged in leasing computer time are classified in **SIC 7374: Computer Processing and Data Preparation and Processing Services**.

NAICS CODE(S)

532420 (Office Machinery and Equipment Rental and Leasing)

INDUSTRY SNAPSHOT

Companies in this industry bought, sold, and leased new and used high-technology equipment. These companies included maintenance companies, refurbishment/reconfiguration firms, transportation companies, financial institutions, original-equipment-manufacturer (OEM) finance companies, software distributors, and industry consultants.

The success of computer rental and leasing companies evolved from the strong urge among U.S. industries to remain on the cutting edge of technology. While many companies wanted to upgrade their computer equipment, few were ready to invest the necessary money up front, and many decided instead to turn to rental and leasing companies. By leasing equipment, companies could experiment with new computers and peripherals, upgrading as they felt necessary.

Sales volume in the computer leasing and remarketing industry was between \$15 billion and \$25 billion annually in the early 1990s. By the late 1990s, equipment leasing had grown to a \$183 billion industry, according to the Equipment Leasing Association. The second half of the 1990s proved to be a profitable environment for the computer leasing industry, despite dramatically reduced purchase prices of new computers. Some computer

leasing companies responded by adding services to their leases, such as computer maintenance and insurance.

ORGANIZATION AND STRUCTURE

The two main types of leases used in the industry were finance leases and operating leases. In direct finance leases, which were excluded from this industry classification, the lessor provided the financing. In leveraged leases, other investors provided debt financing. Operating leases were considered the best option for companies trying to avoid depreciation deductions. In an operating lease, the lessor owned the equipment and took the depreciation, so the user incurred no liability. The cost of leasing was considered an expense on a company's income statement but did not show up on its balance sheet. There were four typical lessors: banks, captives (usually manufacturers' subsidiaries), independents, and financial services organizations.

Other kinds of leases included the purchase option lease, in which a business owned the equipment but did not carry the balance-sheet debt; the sale-leaseback, in which a company sold its own computer equipment to a lessor to remove it from the balance sheet and then leased it back; and the dollar-out lease, in which the business could acquire the equipment at the end of the lease for one dollar. In some cases the purchase price was determined at the end of the lease based on the fair market value of the equipment at that time, and in other cases the price was determined at the lease negotiation.

Computer rental and leasing companies selected their clients carefully. They considered credit ratings, as well as the type of company they were dealing with, before structuring the lease. Some lessors required several payments up front. Others took their first payment upon delivery of the equipment. They also offered various levels of service that accompanied the lease. The industry is tied to the client's ability to obtain credit approval and money lending institutions' willingness to fund computer leases. This ability fluctuates with the economy.

Rentals were attractive to corporate buyers who were not ready to commit to a purchase or a long-term lease while personal computer (PC) prices were falling. On the other hand, rental rates needed to reflect the cost of PCs, and rental firms suffer smaller margins when the prices are low. The key to survival for these rental firms is service. Many offer delivery, installation, and maintenance along with the rental.

Some companies rented or leased computers until they decided what kind to buy. Others rented or leased in order to save enough money to buy equipment. Still others used rental or leasing as a way to upgrade their existing computer systems without the immediate output of money. Monthly payments for leased equipment were

usually lower than monthly payments on loans taken out to buy computer equipment.

With high-tech equipment, companies kept an eye on evolving technology by leasing computers and trading up when they were ready for the latest development. The drawback of leasing was that it cost more in the long run and did not provide companies with ownership of new computer equipment. Vying for customers, companies in the computer leasing and rental industry approached the twenty-first century with attractive rates as well as promises of service and support.

Two associations of companies involved in the U.S. computer leasing industry were the Information Technology Resellers Association (ITRA) and the Equipment Leasing Association of America (ELA). ITRA was formed in 1998 by the merging of the Computer Dealers and Lessors Association (CDLA) and the Digital Dealers Association (DDA). The CDLA was created in 1981 from the Association and the Computer Dealers Association. The member companies signed a Code of Ethics that was backed up by a standing committee formed in 1974. ITRA advertised on behalf of its member companies, emphasizing their flexibility, concern with ethics, and ability to save clients money.

ELA, which was organized in 1961, helped introduce information-sharing among its members. As a non-profit trade association, ELA worked with Dun & Bradstreet to create a database with credit histories of lessees while also tracking industry statistics and creating educational programs for members. ELA is a nonprofit organization headquartered in Arlington, Virginia, representing more than 800 member companies, which provide a variety of asset-based financial products, primarily equipment leasing.

BACKGROUND AND DEVELOPMENT

Rental and leasing had a continuous history from ancient times through the present. In the 1980s, leasing grew twice as fast as business. According to a CDLA survey conducted in late 1994, 70 percent of computers and peripherals were leased versus 30 percent which were purchased. These included desktop computers, large and small servers, and telephone systems.

The rapid rise of technology after World War II caught many businesses unprepared. In 1956, after the U.S. Justice Department decided a complaint against IBM, a Consent Decree paved the way for companies to purchase IBM machines that would be leased to users. IBM had previously rented its own equipment to businesses and received the equipment back at the end of the rental term, which prevented a secondary market from developing. The Consent Decree was still in effect in the 1990s, and it offered maintenance to IBM owners, replacement parts, and training for independent companies.

Equipment leasing and remarketing reported industry-wide volumes of \$138 billion in 1998. As a rule, the computer rental and leasing industry was strongest when the computer industry was healthy and strong. When the economy suffered, so did this industry. Like the retail computer industry, the rental industry went through a period of consolidation. Some smaller leasing companies specialized in particular products, services, and support, marketing themselves as being knowledgeable and quick. Some offered special equipment for their customers.

In 1992, computers replaced aircraft as the most frequently leased item in the United States. According to *Equipment Leasing* magazine, total new business for the second quarter of 1999 was \$7.2 billion, up 4.3 percent from the previous year. Computer leasing companies either leased their merchandise directly or arranged the lease and provided some or all of the financing. Many different lease terms were offered, although most customers chose three- to five-year leases for computers, computer peripherals, and related equipment. By comparison, furniture was often leased for as long as ten years.

Leasing made sense for many businesses partially because lease payments were fully deductible for tax purposes, and sales taxes and interest payments used when purchasing equipment were not deductible. In 1986, the Tax Reform Act removed the investment tax credit while stretching out depreciation schedules. But companies unable to use their depreciation were able to transfer tax benefits to lessors in exchange for reduced equipment costs. For tax purposes, leases were required to be short enough so that 20 percent of the estimated useful life of the equipment remained after the lease term. Options to buy the equipment at the end of the lease were required to specify how the price would be determined after the lease was over.

CURRENT CONDITIONS

The equipment leasing industry is continuing to enjoy growth into the twenty-first century. With the growth of e-commerce and e-tailing, the need for current technologies in the workplace is growing. Although the cost of computing equipment continues to fall, the issues of maintenance and support are significant, and lessors are often bundling training, software, maintenance and support into their contracts to make leasing more attractive. A Gartner Group study quoted in *Information Week* stated that \$4 billion in desktop PCs were leased in 1998 and predicts more than \$6 billion worth will be leased in 2002.

In the mid to late 1990s, computer equipment manufacturers and computer leasing and remarketing firms had a symbiotic relationship. By working together, each tried to maximize its success, but the first step to a successful relationship was for manufacturers to develop policies

and practices that permit and maintain healthy secondary markets in their equipment. ITRA (previously the CDLA) played the role of watchdog to ensure that the computer leasing and remarketing industry had a strong, unified voice through effective working relationships with major manufacturers of computer and telecommunications equipment.

Industry relations between computer equipment manufacturers and computer leasing and remarketing firms evolved with the industry, according to ITRA. As the companies focused on a greater diversity of equipment, they also established working relationships with a number of manufacturers. Independent computer dealers and lessors provided a valuable service to the end user and a steady source of additional sales and maintenance revenue for the manufacturer.

Roberta Furger, in a 1998 article in *PC World*, suggested that the straight math for leasing PCs didn't make sense when compared to outright purchase or purchase on credit. With the decreased cost of purchase, the industry may well need to continue to provide the extras of reliable support in order to maintain their markets.

INDUSTRY LEADERS

Many of the industry's firms were small and operated by entrepreneurs, while a handful of larger firms dealt in equipment leasing worldwide. Most leased both new and used computer equipment and remarketed pre-owned computer systems. Some also provided extra services, such as systems integration, installation, and maintenance.

Most major computer manufacturers, such as Dell, Hewlett-Packard, and Compaq, also dealt in leasing and remarketing. However, since those companies were also engaged in manufacturing, they were classified separately.

Comdisco, Inc., formerly a computer leasing leader with revenues of \$4.159 billion, was the largest company in the industry in the mid 1990s. In 1999, Comdisco restructured and sold its mainframe leasing to IBM. Comdisco is now focusing on providing high tech e-services to corporations.

Larger lessors were able to create leases that included computer equipment as well as other supplies, while specialty lessors were able to help their clients choose appropriate equipment by suggesting such options as combining new and used equipment to save money.

IBM Corp., based in Armonk, New York, with 1999 sales of over \$87 billion, has a financing division, IBM Global Financing, that deals internationally in computer leasing and financing. Symix Systems, Inc., based in Columbus, Ohio, recently partnered with IBM Global Financing and EAB Leasing Corporation's Softech Fi-

ancial division to offer a comprehensive technology leasing program, according to a September, 1999, Symix press release.

Other industry leaders included General Electric Capitol Information Technology Solutions, located in Stamford, Connecticut; El Camino Resources International, located in Woodland Hills, California, with 1999 sales of \$668 million; GENICOM Corporation, located in Chantilly, Virginia, with 1998 sales of over \$452 million; and Leasing Solutions, Inc., located in San Jose, California, with 1998 sales of nearly \$300 million.

WORKFORCE

The major companies in the computer rental and leasing industry had a combined total of 9,647 employees in 1997. The total payroll for the 972 establishments doing business in the industry was \$604 million, according to the U.S. Census County Business Patterns. In a 1999 article in *Equipment Leasing*, it was indicated that the total number of employees in the industry is leveling off after several years of growth, most likely due to an increase in acquisitions and mergers which have consolidated the work force.

Changes in state and federal tax codes affected salespeople in the rental and leasing business. They needed to understand the tax implications of their leases for potential customers. Customers served by this industry were also more knowledgeable about the equipment itself and looked for rental and leasing companies that offered equipment plus several lease options and a high level of service.

AMERICA AND THE WORLD

The U.S. market for rental and leasing of computer equipment was quite self-sufficient. While few of the leasing companies not affiliated with computer manufacturers had a large presence overseas, there was very little competition from foreign firms. In fact, the only leasing business run by European or Asian companies came from several large banks. New business opportunities for U.S. firms in Canada and Mexico have also resulted from the passage of the North American Free Trade Agreement (NAFTA).

RESEARCH AND TECHNOLOGY

The computer rental and leasing industry was vitally connected to technology, and only the companies that remained on top of the most recent trends and industry changes were successful. Automated reservation systems were used effectively by even the smallest computer leasing or rental companies to avoid delays or inventory problems for customers. Companies in the industry spent money and time developing protocols for leasing such

technologies as Internet servers and parallel-processing mainframes.

The rapid growth of e-commerce is also a driving force in the need for current computing power, though much of this technological need is being outsourced by smaller companies who contract for web hosting and online shopping cart services rather than maintain the hardware and software in-house. However, these web based services, which are often offered business to business, are requiring companies to update employee desktop computers to support the client software needed for access.

Service on computers and peripherals is increasingly done remotely, via dial-in diagnostic tools, Internet connections, and automated web-based support centers. This type of troubleshooting service saves the lessor and the lessee the expense of sending someone out personally. As service becomes more central to the financial success of computer lessors, the prices of hardware and software continue to drop. Therefore, the lessors are also expected to lease lower-priced items more frequently.

SIC 7378

COMPUTER MAINTENANCE AND REPAIR

This category covers establishments primarily engaged in the maintenance and repair of computers and computer peripheral equipment.

NAICS CODE(S)

443120 (Computer and Software Stores)

811212 (Computer and Offices Machine Repair and Maintenance)

Two main types of companies operated in the computer maintenance and repair industry: third-party maintenance (TPM) companies, which performed service contracts on equipment from various manufacturers; and original equipment manufacturers (OEM), which both manufactured and serviced computers and peripheral equipment. This distinction was less pronounced in reality, however, because OEMs often subcontracted their service agreements to either affiliated or unaffiliated TPM firms.

The computer maintenance and repair industry grew dramatically in the 1980s and 1990s as computer sales skyrocketed. From total shipments of less than 2,000 units and \$600 million in 1960, the computer industry topped 900,000 units and \$16 billion by 1980, and reached 7 million units and \$44 billion by 1990. By 2003, this number was expected to double to more than 15 million units annually. This rapid growth, along with a shift from mainframes to PCs, introduced opportunities for small, independent TPM companies to compete against the large OEMs. Nonetheless, in the late 1990s, OEM companies were reported to hold as much as 80 percent of the maintenance and repair market in some categories, such as high-end system and mainframe services.

Leading OEM firms included many of the nation’s best-known technology companies, such as IBM Corp., Sun Microsystems, Compaq, Electronic Data Systems,

and AT&T Corp. While the majority of TPM firms were smaller local and regional providers, several service firms operated on the national level, including the Cerplex Group, ENTEX Information Services Inc., and Inacom Corp.

The U.S. Census Bureau estimated revenues specific to this industry at \$15.4 billion by the late 1990s, up more than 50 percent from \$7 billion in 1990. The total U.S. market for services performed by this industry was estimated at much more—\$62 billion for 1998. Less than one-quarter of this market, however, was served by firms primarily engaged in computer maintenance and repair. Instead, the bulk of maintenance and repair revenues were generated by larger, diversified companies like IBM and AT&T that had a presence in many industries. The *New York Times* reported that the lucrative PC segment of the computer repair market was worth \$28 billion alone in 1995, based on a Dataquest study, and was expected to grow at 14 percent annually in the late 1990s. Within the PC segment, the home PC repair market was considered an emerging—but largely untapped, according to Dataquest—customer base for this traditionally business-focused service industry.

As demand for computer maintenance and repair surged in the 1980s and 1990s, TPM companies developed new strategies to address the lower cost and increased reliability of computer hardware. First, TPM firms reduced repair time by replacing components instead of repairing them. Next, they developed remote diagnostic software to minimize the need for costly on-site service. Finally, they expanded their services to include installation and software maintenance, including virus protection, Internet connectivity, and site-authoring services by the late 1990s.

OEMs also changed their strategies as computers became increasingly similar. They began to differentiate their products by enhancing their maintenance services. Many even started supporting competitors' equipment. As the industry entered the late 1990s, several discount or "clone" manufacturers reduced their support and forced customers to handle their own maintenance. This provided a new opportunity for TPM firms, which offered disaster-recovery services and started supporting software and multimedia to satisfy more demanding customers. At the same time, corporate emphasis on outsourcing—the practice of hiring external firms to perform specialized functions formerly done in-house—translated into new business for TPM providers. Cerplex, for example, actively branded itself as an outsourcing solution.

"The increasing complexity of software and interactive multimedia made hardware troubleshooting a more complex task that required a different kind of TPM," said David Glascock, president of the North American Com-

puter Service Association (NACSA). As computer and communication technologies merged in the late 1990s, Glascock believed that TPM companies would expand their services to include supporting high-definition computer displays and wireless communication devices.

Growth in the industry is often dependent upon external trends and events, such as new software releases and technological change. The release of Microsoft's Windows 95 operating system, for example, led to increased demand for system maintenance—particularly upgrades—as home and corporate users coped with new demands on memory and other system resources. Similarly, one-time events, such as converting older systems to process calendar dates past the year 1999, created new business for the short term.

Employees in the computer service industry generally possessed a high school degree and technical training in computer science, electronics, and circuitry. Training programs were offered by computer manufacturers, TPM companies, and vocational/technical schools. Some study programs took 3-6 months, but formal programs required 1-2 years. Continuous education was required to keep up with fast-paced technology improvements.

Job prospects for computer equipment servicers were excellent. According to the Bureau of Labor Statistics, in the late 1990s there were more than 80,000 workers in this industry. This number represented an increase of 67 percent since 1995 and was projected to increase steadily. Overall, the number of data-processing machine repairers was anticipated to rise another 36 percent by 2006. In the late 1990s, the median annual earnings for computer repairers was just over \$32,000. The highest earners made \$50,000 or more a year.

In the opening years of the new millennium, the mostly small firms in the computer repair business may be facing competition from a brand new quarter. Wal-Mart Stores, which has given mom-and-pop retailers around the country a real run for their money, in the fall of 1999, launched a test to see whether it could interest its customers in getting their computers repaired at the same place they shop for clothing and toiletries. The company contracted with Computer Doctor to open computer repair shops inside ten of the giant retailer's Midwest Supercenters. Computer Doctor, headquartered in Aberdeen, South Dakota, opened its first Wal-Mart repair shop on Sept. 15, 1999, in Ankeny, Iowa. If the experiment proves successful, Wal-Mart is likely to expand the service to all of its Supercenters, which numbered more than 600 in late 1999.

Another novel experiment in computer repair was launched in the Cincinnati area in the latter half of the 1990s. Entrepreneur Steve Pollak's mobile computer repair service, PC On Call, started with a single service van

but by early 1999 had expanded to 16 vehicles and 30 employees. PC On Call had also set up shop in Columbus, Ohio, and had its sights on Dayton as well. According to Paul Cashen, the company's chief executive, PC On Call was planning to expand into up to 10 new markets by the end of 2000 and hoped eventually to serve 40 cities nationwide. Cashen said the company usually responds within 24 hours to service calls, of which it receives between 100 and 150 daily.

SIC 7379

COMPUTER RELATED SERVICES, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in supplying computer related services, not elsewhere classified. Computer consultants operating on a contract or fee basis are also classified in this industry. Establishments primarily engaged in producing prepackaged software are classified under **SIC 7372: Prepackaged Software**; and those engaged in offering data processing courses or training in computer programming and in computer and computer peripheral equipment operation, repair, and maintenance are classified under **SIC 8243: Data Processing Schools**.

NAICS CODE(S)

541512 (Computer Systems Design Services)

541519 (Other Computer Related Services)

INDUSTRY SNAPSHOT

More than a decade ago, a handful of companies like IBM Corporation and some smaller rivals dominated this

industry. Corporate downsizing and reengineering in these companies forced economic power to shift from a handful of monopolies to hundreds of smaller high-tech specialists, according to the *Dallas Business Journal*. The power in the marketplace also shifted during the 1990s from those making the computers to those using the computers. A direct and striking result of this trend was the explosion in demand for computer services.

The computer related services industry was only a small part of the computer professional services industry. According to the International Trade Administration of the U.S. Department of Commerce, the computer professional services industry had 1997 revenues of nearly \$109 billion—an increase of more than 63 percent from \$66.7 billion in 1994. Within this computer services category, the single biggest component was computer system design services, accounting for \$51.2 billion of revenue. Computer facilities management services brought in another \$15.1 billion. Bringing up the rear within the computer services sector were computer related services, not elsewhere classified, which produced revenue of approximately \$4.3 billion.

The growth of firms in the computer related services industry was in double digits toward the end of the twentieth century. Companies increasingly turned to computer specialists to handle their disk conversions, database developments, or troubleshooting. The popularity of the information superhighway and its effects on U.S. companies meant a larger role for consultant services. Although many companies developed extensive in-house computer centers from the 1960s through the 1980s, in the 1990s they turned to computer service firms in increasing numbers, particularly to handle special assignments. Some found that it was more cost effective to lay off or reassign their own computer personnel while using third-party data processors, systems integrators, or computer consultants. Computer services firms made it their responsibility to stay on the cutting edge of technology and to offer services that most in-house departments could not match.

ORGANIZATION AND STRUCTURE

Those computer related services not classified under other SIC codes included hardware and software requirement analysis and diskette conversion services. Some consultants marketed themselves to businesses as experts in a particular area. Those who performed hardware requirement analysis thrived in the computer-centered economy by recognizing the need for business to select the best computer equipment for its goals. These analysts were usually hired on a contract basis to spend several weeks or months working with a company to select the company's computer hardware. Often they discovered that existing equipment was not satisfactory and that

either upgrades or complete overhauls were necessary to bring the company up-to-date. At the opening of the twenty-first century, these computer consultants and analysts were in a good position to succeed financially.

The National Association of Computer Consultant Businesses (NACCB) is a nonprofit trade organization, based in Washington, DC, whose members include skilled professional consultants or programmers. Founded in 1987, NACCB supports legislation, provides job fairs and model legal contracts for members, and encourages professional standards among its members. NACCB also lobbies Congress to consider the needs of independent contractors and employees in the industry.

The Independent Computer Consultants Association (ICCA) is a nonprofit trade association based in St. Louis that was founded in 1976. Its members are experts in hardware and software. ICCA publishes tips for hiring computer consultants as a support for its members. It also compiles industry statistics, offers insurance programs for member companies, and develops standard consulting contracts.

Computer related services consultants perform tasks similar to those performed by other computer professionals. Many work for large computer firms before going off by themselves or joining consulting firms. The consulting firms tend to be small to medium in size and can be found in every kind of community in the United States, from large metropolitan areas to rural communities. Those consultants working in the smaller areas commute to their clients' offices, often working there for the duration of a project.

BACKGROUND AND DEVELOPMENT

As computers and computer systems became commonplace in the working world, the necessity for computer related services increased. From the 1950s through the 1980s, technology made huge leaps forward. As costs fell in the 1970s and 1980s, more businesses came on line for straightforward tasks. By the late 1980s and early 1990s, very sophisticated computer equipment needed equally sophisticated specialists who could handle disk conversion, database development, and recertification of disks and tapes. These consultants worked to make a niche for themselves among businesses of all sizes and types.

Computer service companies were originally hired to automate such record-keeping tasks as payroll. They expanded into such customer-related areas as fund transfer systems, just-in-time inventory systems, and customer information systems. Many companies could only hire these service firms in the best of financial times given the high cost of the services. Early programming was highly individualized, but the needs of business by the 1990s necessitated more standardization.

New tax laws and proposed health care changes were some of the areas of concern to the computer consulting industry. The National Association of Computer Consultants Businesses (NACCB) wanted computer systems analysts and other computer consultants to be considered professionals exempt from overtime rates. Their staff members worked with the U.S. Department of Labor to create laws that dealt fairly with NACCB's members. The 1986 tax law's Section 1706 indicated that only technical services firms could deduct the use of independent contractors. NACCB actively tried to repeal this part of the law. President Clinton proposed to repeal Section 1706 as part of his health care reform bill, saying that more workers needed to be treated as employees.

Pennsylvania enacted a 6 percent sales-and-use tax for computer related services. It met with strong resistance from the industry, whose leaders said that computer services firms were in the early stages of development and could be harmed by the steep tax. At the same time, these firms were contending with an influx of products that were designed to be operated by average office personnel without the assistance of specialists.

Prepackaged software also took away some of the steam of these companies, as more users of computer hardware and software became familiar with their equipment, needing less support from computer services professionals. There was also a longer lag between the purchase of computer equipment and the need for computer professional services, which forced these companies to operate "leanly." As more companies integrated computer systems into their operations, new additions to the installed base increased slowly because many purchases were just upgrades.

By the mid 1990s, an increasing connection existed between the computer and telecommunications industries, especially in Europe and Japan. This was expected to help computer professional services firms as consultants were called in to connect changing technologies so that performance was seamless.

The Independent Computer Consultants Association (ICCA) encouraged its member consultants to use formal contracts that outlined such details as payment terms, length and scope of the project, and copyright information on the finished project. Custom software developers, for example, usually held the rights to the computer code they developed, and the customer was allowed to use the system, but not to sell it.

Beginning in 1988, the Internal Revenue Service (IRS) penalized companies for calling employees independent contractors and not paying taxes for them. The IRS used several factors to determine whether a part-time worker was an employee or an independent contractor. These included employee training, working hours, pay-

ment practices, and the company's right to discharge the worker or the worker's right to terminate the working relationship. As long as the employer controlled what the work was and how it was to be done, the worker was considered an employee.

Many in the industry were also concerned about competition from foreign computer experts. NACCB fought the abuse of immigration laws that allowed foreign workers to do computer consulting work at illegally low rates and without proper visas.

CURRENT CONDITIONS

Worldwide revenues of the information technology industry rose to more than \$1 trillion in 1998, up from \$688 billion only three years earlier, according to the Information Technology Industry Council (ITIC). These revenues represented sales of computers and related equipment, software and services, business equipment, and telecommunications equipment and services.

U.S. Census Bureau data put revenues of the U.S. computer services industry at nearly \$109.0 billion in 1998. Spending for computer-related services, not elsewhere classified, accounted for a little over \$4.3 billion of this total.

INDUSTRY LEADERS

More than 80 percent of the companies in this industry were smaller, entrepreneurial firms with annual sales below \$2 million. Many of these computer services companies were owned by minority Americans, according to a 1987 Census Bureau survey of minority-owned enterprises. Many non-computer firms joined the industry by adding divisions or by acquiring computer services companies. Banks, publishers, airlines, and telecommunications companies were among those whose information technology divisions were involved in this industry.

There was much industry consolidation in the 1980s and early 1990s. Larger firms laid off workers, and some smaller firms merged, while large firms acquired computer related firms to enhance their position in the industry. Many U.S. companies attempted to meet all of their computer needs with one large contract. This trend forced some smaller computer-related services firms to join forces with other small firms in order to get the bigger projects.

Computer professional services included custom software, system design, and outsourcing services. Among the major players in this industry in the late 1990s were Automatic Data Processing (ADP), Ceridian Corp., and Perot Systems Corp. Acxiom Corp. ADP, headquartered in Roseland, NJ, employed 37,000 workers worldwide and posted sales of \$5.5 billion in fiscal 1999, the twelve months ended June 30, 1999. Based in Minneapolis, MN, Ceridian employs a workforce of nearly 10,000

and reported 1999 sales of \$1.3 billion. The employer of 6,000 people, Perot Systems Corp., based in Dallas, TX, posted 1998 sales of \$993.6 million.

WORKFORCE

The Information Technology Association of America (ITAA), looking forward to 2005, predicted that computer services would have the largest increase in personnel among information technology fields—including computer hardware and telecommunications industries. According to the Information Technology Industry Council, export and employment statistics forecast were also strong. The information technology industry employed 2.06 million Americans in 1997, according to a study commissioned by the Computer Research Association. That was up more than 63 percent from an IT workforce of 1.26 million in 1988. The composition of the IT workforce, however, changed considerably over those nine years. In 1988, computer programmers made up 45 percent of all IT employees, against computer scientists at 38 percent. In 1997, computer scientists made up 60 percent of the IT workforce, compared with 30 percent for programmers.

Those consultants and analysts who took advanced training in new technologies and who had a broad base of knowledge were better placed to succeed in the competitive world of computer services. The ICCA had its own certifying organization known as the Institute for Certification of Computer Professionals. This institute administered a standard computerized examination at more than 140 sites around the world. Those who passed the exam were designated Certified Computing Professionals and could market themselves as experts in computer systems.

AMERICA AND THE WORLD

The United States comprised the largest market for computer services, with almost half of the information services used by consumers worldwide used in the United States. Computer consultants and consulting firms, therefore, were on solid ground in the U.S. market. Many foreign companies used U.S.-based computer related services as they tried to enter U.S. markets or as they concentrated on their own markets.

Overall, U.S. computer professional services were highly successful abroad. Computer related services were encouraged by the passage of the North American Free Trade Agreement (NAFTA) and the expansion of the General Agreement on Tariffs and Trade (GATT). The 1989 U.S.-Canada Free Trade Agreement led some U.S. computer services companies to expand into other markets by buying Canadian firms. As an export, computer related services thrived in Canada, which was the major importer of U.S. computer services as well as of computer software, hardware, and telecommunications ser-

vices. Some U.S. companies also had subsidiaries in South America and Europe.

Computer related services were being exported by U.S. firms at an increased rate in the 1990s. The U.S. Department of Commerce described the industry as having outstanding prospects for exporting success. According to the Bureau of Economic Analysis, the export of U.S. computer services was \$2.04 billion in 1998, while imports were only \$365 million. This represented an increase of more than 97 percent in exports from a level of \$1.03 billion in 1990. Imports, on the other hand, climbed more than seven-fold from \$44 million in 1990. The Information Industry Association (IIA) and ITAA both supported the efforts of U.S. firms overseas.

As countries around the world began to allow corporations to operate privately, computer services firms stood to gain new entry into foreign markets by helping the companies bring their operations up-to-date. Many consulting operations increased their marketing campaigns abroad in response to waning interest at home.

The European Community encouraged mergers and acquisitions among Western Europe's computer professional services firms. This trend had potential to create steep competition for U.S. companies. At the same time, a few Japanese, Canadian, and British computer services firms bought U.S.-based computer services firms in the early 1990s.

RESEARCH AND TECHNOLOGY

Such new technologies as computer-aided software engineering, or CASE, allowed some companies to handle their own computer programming without bringing in consultants. Some consulting companies fought this trend by offering skilled specialists who could perform computer tasks at rates far below the company's cost to do the work in-house.

In the early 1990s, an increasing proportion of computer related services was in electronic mail systems and services. This technology included the proliferating voice mail systems as well as electronic messaging systems that traveled across computer networks. Other telecommunications areas were expanding into computer consultants' territory as well. Integrated services digital networks, or ISDNs, provided computer professionals with another field in which their services could be used. The key for companies in the computer related services industry was to stay ahead of the corporate world and to continue offering services that enabled corporations to focus on their business while the consultants took care of their computer needs.

In the late 1990s, as the dawning of the new millennium neared, computer consultants reaped a bonanza as American businesses, large and small, spent heavily to

have their computer systems safeguarded against the so-called Y2K bug. The widespread fear was that computer systems would fail to recognize the arrival of the year 2000 and would either stop functioning altogether or would malfunction. As it turned out, perhaps because of the billions spent on preparations or perhaps because the threat was never so big as it was reported to be, the new millennium arrived with virtually no dislocation in the computer sector. However, as long as bugs in software continue to pose a problem, computer consultants will have plenty of business trying to track down and eliminate them. Examples of the damage such a bug can cause are numerous. In January 1990, AT&T's long-distance switching system crashed because of such a bug. Sixty thousand customers lost service for the nine hours it took to get the system up and running again. In another case, the results were deadly when a Therac-25 radiation therapy machine produced a "Malfunction 54" error message. Unaware that the message meant "radiation overdose," the machine's operator reset the machine and continued to treat patients, several of whom later died.

The new uses of the Internet, especially the potential for e-commerce, promises to spur further growth in this industry. Since Web site errors have the potential to drive customers into the arms of competitors, the explosive growth in the Internet undoubtedly will produce a wealth of business for computer consultants. In a mid 1999 example of the new opportunities for computer consultants, Neal N. Gibbons Services Plus +, a computer consultancy based in Magnolia, Texas, announced a new service for auto dealers with Web sites. The product, called Auto DIA (Auto Dealer Internet Audit) monitors the Web sites of new car dealers continually for errors, ensuring smooth operation.

SIC 7381

DETECTIVE, GUARD, AND ARMORED CAR SERVICES

This category covers establishments primarily engaged in providing detective, guard, and armored car services. Establishments primarily engaged in monitoring and maintaining security systems devices, such as burglar and fire alarms, are classified in **SIC 7382: Security Systems Services**.

NAICS CODE(S)

561611 (Investigation Services)

561612 (Security Guards and Patrol Services)

561613 (Armored Car Services)

INDUSTRY SNAPSHOT

The security and investigations industry is a \$100 billion business worldwide that has been in existence for at least 125 years. In the United States, there are approximately 11,000 businesses that make up the \$11 billion contract security industry. After years of relative obscurity, this industry was squarely in the spotlight after the events of September 11, 2001, bringing not just added attention but financing as well. The newly formed Office of Homeland Security is planning on bringing \$37.7 billion to this sector, while insurance companies are forming standards for corporate security that must be adhered to in order to qualify for coverage. One estimate puts revenue expansion in this field at nearly 9 percent a year, and one earnings projection puts revenue for the security industry in 2004 at \$158 billion worldwide. Noting the changing demand in the United States, more companies within this industry were shifting their focus in the early 2000s to terrorism and homeland security.

Organizations and individuals within the security industry provide products and services, including video-surveillance services and equipment, security guard services, armored car services, corporate investigations, biometric identification and devices, and concertina wire.

The industry has benefited from newer technology, including the Internet, but remains relatively primitive in terms of marketing its products and services, which are usually handled via word of mouth, direct mail, e-mail, print advertising, and industry conferences. Indeed, e-mail has become one of the most important new advertising vehicles and the ongoing focus of many companies.

ORGANIZATION AND STRUCTURE

Detective agencies provide investigative services. The area of investigation can vary widely, from uncovering corporate espionage to uncovering an unsavory episode in the background of a courtroom witness for the purpose of discrediting that witness. These enterprises range in size from small independent agencies to larger corporate businesses.

Business, industry, and government agencies all use guard services. Uniformed guards are hired to protect client property against theft, trespassing, vandalism, or to protect clients from physical harm. Some companies that provide guard services also provide security systems services (see **SIC 7382: Security Systems Services**). There are more than twice as many security guards in the United States as police officers.

Approximately 150 armored car services exist in the United States, some of which are subsidiaries of large corporations and others that are independently operated and may belong to the Independent Armored Car Operators Association. In addition to providing armed transport of cash between banking locations (for example, between the Federal Reserve Bank and bank branches), armored car companies also have what they call commercial accounts. These include food stores, restaurants, fast-food chains, department stores, and, potentially, any business that needs to move large sums of cash off site to a bank. Many armored car companies also have a money room, where money is stored temporarily and where services such as auditing deposits and processing orders for change are performed for client banks. In some cases, the cash may even move from a retailer to a money room, and then straight to the Federal Reserve, bypassing the retailer's bank altogether.

The money-courier industry is largely unregulated. There are no federal regulations covering who may transport money or how. Although the top companies use armored vehicles and try to screen out employees with criminal records, other companies may use ordinary minivans and do little to screen employees. Law enforcement officials, as well as officials within the industry, have charged that the lack of a government regulated licensing process, one which would require a thorough background check of potential employees, has bred an industry in which robberies are all too frequently “inside jobs.”

U.S. manufacturers, in an attempt to prevent theft and counterfeiting of their patented products and ideas, are turning to private investigation firms for undercover operations. In one case, a female private detective was hired to apprehend those responsible for the theft from two major U.S. companies of proprietary plans for industrial compressors. A spokesman for the American Society for Industrial Security (ASIS) estimated that theft of proprietary information costs U.S. and Canadian firms \$20 billion each year. A survey of ASIS members revealed that theft of manufacturing process technology is on the rise. Another area of concern to U.S. industry is protection of pharmaceutical trade secrets.

An emerging field for private detective work is the investigation of environmental crime. This might involve tracing illegal industrial sewage discharge to the guilty party or conducting research to determine which companies had in the past disposed of toxic waste at a particular site. Another unfortunate field of opportunity for detective work is urban terrorism. This was the case in 1991 when Laidlaw Transit, in Seattle, Washington, received three letters warning that school buses operated by Laidlaw would be blown up on Friday the thirteenth. (Private investigators, working with the Seattle police, determined the threat to be a hoax.) Other developing areas include computer and communications crime detection and forensic accounting, in which a firm's books are examined for instances of in-house fraud.

In 1997, detective, armored guard, and armored car services was a \$14.5 billion industry. It remained an industry that enjoyed growth in the recent past; industry sales in the early 1990s were seven times what they were in 1956. Twenty years ago there was concern within the industry that the use of credit cards would eliminate the need for armored car services. These fears have yet to become a reality, though, and credit card companies have themselves become major users of armored car services. Transportation of food stamps has provided another growth area for the armored transport industry, as has the use of ATM machines. However, there are those who believe that all cash transactions eventually should be replaced by a federally operated electronic money system, which would eliminate many criminal activities. If such a system were to be implemented in the future, armored car companies could expect a drastic decline in demand for their services.

The industry may be approaching maturity, however; as banks consolidate and close branches, demand for armored car services is lessened. It has been speculated by Jim L. Dunbar, chief executive of Federal Armored Express, that in the future there will be increased emphasis on money-room services as a source of revenue for armored car companies. The industry has also attracted new entrants who are competing based on price.

Some companies are able to offer price reductions by cutting back on such security precautions as well-fortified vehicles. And if the courier is insured to protect the client against loss or theft, the client may be persuaded by the cost savings offered to forego optimal security.

The demand for security guards, on the other hand, enjoyed steady, rapid growth through the 1990s. During the 1990s, the industry experienced average annual growth of 8 percent. Fueled by public perceptions of increasing crime, a growing schism between the haves and have-nots, the rise of gated communities, and an apparent willingness on the part of federal, state, and municipal authorities to leave public security to private firms, employment opportunities in the security guard industry were expected to grow rapidly in the coming decade.

The climate of fear that proved so hospitable to the security guard sector was heightened by the terrorist bombing in Oklahoma City in 1995. On the day after the bombing, the stock price of Wackenhut Corporation, America's third largest provider of security guards, jumped 20 percent. Though the panic was short-lived, demand for security guards continued to grow.

Guard companies, on the other hand, struggled during this period, facing what one analyst described as unacceptably high guard contract turnover. The reason for this was the conservatism and traditionalism of guard company management. Instead of assessing and reacting to changing levels in the customers' risk profile, most companies made operational changes only in response to customer criticism. By the mid-1990s, security firms began to take tentative steps to enhance the effectiveness, scope, and productivity of security officers with information-related technology. These technologies made it possible for a guard company to upgrade its customer service by tracking client asset changes and making the corresponding changes in guard services automatically. Online central information processing allowed direct management of the guard force, while three-dimensional modeling programs and high-speed portable equipment made it possible to create customized security plans on a daily basis rather than working from specifications that changed infrequently, if at all.

CURRENT CONDITIONS

Already one of the fastest growing sectors in the United States, the demand for security on all levels only continued to grow after the terrorist attacks of September 11, 2001. Spurred largely by the events of 9/11, growth came from a large number of businesses within the United States beefing up security. The trend toward outsourcing security services could be seen in organizations such as commercial offices, warehouses, and correctional facilities. This contributed to all sectors within this indus-

try, showing healthy growth in 2001. Demand for private security rose 6.8 percent per year since 1996, reaching \$33.55 billion in 2001, with guarding services taking the biggest share within that market at 35 percent in 2001. Guarding, a \$10 billion business in 1996, grew to \$11.7 billion in 2001, a 3.1 percent annual growth rate. Alarm monitoring brought in almost \$11.1 billion in 2001, up from \$6.9 billion in 1996, reflecting a 9.9 percent annual growth. Private investigations comprised the next largest sector in the private security industry, with \$2.1 billion in 2001, up from nearly \$2 billion in 1996. Private correctional facilities management showed the largest annual growth rate from 1996 to 2001, up 24.2 percent to reach approximately \$2 billion in 2001. Armored transport stood at \$2.1 billion in 2001; systems integration, \$1.5 billion; security consulting, \$910 million; and pre-employment screening and other services, \$2.3 billion.

Airport security was one sector that was the focus of much scrutiny and publicity in the months following 9/11. Employee screening and hiring processes became a major concern. Increased passenger screening after 9/11 increased costs to the U.S. government by nearly fourfold in the form of additional screening personnel, transition costs from private screeners to a federal environment, and increased wages and benefits. The Transportation Security Administration estimated it would pay some \$211 million per month in passenger screening costs in 2002, up from the \$55 million per month the airlines paid for the same services in 2000. Airport security was also on the verge of getting a high-tech upgrade as a result of terrorism. A number of intelligent security systems were being developed and proposed for use in passenger screening in airports nationwide.

Another post-9/11 trend in security was the shift to better trained personnel and, accordingly, higher wages for those better qualified. Security firms were replacing entry-level guards with former military or police personnel, while sometimes doubling pay in hopes of better services and improved profit margins.

Growth within this industry was expected to continue in the next few years, with a predicted 29 percent annual growth rate generating an estimated \$15 billion by 2004. There were concerns that with such high demand, the supply of qualified personnel—required in some cases to carry firearms—was somewhat limited. Other problems the industry must address include the lack of uniform training requirements, standardized background checks, and government negligence. Indeed, the lack of regulations in some states currently allow convicted felons to become security guards and private detectives.

RESEARCH AND TECHNOLOGY

Technology is an important part of the security industry, with new products and services being developed

as new technologies arise. More advanced products available to the industry in the early 2000s included audio listening devices and electronic countersurveillance devices, robot guards, “intelligent” fences, handheld guard tour scanners, explosion detection devices, and electronic key management systems.

INDUSTRY LEADERS

Borg-Warner Corp. (BWC) was formed in 1928 through the merger of four firms engaged in the manufacture of auto parts. Throughout subsequent years, this Chicago-based firm diversified into other areas such as chemicals, industrial equipment, air conditioning, and with the purchase of Baker Industries in 1978, protective services. After being bought out by Merrill Lynch Capital Partners in 1987, BWC divested itself of all operations except for the automotive and protective services businesses. Principal subsidiaries in the protective services group, in addition to Baker Industries, which provided a wide range of protective services, included Wells Fargo Guard Services, providing detective and guard services to institutional and residential clients; Burns International Security Services, providing security guard and investigative services to industrial and institutional clients throughout the United States, Canada, the United Kingdom, and Columbia; and Wells Fargo Armored Service Corp., providing armored car service as well as ATM servicing and cash services.

Burns underwent a restructuring that resulted in a change of name to Burns International Services Corporation, which, in turn, was the result of combining Wells Fargo Guard Services and Burns International Security Services.

The country's first detective agency was established in 1850 by Allan Pinkerton, an immigrant from Scotland. Pinkerton's had clients in the United States, Canada, Mexico, and the United Kingdom. In 1999, about 85 percent of revenues came from security guard services. Pinkerton's guards were used by hospitals, governmental units, special events promoters, and other industrial, commercial, financial, and retail customers to provide security, access control, traffic control, theft prevention, and related services. Pinkerton's also offered design and consulting services, conducting on-site analyses and making recommendations to design or improve systems. Pinkerton's enjoyed strong name recognition; capitalizing on this, Sun Coast Merchandise Corp. licensed the Pinkerton's name in 1992 to apply to a line of emergency lighting—Pinkerton Home Security & Safety Products.

By 2000, both Burns International and Pinkerton's were purchased by Securitas, a Swedish firm that is Europe's largest security company, which merged the two U.S. security companies. In July 2003, Pinkerton's

and Burns International officially become Securitas Security Services USA. Securitas USA is now the largest security company in the United States.

The Pittston Company was created by the Alleghany Corporation (which operated the Erie Railroad and Pennsylvania Coal Company) in 1930 as a means of dodging antitrust regulations in the U.S. coal market. (Pittston leased mines from the Erie Railroad and sold the coal through its own distributors.) Alleghany again faced the antitrust issue when it purchased the New York Central Railroad in 1954. This time, the solution for Alleghany was to divest itself of Pittston, leaving the latter an independent company. In 1956, Pittston, which had already diversified into trucking and warehousing, diversified further with its purchase of a 22 percent interest in the Chicago-based security transportation company, Brink's, Inc. Brink's was founded in Chicago in 1859 as a delivery company and began making payroll deliveries in 1891. By 1956, it was the world's largest company providing armored car services. In 1962, Pittston completed its purchase of Brink's, but in 1976 Alleghany's legacy of antitrust confrontation fell upon Pittston: a federal grand jury indicted Brink's with antitrust violations. The charges cost the armored car company millions in settlements, the last of which was \$2.7 million paid in 1980 to 12 Federal Reserve banks. In spite of this, Brink's grew during the 1980s even as Pittston's older oil and warehousing operations were sold off. In 1998, the Pittston Brink's Group employed 41,800 people and had sales of approximately \$1.45 billion. Pittston changed its name to The Brink's Company in 2003 and had 2002 sales of \$3.77 billion and employed 50,000 people.

The Wackenhut Corporation, founded in 1954 by ex-F.B.I. agent George R. Wackenhut, is another leading U.S.-based security company. It provides a broad range of security services at home and abroad, including executive protection and security for embassies and international airlines. The company's primary business is in uniformed security guard services, but Wackenhut is also involved in the business of private investigations, as well as activities under other SIC classifications such as correctional facilities management, classified in **SIC 8744: Facilities Support Management Services** and security systems implementation, classified in **SIC 7382: Security Systems Services**. In July of 1993, Wackenhut acquired United Kingdom-based International Maritime Services, Ltd., a company that provided security systems to the maritime industry. Wackenhut had sales of approximately \$2.8 billion in 2002, a 12 percent increase from 2001, and employed 57,000 people.

Another leading firm providing investigative services is Kroll Associates. J. Kroll Associates was formed in the early 1970s by Jules Kroll to offer companies a service that would audit their purchasing process to prevent devious

practices by the company's employees, such as receiving kickbacks or charging payments to fictitious suppliers. Kroll's services have expanded considerably since then. During the 1980s, Kroll's company provided investigative services to Wall Street financial institutions, such as tracing money through foreign banks, analyzing the credit of a principal in a takeover deal, determining the true financial value of a targeted acquisition, and detecting illegal insider trading. Kroll also provided services to U.S. and foreign governments. For example, Kroll assisted in the Federal Deposit Insurance Corporation's investigation of the savings and loan scandal and was asked in 1992 by the Republic of Russia to locate money believed to have been taken out of the country by directors of state-run enterprises who feared the advent of privatization.

In 1997, J. Kroll Associates merged with another firm to become The Kroll-O'Gara Company. The new venture expanded the company's capabilities; in addition to Kroll's range of services, the new firm conducts personnel background checks and provides both (security) driver and security training. A Kroll-O'Gara subsidiary modifies vehicles for private, corporate, military, and government clients. Another subsidiary, Laboratory Specialists of America, provided employee drug-testing. By 2003, the company became known simply as Kroll and posted 2002 sales of \$289.2 million with 2,359 employees.

WORKFORCE

As of 2001, there were an estimated one million people employed in the private security industry. Anyone can hang out a sign and claim to be a detective, and there appears to be no single career route that one follows to become a private eye, although a prior career in law enforcement is common. Anthony Pellicano, who has made a name for himself by providing detective services to Hollywood stars, is a high school dropout and former bill collector for Spiegel; Jules Kroll, on the other hand, has a law degree from Georgetown Law School and worked for the Manhattan District Attorney's office. Kroll operatives include a former security chief for IBM, a former CIA station chief, a former Green Beret and international crime and terrorism expert for Rand Corporation, and a former New York City Police Commissioner. The company has 40 investigators, 10 of whom are women. Kroll also uses the services of behavioral researchers and independent private investigators, many of the latter being ex-police officers.

Hiring practices for many in this industry came under scrutiny after 9/11. Crimes committed by security guards—some convicted felons—that have been publicized was another reason screening employees in this sector came under fire in the early 2000s. There are at least 10 states that completely lack any regulations in the area of security guard services, with some candidates

even being hired before a background check for a criminal record is performed.

SIC 7382

SECURITY SYSTEMS SERVICES

This classification includes establishments primarily engaged in monitoring and maintaining security systems devices, such as burglar and fire alarms. Establishments of this industry may sell or lease and install the security systems that they monitor and maintain. Establishments primarily engaged in the sales and installation, or installation only, of such devices are classified in **SIC 1731: Electrical Work**.

NAICS CODE(S)

561621 (Security Systems Services (except Locksmiths))

INDUSTRY SNAPSHOT

Simple on-site burglar alarms, which may deter an intruder with their noise and attract the attention of a passerby, are usually insufficient for the higher security needs of many businesses and some residences. Security systems services provide added security by continuously monitoring property alarms for multiple clients through their own off-site central station. Accordingly, these companies often are referred to as central stations.

Central station-monitored alarms, when triggered, send a silent alarm signal to the station through a leased telephone line, a coaxial cable (television) line, or a reserved radio frequency. Unless contacted by the subscriber within a few minutes to cancel a false alarm, the station then calls the police, possibly dispatches its own guard, and notifies the client. The monitoring agreement may involve keeping the central station notified of the business's regular hours and when the alarm is turned on or off, thus sharing the responsibility for and the control of operating the alarm system.

Most of the commercial alarm monitoring businesses deal with burglar alarms. Only a small number of police stations are willing to directly monitor alarm systems themselves because of the high incidence of false alarms and limited police resources. Alarm systems connected directly to police stations usually only exist when no private central station is operating within a particular area. Private monitoring companies are considered to have greater security advantages than police station monitoring systems. Fire alarm systems, on the other hand, generally are monitored directly by fire departments, because false alarms occur less frequently.

Burglar alarm systems typically include both door and window trip switches to detect break-ins and sensors to detect motion. Both kinds of devices are linked by wires or short-range radio transmitters to a central console, where the system is switched on or off. Different detection systems provide varying levels of security. Alarm systems are rated by Underwriters Laboratories (UL), an independent product testing organization that serves insurance underwriters.

UL not only tests alarm equipment but also inspects and rates the firms installing and monitoring the equipment. UL also certifies alarm service companies upon approval. Central stations are graded according to the length of time they take to dispatch a guard to the property and whether the line that runs from the property to the central station is protected from electronic tampering. Other than UL's services, the industry is relatively self-regulated. Not every state requires the licensing of alarm installers.

Central stations often install the alarm systems, a service the manufacturer of the system usually does not perform. As for the maintenance of alarm systems, installers typically provide a one-year warranty on parts and labor. Thereafter, annual maintenance contracts usually cost around 10 percent of the original installation price.

ORGANIZATION AND STRUCTURE

There are approximately 2,000 establishments in the United States engaged in security systems services. These include both private and publicly held companies

and a number of unincorporated individual proprietorships or partnerships. The majority of firms concentrate on the monitoring of burglar alarms. Most provide only local service, although several are national in scope. Central stations serve both residential and business clients and occasionally specialize in particular types of clients. Many central stations are specialized in the business of security service monitoring, but some companies also offer on-site security guard services, other electrical equipment installation contracting, and other building maintenance activities, such as janitorial services.

BACKGROUND AND DEVELOPMENT

In the 1920s, crime increased significantly in the United States, and new burglar alarm systems were devised as a response. Originally, most alarms were monitored directly by the police, but police stations gradually became overwhelmed by false alarms. In some cities, they responded only to alarms owned by special permit holders or only to alarms protecting businesses requiring high security, such as banks and jewelry stores. Private enterprise central stations gradually took over for the police.

In the 1980s and 1990s, private central stations began monitoring fire alarms as well. Fire alarm monitoring, however, tended to be contracted out by municipal fire departments, rather than directly by property owners. A number of cities were beginning to privatize their fire alarm monitoring services to save money, to avoid having to make continuous investments to keep up with the latest technology, or to avoid having to compete against private companies. Often, central stations that already handled other types of alarms, such as burglar alarms, took on fire alarm monitoring as well.

The number of alarm monitoring companies in the United States declined because of a number of acquisitions. The industry was originally very fragmented and localized but began to consolidate in the late 1980s, a trend that accelerated in the early 1990s. Larger companies took over smaller ones by offering limited partnerships. Alert Holdings Inc., for example, acquired close to 400 companies between 1985 and 1991. Smaller companies found it difficult to compete with larger ones that offered lower-priced installations. The alarm monitoring business easily benefited from economies of scale. National companies could monitor clients in other states through one central station.

In the late 1980s, alarm monitoring services began to target their marketing efforts more seriously toward private home owners. The residential market was not as well penetrated as the business market because home owners usually took care of their security needs with simple on-site siren systems they had installed themselves. Decreasing alarm-system installation prices and rising

crime, however, boosted the residential business of central stations. Installation costs of centrally monitored systems fell from around \$3,250 in 1970 to \$1,250 in 1993. Occasionally, installations were offered at no charge as part of a multiyear monitoring contract. Residential monitoring services also began to offer other security services, including the monitoring of medical alert signals, possible water pipe and gas leaks, and thermostat controls. Consequently, centrally monitored alarms represented the fastest growing segment of the home alarm business in the early 1990s.

About one million home systems were installed in 1992, for roughly \$1.4 billion in service fees and equipment expenses. About 75 percent of these professionally installed systems were connected to central stations, accounting for \$1.9 billion in annual revenue from monthly residential security monitoring and maintenance fees.

In 1990, alarm monitoring represented the third largest use of information services over telephone lines, after database services and transaction processing, and ahead of telephone answering services and 900 telephone number services. Alarm monitoring through telephone lines accounted for about \$2.5 billion worth of services.

Growth was fueled not only by an increasing fear of crime, but also because some property insurance underwriters required their clients in high-risk businesses to obtain security services before a policy was issued. The security systems services industry experienced steady growth; total revenues increased markedly due to continued public concern over security issues. In 1987, the security systems services industry recorded \$2.2 billion in revenue. The industry had an average yearly growth pattern of over 6 percent from 1993 to 1997. Most notably, during the intervening decade, total industry annual receipts more than doubled by 1997 to \$5.9 billion.

Some commercial alarm monitoring services have broadened their services in response to client requests, including drive-by spot-checks and the dispatching of guards. In the wake of the Oklahoma City bombing in 1995, fear of crime was at an all-time high—though actual crime statistics failed to support public perceptions—and security companies tooled up for an anticipated surge in demand. As it turned out, although demand for more security remained strong, that sector of the industry involved in reselling, installing, and monitoring remained unsettled.

Alarm monitoring brought in about 20 percent of all dollars in 1996, with equipment and installation accounting for most of the rest. Greater consolidation also continued within the industry in 1996, as the largest national and regional firms bought up smaller firms and accounts. The trend was expected to continue as cash-rich utilities,

Wall Street investors, telephone companies, and power-house retailers all bought their way into the security industry. Companies also showed less interest in the home security market, an amorphous area that was overly price-sensitive and whose needs were difficult to gauge. Also worrying was the growing do-it-yourself (DIY) business. The sale of home computers with home automation bundled in, and the sale of DIY sensors, detectors, and even CCTV components posed a serious threat to alarm installation and monitoring firms. As a result, many companies turned their attention to the large commercial market where they were able to offer systems integration services, reap higher profits, and build longer-lasting client relationships.

CURRENT CONDITIONS

Already one of the fastest growing industries in the United States by 2000, electronic security products and services as a whole brought in an estimated \$22.4 billion in 2002, up 9.7 percent from 2001, and as of 2003, there were about 14,000 electronic security businesses in the country. In 2001, alarm monitoring—a section of this industry—had grown into an \$11.1 billion business, up 9.9 percent from \$6.9 billion just five years earlier. The security industry thrived in a post-9/11 environment, with everyone from big businesses to private residences beefing up or adding new security systems. Updated technology was probably the other major contributor to this sector's good fortune, with more customers upgrading their systems in a quest to own the latest security had to offer. Sales for digital video recorders and access control systems increased so significantly that some sources began dubbing 2002 "The Year of the DVR." The annual study by *Security Distributing & Marketing*, (SDM), found that 16 percent of total dealer/integrator revenues came from video surveillance systems in 2002. A strong housing market in the early 2000s, driven in part by lower than ever interest rates, also aided sales in security. Many new homeowners were purchasing alarm systems. However, most security companies found commercial customers were still the key to sales. This industry also saw some growth in the government and food markets. Some markets were not as profitable; with school budgets being cut, educational institutions contributed little to demand in new security systems.

In the products category, burglar alarms made up the largest percentage of revenue in 2002, with 43 percent, down from 64 percent a decade earlier. Fire alarms made up 18 percent of 2002 revenue; home systems other than burglar or fire made up 16 percent; video surveillance had 16 percent; access control, 9 percent; integrated security systems, 5 percent; and other types of security products, 2 percent. In the services category, residential security sales/installation accounted for 32 percent of 2002 revenue; home systems sales/installation, 9 percent; nonresi-

dential sales/installation, 28 percent; service/maintenance, 12 percent; monitoring/leasing, 17 percent; and other services, 2 percent.

Along with demand, prices of residential security also rose, going from \$1,293 in 2001 to \$1,424 in 2002. Monthly monitoring charges also went up, from \$22.00 in 2001 to \$22.75 in 2002. Accordingly, SDM showed that security systems dealers received a larger percentage of total revenue from sales and installation in 2002 than in the previous year.

INDUSTRY LEADERS

As the twentieth century ended, the security services industry became a microcosm of widespread globalization of markets and trends toward acquisitions by conglomerates in related businesses. As a result, total revenues reported for most firms in the industry were not solely derived from security services activity and operations. One of largest companies in the industry was Securitas Security Services USA, which had sales of almost \$1.4 billion. Ranked as the leading security company on the 2002 SDM 100 was ADT Security Services, Inc. (operated as a subsidiary of Tyco International Ltd.), with gross revenues of \$2.5 billion in 2001. The largest electronic security services company in North America, ADT provided electronic security monitoring services to business customers in retailing, financial services, manufacturing, and to the public sector in North America and Europe.

At the beginning of the new millennium, other viable competitors operating in the security services industry were also subsidiaries or divisions of conglomerates. With \$3.8 billion in sales in 2002, Brink's Company (formerly Pittston Brink's and the Pittston Company) operated in two related security operations, Brink's (armored transport) and Brink's Home Security. The Wackenhut Corporation offered even more diverse security services and recorded total revenue of almost \$2.8 billion in 2001. Perhaps most illustrative of the continuing trend of leading security systems industry firms to operate as part of a consolidated corporate structure comprising a variety of security services, Wackenhut engaged in private prison management, (security) employee staffing, and security services (which included security systems) in sensitive markets such as background investigations and facilities in airports, nuclear power plants, and embassies.

RESEARCH AND TECHNOLOGY

Central stations benefited from technological advancements achieved during the 1980s and 1990s, particularly those emanating from the telecommunications industry. To prevent criminal tampering of leased telephone lines that carried the alarm signal, alarm services developed a computerized method of sending signals, made up of thousands of signals sent at random, that

burglars could not duplicate. There also was progress in wireless communications, including tests that used cellular telecommunications, rather than regular phone lines.

Computer software for alarm monitoring became more sophisticated. There were improvements in installed alarm systems. In particular, efforts were made to reduce the incidence of false alarms through more advanced sensing devices and better consumer and dealer education. One innovation on the technological side was the introduction of shock glass break sensors tuned to the frequency of the glass. Unlike acoustic sensors, these responded only to changes in the glass itself, resulting in significantly fewer false alarms.

Agency), industry-specific services (Computer Wire and International Business News Service), and government information (Federal News Service and Capitol News-wire), to name a few.

The genesis of U.S. news syndicates can be traced to the construction of the first successful telegraph line in 1844. When completed, the line connected the cities of Washington and Baltimore and was immediately utilized by newspapers in Washington as a means of receiving news of the Maryland State Convention in Baltimore. As more lines were constructed, more and more newspaper publishers recognized this new communications technology as a valuable means of receiving news from distant locations. It was through the effort by newspaper publishers to share access to the telegraph lines, and to share the costs associated with using this new technology as a news gathering tool, that news syndicates came into being.

The National Associated Press (AP) was a collective formed in 1897 from various city, state, and regional Associated Press units. AP bylaws allowed its members to refuse association membership to applicants whose newspapers were located in the same city as those members (a practice which the U.S. Supreme Court in 1945 held to be an illegal restraint of competition). By 1907, there was a growing pool of newspapers that had been denied membership into AP, including most of the newspapers owned by E.W. Scripps. That year, Scripps challenged the AP monopoly on national news brokering by establishing the United Press Association, a commercial venture which, after taking over William Randolph Hearst’s International News Service in 1958, would go on to become United Press International (UPI).

During the 1960s and 1970s, the number of competing newspapers declined, leaving many cities with only one newspaper. Newspaper publishers who had felt competition-driven pressure to subscribe to both the AP and UPI services now felt that it was safe to let one of them go. In the ensuing fight to retain its subscribers, AP fared better than its rival. Although UPI was still one of the four major news syndicates serving the international market—along with AP, London-based Reuters, and France’s Agence France-Presse—and was second only to AP domestically, it reported a pre-tax loss of \$12 million in 1980. Financial difficulties continued on through the decade, and in June, 1992, UPI was acquired in bankruptcy court for \$3.95 million in cash by Middle East Broadcasting Center Ltd. (M.B.C.), a London-based television news and entertainment company owned by a group of Saudi businessmen. At the time of the sale, UPI employed about 450 people full-time, and another 2,000 part-time. Its new comeback strategy as a privately held company focused on small-market newspapers and radio stations. In the area of new media, UPI provides national news online to The Microsoft Network.

SIC 7383

NEWS SYNDICATES

This category covers establishments primarily engaged in furnishing news, pictures, and features and in supplying news reporting services to newspapers and periodicals. Separate establishments of newspaper and periodical publishers that are engaged in gathering news are classified as auxiliaries.

NAICS CODE(S)

514110 (New Syndicates)

As of 1997, there were 527 establishments classified as news syndicates employing more than 9,400 people, with combined industry sales reaching \$1.4 billion. In addition to the broad coverage of mainstream wire services, organizations within the news syndicates category cover specialized areas such as regional news services (Panafrican News Agency and Macedonian Press

The Associated Press was the world's largest news-gathering organization during the late 1990s, with more than 235 news bureaus in about 70 countries around the world, providing news, photos, graphics and audiovisual services to more than 1,700 newspapers and 5,500 television and radio stations.

Founded in 1865, Reuters relayed news and financial information from more than 340,000 computer terminals in 158 countries in 1995. It also provided data feeds to financial markets and sold software for analyzing bonds, currencies, futures, options and stocks. Information was gathered from 267 exchanges and over-the-counter markets, from 4,700 subscribers who contributed data directly to Reuters, and from a network of about 1,936 journalists, photographers and camera people.

In addition to providing reports of general-interest news for the print and broadcast media, the news syndicates have expanded into areas of specialized interest. One area that has experienced significant growth is business news services. In 1967, AP joined with Dow Jones & Company to create a worldwide economic news service to foreign subscribers. In addition to the AP-Dow Jones News Service, Dow Jones also operates the Dow Jones News Service in both the United States and Canada. This service provides business information to brokerages, banks, corporations, and investment houses.

The 1990s also saw the Internet gain prominence for news syndicates, with Reuters entering the fray aggressively, providing news to all major on-line services, including The Microsoft Network. At AP, officials had also committed to increase their role in cyberspace and formed anew-media department, offering services such as new multimedia Internet "pages" via member newspapers' on-line services.

SIC 7384

PHOTOFINISHING LABORATORIES

This industry classification includes establishments primarily engaged in developing film, making photographic prints and enlargements, or retouching photographs for businesses or for the general public.

NAICS CODE(S)

812921 (Photo Finishing Laboratories (except One-Hour))

812922 (One-Hour Photo Finishing)

INDUSTRY SNAPSHOT

The photo finishing laboratories industry group includes establishments whose core business is developing and printing film (except for commercial motion picture film); duplicating, enlarging, or retouching photographs; developing and processing home movies; and providing transfer and other film photography services related to digital imaging, photo CD, and other forms of electronic photography. Many retail stores, discount stores, drug-stores, supermarkets, camera stores, photography studios, and other businesses also offer commercial photofinishing services, whether through onsite (or "captive") labs or through commercial wholesale laboratories; such ancillary photofinishing services are the primary competition of the photofinishing laboratory businesses that fall within this category.

According to the *1997 Economic Census*, the number of photofinishing laboratories showed a slow but steady decline throughout the 1990s. From 1992 to 1997, the number of labs in the United States declined by 10 percent to 7,055 establishments. Conversely, annual receipts rose steadily from \$4.4 billion to \$7.7 billion. Consolidation within the industry was largely attributable to a growing trend for the public to have their rolls processed by wholesale and mail order labs. As discount stores and supermarkets continued to equip themselves with minilabs, dominance by central labs was expected to disappear by the year 2000, when the number of minilabs finally would likely outnumber central labs.

ORGANIZATION AND STRUCTURE

In the 1990s, photofinishing laboratories relied primarily on automated equipment that reliably produced quick results. Photographic laboratories could be classified as minilab outlets, mail order laboratories, or wholesale laboratories.

Minilabs Outlets. Photofinishing laboratories featuring onsite minilabs could be independent or affiliated with photofinishing chains, and physically autonomous or situated within larger businesses. Minilab systems, which consisted of compact automated photoprocessing equipment, often required less than 1,000 square feet of floor space. Minilab outlets specialized in fast photofinishing (with photographs processed in as little as 30 minutes to an hour) and commanded relatively high photoprocessing rates. Leading minilab chains included Moto Photo; CPI Photo Finish; Fox Photo 1-Hr Labs; and Fotomat Express.

Mail Order Laboratories. Mail order laboratories, often with nationwide markets, generally provided amateur photographer customers with envelopes and instruction forms for mailing in photoprocessing orders. Mail order laboratories generally relied on repeat orders from established customer bases, often enclosing additional mailing envelopes for customer use when returning photoprocessing orders. Some mail order laboratories distributed mailing envelopes through camera stores or methods such as direct mail campaigns and newspaper inserts. Some mail order laboratories sold "prepaid" mailers through outlets such as camera stores. Mail order laboratories generally offered convenience (orders could be sent from anywhere and received at any mailing address) and relatively low prices. However, some mail order laboratories were premium operations emphasizing customized services and rigorous quality control. Photoprocessing through mail order laboratories generally took one to two weeks. Leading mail order laboratories included Clark Color Labs; Custom Quality Studio; Kodalux (formed through the merger of the former Kodak photofinishing laboratories and Fuqua Industries); Mystic Color Lab; PhotoWorks (formerly Seattle Film Works); and Skrudland Photo.

Wholesale Laboratories. Wholesale laboratories, often with nationwide markets, generally processed commercial orders and/or orders dropped off by amateur photographers at supermarkets, discount stores, drugstores, and other locations. Wholesale laboratories often operated anonymously behind the imprimatur of such retailers. Drop-off boxes provided for amateur photographers were often very simple affairs; in the early 1990s, however, IBM manufactured an automated drop box developed by Delphi Technologies, whereby membership card or credit card customers could drop in photoprocessing orders and key in instructions through computer screens. Wholesale laboratories, which processed thousands of rolls of film daily, generally offered less-expensive rates than minilab outlets and a turnaround of one day to one week. Leading wholesale photofinishing laboratories included Allprints Quality Photo Services, Dean's Photo Service, Guardian, Fuji TruColor (established in 1993 by Fuji Photo Film USA), Qualex, TruColor Photo, True Color, and United Photo.

The primary association related to commercial photofinishing and the photography industry as a whole was the 16,000-member Photo Marketing Association (PMA), which was established in 1924. The PMA, previously known as the Master Photo Dealers' and Finishers' Association, was formed by the merger of the Master Photo Finishers of America (founded in 1924) and the National Photographic Dealers Association (founded in 1933). The PMA sponsors several important industry publications and maintains a photofinishing and photog-

raphy retailing reference library and hall of fame at its Jackson, Mississippi, headquarters.

CURRENT CONDITIONS

According to the Photo Marketing Association's *Industry Trends Report 1995-96*, photo processing held the largest share of the revenue in the amateur market with 43.1 percent. Within the amateur market, 710 million rolls of film were developed in 1995. Total rolls were down slightly from the 1994 figure of 716 million, but higher than the 1993 total of 694. Sales in the amateur market continued to remain fairly stagnant since 1988. In that year sales totaled \$5 billion, rising by \$200 million every year until 1991. From 1992 to 1994 sales remained at \$5.5 billion every year, and dropped slightly to \$5.4 million in 1996.

Drugstores continued to lead the market of photofinishing with 23.8 percent of total sales and 24.8 percent of total rolls processed in 1995. Drugstore share was down slightly from 24.5 percent in 1994 as discount stores continue to gain more share but drugstores continued to lead. Stand-alone minilabs had 22 percent of the photofinishing market in 1995, also down from 1994. However, minilab statistics do not include minilab equipment used in other stores. Only 40.5 percent of minilab equipment was used in stand-alone minilabs. Almost 21 percent were in discount stores, 17 percent in camera stores, 13 percent in drugstores, and 7 percent in supermarkets. Discount stores held 21.9 percent of the total market in 1995, one of only two retail channels to show growth from 1994 when it had 18.8 percent of photofinishing sales. Supermarkets accounted for 12.6 percent, the other retail channel to grow from 1994 when it held 11.8 percent. Mail order held 5.4 percent, down slightly from 5.6 in 1994. Other outlets accounted for the remaining 3.2 percent of 1995 photofinishing sales. According to the PMA, in 1997, 65.1 percent of photoprocessing was done by wholesale, captive, or mail order labs; the remainder was done by retail labs.

Minilab equipment has become increasingly common in the photofinishing industry, accounting for 33.5 percent of the amateur market photofinishing dollar sales in 1986, 40.3 percent of dollar sales in 1988, 43.4 percent of dollar sales in 1990, 44 percent of the amateur market photofinishing dollar sales in 1992, and 44.4 percent in 1995. The estimated number of minilabs nationwide increased from 5,200 laboratories in 1984 to 11,900 laboratories in 1986 and 15,300 laboratories in 1988. After that year, growth in the number of minilabs leveled off to a degree. In 1991, the estimated number of minilabs nationwide was 17,200, and grew by only about 150 per year to 17,500 in 1993. But in 1994, minilabs began to grow quickly again, shooting up to 18,900 in that year and 20,500 in 1995.

Within the various film formats, 35mm film increasingly dominated the market, accounting for 57 percent of exposures in 1984, 65 percent of exposures in 1986, 75.4 percent of exposures in 1988, 83.1 percent of exposures in 1990, and 88 percent of exposures in 1992. With the introduction of the disposable camera, 35mm dropped slightly to 80.5 percent of exposures in 1995, with disposable cameras filling in with 6.9 percent of exposures. Conversely, 110/126 film accounted for 18 percent of exposures in 1984, 17.6 percent of exposures in 1986, 15.1 percent of exposures in 1988, 12.3 percent of exposures in 1990, 9.6 percent of exposures in 1992, and only 6.5 percent of exposures in 1995. Disc camera film dropped off quickly as the novelty and excitement for the product dropped off. Disc accounted for 22 percent of exposures in 1984, 14.5 percent of exposures in 1986, 7.4 percent of exposures in 1988, 3.8 percent of exposures in 1990, only 1.6 percent of exposures in 1992, and nearly disappeared in 1995 with only .8 percent of exposures. The rest of exposures in 1995 were taken by instant film with 2.7 percent, and slide film with 2.6 percent of exposures.

Camera stores and stand-alone minilabs had strong commercial sales increases in 1995, especially from commercial sources such as graphic arts and advertising. With 35mm's slight drop in share (its first ever), large format film types from these commercial sources helped fill in the gap along with disposable cameras. As Advanced Photo films, introduced in April 1996, take on more of the market (it took an estimated 7 to 8 percent of the share in 1997), it will also take some of the 35mm share.

While roll volume decreased by just under 1 percent, total exposures fell even more with a 3 percent decline. The total number of exposures per roll sold decreased in 1995, bringing about the decline in total exposures. Enlargement volume as a percentage of total photofinishing sales also continued to decline to 5.4 percent, down from the high of 7.5 percent in 1991. Although volume sales are increasing — mostly through labs developing online ordering services — pricing competitions keep the total percentage of revenues down.

INDUSTRY LEADERS

In 1991, the end of a photofinishing retail era was marked with the acquisition by CPI Corporation of Fox Photo, a pioneer in photofinishing retail "kiosks." This acquisition added more than 250 retail sites and 50 minilabs outlets to CPI's base of approximately 1,360 photofinishing retail sites, including almost 1,000 outlets situated within Sears stores. In the early 1990s, Fuji Photo Film U.S.A. and its sister company Fujifilm Photofinishing U.S.A. acquired or gained controlling interest in Allprints Quality Photo Services, Dean's Photo Service, McJohn

Inc., Northern Photo, and TruColor Photo, all wholesale photofinishing laboratories. The Photo Marketing Association's *Industry Trends Report 1992-93* indicated that "continued consolidation among central labs produced double-digit dollar expansion for those firms."

CPI Photo placed first in the industry with 2000 sales of \$319.1 million, and 8,178 employees. Other industry leaders include PhotoWorks (formerly Seattle Film Works) with 1999 sales of \$89.6 million and 690 employees, and Moto Photo with 999 sales of \$36.6 million and 478 employees.

WORKFORCE

In 1982, there were approximately 71,700 photofinishing laboratory employees nationwide. By 1987, this figure increased to 82,500. In 1992, however, the number had dropped to 69,300, and by 1994, there were only 57,000 jobs as photographic processors. By 1997, this number had rebounded to 71,991 employees, 15,123 of whom worked in one-hour photofinishing labs. In 1995, the states with the greatest number of photofinishing laboratory employees were California (12,671 employees, or 17.1 percent of the national total), New York (6,461 employees), and Texas (5,079 employees).

In 1982, the total national photofinishing laboratories payroll was \$813.8 million. By 1987, the total payroll had increased to \$1.12 billion. And in 1993, payroll had increased again to \$1.28 billion. The states with the highest total photofinishing laboratories payroll were California (\$177.3 million) and New York (\$106.8 million). In 1992, the national average payroll per establishment was \$154,531 (compared to \$314,133 per establishment for service industries as a whole); the average payroll per photofinishing lab employee was \$17,330 (compared to \$23,335 per employee for the service industries as a whole). The states with the highest average payroll per employee were Maine (\$20,145) and New York (\$16,533). The average payroll per employee was lower in Texas (\$14,491) and California (\$13,922); and among the states with the lowest average payroll per employee were Arizona (\$10,504), Tennessee (\$10,535), and Vermont (\$10,710).

AMERICA AND THE WORLD

Internationally, film sales per household are highest in Germany (165.0 million units, or 6.5 units per household), Austria (15.8 million units, or 5.6 units per household), and France (106.4 million units, or 5.5 units per household). In 1992, photo processing accounted for 53 percent of \$3.7 billion in photographic expenditures in Germany; 47 percent of \$1.56 billion in amateur photographic expenditures in Australia; 42.9 percent of photographic expenditures in Canada; and 40 percent of \$58 million in photographic expenditures in the United Kingdom.

RESEARCH AND TECHNOLOGY

Microlabs are scaled-down photofinishing laboratories that are less expensive than minilabs — and they require as little as 7 square feet of floor space for equipment and 18 square feet of total working space. Systems such as the Fuji Mini 27 and the Konica Nice Print are also waterless, and thus do not require special plumbing. In the early 1990s, Photogo launched a chain of microlabs based on the P135 system in the United States, Europe, and the Far East. The microlabs' features have encouraged retailers and other businesses to set up in-store photofinishing booths.

The emergence of computer-based digital imaging technology and photo CDs are particularly suited for media, publishing, and other commercial uses that rely on fast electronic processing, transmission, and reproduction. While digital imaging is not expected to replace film photography, photofinishing laboratories have increasingly offered digital imaging and photo CD services.

Some of the biggest retail photo labs across the country, including Wolf Cameras and Konica Photo Services USA, Inc., were developing digital imaging in the form of photos over the Internet. In the mid 1990s, these labs would process the film normally, and if desired, would scan the pictures into digital format and place them on a Web site. The customer was given a highly secure access code and password. From a home computer the customer could view, download, and manipulate the photos, even giving access codes to friends and family who could order reprints online. Early statistics showed that customers ordered five times as many reprints and enlargements over the Internet than through standard procedures.

Local environmental regulations, which were often the most strict, were sometimes enforced through the processing of annual permits for photofinishing laboratories. Photofinishers have made efforts to recycle chemical drums, toner cartridges, single-use cameras, film cartridges, film canisters, and film spools. They have attempted to reduce the use of toxic chemicals such as photoreceptors, recover the silver used in photoprocessing, and to reduce or capture waste effluent.

522320 (Financial Transactions, Processing, Reserve and Clearing House Activities)
 561499 (All Other Business Support Services)
 561990 (All Other Support Services)

The miscellaneous business services industry encompasses a broad range of specialties, ranging from baby shoe bronzing services and yacht brokers to window trimmers and playwrights. Establishments classified in this industry are generally engaged in providing services that do not generate a sufficient amount of national revenue for the U.S. government to track alone.

Roughly 212,000 firms were engaged in this industry in the mid 1990s. Government statistics indicate that about two-thirds of the companies classified in this industry are corporations, with the remainder being either sole proprietorships or partnerships.

According to government sources, the industry generated \$32 million in sales in 1992. Notable industry statistics for 1992 included sales for sign painting shops (\$523,000), interior designing (\$2.3 million), and phone answering services (\$1.0 million). The average company engaged in this industry generated annual revenues of \$450,000, for an industry total of about \$20 billion

While the employment outlook varies by segment, overall industry employment is expected to rise over the course of the next decade. A few major occupational groups, however, such as switchboard operators and telephone message specialists, were expected to diminish in size during this period. The corporate and management training industry, as one example of the specialty services provided in this category, benefited from the \$58 billion corporate budget dedicated to training in 1996. In 1995, 93 percent of all organizations offered some form of basic computer training.

Sears, Roebuck and Co. of Hoffman Estates, Illinois led the industry in 1999 with sales of more than \$41 billion. Sears employed 324,000 workers, creating a sales-per-employee standard of \$126,762. Houston-based Waste Management Inc. followed with 1998 revenues of more than \$22.7 billion, employing 68,000 workers who generated \$334,047 each. New York City-based Time Warner Inc. employed 675,000 who each contributed \$216,030 toward the company's 1998 sales of almost \$14.6 billion. Unisys Corp. placed fourth in the industry with 1999 sales of more than \$7.5 billion, behind the strength of 33,200 employees who each generated \$7,545 toward that total.

Among the myriad of other companies that are involved in providing miscellaneous business services, leaders include such diverse firms as RGIS Inventory Specialists, VIP Event Services Inc., Sotheby's Inc, Freeman Decoration Co., and Michael Fox Auctioneers Inc.

TRUCK RENTAL AND LEASING, WITHOUT DRIVERS

This category covers establishments primarily engaged in short-term rental or extended-term leasing (with or without maintenance) of trucks, truck tractors, or semi-trailers without drivers. Establishments primarily engaged in finance leasing of trucks are classified in Finance, **SIC 6159: Miscellaneous Business Credit Institutions**; those renting trucks with drivers are classified in various trucking and courier service industries; and those primarily engaged in renting and leasing, except finance leasing, of industrial trucks are classified in **SIC 7359: Equipment Rental and Leasing, Not Elsewhere Classified**.

NAICS CODE(S)

532120 (Truck, Utility Trailer and RV (Recreational Vehicle) Rental and Leasing)

INDUSTRY SNAPSHOT

Growth in the truck rental market slowed in the mid 1990s after an expansive period in the late 1980s and early 1990s. By the end of the 1990s, the industry continued to grow, and 35 percent of all trucks in service in the United States were owned by rental or leasing companies. The industry leader, U-Haul International Inc., continued to dominate, owning well over half of all the rental trucks in service in the United States and owning 52 percent of the market. The Budget Group, with Budget Truck Rentals and Ryder TRS comprised 27 percent of the market. The remaining 21 percent was made up of a few

other midsized players, such as Rollins Truck Leasing Corp. and Penske Truck Leasing, plus thousands of small operators. The industry generated 1997 revenues of \$10 billion, employed 46,566 workers, with an annual payroll of \$1.4 billion.

CURRENT CONDITIONS

Growth in the truck rental market slowed in the mid 1990s after the expansive period of the late 1980s and early 1990s, as U-Haul and Ryder competed for expansion of dealer locations and market share in the consumer truck market. Ryder sold its Ryder Consumer Truck Rental division during 1996, but the Budget Group, the new owners, have indicated a commitment to their current name and market identity as Ryder TRS.

In 1999, U-Haul International led the industry with some 190,000 trucks for rent from over 15,000 dealerships. It reported U.S. rental revenues of over \$1.5 billion and employed 14,400 workers. U-Haul's business consisted entirely of rentals to do-it-yourself movers.

Ryder TRS owned a fleet of 33,500 trucks from 3,500 dealer locations. It reported 1999 U.S. rental revenues of \$550 million. Some 70 percent of its business was on the consumer side, the remainder coming from business rentals.

Among important trends affecting the industry in the 1990s were changing tax laws, stricter environmental regulations, and efforts by large corporations to keep trucking assets off their books. These all seemed to indicate a strong future for the leasing industry. Larry Miller, then president of Iowa-based Ruan Transportation Management Systems, the third largest truck-leasing company with about 10 percent of the market, told *Commercial Carrier Journal* in 1990, "Pride of ownership is a luxury. It's the old way of doing business." Among newer regulations affecting fleet ownership were federal laws that required commercial vehicles over 10,000 pounds gross weight to undergo an extensive safety inspection every 12 months; in addition, there were new Environmental Protection Agency regulations regarding underground storage tanks, and the federal Clean Air Act required vehicles to meet tougher emission standards.

Amtralease, a network of independent leasing companies, estimated that 30 percent of all commercial trucks in the early 1990s were leased, compared to less than 20 percent in the 1980s. However, Amtralease also reported that profits for truck-leasing companies were flat despite the increase in market share. Although some companies leased large fleets, *Commercial Carrier Journal* reported that the typical customer leased three to four trucks.

In the late 1980s, many companies with transportation needs began moving to full-service leasing, with the leasing firm assuming responsibility for all matters re-

lating to the vehicle, including purchase, fuel, taxes, licenses, and hauling permits. Don Estes, then president of Ryder Truck Rental, told *Beverage World* that "full service leasing is basically turning truck transportation problems over to the leasing company." Although drivers sometimes complained about the quality of maintenance with full-service leasing, surveys indicated that repair and maintenance operations at larger lease companies often were better managed and their mechanics better trained than with private fleet operations.

By the turn of the twenty-first century, the larger companies had developed Web sites and launched Internet on-line booking. Internet access allowed customers to communicate directly with the companies, receive instantaneous confirmation of booking, and make payments on-line.

INDUSTRY LEADERS

Ryder System, Inc. was founded in 1933 by James A. Ryder. In 1996, in addition to its full-service truck leasing and rental operations, Ryder also provided a variety of aviation and other transportation services, including automobile transport.

In 1932, James Ryder was a high school student in Florida working as a summer laborer for 25 cents an hour when he learned that another student was making 35 cents an hour to drive a truck. The next summer Ryder purchased a 1931 Model A Ford and went into business as a commercial hauler. Ryder struggled through the Depression, slowly building a fleet, and by 1937 the Ryder Trucking Co. owned 37 trucks. In 1938, Ryder learned that a Miami beer distributor was interested in leasing five large trucks. Ryder presented the distributor with a proposal, and Champagne Velvet Beer became the company's first lease account.

Ryder continued as both a local leasing company and an over-the-road transport service for several years. Then, in 1945, two businessmen from Tampa, who had acquired the Anheuser-Busch beer distributorship for Florida, contacted Ryder. The beer was beginning to arrive from the brewery in St. Louis, and the distributors needed trucks in a hurry. Ryder met the need by pulling trucks from its over-the-road fleet. Overnight, Ryder became the largest truck leasing firm in Florida. By the end of the 1940s, Ryder's leasing operations topped \$1 million and far exceeded its over-the-road trucking business. Ryder also signed a lease agreement with the Minute Maid Corporation, which gave Ryder national exposure. By 1949, when the company changed its name to the Ryder Truck Rental System, the leased fleet had grown to more than 500 trucks.

In 1955, Ryder reorganized and went public, creating Ryder System, Inc., a holding company that owned the Ryder Truck Rental System and the Great Southern

Trucking Company, which Ryder acquired in 1952. In 1956, Ryder initiated a corporate identification program, and by the following year, the entire leased and over-the-road fleet carried the familiar red and black “Big R” trademark. The leasing division also became known as Ryder Truck Rental.

Between 1956 and 1959, Ryder acquired 21 more companies, including the Denver-based Baker Truck Rental, which was then the largest truck leasing firm west of the Mississippi River, and the Alabama-based Dixie Drive-It-Yourself System. Although the “Big R” trademark created some uniformity, the rapid growth left Ryder with trucks painted almost every color imaginable. In 1962, Ryder adopted a common color scheme for all its trucks: bright lemon yellow with a black undercarriage. In 1965, Ryder sold its motor carrier division to International Utilities and focused on the growing truck leasing business. International Utilities continued to operate the trucking business under the Ryder name until 1982.

In 1968, Ryder formed a consumer truck-rental operation known as Ryder One Way. Initially, Ryder planned to purchase 300 trucks for consumer rental; however, a market test in six southern states indicated a greater demand, and Ryder began operations with 1,000 trucks and vans. By the end of the year, Ryder One Way had dealers in 325 cities across the country and ordered another 2,000 trucks. In the mid 1970s Ryder secured a contract with the Department of Defense to provide rental trucks for military personnel at 110 bases in the United States. By 1987, Ryder had surpassed U-Haul as the largest consumer truck-rental operation in the United States. However, U-Haul regained the lead in the early 1990s. In June of 1998, the Budget Group purchased Ryder’s truck rental division and ran it under the name Ryder TRS. Ryder maintained 25,000 rental trucks at 80 locations, but its primary area of business was full-service commercial leasing with 109,000 trucks. Ryder had also become a major supplier of integrated logistics services in the United States.

U-Haul International, Inc., was founded in 1945 by L. S. Schoen. Today U-Haul is the largest consumer truck-rental business in the world. U-Haul is a subsidiary of AMERCO, one of the largest privately-owned companies in the United States. The company entered the self-storage industry in 1975 and is now the second largest operator of self-storage in the United States, with 232,000 rooms, over 19 million square feet of space, and 800 company-owned storage locations. U-Haul reports that more than 98 percent of the American public recognize the name U-Haul, making it among the most recognizable registered trademarks in the world.

In 1945, L. S. Schoen slipped out of a military hospital to move his wife and newborn son from Los

Angeles to nearby Corona, California. He rented a beat-up utility trailer from a service station, and that night he made a notation in his diary: “I am intrigued by the business potential of this idea especially from the standpoint of one-way rentals.” He was discharged from the military later that year and moved his family to Portland, Oregon. Within two weeks, he had purchased his first trailer and painted “U-Haul Co.; Rental Trailers; \$2.00 per day” on the sides.

By 1946, Schoen had a fleet of 70 trailers spread out from Seattle to Los Angeles, and in 1948, he decided to go national. He offered one-way rentals from the West Coast to anywhere in the United States. The only catch was that customers had to find service station managers at the end of their trips who were willing to become Schoen’s agents. The plan worked, and by the end of the year, U-Haul had a fleet of 200 trailers and a network of agents nationwide.

In 1951, U-Haul launched a low-risk program for fleet ownership of its trailers as a way to raise money and expand the network even faster: investors would purchase trailers from U-Haul, which would assume full responsibility for insurance, maintenance, and distribution. Each month, fleet owners would receive a report and payment for rental activity on their trailers. The fleet-ownership plan raised \$2 million in the first two years. By 1955, there were more than 10,000 U-Haul trailers in 200 fleets scattered around the country, and U-Haul was adding 600 trailers a month.

U-Haul began renting trucks in the late 1950s and dominated the consumer truck-rental industry into the 1970s. However, in 1970, U-Haul acquired A to Z Rental and began a transition from renting trucks and trailers to renting everything from garden tools to dinnerware. In 1974, U-Haul opened more than 100 U-Haul Rental Centers. The transition was hastened by the Arab oil embargo in 1973, which eventually resulted in the closing of many independent service stations that had been the backbone of U-Haul’s rental network. In the late 1960s, U-Haul trucks and trailers were available at more than 14,000 service stations, but by the mid 1970s more than 6,000 had gone out of business.

By the early 1980s, there were more than 1,100 U-Haul Rental Centers. However, while it was expanding into new rental businesses, U-Haul was paying less attention to its aging fleet of trucks and trailers. Ryder, whose trucks were air conditioned and featured automatic transmissions, began cutting into U-Haul’s market share and overtook U-Haul in 1987. The year before U-Haul was knocked out of first place in consumer truck rentals, two of Schoen’s sons gained control of the company and forced their father to resign. They began closing the rental “supermarkets” and refocused on renting truck and trailers. U-Haul eventually regained the market lead

it had lost to Ryder. In 1999, U-Haul controlled 52 percent of the truck rental market.

PASSENGER CAR RENTAL

This category covers establishments primarily engaged in the short-term rental of passenger cars without drivers.

NAICS CODE(S)

532111 (Passenger Cars Rental)

INDUSTRY SNAPSHOT

Along with the travel industry, the passenger car rental business was negatively impacted in a post-September 11 environment. The conflict in the Middle East, the SARS virus outbreak, and political unrest in the early 2000s also contributed to a drop in travel in the United States. In 2000, the car rental industry took in \$19.4 billion, which dropped to \$18.2 billion in 2001. By 2002, revenue had dropped another 2 percent at \$17.9 billion, the lowest in several years. Car rental companies were forced to cut down on their fleets, while at least one company filed for bankruptcy protection. As in other sectors, consolidation was a major trend, with several of the major car rental players merging to lower costs. Companies also raised car rental prices in order to see an increase in revenue. Analysts predicted a better year for the industry in 2003, with mild recovery and cautious growth expected.

BACKGROUND AND DEVELOPMENT

The car rental industry—better known as the “Drive-Ur-Self” business in the early years—had its beginnings not long after the Ford Motor Company introduced the Model T automobile in 1908. An entrepreneur named Joe Saunders is known to have begun renting a secondhand Model T in Omaha, Nebraska, in 1916. He affixed a mileage meter to the left front wheel and rented the car for 10 cents a mile. His first customer was a traveling salesman who had a date with a local girl. By

1925 Saunders had car rental operations in 21 states. The Chrysler Company ran full-page ads boasting that Saunders had purchased \$1 million worth of Chrysler automobiles. Saunders went bankrupt, though, during the Great Depression of the early 1930s.

In the early days of the industry, most Drive-Ur-Self cars were rented by local residents. The industry gained a shady reputation because rental cars were often used by bootleggers, bank robbers, and prostitutes. In 1952, *The Saturday Evening Post* estimated that as many as 90 percent of the cars rented during Prohibition were used for illegal purposes. The industry began to gain more respectability after the Eighteenth Amendment, which outlawed alcohol, was repealed in 1933.

In 1940 the loss of passengers to private automobiles prompted a group of railroads to form Railway Extension Inc., which franchised car rental dealerships in cities stretching from Chicago to New Orleans. The railroads provided space for car rental booths in stations and free telegraph service so passengers could wire ahead and reserve cars, which would be waiting for them when they arrived. The railroads also paid for the advertising. The American Drive-Ur-Self Association, controlled by Hertz, negotiated a less favorable relationship with railroads east of Chicago. Under the Hertz plan, car rental dealerships paid for their own advertising and telegraph service, and cars were not available on-site at the train stations.

During World War II, the U.S. Office of Defense Transportation (ODT) limited rental cars to 1,500 miles per month to conserve gasoline. The limit was cut to 650 miles per month in the Miami area when the ODT discovered that local residents were using rental cars to circumvent gas rationing in the use of private automobiles. Rental car dealers also were not allowed to buy new or replacement cars for their fleets during the war and were required to maintain a record of each rental, including the person’s name, address, occupation, and purpose of trip. Rates were frozen at 1942 levels, which averaged between 14 and 18 cents per mile for the first 50 miles. Government agencies and industries with war material contracts often monopolized available cars.

Airline Service. After the war, the car rental industry grew rapidly, carried along by the expanding economy. The railroads revived their car rental plans in 1947, establishing dealers in some 300 cities. But the real growth coincided with a boom in airline passenger service. In 1947 the Hertz Drive-Ur-Self System, then with about 2,300 rental cars nationwide, opened operations at airports in Atlanta and Milwaukee. That same year, Warren Avis, then president of Frost-Avis Inc., a Ford dealership in Detroit, formed the Avis Airline Rent-A-Car System.

Avis was a former Army Air Corps flyer who recognized that airplanes would soon replace passenger trains as America's favorite form of travel. He started with car rental booths at airports in Detroit and Miami and by 1949 had licensed use of the Avis name to rental agencies in New York, Chicago, Dallas, Washington, D.C., Los Angeles, and Houston. More aggressive than Hertz, Avis also arranged for American Airlines and Eastern Airlines to include information about Avis in passengers' ticket envelopes. In 1949, *Business Week* reported, "this kind of business is operated on an exclusive franchise basis; the first firm in has a big advantage. At present, Avis seems to have a substantial lead."

Hertz, however, was not long in responding. By 1952 Hertz and its franchised dealers were operating at more than 120 airports. In 1953 General Motors Corp. sold the business back to John Hertz, then chairman of the Omnibus Corporation, which had shed itself of bus operations to concentrate on car and truck rentals. The price was \$10.8 million. The following year Hertz opened operations in 50 additional airports and 20 more railroad stations. The company also began buying up franchised dealers. By 1955 the Hertz Rent-A-Car System encompassed nearly 1,000 company-owned or licensed dealers with total revenues of \$90 million. Avis had 850 dealers and \$35 million in revenues.

In 1956, Hertz and National Rent-A-Car, then the third largest rental car operation in the country, cracked the exclusive franchise that Avis had held with the Miami International Airport for eight years. This opened up the lucrative Florida vacation business.

Price Wars. By the early 1960s, Hertz, Avis, and National were entrenched as the industry leaders. However, there were hundreds of independent companies, many with only a few cars, eager to cash in on the growing market. In 1965 there were more than 135,000 rental cars available in the United States. The industry at that juncture was a \$450-million-a-year business, an increase in value of 80 percent from only three years previously.

The average Hertz or Avis rental in a resort city such as Miami or Las Vegas was \$10 a day, but the frugal renter could find rates as low as \$1. These discount companies often purchased used cars or replaced new cars less often. They also saved by locating their businesses near targeted airports, thus avoiding fees the leaders paid for on-site locations. Budget-conscious vacationers did not seem to mind the inconvenience. Many discount companies, however, were fly-by-night operators and managed to give the car rental industry a bad name before dropping by the wayside. But the success of reputable companies such as Budget Rent-A-Car eventually forced the industry leaders to cut their rates. Avis began offering compact, British-made Ford Cortinas for

\$3.95 a day and 9 cents a mile. Hertz and National also began offering lower rates on smaller cars. The price wars lasted until 1985, when car rental companies suffered through one of the worst financial years in industry history. After a few years of uneasy truce, the price wars were revived in the early 1990s.

Energy Crisis. The industry was detoured by the energy crisis in the early 1970s. In 1973, federal regulations limited the amount of gasoline available to car rental companies to 1972 levels. This forced rental companies to replace full-size cars with more fuel-efficient vehicles. Even then, many rental cars were sent out with half-empty gasoline tanks. Hertz survived by buying a fleet of ten tanker trucks to shift supplies of gasoline from city to city to deal with local shortages.

The industry also moved into the used-car business in the early 1970s. When it came time to update their fleets, rental companies had traditionally sold their cars to wholesalers, who auctioned them off to used-car dealers. However, the rising cost of new cars and a decision by automakers to curtail fleet discounts made it more attractive for rental car companies to sell their cars directly to the public. In 1975, Kenneth Krabbe, then vice president of Dollar-Rent-A-Car, told *Business Week*, "You've got to run a rent-a-car business on what you can sell. If you don't make money there, you're through."

Hertz was the first rental car company to move into retailing in a serious way. Hertz opened its first small showroom in southern California in 1971, and by 1974 the company had more than 100 used-car outlets across the country. By 1980 Hertz had become the largest used-car dealer in the United States, selling 70,000 cars at 139 locations. Frank Olson, then chairman of Hertz, told *Forbes* that the automakers "did us a favor. They put us out of a lazy man's business." Avis, which unlike Hertz had previously leased most of its cars to reduce financial risk, began buying its cars outright in 1978 so they could then be sold in the used-car market. By 1987 Avis was selling about 50,000 used cars annually. In 1992 rental car companies sold more than 1.5 million used cars.

Unfair Practices. In 1975 the Federal Trade Commission (FTC) accused Hertz, Avis, and National of conspiring to monopolize the airport car rental market. The FTC said the companies, then armed with 96 percent of the airport business, pressured airport authorities into establishing requirements for on-site operations that smaller companies could not meet, such as offering a nationwide reservations system. Off-airport car rental companies were not even allowed to advertise in some airports. An executive at the Philadelphia International Airport told *Business Week*, "If you're getting 10 percent from one company and 0 percent from another, you don't want to hurt those giving you the money." The FTC also

accused the major car rental companies of illegal price fixing.

The case was settled out of court in 1976, without any of the companies admitting guilt. However, they agreed not to engage in any predatory practices in the future. As a result, smaller car rental companies found it easier to negotiate on-site locations at major airports. Budget was especially aggressive, more than doubling its share of the airport car rental business from about 7 percent in 1976 to 17 percent in 1982. In 1983 Olson told *Fortune*, "Short-term we have to worry about Avis. Long-term it's Budget."

The increased competition also led rental car companies into a battle of give-away programs. The leaders—Hertz, Avis, National, and Budget—offered everything from athletic equipment and luggage to televisions and airline tickets for repeat customers who piled up points. In 1983 *Fortune* reported, "Unintentionally but predictably, the industry has imprisoned itself in a campaign that is horrendously expensive, poisonous to profits, and difficult to stop." By 1985 the companies were financially battered and bruised, but market share had stayed about the same. The companies called an unofficial truce.

Restructuring. The 1980s saw a major restructuring of the car rental industry, as automobile makers purchased controlling interests in the leading companies. In 1987, an investment group headed by Ford Motor Co. paid \$1.3 billion to buy Hertz from the Allegis Corporation, which also owned United Airlines. Ford later sold a 20 percent share to Volvo North America Corporation, retaining a 60 percent interest. Ford purchased Budget in 1988. Avis was sold five times between 1983 and 1987, finally ending up in the hands of an employee stock ownership plan (ESOP). In 1989 General Motors Corp. purchased a 25 percent share of Avis. General Motors also purchased a 45 percent share of National in 1988, later increasing its share in that company to 80 percent. The Chrysler Corporation owned Pentastar Transportation Group, which operated General Rent-A-Car, Dollar Rent-A-Car, Thrifty Rent-A-Car, and Snappy Car Rentals.

The manufacturers' interest in the rental car industry stemmed from the fact that rental companies were their biggest single customers and purchasing the company locked in sales. Each of the four major rental companies agreed to purchase 70 percent or more of their fleets from their auto company owners. In 1988, Ford sold more than 100,000 cars to Hertz; GM sold about 85,000 cars to Avis and National; and Chrysler sold about 75,000 cars to its car rental firms. When Mitsubishi Motor Sales of America purchased Value Rent-A-Car in 1991, it replaced the fleet's 25,000 mostly Ford automobiles with its own. Car rental companies accounted for about 10 percent of all domestic auto sales in the early 1990s.

Rental cars also provided manufacturers with an effective marketing tool. Millions of potential buyers were exposed to the car makers' newest models every year. Renters also helped eliminate glitches in new cars by providing feedback to the manufacturers. Car makers generally offered to buy their cars back from the rental companies after four to six months and often shared the cost of advertising if the ads mentioned the manufacturer. In the early 1990s car makers began to request that rental cars be kept in service longer, from six to nine months, because the "almost new" fleet cars were cutting into sales of new automobiles.

Issues in the 1990s. The booming economy of the mid-1990s erased any lingering effects of the previous recession, which had limited air travel and, thus, airport car rentals. Industry-wide revenues jumped from \$13 billion in 1995 to nearly \$15 billion in 1996. The industry closely watched the economic indicators for any signs of a new recession, but several more immediate issues dominated the headlines in 1996-97.

In March 1997, New York state's highest court ruled that rental car companies can not refuse to rent cars to young drivers solely because of age. As the *Wall Street Journal* reported in its story, most of the major car companies, including Hertz, Avis, and National, routinely refused to rent to drivers under 25 years old, citing higher accident rates. The decision by the New York Court of Appeals was the first major ruling on what had been an industry-wide practice for decades, legal experts said. The rental car companies criticized the decision, saying it made them too vulnerable to a dangerous group of drivers. Consumer advocates, however, praised the decision. It is now standard practice for rental companies to rent to "under-age drivers," but to compensate their risk by charging a higher rate.

Avis also faced a barrage of bad publicity over a race discrimination case involving one of its franchise owners in the South. The franchisee, who owned several Avis outlets, had allegedly instructed his workers to refuse rentals to African Americans. When the practice was exposed, it received widespread publicity on the television program *60 Minutes* and elsewhere. Avis vowed to end the practice immediately, although bad feelings lingered because the practices had reportedly been continuing for several years before Avis moved to halt them.

In early 1997 there arose another controversy, this time over bank debit cards. Hertz, Avis, and other companies decided not to accept debit cards as payment, despite their similar appearance to credit cards. As *The New York Times* reported, for years the rental companies used possession of a credit card as a crude way to weed out potentially risky renters. But this test no longer works with debit cards; because no loan is involved in a debit

card transaction, banks will now give them to nearly everyone with a bank account. Hertz spokeswoman Lisa LoManto told the *Times* that Hertz was entitled to a certain level of confidence because in car rental, unlike almost any other business, the customer is given total control of a vehicle worth \$20,000 or more. Still, it is certain that with more than 60 million bank debit cards now in circulation, the decision not to accept them will lead to some confusion and frustration at rental agency counters.

Meanwhile, automakers are also expected to continue playing a major role in the development of the industry. Automakers influence what makes and models of rental cars are available, how long they stay in service before being replaced, and the direction of car rental advertising. During 1996, automakers sold almost 1.5 million vehicles to the rental companies, a volume equivalent to about 10 percent of total production by “the Big Three.” In 1991 Vincent A. Wasik, then chairman of National, told *Automotive News*, “With the substantial ownership positions in the major rental car companies (GM, Ford and Chrysler) the game is really being played at a different level. Customer satisfaction through superior service is now the ‘product’ that makes the difference.”

The mid- to late 1990s saw another wave of ownership changes and consolidation. In 1996 HFS, Inc., a New Jersey-based company with significant holdings in lodging and real estate, took over ownership of Avis, Inc. Republic Industries announced that its intention to purchase Alamo Rent-A-Car for \$625 million. In 1994, Ford Motor Co. went from 49 percent ownership in Hertz to 100 percent. That same year, Chrysler sold Snappy Car Rentals to company management and the Jacobson Partners. As Jon LeSage, executive editor of the trade journal *Auto Rental News* wrote in his *1997 Fact Book*, “Car rental is a mature industry . . . dominated by a small number of major companies. While it is not the most profitable industry in the world these days, there are several advantages in controlling part of the market for the companies and investors who are buying car rental companies.”

Overall, the industry was expected to remain very competitive, with many of the leading companies becoming more aggressive in the leisure market. Unlimited mileage offers became a common promotional weapon in the leisure market. There also were increasingly fewer distinctions between on-airport and off-airport car rental companies. Major airports had become so congested—and rental fleets had become so large—that on-site rental companies were forced to shuttle customers to distant car lots. Off-airport companies were able to offer similar service by running shuttle buses between airport terminals and their own locations. Conversely, off-airport rental companies began to lose their financial advantage,

as airports introduced access fees for airport shuttle buses.

CURRENT CONDITIONS

Like many U.S. industries, the passenger car rental sector was greatly affected by the events of 9/11, which led to fewer Americans traveling and, thus, renting cars. Further challenges in the early 2000s included the war with Iraq, political unrest, high unemployment rates, and lessened travel due to the SARS virus outbreak. From a 2000 high of 19.4 billion industry-wide, 2001 revenues dropped to \$18.2 billion and sunk a further 2 percent in 2002 to \$17.9 billion, slightly higher than 1999 levels. Accordingly, car rental companies cut back their fleets. There were 1.82 million cars in service in 2000, which dropped to 1.74 million in 2001 and 1.64 million in 2002.

By 2003, the non-airport market had become more important to this industry. The non-airport market helped offset the loss from fewer people traveling by plane. Travelers who used non-airport car rental agencies marked the trend in travelers using rental cars for short-haul trips. The average price of a rental car in 2002 was \$58.52. A midsize rental car averaged \$55.88, and a full-size car, \$61.16. Baltimore was the city that ranked as the most expensive city to rent a car, averaging \$86.24 in 2002, whereas Rochester, Minnesota, was the least expensive in the top 100 ranked, averaging \$39.32 for a rental car.

Booking rental cars online was another important industry trend in car rental and travel in general. Of the \$12.9 billion made in online travel bookings in 2000, 9 percent came from car rentals. National Car Rental introduced its “QuickRent” program in 2003, which allowed customers who booked online to avoid stopping at the counter and go straight to the lot and choose a car from the class reserved.

In an effort to cut costs and raise revenue, mergers and partnerships abounded in the early 2000s. Alamo and National brands merged at many counters in the United States, whereas Dollar Thrifty Automotive Group announced it would combine its two rental car units. Thrifty also partnered with Walmart.com in 2002, with customers able to book their cars online and pay with Wal-Mart credit cards. In 2002, Alamo teamed with Walt Disney Co. and became the official rental car company of Walt Disney World and Disneyland resorts. National had previously been the official rental car of Disney for 22 years. Avis teamed with Sears in 2002, with Sears converting all its Sears Car Rental locations into Avis Rent-A-Car operations that would accept Sears credit cards.

Although some analysts saw the beginnings of a recovery within the industry in mid-2002 and 2003, it was difficult to predict how the industry would fare in the

short term. Most agreed there would be moderate growth and some slow expansion in 2003.

INDUSTRY LEADERS

In 2002 the three leading companies in the car rental industry were: Enterprise Rent-A-Car, Inc. (27 percent, with a 2002 fleet of 525,000 cars); Hertz Corporation (20 percent, with a 2002 fleet of 525,000 cars); and Alamo/National, (16 percent, with a 2002 fleet of 150,000 cars). Others dominant in the industry included Avis Rent A Car, Inc., now a subsidiary of Cendant Corp., (more than 200,000 cars); and Budget Group, Inc., also bought by Cendant in 2002. These companies accounted for more than 90 percent of the airport and near-airport car rentals. Hertz, Avis, and Budget also had strong international presences. Hertz alone had 500,000 cars for rent in 140 nations.

Enterprise Rent-A-Car, Inc. Enterprise represents the greatest growth story of the past few years. Since 1993 it has nearly doubled the size of its fleet and is now the largest car rental company in the United States. Its strategy was to leave the highly competitive airport rental market to the other companies and concentrate on the non-airport market. It operates more than 2,600 outlets (Hertz operates about 1,200), many near auto repair shops, so that Enterprise could rent to customers whose vehicles were in the shop for work. With the exception of Alamo, many of the major airport and near-airport car rental companies are owned wholly or in part by automakers, although the amounts of ownership continue to vary as firms buy or sell controlling interests. In 2002, Enterprise had sales of \$6.5 billion and employed 50,000 workers. It offers lower rates than its competitors and is the only company to target local rentals.

Avis. With the rise of Enterprise, Avis Group Holdings, Inc. has slipped from its long-time position as second largest car rental company in the United States to third. Avis was bought by the Cendant Corporation in 2001. Avis, with a fleet of some 220,000 automobiles, had sales of \$2.5 billion in 2002 and employed 19,500 workers. With the majority of its business comprised of business rentals, Avis made plans to draw more of the leisure market. In an effort to bolster revenue, the company opened test kiosks in several California locations that sold products for travelers, including maps, batteries, and snacks.

Originally known as Avis Airlines Rent-A-Car System, the company was founded in 1946 by Warren Avis, who owned an automobile dealership in Detroit. Avis started with rental operations at Detroit's Willow Run Airport and Miami International Airport. He then licensed the Avis name to independent car rental companies to serve airports in New York, Chicago, Dallas, Washington, D.C., Los Angeles, and other cities. In 1948,

Avis began to open offices near hotels and business districts and dropped "Airlines" from the company name.

Avis sold Avis Rent-A-Car System in 1954 to Richard S. Robie, operator of a car rental business in New England, for \$8 million. At the time, there were 185 Avis locations in the United States and Canada, and working agreements had been established with local companies throughout Europe. Under Robie, the company developed the first nationwide plan for one-way rentals and introduced its own credit card. Robie sold the business in 1956 to the Amoskeag Company, which created a holding company—Avis, Inc.

Avis grew rapidly in the late 1950s and early 1960s, expanding its fleet from 1,200 to 7,500 vehicles, but the changes in ownership that would characterize Avis continued. Amoskeag sold the business in 1962 to Lazard Freres & Co., a New York investment banking firm. In 1965 Avis was purchased by the International Telephone & Telegraph Corporation (ITT). Under ITT's leadership, Avis strengthened its presence in Europe, where it became the leading car rental company. Avis also created the first online computerized car rental reservation system in 1972 with the introduction of the Wizard System. ITT was ordered to divest Avis in 1972 as part of federal antitrust proceedings. When ITT was unable to find a buyer, Avis became a public company in 1974, with 52 percent of the stock held by a court-appointed trustee.

In 1977 Norton Simon, Inc. purchased control of Avis for \$174 million. Revenues had grown to more than \$673 million, with Avis accounting for about 25 percent of the car rental market. Under Norton Simon, Avis was riddled by dissension from its licensed dealers. The dissension became public in 1982 when Avis launched an advertising campaign with Norton Simon chairman David Mahoney as spokesman. The franchise group took its \$5 million advertising budget to a different agency and created its own ads promoting low rates. In the confusion, Hertz widened its lead over Avis. National and Budget also gained market share. Avis posted a \$50 million loss in 1982.

Changes in ownership continued in the 1980s. In rapid succession, Esmark, Inc., purchased Norton Simon in 1983, and Beatrice Company acquired Esmark in 1984. In 1985 Kohlberg Kravis Roberts & Company acquired Beatrice in a leveraged buyout. A year later, a management group and the Wesray Corporation purchased Avis for \$265 million and the assumption of \$1.34 billion in debt. In 1986 Wesray disposed of about half of Avis' European rental operations and its leasing operations in America. In 1987 Wesray sold the rest of Avis to an employee stock ownership plan for \$750 million and the assumption of \$1 billion in debt. General Motors

purchased its 25 percent share of Avis in 1989. These changes continued with the HFS deal in 1996.

Hertz. In 2002, Hertz operated a worldwide fleet of some 525,000 vehicles at 7,000 company-owned or licensed car rental locations in 150 countries and reported sales of \$4.9 billion and 28,900 employees. In 2002 the majority of Hertz's sales came from the airport rental market, both business and leisure. Ford Motor Company bought all remaining shares of Hertz, the company it spun off in 1997, in 2001 and is now its full owner.

Hertz had its beginnings in 1908, when Walter L. Jacobs founded the Rent-A-Ford Co. in Chicago. By 1923 Rent-A-Ford had a fleet of 200 cars and \$1 million in revenue. That same year Jacobs sold the business to John Hertz, then president and owner of the Yellow Cab and Yellow Truck and Coach Manufacturing Co. Hertz renamed the business the Hertz Drive-Ur-Self System. Hertz converted the rental fleet to the oversized sedans used by Yellow Cab, but customers balked at renting the bulky automobiles, and the fleet was switched back to regular passenger cars. General Motors Corp. purchased Hertz in 1926 and sold it to the Omnibus Corporation, then headed by John Hertz, in 1953. Omnibus changed its name to the Hertz Corporation in 1954. The RCA Corporation purchased Hertz in 1967.

In 1985 Hertz was purchased by UAL, Inc., the owner of United Airlines, which planned to expand into other travel-related services. UAL, however, which changed its name to the Allegis Corporation, abandoned the strategy within months. Allegis sold Hertz in 1987 for \$1.3 billion—more than twice what it paid in 1985—to the Park Ridge Corporation, a holding company created by Ford and Hertz management.

In 1988, Hertz pleaded guilty to defrauding insurance companies and motorists by inflating the cost of repairs—or charging for repairs that were never performed—after cars were damaged in more than 100,000 accidents between 1978 and 1987. Hertz was ordered to pay a fine of \$6.85 million—the largest fine ever imposed at that time in a criminal consumer fraud case. The company was also ordered to pay restitution of more than \$13 million to the motorists and insurance companies.

In 1999, Hertz announced plans to offer a navigation system in 50,000 of its rental vehicles. The system is offered in several different vehicle makes and models.

Budget. Budget Group had car and truck rental operations at more than 5,000 locations in the United States in 2002 with 2001 sales of \$2.16 billion and 11,400 employees. Ford was a minority owner in the company until it was wholly acquired by Cendant Corp. in 2002.

Budget Rent-A-Car was founded in Los Angeles in 1958 by Morris Mirkin, who started with a fleet of 10

cars. The Budget Rent-A-Car Corporation was started in 1960. Initially, the company focused on the discount leisure market with its off-airport locations, but its image also appealed to economy-minded small business travelers. Budget began pursuing corporate accounts aggressively in 1989. Budget promoted its cars with the advertising tagline “The Smart Money Is On Budget.”

Hoping to increase sales and visibility, Budget began offering its cars for price bidding online in late 1999. In this way, consumers can comparison shop without going to another rental company.

Alamo/National. With rentals waning in a post-9/11 environment, parent of Alamo and National, ANC Rental Corporation, filed for bankruptcy protection in 2001. To cut costs, ANC combined the operations of Alamo and National brands at the end of 2002. ANC had total revenues of \$2.3 billion in 2002. Alamo/National was also the leading car rental company in Florida and the largest independent car rental company in the country. In 2002, Alamo had a fleet of 150,000 automobiles in 550 locations worldwide. Leisure customers account for 75 percent of Alamo's market share.

Alamo was founded in 1974 with a fleet of 1,000 cars and operations in Miami, Fort Lauderdale, Tampa, and Orlando. The name “Alamo” was chosen because it placed the company ahead of its major competitors in the telephone directory. Alamo initially focused on the discount rate leisure market, cultivating relationships with travel agents, and operated solely at off-airport locations. Travel agent referrals continued to account for more than 50 percent of Alamo's business in 1993.

Alamo opened its first on-airport site in 1981 in Atlanta and began moving into business rentals aggressively in the mid-1980s. In 1983 the company also opened a 77,000-square-foot rental plaza near Orlando International Airport. Alamo claimed that the plaza was the largest car rental facility in the world.

The crimes against tourists in Florida in 1993 rocked Alamo, the rental leader in the state. The family of a slain German tourist eventually sued Alamo for \$10 million, charging that the company had been negligent in complying with the Florida governor's executive order concerning the removal of identifying marks from rental vehicles.

SIC 7515

PASSENGER CAR LEASING

This category covers establishments primarily engaged in extended-term leasing of passenger cars without drivers. Establishments primarily engaged in finance leasing of automobiles are classified in **SIC 6159: Miscellaneous Business Credit Institutions**.

NAICS CODE(S)

532112 (Passenger Cars Leasing)

INDUSTRY SNAPSHOT

The passenger car leasing industry is comprised primarily of companies that provide corporate clients with a range of fleet management services in addition to automobile leasing. About 30 percent of all “company cars” in the United States are leased. According to *Consumers Research* magazine, a third of all cars were leased in 1996

and one in four persons who bought a new car leased it. That figure represented an increase of 400 percent from 1984, and many industry analysts were optimistic that 50 percent of all vehicles would be leased during the early 2000s. However, after a record year in 1999 lease volumes quickly plummeted. A number of factors contributed to this decline, including zero-percent financing incentives that made new vehicle purchases more attractive, as well as weak economic conditions that had a negative impact on corporate spending and employment levels.

Fleet management services can be classified broadly as vehicle acquisition, maintenance management, fleet disposition, and fleet support services, which range from fuel credit cards to driver safety programs. The National Association of Fleet Administrators reported that the most popular services were vehicle ordering, delivery to individual drivers, insurance subrogation, and accident repairs. Most companies in the industry also leased light trucks and utility vehicles.

Leasing of cars to individuals boomed during the early 1990s, and many automobile manufacturers began to coordinate more closely with their financing arms and dealer networks to capture a share of this growing market. The automakers’ efforts lured some customers away from banks and independent finance companies. However, by the early 2000s the automotive industry was moving away from leasing. Several leading finance companies exited the leasing business altogether, while those owned by automakers scaled back their activity. This was because of the hefty financial losses these institutions incurred when used vehicle values fell significantly during the early 2000s, affecting the residual values of off-lease vehicles.

BACKGROUND AND DEVELOPMENT

The automobile leasing industry developed in the 1940s as companies looked for affordable ways to provide their sales and service personnel with reliable transportation. Petrolager, a large pharmaceutical company in Chicago, was an early case in point. Petrolager began by paying part of the cost for employees to purchase their own cars, but that became a losing proposition when the employees left for other jobs and took the automobiles with them.

In 1939, Zollie Frank, a car dealer in Chicago, suggested that Petrolager lease five automobiles for its salesmen instead of purchasing them. The benefits were twofold. Petrolager would retain control of the vehicles and also avoid large cash outlays. Petrolager agreed, and soon afterward Frank and his brother-in-law Armund Schoen founded the Four Wheels Co., which many in the industry identified as the first automobile leasing company. In 1954, the company became known as Wheels,

Inc. It remained one of the largest fleet management companies in the United States in 1997 with more than 160,000 automobiles under lease.

The industry developed slowly, however, especially after the United States entered World War II and wartime restrictions made it almost impossible for leasing companies to purchase new automobiles or replacement parts. However, the industry began to grow in the late 1940s during the post-war economic expansion.

Finance Leasing. In 1946, three former servicemen—Duane L. Peterson, Harley W. Howell, and Richard M. Heather—formed a partnership in Baltimore, Maryland, to counsel companies on fleet management. By 1954, Peterson, Howell & Heather had incorporated and moved into the leasing business.

The company was credited with developing the industry's first "finance lease." Under the PHH Car Plan, Peterson, Howell & Heather would purchase automobiles and lease them to a client for a set monthly fee. When the lease ended, the company would sell the cars to pay off the balance on its original loan. Any surplus was returned to the client, but the client was billed if the resale failed to cover the loan. In a "closed" or "walk-away" lease, by contrast, the lessee had no financial obligation at the end of the lease period.

In 1981, a U.S. District Court ruled that finance leases were conditional sales contracts, which eliminated many of the tax benefits of "open-ended" leasing. However, although the percentage of closed or "operating" leases increased, open-ended leasing remained popular even after the court ruling. Automobiles were often sold to the client's employees when the lease expired.

Competition. The car leasing business grew rapidly in the late 1950s. In 1963, *Time* described the industry, reporting that leasing volumes had doubled to 600,000 vehicles in only five years. This explosion had led to the formation of a new, highly competitive industry worth \$750 million, in which some 3,000 companies participated.

Car makers were also beginning to take note of the industry. In 1962, Chrysler Corp. formed its own leasing company, the Chrysler Leasing Corp., which was phased out in 1968. Ford Motor Company and General Motors also announced special financing programs in the early 1960s to encourage car dealers to offer fleet leasing. By 1970, more than 11,000 car dealers were involved in leasing, and the total number of automobiles under lease in the United States exceeded 1 million.

Restructuring. Rising interest rates, as high as 21 percent in 1980, forced many smaller companies out of the industry. However, the Economic Recovery and Tax Act of 1982, which gave vehicle leasing companies substantial tax benefits, attracted several powerful new players. In 1987,

for example, General Electric Company purchased GELCO Fleet Management Services, and Ford Motor Company purchased United States Fleet Leasing, Inc. GELCO was later renamed GE Capital Fleet Services.

Impact on Detroit. Because leasing represented a major share of the domestic automobile market, leasing companies had a major influence on U.S. car makers. Clients generally followed their leasing company's recommendations, from broad suggestions about size and optional equipment to specific models.

Until the 1960s, most leasing companies recommended standard six-cylinder automobiles with manual transmissions and very limited optional equipment. But in the 1960s, companies began recommending bigger cars with automatic transmissions, power steering, air conditioning, and radios. By the end of the decade, most corporate fleets consisted of full-size, eight-cylinder automobiles.

In the early 1970s, leasing companies began recommending intermediate-sized cars for better fuel economy. Intermediates accounted for 16 percent of the leased fleets by 1973 and 80 percent by 1977. In 1981, Peterson, Howell & Heather (later PHH FleetAmerica) became the first major leasing company to recommend compact cars. More than half the fleet automobiles leased in 1981 were four-cylinder cars. The most popular cars leased in 1995 were midsized: Ford Taurus, Honda Accord, and the Ford F-Series pick-up. Until the late 1980s, leasing companies almost never recommended foreign makes of automobiles, even if they were built in the United States.

Corporate downsizing and cost-cutting in the early 1990s also affected the automobile leasing industry. Fleets were reduced either because corporations had fewer employees or because they eliminated benefits such as company cars. The number of car leasing establishments decreased significantly from 1,144 in 1990 to 531 in 1996. The number of industry employees also decreased, from 10,800 in 1990 to 5,700 in 1996, a decline of almost 50 percent. However, the largest leasing companies gained business during the same period.

In late 1999, the decline of personal use leasing continued, with leased cars accounting for 31.8 percent of the new car market, down 3 percent from the previous year.

In general, leasing companies that also provided fleet management services were optimistic about the future, as more corporations began to contract for services that previously were provided in-house or new services that offered better control of costs. Many corporations with large fleets also looked to leasing companies for help in meeting federal regulations regarding fuel efficiency.

The Uniform Consumer Leases Act was expected to be in force by the year 2000. This Act was expected to harm automobile lessors, primarily because it was a largely one-sided document, emphasizing consumer needs. It included language regarding lease rate disclosure, open-end lease restrictions, GAP coverage provisions, and limitations on determination of excess wear and tear.

Automobile manufacturers found that leasing increased brand loyalty and provided dealers with a steady stream of good used cars. However, some analysts worried that as leasing gained in popularity, the resulting flood of used cars could deflate prices and detract from new car sales. The trend toward used vehicle leasing was expected to combat such issues. In addition, some car makers found that short-term leases meant that products needed to be updated more quickly, or else consumers would likely switch to a competing product. In order to distinguish themselves in the increasingly competitive leasing field, manufacturers developed innovative programs, including a 12-year lease with replacement every two years, and a weekend-only lease for urban residents. In 1999, fleet dealers were focusing on customer service and marketing segments to retain their competitive edge.

CURRENT CONDITIONS

Passenger car leasing remained a significant component of the nation's economy during the early 2000s. At that time, the National Association of Fleet Administrators, Inc. (NAFA) reported that its members were "responsible for the specification, acquisition, maintenance, and disposal of more than 2.7 million vehicles. These vehicles, with an average initial cost of \$16,400, put NAFA Members in control of more than \$44 billion worth of assets."

Nonetheless, the industry was not without its challenges. Although passenger car leasing industry revenues increased approximately 3 percent in both 1999 and 2000, U.S. Census Bureau figures reveal that revenues fell almost 3 percent in 2001. By that year the U.S. economy had started to decline. Although some industry observers noted that commercial leasing remained an attractive option for corporate America, the weak economy led companies in many American industries to implement massive workforce reductions and cut back on spending. These factors challenged automotive leasing companies in 2002 and 2003 and likely had a negative impact on overall industry revenues.

One factor that worked against the leasing industry during the early 2000s—namely in the consumer market—were zero-percent financing incentives from automakers. These offers affected the leasing market in two ways. First, they brought down the value of used vehicles. This worked against the residual values of leased vehicles (the amount vehicles are worth at the end of a lease), which is a key factor when determining

monthly lease payments. As *Automotive News* explained in its February 1, 2003, issue, *Automotive Lease Guide* figures revealed that average vehicle values following a 36-month lease had fallen to 47 percent of sticker price. This was a decrease from 53 percent in late 1998.

In the past, some leasing companies overstated residual values in order to lower monthly payments for consumers and increase new lease volumes. These practices contributed to the significant financial losses incurred by banks and other financial institutions during the early 2000s. In August 2002, the *Pittsburgh Post-Gazette* cited results from a Consumer Bankers Association survey revealing that, on average, both automaker-owned and independent finance companies lost \$2,451 per vehicle in 2001. This was an increase over per-vehicle losses of \$2,342 in 2000 and \$1,200 in 1998. In the wake of these losses, leading financial institutions like Bank One Corp., Bank of America Corp., KeyCorp, and GE Capital Corp. stopped offering vehicle leasing.

Zero-percent financing deals also hurt the automotive leasing market because they made buying a new vehicle more attractive than leasing one. According to the Association of Consumer Vehicle Lessors (ACVL), new lease volumes fell from 2.57 million in 2000 to 1.5 million in 2001—a decline of 40 percent. This trend continued in 2002. From January through November 2002, the ACVL reported that, in comparison to the same time frame the previous year, new lease volumes declined almost 15 percent. Considered together, the association explained that these figures meant that lease volumes fell about 50 percent from 2000 to 2002.

INDUSTRY LEADERS

The largest vehicle leasing company in the United States and the world, Eden Prairie, Minnesota-based GE Capital Fleet Services was founded in 1957 as the General Leasing Co. General Leasing, which changed its name to GELCO Corporation in 1972, acquired six other companies between 1968 and 1974, including Interstate Vehicle Management; the Interstate Fleet Corp.; Selig Leasing Co.; Lease Plan, Inc.; and the Valley Leasing Co. In 1987, the company was purchased by GE Credit Corporation, which formed GE Capital Fleet Services. In 1996, the company acquired JMJ Fleet Services and began offering fleet management services to corporate and governmental customers throughout Australia. In 2003, GE Capital Fleet Services was a business unit of General Electric subsidiary GE Equipment Management, which recorded sales of \$4.3 billion in 2002. At that time, the company employed 3,500 workers and was responsible for more than 1.2 million vehicles.

PHH Arval, a subsidiary of Cendant Corp., based in Hunt Valley, Maryland, was the second-largest automobile leasing company in the United States. PHH also

provided a full range of fleet management services. In 2001, the company employed 1,200 workers. PHH was founded in 1946 as Peterson, Howell & Heather, Business Consultants, with the intention of advising companies on fleet management. The business was incorporated in 1954 and moved into leasing with the industry's first finance lease program. In 1975, Peterson, Howell & Heather also became the first major leasing company to recommend compact cars to its clients.

The company became the PHH Group, Inc., in 1978. The fleet management division retained the name Peterson, Howell & Heather until 1986, when it became PHH FleetAmerica. PHH FleetAmerica also acquired the domestic operation of Avis Car Leasing, Inc. in 1986. In 1972, PHH offered vehicle managing and leasing operations in the United Kingdom, expanded to Germany in 1987, and extended service to clients in France, Italy, and Belgium in the mid-1990s. In 1988, PHH Group became the PHH Corporation. In addition to vehicle leasing and fleet management, the PHH Corporation provided international relocation, real estate, and mortgage banking services. In 1997, PHH was acquired by HFS, Inc. (predecessor to Cendant Corp.), and in 1999 was sold to Avis Rent A Car. In 2001, Cendant bought Avis and reacquired PHH in the process, making it one of many subsidiaries.

SIC 7519

UTILITY TRAILER AND RECREATIONAL VEHICLE RENTAL

This category covers establishments primarily engaged in daily or extended-term rental of utility trailers and recreational vehicles (RVs). Establishments primarily engaged in renting motorcycles, bicycles, golf carts, go-carts, or recreational boats are classified in **SIC 7999: Amusement and Recreation Services, Not Elsewhere Classified**; and those engaged in renting airplanes are classified in **SIC 7359: Equipment Rental and Leasing, Not Elsewhere Classified**. Establishments primarily engaged in the rental of mobile homes on site are classified in Real Estate, **SIC 6515: Operators of Residential Mobile Homes Sites**.

NAICS CODE(S)

532120 (Truck, Utility Trailer and RV (Recreational Vehicles) Rental and Leasing)

The utility trailer and recreational vehicle (RV) rental industry is comprised of two distinct operations. Utility trailers are rented generally by establishments that also rent trucks for the consumer market, such as U-Haul International. Most of those establishments are automotive service centers or centers affiliated with a major truck rental company. Recreational vehicles generally are rented by establishments that focus exclusively on renting RVs for the vacation market, or by RV dealers for whom the rental market is a sideline to RV sales and service. Some establishments rent utility trailers and camper-trailers, considered the low-end of the RV rental business. In 1996, an estimated 450 establishments rented utility trailers, recreational vehicles, or both. These establishments had sales of \$294 million and employed 1,800 people. Annual payroll was \$52 million. According to the Census Bureau, in 1997 there were 5,296 establishments engaged in truck, utility trailer, and RV rental and leasing; they generated revenues of more than \$10.3 billion and employed about 47,000 people.

Most of the larger establishments renting recreational vehicles belong to the Recreation Vehicle Rental Association (RVRA), a division of the Recreation Vehicle Dealers Association (RVDA). In 1992, 56 percent of RVRA members reported having 10 or fewer recreational vehicles available for rent, while 35 percent said they had fleets of 11 to 50 vehicles. About 8.5 percent had fleets larger than 50 vehicles.

Utility Trailers. L. S. Schoen, the founder of U-Haul International, generally is credited with turning the haphazard rental of utility trailers into an organized industry. In 1945, Schoen, then in the military, rented a beat-up trailer from a service station to move his family's belongings from Los Angeles to Corona, California. That night he made a notation in his diary: "I am intrigued by the business potential of this idea especially from the standpoint of one-way rentals."

Schoen was discharged from the military later that year and moved his family to Portland, Oregon. Within two weeks he had bought his first trailer. He painted "U-Haul Co. — Rental Trailers — \$2.00 per day" on the sides. By 1946, Schoen had a fleet of 70 trailers stretching from Seattle to Los Angeles, and in 1948 he decided to go national. He offered one-way rentals from the West Coast to anywhere in the United States. The only catch was that customers had to find service station managers at the end of their trips who were willing to become Schoen's agents. The plan worked, and by the end of the year, Schoen had a fleet of 200 trailers and a network of agents nationwide.

In 1951, Schoen launched a low-risk program for independent fleet ownership as a way to raise money and expand the U-Haul network even faster: investors would buy trailers from U-Haul and would assume full responsibility for insurance, maintenance, and distribution. Each month, fleet owners would receive a report and payment for rental activity on their trailers. Schoen raised \$2 million in the first two years. By 1955, there were more than 10,000 U-Haul trailers in 200 fleets scattered around the country, and Schoen was adding 600 trailers a month.

In the late 1960s, U-Haul trailers were available at more than 14,000 service stations. Although the number of outlets declined during the 1970s, when many service stations closed, U-Haul remained the leader in utility trailer rentals. U-Haul also began renting trucks in the late 1950s, and came to dominate the consumer truck-rental industry as well. For 1997, U-Haul had revenues of \$1.2 billion. AMERCO became the holding company of U-Haul International in 1997.

In 1999, U-Haul rented its trailers, trucks, and tow dollies through 1,100 company-owned centers and 15,000 dealers in the United States and Canada, and sales topped \$1.5 billion. This wasn't enough to top industry leader Ryder System, Inc., who had 199 sales of \$5 billion. Penske Truck Leasing placed second with 1998 sales of \$1.8 billion. Other utility trailer rental companies include Transamerica Leasing Inc., which had 1997 sales of \$734 million, and XTRA Lease Inc., which had 1998 sales of \$300 million.

Recreational Vehicles. Recreational vehicles became widely popular in the United States during the 1960s, and,

in 1970, RV dealers formed the RVDA. The RVDA worked to enhance the image of RV dealers and to improve warranty programs offered by RV manufacturers. By 1982, RV rentals had emerged as a separate industry, which led to the formation of the RVRA. The group later became a division of the RVDA. In 1988, the RVRA began publishing *Rental Ventures* (now called *RVRA Rental Directory*), a consumer guide to renting recreational vehicles. That was followed in 1991 by the *Rental Operations Manual*, which provides guidelines and marketing suggestions for RV rental dealers. The RVRA also publishes an annual membership directory.

In the late 1990s, baby boomers, who liked to rent or lease all types of products, were boosting demand for RV rentals and causing the traditional rental season to lengthen. Their most common rental choice was a Class C RV, or mini-motor home. In 1998, fleet owners planned to expand their fleets by 11 percent, as RV rentals were expected to increase 24 percent.

The largest RV rental establishment is Cruise America of Mesa, Arizona, with more than 100 company-owned facilities and satellite rental centers in the United States. The company, as part of Budget Group, Inc., has a fleet of more than 4,300 vehicles, including self-contained RVs, motor homes, camper homes, truck campers, and motorcycles. In 1997, Cruise America had revenues of \$95.6 million. Cruise America operates a joint venture with Thor Industries, Inc., a leading maker of RVs, for renting to the public.

SIC 7521

AUTOMOBILE PARKING

This classification covers establishments primarily engaged in the temporary parking of automobiles, usually on an hourly, daily, or monthly contract or fee basis. Establishments primarily engaged in extended or dead storage of automobiles are classified in **SIC 4226: Special Warehousing and Storage, Not Elsewhere Classified**.

NAICS CODE(S)

812930 (Parking Lots and Garages)

INDUSTRY SNAPSHOT

According to International Parking Institute sources, the automobile parking industry generated \$43 billion in 1998, with \$28 billion coming from the private side and \$15 billion coming from the public side. This was a substantial increase over figures reported in previous years. The financial success of the automobile parking industry is tied to commercial real estate growth—a boom in new office buildings (and high occupancy rates within them) requires more lots to house the cars of commuters, clients, and related service industries in the area.

The International Parking Institute also reported that there were roughly 18,500 parking establishments in the United States in 1998. Approximately half of them were owned by municipalities, and the rest were privately held. There were about 105 million parking spaces in the United States with a 2 to 1 ratio of off-street versus on-street parking.

The industry employed about 73,400 workers, the majority of which were parking lot attendants and cashiers. Other positions included enforcement officers, maintenance personnel, office personnel, and information managers. According to the U.S. Bureau of Labor Statistics, the outlook for these jobs looked excellent through the year 2008, with the expected growth at 24 percent, industry-wide.

ORGANIZATION AND STRUCTURE

Often, parking lot operators do not own the land on which their businesses sit. Arrangements with the real estate holder are primarily of the fixed-fee management contract type, which does not require an outlay of capital from the operator; the parking company simply contracts to run a parking lot on the land and then collects a percentage of the parking revenues. Fixed-fee management contracts usually run one to three years. In another, less common type of contract, known as a lease arrangement, contracts run three times longer but provide a greater profit potential. In leasing a lot, a parking-lot operator is required to invest their own capital in the expansion or improvement of the lot, but receives a greater share of the profits.

The National Parking Association (NPA), founded in 1951 and based in Washington, D.C., had a membership of more than 1,000 private and public parking professionals. The association organized annual conventions and trade expositions, and published *Parking*, a trade periodical. The NPA also lobbied for industry concerns and reported on its activities in periodic *Legislative Updates* and *Issue Alerts*. The NPA's Parking Consul-

tants Council, formed in 1972, was a professional and technical advice group within the association concerned with design issues, economic analysis, financial counseling, and analysis and maintenance of off-street parking facilities. The NPA also operated a foundation, the Parking Industry Institute, which granted scholarship awards to employees of member organizations and their families.

The International Parking Institute (IPI) was founded in 1962. It has a company member base of more than 1,300. Its mission is to provide leadership, technical resources, and information to the parking profession and related fields. The IPI provides professional training, holds an annual conference and publishes a monthly magazine called *The Parking Professional*, among other services and activities.

BACKGROUND AND DEVELOPMENT

The growth of the parking industry has, of course, coincided with the growth of the automobile industry itself. According to the International Parking Institute, the first parking garage was built out of timber in 1909 in Columbus, Ohio. In 1912, the city of Chicago developed municipal parking lots in an effort to relieve the heavy downtown traffic congestion. The first parking meter was displayed in 1935 in Oklahoma City. Over the years, the number of off-street and on-street parking spaces and facilities has grown rapidly in response to the popularity of the automobile and the development of public roadways. Parking equipment has also grown more sophisticated, including automated gates and machines that accept money, calculate fees, and print tickets with and without the aid of an attendant.

INDUSTRY LEADERS

Ranked according to sales volume, the three largest automobile parking companies in the United States in 1999 were Standard Parking Corp, based in Chicago, Illinois, with \$450 million in sales and 3,800 employees; APCO, Inc. based in Cleveland, Ohio, with \$350 million in sales and 3,500 employees; and Central Parking Corp, based in Nashville, Tennessee, with \$232 million in sales and 9,300 employees.

SIC 7532**TOP, BODY, AND UPHOLSTERY REPAIR SHOPS AND PAINT SHOPS**

Firms in this category repair automotive tops, bodies, and interiors, or engage in automotive painting and refinishing. This includes non-factory customizing of vans, trucks, and automobiles. Firms building custom-designed vehicles on a factory basis are classified in **SIC 3716: Motor Homes**. Franchise operations are classified under **SIC 6794: Franchises, Selling or Leasing**.

NAICS CODE(S)

811121 (Automotive Body, Paint, and Upholstery Repair and Maintenance)

INDUSTRY SNAPSHOT

For almost as long as there have been cars, “scratch and dent” shops have been in business to rejuvenate them. Not long after cars became affordable for most of the public, car owners began looking for ways to “jazz up” their vehicles to suit their individual tastes. Such customizing uses the technology and expertise of the body and paint shop to convert mass-produced cars, vans, and trucks into special-use vehicles.

As the cost of new cars escalated, increasing numbers of Americans were extending the life of their current vehicle with a little paint and body filler. According to the *1998 Statistical Abstract of the United States* published by the U.S. Census Bureau, automotive repair shops of all kinds took in \$65.3 billion in 1997, up from \$62.0 billion in 1996. In 1997, car owners spent \$19.8 billion on auto body repair and paint services, nearly one-third of total industry revenues, up from \$18.7 billion in 1996.

ORGANIZATION AND STRUCTURE

Most firms in the industry were relatively small; many were owner-operated “mom-and-pop” shops. Individual proprietors ran 15,977 firms in 1993, partnerships accounted for 1,757 establishments, and corporations and other business groups accounted for operation of the remaining 17,734. According to the U.S. Census of Service Industries, in 1993 there were 35,074 establishments, a slight increase from 1992. The number of establishments was projected to reach 36,815 in 1998.

Although the operations must be physically separated, many body shops also had onsite painting facilities. Generally, these shops strive for a craftsman image, emphasizing quality rather than speed of delivery. Consumers, however, chronically placed auto repair shops in general, and body shops in particular, high on their complaint lists. Many firms adapted an assembly-line system

to the repainting process. These shops performed only minor body repair, concentrating instead on a high-volume business in quick paint jobs. In the 1990s, franchising became an important segment of the industry, combining the small, personal craftsman image with the impact of nationally-recognized trademarks.

In 1987, more than 3,000 converters supplied specialty vans to car dealers and individual buyers. However, the product was often unacceptable to consumers, prompting Ford, General Motors, and Chrysler to establish “consignment pools” of preferred converters. That policy and increasing competition for a dwindling market share drove the number of active converters down to between 300 and 600 by the early 1990s. It was predicted that this number would decrease even further as larger, better-capitalized conversion firms such as the Starcraft Corporation (the holding company for Starcraft Automotive Group) forced out the craft-shops through intense price and service competition. Posting almost \$53.1 million in sales in 1999, Starcraft was the largest company in the industry. Firms manufacturing for the consignment pool are classified under **SIC 3716: Motor Homes**.

BACKGROUND AND DEVELOPMENT

In 1937, the price of painting a car ranged between \$85 and \$350 and took from six days to two weeks to complete. Then came the assembly-line paint job, pioneered by Earl Scheib Inc. of California, offering the same job for \$19.95 and same-day service with a three-year guarantee. Scheib’s technological innovation led to a basic division in the paint and body shop industry that continues to persist.

Small shops provided detailed precision work using high-grade materials and tools developed for the modern automobile. In the 1980s, the major auto manufacturers switched to unibody construction and metallic paint finishes. Consequently, frame straightening and quality paint application began to require specialized equipment costing hundreds of thousands of dollars. Those shops, which could not afford the massive capital investments in this technologically advanced machinery, became noncompetitive.

Assembly lines also provided quality work by specializing in repainting and confining their body work services to surface preparation and minor repairs. During the early 1970s, MAACO Enterprises Inc. of Pennsylvania combined the best of both systems with its franchising concept. Instead of creating a chain of company-owned shops, MAACO used its name and national image to tie together a system of 553 independently-operated facilities in 1999. A 1997 issue of *Entrepreneur* magazine ranked MAACO number one in auto appearance services. MAACO claimed that they painted and repaired more vehicles than anyone else in North America. In March 1997, MAACO painted

its 10 millionth car in a special promotion commemorating their 25th year in business.

Other firms, like One-Day Paint and Body and Econobake followed. The national clout of these chains and their access to sophisticated tools and training forced many of the marginal craft shops out of business. These franchise operations are covered in **SIC 6794: Franchises, Selling or Licensing**.

CURRENT CONDITIONS

Increased environmental protection legislation brought additional challenges to paint shops in the 1990s. Paint and body shops were primary sources of air and water pollution and contributed significantly to toxic waste stocks. To address this problem, the industry attempted to reduce and recycle waste thinners, solvents, and paints. The Federal Clean Air Act of 1990 mandated a reduction in volatile organic compounds (VOCs); consequently, paint shops had to invest in a major retooling of their facilities. The industry warned that it possibly would not be able to meet the new standards, and if it could, prices would soar and quality would plummet. Paint shops were faced with higher handling costs for chemicals, particularly for disposal, in addition to increased retooling and re-education costs. Major assembly plants had been able to reduce their VOC emissions by 60 to 90 percent over the decade preceding the Clean Air Act, thanks to multimillion dollar investments in ever changing technology, but small shops lacked the capital to invest in modern innovations. In 1990, the switch from oil-based to water-based paints began successfully, but painting processes still produced toxic sludge that often ended up in waste dumps. Studies in the early 1990s found that up to 40 percent of sprayed paint was wasted in this manner.

Environmental regulations also made companies legally liable for toxic contamination in waste containment facilities. One of the largest companies in the industry, Earl Scheib, faced two such lawsuits in 1992 for solvents dumped at landfill sites during the 1960s and 1970s. Clean-up costs for these violations reached an estimated \$988,000.

Chrysler Corporation began using a method developed by Haden Environmental Corporation of Troy, Michigan, to combat toxic waste produced by auto paint. According to *Ward's Auto World*, the process recycled the over-spray into a powder, which was then used for under-body paint on Dodge trucks.

Automotive manufacturers introduced water-based paints into their assembly line process with reasonable success in 1982, but these paints required a high-temperature "bake," making them impractical for most aftermarket paint shops. In 1993, Imperial Chemical Industries PLC (ICI) of Britain began preparations to market a new version that eliminated the need for high

temperature treatment. The acrylic polymer compound produced an excellent film at 60 degrees Celsius. In England, the new paint commanded a premium of only 5 percent, but in Germany and Italy, it increased the price of a can of paint by as much as 30 percent. Some American paint shop operators estimated that the paint and associated equipment could increase their costs between 10 percent and 40 percent, but their main customers, the insurance companies, were not responding quickly to the suggestion of an increase. According to ICI, tests on the process in Germany and Italy found that no major equipment or retraining investments were necessary. Moreover, the system was expected to improve conditions for painters by making the work environment healthier and cleaner. A water-based paint produces 72 percent less VOC emissions than the industry's standard solvent-borne metallic paints, which contain as much as 85 percent solvent. By some estimates, metallic paint spray accounted for one half of all industrial solvent emissions. Powder coatings emit zero VOCs, and were the fastest growing product in the paint and coatings industry.

Acrylic powders were being used in the late 1990s in primer surface applications. In 1992, General Motors started using an acrylic-based primer and an acrylic trim coating at its Shreveport, Louisiana, plant, and has since started using acrylic based powder primer surfacer at two other plants. Most producers, however, were aiming to develop clearcoats. In the late 1990s, Ferro—one of the world's largest paint suppliers—developed a powder coating that greatly reduced waste and solvent emissions. Their sales grew much faster in North America than in Europe, where powder coatings have been commercialized for a longer period. It was predicted that most primers and clearcoats would eventually be converted to powder, while the color coats were likely to be converted to waterborne coatings, which retain better color consistency and depth than powder.

In addition to reducing their VOC emissions, auto body shops must also recycle and capture refrigerants whenever a car's air conditioning system is repaired or scrapped. Before topping up systems, workers are required to check for leaks. Various pieces of equipment, from leak detection gear to recycling/recovery devices are necessary to complete this process. This equipment, all combined, can cost several thousand dollars.

Image also became an issue for body shops. Shedding the gritty, junkyard image, new shops stressed customer service in clean, friendly environments with easy main-street access. Some firms used central major repair centers to handle the "heavy-hitters," vehicles that needed more than \$2,500 in body repairs. This practice kept the "wrecks" out of the public eye, improving the body shop's good-neighbor image.

INDUSTRY LEADERS

In 1999, the paint and body portion of the industry was dominated by the Starcraft Corporation of Goshen, Indiana. Specializing in aftermarket van conversions, Starcraft posted \$53.1 million in sales and employed 555 people. Other industry leaders included Earl Scheib Inc. of Beverly Hills, California, with sales of \$50.8 million and 1,600 employees; CSI Holdings Inc., with \$40.2 million in sales and 190 employees; 1-Day Paint and Body Centers Inc., with \$30 million in sales and 520 employees; and Dealers Truck Equipment Company Inc., with \$26.4 million in sales and 120 employees.

WORKFORCE

Traditionally, the industry has used a skilled work force trained by apprenticeship. The federal government's Bureau of Apprenticeship and Training worked through state and territorial agencies to promote cooperative programs with employers.

Even so, the average body shop employee stayed with one employer for only two years. Between 1987 and 1996, the total number of employees in the industry increased from approximately 162,800 to 168,800, although there were fluctuations in the labor force during the nine-year period. Most of that increase was in the labor-intensive body repair and van conversion segments. The paint shop segment showed a 2.3 percent decline between 1982 and 1987, with employment dropping from 18,488 to 15,050. This reflected an ongoing trend toward automation, mechanization, and the consolidation of small shops into larger units. According to the U.S. Census Bureau, 186,000 people worked as paint and coating operators in 1998, in a variety of industries including automotive.

A 1999 survey sponsored by *Auto Body Repair News* revealed that independent repair shops made up 82 percent of the industry and were staffed by craftsmen who were often the shop owners.

Since the average shop had less than five employees, most workers performed tasks with materials and components used for jobs other than grinding and sanding, body repair, or detailing and painting. They might also work on suspensions and electrical systems, replace glass, or do minor mechanical repairs anywhere on the vehicle. Most workers were paid a flat rate, based on an industry standard for the number of hours required to perform the repair. In 1998, employees had gross payroll wages in excess of \$4.7 billion.

RESEARCH AND TECHNOLOGY

In an *Automotive News* article, Emil Hassan, vice president of engineering for Nissan Motor Manufacturing Corp. USA, reported, "Paint plant technology has progressed faster in the past 10 years than in the previous 30

years." This technological revolution would inevitably impact the small aftermarket paint and body shop in the late 1990s. Small shops would have to find capital to invest in new materials and costly equipment to remain competitive in the industry.

Clearcoat paints were introduced in the early 1990s. These paints cover color coats, provide a glossy finish, and reduce acid-etching from today's high pollution levels in cities. In 1995, Dupont was working to produce a one-coat clearcoat system to replace the cumbersome and expensive multi-coat process that was widely used in the industry. It used the process of group transfer polymerization to achieve 3 percent to 4 percent higher solids, solvent-based coating, while reducing VOC content and yielding better color. Dupont was the first company to introduce waterborne finishes to a U.S. OEM assembly plant. Powder clearcoats soon became wide spread throughout the industry.

The "green" evolution was also progressing at manufacturer paint facilities in the 1990s. At the Subaru-Isuzu plant in Indiana, managers were pushing for a 95 percent reduction in VOCs, rather than the 72 percent expected elsewhere, by combining the use of water-based paint applied electrostatically along with a paint-solvent after-burner. In 1995, the U.S. Council for Automotive Research, a consortium including Ford, General Motors, and Chrysler, built a \$20 million test facility at Ford's Wixom, Michigan, assembly plant to develop standards, materials, and process equipment for powder coatings. The demand and popularity of powder coatings increased rapidly due to their zero-VOC content and durability.

In 1996, the National Paint and Coating Association announced its coatings CARE Program, which was a progressive initiative that enabled companies to follow a common, effective management approach for their health, safety, and environmental programs. Participation was voluntary, but because the program offered expanded resources, improved communications, and opportunities for heightened industry performance in health, safety, and education, the NPCA believed that participation was vital to an organization's future. They believed that the industry, regardless of size, product or specialty, would have to adopt to new technologies and respond quickly to keep pace and satisfy growing consumer demands.

New materials being used by automobile manufacturers also impacted the paint and body shop industry in the 1990s. Automakers, intent on reducing car weight to improve gas mileage, began using more plastic, fiberglass, and aluminum in place of steel. These materials require specialized paint application processes that must be performed by trained professionals.

Such new technologies as laser wheel-alignment machines, hydraulic frame straighteners, and high-

temperature bake ovens were becoming common at many body shops in order to comply with the consumer demand that the repaired car look just as good as it did when it rolled off the manufacturer's assembly line. Auto repair and paint shops were also making use of another new technology — the computer.

SIC 7533

AUTO EXHAUST SYSTEM REPAIR SHOPS

This industry classification includes establishments primarily engaged in the installation, repair, or sale and installation of automotive exhaust systems. The sale of mufflers, tailpipes, and catalytic converters is considered to be incidental to the installation of these products.

NAICS CODE(S)

811112 (Automotive Exhaust System Repair)

INDUSTRY SNAPSHOT

This industry covers exhaust system repair which primarily involves the sale, installation, and repair of mufflers, tailpipes, and catalytic converters. It is distinct from businesses engaged in the overall repair of automo-

biles. Such businesses are primarily categorized in **SIC 7532: Top, Body, and Upholstery Repair Shops and Paint Shops** and **SIC 7538: General Automotive Repair Shops**. Businesses engaged in specialized automotive repair, such as fuel service, brake repair, wheel alignments etc., are classified in **SIC 7539: Automotive Repair Shops, Not Elsewhere Classified**.

ORGANIZATION AND STRUCTURE

Car exhaust system service is typically provided by dealership garages and auto exhaust repair shops. Besides the existence of numerous "mom and pop" auto service businesses, the industry was led by a few relatively well-known repair shop chains. Among them were Monro, Meineke, and Speedy International, Inc. No single company has dominated the industry.

According to the U.S. Census Bureau, the auto exhaust repair industry consisted of 6,237 establishments in 1998, up from 6,071 in 1997. Employment figures showed that 28,800 people were employed in the industry in 1998. Revenues totaled \$2.63 billion. In the same year, the industry had a \$665.5 million payroll.

Exhaust Systems. The exhaust system of every modern automobile requires frequent care and repair. Condensation in the typical exhaust flow, coupled with ordinary wear, will often result in the necessary replacement of the car's muffler and exhaust pipes. The result is a vehicle with minimal engine noise and an exhaust system that more effectively funnels toxic fumes produced by the vehicle away from the car's interior. When owners determine that their exhaust systems may need repair, they typically avoid do-it-yourself (DIY) replacements and seek the services of exhaust system repair shops. These repairs are also necessary for the owner to maintain car emissions that meet Environmental Protection Agency (EPA) standards. Auto exhaust repair shops install, repair, and inspect the proper pollution control devices.

A car's exhaust system consists mainly of an exhaust pipe, a muffler, and a tailpipe. The exhaust pipe collects the exhaust of a car through a series of exhaust ports in the internal manifold of a car engine. This exhaust is funneled to a downstream pipe and moved through the muffler. The tailpipe discharges the car's exhaust into the atmosphere after it has passed through the muffler.

The muffler is the main component of the exhaust system. It is basically a device that reduces the noise produced by the movement of gas and internal combustion of the car's engine. The typical shell of an automobile muffler is shaped like an oval that measures roughly 20 inches long, 10 inches wide, and 6 inches high. Its internal architecture is comprised of perforated steel tubes and a number of chambers separated by steel partitions. This combination of filters and tubes acts as a

honeycomb that acoustically filters the exhaust sound. The typical muffler can reduce the sound pressure of a car's exhaust from 90 to 60 decibels, a 1,000-fold decrease. More expensive dual exhaust systems have four or more mufflers.

Federal regulations require that motor vehicles be fitted with emissions control devices. Therefore, a mechanism such as a catalytic converter has become an addition to a car's exhaust system. Since their initial requirement in 1975, catalytic converters have served to reduce harmful exhaust. Improved emissions allow the owner to comply with standards mandated by the Environmental Protection Agency.

Legislation to control automobile pollution is in the Clean Air Act, which was passed in 1956 with significant amendments in 1970 and 1977. Regulation of mobile pollution sources was considered controversial. In fact, an EPA study in 1979 attested to the difficulty involved with getting automobile owners to comply with state and federal standards requiring the installment and maintenance of properly functioning pollution control equipment, specifically the catalytic converter. The converter cleans up the car's exhaust gases to meet those standards created by the EPA. Today's converters are made of a honeycomb-like material that is lightly coated with palladium and platinum. These two elements, when in the presence of oxygen, aid in the reduction of hydrocarbons and carbon monoxide.

The emissions control system of a car does not become the responsibility of the owner until the manufacturer's warranty expires. At that point, problems with the catalytic converter usually lead the car owner to an auto exhaust repair shop that provides emissions control work. The most common difficulties with the converter are clogging and melt down. These two problems typically occur in high-mileage engines and result in exhaust problems. Converter failures can also be symptomatic of other problems.

The technicians at auto exhaust repair shops who are faced with converter problems have a number of options for diagnosis of the converter and accompanying emissions systems. Technicians may begin with a visual examination of the mechanism to discover any evident rust destruction, leaks, or broken connections. More complicated methods of testing the system include thump, temperature, and back pressure tests. These tests detect difficulties of the converter caused by circumstances such as build-up of phosphorous on the surface of the converter due to burning oil, foreign matter plugging the interior of the converter, excessive sulfur content in the fuel, anti-freeze leaks into the engine which pollute the converter, or broken or ineffective exhaust air pumps.

CURRENT CONDITIONS

Overall, the industry expanded its sales throughout the late 1990s. In 1998, auto exhaust repair shops earned \$2.62 billion, up slightly from 1997's \$2.57 billion.

The industry outlook for auto exhaust repair shops was quite promising in the late 1990s. Advancing technology (particularly in the area of mufflers and catalytic converters) and increased automobile emissions regulations promised to create more work for exhaust repair shops. Also, an increase in the number of older cars on the road (mainly the result of high car prices and a prolonged recession) meant that more car owners were maintaining and repairing their cars rather than simply replacing them. Because most gas stations began exiting the repair industry in the mid to late 1980s, and many new specialty shops did not perform exhaust repair, there appeared to be a shortage of exhaust repair service providers in the mid 1990s. In fact, since 1975, a 70 percent decline in the number of repair outlets resulted in remaining repair shops increasing their average number of repair jobs per year from 398 in 1980 to 460 in 1988.

Although there was some fluctuation in exhaust repair business from year to year — largely a result of weather (salt on snowy and icy roads causes corrosion) and the amount of technological change — the overall market for automotive aftermarket repair was large, fragmented, and growing. Acting as factors in favor of the industry were the declining ability of car owners to perform their own repairs because of more complex vehicles (particularly the dramatic increase in electronic components), less leisure time, and increasingly stringent emissions regulations that made more exhaust system inspections necessary. Likewise, the increase in vehicles on the road, vehicle miles driven, and the average age of cars contributed to the strength of the industry.

The greatest threat posed to industry participants going into the mid 1990s was new entrants. In 1992, General Motors entered the auto exhaust repair industry by offering such repair work to its dealers' service and parts operations. General Motors dealers began the Goodwrench Exhaust Program, which provided them with mufflers, resonators, pipes, accessories, and service tools necessary for exhaust system repair. Dealers were allowed to decide the extent of the inventory they would maintain (from \$3,000 to \$40,000), while stocking racks and service tools were provided free. The new program was General Motors' attempt to muscle in on a growing and lucrative industry. The program was backed by substantial marketing and advertising efforts. The automaker's move threatened the current leaders in the industry and forced them to develop better marketing and service programs.

INDUSTRY LEADERS

One of the most successful competitors in the early 1990s was *Monro Muffler Brake Inc.*, which began as a *Midas International Corp.* franchise in the 1950s. Founder *Chuck August* added brake shops and took the company public in 1991. In 1984, a group led by *Wall Street* executive *Peter J. Solomon* bought a controlling interest in the company; the group owned about 20 percent of the company in 1996.

Between 1987 and 1992, the company more than doubled its sales. Since the early 1990s, the company aggressively opened new shops. In 1992, the company had 167 shops in eight states, predominantly in the Northeast. Overall, *Monro's* rapid expansion has added 15 percent to square footage every year. Substantial growth occurred between 1991 and 1996, when sales climbed from \$21.5 million to \$117 million. By 1996, the company owned and operated 274 muffler and brake repair shops. *Monro* also came close to doubling its number of stores again in 1997. In 1999, *Monro* achieved sales of \$154.3 million and employed 2,138 people.

Monro's management strategy relied on advanced inventory control systems and exceptional customer service. The focus on customer service gave the company an advantage over its larger franchise competitors. The strategy manifested itself even in chairman *Jack Gallagher's* policy of personally replying to all customers' letters. This strategy tended to create a focus on customer satisfaction even at the shop level. The end result was a 77 percent repeat customer rate in the mid 1990s. This approach appeared to be successful as business continued to grow in the late 1990s.

The typical *Monro* outlet and repair shop had six service bays and 4,500 square feet. *Monro* organized its stores around one key outlet, which carried a larger inventory and acted in a support role for smaller satellite shops. *Monro* improved its overall service ability when it implemented measures designed to result in more effective inventory management. Since the 1989 installment of a point of sale (POS) inventory tracking system, the company dramatically increased its ability to meet customer needs with on-hand inventory. This system improved customer satisfaction and increased gross margins, and allowed *Monro* to react more efficiently and effectively.

Monro repair shops were staffed by four to six mechanics who reported to a store manager. The company retained its quality mechanics by providing them with career growth opportunities. In fact, most regional and store managers began their careers with the company as service technicians. Also, the company paid a premium hourly wage to its mechanics who received an *Automobile Service Excellence* award. This emphasized the company's desire to insure quality service and acted

as an incentive for employees to become certified mechanics.

A standard *Monro* repair shop broke even after only its first year of operations. This required achieving an average in first year sales of \$300,000. Nearly all stores opened in the mid 1990s met this goal. The success attested to *Monro's* strategy of placing shops in high-visibility and well-traveled locations.

Besides *Monro*, significant players in the industry included Toronto-based *Speedy International, Inc.*, which not only replaces and repairs mufflers but also provides tire, suspension, oil, and alignment services. Founded in 1956 by *Fred Karp*, *Speedy* became a private, multinational company with operations in Canada and the United States (through *CarX Muffler and Brake*). Although he sold it to *Tenneco Inc.* in 1968, *Karp* bought the chain back in 1988 when *Tenneco* underwent a major restructuring. In 1999, *Speedy* posted third quarter revenues of \$41.3 million, 76.3 percent lower than the same period in 1998. This dramatic decline resulted from *Speedy's* sale of its European operations in early January, 1999, and the sale of its stores operating under the *Speedy* brand in the United States in September, 1998.

RESEARCH AND TECHNOLOGY

Technological threats to the exhaust repair industry have occasionally appeared in the form of improved components that require less repair. For example, in the late 1980s a stainless steel muffler was introduced that promised less erosion. Many of these advances acted to improve business. In 1992, the EPA proposed tougher rules for checking vehicle emissions. The change was expected to cost Americans \$1 billion, much of which would go to repair shops required to perform the work. The proposed rules subjected 100 million cars to the tougher, costlier testing.

Advancements in muffler and converter technology have taken the shape of improved efficiency. Researchers at the *Noise Cancellation Technology Labs* in Connecticut invented a new electronic muffler that utilized computer generated "anti-noise" to further muffle engine noise. The new muffler, which can be produced for the same cost as conventional mufflers, improves engine power and fuel efficiency. Meanwhile, *Corning Inc.* developed a catalytic converter that would not require a car to warm up before operating effectively. These and similar developments for improvement to automobile exhaust systems did not appear to threaten the industry's steady increase in size and revenues.

SIC 7534

TIRE RETREADING AND REPAIR SHOPS

This classification covers businesses that primarily repair and retread automotive tires. Industry firms either retread customers' tires or retread tires for sale or exchange.

NAICS CODE(S)

326212 (Tire Retreading)

811198 (All Other Automotive Repair and Maintenance)

Tread increases a tire's traction, particularly on wet roads. The forward portion of a tire's contact area wipes away water so the rest of the contact area will grip a dry surface. Continuous channels from the center to the edge of the tread propel water outward, eliminating potentially dangerous "aquaplaning." Snow tires and off-road tires have deeper treads designed to grip through snow and dirt. After tire treads wear down, tire retreading and repair shops repair the tires by cutting or stamping new treads into the rubber on the tire.

Because about 70 percent of a new tire's cost is in its body rather than its tread, tire retreading shops provide a valuable and cost-effective service, especially for companies running a large vehicle fleet. A typical retreaded tire costs about 50 to 70 percent less than a new tire. And retreads typically offer service, mileage, dependability, and warranties comparable to new tires. Most truck tires can be retreaded two or three times, resulting in up to 750,000 miles of service.

Although pneumatic automobile tires—invented in 1888—were used in the United States during the early 1900s, treads, which reduced "sideslip," were not introduced until 1910. Soon after, treads became standard on all types of tires. The massive expansion of the automobile industry, combined with the development of a na-

tional highway system, generated a strong demand for tires and retreading services during the mid 1900s. By the early 1980s, tire retreading industry revenues topped \$935 million.

Because of advances in technology and gains in manufacturing productivity during the 1980s, automobile tire retreading became more cost-effective than it was during the 1960s and 1970s. Still, industry revenues grew meagerly, to about \$1.1 billion by the late 1980s as the incidence of truck tire retreading slowly increased. Eventually the industry disproved consumers' perceptions that retreaded tires were not as durable as new tires and that they "unraveled," so that by 1995 retreaded tires outsold new tires in the replacement market. The industry also benefits the environment. It takes 7 gallons of oil to retread a truck tire compared to 22 gallons to manufacture a new one. Overall, retreading conserves more than 400 million gallons of oil a year. Further, the new tread applied can contain up to 10 percent recycled, reprocessed rubber. In addition, retreading tires reduces solid waste disposal problems by up to 75 percent. Because of these environmental benefits, President Clinton signed an executive order in 1998, which superseded one issued in 1993, that mandated the use of retreaded tires on all federal government vehicles.

In addition to government vehicles, nearly all off-the-road, heavy duty vehicles, and all of the world's airlines use retreaded tires, as well as school buses, trucking fleets, taxis, race cars, and emergency vehicles. Marvin Bozarth stated: "Aircraft tires routinely receive 12 or more retreads; haulage and local pickup and delivery truck tires are often retreaded five times or more; and high-speed long haul truck tires generally receive two or three retreads. Passenger tires are usually retreaded only once." Safety standards developed by the U.S. Department of Transportation govern the manufacture of retreaded passenger car tires, and manufacturers of retreaded truck tires must comply with industry standards. The Federal Aviation Administration approves commercial aircraft retreads, while the military branches approve military aircraft retreads.

During the 1990s, the industry underwent considerable consolidation. According to government statistics, there were 1,845 companies in this category in 1992, down from 1,930 in 1987. Most of these were small, local tire repair shops. Total annual receipts for the industry were \$1.3 billion in 1992, a 19 percent change from the 1987 sales total of \$1.1 billion. In 1997, there were 632 companies, operating 754 establishments. Their shipments were valued at \$983 million. The top five states, in terms of establishments, were Texas, Ohio, Pennsylvania, North Carolina, and Illinois. In 1992, 12,898 workers served the tire retreading and repair shop industry, down from 13,808 in 1987. By 1997, the number of workers

had dropped to 7,939. The Tire Retread Information Bureau reported in its *1999 Fact Sheet* that “Approximately 30.9 million retreaded tires were sold in North America (produced by some 1415 plants in the United States and Canada) in 1998, with sales totaling more than 2 billion dollars.” Most plants were independent owner/operator businesses; others were owned by new tire manufacturers and a major tread rubber supplier.

Two industry leaders are Treadco Inc., of Fort Smith, Arkansas, and Bandag, Incorporated of Muscatine, Iowa. Treadco, which retreads more than 500,000 truck tires annually at its 26 production facilities, had 1998 sales of \$181.3 million. A subsidiary of Arkansas Best Corporation, Treadco also sells new tires at 29 stores strategically placed by interstate highways. Bandag supplies about 15 percent of the market for light and heavy-duty truck retreaded tires; the company had 1998 sales of \$1.06 million. New tire manufacturers, including Goodyear, Michelin, Bridgestone, and Marangoni, also participated in retreading, albeit to a lesser extent.

According to The Tire Retread Information Bureau, “Because of the competitive nature of the retreading industry, [customers] can expect to see continuous improvement in quality, durability, and reliability, as the major retread suppliers annually invest millions of dollars in research and development.”

SIC 7536

AUTOMOTIVE GLASS REPLACEMENT SHOPS

This category covers establishments primarily engaged in the installation, repair, or sales and installation

of automotive glass. The sale of the glass is considered incidental to the replacement.

NAICS CODE(S)

811122 (Automotive Glass Replacement Shops)

INDUSTRY SNAPSHOT

Automotive glass replacement shops catered to such common problems as windshields that were cracked or punctured—either by stones and other debris thrown up by the road—or by the sharp difference in temperature between the interior and exterior surfaces during the winter. They also repaired damage to other glass areas found on automobiles, as well as stopped leaks—traditionally one of the most challenging problem areas to correct. None of these repairs was of a type that drivers were likely to attempt for themselves.

ORGANIZATION AND STRUCTURE

Three types of businesses were available to fix and install automotive glass: those undertaking various kinds of glass repairs; those specializing in automotive glass; and those working on all parts of a vehicle body, including glass. Many repair businesses specializing in automotive glass were franchises connected to large chains.

BACKGROUND AND DEVELOPMENT

The earliest automobiles were open bodied and traveled at such low speeds that windshields were hardly necessary. Only when automobiles became significantly faster and featured closed construction did the windshield and windows become significant features of automotive design, and hence of automotive repair.

Windshields were first introduced as an option on Ford’s Model T in 1909, but became standard on all automobiles within a couple of decades. Windshields were originally flat, mounted at a right angle to the body of the vehicle, and upon shattering, would fly apart in numerous sharp fragments. As Caleb Hornbostel noted in *Construction Materials*, “Laminated glass was evolved as a result of developments within the automobile industry and to a lesser extent the plastic industry. The tremendous demand for shatter-proof glass for the closed automobile (in the late 1990s, over 90 percent of the total production of automobiles were closed cars) stimulated the glass industry into producing laminated glass.”

Another important innovation occurred in 1932 when the French developed tempered glass. Although it eventually became the standard for side and rear windows, “tests demonstrated that tempered glass wouldn’t work in windshields. While its resistance was great, it broke into patterns on impact that were so dense that vision was impaired,” according to James L. Polak in *Automotive Engineering*. In addition, the very toughness

of tempered glass represented a hazard when windshields were struck by the head of a driver or passenger in the event of an accident or sudden stop. Unlike laminated glass, it was too hard to give way, and thus could thus potentially cause severe injuries.

Though laminated glass would yield under such circumstances and could also be cracked more easily than tempered glass, its construction guaranteed that even the severest shattering would not lead to dangerous fragmentation—the plastic interlayer that was bonded between two sheets of glass to create the laminate adhered so strongly that no particle of glass could break free. The first laminated glass had celluloid interlayers, which proved apt to discolor in certain climates. Toward the end of the 1930s, the introduction of a polyvinyl butyryl (PVB) interlayer overcame this problem. The durability of PVB was further enhanced in the mid 1960s with a quadrupling of its impact resistance.

One-piece curved windshields—an expensive Chrysler option in 1934—became a Nash standard feature in 1949 and, like wraparound rear windows, spread quickly thereafter. General Motors applied the wrap-around design to windshields in 1954. The increased use of curved glass complicated installation and repair, requiring greater levels of care and precision, but also made possible improvements in styling and, ultimately, aerodynamic efficiency. With the advent of the oil crisis of the 1970s, streamlining became an economic, as well as aesthetic, priority. This was partially accomplished not only by curving windshields, but also by safely thinning (and thereby reducing the weight of) all automotive glass, and by flush glazing the joints between glass and body parts that had once required obtrusive metal trims.

Some manufacturers introduced green-tinted windshields in the 1940s, which soon became somewhat controversial. According to Polak, “Critics claimed that the shading would diminish night vision. Tests showed, however, that the night vision reduction would be negligible while the cut in glare from the day’s sun and the night’s headlights would be a significant improvement.” Overcoming that controversy paved the way for such further refinements as the introduction of sun strips in the 1950s and, near the end of the next decade, of polarized windshields that were nonreflective and glare eliminating. In the 1980s, automotive designers took an important step toward overcoming the hazards of snow and frost with the introduction of electrically heated windshields.

Safety standards governing automotive glass durability and impact resistance were introduced by the American Standards Association (ASA) in the 1930s. Initially subject to voluntary compliance, these standards shortly became part of state and federal regulation, and thereafter were made more rigorous when the ASA became the American National Standards Institute (ANSI).

Another area of regulation of critical concern to automotive glass replacement shops was the possibility of instituting standards in relation to levels of windshield hazing. As explained in *Automotive Engineering*, “This phenomenon results from small craters created by salt, sand, and pebbles as they strike the glass, in addition to streaking caused by windshield wipers, ice scraping, and cleaning with abrasive substances. Haze caused by these factors not only tends to obscure drivers’ vision of the road, but also contributes significantly to driver fatigue and impairs concentration.” The institution of such standards seemed likely to generate a significant amount of business for automotive glass repair services, given that an estimated one percent of vehicles on the road had windshields with excess haze.

CURRENT CONDITIONS

Recent trends in automobile design have created an even greater need for replacement glass accessories: glass makes up more than 30 percent of a car’s exterior surface area, an increase of approximately 30 percent from the early 1990s.

As of 1998, 5,542 operations made up the industry, employing 26,400 workers. The industry also had a total payroll of \$681 million, and posted revenues of \$3.68 billion. Of the total, 3,272 establishments in the industry staffed under 5 employees, 1,171 employed under 10 workers, and only 112 had over 20 employees.

INDUSTRY LEADERS

At the end of the 1990s, the leaders in the automotive glass replacement industry were Harmon Glass Company, Inc. with \$259.8 million in sales and 1,532 employees; Lear Siegler Holdings Corporation, posting \$190.7 million in sales and 3,400 employees; Auto Glass Specialists Inc. with \$56.1 million and 540 employees; Diamond/Triumph Auto Glass, Inc., with \$31.2 million and 624 employees; and Diversified Glass Services, Inc. with \$25.0 million and 500 employees.

WORKFORCE

Automotive glass installers and repair personnel received training either from classes in glazing or by learning on the job. They had to exercise care and precision in the removal of broken and sharp-edged glass, in cutting and fitting sheets of glass with the requisite degree of accuracy, and in fitting such strips and seals as were necessary to achieve a weatherproof finish.

Beginning in the late 1980s, the efforts taken to ease factory installation of increasingly large and complex glass shapes had obvious advantages to those repair businesses also engaged in the installation of such glass. The major breakthrough came with the introduction of modules, because these “provide almost a perfect seal in the

vehicle since each module is precisely produced in the same mold and fits almost perfectly into the sheet metal opening," according to Joseph M. Callahan in *Automotive Industries*. "It's estimated that about a quarter of all windows in U.S. cars are now modular, with the expectation that it will reach 75 percent or more in the next several years," Callahan continued.

AMERICA AND THE WORLD

As the foremost car culture in the world, the United States generated a great volume of general maintenance and repair business. In the area of automotive glass in particular, one key difference between the United States and Great Britain lay in the fact that windshields in the latter country were commonly made of tempered glass. In addition, European designers were leading the way with experiments in automotive double glazing. As Peter J. Mullins explained in *Automotive Industries*, "Two layers of glass, very precisely made with an air gap of a few millimeters between them, help to reduce . . . noise amplifications and also cut road and engine noise. One maker has even connected a small vacuum pump to the gap to evacuate the air and improve performance; another is circulating dry air to cut condensation."

RESEARCH AND TECHNOLOGY

The overall trend in U.S. automotive design near the end of the twentieth century toward using increased expanses of technologically complex glass could only prove beneficial to businesses specializing in glass repair and installation. However, a problem associated with such an emphasis on glass in vehicle body design was the material's heavy weight, and hence its tendency to impair fuel economy and overall performance. *Ward's Auto World* reported that the amount of glass in American-made cars increased from 83.5 pounds in 1980 to 97.0 pounds in 1999. Polycarbonates were increasingly being considered as lighter alternatives to glass in automotive design, but no plastic had attained the resistance to scratching and discoloration that glass possessed. Another alternative was the use of thinner glass, about 70/1000ths of an inch thick compared to the conventional 88/1000ths. Eisenstein claimed that this change would reduce the weight of an average windshield by 3 pounds.

In addition to increasing weight, larger expanses of automotive glass also raised interior temperatures. In fact, about 71.7 percent of the typical sources of passenger compartment heat were attributable to glass. Moreover, the increased heat on plastic interior trim could lead to the release of vapors, which would tend to settle as a film on interior surfaces of the glass. Higher temperatures from greater reliance on glass were a particular cause of concern in the automotive industry because of impending legislation requiring the replacement of traditional air-

conditioning systems with more environmentally friendly but generally less efficient alternatives.

In response, automotive designers experimented with various kinds of films and tints capable of reflecting or absorbing greater quantities of temperature-raising infrared light and with photochromic materials darkening or lightening in automatic response to the amount of sunshine. They also sought comparable methods of reducing the damage to interior plastics created by ultraviolet light. As Callahan pointed out, however, any new developments along these lines had to take into account that "the government requires that automotive glass transmit at least 70 percent of the visible light striking it."

Other innovations focused on overcoming problems associated with bad weather: devices not only for rapid melting of ice or snow on glass but also for defogging more efficiently and for controlling windshield-wiper operation through moisture sensitivity.

SIC 7537

AUTOMOTIVE TRANSMISSION REPAIR SHOPS

This category covers establishments primarily engaged in the installation, repair, or sales and installation of automotive transmissions. The sale of transmissions

and related parts is considered incidental to the installation or repair of these products.

NAICS CODE(S)

811113 (Automotive Transmission Repair)

INDUSTRY SNAPSHOT

By the late 1990s, developments in U.S. automotive technology and design ensured that both manual and automatic transmissions were among the most reliable parts of an automobile. But the complexity of the transmission as a system of many precisely interrelated components, as well as the difficulty of diagnosing and correcting faults, meant the problems that did occur were unlikely to be tackled by drivers in their own garages. Instead, this situation created a market for professional mechanics specializing in transmission repair.

ORGANIZATION AND STRUCTURE

In 1998, 10.7 percent of new cars sold in the U.S. came with a manual transmission. This reflected a major shift from the 1970s, when, because of sharp increases in oil and gas prices, manual transmissions dominated the new car market. Manual transmissions were far more fuel efficient, and were standard on small foreign imports, which became popular during the efficiency-aware '70s. But as prices settled and automatic transmissions became more fuel-efficient and increasingly advanced, they rose in again in popularity through the 1980s and into the 1990s.

Routine maintenance demanded the periodic checking and changing of automatic transmission or transaxle oil, and possibly the replacement of the transmission filter. As with engine oil, transmission fluid could be checked by means of a dipstick. The detection of signs of contamination of the transmission fluid, by metal, dirt, moisture, or friction material from internal parts, was an important step because such contamination could lead to rapid wear of parts and to premature transmission failure.

Inspection of the transmission fluid also provided an invaluable guide to the diagnosis of existing or potential problems. Fluid that was milky typically became intermixed with the engine coolant; fluid that was blackened or had a burnt odor indicated serious damage to the transmission; and fluid with a light brown color usually had broken down, which led to a wide variety of further problems.

Manual transmissions required the operation of a clutch mechanism subject to high levels of wear and tear. Among the problems tackled by transmission specialists working on manual transmissions were pulsating or stiff clutch pedals; clutches that grabbed, chattered, dragged, or slipped because of improper clutch adjustment; a binding clutch release mechanism; a broken engine mount; or

oil or grease on a clutch disc. Repairs to the clutch often required the removal of drive axles, transaxles, and even entire engines. Other problems found in manual transmissions were noise, leaks, grinding of gears during shifting, difficulty in making gear shifts, or transmissions locked in one gear or jumping out of the gear selected.

In automatic transmissions, the most common adjustments that could be made with the transmission still in place were adjustments to the transmission band, the shift linkage, or the neutral safety switch. More major internal problems required the removal of the entire transmission. In the removal and disassembly of all kinds of transmissions, the utmost care had to be taken to avoid damaging the component parts. In addition, any worn or damaged parts needed to be replaced, or else the reassembled transmission would soon require another disassembly for a future problem.

BACKGROUND AND DEVELOPMENT

The earliest automobiles required constant but low-level maintenance. The earliest drivers were either enthusiastic enough to perform the necessary minor adjustments themselves or wealthy enough to employ a mechanic for this purpose. The earliest automobiles were also slow. Only with the advent of faster vehicles did transmission technology—designed specifically to maximize engine efficiency by adjusting performance in coordination with changes in speed—become an important feature of automotive design, and thus a sophisticated mechanism requiring expertise to maintain, repair, or replace.

The first transmissions were manual. Easier to drive but harder to fix, automatic transmissions began appearing in the United States in significant numbers after World War II. At first, auto manufacturers were reluctant to adopt what they considered to be an overly complex gadget, but its popularity with consumers soon convinced them.

By the early 1970s, transmission repair specialists were a solidly established sector of automotive mechanics. However, at this time the automotive repair industry became the number one source of consumer complaints about incompetence and dishonesty. In the field of transmission repairs, the heavily advertised AAMCO chain suffered from bad publicity due to the number of franchises found guilty of some form of systematic abuse of their customers. Some franchises offered free diagnoses, on the basis of which transmissions were dismantled and then not rebuilt until the consumer consented to the performance of repairs that often proved to be both unnecessary and expensive. Many AAMCO franchise holders were not experienced mechanics, so there was no guarantee that the work performed would be competent. All franchise holders were also pressured to achieve an as-

signed average repair order — something they could not do without performing unnecessary repairs at least some of the time.

Consumer protection groups and changes in legislation curbed the grossest of these abuses, but the entire automotive repair industry in the United States remained largely unregulated toward the end of the 20th century. In the case of transmissions, consumers had little choice but to trust that a given mechanic performed repairs in a conscientious and competent way. As Arthur P. Glickman noted in *Mr. Badwrench*, “The unknowing motorist whose car won’t shift or shifts badly can easily believe that his car is in need of \$250 to \$600 worth of repairs, though the problem may actually be minor.” Conversely, however, the complexity of transmission systems presented acute difficulties for mechanics who had to produce honest estimates before probing for problem areas among many interrelated parts.

CURRENT CONDITIONS

The automobile repair and service industry had a total revenue of \$69.6 billion in 1998, while the automobile transmission repair sector accounted for \$2.9 billion of the market.

In 1997, there were a total of 6,768 establishments performing automotive transmission repairs, an increase of nearly 12 percent over an estimated 6,060 in 1996.

By the mid 1990s, automatic transmissions appeared in more than 85 percent of new American cars, although a gasoline price spike could again bring manual transmissions back into fashion as they were in the 1970s. While the new automatics of the late 1990s were smoother shifting and more fuel-efficient than their predecessors, manuals were still more fuel-efficient than even the best automatic.

INDUSTRY LEADERS

At the end of the 1990s, the leader in automotive transmission repair was AAMCO Transmissions Inc., a franchise with \$40.9 million in sales and 225 employees. AAMCO was rated as the ninth largest franchise in the United States by the *1999 Business Rankings Annual*.

WORKFORCE

Transmission specialists were generally regarded as among the most extensively trained and knowledgeable of all automotive mechanics. To perform their job adequately, they needed to be familiar with all features of transmission technology, including electronic, hydraulic, and computer systems. In addition, they had to understand automotive fundamentals outside their chosen area of expertise in order to distinguish between transmission-related problems and those stemming from some other source. In fact, transmission specialists had to achieve

much the same level of coverage as National Institute for Automotive Service Excellence (NAISE or ASE) certified “master mechanics” in order to perform repairs on what was arguably the most sensitive and complicated area of an automobile.

The many interrelated components of a transmission, and the different technologies regulating their functioning (hydraulics, electronics, and computers, for instance), means that transmission specialists have to be able to wield a wide variety of tools, including micrometers and telescoping gauges, special pullers, electronic stethoscopes, and transmission jacks. Transmission repair experts also face a variety of dangers on the job, from the weight and bulk of transmissions, the hot transmission fluid, and the asbestos from which clutch disc linings or friction material is made.

Approximately 29,500 employees worked in this industry in the late 1990s. This was a substantial 19 percent increase from 1993’s 24,800 employees. Total payroll in this industry reached over \$709 million.

AMERICA AND THE WORLD

Transmission specialists outside the United States were likely to encounter a significantly higher proportion of manual transmissions than their American counterparts. In addition, one important new design concept seen in some foreign cars was the continuously variable transmission (CVT), which featured an infinite number of driving ratios rather than the three, four, or five forward speeds found in traditional types. As James E. Duffy explained in *Modern Automotive Mechanics*, the CVT was “capable of increasing fuel economy approximately 25 percent because it keeps the engine at its most efficient operating speed. Engine RPM can be kept relatively constant. The engine does NOT have to accelerate through each gear, resulting in an almost smooth increase in vehicle speed.” In the late 1990s, automatic transmissions were beginning to make some headway in Europe, where most drivers still preferred manuals. But a new generation of high-tech, smoother shifting and more fuel-efficient automatics—not to mention congested roadways that make frequent shifting a hassle—has made the automatic transmission more popular overseas.

RESEARCH AND TECHNOLOGY

Key areas of concern for the U.S. automotive industry in the 1990s included the wider use of electronics in conventional vehicles and the development of electric cars. As a result, transmission repair shops prepared themselves to work on increasingly sophisticated systems. As Stephen Plumb explained in *Ward’s Automotive Yearbook 1993*, “In 1991, electronic transmissions accounted for less than 20 percent of all gearboxes installed on domestically produced cars. This figure is expected to

rise to over 80 percent by the late 1990s, which means virtually all automatic transaxles will be electronically controlled. Electronic transmissions help improve drivability, shift smoothness, and fuel economy.” Plumb’s estimate was not far from reality. In 1997, one car in nine came with a stick shift—most being sportscars and ultra-economy compacts. And for the manual-shift enthusiasts who wanted the best of both worlds, in 1996, Chrysler introduced the Autostick, a transmission that’s part automatic and part manual. It had no clutch, but drivers could drop the shifter out of automatic and change gears.

SIC 7538

GENERAL AUTOMOTIVE REPAIR SHOPS

This category covers establishments primarily engaged in general automotive repair, including those specifically engaged in repairing engines. Establishments primarily engaged in industrial truck repair are covered in **SIC 7699: Repair Shops and Related Services, Not Elsewhere Classified**.

NAICS CODE(S)

811111 (General Automotive Repair)

INDUSTRY SNAPSHOT

The general automotive repair industry, once dominated by small, independent service stations offering personal attention, evolved toward heated competition between manufacturers, dealer networks, and large, chain service centers. The rapidly increasing complexity of vehicles in the 1990s and early 2000s led to greater specialization among automotive mechanics. In some cases, however, the abundance of electronic engine components facilitated the diagnosis of problems.

ORGANIZATION AND STRUCTURE

Four types of businesses in the United States offer general automotive repair services: full-service gasoline stations, independent garages, automotive dealerships, and chain automotive centers. In the mid-1990s, full-service gasoline stations and independent garages experienced a decline due to the trend toward specialization in automotive mechanics and the competition offered by automotive dealerships and chain automotive centers. Results of a study conducted by Lang Marketing Resources, Inc., a consulting and analysis firm, showed a decrease in the service station and garage population from 227,000 to 155,000 between 1980 and 1996. Many of those stations were light vehicle repair locations. The Lang study showed that in 1980, service stations and garages installed nearly half of the aftermarket products in the United States, but by 1996, they installed only 35 percent of the product volume. According to U.S. Census Bureau figures, the number of automotive repair services had risen to 192,000 by the late 1990s.

Some owners of independent service stations complained that auto manufacturers reduced the repair options available to consumers by limiting availability of factory manuals and instruction to their own dealer networks. Other concerns about dealer repair centers focused on the expense of parts and repairs, as well as the conflict of interest involved when the same companies that sold new vehicles also provided most repairs. On the positive side, dealerships did offer a greater number of specialists with up-to-date training than most independent repair shops.

Because of their size, chain automotive centers garnered high levels of general automotive repair business and typically charged lower rates than dealerships. In the absence of any comprehensive regulatory standards, they also appealed to consumers because of their name recognition. Disturbingly, however, there were numerous cases in which such centers were found guilty of undertaking unnecessary repairs, and even of punishing employees who failed to maintain a set sales target for parts and service. In his book, *Mr. Badwrench*, Arthur P. Glickman quoted a study conducted at the University of Alabama at Huntsville in 1972 that found five major chains guilty of

unnecessary repairs ranging from 22 percent to 47 percent of the total number performed. Similarly, in 1993 both Sears and K-Mart faced charges of making unnecessary repairs in their automotive service centers. Problems of this nature continued to arise with other companies through the late-1990s.

In an independent study conducted by Wiese Research Associates, Inc., independent neighborhood automotive repair shops scored higher than all other automotive service centers in five out of seven categories. They rated highest in the categories of honesty/integrity, pricing fairness, responsiveness, answer questions, and friendliness. The categories receiving lower ratings than the other shops were cleanliness/appearance and management.

By the late 1990s, automotive dealers and service stations had made strides to address customer service issues. In a survey conducted by Medical Economics, independent service facilities ranked seventh in customer satisfaction—behind Lexis and Infiniti, Saturn Corp., Shell Oil Co., Audi, Acura, Mobil, and Buick.

Common performance problems addressed by engine repair mechanics were no-start, hard starting, stalling, misfiring, vacuum leak, hesitation, surging, back-firing, run-on, pinging, vapor lock, gas line freeze, poor fuel economy, and lack of engine power. In many cases, these problems were easy to identify but hard to diagnose, given the wide range of causes that led to them.

Engine analyzers typically combined methods of checking the battery, charging, and starting systems, ignition systems, engine condition, fuel systems, and emission control systems into one unit. Alternatively, engine repair mechanics tested facets of engine performance with dozens of specialized instruments, including tach-dwell meters, exhaust gas analyzers, and volt-ohm-milliammeters.

The performance of tune-ups was necessary in the case of gasoline engines to limit exhaust pollution and to maintain engine power and acceleration, economical fuel consumption, smoothness of engine operation, ease of starting, and engine service life. Diesel engines did not require the same level of tune-ups because they did not contain spark plugs or an ignition system.

Common mechanical problems addressed in engine repairs included leaking gaskets, worn piston rings, burned and leaking valves, loose or worn engine bearings, worn timing chains, and cracked, broken, or scored engine parts. Stethoscopes aided in the detection of abnormal noises. Color of exhaust smoke was often useful in diagnosis as well. But mechanics above all had to refer to service manual troubleshooting charts covering specific makes and models of engines.

BACKGROUND AND DEVELOPMENT

The earliest automobiles were driven by wealthy enthusiasts who could either perform their own repairs or afford to employ a personal mechanic. The advent of the affordable, mass-production, assembly-line automobile created many more drivers but was based on a simple design and required easy repairs. As the number of drivers and roads in the United States grew, and as vehicles became more varied and complex, gasoline stations offering not only fuel but also routine maintenance and repair services proliferated. These full-service gasoline stations were augmented by independent garages capable of working on more difficult mechanical problems.

At this stage, the United States enjoyed what many analysts of the automotive repair industry described as a golden age. Full-service gasoline stations offered an ideal mode of apprenticeship for would-be mechanics who learned on the job as they went from pumping fuel to routine maintenance and repairs. However, oil companies began replacing full-service, independent gasoline stations with their own self-service stations offering no repairs. Consumers welcomed the cheaper fuel prices, even if they did not fully appreciate what they lost in terms of personal service.

In the late 1980s, smaller operations were also threatened by environmental legislation dictating insurance coverage for possible leaks in underground gasoline storage tanks and replacement of old units. The industry also anticipated further, expensive renovations to accompany the increasing emphasis on alternative fuels causing less damage to the environment. However, some small service stations planned to retain their repair facilities even if they were forced to discontinue selling fuel.

According to the National Automobile Dealers Association (NADA), the service and parts department in the average franchised car dealership reported \$2.7 million in revenue during 1996, a 10 percent increase in dollar sales over 1995. Profit margins increased to 5.9 percent, from 5.3 percent the previous year. In a survey conducted by *AutoInc. Magazine*, “37 percent of responding Automotive Service Association (ASA) mechanical repair shops listed total annual revenue in 1996 as between \$250,000 and \$500,000; 17 percent indicated between \$500,000 and \$750,000; 15 percent were from \$100,000 to \$250,000; and 14 percent listed between \$750,000 and \$1 million. Eleven percent showed revenues greater than \$1 million.”

CURRENT CONDITIONS

Despite special incentives like zero-percent financing, which made new car purchases more attractive and drove down the value of used vehicles, the demand for automotive repair remained strong in the early 2000s. According to some analysts, weak economic conditions

during the early 2000s caused many consumers to keep existing vehicles or purchase used ones, boding well for automotive repair shops. Even after factoring in costs for repair, maintenance, and other fees, this approach resulted in significant savings for vehicle owners. Citing figures from Runzheimer International, *Motor Age* reported that after paying off their vehicles, consumers could save almost \$2,500 a year by trading them in every eight years, as opposed to doing so every four years.

One of the reasons consumers found it more affordable to drive used vehicles were reasonable repair rates. As *Motor Age* reported in its February 2003 issue, in recent years automotive repair charges have increased at a slower rate than some U.S. industries. The publication explained that, based on figures from the Car Care Council, automotive maintenance and repair costs had increased 44.5 percent since the early 1990s, while financial services had increased 90 percent and hospital services had increased upwards of 100 percent.

U.S. Census Bureau figures reveal that in 2001 establishments engaged in automotive mechanical and electrical repair and maintenance achieved sales of \$47.1 billion. This was an increase of 5.5 percent over 2000, when sales totaled \$44.6 billion. In 2001, NADA figures show that the average franchised car dealership generated \$3.7 million in service and repair revenues, a near 9 percent increase from 2000 levels. Industry-wide, this resulted in more than \$80 billion for dealerships. *Automotive News* reported that, according to consulting firm Sullivan & Frost, the North American automotive maintenance market is expected to grow 6 percent between 2000 and 2007.

INDUSTRY LEADERS

The most successful automotive repair shops during the early 2000s were dealerships and franchises. Among the leaders at this time was Jiffy Lube International, Inc. With 2,200 service centers in early 2003, Jiffy Lube serviced some 29 million cars each year. Other industry leaders included AAMCO Transmissions, Inc.; Speedy Transmissions Centers; Group 1 Automotive; United Auto Group; and Midas, Inc.

WORKFORCE

Automotive repair shops employed 683,640 workers in 2001, up from 673,390 the previous year. The industry's average hourly wage was \$14.79, up slightly from 2000 when workers earned \$14.28 per hour. The number of jobs available for automotive mechanics was anticipated to increase through the year 2005 at about the average rate for all occupations, with continued declines in employment at full-service gasoline stations balanced by growth in employment at dealerships and elsewhere. This growth was attributed in part to the increasing

average age of automobiles. With the aging of the vehicle comes the need for service and repairs.

Mechanics engaged in general automotive repairs had to wield a variety of tools and work methodically through a checklist of important parts to isolate a problem area or to guarantee that all areas of an automobile were being adequately maintained. Working conditions varied from business to business, but in general much of the work performed was necessarily dirty, greasy, and uncomfortable, with strenuous lifting of heavy equipment often required and minor injuries common.

Whereas automotive electronics and electrical systems had once been the province of specialists, by the late-1990s they had become so much a feature of automotive design that mechanics in general had to become increasingly familiar with them. As a result, employment opportunities favored those mechanics who had completed some training in the area of electronics. The overall trend toward heightened technological complexity also stressed the need for greater levels of training and made specialization an increasingly probable step for mechanics.

AMERICA AND THE WORLD

The lack of regulation involved in the performance of automotive repair and maintenance in the United States, especially compared to the stringent standards enforced in other parts of the world, drew harsh criticism from some analysts. These differences generally became less extreme by the late-1990s, as increased automotive complexity led to demand for skilled mechanics worldwide.

RESEARCH AND TECHNOLOGY

With fuel economy and environmental concerns of paramount importance to the automotive industry, engine repair specialists expected changes in engine design, with a particular emphasis on new technologies taking advantage of alternative fuels. The overall increasing sophistication of all areas of automotive design had mixed consequences for automotive mechanics. New technologies made available a variety of electronic and computer systems for increasingly swift and accurate measurement of aspects of automotive performance, which facilitated the diagnosis of problems. On the other hand, the growing importance of electronic and computer systems in the actual running of most parts of a vehicle ensured that mechanics would need to become ever more highly skilled and specialized.

SIC 7539

AUTOMOTIVE REPAIR SHOPS, NOT ELSEWHERE CLASSIFIED

This category covers businesses that primarily do specialized automotive repair, not elsewhere classified, such as fuel service (carburetor repair), brake relining, front-end and wheel alignment, and radiator repair. Businesses that primarily do automotive welding are in **SIC 7692: Welding Repair**.

NAICS CODE(S)

811118 (Other Automotive Mechanical and Electrical Repair and Maintenance)

Miscellaneous services done by automotive repair shops included automotive tune-ups, automotive electrical repair, battery and ignition repair, fuel system conversion, generator and starter repair, and brake work. This broad classification had 9,674 businesses in the mid 1990s, many of which were sole proprietorships or partnerships. These shops employed 42,234 people and had annual sales of nearly \$3.5 billion in 1997.

As cars became a staple of American life during the mid 1900s, demand for specialized repair services rose. When annual car sales peaked at about 11.5 million annually in the late 1980s, repair shop revenues in this

industry reached \$2.23 billion in 1987 and industry employment swelled to 40,302. Although most automotive-related industries suffered during the U.S. recession in the late 1980s and early 1990s, repair shops were less affected. As consumers put off buying new cars, they spent more on maintenance and repair, so the industry's sales remained steady. Automotive repair services benefited from the mid 1990s economic recovery as well.

Industry firms generated average revenues of \$10 million during 1990s. The majority of shops were local and privately owned, but there also were regional chains that surpassed that median, such as Brake Centers of the Southwest, which had sales of \$34.1 million and had 550 employees. In addition, there were industry giants, (many of which were franchises) that generated hundreds of millions of dollars in income, such as Monro Muffler Brake, a Rochester-based company that employed more than 2,100 people and earned \$193 million in 1997. Several of these industry giants had products and services that crossed over into other business categories, such as Pep Boys, which offered not only automotive repair services, but also sold auto parts. Pep Boys had sales of \$2.3 billion and employed more than 27,000 people in the late 1990s.

Automotive repair jobs were expected to rise at the same rate as the average for all occupations through 2006, according to the Department of Labor. New job openings for mechanics, however, would most likely be filled by technicians with advanced technical or vocational training—especially those with knowledge of electronics and emissions control equipment. Competition would be more intense for entry-level positions.

More than 100 community colleges offered two-year degrees sponsored by the major automobile makers. In addition, the National Automotive Technicians Education Foundation (NATEF) certified quality training programs offered by high schools and technical schools. In the mid 1990s, mechanics earned a median income between \$333 and \$667 weekly. Less-skilled mechanics earned less than \$250 per week. Master mechanics can earn between \$70,000-\$100,000 annually.

SIC 7542**CARWASHES**

This category covers establishments primarily engaged in washing, waxing, and polishing motor vehicles (including automobiles, trucks, and buses), or in furnishing facilities for the self-service washing of such vehicles.

NAICS CODE(S)

811192 (Car Washes)

INDUSTRY SNAPSHOT

An estimated 97 percent of Americans take their automobiles to commercial carwashes. In 1998, the International Car Wash Association estimated that there were 9,570 full-service carwashes in North America, approximately 4,546 exterior-only carwashes, nearly 30,000 self-service carwashes, and about 30,000 rollover/high pressure washes, the majority of these being affiliated with gas stations or convenience stores. Together these carwashes generated more than \$14 billion in annual revenue.

The carwash industry grew rapidly from 1977 to 1987, but its growth began to slow in the decade following 1987. In 1977, there were 5,785 carwash establishments nationwide classified in SIC 7542. It was a business oriented to small-scale proprietors: these establishments were owned by 5,290 firms, of which 5,091 operated only one carwash. Approximately 45 percent were incorporated, another 42 percent owned by individual proprietors, and just 3 percent by partnerships. The total receipts for carwash establishments nationwide came to \$668.6 million in 1997. Forty-two out of 5,290 carwash firms and 243 out of 5,785 carwash establishments reported annual receipts of \$1 million or more.

Just ten years later, there were 9,132 commercial carwash establishments nationwide, an increase of almost 60 percent. The proportion of incorporated establishments had risen to just over 50 percent (but still a low figure for the service industries as a whole, in which 60 percent of all establishments were incorporated). The number of sole proprietors had dropped to 37 percent (compared to 32 percent for all service industries), and partnerships had jumped to almost 13 percent, nearly double the overall service industry figure of 7.3 percent. The total national revenues for the carwash sector had reached \$1.8 billion, with California and Texas together representing more than one-quarter of nationwide revenue. Nationally, the average revenues per establishment were just over \$197,000 a year (only 34 percent of the average for the service industry as a whole.) But because carwashes tended to be less labor-intensive than many

other service industries, average revenues per employee for carwash establishments (\$23,534) were slightly more than 50 percent of the service industry average.

In 1992, the number of carwash establishments in the nation had risen to 11,589, an increase of 27 percent. This indicated a slight leveling off in the rate of increase compared to the 1977 to 1987 period. The proportion of incorporated establishments had increased to 56 percent while the service industry average remained at 60 percent; individual proprietorships had dropped another two points, to 35 percent (slightly more than the service industry average), and partnerships accounted for only 9 percent. The leading state in the nation remained California (1,408 establishments), followed by Texas and New York. National revenues had increased by 47 percent to \$2.64 billion, or \$228,158 per establishment; but this was still only about 35 percent of the service industry average. Revenues per employee had increased by 21 percent, to \$28,407; a mere 46 percent of the industry average.

The carwash industry is heavily affected by such issues as weather, climate, and time of day. A May, 1996, survey by *Auto Laundry News* reported that Saturday was overwhelmingly the best day for business, with an 82 percent vote. February, with 19 percent, was chosen the best month of the year, and November (0.5 percent) the worst. Not only did carwash owners have a favorite season (winter, with more than half the votes, as opposed to fall, with only 3 percent), they even had a favorite time of day. Just over 40 percent of respondents said the majority of their business was conducted between 1:00 and 3:00 p.m.

ORGANIZATION AND STRUCTURE

The carwash segment of the SIC 7540 industry group (which also includes Automotive Services, Except Repair) covers commercial establishments primarily offering car washing; car cleaning, polishing, and detailing; and bus and/or truck washing. These services are provided both to private individuals and to automotive dealers, automobile rental establishments, automobile fleet owners, and other businesses. Although carwash establishments may offer a combination of facilities and options, carwashes generally can be classified as coin-operated, self-service facilities, automatic facilities, full-service conveyerized facilities, or automobile detailers.

Coin-Operated Self-Service Facilities. In these self-service facilities, which generally do not require full-time supervision, customers clean their cars in drive-through bays equipped with "wand" type high-pressure spray nozzles and other car-cleaning accessories. Coin-activated controls determine the length of spray nozzle operation and allow the customer to switch among presoak; engine cleaning; tire cleaning; and foam, rinse, and wax sprays. In addition, these facilities generally

provide coin-operated vacuums for the cleaning of car interiors and may have car care products such as towels and polishes available through coin-operated dispensers. In 1996, an average customer spent \$1.50 for a five-minute cycle at a coin-operated self-service carwash. In 1998, average in-bay pricing for a self-serve carwash was about 32 cents per minute. The typical self-service carwash bay grossed \$1,100 per month. Of the 98 percent of self-serves that had vacuums on the premises, the average monthly revenue per vacuum was \$169. The average self-serve location has 5.4 vacuums.

Automatic Facilities. Like self-service washes, automatic facilities do not require full-time supervision, and they can service approximately 20 vehicles an hour. Here customers activate the automatic system by driving their cars onto platforms within open-ended bays. Rollover carwashes are based on guide wheels that follow a vehicle's contours with horizontal overhead brushes and vertical "wraparound" brushes that clean the car in presoak, undercarriage, foam, rinse, and wax spray cycles, followed by a hot-air dryer. Customer concerns about vehicle and paint finish damage have led to the development of "brushless" soft-cloth systems, and subsequently to the marketing of "frictionless" spray-only systems controlled by electric eyes and robotics technology. Like self-service facilities, automatic carwashes generally provide coin-operated vacuums for the cleaning of car interiors. In 1996, the average cost of a basic automatic carwash (as opposed to one offering extra cycles) was \$3.40.

Full-Service Conveyor Facilities. Full-service facilities not only require more space than self-service or automatic systems, they are also more labor-intensive. In these facilities, full-time workers service 60 or more cars per hour as an automatic conveyor carries the vehicle through an open-ended service tunnel. In 1990, the International Car Wash Association reported that among full-service conveyorized facilities, 59 percent used cloth-only systems, 20 percent used friction/frictionless wash combinations, and 8 percent used frictionless washes only. On-line services typically provided by conveyorized facilities include exterior wash, rust-inhibiting undercarriage wash, tire and whitewall cleaning, various waxing options, and the scenting of interior air. Off-line services typically include cleaning and polishing of exterior and interior vinyl and leather, shampooing of carpet and upholstery, cleaning floor mats, cleaning ashtrays, cleaning the engine, and applying a polymer protectant. In the early 1990s, the typical cost of a customized car cleaning package at a full-service conveyorized system was approximately \$30. In 1998, a full-serve carwash had an average wash volume of 65,113 vehicles. The average 1998 price for a full-service wash was \$9.93. The average gross revenue per car was \$11.21. The average gross

income for a full-service carwash is approximately \$730,000. Meanwhile, the average annual operating costs were \$527,900, of which 46 percent was on-line labor costs.

Automobile Detailers. In these facilities, the focus is on manual cleaning of cars both inside and out, using hoses and brushes as well as hand-held tools rather than high-technology car washing equipment. The "detailing" of an automobile is an exhaustive process. A September, 1993, *Harper's* magazine article described detailing as the "cleaning of a car beyond all reason." In addition to essentially manual versions of the on-line and off-line services provided by full-service conveyorized systems, detailing operations focus on such car parts as hood interiors and spare tires and on "details" such as shining the interior of gas caps and dusting the spaces between radio buttons. In 1996, the typical cost for detailing was \$131.10 for complete interior/exterior services.

The cost of carwash equipment may vary regionally, based on such factors as water availability and water quality and area soils or pollutants. According to the International Carwash Association, in 1998, annual operating costs for a five-bay self-service carwash were \$56,500, whereas the cost of operating a full-service wash were more than ten times as much, or \$527,900. The leading professional trade organization was the 5,000-member International Carwash Association, which publishes a semiannual directory and a monthly management report both in print and on the Internet. Chief among industry trade publications was *Professional Car washing and Detailing*.

BACKGROUND AND DEVELOPMENT

An article in a 1923 edition of *Literary Digest* discussed the "first automobile wash-bowl that has been built in this country," a carwash located in St. Paul, Minnesota. For this three-minute carwash, "the owner drives his car in and around the bowl until he is satisfied that the mud has been cleaned from the chassis and wheels . . . at the exit door there is a spray with forced water which cleans the body . . . an electric drier completes the job." Three years later the same magazine described a seven-minute "Automobile Laundry," a carwash relying on two pitmen; hoses of hot, cold, and soapy water for car exteriors; and a compressed air hose for car interiors. The article predicted that the carwash would become "one of the largest specialized industries in the country."

The modern carwash industry began in 1946 in Detroit with the opening of Paul's Auto-Matic Car Wash, the "first automatic autowash in the world." The establishment was a conveyor-style carwash in which the car was pulled through by a moving chain. Twelve years later, the first full-service Jax Kar Wash opened in De-

troit. This pioneering operation serviced 280,000 cars in its first year of business. Coin-operated self-service facilities and automatic rollover carwashes emerged in subsequent decades.

In the early 1990s, the carwash industry was in a dynamic phase. Important trends in the carwash industry included a customer preference for soft cloth or frictionless carwashes over automatic brush rollovers and the emergence of detailing operations and growth in the high-quality carwash segment. The adoption of sophisticated computer software for business planning, customer service, and bookkeeping needs, and an industry focus on environmental issues were other important trends.

At the beginning of the 1990s, *Forbes* magazine had described carwashes as "one of the largest small businesses in the United States and one that's growing at five to ten percent a year." But conditions began to change by the latter part of the decade, and while the industry continued to grow at a rate of six percent, new forces—particularly environmental laws and competition from service stations offering free carwashes with a fill-up—had begun to encroach.

CURRENT CONDITIONS

States and communities have passed sewage, water conservation, and water reclamation codes that affect or are directed at commercial carwash establishments, and individual businesses are increasingly turning to a combination of fresh and reclaimed water in the operation of their car cleaning systems. In addition, the federal Environmental Protection Agency has begun to regulate the underground tank storage systems and to analyze the chemicals, detergents, and wax products used by the carwash industry.

Establishments in this industry sector have also faced increasing competition from service stations, convenience stores, and other facilities that offer washes as one of several on-site profit centers. Some of these utilize innovative technology such as a television, which customers view while pumping gas. On the screen they see an advertisement for a carwash, which they can purchase when they pay for their fuel. Others give away free washes with a gas fill-up.

INDUSTRY LEADERS

The leading carwash chains, as reported in *Ward's Business Directory of U.S. Private and Public Companies* (1997) are National Pride Car Wash Systems, based in Fort Worth, Texas; Stanton Corp. of Virginia Beach, Virginia; Buffs-N-Puffs Ltd. of Murray, Utah; Hollingshead Industries Inc. of Sacramento, California; and Wash on Wheels Inc. of Sanford, Florida. Other national leaders included Tankar Stations, McKinley Car

Wash, Car Salon Inc., White Glove Automatic Care Inc., and Gateway Waterworks Inc.

WORKFORCE

Employees of the carwash industry include vehicle washers; equipment operators and maintenance workers; secretaries, bookkeepers, and general office clerks; cashiers; and laborers and helpers. In the early 1990s, "revolving door" workers became an industry concern, in part due to the negative impact of employee turnover on customer service. This concern has prompted more careful hiring and training of employees and the implementation of incentive and commission programs, particularly in full-service conveyerized carwashes and in automobile detailing operations.

SIC 7549

AUTOMOTIVE SERVICES, EXCEPT REPAIR AND CARWASHES

This category covers establishments primarily engaged in furnishing automotive services, except repair and carwashes. Establishments primarily providing automobile driving instructions are classified in **SIC 8299: Schools and Educational Services, Not Elsewhere Classified**.

NAICS CODE(S)

811191 (Automotive Oil Change and Lubrication Shops)

488410 (Motor Vehicle Towing)

811198 (All Other Automotive Repair and Maintenance)

Examples of miscellaneous automotive service providers include emissions testing centers, inspection services, do-it-yourself garages, diagnostic centers, lubricating and oil change shops, emergency road services, rust roofers, window tinting shops, and towing services. The industry consisted mostly of small repair shops. The average number of employees per establishment, for example, was 6 in the mid 1990s, while the average for all service industries was 13. In addition, only the top 10 companies in the industry generated annual revenues of more than \$10 million. The majority of establishments

within this classification had sales that fell within the \$100,000 to \$249,000 range.

The automotive services industry grew out of America's love affair with the automobile. Immediately after Henry Ford's introduction of the Model T in 1905, car sales boomed. From just 2.2 million in 1920, annual automobile production rocketed to more than 8 million by 1950. As auto output fluctuated around 8 million annually throughout the mid 1900s, the automotive services industry ballooned. Importantly, federal safety and emissions regulations developed in the mid 1960s bolstered demand. By the early 1990s, the miscellaneous auto services industry generated \$3.4 billion in revenues each year and employed 67,400 workers. By the mid 1990s, revenues and employment reached almost \$4.4 billion and 86,300 workers, respectively.

Demand for miscellaneous automotive services expanded during the 1980s, due to a surge in car sales to almost 11.5 million per year in 1986 and 1987. Furthermore, the rapid proliferation of quick and convenient oil change and lubrication shops allowed the industry to encroach on traditional service stations.

A U.S. recession in the late 1980s and early 1990s hampered growth in most segments of the industry. Markets for some fast-growth services, such as quick oil changes and window tinting, became saturated. The U.S. Environmental Protection Agency significantly boosted local demand for services with its IM 240 emissions testing legislation, even though many states resisted its regulations.

The largest company in the industry in 1999 remained Envirotest Systems Corp. of Phoenix, Arizona, with assets of \$141 million. Other industry leaders included Q Lube, Industrial Powder Coatings, Interstate national Dealer Services, Inc. and Grease Monkey.

Job prospects for miscellaneous automotive service providers were promising going into the late 1990s. In fact, most occupations were expected to increase by over 40 percent between 1990 and 2005, according to the U.S. Bureau of Labor Statistics. Positions for coating and decorating workers, for example, appeared likely to rise by about 30 percent. Jobs for miscellaneous mechanics were anticipated to jump by about 50 percent. Wages in this industry, however, were low in relation to most other service industries, including automobile-related sectors. Because most positions required a relatively low level of skill and training, the average industry employee earned about 72 percent as much as the average service industry worker in the early 1990s.

SIC 7622

RADIO AND TELEVISION REPAIR SHOPS

This classification covers establishments primarily engaged in repairing radios, televisions, phonographs, stereo equipment, and tape recorders. Also included are establishments engaged in installing and repairing television, amateur, and citizens' band antennas, or in installing and servicing radio transmitting and receiving equipment in homes, offices, boats, automobiles, or other vehicles. Establishments primarily engaged in installation, repair, or maintenance of radio and television broadcast transmitting antennas and towers are classified elsewhere.

NAICS CODE(S)

811211 (Consumer Electronics Repair and Maintenance)

811213 (Communication Equipment Repair and Maintenance)

443112 (Radio, Television and Other Electronic Stores)

INDUSTRY SNAPSHOT

Television and radio repair in the United States is performed by many service centers operated by the manufacturers of electronic equipment or by appliance, department, electronics, or specialty stores. Only about 25 percent of the firms participating in the industry are independent repair shops; for government classification purposes, only the independents are considered part of this industry.

The radio repair segment of the industry has diminished significantly as technology has changed. However, when the industry emerged in the 1930s, radios were the only consumer electronic equipment requiring servicing. All that changed as broadcasting came into its own and households acquired television receivers. Depending on their area of specialization, establishments classified under the radio and television repair shops category install and service household and citizens' band (CB) antennas; they also repair aircraft radio equipment, automotive radios, intercommunications equipment, stereos, hi-fi equipment, tape recorders, phonographs, compact disc

players, digital video disc players, public address systems, stereophonic equipment, electronic organs, home security systems, microwave ovens, slide and motion picture projectors, and video recorders or players.

In 1998, there were an estimated 4,678 establishments in this industry. About half of the establishments were corporate entities and half sole proprietors/partnerships. The establishments were concentrated in the Northeast, Southeast, and Great Lakes regions of the United States. The top seven companies by sales in 1998 were: ABC Appliance Inc., Contec L. P., Electra-Sound Inc., Technicar Inc, Markey's Audio-Visual Inc., Audio-visual Inc., and Electronic Maintenance. According to the U.S. Census Bureau, collectively all firms in the industry brought in \$2.8 billion in 1998.

BACKGROUND AND DEVELOPMENT

Principles discovered in the nineteenth century were the basis for the wizardry of current audio and video home and mobile electronics. Heinrich Geissler first demonstrated in the 1850s that electricity discharged in a vacuum tube caused small amounts of rare gases in the tube to glow. In 1898, Karl Braun produced the first cathode ray tube that could control the glow caused by the freeing of electrons in a vacuum. In 1907, Lee De Forest, known as the father of radio, developed the first amplifying tube capable of strengthening electronic signals.

A few more years would elapse before new developments would make it possible to combine the basic elements of television transmission into a system. In 1922, teenager Philo Farnsworth developed a practical electronic scanning system. The following year, Vladimir Zworykin developed the iconoscope and kinescope, which are the respective basic elements of the television camera and the television receiver. The first public demonstration of Zworykin's all-electronic television system was in 1929.

Radio also developed from technology discovered in the 1800s and gradually perfected in the twentieth century. The infant radio and television medium did not develop enough to warrant a sales and service industry until regular commercial broadcasting began and people started to purchase receivers. Stations KDKA in Pittsburgh and WWJ in Detroit launched commercial radio broadcasting in 1920. Six stations initiated regular television broadcasting in 1946. Both broadcast industries grew rapidly, but television's growth was phenomenal. The United States had 6 million television sets by 1950 and more than 100 million by 1989. In the 1990s, almost every U.S. household had at least one television, while almost two-thirds had two or more.

The need for repair technicians was low when commercial broadcasting first hit the airwaves. Early radio

sets were simple, with only a limited number of things that could fail and cause reception problems, so owners made most of their own repairs. But as new developments and improvements occurred in the broadcasting industry, the receivers became more complicated. Trade and technical institutes were founded to train technicians capable of fixing radio sets. During the Great Depression of the 1930s, a number of people seeking new careers or ways to supplement their incomes took correspondence courses in radio repair.

After World War II, trade and technical schools flourished to meet the burgeoning demand for trained television service technicians. Aided by the GI Bill's educational benefits, many ex-servicemen who had been communications or electronics technicians in the armed forces entered the field. The invention of the transistor, stereophonic sound, color television, and other innovations ensured the job security of those in the repair industry who kept current with technology. These innovations meant that only trained technicians with the proper testing equipment and tools could repair the resulting television sets, radios, and other home electronics equipment.

The number and variety of electronic devices for home and business use proliferated throughout the 1970s, 1980s, and 1990s. Miniature and super screen projection televisions, video cameras and videocassette recorders (VCRs), and other new electronics equipment sustained a continuing need for trained technicians to install, maintain, and repair what had become essential household items for most Americans.

WORKFORCE

Radio and television service technicians diagnose and repair malfunctions in electronic home entertainment equipment, including radios, television sets, stereos, VCRs, video cameras, compact disc players, audio recorders, video games, and related electronic equipment. Outside technicians make service calls on customers, while bench technicians use test equipment and hand tools in a shop setting to fix problems.

Workers in this industry use their knowledge of electrical and electronic circuits to service and install equipment. Most enter the field by graduating from an accredited technical training program and working for at least a year under shop supervision. Junior colleges and correspondence, private, and vocational schools offer training programs. In addition, technicians may learn the field through apprenticeships or on-the-job training. The latter option generally is limited to existing service shop employees who display a basic understanding of electronics. Because of the constantly changing technology of electronics devices, successful service technicians attend short courses given by manufacturers to learn about special areas and current developments.

Some 33,000 electronic home entertainment equipment repairers held jobs in the late 1990s, out of 120,800 employed in electronic repair shops. Of those, about one in seven were self-employed, more than in most other repairer occupations. The level of employment is expected to decline by the year 2006 as continuing improvements in electronic devices and advances in component technology make equipment more reliable and easier to service. Those entering the field will mainly be replacing those service technicians who transfer to other occupations.

SIC 7623

REFRIGERATION AND AIR-CONDITIONING SERVICE AND REPAIR SHOPS

This classification covers establishments primarily engaged in servicing and repairing household and commercial electrical refrigerators and air-conditioning and refrigeration equipment. Establishments primarily engaged in servicing and repairing gas refrigeration equipment are classified in **SIC 7699: Repair Shops and Related Services, Not Elsewhere Classified**; and those repairing automotive air-conditioning equipment are classified in **SIC 7539: Automotive Repair Shops, Not Elsewhere Classified**.

NAICS CODE(S)

443111 (Household Appliance Stores)

811310 (Commercial and Industrial Machinery and Equipment (except Automotive and Electronic) Repair and Maintenance)

811412 (Appliance Repair and Maintenance)

INDUSTRY SNAPSHOT

In the past 50 years, refrigeration and air-conditioning products have evolved from luxury items primarily offering comfort and convenience to vital components of many industries. Today, virtually every scientific and technological industry relies on cooling systems and equipment that control the temperature, humidity, air

movement, and air quality of enclosed environments. Commercial, residential, and other buildings also rely on climate control systems.

Refrigeration and air-conditioning service and repair shops employ the mechanics and service technicians who keep self-contained and split-system air-conditioner units, electric refrigeration equipment, and electric refrigerators in good repair. In the mid 1990s, there were an estimated 3,658 establishments in this category. Typically these firms were small, employing an average of 6 employees and generating a total of \$3 billion.

ORGANIZATION AND STRUCTURE

The three main employers of refrigeration and air-conditioning service and repair technicians are manufacturers of environmental control equipment; distributors or dealers who sell and service equipment; and firms involved in air-conditioning, heating, and refrigeration, among other fields. Some technicians also establish themselves as entrepreneurs, opening up their own repair businesses.

The majority of establishments operating in the refrigeration and air-conditioning service industry—some 67 percent—are corporate entities. Of the remaining establishments, 31 percent are sole proprietorships and 2 percent are partnerships. Industry establishments are located throughout the United States.

Small appliance products serviced by industry technicians include home refrigerators and freezers, room air conditioners, packaged terminal heat pumps, dehumidifiers, under-the-counter ice makers, vending machines, and drinking water coolers. Industry service technicians also work on complex customized appliances used in the chemical, pharmaceutical, petrochemical, and manufacturing industries, as well as in industrial ice machines and ice rinks.

BACKGROUND AND DEVELOPMENT

The earliest climate control systems — piped steam installed to heat factories, churches, assembly halls, and other large buildings — eventually led to ventilation systems that combined heating with circulation of fresh air. About the same time heating systems were being developed, experimentation with artificial refrigeration began. By the mid 1800s, inventors understood the principles on which mechanical refrigerators operated. Dr. John Gorrie applied those principles when he invented a cold-air machine to relieve the suffering of yellow fever patients in a Florida hospital in 1842. After the Civil War, several companies in southern states applied them in ammonia-absorption machines to make artificial ice. Still, until the early part of the twentieth century, refrigeration continued to rely on ice cut during the winter and stored for later use.

While the technology to cool and circulate air was developed by the turn of the century, nothing was known about regulating its moisture content, or humidity, until Willis Carrier carried out a scientific study on air-conditioning. In the summer of 1902, he designed the first system to control the temperature, humidity, and circulation of indoor air. Soon afterward he devised a way to cool using an artificial fog instead of coils. The two methods became the basic ones involved in all later air-conditioning equipment. Industry after industry adapted Carrier's invention for controlling humidity to their particular production purpose. Because of his pioneering research and inventions, Carrier became known as the father of air-conditioning.

In 1914, Carrier developed the first residential air-conditioning system. Seven years later he created the centrifugal refrigerating machine. This machine had a refrigerant that made it possible to produce safe, dependable, large-capacity cooling devices. By the 1930s, air-conditioning spread from industry to become common in stores, theaters, and other large buildings.

In the early days of the industry, manufacturers and distributors trained most technicians and mechanics in how to repair air-conditioning and refrigeration equipment. The equipment had limited capacity to cool and regulate air quality, and thus the systems and the skills needed to maintain them were relatively simple. Over the years the equipment became increasingly sophisticated, and the knowledge and skills required to maintain cooling systems became more specialized. Modern equipment utilizes a wide variety of synthetic refrigerants, depending on the cooling job to be done and the types of evaporators, condensers, and compressors in the system. In addition, components are being installed with micro-computer controls. Because of the high-technology aspects, modern refrigeration service and repair workers generally receive training at community colleges, vocational-technical schools, and trade associations. Preparatory courses include electronics, chemistry, physics, mathematics, drafting, and writing. According to Marvin M. Kaplan in "Keeping Cool Is Hot," females comprise up to 20 percent of training programs, and "each year, more than 30,000 new graduates are hired."

Stratospheric Ozone Protection. The biggest challenge facing refrigeration and air-conditioning service and repair technicians in the 1990s and the early part of the next century was compliance with rules and regulations governing refrigerants. During the early 1970s, scientists identified the use of chlorofluorocarbons (CFCs)—a common refrigerant—as a primary cause of the depletion of the ozone layer of the earth's atmosphere, which protects life from harmful radiation. The U.S. Environmental Protection Agency (EPA) and the Food

and Drug Administration (FDA) banned the use of CFCs in all but a few essential applications in 1978.

In 1986, further research showed a connection between CFCs and global warming. Scientists also found an opening in the ozone layer over Antarctica. Recognizing the global nature of the problem, 24 nations and the European Economic Community (EEC) convened in Canada in 1987. As a result of the meeting, in 1992 most of the major CFC and HCFC (halon) producing and consuming nations signed the Montreal Protocol on Substances That Deplete the Ozone Layer. The Montreal Protocol, along with later amendments, called for a gradual reduction in worldwide consumption of eight chemicals and, ultimately, their complete phase-out. The agreement also encouraged countries to recover, recycle, and reclaim controlled refrigerants.

The United States drafted additional regulations regarding CFC and HCFC substances as part of the 1990 Amendments to the Clean Air Act. The act contained regulations affecting mechanics repairing or servicing an appliance or industrial process refrigeration. As of July 1, 1992, a service technician could not knowingly release or dispose of any substance used as a refrigerant in a manner which permitted the substance to enter the environment. Furthermore, effective November 1995, the prohibition applied to substitutes for CFCs and other banned refrigerants, unless the EPA specifically determined the substances posed no threat to the environment. By 2000, CFC production was completely banned. The penalties and fines for violating the act's provisions could be severe.

In 1993, the EPA published additional regulations for refrigerant recycling and emissions reduction. The regulations provided guidelines designed to minimize release of CFC and HCFC refrigerants into the environment during the service, maintenance, repair, and disposal of appliances. Technicians were required to follow the act's required practices and use equipment certified for the type of appliance opened for service. These guidelines applied not only to technicians, but to refrigerant reclaimers, appliance owners, and manufacturers of appliances and recycling and recovery equipment.

CURRENT CONDITIONS

Air-conditioning and refrigeration are essential in all segments of modern society. Nearly every newly-built home has central air conditioning installed, and many existing buildings are retrofitted with air-conditioning equipment. Carefully controlled temperature and humidity conditions are crucial to the manufacture, transport, and storage of numerous products. Numerous chemicals, pharmaceuticals, explosives, solid state electronic devices, and oil products require refrigeration during their production. Fully 95 percent of food production depends

on refrigeration, including some half-billion tons of perishable food each year. In addition, refrigeration supports surgery by safely storing drugs, blood, bone, and tissue, and by supplying clean, pure ice for such purposes as frigid anesthesia.

Each refrigeration and air-conditioning application represents a different segment of the large and very diverse service industry. Each segment requires engineers and technicians who can keep the equipment and systems operational. Opportunities for establishments that service and repair refrigeration and air-conditioning equipment should increase as the number of applications increases.

WORKFORCE

Most of the refrigeration and air-conditioning repair industry's employees worked for cooling and heating contractors. Others worked in large buildings, schools, and factories. Approximately one out of eight technicians was self-employed. The average wage was \$13.95 per hour in 1999. Analysts predicted that jobs in the air-conditioning and refrigeration service field would increase into 2006.

Apprentices usually start out at half the wage rate of experienced workers. Approximately 20 percent of the technicians are union members, most belonging to the Sheet Metal Workers' International Association and the United Association of Journeymen and Apprentices of the Plumbing and Pipefitting Industry of the United States and Canada. Many employers provide such benefits as health insurance, pension plans, work-related training, uniforms, company vans, and tools.

Technicians learn the trade through technical school, apprenticeship training, or occasionally, informally on the job. Six-month to two-year programs in air-conditioning, heating, and refrigeration are offered by secondary and post-secondary technical and trade schools, junior and community colleges, and the armed forces. Besides the basics of installation, maintenance, and repair, students study theory, design, equipment construction, and electronics. Frequently sponsored by trade and union organizations, formal apprenticeship programs usually run three or four years and combine classroom instruction and on-the-job training. Those who learn the trade informally usually begin by helping an experienced technician and performing tasks that gradually become more difficult.

All technicians who purchase or handle refrigerants must pass a written certification examination administered by organizations approved by the EPA. They may become certified in three possible areas: Type I, servicing small appliances; Type II, high pressure refrigerants; and Type III, low pressure refrigerants. Some trade organizations provide training programs to prepare technicians for

the examination, as well as general skills improvement training and self-study courses.

SIC 7629

ELECTRICAL AND ELECTRONIC REPAIR SHOPS, NOT ELSEWHERE CLASSIFIED

This industry category includes establishments that primarily repair electrical and electronic equipment, such as electrical household appliances and electrical and electronic industrial equipment.

NAICS CODE(S)

443111 (Household Appliance Stores)

811212 (Computer and Office Machine Repair and Maintenance)

811213 (Communication Equipment Repair and Maintenance)

811219 (Other Electronic and Precision Equipment Repair and Maintenance)

811412 (Appliance Repair and Maintenance)

811211 (Consumer Electronics Repair and Maintenance)

Specialized electronic repair emerged as an industry after electrical devices appeared in the late 1800s and early 1900s. The development of electronic standards and measuring devices in the 1890s was pivotal to the industry's birth. The profusion of new electrical and electronic goods after World War II pushed miscellaneous electrical repair industry revenues to nearly \$2 billion by the end of the 1970s.

Widespread semiconductor use during the 1970s and 1980s in turn expanded the use of electronics in American homes and businesses. Miniaturized electronics were integrated into traditional items, such as home appliances and razors. They also created new product categories, such as microwave ovens and fax machines. As sales of that equip-

ment doubled to reach more than \$6 billion during the late 1980s and early 1990s, demand for repair of new semiconductor manufacturing equipment went up.

The growth of new applications boosted electrical repair industry billings to about \$3.5 billion by 1987 — a 60 percent increase from early 1980s revenues. As sales rose in the 1980s, industry jobs went from 41,000 in 1982 to about 56,000 in the late 1980s. The number of companies in the industry expanded from 6,800 to 8,600, although a recession in the late 1980s and early 1990s stalled industry growth. Slowly recovering markets in the mid 1990s allowed many companies to boost sales and strengthen margins. In 1996, the industry as a whole had approximately 11,295 establishments and estimated revenues of \$8.17 billion. In 1997, the industry had 12,490 establishments and receipts of \$13.02 billion.

The leader in this sector is Sears Roebuck & Co. In 1997 Sears had a 10 percent share in the appliance/electronics repair market, with some \$2 billion in revenues. Other successful companies engaged in this sector include Black and Decker Corporation's Products Service Division in Hampstead, Maryland, with 1997 sales of \$172.7 million; Barfield, Inc., which repairs aircraft flight instruments, with 1997 sales of \$35 million and 300 employees; and Tandy Corporation's Radio Shack.

About 396,000 electronic equipment repair specialists held jobs in the mid 1990s. According to the Bureau of Labor Statistics, overall employment of these repair people was expected to grow slowly through 2006. Although demand for computer and office machine repairers, commercial and industrial electronic equipment repairers, and communications equipment mechanics is expected to expand, jobs for electronic home entertainment equipment repairers and telephone installers and repairs are forecast to plunge.

Jobs in this industry pay well compared to other service industries. The payroll per employee in the early 1990s was about \$20,000 per year, compared to about \$18,000 for other service sectors. In 1996, the average service technician made \$9.03 to \$15.48 per hour, according to a private industry survey. Most electrical repair people earned \$500 to \$600 per week, but these jobs required a more educated worker. Most entry-level positions required completion of a one- or two-year vocational training program, or on-the-job training in the U.S. armed forces.

Service Dealer's Newsletter. 1997 Press Release Summary from The Electronics Technicians Association International.

SIC 7631

WATCH, CLOCK, AND JEWELRY REPAIR

This category covers businesses that primarily repair watches, clocks, or jewelry. Companies that primarily assemble watches from purchased parts are in **SIC 3873: Watches, Clocks, Clockwork Operated Devices, and Parts**.

NAICS CODE(S)

811490 (Other Personal and Household Goods Repair and Maintenance)

The watch, clock, and jewelry repair industry consists of a few large industry leaders and many small local shops. Most watch, clock, and jewelry repair shops are small, privately-owned firms, often affiliated with local jewelry retailers. Large watch, clock, and jewelry makers may also have divisions devoted solely to repairing their products.

Watch, clock, and jewelry repair firms fix malfunctioning and broken timepieces and jewelry. The industry's repair technicians (called horologists) replace broken or worn parts mainly with factory replacement parts. Technicians are able to repair both older mechanical and newer battery-operated quartz timepieces. When working with older timepieces, however, technicians often make replacement parts themselves.

Approximately 80 percent of the watch repairers in the United States are self-employed. They operate their own repair shops or have contracts with jewelry retailers and department stores. Many new horologists found jobs with jewelry retail stores or department stores. Furthermore, many large clock, watch, and jewelry makers employed horologists in their repair departments. Most repair technicians were members of the American Watchmakers Institute, the national watch, clock, and jewelry repair trade organization.

New York City-based SMH Inc. led the industry with sales of \$200 million for 1997, according to the most recent results available from Infotrac databases. That year, SMH entered into a joint agreement with Calvin

Klein to manufacture CK branded watches. Second in the industry, Mayor's Jewelers Inc. of Sunrise, Florida was bought out in early 1998 by Jann Bell Marketing, which decided to retain the "Mayor" name for its subsidiary. Mayor's generated \$120 million in the year before the buyout, and sales rose to \$140 million for 1998, the year of the buyout.

Two Toledo companies placed third and fourth in the industry. Peoples Jewelry Company Inc. garnered revenues of \$78 million for its fiscal year ended September 30, 1999, and Time Service Inc. generated sales of \$20 million for its fiscal year ended August 31, 1999. S. Joseph and Sons Inc. of Des Moines, Iowa rounded out the top five industry leaders, with sales of \$16.5 million for its fiscal year ended January 31, 1999.

In the early 1990s, the United States had a shortage of qualified repair technicians. Analysts estimated that nine out of ten Americans owned watches, and watch and jewelry sales rose consistently throughout the 1990s. Widespread sales of inexpensive electronic watches reduced business for repair shops, because these watches are cheaper to replace than repair. The decrease, however, has been offset by higher replacement battery sales.

Watch, clock, and jewelry repairers trained for one or two years at vocational schools, technical institutes, or junior colleges. Some states require repair technicians to be licensed. Repairers generally worked 40 to 50 hours per week and earned between \$200 and \$400 per week. Self-employed repairers generally worked more hours and had larger salaries.

According to U.S. government statistics, there were 1,662 businesses in this category in 1992, a tiny increase from the 1,661 in 1987. Total industry sales for 1992 were \$274 million, an 18.8 percent increase from the \$231 million in sales for 1987. In 1992, the industry employed 5,141 workers, with a total payroll of \$78 million. According to Dun & Bradstreet's *Industry Norms*, the average watch, clock, and jewelry repair firm had total assets of \$94,072, net sales of \$199,043, and net profits after taxes of \$21,298 in 1992.

SIC 7641

REUPHOLSTERY AND FURNITURE REPAIR

This classification covers businesses that primarily reupholster and repair furniture. Companies that primarily sell upholstery materials for personal or household use are in **SIC 5714: Drapery, Curtain, and Upholstery Stores**; and those making furniture and cabinets on a custom basis are in **SIC 5712: Furniture Stores**.

NAICS CODE(S)

811420 (Reupholstery and Furniture Repair)

Furniture making became more automated after water- and steam-powered tools were introduced early in the nineteenth century. The artisan's role was largely eliminated in the mainstream furniture industry, and inexpensive furniture produced by high-volume manufacturers reduced demand for labor-intensive repair services.

Renewed interest in antiques and corporate cost-consciousness during the late 1980s hiked industry activity. Many refinishing and repair shops found new demand for refurbishing high-quality case goods, seating, and other pieces designed in classic, popular styles and produced by reputable makers. Corporate buyers could save up to 70 percent over the cost of new furniture by having their office furniture and equipment revitalized, or they could buy used furniture. By 1996, total U.S. furniture repair industry sales were an estimated \$1.2 billion, up from \$980 million in 1992.

Despite a U.S. recession in the late 1980s and early 1990s, the furniture repair industry grew. The market for refurbished and used furniture grew at 15 percent annually going into the 1990s, leading most other furniture industry segments. Demand for on-site refurbishing services was strong and growing in the late 1990s. Such companies replaced laminated desk- and counter-tops, repainted file cabinets and other metal equipment, and refurbished wall panels. Companies also repaired and refurbished antiques and other furniture on-site for non-business customers.

Trends through the mid 1990s included more partnering, where furniture dealers and refinishing/refurbishing services teamed up to provide long-term, one-stop shopping services for clients. Another trend was more government regulation. Due to strict federal mandates from the

Clean Air Act Amendments of 1992, refinishers and painters were forced to follow sometimes costly procedures related to indoor air quality and waste disposal.

The U.S. reupholstery and furniture repair industry was diverse and fragmented in 1997, with 6,598 firms offering services ranging from antique furniture repair and home furniture reupholstery to refurbishing office furniture. Most firms were small, local, and provided a range of services. The industry generated \$1.2 billion in receipts in 1997.

Furniture Medic was the largest franchiser in furniture repair and restoration in the late 1990s. Furniture Medic was founded in 1992 and acquired by ServiceMaster in 1996. Based in Memphis, Tennessee, it had 600 franchised locations across the United States, as well as locations in Canada and Europe.

Industry firms employed an estimated 22,315 workers in 1997, up from 21,200 in 1992. The total industry payroll for 1997 was \$389 million, up from \$311 million in 1992. According to the Bureau of Labor Statistics, industry jobs may grow 20 to 40 percent between 1990 and 2005.

SIC 7692

WELDING REPAIR

This classification covers businesses that primarily do general repair work by welding, including automotive welding.

NAICS CODE(S)

811490 (Other Personal and Household Goods Repair and Maintenance)

Welding joins materials by applying heat, and sometimes pressure, with or without the use of a filler metal. The process joins metals by melting, fusing, and then solidifying the joined area. Welding is used to make structural components, aircraft, cars, ships, and most other metal industrial products. Industry firms do general repairs in their own shops on welded items, such as motor vehicles. Welders that travel to construction sites are in **SIC 1799: Construction, Industry**.

There are eight major welding techniques used for different applications. One of the most common is shielded metal-arc welding, which uses an electric arc to quickly weld a point. Cold welding, a more specialized technique, uses pressure alone to join metals without any heat. Explosion welding uses a controlled blast to pressure two metals. Other welding techniques include: diffusion, which uses heat and pressure; laser-beam; ultrasonic, which utilizes high-frequency vibration; and variations of electric arc welding.

Massive U.S. industrial expansion during the mid 1900s created an identifiable welding repair industry. Post-World War II car and truck sales also caused demand for welding repair shops. By the end of the 1970s, welding repair revenues approached \$1 billion and industry jobs surpassed 24,000. Although U.S. industrial output, particularly for cars, rose during the 1980s, inflation-adjusted welding repair revenues stagnated. The development of new welding techniques, which increased durability, was one reason for a decline in repair work. Also, increased use of synthetic metal substitutes reduced demand for future welding repairs.

There were an estimated 5,629 welding repair shops in 1998, down from 5,985 in 1987. Sales for 1998 totaled \$3.1 billion, up from \$1.2 billion in 1987, and a 14 percent increase from 1997. In 1998, the industry employed 26,600 workers. The total industry payroll for 1998 was \$626 million. Most industry firms averaged sales of about \$200,000 per year. More than 50 percent were sole proprietorships, and the average shop employed four workers. Most of the 25 biggest companies billed less than \$5 million.

The largest firms in 1999 appeared to be Industrial Hardfacing Inc. of Elk River, Minnesota; Crookston Welding and Machine of Crookston, Minnesota; and Vopalensky's Inc., of North Bend, Nebraska.

Many welders got their training on the job, though vocational and technical schools offered formal training programs. Also, the U.S. military ran welding schools for its enlisted personnel. While the demand for welders by manufacturers may decline, the job outlook for welding repairers was positive because they were less likely to be replaced by automation. The Bureau of Labor Statistics estimated the demand for welding repairers will increase 25 percent by the year 2005. Unfortunately, industry workers were paid relatively low wages, an average of \$13.95 per hour.

SIC 7694

ARMATURE REWINDING SHOPS

This category covers businesses that primarily rewind armatures and rebuild or repair electric motors. These companies may either repair customers' equipment, or repair or rebuild for sale or exchange to users or the trade.

NAICS CODE(S)

811310 (Commercial and Industrial Machinery and Equipment (Except Automotive and Electronic) Repair and Maintenance)

335312 (Motor and Generator Manufacturing)

A generator, or dynamo, converts mechanical energy into electrical energy by rotating an armature through a magnetic field. Most electricity used in cars, homes, and industry is made by generators. The armature — usually made of copper wire wound around a laminated core of soft iron — is the rotating or stationary assembly in the generator, and is the main current-carrying conductor. A steel shaft is fitted through the center of the core to which the two ends of the copper wire connect.

Companies in the armature rewinding business rewind damaged coils or stators, fix hermetic seals on electric motors, and generally restore electric motors and components. They fix everything from small automotive generators to giant industrial and utility devices. The industry consisted of 2,119 companies in 1998, most of which were small service centers.

Englishman Michael Faraday and American Joseph Henry developed the generator during the 1830s after discovering they could make a magnet produce electric current. Generators became widely used during the late 1800s, which, in turn, created a demand for repair shops to service them. After World War II, the industry benefited from U.S. economic expansion, which increased electricity consumption and generated a need for motor vehicle generators. Throughout the twentieth century, the basic design of the generator and armature have hardly changed.

By the early 1980s, armature rewinding shops billed \$1.8 billion annually and employed a work force of

31,000. Industry revenues climbed at a rate roughly equivalent to inflation during the 1980s, pushing sales to \$1.9 billion by 1987. Total sales for 1992 were \$2.3 billion. There were 2,498 industry firms in 1992, down from 2,830 in 1987. There were 26,607 industry workers in 1992, down from 27,255 workers in 1987. This job decline may have been due to increased automation and efficiency within the industry. A recession weakened some firms in the early 1990s, but by the mid 1990s the both the industry and the economy began to recover. In 1998, this industry reported \$2.8 billion in sales, a 10 percent increase from the previous year.

Some of the largest armature rewinding shops in 1999 were Brithinee Electric of Colton, California and Southwest Electric Company of Oklahoma City, Oklahoma. Even the top 25 competitors in the mid 1990s, however, had sales of less than \$15 million and employed fewer than 100 workers.

Although efficiency gains reduced industry jobs during the 1980s, positions for armature rewinding industry workers were expected to rise between 1990 and 2005, according to the Bureau of Labor Statistics. Jobs for general repairers were predicted to climb as much as 35 percent by 2005, and electrical equipment positions were expected to increase by at least 9 percent. In the late 1990s, there were an estimated 22,700 employees in the industry.

SIC 7699

REPAIR SHOPS AND RELATED SERVICES, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in specialized repair services, not elsewhere classified.

NAICS CODE(S)

- 561622 (Locksmiths)
- 562991 (Septic Tank and Related Services)
- 561790 (Other Services to Buildings and Dwellings)
- 488390 (Other Support Activities for Water Transportation)
- 451110 (Sporting Goods Stores)
- 811310 (Commercial and Industrial Machinery and Equipment (except Automotive and Electronic) Repair and Maintenance)
- 115210 (Support Activities for Animal Production)
- 811212 (Computer and Office Machine Repair and Maintenance)
- 811219 (Other Electronic and Precision Equipment Repair and Maintenance)
- 811411 (Home and Garden Equipment Repair and Maintenance)
- 811412 (Appliance Repair and Maintenance)
- 811430 (Footwear and Leather Goods Repair)
- 811490 (Other Personal and Household Goods Repair and Maintenance)

Miscellaneous repair shops service a plethora of items such as motorcycles, bicycles, leather goods, lawn mowers, window shades, camping equipment, pianos and organs, septic tanks, surgical instruments, surveying equipment, and bowling pins. This industry also encompasses taxidermists, locksmiths, and other miscellaneous services. While many companies, such as furnace cleaning firms, specialize in one type of activity, other industry participants are general maintenance companies that supply a variety of repair and related services. The largest single occupational group is welders and metal cutters.

General maintenance workers are jacks-of-all-trades, and they work as plumbers, carpenters, and mechanics. They repair and maintain machines and equipment, for example, and fix air-conditioning systems, repair roofs and floors, maintain cafeterias, restore tools, refurbish furniture, inspect mechanical systems, and perform many other services. They are often self-employed, will travel to a work site, and work for governments, institutions, and private industry. Although earnings vary widely by industry, geographic area, and skill level, general maintenance personnel earned around \$9.40 per hour in the mid 1990s, according to the U.S. Department of Labor's *Occupational Outlook Handbook*.

The demand for miscellaneous repair and related services mimicked U.S. economic expansion during the mid 1900s. By the early 1980s, about 24,000 companies and 130,000 employees were classified in this industry, and total revenues approached \$6.5 billion. General economic growth boosted industry billings to about \$10 billion by the late 1980s, reflecting a 35 percent increase over early 1980s levels. In the late 1990s, there were an

estimated 36,584 repair shop establishments employing 232,800 people, with aggregate receipts of \$19.8 billion.

The business is extremely fragmented. The average industry participant employed only five workers in the late 1980s and generated billings of about \$340,000 per year. The average establishment in the mid 1990s had 6 employees and receipts of \$441,585. In terms of annual sales, in 1999 the largest company in the industry was Institutorm Technologies Inc. Other leaders were Roto-Rooter, Inc., of Cincinnati, Ohio; Leamco-Ruthco of Texas; and Siemens Power Corp., of Milwaukee, Wisconsin. There were only 17 companies with annual sales above \$10 million, and only four had more than 1,000 employees.

Future employment prospects in the miscellaneous repair industry are generally positive. Most occupations will realize growth of 20 percent to 30 percent between 1990 and 2005, according to the Bureau of Labor Statistics. Jobs for welders and cutters, for instance, will likely rise about 23 percent. General management jobs, which account for approximately 7 percent of the work force in this category, will increase about 17 percent by 2005. Openings related to machinery and automotive repair will rise 35 percent, as will miscellaneous service positions related to construction.

SIC 7812**MOTION PICTURE AND VIDEOTAPE PRODUCTION**

This category covers establishments primarily engaged in the production of theatrical and nontheatrical motion pictures and videotapes for exhibition or sale, including educational, industrial, and religious films. Included in the industry are establishments engaged in both production and distribution. Producers of live radio and television programs are classified in **SIC 7922: Theatrical Producers (Except Motion Pictures) and Miscella-**

neous Theatrical Services. Establishments primarily engaged in motion picture and videotape reproduction are classified in **SIC 7819: Services Allied to Motion Picture Production** and those engaged in distribution are classified in **SIC 7822: Motion Picture and Videotape Distribution.**

NAICS CODE(S)

512110 (Motion Picture and Video Production)

INDUSTRY SNAPSHOT

The U.S. motion picture and video production industry serves as a major supplier of entertainment and information to the world by producing videos, television programs, and movies that can be seen in more than 100 countries.

Despite hefty profits, some segments of the industry felt the effects of the recession in the early 1990s. Fewer people went to the movies in 1992 than during any single year in the 1980s. Following the recession, box-office revenues climbed again, but competition from cable television and video sales continued to erode the theatrical audience. A challenging economic climate emerged again during the early 2000s. However, the industry fared relatively well as interest in movies—at the theater and on home video—remained strong.

The home video market played an increasingly important role for the industry during the early 2000s. Fueled largely by the popularity of affordable digital videodiscs (DVDs), video sales outpaced movie theater tickets more than two to one. The television market also was very lucrative for industry players. According to research from Standard & Poor's, in 2002 sales garnered from television licensing were expected to surpass \$10 billion, while movie ticket revenues were expected to reach \$4 billion.

Several media conglomerates dominated the industry through the early 2000s. In 2002, six companies had a combined U.S. box office market share of approximately 70 percent: Walt Disney; Viacom; Sony; Fox Entertainment Group; AOL Time Warner; and Universal Studios, Inc. By 2001, box office revenues for the leading film companies totaled more than \$8 billion. More than 90 percent of these revenues were attributable to the leading 10 entertainment companies.

ORGANIZATION AND STRUCTURE

Motion picture and videotape production is one element of a larger three-part industrial structure. After a movie or a video has been produced, it is usually transferred to a distributor, who in turn arranges to make the product accessible to the consumer through movie theaters, video rental and/or sale outlets, and television broadcasts. In the case of movies, the distribution company and

the theater usually split the box office receipts. The financial and management structures of a production company often depend on the company's relationship to the distribution arm of the industry, which in turn often depends on a company's size.

Production companies can be classified according to three major categories: the "majors," the "mini-majors," and the "independents." The majors include large conglomerates such as AOL Time Warner, Disney, Sony, and Viacom. In the case of the majors, a single corporate structure often controls both the production and distribution of films, as well as an array of related operations through which the corporation can market movie soundtracks, toys, and other promotional tie-ins. Warner Bros., whose merger with Time, Inc. in 1989 dramatically strengthened its distribution system, presented one of the most striking examples of coordinated production and distribution. Some major film corporations have also invested in movie theaters, despite the history of antitrust actions against theater chains owned by studios. Slightly smaller companies, often called "mini-majors," may have weaker distribution powers and may specialize in a specific segment of the film market, such as art films or action films. Small independent filmmakers may have no distribution capability at all and must depend entirely on outside distribution companies.

Because success in the film production industry depends largely on a wide distribution network and access to the substantial capital required for film production, major film companies have obvious advantages over smaller companies. In addition to distribution capabilities, many of the major studios have been operating long enough to build up sizable film libraries, which provide revenue through video sales or through sale or rental to television stations. These well-established companies are likely to wield substantial financial leverage and control physical production facilities. In fact, small production companies and independent filmmakers often rent the production facilities of the larger companies.

During the studio era, which lasted from 1920 to 1950, major studios considered their stable of stars, directors, and other talent under long-term contract as assets. Movie companies in the 1990s and early 2000s, however, were more likely to sign contracts with artists for a single project. Such one-shot contracts have given talent agents considerable power over the production process. Often agents will assemble a "package" including a script, a director, and a star and sell the whole project to a studio. By performing much of the preproduction work on a project themselves, agents give clients greater control over the kinds of projects they undertake. This sort of arrangement limits the movie company's artistic involvement to that of an investor who simply provides the

money, facilities, and equipment required to complete the project.

The explosion of new television technologies since the late 1970s has had a significant impact on the financial structure of film production and has helped to encourage independent production. Developments such as cable TV, videocassettes, and pay-TV services like Home Box Office (HBO) have stimulated demand for new films and created new options for film financing. These ancillary markets allow movie companies to sell distribution rights before production has even begun on a movie. HBO, for example, has helped to finance new movies in order to ensure the steady supply of films necessary to fill its programming schedule. Video rentals have proven to be an even greater source of revenue for motion picture companies. During the late 1990s, a report by the American Film Marketing Association stated that slightly more than 43 percent of motion picture sales were derived from television, while video contributed nearly 26 percent and theatrical releases a little more than 31 percent. By the time a feature film has been fully exploited, it will have been released in a theater, on home video and pay-per-view channels, on cable television, and on the major television networks—most likely in that order.

Ancillary markets have been a boon to production companies of all sizes, but independent producers have had special cause to celebrate their rise. Lacking the financial leverage of the majors, small movie companies have often had to struggle to gather the capital required to make a film. The ability to sell ancillary rights to pay cable and video companies has expanded the financial resources available to independents, resulting in a healthy growth of independent film production since the mid-1980s. During the mid-1990s a growing network of satellite broadcasting systems; the arrival of an exciting new high-quality, low-cost consumer digital video system (DVD); and the latent potential of the emerging Internet created an ever-widening range of distribution channels, all hungry for new content.

In addition to producing a steady supply of feature films, many movie studios also provide programming for television. Telefilm productions range from made-for-TV movies to half-hour situation comedies. Major movie studios accounted for approximately half of all prime-time programming for the networks during the early 1980s, with gaps filled by independent telefilm producers such as Mary Tyler Moore's MTM Enterprises. Prior to 1991, the Federal Communications Commission (FCC) actually restricted the amount of programming that networks could produce for themselves and prevented networks from owning a share in the syndication rights of the shows they exhibited. These restrictions were designed to prevent the networks from developing a monopoly over television programming and to maintain a

competitive environment for the program production industry. On June 15, 1991, the FCC altered some of these restrictions, permitting networks to hold the syndication rights for 40 percent of the programming that they run during prime time.

BACKGROUND AND DEVELOPMENT

The U.S. film industry was born in Thomas Edison's laboratories in West Orange, New Jersey, when William Kennedy Laurie Dickson successfully devised a motion picture camera and the kinesiograph, a device that allowed a single viewer to watch a short film through a peephole. Dickson's invention enjoyed a period of brief profitability as consumers paid a nickel to enjoy the novelty of moving pictures, but widespread commercial success of motion pictures did not materialize until projectors made it possible to show a movie to more than one viewer at a time. The Vitascope, invented by C. Francis Jenkins and Thomas Armat, became the first movie projector to be publicly exhibited in the United States on April 23, 1896. The Cinematographe of Louis and Auguste Lumiere ran a close second, debuting in New York City on June 29, 1896—several months after its unveiling in France. Former Edison employee Dickson introduced his own Biograph projector on October 12, 1896.

Early manufacturers of cinematic equipment were also the first motion picture producers, who made the films to be shown on their own hardware. Before the advent of movie houses, production companies had to provide projectors, projectionists, and films to exhibitors. Employees of movie companies or owners of franchises purchased from movie companies would take the company's equipment and movies on the road, showing the films in vaudeville houses, empty storefronts, and a wide variety of other makeshift venues. Films for the Vitascope projector were produced by the Edison Manufacturing Company in a crude, black-painted shack known as the "Black Maria," whereas Biograph filmed its motion pictures on a movable outdoor stage with a camera that could be moved back and forth on wheels. The Biograph filmmakers and the Lumiere brothers gained a competitive edge by producing travel and documentary films on location in addition to studio productions. In all of these cases, the cameraman served as the chief creative intelligence behind each short film and was responsible for the subject matter, photography, printing, and editing.

This system was well adapted to a relatively low volume of production. A number of developments in the first decade of the twentieth century, however, worked dramatically to expand the market for new motion pictures and encourage the application of mass-production techniques to movie making. As more movie companies began selling movies outright to independent exhibitors, the number of exhibitors increased, and the need for an

improved distribution system became clear. In order to be cost-effective, film exhibitors had to have access to a greater number of films than they could afford to buy. Harry and Herbert Miles solved this problem in 1903 by organizing a “motion picture exchange” that bought a large stock of films and then rented them to exhibitors. Other such exchanges followed, and the increased film supply fostered a proliferation of “nickelodeons”—makeshift theaters named for the price of admission—equipped with seats, a projector, and a piano. Many nickelodeons were originally installed in working-class neighborhoods, but around 1905 exhibitors worked hard to widen the movie-watching market to include the middle class. Demand soon escalated, and movie companies adapted by developing better mass production and techniques.

Mass production entailed a transition from the cameraman system of creative control to the director system and initiated an industry-wide shift away from documentary films toward narrative films. Under the director system, production labor was divided between a director, who coordinated and managed all aspects of production from scenario development to editing, and the cameraman, who handled the nuts and bolts of the photography and film developing. Narrative fiction became the budding industry’s genre of choice because it offered producers greater control and efficiency than was possible for documentary films, which depended on the uncertain supply of newsworthy events. Edwin S. Porter’s film *The Great Train Robbery*, filmed for Edison in 1903, broke new narrative ground in its length (around 15 minutes) and its depiction of a multiscene story, complete with close-ups and an unprecedented use of editing to build suspense.

Thomas Edison initiated the movie industry’s long tradition of corporate struggle for monopolistic control. Patent infringement suits were Edison’s first weapon against his competitors. With aggressive litigation, Edison sought to preserve exclusive rights to all motion picture devices, and he did manage to intimidate some companies from the U.S. market for a while. But Biograph held its ground and won an appeal of an important test case that Edison had won in a lower court. Before the legal battle could reach its conclusion, however, Edison changed tactics and began making pacts with his competitors. The final result was the Motion Picture Patents Company (MPPC), an organization formed in 1908 for the purpose of preserving the patent rights of all of its members, which included Biograph and other major producers. Through a system of licenses and fees for the use of motion picture equipment, the MPPC managed to exclude newcomers to the industry while sewing up the market for the technologies and films owned by its members. Ultimately, the MPPC, known informally as “the

Trust,” bought out almost all of the distributors to which it had granted licenses and formed its own distribution organization: the General Film Company.

The power of the Trust was eventually challenged by independent companies. Some independents confronted the Trust head-on by offering theaters a full program of short subjects that could rival those marketed by the MPPC. Carl Laemmle’s Independent Motion Picture Company, for example, bypassed the Trust’s distribution system by banding together with other independent filmmakers to create Eastman Kodak.

Other filmmakers, such as Adolph Zukor, avoided direct competition over the market for one-reel short subjects by pioneering the multiple-reel feature film and creating the distribution and exhibition system necessary to market the new form. Producers of feature films aggressively promoted products and, starting with small-time vaudeville houses, gradually built up a network of exhibition venues that could generate the revenues required to pay for the high production costs of long features. The expansion of the feature film market led to the construction of palatial theaters dedicated solely to the exhibition of motion pictures. This sort of movie theater served the needs of the feature film producer much more effectively than the nickelodeons, which could accommodate only small audiences. Feature films also encouraged the development of the star system. By promoting individual actors and actresses, movie companies could guarantee a market for risky high-cost features. Performers like Charlie Chaplin, Mary Pickford, and Douglas Fairbanks quickly became hot commodities and commanded enormous salaries.

Competition and an antitrust suit, *United States v. Motion Picture Patents Co.*, ultimately broke the hold of the MPPC over the industry. Other companies, however, were already integrating production, distribution, and exhibition operations on an unprecedented scale. This process of cohesion soon left the industry in the hands of a few massive studios known as “integrated majors” and ushered in the “studio era” of movie history. In 1916 Adolph Zukor executed a takeover of Paramount, a national distribution company that was created in 1914 to fill the distribution needs of feature film producers. Paramount then became a subsidiary of the new corporation formed by the merger of Zukor’s own Famous Players company with the Jesse L. Lasky Feature Play Company. By the time the restructuring was completed in December of 1917, the Famous Players-Lasky Corporation had set a new standard of scale for the motion picture industry. In 1919, Zukor set about acquiring theaters, and in 1926 he inaugurated the Publix Theater Corporation. By controlling the production, distribution, and exhibition of its films, Zukor’s organization became the first fully integrated movie company. Marcus Loew achieved a similar

integration starting from the exhibition end of the industry, adding producer-distributor Metro to his theater chain in 1920. His company went on to acquire Goldwyn Pictures Corporation and Louis B. Mayer's production company, creating the studio that would eventually be known as Loew's Metro-Goldwyn-Mayer. By 1925 four companies held most of the power in the industry: Zukor's Paramount, Loew's, First National, and Twentieth Century Fox.

In the early 1920s, the major movie companies set about consolidating their gains and securing the place of movies in American culture. Financial institutions began to see the prospering movie industry as a legitimate investment. Although bank loans for movies were unheard of before the 1920s, in 1926 \$1.5 billion of the industry's capital came from outside investment. To combat attempts by outside groups to censor movies, industry leaders created the Motion Picture Producers and Distributors of America (MPPDA) and hired prominent Republican Will Hays to head the organization and enhance the industry's respectability.

Just as the industry was settling into a stable status quo, the advent of sound technology upset the balance and resulted in two new major competitors: Warner Brothers and RKO Corp. Warner Brothers paved the way for the "talkies" when *The Jazz Singer*, using Western Electric's Vitaphone system, set off a national craze for movies with sound in 1927. Riding the flood of profits from the breakthrough, Warner was able to finance a massive expansion effort that put it in the ranks of the industry giants. Meanwhile, RCA had been working on a sound system to rival Vitaphone, which it called Photophone. In October of 1928 RCA created the Radio-Keith-Orpheum (RKO) Corporation, a fully integrated major studio from the very moment of its birth, in order to make use of the new technology. A slightly altered hierarchy of industry leaders emerged from the talkie revolution, with Warner Brothers, MGM, Twentieth Century Fox, Paramount, and RKO dominating the field as integrated majors. Columbia and Carl Laemmle's Universal (a later version of his Independent Motion Picture Company) controlled powerful production and distribution arms but lacked theater chains and were relegated to the status of "major minors."

Most majors and major minors employed similar systems of production in the late 1920s and early 1930s. The owners and corporate officers of a company were typically based in New York City, whereas most production took place in sprawling studio complexes in Hollywood, California. Hollywood's colony of movie studios had been growing since the early 1910s as more and more producers took advantage of the area's sunny weather and diverse scenery for movie making. In a studio's West Coast operation, a central producer served as an interme-

diary between the financial concerns of the New York office and the creative concerns of Hollywood, overseeing such aspects of the process as script development, casting, and the production schedule to ensure that the studio produced marketable films as quickly and economically as possible. At MGM's Culver City studio, for example, central producer Irving Thalberg oversaw the production of one-third of the studio's projects himself (usually the big budget features that used the studio's most popular stars), whereas the rest were handled by supervisors nicknamed "Thalberg men" who answered directly to Thalberg. Thalberg shared the upper ranks of the Culver City management with studio boss Louis Mayer, who handled the studio's talent (the stars and directors), and E.J. Mannix, who handled the physical production facilities.

Censorship continued to be an issue during this period as reform groups pressured the industry to adopt stricter standards of decency in movies. Will Hays and the MPPDA responded in 1930 by replacing the trade organization's relatively informal list of "Don'ts and Be Carefuls" with a more comprehensive document entitled *The Motion Picture Production Code*. Although the new guidelines provided a more rigorous standard of decency for film producers, it made no provision for its own enforcement. Producers began to ignore the code when the economic pressures of the Great Depression made them resort to more controversial material to attract viewers, and the Legion of Decency waged a bitter protest in response. In 1934 the MPPDA created the Production Code Administration, a censorship board empowered to prevent offending films from reaching audiences in theaters affiliated with the MPPDA. This form of industry self-censorship proved to be acceptable to champions of moral decency and remained intact for decades.

The Depression dealt a heavy blow to the movie industry, but with the help of President Roosevelt's National Industrial Recovery Act (NIRA), the industry was able to regain its footing quickly and maintain a healthfulness unusual for the era. Between 1930 and 1931 the total profits of the eight leading movie companies fell from \$55 million to \$6.5 million. NIRA, enacted in June 1933, loosened restrictions on monopolistic business practices in hopes that the increased freedom would help large corporations lead an economic recovery. When NIRA was ruled unconstitutional in 1935, it had already helped the major studios strengthen their hold on the movie industry and get back on their feet. The latter half of the decade marked the beginning of a new period of creative fertility and financial prosperity for the film industry.

The 1930s also marked the transformation of the central-producer system of production management. Although the central producers of the 1920s had helped the

majors develop production methods, it eventually became clear that these methods had become so ingrained in the studio system that they no longer required the guidance of central producers like Thalberg. The middleman between the administrative and creative branches of the typical corporate structure disappeared, widening the split between the New York corporate headquarters and the production process and allowing individual artists greater control over film production. The central management teams at the Hollywood studios came to assume a more purely administrative character, backing away from the sort of hands-on approach they had taken in the past. The unit production system that came to replace the central-producer system dispersed production authority over a number of “unit producers.” These unit producers were essentially “Thalberg men” without a Thalberg—supervisors who oversaw a relatively small number of projects without having to report constantly to a central supervisor.

In 1938 the U.S. Justice Department began the campaign of anti-trust litigation that would eventually result in the demise of the studio system. By controlling the production, distribution, and exhibition of movies, the integrated majors had been able to use strategies such as block booking, the practice of forcing theaters to book movies in blocks, which included a few quality films with several B-grade productions. As a result of the 1938 court battle, the integrated majors consented to curtail block booking and other tactics that took advantage of the integrated structure.

Before the final demise of the integrated studio system, however, the majors enjoyed a boom brought about by World War II. The wartime economy gave Americans the money they needed to go to the movies, and the movies satisfied their hunger for morale-boosting entertainment. The prohibition of block booking forced studios to de-emphasize B-movie production, which led to an increase in the quality of films that ultimately benefited the majors. Following recommendations issued by the Office of War Information, Hollywood fed America a steady diet of war movies and other patriotic fare. This boom lingered for several years after the war ended.

In the late 1940s, however, the Justice Department resumed its anti-trust campaign against the majors, and with the advent of television, the end of the studio system was drawing near. The consent decrees forced out of the integrated majors by the 1938 court battle had expired toward the end of the war. In May 1948, however, the Supreme Court upheld a decision against Paramount that restricted block booking, admission price fixing, and other practices classified by the decision as illegal restraint of trade. The battle continued as the Justice Department pursued its ultimate goal of forcing the integrated majors to give up theater chains. In order to avoid further legal

conflict, Paramount and RKO signed consent decrees requiring them to divest all theater holdings, and Loew's MGM, Twentieth Century Fox, and Warner Bros. soon followed suit. The five integrated majors became producers and distributors but lost exhibition powers. Independent producers soon took advantage of the increased access to theaters created by this divestment. The number of independents doubled between 1946 and 1956. Divestment also weakened the power of the Production Code Administration. Without the theater chains, the five majors who dominated the MPPDA could no longer threaten to deprive offending movies from exhibition.

The year 1948 also marked the beginning of the television era. Americans owned 172,000 television sets in that year, compared with 14,000 the previous year. Combined with the post-war trend toward suburbanization, the rise of television ate into movie companies' profits. Between 1946 and 1956 the combined profits of the top 10 movie companies fell 74 percent. As companies tightened their belts, they discarded the practice of maintaining a stock of actors and directors under long-term contract. As a result, talent agencies assumed a more important role in the industry, frequently operating as “packagers” who sold the studios a preassembled combination of star, director, and story scenario or script. In order to provide consumers with entertainment they could not get on a small black and white television screen, moviemakers produced more color films and blockbuster epics and experimented with gimmicks like 3-D and the wrap-around screen of Cinerama.

At the same time, some movie companies tried to exploit the television market. While a number of independent companies like Desilu Productions were created specifically for the purpose of producing television programming, established movie companies also began to explore the possibilities of “television” production. Columbia led the way in 1949 by converting its Screen Gems subsidiary into a television outfit. The Walt Disney Co. combined program production with advertising when it created its *Disneyland* television series, complete with plugs for its current movies. By 1963 almost 70 percent of prime-time television programming was being produced in Hollywood. Some of the leading Hollywood television outfits were run by old major movie studios, while others like MCA (originally a talent agency) became major production operations only after the advent of television.

Movie companies also took advantage of the new market created by television by selling old films to television stations. In December of 1955 a programming syndicate bought RKO's library for \$15 million; Warner's library went for \$21 million the following February. Before long all of the major studios were capitalizing on this type of asset, and they soon realized the true value of

old films to television networks hungry for programming. By the 1960s an amicable relationship had developed between Hollywood and the networks, with Hollywood-based companies providing both new programming and old products.

Federal action further solidified the role of the major studios and other non-network producers of network programming. Fearing that the networks could gain monopolistic power over television communication, the Department of Justice filed an antitrust suit in 1972. As a result, the networks signed consent decrees limiting the amount of program hours a network could produce for itself and stipulated that networks could gain no financial benefit from the syndication of programming. The Federal Communications Commission (FCC) altered this rule 19 years later to allow networks to own up to 40 percent of the syndication rights of their prime-time programming.

Having experienced the benefits of diversification into television, the majors diversified into other entertainment markets, such as music recording, by acquiring or creating new companies. Some production companies became a part of diversified corporate structures through a different route: by being acquired themselves. In 1966, for example, Gulf + Western took over Paramount. Hotel developer Kirk Kerkorian acquired MGM in 1969, and the same year Kinney National Services took over Warner Brothers. By the end of the 1960s the heavily diversified media conglomerate had become the standard corporate structure in the movie and telefilm production business.

In 1969 this trend toward expansion was interrupted by an industry-wide crisis. The heavy emphasis on high-grossing films had placed many movie companies in risky financial positions, and the advent of three new major production companies (ABC, CBS, and National General) created a glut of big-budget pictures. At the same time, the market for feature films on television also became saturated. Television audiences could watch a feature film on network television every night of the week, and the networks had accumulated a stock of films that would last for several years. Hollywood had come to rely on the television ancillary market as a way to stabilize risky productions, and this crutch was suddenly no longer secure. As movie studios tried to cope with the losses created by over-production, they trimmed corporate structures and began to emphasize low-budget films. Although the success of *The Godfather* in 1972 quickly revived the credibility of the blockbuster strategy, movie companies had learned to be cautious. They realized that the market could support only a few big hits a year, and they began to capitalize on the reliable profitability of sequels to popular films like *Rocky* and *Jaws*.

The next revolution in television and film production took place in the 1980s, as new television technologies

became commonplace. Videocassette recorders allowed consumers to do their own television programming, and cable television and satellite broadcasting popularized such programming innovations as pay TV services and 24-hour music video stations. Although some analysts feared that these new technologies would threaten the motion picture industry, they actually had the opposite effect of providing new ancillary markets for feature films. Home Box Office (HBO) led the way for pay television by using satellite broadcasting at a time when few cable companies had the equipment to receive such broadcasts. The gamble paid off as more and more cable companies bought receiving dishes. After HBO successfully fought FCC regulations designed to protect free television, other premium channels such as the Movie Channel and the Disney Channel debuted. Not only did these channels need films to fill programming schedules, they also occasionally financed the production of new movies in order to supplement their supply.

Home video similarly affected the financing of movies. Producers could sell video rights before production on a film even started and apply the proceeds toward the cost of the film—an arrangement particularly useful for small independent producers. Videocassettes provided yet another arena in which filmmakers could exploit products. At the same time, however, videocassette rental and home taping of movies from television decreased the power of studios to garner profits from every exhibition of a film. Once a rental store or home viewer had its own copy of a movie on tape, that tape could be shown repeatedly and the production studio would gain nothing. MCA and Disney had tried to nip these practices in the bud in 1976 by accusing Sony, the manufacturer of the Betamax Videocassette Recorder, of copyright infringement. By 1981 the *Betamax* case had reached the Supreme Court, which ruled that neither taping a broadcast for home use nor purchasing a cassette for the purpose of rental constituted copyright infringement. Although the Betamax machine itself eventually became extinct due to the popularity of the VHS cassette format, cassette rental and home taping became everyday practices.

In addition to these new ways of exploiting the feature film, new technology also brought a new form of film and video art—the music video. Music videos originated in the United States as a programming strategy for the Warner Cable Corporation (WCC), a division of the giant media corporation Warner Communications Inc. By April of 1979, WCC had two satellite-broadcast channels available for cable systems: Nickelodeon and Star, a pay channel that later became The Movie Channel. When John A. Lack became executive vice president of WCC, the operation was losing money, and he attempted to turn WCC around by expanding the preschool audience of Nickelodeon to include teenagers. The centerpiece of

Lack's new format was a show called *Pop Clips*. Produced by Mike Nesmith, formerly of the rock group the Monkees, and his Pacific Arts Corporation, *Pop Clips* consisted of a half-hour of short video clips accompanying pop songs. The idea caught on, and Lack went on to create Music Television (MTV), a 24-hour cable channel composed entirely of such clips or "videos." The new channel debuted on August 1, 1981.

Initially, a scarcity of programming material posed a problem for the network. The videos were provided at no charge by recording companies and were originally produced as promotional material for distribution to European television networks. MTV's original library of videos numbered no more than 125. Only when the value of MTV as a promotional medium started to assert itself did the recording industry invest in large-scale video production. Companies continued to provide videos free of charge until competing video music programs like NBC-TV's *Friday Night Videos* entered the market, creating a potential demand for exclusive rights to exhibit videos. NBC broke the ice by offering to pay for the right to premiere a video and have exclusive access to it for two days. By the time this "pay for play" policy became common practice, however, it became obvious that MTV had the competitive advantage in bidding for exclusivity. Recording companies valued the access offered by a 24-hour station to acts that might not make it onto a two- or three-hour video show, and MTV threatened to withhold this access from labels that favored other video programs with exclusive deals. Using tactics like these, MTV fiercely defended its status as the nation's primary source of video music entertainment. Rival 24-hour music video channels, such as the Discovery Music Network and Ted Turner's short-lived Cable Music Channel, challenged MTV's reign and failed.

With undertakings like MTV, Warner and other leaders of the motion picture and video production industry continued to diversify, expand, and set new standards of scale for media conglomerates. For many corporations, this sort of expansion could not continue indefinitely. Gulf + Western jettisoned many of its non-communications holdings in order to concentrate its corporate structure on the entertainment industry, and in 1989 renamed itself Paramount Communications Inc. to reflect this newly found focus. Similarly, when the popularity of Atari collapsed in 1982, Warner sold its video game operation along with many of its other ventures, including MTV. Nevertheless, Warner went on to merge with Time Inc. in 1989, and Time Warner became a media conglomerate of unparalleled size.

In the shadows of these giants, smaller film and video producers continued to make their voices heard. The new options for film financing offered by home video and other ancillary markets fueled a boom in independent production

during the mid-1980s. Mini-majors and independents increased production by 100 movies per year between 1984 and 1987. In the late 1980s and early 1990s this boom resulted in a glut that damaged some independents.

In the early 1990s the motion picture industry suffered from the effects of the recession. While movies brought in a record \$5 billion at U.S. theaters in 1989, box office receipts declined in the following two years, totaling approximately \$4.8 billion in 1991. Box office receipts rose to about \$4.9 billion in 1992, but increased ticket prices accounted for much of this rise. Admissions actually declined from 1.1 billion in 1990 to about 977 million in 1992, sinking below the lowest levels of the 1980s. Decreasing attendance seemed to translate into a decreased volume of production. In the first half of 1992 production started on 173 films, down from the 224 films that were started in the first six months of 1991. Independent production companies accounted for 150 of the 1991 film starts and 122 of the 1992 starts.

Increasing video sales softened the blow of falling box office figures. In 1992 an estimated \$12.2 billion in revenues were gained from home video sales at retail outlets, up from \$11.5 billion in 1991 and \$10.8 billion in 1990. The demand for videotapes has been stimulated by a steady increase in the number of households with videocassette recorders (VCRs). According to the Electronic Industries Association, 77 percent of U.S. homes owned a VCR at the beginning of 1992, up from 72 percent in 1991. Just six years earlier less than 20 percent of U.S. homes were equipped with VCRs.

The demand for movies, television shows, and other forms of filmed entertainment has grown over the last 15 years as cable and home video have made it easier to deliver a wide variety of programming to consumers in their homes. In coming years the continued growth of movie and video production may depend on new innovations in delivery systems. Pay-per-view (PPV) systems may offer one such direction for growth. U.S. consumers paid a total of \$350 million for PPV programming in 1992. This amount represents 3 percent of total spending on videocassettes.

By 1995, box office sales were back up over the \$5 billion mark, but profits continued to erode in spite of increasing sales to the video and TV markets. Much of the decline could be attributed to the rapidly inflating costs of production and the industry's increasing reliance on "blockbuster" films as a primary source of revenue. After the release in the early 1990s of such films as *Jurassic Park* and *Terminator 2*, Hollywood movies became special-effects extravaganzas, with each new film upping the ante in an attempt to dazzle an ever-more jaded audience. Each year saw a new record set for production costs, with 1995's *Waterworld* totaling \$150 million. Although some of these films—like 1996's *Inde-*

pendence Day —were hugely profitable, they seldom brought in enough to cover less successful films. Not surprisingly, profit margins shrank, pressuring film producers to focus even more on producing sure-fire hits. So-called “big-event” films became the mainstay of Hollywood. In addition to pumping out a seemingly endless stream of sequels, the industry turned to old television shows and comic books in search for product with a built-in audience. Major films of the 1990s, including *The Flintstones*, *The Addams Family*, *The Beverly Hillbillies*, *The Brady Bunch*, *Mission Impossible*, *The Saint*, and *The Prisoner*, were all based on television programs from the 1960s and 1970s. Comic book heroes such as *The Phantom* and *Judge Dredd* were also turned into film stars, though with less success.

Hollywood inflation was also fueled by the studios’ need to grab attention in a crowded marketplace. Marketing costs rose dramatically through the early part of the decade, jumping 20 percent between 1995 and 1996 alone. Talent fees also rose rapidly through this period, with actors such as Tom Cruise, Tom Hanks, Jim Carrey, and Arnold Schwarzenegger routinely getting anywhere from \$10 to \$20 million per picture. With costs leaping out of control, even major studios found it increasingly difficult to come up with the funds necessary to produce a “big-event” film. One solution was collaboration. In 1996, for example, Tri-Star teamed up with Disney to produce *Starship Troopers*, a big-budget science fiction film directed by *Robocop*’s Paul Verhoeven. Even without any major stars, this film was still expected to cost more than \$100 million.

The trend in the motion picture industry at the close of the 1990s was the belief that the bigger the budget, the more successful the film. As the production costs for more and more motion pictures reached or exceeded \$100 million, the studios were in the perilous position of trying to recoup costs at a box office that was increasingly being threatened from cable television, video sales, and the Internet and other new communication technologies. For every mega multimillion dollar hit like 1997’s *Titanic* and 1999’s *The Phantom Menace*, there were scores of underachievers that further depleted the coffers of the major studios.

In 1998, in an attempt to increase revenue sources, the motion picture companies increased the amount of money cable companies had to pay them for the rights to air pay-per-view movies. Motion picture companies were asking for a 5 percent increase in revenues that would bring up their cut of the pay-per-view fee to one-half. Cable operators were fighting this increase as the decade ended. The revenue-sharing agreement between the studios and video rental chains was also revised, although this revision was a bit more amenable to both participants. Previously, the studios charged a costly fee, some-

times \$50 per copy of a rental videocassette to the video stores because the stores kept the income generated from each rental of the tape. As a result, stores would often purchase only a few copies of a popular title because of the prohibitive cost involved. The studio began to change that practice in the late 1990s as they set up revenue-sharing agreements with the video chains in which the studios would cut the cost of the rental cassette and share in the profits from the rentals of the tape.

Late 1999 saw the addition of the newest player in the motion picture distribution arena, Amazon.com, the Internet book and music superstore. Amazon.com has become involved in the distribution of independent films that may not have had a chance to be released any other way. Amazon touted independent distribution outlet as a new avenue for acclaimed and underground filmmakers.

CURRENT CONDITIONS

According to research from the Motion Picture Association of America (MPAA), box office sales continued to increase in the early 2000s despite the rising popularity of home entertainment options like DVD, weak economic conditions, and rising U.S. unemployment levels. Sales increased from \$7.7 billion in 2000 to \$8.4 billion in 2001, and then grew more than 13 percent in 2002, hitting \$9.5 billion. The number of films produced by the industry has declined in recent years, falling from 683 in 2000 to 611 in 2001, and 543 in 2002. On a per-feature basis, the MPAA reported that in 2002 its members incurred average production, overhead, and interest costs of \$58.8 million. Average marketing costs that year totaled \$30.6 million, the majority of which (\$27.3 million) was attributable to advertising. Production and service-related industry employment was projected to reach 259,000 in 2002, down from 270,000 in 2000 and 265,000 in 2001.

By the early 2000s, DVD technology was making big waves throughout the entertainment industry. As consumer sales of DVD players exploded, strong growth took place in the home video market. Consequently, the leading entertainment companies released remastered versions of older titles from their libraries, in addition to new blockbuster releases. According to the MPAA, the number of titles available on DVD increased from 8,500 in 2000 to 20,000 in 2002. During this period, average DVD prices declined from \$22.65 to \$20.78.

The Consumer Electronics Association (CEA) revealed that manufacturer sales of DVD players reached 17.6 million units in 2002. This represented an increase of 39 percent over 2001 and pushed DVD penetration among U.S. households to 35 percent. Unit sales were expected to exceed 20 million units in 2003, fueling growth of 14 percent. The DVD Entertainment Group predicted that DVD penetration would exceed the 50 percent mark by the end of 2003. Citing figures from

Adams Media Research, the MPAA reported that industry sales of home entertainment on videotape declined from nearly 670 million units in 2000 to 483 million units in 2002. Meanwhile, DVD sales increased almost 103 percent from 2000 to 2001, growing from 188 million units to 382 million units. Sales climbed another 84 percent in 2002, reaching 702 million units.

INDUSTRY LEADERS

If one measures success in terms of box office market share, six large producer-distributors consistently lead the film entertainment industry: Warner, Disney, Fox, Universal, Sony, and Paramount. Competition is fierce, and rarely does a single company hold the top position for long. The multimedia conglomerate AOL Time Warner was the industry leader in 2001; Universal and Paramount were close behind. Disney, Fox, and Sony rounded out the top six. Together these companies accounted for about 70 percent of domestic box office sales in the early 2000s.

Warner and Paramount have both continued to rank as major studios since the studio era. Warner first achieved major status with the success of its sound technology. Paramount was, in fact, a division of the first studio to become fully integrated. Universal, a descendent of Carl Laemmle's Independent Motion Picture Company (a rival to Edison's "Trust"), was classified during this period as a "major minor" studio in spite of its major production and distribution capabilities, primarily because it lacked an exhibition arm.

Unlike these three studios, Disney operated as an independent studio specializing in animation during the studio era. Only when it began producing live action movies in 1953 did it attain major status. Throughout the 1950s and 1960s, Disney blazed the trail for diversification into a variety of entertainment markets. With its "Disneyland" network series it became one of the first movie studios to explore the promotional possibilities of television. The company's theme park in California provided 60 percent of its profits in 1969. Universal later followed suit with its Universal Studios theme park, and in 1992 Paramount bought into five theme parks. Disney's other early diversification efforts included publishing, recording, and merchandising. Throughout its development as an entertainment corporation, Disney has specialized in the family market. Not until the 1984 release of *Splash* under its new Touchstone division did Disney try to break into the adult market. Since then, the company has increasingly entered the adult market, but its target audience remains the family.

The entrance of the Sony Corporation into the film market in 1989 with its acquisition of Columbia Pictures and Tri-Star brought another major player into the business. Sony's vast resources and eagerness to integrate its

hardware and software divisions with its new entertainment arm helped spur the explosion of production costs that occurred in the 1990s. Other Japanese electronics giants such as Matsushita Electric (Panasonic) and JVC followed Sony's lead, briefly leading to fears that Hollywood would fall under foreign control. But Matsushita's 1992 purchase of Universal Pictures soon proved a bust and the company sold 80 percent of its shares to Seagram's Co.

SERVICES ALLIED TO MOTION PICTURE PRODUCTION

This category includes establishments primarily engaged in performing services independent of motion picture production, but allied thereto. These include motion

picture film processing, editing and titling, casting, wardrobe and studio property rental, motion picture and video tape reproduction, and stock footage film libraries.

NAICS CODE(S)

- 512191 (Teleproduction and Other Post-Production Services)
- 561310 (Employment Placement Agencies)
- 532220 (Formal Wear and Costumes Rental)
- 532490 (Other Commercial and Industrial Machinery and Equipment Rental and Leasing)
- 541214 (Payroll Services)
- 711510 (Independent Artists, Writers, and Performers)
- 334612 (Prerecorded Compact Disc (Except Software), Tape, and Record Manufacturing)
- 512199 (Other Motion Picture and Video Industries)

INDUSTRY SNAPSHOT

This highly fragmented industry covers a range of services and products geared toward the production of motion pictures. Usually, firms engaged in this sector focus mainly or exclusively on a specialized operation and generally contract their services to motion picture producers or distributors. As small, relatively unleveraged firms, these hired guns are often forced to compete with each other on pricing in order to attract major Hollywood studios as well as independent filmmakers, who typically work with a tight budget.

By the late 1990s, major studios, such as Disney and Twentieth Century Fox were investing in large facilities to house equipment for post-production activities such as editing and sound mixing that can be accomplished on site. Some, like Twentieth Century Fox, boast complete ground-up digital integration, bypassing the need for analog sound conversion. Others include wardrobe and scenery stocks and tape reproduction facilities; thus, the firms engaged in services allied to motion picture production were scrambling to maintain their viability in this increasingly consolidated marketplace, often positioning themselves as an attractive purchase for major studios.

The hottest sector of the industry in the late 1990s was the production of special effects and animation. The astounding success and proliferation of films and movies featuring computer-generated special effects led to a rapid expansion and enhancement of these technologies. Film studios were engaged in competition to dazzle audiences with the most amazing visual images. By the end of the 1990s, 16 of the 20 largest all-time box-office hits had sold themselves primarily on special effects.

ORGANIZATION AND STRUCTURE

The overall structure of the services allied to motion picture industry is distinguished by a heavy reliance on subcontracting and freelance talent. Firms rarely enjoy

movie-gross percentages and remain fixed on jumping from one short-term contract to another. As a result, these companies are usually in a poor bargaining position with studios, a feature that is exacerbated by the highly fragmented nature of the industry. They are continually forced to monitor the contracts competitors enter into in an effort to out-price them and attract studios.

The key players in the industry—directors and producers—develop strong relational networks based on previous successes and reputations. The production team, which is composed of primary and allied production services, brings together a diverse group of professionals, services, and capital equipment. These relationships are temporary, created for the single purpose of producing a particular film. However, such temporary organizations are reassembled with the production of each new film; a service provider's reputation is a paramount factor in his/her ability to facilitate membership in the new network.

Motion picture production is a highly complex business that involves an interplay of commercial and creative considerations. There are a number of interrelated activities that may be broken down into four phases: development, pre-production, production, and post-production.

Development. The development stage involves acquiring literary rights, writing and developing a screenplay, and hiring key creative personnel such as the director and the cast. Key allied services during the development stage include those offered by literary agents and talent and casting services.

Literary agents represent writers and directors. Agents negotiate for their clients and review scripts. They make determinations regarding what projects constitute good film property and then convince producers and actors to take on these projects. Most literary agents are involved in the development of potential deals, concept development, and the provision of creative and practical advice on translating a script into a motion picture.

Casting for a motion picture is usually the result of interaction between the casting director and casting consultants or services. The casting director is responsible for casting roles and maintaining an ongoing relationship with talent and casting consultants. Casting consultants are hired on an individual-project basis. They function as an actor clearinghouse for the director. Casting consultants seek out and hire actors, negotiate salary and billing issues with the actors' agents, prepare contracts for all actors, and make "first work" calls. In the late 1990s, the key player in the casting service business was the Casting Society of America. Most other major casting service firms were located in and around the Los Angeles/Hollywood area.

Pre-production. During pre-production, the remaining creative personnel are hired, a budget is developed, shooting schedules and locations are planned, and other necessary steps are taken to prepare the motion picture for primary photography. Key allied services during the pre-production stage include studio and production facility rental services.

The most prominent studio facilities are the mainstream producers of large-scale release motion pictures. These include Twentieth Century Fox, Warner Brothers, Columbia/Tri-Star, Universal Studios, Paramount, Disney/Buena Vista, Sony, New Line, Miramax, and MGM. However, the industry is really a continuum ranging from mainstream studios to true independent producers. The mainstream studios control nearly 90 percent of the revenue in theatrical rentals but are responsible for only 42 percent of the production starts. There are many small productions, then, that utilize small, independent production facilities; this is especially true of productions filmed outside of the Los Angeles/Hollywood area.

Production. This phase of motion picture development includes the actual filming. Key allied services include animation, camera-equipment rental and operation, costume design and rental, lighting equipment rental and operation, and property and scenery design, rental, and maintenance.

It is during the production stage that the division between equipment rental/provision and operation is manifested. Equipment provision services are conducted by a number of independent firms; equipment operation, on the other hand, is conducted by union employees. The most prominent entertainment unions in this area is the International Alliance of Theatrical Stage Employees (IATSE) and Moving Picture Machine Operators of the United States and Canada.

Animation is the process of exposing film by individual frames while introducing a slight change in the photographed object or drawing following each exposure. By linking hundreds or thousands of frames, the materials become animated, moving in accordance with the intention of the individual creating the film. Other animated files are created by single frame exposures of models or objects. Film special effects are increasingly dominated by digital animation. Technological advances have allowed lower production costs in animation, allowing increased use of animation in motion picture openings, commercials, and special effect simulations. Animation and special effects are dominated by a small number of firms, unlike most sectors of this industry. This sector generates estimated revenues of \$600 million each year, a figure that has more than doubled since 1993, as more movies incorporate or feature animation and special effects. Prominent players include George Lucas' Indus-

trial Light & Magic, James Cameron's Digital Domain, Sony Corp.'s Imageworks, Hanna Barbera, Rankin/Bass Productions, and Walt Disney Studios.

Camera equipment and personnel are an important aspect of motion picture production support. Such elements include the actual photographic device for shooting film; camera-hauling vehicles; the director of cinematography and associated camera crew; and individuals responsible for lighting, setting up, and composing shots. Although camera supply houses do not provide operators, they usually offer ancillary services such as equipment repair.

Costume design is a vital part of the film production process. Costume rental firms exist in virtually every major city, due to demand not only from motion picture production, but local theater and private costume rental.

Lighting equipment rental and operation is another important service. Although setting the position of lights on the set is the responsibility of the director of photography (cinematographer), the cumbersome nature of film lighting equipment makes actual implementation both difficult and time consuming. There are more than 100 lighting equipment firms in both Los Angeles/Hollywood and New York. Lighting technicians, repairmen, and lighting operators all fall under this category.

Property and scenery design, rental, and maintenance is an important production element as well. Property (or "props") includes any moveable item seen or used on a motion picture set. Scenery includes any background or backdrop used in a studio. There are several key professionals engaged in prop design and maintenance. A "prop maker" is frequently a member of the construction department (usually a carpenter) who is responsible for making the necessary props. A prop master is responsible for maintenance, availability, and placement of props on the actual set. Scenic artists are responsible for production of all illustrations, scenery and set designs, scale models, props and other set dressings. More than 90 percent of property and scenery rental firms make their homes in the Los Angeles and New York areas.

Post-production. In post-production, the picture is edited into its final form; music, dialogue, and sound effects are synchronized with the picture, and special effects are completed, resulting in the negative from which release prints are produced for distribution. Key allied services include computer colorization, cutting rooms, editing equipment and services, film processing and preservation, music libraries and cutting services, sound and recording services, special effect services, subtitle services, and trailers.

Editing equipment and services are essential to the post-production process. Editing involves joining to-

gether the various pieces of film shot by the cinematographer into a single, cohesive, and dramatic whole. The autonomy experienced by the editor depends on the director. For some films, the editor and director will work closely in selecting each shot and determining where to cut, splice, and edit. Accordingly, some directors shoot a large quantity of footage, allowing the editor a great deal of choice; other directors shoot less footage, providing the editor with less autonomy.

As is common in this fragmented industry, editing equipment, editing services, and editing personnel are provided by three different groups of organizations. There are more than fifty editing equipment firms, the majority of which are located in Los Angeles and New York. More than 100 firms, represented equally between New York and Los Angeles, provide film editing services.

Other major post-production services include: (1) Cutting rooms—specially designed facilities equipped with editing equipment where the editor and assistants can put the final film together. (2) Film processing and preservation—the actual development of the film into a negative and subsequent processing, copying, and preservation. Technicolor was an industry leader for this service. (3) Music libraries and cutting services; sound and recording services—these services include the process of recording sound during production and subsequently editing and adding sound to the final product. Some producers use stock music by anonymous composers to develop a sound track, while others utilize commissioned musicians. Again, this segment of the industry is highly fragmented, with more than 100 firms engaged in music cutting and music libraries and more than 100 firms that provide sound and recording services. Sound technicians include: production mixers who are responsible for sound equipment and recording on set; boom operators who operate the microphones to pick up actor's dialogue; re-recording mixers engaged in combining sound in the studio; and sound effects mixers, responsible for sound effects both on the set and in the studio. (4) Special effect services—special effects include a wide variety of creative photographic and sound effects. There are more than 50 special effects firms, which operate primarily in Los Angeles and New York, but also in such locations as Las Vegas, San Francisco, and Orlando. Prominent firms include Buena Vista Visual Effects Group in Burbank, California; Lucasfilm, Ltd., in San Francisco; and Walt Disney/MGM Studios in Orlando. (5) Subtitle services—subtitles refer to titles that appear at the bottom of the screen of foreign language films or to narrative titles in silent films.

CURRENT CONDITIONS

Firms engaged in services allied to motion picture production are intimately tied to the success of the film industry as a whole and, as such, keep a close eye on box

office receipts. The late 1990s did not disappoint. Box office receipts finally emerged from their stubborn mid 1990s stagnation, increasing from \$5.9 billion in 1996 to \$7.0 billion in 1999. Foreign sales showed an even faster growth in the last 1990s, rising more than 10 percent annually between 1996 and 1999.

As major studios attempt to streamline their production operations and limit costs, they increasingly integrated operations covered by this industry into their organizations. Firms specializing in the various sectors of services allied to motion picture production were purchased by large film and telecommunication firms, such as when AT&T's Liberty Media Corp. purchased the California-based Four Media Co. in 1999. The effects company Digital Domain was likewise purchased by chip-manufacturer Intel. Such moves were indicative of the overall trend toward integration of high-level technological platforms for use in both entertainment and communications.

There was tremendous concern in the late 1990s in the film industry over the loss of jobs to runaway production, in which film producers take production to Canada and other foreign countries, largely to capitalize on the favorable exchange rates that make production in those countries significantly cheaper. In 1998, U.S. film and TV production conducted out of the country cost the U.S. economy \$10 billion, an increase of 500 percent since 1990, according to the Screen Actors Guild and Directors Guild. Legislators in California and other states, and at the federal level, responded by introducing bills that offered tax breaks to production that was conducted in the U.S. Despite the growth of runaway production, however, over the same period employment in California's film industry nearly doubled.

For consumers, Hollywood's budget problems meant more sequels and increasingly formulaic films. For businesses involved in providing support to motion picture production, it meant a shrinking market in which relationships with studios were a top priority.

RESEARCH AND TECHNOLOGY

A relatively recent technological advance in the film industry has been the colorization of old films. Colorization is the process by which black-and-white films are transformed into color. The process involves breaking down each frame into 525,000 dots. An art director examines the first and last frame of each scene and programs the colors for each object. There are two primary firms engaged in colorization, American Film Technologies and Color Systems Technology, both of which are located in the Los Angeles area.

Undoubtedly, the most significant technological developments in the film industry in the 1990s occurred in the special effects sector, where computer-generated im-

ages quickly became a staple of Hollywood films, thrusting firms like George Lucas's Industrial Light and Magic and James Cameron's Digital Domain into the national spotlight. Increasingly, the level of special effects assumed a primary selling characteristic for blockbuster films, such as *Titanic*, which featured a special effects budget of \$40 million.

Though computer-generated images have been making tentative forays into films since 1984's *Tron*, manipulating images this way requires vast amounts of memory due to film's superior picture quality. Since the powerful technology needed for this process was too expensive, few movies made in the 1980s used computer-generated images. By the late 1990s, however, cheap, powerful workstations and a wide range of versatile graphics software made computer graphics a viable alternative to the models traditionally used for special effects. The widespread transfer of high-end digital production to computer platforms, which offer tremendous cost benefits, especially in computer animation, afforded allowed major studios to invest more heavily in attracting the top graphic artists and less on expensive equipment. Moreover, small, independent filmmakers were able to process high-level special effects in-house.

The film industry also made aggressive moves toward the use of digital cinema as a replacement for film, a move that has been discussed in the industry for several years. Digital cinema is likely to be incorporated into use with DVD-ROM, a physical distribution that, in the meantime, seems more attractive than satellite and cable due to the increased delivery control afforded by the physical format.

In a development not likely to prove popular among actors, industry observers noted that digital technology had reached a point where just around the corner waited the implementation of virtual actors into major motion pictures, one of the primary foci of the digital animation industry. By combining scores of photographs in a data memory bank, graphic artists can shape features and movements tailored to the needs of the director. While the technology has yet to reach a stage in which the actors appear truly real, analysts note that it is simply a matter of time. Such moves take selective casting of actors to the next level, by literally creating actors from the ground up, allowing directors to get the precise features and capabilities they desire. Such actors could pull off physical stunts beyond the capacities of live stunt actors—without necessitating elaborate set designs.

SIC 7822

MOTION PICTURE AND VIDEOTAPE DISTRIBUTION

This classification covers establishments primarily engaged in the distribution (rental or sale) of theatrical and nontheatrical motion picture films or in the distribution of videotapes and disks, except to the general public. Establishments engaged in both distribution and production are classified in **SIC 7812: Motion Picture and Videotape Production**. Establishments primarily engaged in renting videotapes and disks to the general public are classified in **SIC 7841: Videotape Rental**. Those businesses engaged in the sale of videotapes and disks to individuals for personal or household use are classified in **SIC 5735: Record and Prerecorded Tape Stores**.

INDUSTRY SNAPSHOT

The U.S. motion picture distribution industry in the early 2000s was stratified into two distinct categories: majors and independents. Major studios control the lion's share of movie distribution revenues and show films in large multiplexes and community theaters alike, whereas independent distributors rely more heavily on smaller art houses and rarely achieve the box-office blockbusters enjoyed by the majors. In recent years, majors invested heavily in purchasing many of the leading independent distributors, such as Miramax and New Line Cinema, in a

massive trend toward vertical integration. The remaining independents benefited from the unexpectedly robust box-office success and critical acclaims of a string of high-profile independent films, briefly breathing new life into this struggling market sector. However, by the early 2000s, independent distributors were once again struggling in the shadows of industry giants.

According to the Motion Picture Association of America (MPAA), in 2002 domestic box office returns equaled \$9.5 billion, up more than 13 percent from the previous year's record. This represented the eleventh consecutive year of box-office expansion and was the greatest annual increase in 20 years. Admissions increased more than 10 percent that year, the greatest increase in 45 years. Ticket prices steadily increased during the early 2000s, rising from an average of \$5.39 in 2000 to \$5.66 in 2001 and \$5.81 in 2002.

During the early 2000s, more than 93 percent of domestic box office revenues were attributable to the 10 leading distributors. A total of 467 films were released in 2002, down from 482 the previous year. Of these, 449 were new releases and 18 were reissued films. Major studios produced 225 of these, 29 more than in 2001, whereas independent distributors released 242 films, a decline from the 287 in 2001. Although these numbers seem to favor independent distributors, those films generally maintained very limited reach; in recent years, nearly 90 percent of all ticket sales were accumulated by the handful of leading major distributors. A landmark was surpassed in 1999 when for the first time two distributors, Buena Vista and Twentieth Century Fox, topped \$1 billion in box-office receipts. In 2002, the average feature film grossed \$21.2 million, up from \$18.2 million in 2001 and \$16.7 million in 2000.

World markets for films and television programs have long been critically important to U.S. producers and distributors. Over the past 30 years, foreign markets have generally accounted for about one-half of major U.S. producers' total sales in these industries. The success of American films and television productions in world markets is indicated both by industry trade balances and by comparisons with other film and television exporting nations. The United States has historically exported more than three times the total television programming exports of the next three leading exporting nations combined. For years, U.S. studios were limited significantly by a variety of barriers to trade in foreign markets. In the mid- and late 1990s, they welcomed the relaxation of such restrictions as a result of free trade agreements enforced by the World Trade Organization. By the early 2000s, the increasing adoption of the English language gave U.S. filmmakers an edge over foreign competitors. Growth in the pay television and home video markets were other factors benefiting the industry abroad.

ORGANIZATION AND STRUCTURE

The organization and structure of the motion picture industry has become concentrated in the major Hollywood studios who have taken control over its three major divisions: production, distribution, and exhibition. The organization of the industry into companies that have become fully integrated producers/distributors/exhibitors represents a structure that existed in the 1920s and 1930s but was disbanded under antitrust regulation and then rekindled during the Reagan Administration. This structure has hurt film distributors without established alliances or reputations, known in the industry as "independents," because many of the nation's prime theater venues have relationships with the major distributors who book the larger theaters months in advance.

Typically, a motion picture studio distributes or licenses the rights to its film to an independent distributor, who in turn sells these rights to theaters or exhibitors across the country and abroad. The distributor licenses films to exhibitors by either bidding or negotiation. To obtain the maximum revenue from motion pictures, they are released in a series of runs to theaters across the country. "First run" indicates a picture's initial widespread release to "high gross" theaters across the country. Subsequently, the films are released to lower gross theaters across the country until the earning capacity of the film is finally depleted in the exhibitor market. The film is then marketed abroad by foreign distributors, then released in video format, and offered on cable television before it is syndicated to the television broadcast network.

When an independent distributor pays for the rights to market a specific film from a Hollywood studio, that company then forms a contract with the exhibitor market to show the end product. These contracts take many forms but normally include several key features. The distributors create "zones" or geographic boundaries for their pictures. Normally, within each zone a distributor would only release a particular motion picture to one theater for exhibition. This practice ensures that the distributor will obtain the largest audience for a film, and it prevents other theaters in close proximity from competing for the same customers who might wish to see that particular movie. There is usually a clearance clause in the contract that relates to the amount of time that must elapse between the end of the first run of a motion picture and the beginning of its subsequent runs. Longer clearances provide more first-run revenues for a picture. Finally, many of the distributors of "A" rated films also practice block booking. Block booking is the practice of offering for license one feature, or a group of features, on a condition that the exhibitor also license another feature, or group of features, released by a distributor during a given period. Block booking ensures outlets for a motion

picture regardless of its quality or box-office potential. The practices of block booking and blind bidding (requiring an exhibitor to bid for a film before reviewing it) by distributors are now regulated in approximately half of the states in the United States. These statutes, although primarily concerned with curbing the practice of blind bidding, also regulate the whole bidding process.

BACKGROUND AND DEVELOPMENT

Since the formation of the motion picture industry by individuals such as Thomas Edison, Louise and August Lumiere, C. Francis Jenkins, and Thomas Armat in the 1880s, movie producers and distributors have attempted to control the industry by engaging in a multiplicity of tactics. Originally, monopolies were attempted through the ownership and protection of patents on the equipment and technology needed to produce and exhibit motion pictures. As technology advanced, the power that these patents could provide decreased. In an attempt to maintain control, industry leaders, led by Edison, merged their companies and formed a cartel, the Motion Picture Patents Company (MPPC).

At first, the MPPC wielded its power by pooling all of the licenses and patents that its individual members held. It defended its position by bringing numerous lawsuits against those who infringed on their rights. At the same time, motion picture exchanges developed to distribute the movies that the MPPC was producing. These entities purchased or leased films from producers and rented them to theater owners. These exchanges became quite profitable, and the MPPC purchased most of them in a vertical integration marketing strategy. As the MPPC purchased exchanges, it instituted practices that were designed to increase its bargaining power and ability to control the exhibitors who needed the product. Using its patents to force compliance from the exhibitors, the MPPC imposed restrictions on these exhibitors, including stipulations that implemented a system of distribution based on theatrical runs, geographic zones, and clearances (the amount of time contracted for between the first run of a motion picture and subsequent runs). The MPPC's successful control over distribution was short-lived. A motion picture antitrust action brought by one of the few exchanges that MPPC did not operate resulted in the dissolution of the trust arrangement. The first attempt by movie producers at organized distribution had failed.

Although this decision brought an end to the MPPC, it was not successful in curtailing the control that motion picture producers and distributors had now gained. In 1916 Paramount Pictures Corporation, a fully integrated production and distribution company, arose from the ashes of the MPPC. Paramount, as a producer, had contracts with many popular film stars. It was able to use the appeal of the stars together with its distribution capabili-

ties to create a new mechanism for control through block booking. Although Paramount was a dominant force in the industry, other companies gained similar control by engaging in similar practices. Block booking, along with the established run-zone-clearance system, effectively put the exhibitors at the mercy of the producer/distributor companies.

In response to these practices, the exhibitors gained bargaining power by forming chains and circuits. In 1917 the First National Exhibitors Circuit was formed. This group of exhibitors gained power and market domination through anticompetitive practices of their own. As a consequence of the power that these exhibitors had gained in their circuits, control of these cinemas meant control of the entire industry, and they became targets for purchase by the big producers. The studios' purchasing was influenced by the realization that if they could control every level in the motion picture industry, from production to distribution to exhibition, they would not only be able to control prices and ensure access to screens for the exhibition of their own pictures, but they would also be able to prevent competition from independent producers and gain control over the entire industry. The studios began to purchase exhibitors to make this complete control a reality. As a result of these monopolistic activities, with studio-owned circuits gaining control over entire exhibition markets, the government felt it was necessary to intervene.

By 1930 the government had filed numerous lawsuits against the circuits and distributors in an attempt to curtail these practices. The industry was clearly dominated by a group of eight major studios. The top five vertically integrated firms—all with a major presence in distribution, exhibition, and production—were Warner Brothers Inc., MGM Inc., Paramount, Twentieth Century Fox Film Corp., and RKO. The other three included Universal Studios and Columbia Pictures (involved solely in production and distribution) and United Artists (distribution only). The majority of these suits charged the defendants with illegally restraining trade by adopting various anticompetitive practices, including the use of arbitrary clearances, discriminatory zoning methods, and block booking. Although the government succeeded in forcing the studios to restrict their conduct, it ultimately lost the battle, as the anticompetitive atmosphere had taken over the industry. By the end of the 1930s, the majority of the most powerful circuits had been purchased by the major studios.

In 1938, as a result of these anticompetitive practices, the U.S. government filed a case against the major studios, which has come to be known as the "Paramount case." The suit alleged that the motion picture producer defendants had attempted to monopolize and had monopolized the production and distribution of motion pictures.

Although the case never went to trial, the major defendants signed a three-year consent decree that enjoined them from block booking more than five pictures, blind bidding, and requiring unreasonable clearances from exhibitors. The agreement also stifled forced rentals and limited the defendants in their quest to purchase exhibitors. This decree was unsuccessful in bringing about change in the industry because the government did not require the separation of production and distribution from exhibition.

In the late 1940s and early 1950s, the government reopened the Paramount case. The final result of this action was that all major motion picture studios were required to license motion pictures on a picture-by-picture basis, solely on the merits and without discrimination in favor of affiliated theaters, circuit theaters, or others. In addition, the government forced the five major companies to divest specific theaters and theater circuits. This action dismantled the fully integrated motion picture industry. The grip that studios had once held over the industry had finally been loosened. By eliminating the domination of vertically integrated studios, the hold over motion picture distribution was sufficiently weakened to give independent producers and distributors access to screens and a chance to prosper in the industry. The number of independent producers grew from 70 in 1946 to nearly 170 in 1950. In early 1953, the U.S. Justice Department concluded that the industry had become "demonopolized" and that competitive bidding and negotiations had become the dominant method of film licensing and distribution. In this environment, independent theaters were given the chance to compete equally for the right to exhibit first-run movies.

The industry operated under this format until 1980, when President Reagan allowed studios to once again become vertically integrated by giving them the right to own movie theaters. This new application of the antitrust doctrine under President Reagan was used by the studios to reshape the motion picture industry. Under the Reagan administration's policies, the Paramount consent decrees were not enforced, and the movie studios once again reassembled the vertical integration path abandoned in 1948. By 1985, the studios were overcome with acquisition fever and were purchasing theaters at a record pace. Although some studios waited with cautious observance to analyze the Justice Department's response to these acquisitions, it raised no objections. Between 1985 and 1988, movie companies spent more than \$1 billion to purchase independent movie theaters. The entire motion picture industry reverted back to the structure that existed before circuit divorcement and theater divestiture in 1948.

With the increasing popularity and mainstream critical acclaim of independent hits in the late 1990s, the

motion picture distribution industry experienced an ever-tightening link between independent producers and Hollywood distributors, who saw in the former's products a lucrative and refreshing break from the increasingly formulaic, sequel- and budget-driven Hollywood market. In that spirit, major distributors entered into revenue-sharing agreements with independents, in which the majors took a share of the receipts in exchange for wider exposure. This practice encapsulated the decade-long efforts of major studios to reach into the independent market.

Meanwhile, rising advertising costs made it more difficult for independents to turn a profit and were likely to result in fewer films in an attempt to scale back budgets, with advertising and exposure efforts devoted to the more hopeful products. Although few independent distributors could expect to reap Hollywood-scale rewards at the box office, some were able to break into the major-studio stratosphere in the late 1990s. Independent films enjoyed spectacular revenues at theaters from widescale features like *The English Patient*, *Shakespeare in Love* (both of which won several Oscar Awards, including Best Picture), *Good Will Hunting*, and *The Full Monty*. Meanwhile, the unlikely runaway success of the independent Artisan's *The Blair Witch Project*; with \$140 million in box-office revenue, generated a record in profitability, as the documentary-style film was produced for less than \$60,000.

The major independent studios included October, Fine Line, Fox Searchlight, and Artisan. The number of independent films released doubled between 1995 and 1998. The bread and butter of independent films were the smaller art houses, which have diminished in number with the trend toward enormous multiplexes, which are dominated by the major distributors. Along with the rising numbers of independent film productions, this has created a fiercely competitive distribution market among independents. As a result, this market has become internally stratified as distributors concentrate their production and promotional budgets on those films likely to achieve the greatest success. Sixty-eight independent films grossed \$1 million in 1998, compared with \$48 million in 1997, but far fewer earned more than \$20 million.

For the independent exhibitors, distributors, and producers, one of the most unsettling aspects of the resurgence of major studio involvement in distribution and exhibition was that the studios hoped to guarantee their access to screens. Although the Paramount decree required divestiture and mandated that motion pictures be distributed theater by theater solely on merit and without discrimination, the reintegration of the industry has removed these safeguards altogether. As affiliated and nonaffiliated circuits continued to grow in size, indepen-

dent circuits were virtually eliminated from the competition to obtain first-run motion pictures. Although there was no evidence of collusive or discriminatory behavior by distributors or affiliated circuits, the market power of the large affiliates was allowed to resurface.

In an attempt to rectify the imbalance of bargaining power that distributors maintained over exhibitors in the licensing of motion pictures, many states passed statutes to regulate motion picture licensing. The majority of these statutes regulated the licensing of motion pictures and the bidding practice used to gain control of a motion picture. Motion picture licensing usually occurs under a competitive bidding, competitive or noncompetitive negotiation, or track system. With competitive bidding, distributors send exhibitors solicitation letters informing the exhibitors of the release of new films. This correspondence contains a minimum amount of information about the film, possibly the stars and a brief plot synopsis, and suggested terms for the licensing of the film. If the distributor is unhappy with the bids that it receives, it will either solicit new bids or negotiate directly with the exhibitors. Lastly, the track system is used when there is an established relationship between an exhibitor and a distributor.

Exhibitors themselves have also attempted to obtain some bargaining strength against the major studio distributors with the use of "split agreements." Split agreements are the practice whereby exhibitors in a given market split the rights to negotiate for the rental of upcoming films. These agreements ensure that each split member has an initial right to bid or an opportunity to negotiate for certain films without competition from other split members. Because other split members agree not to submit bids for films that have not been designated to them, participants in split agreements initially face competition only from exhibitors who are not members of the split. Distributors have tried to fight these agreements in court in order to maintain their bargaining strength.

The nature of motion picture distribution was dramatically altered by the rise of home video in the 1980s and 1990s. Distributors increasingly relied on small-screen revenues to recoup their costs. With box-office receipts shared between distributors and theater operators, the home video market came to be an important part of the distribution system. In 1998, movie distributors earned about \$8.5 billion in video rentals from U.S. and Canadian theaters and a similar amount overseas. On the other hand, video sales and licensing films for television broadcast brought in more than \$12 billion. Nevertheless, home video has become the leading source of profit for distributors. It offers many movies a new lease on life, because films that would otherwise go straight into the company vaults are now routinely released on video without a theatrical run. However, box-office perform-

ance remains critical to a film's future success in the home video and television markets.

Another growing market for film runs in the late 1990s was in satellite broadcasts. By 1999 made-for-satellite films constituted a \$543 million distribution market. There were approximately 10 million pay-per-view subscribers in the United States, a figure that was expected to increase with the further proliferation of DirecTV service. Furthermore, satellite broadcasters were leaning increasingly toward on-demand video service, in which customers could download any film licensed to the broadcaster directly to their homes. Several major Hollywood directors, including Francis Ford Coppola and John Landis, boosted the satellite movie market by producing made-for-satellite films, in which producers contract directly with satellite broadcasters for exclusive rights to show the films.

CURRENT CONDITIONS

Although a number of very successful independent films were released during the early 2000s—including *My Big Fat Greek Wedding*—this sector of the film market was not attracting the attention it had during the late 1990s. As larger industry players swallowed up independent distributors, some observers argued that profits had become a primary concern and the quality of the films had suffered. As *Newsweek* explained in September 2001, "Truly independent films are subsidized by multiple credit cards, loans from Mom or lucky encounters with the idle rich. And it is those films that are struggling to reach moviegoers today. . . . Like so much of what ails Hollywood, the slump in the art-film scene is directly tied to the pursuit of profits. The studio-owned specialty-film divisions like Fox Searchlight were partially victimized by their own success. Movies with modest expectations like 'The Full Monty' turned in huge earnings, making the studio parents expect similar profits from subsequent films. Independently financed movies couldn't meet that unreasonable test, so the studio-owned outfits started producing more of their own movies, but the results were generally unimpressive and left less room for films made outside the studios."

Conditions such as these led to outcries from independent producers, some of whom claimed that a distribution crisis existed for those with small budgets. These problematic conditions extended to the home video market, in which distribution companies owned by the largest industry players pushed smaller distributors out of the way. On the bright side, the rapid adoption of digital video disc (DVD) technology opened up a new market for independent distributors. *Variety* reported that potential revenue from DVD sales was helping to increase the outlook for independent film companies in search of financial backing. According to the MPAA, the number of

titles available on DVD increased from 8,500 in 2000 to 20,000 in 2002. During this period, average DVD prices declined from \$22.65 to \$20.78, inspiring movie enthusiasts to purchase movies with enhanced content and extra features for their entertainment libraries, as opposed to renting them. Citing figures from Adams Media research, the MPAA reported that DVD sales increased almost 103 percent from 2000 to 2001, growing from 188 million units to 382 million units. Sales climbed another 84 percent in 2002, reaching 702 million units.

By the early 2000s, the transition to digital technology was underway in the film industry. Citing figures from Texas Instruments, the MPAA revealed that the number of digital cinema screens increased from 31 in 2000 to 45 in 2002, and then spiked to 124 in 2002. However, digital technology also was making an impact in the way movies were delivered to viewers. In late 2002, Warner Brothers forged an agreement with CinemaNow in which, for \$3 to \$4, consumers could download movies to their personal computer for a period of 30 days. By the spring of 2003, 20th Century Fox had also entered into an online distribution agreement with CinemaNow. In November of 2002, a competing online movie service called Movielink—a joint venture between Paramount Pictures, Metro-Goldwyn-Mayer Studios, Warner Bros., Universal, and Sony Pictures Entertainment—began serving customers. According to *The Online Reporter*, by 2005 feature films delivered via the Internet were expected to result in revenues of \$882 million.

INDUSTRY LEADERS

In terms of box office market share, six large producer/distributors consistently lead the film entertainment industry: Warner, Disney, Universal, Sony, Fox, and Paramount. Competition is fierce, and rarely does a single company hold the top position for long. The multimedia conglomerate AOL Time Warner was the industry leader in 2001; Universal and Paramount were close behind. Disney, Fox, and Sony rounded out the top six. Together these companies accounted for about 70 percent of domestic box office sales in the early 2000s.

AMERICA AND THE WORLD

World markets for films and television programs have long been critically important to U.S. producers and distributors. During the past 30 years, foreign markets have generally accounted for about one-half of major U.S. producers' total sales in these industries. The success of American films and television productions in world markets is indicated both by industry trade balances and by comparisons with other film and television exporting nations. The United States has historically enjoyed tremendous advantages in these areas.

Motion picture and home video distribution to other countries is, however, hindered by several factors. Trade problems encountered in the media industries fall into two general classes: government-imposed nontariff barriers and various forms of film and video piracy. These problems greatly reduce American industries' revenues in many markets. Nontariff barriers include various quantitative restrictions, limitations on the repatriation of earnings, and discriminatory taxes, usually aimed at protecting domestic markets from foreign competition. Perhaps even more important in terms of its effect on export earnings is video piracy. Producers' and distributors' losses due to piracy have increased enormously as a result of the growth of new copying and distribution technologies. Copyright enforcement problems of varying degrees are encountered in all markets throughout the world. Moreover, the nature and severity of copyright infringement differs among individual markets and channels of distribution. Copyright infringement problems fall into four broad categories: unauthorized public exhibition, print theft, videocassette piracy, and theft of broadcast signals.

The first of these activities, unauthorized public exhibition, has been reported to occur primarily in more developed countries. Unauthorized presentations of copyright-protected films often occurs in hotels, cafes, homes, and theaters around the globe. A second, related category of copyright infringement is the actual theft of film prints themselves. Copies of prints can be stolen at various stages of distribution, and the negatives can subsequently be used to produce unauthorized prints. The third, and perhaps most widespread, form of copyright infringement is videocassette piracy, which has become a global phenomenon. Analysts estimate that hundreds of millions of dollars are lost to videocassette piracy each year. These copyright infractions, coupled with other forms of piracy such as the theft of broadcast signals, has resulted in poor relations between U.S. producers and distributors and foreign agencies. As motion picture technology converts to a purely digital format, as it is expected to during the 2000s, film distributors are hoping to outpace pirates in establishing safeguards against illegal copying with the new technology. In that spirit, a number of telecommunications and film companies joined forces in 1998 to implement a restrictive encryption standard on digital films and music to prevent piracy.

RESEARCH AND TECHNOLOGY

Advancements in technology in the multimedia marketplace are being incorporated into the motion picture industry and are changing the way traditional products are being developed, licensed, and distributed. Film is becoming a digital media and is acquiring many of the similarities found in software products such as video games. Conventional film companies are exploring the

opportunities in interactive transmission and technology. Companies are digitizing their film libraries and exploring new ways to make this product available to distributors and consumers. The transformation of the motion picture industry to a digital format and the increase in new technologies available to cable companies, the broadcast networks, and consumers will provide the public with an array of viewing possibilities.

Improved technology also has made the World Wide Web a film-viewing medium, thus creating an inexpensive outlet for filmmakers without significant financial backing. With decreased production costs and inexpensive computer software, these filmmakers only need space on a Web server to bring their films to public exposure.

By the 1990s, distributors and producers were far less wary of new technologies than they had been. The arrival of home video recording in the late 1970s, once viewed as a threat, had proven to be a vastly lucrative new source of income. Hence, the arrival of the new DVD digital video format—which allowed an entire film to be stored on a disc similar to a CD—in late 1996 was widely supported by the industry. Copy protection systems and a regional coding system that prevented discs manufactured in one country from playing on players manufactured in another country assuaged fears that a given country would be flooded with high-quality digital copies of a motion picture before its actual theatrical release. During the early 2000s, rapid adoption of DVD technology was underway throughout the world. In addition to new releases, distributors remastered and re-released older films with extra features on DVD, which consumers purchased for their home entertainment libraries.

SIC 7829

SERVICES ALLIED TO MOTION PICTURE DISTRIBUTION

This classification includes establishments primarily engaged in performing auxiliary services to motion pic-

ture distribution, such as film delivery service, film purchasing and booking agencies, and film libraries.

NAICS CODE(S)

512199 (Other Motion Picture and Video Industries)

512120 (Motion Picture and Video Distribution)

INDUSTRY SNAPSHOT

Services allied to motion picture distribution faced challenges on a number of fronts in the late 1990s. Shifting patterns in the theater market threatened to undercut film booking and purchasing agencies; film technology was forcing film carriers to rethink their operating strategies to accommodate emerging trends; and major motion picture distribution companies were quickly encroaching on the traditional film-library market.

Businesses in this industry are allied to the process of film distribution, instead of directly providing services to film distribution companies. In other words, these firms contract with companies in the film exhibition industry, including theater houses, rather than with the distributors. Industry players tend to specialize in their particular market segments, which include film booking and purchasing agencies, film libraries, and film delivery services. Companies in this industry tend to be small; many serve only regional areas.

ORGANIZATION AND STRUCTURE

Film Booking and Purchasing. Film booking and purchasing agencies were contracted by movie theaters to act on their behalf in the process of acquiring and negotiating the terms to rented feature films from motion picture distribution companies. (The terms “purchasing” and “buying” do not mean the actual sale of films, but a form of rental.) Traditionally, the term “booking” referred to agreeing which films to play, while “buying” referred to negotiating the payment for the film and its length of run. Both activities, however, were performed by the same agencies. Accordingly, booking and purchasing agencies were synonymous designations. Agencies also helped theaters select films by screening them first when possible. Booking agencies occasionally offered additional business services to theaters, such as market research, consulting, accounting, and bookkeeping. Booking agencies were hired by a majority of independently-owned theaters, whereas larger chains of theaters tended to perform their own booking.

Booking agencies tended to be very small companies, many serving only a handful of theater clients operating a total of 20 to 30 cinema screens. While most booking agencies employed few workers, some were simply self-employed agents. Larger agencies occasionally operated branch offices and served theaters in differ-

ent parts of the country but rarely employed more than a dozen workers.

Especially with the move toward megaplexes — large movie houses featuring a number of screenings simultaneously — film booking agencies are likely to play a diminishing role in the U.S. film industry. The number of movie screens has increased by about 4,000 since the mid 1990s; however, during the same period, theaters housing 16 or more screens grew by 400 percent. Leading theater operators like Carmlike Cinemas and Regal Cinemas, Inc. typically negotiate with distributors directly.

Film Libraries. There were several different types of entities that were all called film libraries. Film libraries that were independent companies involved in renting out films tended to serve the non-theatrical market, namely educational institutions and other non-profit organizations. They differed from the film exchanges that distribution companies used by holding their collections for longer periods of time, and having complete control over their distribution and rates. Since they served a non-profit market, film libraries charged a relatively low flat rental fee, instead of requiring a share of the profits, as did commercial distributors. Film libraries increasingly offer film on videotape in addition to reels. In addition to film library companies, there are also non-profit organizations that rent film free of charge to educational institutions.

The term film library was also used to designate the film collection held by a motion picture production company or distributor. These film libraries, however, were not independent enterprises, but represented the assets of the companies. Theaters showing older films contracted with the company whose library contained the desired film. For films dating back several decades, the owner was not necessarily the original producer, since film studios and distribution companies have at times acquired the rights to each others' older films. In fact, the term “film library” did not necessarily correspond to the physical location of the films, but referred to the ownership of the copyrights.

The issue of film copyrighting came into play when copies of film were to be sold, rather than rented. A market for the sale of film, especially shorter film clips, existed among the producers of television programs, commercials, and videos, which incorporated the old clips into their new productions. When producers were unable to purchase film clips directly from the film libraries of the studios or distributors, they turned to a third type of film library. Stock-shot and archival footage film libraries owned and licensed film clips of interest to other producers.

Finally, there were film archives. These tended to be non-profit organizations that preserved original prints of

films for posterity. Some exhibited their films on a limited basis, while others did not exhibit them at all, in order to preserve the films' quality. Thus, archives were not involved in the distribution process.

The 1990s witnessed a large-scale rearrangement of the ownership structure of the film-library market, as libraries were rapidly bought and sold, often in merger deals. Independent film libraries, meanwhile, have been swept up in the rapid consolidation of the major film studios. The film-library market has thus been characterized by the scramble to find buyers.

Film Delivery. Film delivery services, also known as film carriers, were usually classified under the transportation services industry, in particular **SIC 4213: Trucking Except Local**, but belonged under both classifications because of their unique services. Film carriers were specialized transportation companies serving the needs of motion picture theaters by delivering and picking up rented theatrical films. Film was transported between the cinemas and the national network of film exchanges (also known as film depots), or directly between theaters, based on their booking schedules. Metal canisters of 16 mm or 35 mm film were delivered to the theaters, usually on a weekly basis. Unlike other delivery services, film carriers had keys to the theaters they supplied so they could drop off and pick up film when the theater was closed. Most delivery was done by truck or van because of the heavy weight of the film canisters, which made them impractical for air freight, except in rush circumstances. Film carriers served only theaters, since other organizations that screened films tended to use the more easily transportable videotape format, or else had only occasional film needs, which could be handled by any non-specialized delivery service.

There were fewer than 30 major film delivery companies throughout the country that served nearly the entire theater market. Most served up to a couple hundred theaters, some covering a region comprising several states. There were also a commensurate number of smaller film carriers that exclusively served single theater chains of around 15 to 20 theaters. Films generally weigh about 62 pounds, and are often accompanied by large cardboard stand-up displays and other promotional items theaters place in lobbies.

BACKGROUND AND DEVELOPMENT

Film Booking and Purchasing. The greatest developments in film booking and purchasing occurred in the booking process itself, and in the terms negotiated. Issues of negotiation in film rentals included the percentage of the gross income paid back to the distributor during consecutive weeks of a film's play, and the sum excluded the percentage that was turned over to the distributor to cover the theater's expenses. Other issues included the amount

of the non-refundable guarantee paid by the theater up front to secure the film, the amount of the refundable advance, and the guaranteed extended playing time for the film.

In the past, block booking was common practice, in which the larger studios would rent out a block of good and mediocre films at an all-or-nothing deal to theaters. A proportion of the films would be rented at a flat rate while others would be paid for in a percentage of the profits. The practice was banned between 1921 and 1932, but continued again until the Supreme Court outlawed it in 1948.

An old practice of blind bidding resurfaced in the 1970s. Distributors convinced theaters to buy films before production was completed, and thus theaters could not view the film before deciding if they wanted to purchase it. Studios had turned to blind bidding to cover their growing expenses, but states began to outlaw it. When nearly half the states forbade blind bidding, the practice was discouraged by the late 1980s.

To avoid competitive bidding among theaters in the same region, theaters devised a practice called "product splitting" by which they agreed among themselves how they would divide the upcoming films. This practice was made illegal following an anti-trust lawsuit in 1977.

Film Delivery. Film carriers quickly became a specialized service within the transportation industry with the emergence of the motion picture theaters in the 1920s. By 1933 the trade association Film Carriers Conference (later renamed National Magazine and Film Carriers Inc.) was formed. Later, film carriers gradually began to diversify into magazine transportation, beginning with services to *Time* magazine in the 1940s, as the film carriers' routes and delivery schedules fit well with the needs of magazine wholesalers. Film carriers diversified into delivering other theater supplies, including popcorn and candy sold at theater concession stands.

CURRENT CONDITIONS

The effect on the services allied to motion picture industry of digital film, and the expected introduction of digital film projectors, is yet to be determined. The new technology, which analysts expect to overtake the film industry early in the twenty-first century, poses a particular concern regarding the control of delivery networks. Eventually, digital films could be transmitted electronically or even by satellite, though in the short term it seems likely that theater operators will favor physical distribution precisely because of the greater degree of delivery control afforded the theaters. Meanwhile, film libraries can expect to reap rewards from the conversion of their collections to digital format.

Equally nebulous was the impact of emerging technology aimed at delivering quality film footage over the Internet. Technology was rapidly developing to turn the World Wide Web into a film-viewing medium, thus creating an inexpensive outlet for filmmakers without significant financial backing. With decreased production costs and inexpensive computer software, these filmmakers only need space on a Web server to bring their films to public exposure. The electronic distribution of film over the Web would, of course, render delivery companies unnecessary. Meanwhile, online entrepreneurs have put out the word that they are in the market for film libraries. While Web film distribution will face legal hurdles in the form of licensing formalities for transmitting films over the Internet, this development could prove attractive to independent film libraries, which have the greatest difficulty finding consistently stable distribution networks.

The segment of film libraries renting for non-theatrical exhibition was being seriously hurt by the conversion of film to videotape and the subsequent growth of video rental outlets. Although it was technically illegal, teachers saved money by renting videos from a consumer video shop instead of renting the film through a film library.

Smaller booking agencies also felt the pinch of new technology and rapidly-consolidating Hollywood's growing concern for the bottom line. An intensified focus on first releases or "event" films in major markets squeezed out many smaller exhibitors, putting pressure on the companies who served them. Theater business was rapidly ushered into large multiplexes throughout the 1990s. At the same time, satellite-distributed digital movies and home videos were reducing the number of trips to the cinema. Over the long term, continuation of this trend was expected to reduce the cultural diversity of film product and downgrade the market to only a few thousand screens, charging exorbitant prices for exclusive runs of event-scale films; ticket prices increased more than 20 percent between 1992 and 1999—8 percent during 1999 alone.

In an effort to reverse this trend, innovative new companies sprang up that took advantage of the rapid development of computer networking technology in the mid 1990s to offer low-cost booking and promotional services via the Internet. Companies like Maine-based Cinema Links used computer technology and computer networks to link hundreds of exhibitors and distributors nationwide, promising to significantly lower the costs associated with booking and promoting films and thereby to increase profit margins. Plot summaries, screeners' advisory notes, release schedules, distributor terms, and other critical booking information were available daily via modem, telephone, or FAX. Box office reports were

uploaded daily, computerized, and then forwarded to the distributors.

The number of stock-shot and archival-footage libraries, on the other hand, increased significantly in the early 1990s. There was a continued drive to archive and restore classic films, interviews, and footage for use in documentary materials and revived screenings. This segment also felt the impact of the World Wide Web; an enormous stock footage library called Footage.net cropped up online. The site is linked to dozens of film libraries around the world, and acts essentially as an online intermediary between the physical libraries and consumers. There also was a growing foreign market for stock footage. The growth of the field was attracting innovative newcomers to the stock footage film library business. Many such film libraries have also started producing their own stock footage to complement their collections by shooting city scenes and natural vistas. Meanwhile, the Film Department at the University of California at Los Angeles allied with Robert Redford's Sundance Institute to initiate a project devoted to archiving, preserving, and presenting independent films. It will be incorporated into the Sundance collection and make films available to film makers and educational programs.

INDUSTRY LEADERS

The leading film delivery company was Airborne Express, which held exclusive deals with Universal Studios, Miramax, Disney/Buena Vista, and a host of other major and minor film distributors through its partnership with Technicolor Entertainment Services. The firm delivered to more than 8,000 studios nationally and generated \$25 million in revenue from its Technicolor-related operations in 1998, registering annual growth of 30 percent since its formation in 1993. Another major film carrier was Benton Express Inc. of Atlanta, Georgia with \$35 million in revenues, some of which derived from its trucking operations.

A leading non-theatrical film library was Films Inc. of Chicago, with 120 employees and 1998 revenues of \$10 million. Leading stock footage film libraries include Film Search Inc. of New York with \$11.0 million in revenues and a payroll of 340 employees, and Archive Films Inc. of New York, which employed 120 and garnered sales of \$14.3 million.

SIC 7832

MOTION PICTURE THEATERS, EXCEPT DRIVE-IN

This category covers commercially operated theaters primarily engaged in the indoor exhibition of motion pictures.

NAICS CODE(S)

512131 (Motion Picture Theaters, Except Drive-In)

INDUSTRY SNAPSHOT

Motion picture theaters are part of an increasingly complex film industry that has been characterized by large initial capital investments and long revenue streams. Movie theaters are one aspect of the film industry, which also includes movie studios, broadcast and cable television, and the sale and rental of both digital video discs (DVDs) and videotapes.

Motion picture theaters remain a significant contributor to the film industry. Although videos have surpassed theaters as the biggest contributor to film industry revenue, the United States' 35,000 movie screens create the initial market for a film's future formats. The industry, along with the rest of the U.S. economy, endured a recession in 1990 and 1991, but box-office receipts rose from \$4.8 billion in 1991 to a record \$6.95 billion in 1998. Weak economic conditions returned in the early 2000s, wreaking havoc on many sectors of the U.S. economy. However, box-office receipts continued to reach record levels each year, peaking at \$9.5 billion in 2002. Admissions reached 1.63 billion in 2002, a 44-year high.

ORGANIZATION AND STRUCTURE

The movie theater industry is represented by the National Association of Theatre Owners (NATO). NATO was formed through the 1966 merger of the Theatre Owners of America, which was founded in 1920, and the Allied States Association of Motion Picture Exhibitors, which was created in 1939. The organization

compiles and publishes statistical and historical information on the economics of theater and concession operations, film producers and distributors, theater equipment, box-office sales, and attendance.

Throughout the movie theater industry's history, entrepreneurs have had to make high up-front investments. Film rental fees are usually negotiated in terms of box-office revenue in which movie studios charge a percentage of the box-office receipts.

Total theater receipts are derived from three sources: admissions, concessions, and screen advertising. Although it accounts for a much smaller percentage of revenues than ticket sales, concession income is a favorite of cinema operators because it commands a high profit margin that is not split with movie studios. Concessions and screen advertising have been recent avenues for growth. On-screen ads included live-action spots and slide-show-type reels that promote local businesses. The advertising concept was not particularly well received by patrons and some distributors, and by the late 1980s several studios rebelled against the practice. In fact, Walt Disney Company and Warner Bros. banned on-screen advertising in theaters showing their films.

BACKGROUND AND DEVELOPMENT

The motion picture theater industry was born at the dawn of the twentieth century following the 1903 release of *The Great Train Robbery*, which is widely regarded as the first feature film. Previously, movies were given second billing in deference to live vaudeville acts, but as the films' technical quality and popularity grew, they became attractions in and of themselves. The first building devoted exclusively to movies was built in Pittsburgh in 1905, and the first movie house opened in Manhattan, New York City, in 1913.

Theaters became the United States' primary source of entertainment during the 1920s, and some theaters boasted full houses three or four times each day. During this decade, elaborate venues seating as many as 5,000 were built in cities and towns across the country. These theaters sometimes upstaged their featured films with architectural styles that ranged from baroque, Greek, and Spanish to Egyptian, Byzantine, and Aztec. Details included imported marble columns, crystal chandeliers, and gold-painted figures; huge pipe organs were built for many theaters to provide music for silent films. Services included immaculately uniformed doormen, ushers, and lounge attendants.

The 1927 release of *The Jazz Singer*, the first film with synchronized sound, revolutionized the motion picture industry. Millions of dollars were spent to upgrade film production facilities and buy equipment for movie houses. Within three years the transformation to sound

was complete—silent films, pipe organs, and many movie stars of the silent film era faded from the limelight.

Many theaters were able to convert efficiently to sound because they had the backing of major movie studios. The motion picture theater industry of the first half of the century was dominated by a handful of companies known as “the five majors”: Paramount, Twentieth Century Fox, Warner Bros., MGM, and RKO Pictures. The five produced, distributed, and exhibited films in company-owned theaters. Columbia, Universal Pictures, and United Artists Corporation, known as the “little three,” were primarily film distributors. Ironically, it was one of the “little three”—United Artists—that became the motion picture theater industry’s biggest player by the end of the twentieth century.

The five major studios controlled the exhibition of movies throughout the 1920s, 1930s, and 1940s. Together they produced 95 percent of all big-budget features released before 1950 and owned 70 percent of the first-run theaters in the United States’ 92 largest cities. Each studio gave the others access to its first-run theaters in exchange for reciprocal privileges. They also enforced “block booking,” whereby independent theater owners wanting to run a big-name movie had to agree to run several of the studio’s lesser pictures. The five majors even dictated admission prices.

The Depression took its toll on movie attendance in 1931 and 1932, and the five majors gained even more control over the remaining market. Even the architectural style of newly constructed movie theaters reflected the tough times. One author surmised that the streamlined art deco look grew popular “as an economy measure of sorts, an attempt to maintain a richness of design without spending quite so much.”

In the 1930s and 1940s, attendance fluctuated from lows of 60 million per week to highs of 90 million per week in the late 1940s, before a significant period of decline set in. From 1946 to 1953, 853 indoor theaters were built, but 4,696 were permanently closed as television siphoned off theater’s audiences. Many in the indoor theater industry blamed booming drive-in attendance for their declining fortunes, but historical analysis has concluded that drive-in theaters actually kept the movie industry alive during the 1950s in the face of bruising competition from television.

In 1949 the federal government ordered the five majors to divest their theater holdings. The industry had been the object of scrutiny by the government since the 1920s, when the major studios emerged, but it took a 1938 lawsuit to get the wrecking ball rolling. Loews and MGM resisted the trust-busting the longest, and it was not until 1957 that the breakup was completed. The

percentage of chain-owned theaters dropped from 70 percent to 46.8 percent by the time of the final dissolution.

The breakup of the theater trust exacerbated the film industry’s decline, because it eliminated the major studios’ guaranteed revenue. This loss of revenue in turn limited production budgets, resulting in fewer and less extravagant films. The court order also compelled movie distributors to negotiate theater-by-theater, movie-by-movie contracts, as opposed to block booking and other agreements that had previously given the dominant theater chains advantages over their independent counterparts.

The flight of affluent city dwellers to the suburbs was the final blow for traditional downtown theaters. Shopping center cinemas with free, abundant parking were closer to the burgeoning suburban population. Nevertheless, weekly attendance at films continued to spiral downward through the 1950s from 60 million per week in 1950 to a decade low of 39.6 million per week in 1958 before bottoming out in the low 40 million range. Because of the country’s population boom, these figures represented even lower percentages of moviegoers than during the Depression. Box-office receipts, employment, and the number of establishments also fell steadily from 1954 to 1963. Industry-wide box-office revenues fell from \$1.17 billion in 1954 to \$803.46 million in 1963. During that same period, the number of movie houses declined from 14,716 to 9,150.

The number of theaters continued to decline throughout the 1960s to just over 8,300 in 1972. Annual ticket sales dropped steadily as well, but ticket prices increased by 110 percent from 1963 to 1974. Despite these factors, industry revenues grew 43 percent to \$1.4 billion from 1963 to 1972.

Multiplexing, the grouping of several relatively small screening rooms in one facility, began in the 1970s. The multiplex attracted more patrons with more films to choose from while using fewer employees. From 1972 to 1977, industry revenues increased by 50 percent to \$2.13 billion as the motion picture industry and the theater business rebounded.

The theater industry recorded consecutive annual gains from 1981 through 1984, with box-office sales peaking at more than \$4 billion in 1984. But admissions fell 11.9 percent and box-office receipts dropped 7 percent in 1985, as construction glutted the market with screens. During the early 1980s, Hollywood produced plenty of films, but there were not enough screens to accommodate them. This resulted in over-construction in the theater industry; from 1980 to 1987 the number of screens increased from 17,675 to more than 23,500. An opposing industry trend found Hollywood releasing fewer and fewer feature-length films; the number of films

produced annually peaked in 1987 at 515 but sunk to about 470 in 1989. The net result of these two trends was that theater owners had to offer larger cuts of the box-office revenue to movie studios to remain competitive and book top films.

The mid-1980s industry recession combined with a relaxation of some regulatory restraints resulted in a revival of the distributor-owned movie theater. Four of the top six distribution companies made sizable gains in theater ownership, including Matsushita Electric Industrial Ltd., which acquired about half of Cineplex Odeon; Sony, which bought the Loews Theatres chain; and a joint venture between Paramount and Time Warner, which bought the Cinamerica theater chain. These four distributors had a stake in about 9 percent of the United States' theater screens, enough to attract the attention of federal regulators, who seemed to indicate that they would keep their distance as long as the distributors did the same. Strengthened by new corporate ties, the top 10 exhibition chains captured 55 percent of the United States' theaters by 1990, up from 27 percent in 1985.

"Expansion madness" gripped the U.S. theater industry in the early 1990s. The number of screens increased from about 24,000 in 1991 to nearly 30,000 by the end of 1996, up 7 percent (about 1,900) in 1996. By the end of the year, there was one screen per 9,000 people. The boom was driven in part by an increase in the number of movie releases from Hollywood, which was generating upwards of 300 feature films each year. The advent of the "megaplex" (16-plus screen complex) increased the number of screens exponentially with each new construction project. Mid-decade, this trend showed signs of migrating to international markets.

The number of movie screens in the United States increased from 30,000 in 1996 to 35,000 in 1998. The market was expected to peak at about 40,000. Large-format cinema remained first in annual growth rate among attraction/entertainment businesses, second only to the gaming industry. In 1998, there were approximately 160 large-format screens operating in the United States. By 1999, there were 29 large-format films in production, with another 19 in development by 2001.

The 1999 summer box-office season broke all previous records. In just 17 weeks, box offices took in \$3.1 billion, a 19 percent increase from 1998. Additionally, 10 films grossed more than \$100 million each. Admissions increased from 1998's 533 million to near 610 million in 1999, a 14 percent increase.

CURRENT CONDITIONS

According to U.S. Census Bureau figures, revenues in the motion picture and video exhibition industry increased from \$9.2 billion in 1999 to \$10 billion in 2000, and reached \$10.4 billion in 2001. Figures from NATO indicate

that box-office receipts continued to reach record levels each year during the early 2000s, rising from \$7.7 billion in 2000 to \$8.4 billion in 2001, and reaching a peak of \$9.5 billion in 2002. According to *Daily Variety*, projections from different industry analysts indicate that box-office receipts will likely range between \$10 to \$12 billion by 2006, and profits are expected to increase by as much as 30 percent. Along with revenues and box-office receipts, average ticket prices also continued to increase, rising \$5.06 in 1999 to \$5.80 in 2002, according to NATO.

Movie screen counts, which increased steadily throughout the 1990s, peaked at a record high of 36,448 in 1999. However, the number of screens then declined for the first time in many years, falling to 35,627 in 2000 and 34,490 in 2001. In 2002, screen totals began to rise again, and the number of indoor movie screens reached 35,170.

By the early 2000s, digital technology was being adopted in many movie theaters. According to the Motion Picture Association of America (MPAA), figures from Texas Instruments show that the number of digital cinema screens increased steadily between 1999 and 2001, rising from a mere 12 to 45. However, in 2002 this number mushroomed to 124. In its June 15, 2002, issue, the *Los Angeles Times* reported that theaters were "under pressure from the Hollywood studios to equip their cinemas for digital films," and explained: "The price tag of digital projection equipment—up to \$200,000—is so daunting that many in the business question its value. But some advocates of digital technology say the payoff is in the alternate programming that the new equipment makes possible, such as live concerts, educational programs, corporate functions and other special events. At the very least, they say, the extra offerings could help fill seats from Monday to Thursday, when moviegoing usually drops off."

INDUSTRY LEADERS

The leaders in the motion picture theater industry during the early 2000s included Regal Entertainment Group (Regal Cinemas, Edwards Theatres, and United Artists Theatre Co.), AMC, Carmike, Cinemark, and Loews Cineplex Entertainment. Regional markets were influenced by a number of other chains.

Based in Englewood, Colorado, Regal Entertainment Group (REG) was formed when an investor named Philip Anschutz obtained control of Regal Cinemas, Edwards Theatres, and United Artists Theatre Co., all of which were headed for bankruptcy. According to the company, REG was the world's largest motion picture exhibitor in 2003, with 5,663 screens in 524 locations across 36 states. REG's Regal Cinemas had become the country's largest theater chain in 1998, when it merged with the Act III chain. REG posted 2002 sales of \$2.1 billion, a 284

percent increase over the previous year. That year, the company employed nearly 22,800 people.

Headquartered in Kansas City, Missouri, in 2003 AMC Entertainment, Inc. operated about 3,500 screens in some 250 theaters in the United States, Canada, Spain, Portugal, Hong Kong, and Japan. Since 1995, AMC has specialized in building megaplexes containing 20 or more screens. These entertainment complexes feature stadium seating with plush, high-backed seats, AMC's own High Impact Theatre System (HITS) with wall-to-wall and floor-to-ceiling screens and unique speaker configuration, and state-of-the-art computer systems to monitor everything from ticket and concession sales to the theater's temperature. In the fiscal year ending March 2002, AMC realized sales of \$1.3 billion, up more than 10 percent from 2001, and the company employed 17,700 people.

Carmike Cinemas, with headquarters in Columbus, Georgia, operates more than 2,260 screens in about 300 theaters across 35 states. Carmike has traditionally concentrated on secondary markets (cities and towns with populations of less than 100,000), although it is beginning to make some tentative forays into larger metropolitan areas. Before 1998, the company grew mostly by acquiring existing theaters and circuits. It then launched an effort to build screens, expand smaller complexes, and renovate its older theaters. In 2002 Carmike was able to reemerge from Chapter 11 bankruptcy protection, for which it filed in 2000, after closing nearly a third of its theaters. In 2002, the company's sales were \$507 million.

With 2,900 screens in more than 450 North American theaters, Loews Cineplex Entertainment Corp. also is an industry leader. The company was created in 1998 as the result of a merger. Loews Theatres joined forces with Canada's Cineplex Odeon Corporation to form Loews Cineplex Entertainment, with headquarters in New York and Toronto. Although Sony Pictures Entertainment and Universal Studios previously had ownership stakes in Loews, by 2003 it was owned by Onex Corporation, the fourth largest company in Canada, as well as Oaktree Capital Management. Sales for Loews in 2002 were \$856 million. That year, the company employed 16,500 people.

WORKFORCE

Motion picture theaters employ more than 132,000 workers, a majority of them part time. In recent years, each theater averaged about 13 employees total, a far cry from the 1920s when elaborately uniformed workers met the patron's every need; a New Orleans theater during that period boasted a corps of 100 ushers who were called "The Soldiers of Service." Ushers, lobby attendants, ticket takers, and food servers still comprised two-thirds of the industry's workforce. Requiring up to one month of on-the-job training, projectionists were the only skilled members of the industry. They also were often union members

AMERICA AND THE WORLD

The European theater industry of the 1980s was reminiscent of its U.S. counterpart in the 1950s and 1960s: run-down and shrinking fast. A recovery of the industry abroad that commenced in the mid-1980s reflected the resurgence of American movie houses a decade before. The European renewal started in 1985 in Britain, when American Multi-Cinema Inc. opened a U.S.-style multiplex. As the new theaters spread, British movie attendance nearly doubled.

The movement emigrated to the mainland during the 1990s. The first movie theaters to be built in Germany's Ruhr Valley in decades were opened in 1991. One was a joint venture of Paramount and Universal (United Cinemas International), and the other was built by Time Warner. Both players sought to revive the Spanish and Italian movie markets in the early 1990s. Although U.S. exhibitors stimulated the overseas theater renaissance, several European chains played a part in the rejuvenation as well.

RESEARCH AND TECHNOLOGY

When television pirated the country's movie audience during the 1950s, Hollywood looked for new ways to get people into theaters. CinemaScope and stereo sound were introduced by Twentieth Century Fox in the 1950s. Cinerama's giant concave screen and Paramount's Vista-Vision big-screen system tried to capitalize on a movie's visual impact, which television could not equal. Other gimmicks, like three-dimensional films, were unique but often less technically impressive and proved to be passing fads.

Movie house owners worked to redefine the "theater experience" in the early 1990s to compete with the public's plethora of entertainment options. Expanded concessions included pastries, cappuccino, mineral water, and frozen yogurt. Credit card and phone-ahead ticket sales, first introduced chain-wide by Cineplex Odeon Corp. in 1991, added convenience. Advance ticket sales and reserved seating followed in 1992 when United Artists Entertainment Co. began testing the service. Movie boutiques stocked with film-related T-shirts, posters, stuffed toys, and other paraphernalia capitalized on the rising popularity of movie licensing.

Motion simulation theaters were developed by Omni Films International Inc., Imax Corp., and Iwerks in the 1990s. Previously, these panoramic, curved screens, designed to give audience members the sensation of being in the film, had been limited to amusement parks, planetariums, museums, and science centers. Omni hoped that its 50-seat motion theaters, which incorporated hydraulically mobilized seats and a computer control unit to synchronize seat movements with the film, would become attractions at shopping malls. The newest theaters

also used state-of-the-industry digital sound and high definition projection systems.

SIC 7833

DRIVE-IN MOTION PICTURE THEATERS

This category covers commercially operated theaters, commonly known as drive-ins, primarily engaged in the outdoor exhibition of motion pictures.

NAICS CODE(S)

512132 (Drive-In Motion Picture Theaters)

INDUSTRY SNAPSHOT

The drive-in theater industry is a phenomenon that peaked in the 1950s, then declined precipitously in the 1970s and 1980s. According to the Motion Picture Producers Association (MPPA), there were 847 drive-in theaters, or "ozoners," as they were sometimes called, in the United States in 1996. This industry has greatly dwindled from its peak in 1952 when it surpassed the traditional theater industry in attendance. The number of drive-in theaters has, however, remained stable since the late 1980s. The affordability and convenience of an evening at a drive-in, the desire to get out of the house during pleasant weather, plus nostalgia for the 1950s, which many drive-ins are playing up, has kept the drive-in from total extinction. "A trip to the drive-in is a movie-going paradox. It's more social than any indoor theater (where you're not even allowed to talk, much less walk your dog or throw a Frisbee with the guy down the row) . . . Likewise, drive-ins combine the best of commercial-theater scale with home-theater indulgence: No home entertainment system gives you a 2,600-square foot screen, and in no multiplex can you eat, smoke and drink yourself silly," said reporter Steve Hendrix in the *Washington Post*.

In 1997, the industry was estimated to employ 1,996 people. Total receipts were \$110.3 million.

ORGANIZATION AND STRUCTURE

The drive-in theater industry was comprised largely of independent operators and a few regional chains. During the late 1940s, chains owned 31.9 percent of establishments and controlled 39.8 percent of car capacity. Some of the larger chains included General Cinema Corporation, which ranked as a top indoor and Park-In Theatres, Inc., both in the eastern United States; Pacific Drive-In Theaters; and Paramount-Richards Theatres, Inc., in the southern United States.

Since the drive-in industry was considered a competitor of the traditional theater industry for many years, their owners were not welcomed into such associations as Theatre Owners of America or Allied States Association of Motion Picture Exhibitors. However, since many drive-in operators were so successful in their early years, they did not perceive a need for professional affiliation or the information-sharing and lobbying services that such an association could provide until the industry reached its demise.

Financial Structure. Like traditional theaters, drive-in theaters derived profits from two primary activities: admission fees and concessions. Most drive-ins were seasonal operations open an average of eight months each year. During their most prosperous years, 88 percent of drive-ins charged admission on a per-adult basis, admitting children for free. As the industry declined in the 1980s, operators desperate for patronage switched to a

per-car admission. During the 1950s, annual profits ranged from 15 percent to 30 percent of invested capital — a very high margin compared to indoor theaters, which averaged about 10 percent at the time. Concessions usually contributed 35 percent to 40 percent of a drive-in's gross receipts.

Drive-ins required a relatively high initial investment. It is estimated that the first drive-in theater cost about \$30,000 to build. After World War II when the industry reached its zenith, the average initial investment was about \$100,000, not including the land. Although high, this capital outlay was only about 30 percent of the average cost of an indoor theater at the time.

Regular expenses included film rental, energy consumption for projection and food preparation, payroll, and real estate. Payroll typically constituted about 28 percent of a drive-in's operating expenses.

BACKGROUND AND DEVELOPMENT

The concept of the drive-in theater was first patented and introduced by Richard Milton Hollingshead, Jr. in 1933. Known as "the father of the drive-in," Hollingshead opened the first establishment in Camden, New Jersey, in June of that year. The "Automobile Movie Theatre" featured rows of inclines on which patrons would park their cars; a large, central screen; three loudspeakers atop the screen to project the movie's soundtrack; and a barricade around the perimeter of the lot to prevent would-be viewers from sneaking in.

Hollingshead had trouble enforcing his patent, and he watched his idea spread unauthorized to Pennsylvania, Texas, California, Massachusetts, Ohio, Rhode Island, Florida, and Michigan by the end of the decade. Many of the new businesses were unlicensed, and Hollingshead was obligated to spend time and money trying to enforce his patent. He eventually petitioned the U.S. Supreme Court in an attempt to uphold his patent, but in 1949 it was declared invalid on the basis that it "lacked invention."

The industry as a whole faced other problems that prevented it from catching on until the late 1940s and early 1950s. Some were technical: poor sound quality and faulty synchronization of image and soundtrack along with distortion of the picture at some vantage points hampered the viewing experience. In addition, neighbors of these early drive-ins protested the loud broadcast of movie soundtracks throughout the evening hours. Other obstacles were rooted in Hollywood studio politics. Many big-budget movie producers, who controlled production and distribution of films throughout the 1940s, refused to circulate their best movies to drive-ins.

These problems were partly alleviated in the late 1930s, when the major Hollywood studios began to make their films available, in later runs, to drive-ins. Improve-

ments in projection technology permitted patrons in drive-ins with a 1,000-car capacity to see a movie more clearly. And the development of individually-controlled, in-car speakers solved the sound problem in 1941. But just as the drive-in industry was poised to erupt into a full-fledged craze, World War II's gasoline rationing, rubber shortages, and building restrictions prohibiting "unnecessary construction" postponed the movement.

In 1942, there were 95 drive-ins in 27 states. The average lot held 400 cars, took up seven or eight acres, and had one screen. The number of establishments remained relatively constant until the end of the war when it exploded. By the end of the 1940s, almost three new drive-ins were opening daily.

Kerry Seagrave, author of *Drive-in Theaters: A History from Their Inception in 1933*, attributed the craze to two social factors: America's love affair with the automobile and the postwar baby boom. Kerry noted that "ozoners were an ideal place for a young family with children — no baby-sitter needed, no parking problems, dress as you like, and (they provided) relatively cheap entertainment." In keeping with the family orientation of drive-ins, free admission for children under 12, playgrounds, and even bottle warmers soon became industry standards.

The industry reached an apex in August 1952, when the average weekly attendance at outdoor theaters surpassed that of traditional theaters by 1.3 million. By 1955, there were more than 3,700 drive-in theaters in the United States. That number peaked in 1958, when more than 4,000 drive-ins brought in \$230.42 million. Despite the technological limitations that dictated a 1,300-car maximum capacity, some operators built 2,500-car theaters to capitalize on the trend. During this peak decade, it did not seem to matter whether the patron could see the film clearly; most of the films shown were still the "table scraps" of the indoor theater industry anyway.

Drive-ins lured return patrons by offering several added attractions. A ticket might entitle the bearer to a free door prize for each child; or a theater might have a live band, dance troupe, or acrobatic act before the show. Some venues offered free milk and diapers for babies, a children's playground, or even a miniature golf and a driving range.

Although many operators of indoor movie theaters blamed the precipitous decline in their attendance figures during the 1950s in part on drive-ins, Seagrave maintained that drive-ins kept the movie industry afloat during the 1950s. But, growth of the industry began to stagnate by the end of the decade. The shakeout between 1958 and 1963, when the number of drive-ins decreased from 4,063 to 3,502, probably eliminated the most inefficient operators from the industry. The industry declined signif-

icantly in the early 1960s then leveled off until the late 1970s. Another steady decline began in the late 1970s and continued into the early 1990s as the drive-in theater neared extinction. This decline occurred for a variety of societal and economic reasons.

Family patronage, which Seagrave called “the backbone of the drive-in,” dropped off in the 1960s and 1970s. Some drive-in playgrounds were eliminated due to the fear of lawsuits resulting from possible injuries. Once the sidelight attractions were eliminated, all drive-ins had left to offer was the film itself, which was still too often second-run or second-rate. Also, the content of films began to change significantly in the late 1960s, hastened by the elimination of the Production Code in 1966, which had restricted the use of potentially offensive material. The introduction of nudity, profanity, excessive violence, and explicit sexuality made going to films less likely to be a regular family activity.

By the 1980s, cable television and VCRs had firmly supplanted the economy and convenience of drive-ins. Rising land values further eroded the viability of drive-ins: it became more cost effective to develop the land, rather than try to maintain outdoor exhibitions for a few months of the year.

Seagrave summarized the demise of the industry in his 1993 book: “Drive-ins today sit poised on the edge of extinction. The last handful may be around yet for decades. A few may be kept alive as sort of living museums, perhaps subsidized. But they are finished as a part of the American landscape. New ones will never be built.”

Bob Wagner, owner of the Bel-Air Drive-In Theater in Churchville, Maryland, agrees. In 1996, he told the *Washington Post*, “We’ll be around for awhile longer, I think. I don’t see anybody ever building a new drive-in. But we’ll keep this one going by doing whatever we can think of.”

No longer venues for low budget B-pictures and second runs of top level films, drive-ins offer the same features that are shown at indoor theaters. As with indoor theaters, the amount of business done by drive-ins depends upon the general popularity of film releases. In the summer of 1996, some drive-ins were filled to capacity during showings of the science fiction blockbuster *Independence Day*.

In addition to being dependent on the appeal of current films, a drive-in’s business depends on good weather. “Weather is the key. On a good Friday or Saturday we can get 1,500 to 2,000 people in here. But even the prediction of rain keeps people away,” Memphis drive-in owner Larry Pankey explained to the *Memphis Commercial Appeal*.

A new problem for drive-ins is the changing style of automobiles. Designed for the low and wide sedans that

were prevalent in the 1950s, drive-ins must contend with vans, trucks, jeeps, and recreational vehicles which can block the view of customers in regular cars. Relegating high and bulky vehicles to the back row is not always possible due to the increasing number of them.

CURRENT CONDITIONS

There was only a slight decline in operating drive-in movie theaters in the United States from 1996-98: down from 847 to less than 800 (although one statistic places the number at 530). Those that have weathered the decline stand to do well: nostalgia and pseudo-nostalgia are at all-time highs. The Drive-In Theater Fanatic Fan Club (www.driveintheater.com/fanclub) and the American Drive-In Movie Theatre (www.americandrivein.com) represent two groups of followers helping to stave off extinction. The status of the remaining drive-ins is expected to remain at a plateau for several years.

In 1998, America’s oldest remaining drive-in movie theater celebrated its 65th anniversary. Shankweiler’s Drive-In, in Orefield, Pennsylvania, is open from April to September. Although few drive-ins turn a profit, many are able to maintain business by appealing to family audiences. By combining playground equipment, “diners” serving old-fashioned hamburgers, and programs featuring general audience films, many drive-in owners hope to carry a fleeting image of Americana far into the millennium.

AMERICA AND THE WORLD

Unlike the traditional movie theater, the drive-in never amounted to more than a novelty in other countries. Until the 1990s, only Canada and Australia came close to rivaling America’s drive-in industry. As Seagrave noted, this was because most foreign countries did not have the prerequisites to establish such an industry: high personal income; cheap, vacant, and accessible land; ubiquitous automobile ownership; and inexpensive gasoline.

One of the only countries that possessed these requirements, however, was Japan. As the U.S. industry declined, almost 20 drive-ins were built in Japan from 1983-93. A country renowned for its expensive real estate, Japan built low-budget drive-ins that used parking lots and other locations that were not used at night by simply installing a screen, a projector, and an office. Rather than being a product of a booming economy like their U.S. counterparts, Japanese drive-ins were money-making ventures spawned by the country’s worst recession since World War II.

VIDEOTAPE RENTAL

This category covers establishments primarily engaged in renting videotapes and disks to the general public for personal or household use. Establishments primarily engaged in renting video recorders and players are classified in **SIC 7359: Equipment Rental and Leasing, Not Elsewhere Classified**. Establishments primarily engaged in selling recorded videotapes and disks to the general public are classified in **SIC 5735: Record and Prerecorded Tape Stores**; those engaged in the wholesale distribution of recorded videotapes and disks are classified in **SIC 7822: Motion Picture and Videotape Distribution**.

NAICS CODE(S)

532230 (Videotapes and Disc Rental)

INDUSTRY SNAPSHOT

Under assault from alternative entertainment media like pay-per-view television and video-on-demand services, video stores in the early 2000s faced a mixed future. After rapid growth in the 1980s and early 1990s, video rentals in the United States stalled in the mid-1990s as the market grew saturated and as competing modes of entertainment chipped away at home video rental. Sales of videos at mainstream retail outlets like Wal-Mart and drugstore chains also cleaved market share away from video stores. The industry staged a modest recovery in the late 1990s, aided by new revenue-sharing agreements with movie studios, but sales fell more than 4 percent from 2000 to 2001. The strong popularity of DVD boded well for the industry during the early to mid-2000s.

The video rental business is fairly fragmented compared to other industries. In recent years, the top five video chains claimed only 41 percent of the U.S. market. However, large chains continue to edge market share away from smaller, independent video stores. Thousands of independents have been forced out of business as big

chains moved in; others have been relegated to niche markets.

ORGANIZATION AND STRUCTURE

Film studios and distributors sell videotapes and DVDs to rental outlets, which then rent the videos to consumers. Under traditional pricing, rental outlets pay \$50 to \$80 per video, which they then rent to customers for typically \$1 to \$4 per night. Under this arrangement the video store keeps all the rental revenues for itself. Increasingly, however, video stores have pursued revenue-sharing deals with studios. These contracts dramatically reduce stores' initial cost of buying videos—sometimes eliminating up-front costs altogether—and convert those into variable costs by paying the studio a percentage of rental income each time a movie is borrowed. Revenue sharing, which came into widespread use in 1998, benefits not only video stores' cash flow but also frequently helps boost overall revenue because stores are able to stock—and rent out—more product.

Typically, video stores earn the bulk of their sales (about 70 percent at large chains like Blockbuster) from video rental fees. The rest come from sell-through videos, whereby tapes and discs are sold as new; gaming software rentals (such as for Nintendo and Sony game consoles); snack food sales; and miscellaneous sources like sales of musical recordings and used videos.

Video specialty stores compete directly with supermarkets, drugstores, and other mainstream retail outlets that also sell or rent videos. Often mainstream stores sell videos at deep discount, creating pricing pressure on video stores.

The number of video stores has fallen significantly as large chain stores and so-called superstores have expanded. From 31,000 in 1990, the number of video stores had dropped below 25,000 by 1999.

Videos vs. Theaters. Video stores have always had a complex relationship with movie theaters. Early on, conventional wisdom held that video rentals cannibalized theater admissions because a typical consumer, the theory goes, would watch a movie either in a theater or at home, but not both. This pattern seemed to hold in the late 1980s and early 1990s, when box-office receipts began to decline as video rentals surged.

The relation between video rental and movie going grew murkier in the mid-1990s; rentals stagnated while business at the box office swelled. Indeed, Census Bureau statistics reveal that in 1996 theater revenues surpassed video store revenues for the first time since 1993, the year rentals first pulled ahead of theaters. To further complicate matters, by the late 1990s both video stores and theaters posted healthy gains side by side. In sum, analysts believe that video stores and movie theaters do vie

for the same audience some of the time—especially when the economy is sluggish—but also that each can create demand for the other.

Video Rights. Owning video rights to films is an important source of revenue for film studios. For example, during the 1990s roughly half of movie revenue in the United States came from home video, according to a study by Veronis, Suhler and Associates and Smith Barney, Inc. By contrast, revenue from theatrical exhibition accounted for 33 percent, and television showings contributed 20 percent.

DVD Format. By the early 2000s, digital video discs (DVDs) quickly became the preferred format for home video viewing, eclipsing videocassettes. Images stored on laser discs are sharper than videotape images, and viewers can move more easily to different places on the recording. Discs can also provide digital stereo audio, which makes them especially attractive for programs involving music.

BACKGROUND AND DEVELOPMENT

Although videocassette recorders and players have been available since the mid-1970s, pay-TV services were more popular early on. At the top was the cable network Home Box Office (HBO), which financed films in exchange for pay-TV rights and thus secured exclusive deals on very profitable movies.

By the mid-1980s, pay-TV viewers grew increasingly disenchanted with programming just as home video technology became more affordable and more widely available. Videos offered far more variety and flexibility in viewing for the customer. The cost of VCRs continued to fall—from \$300 to \$400 in the industry's early days for lower-priced models to \$150 to \$250 in 1993—further contributing to the rise in popularity. By the late 1990s, 84 percent of U.S. households owned at least one VCR.

Entering the mid-1990s, consumer demand for video rentals began to stabilize somewhat as sales of VCRs began to slow. In 1995 revenues from video rentals and sales actually declined, and rental business was essentially flat for the next two years. Though statistics vary, annual figures compiled by Alexander & Associates, a market research firm for the industry, portrayed video unit rentals falling in all but one year between 1995 and 1999. According to the same research, rental revenues managed to stay afloat largely through price hikes.

On the other hand, sell-through videos performed the best in the mid-1990s. One explanation for this trend was the decreasing cost of buying videos. In 1995, according to *Billboard*, Disney-owned Buena Vista Home Video began pricing quality features at \$9.99. Other studios followed suit with similar programs.

The industry's 1998 shift toward revenue sharing with film studios, allowing video stores to stock more titles at lower up-front costs, helped lift industry-wide revenues out of their mid-1990s doldrums. According to widely cited figures from Paul Kagan Associates, rental revenue in 1998 totaled \$8 billion and sell-through sales reached \$9 billion, bringing industry revenues to \$17 billion for the year. Though estimates vary, this translated into somewhere between three and four billion videos rented and some 676 million sold. The media research firm predicted sales would surpass \$20 billion by 2002.

Though lauded by many as a major breakthrough, revenue sharing appeared to further entrench a few large chains at the expense of smaller outfits, according to both statistical and anecdotal evidence. One reason was that the large chains were able to secure more favorable deals with studios, and thus the playing field was far from level. Big chains negotiated with studios directly, whereas small stores usually went intermediaries. Because small stores received worse pricing, they often opted out of revenue sharing. Meanwhile, their large competitors were able to stock more videos and more copies of each (known as copy depth), and saw a rise in revenue as a result.

Besides revenue sharing, another factor contributing to growth was the popularity of DVD-format videos. In 1998 the number of DVD players topped one million units, and the number was estimated near three million in 1999. Indeed, by 2007, more than 40 million units were forecast to be in use. Sales of DVDs were strong during the late 1990s, and this benefited activity within the rental market. In 1999 DVD only accounted for around 4 percent of one leading chain's sales, but that proportion was expected to grow rapidly in the early 2000s.

The conventional video store business competes increasingly with other services that can deliver movies directly to the home, such as pay-per-view and direct-broadcast satellite television. In 1999 pay-per-view was a \$1.1 billion business and growing rapidly.

A relatively undeveloped technology during the late 1990s posed perhaps the greatest threat. Video-on-demand services, which allow consumers to receive broadcast movies of their choice at any time, held the potential to lure a large portion of the market away from video rentals and sales. Under testing by various cable systems, movies are served up from the cable provider's digital network at the viewer's discretion. Pricing is similar to pay-per-view—and comparable to rental fees—only the movies can be started at any time and can be paused or fast-forwarded, and the consumer never has to leave home. By some estimates, such services held the potential to garner \$3 billion by 2005, mostly at the expense of video rental.

CURRENT CONDITIONS

U.S. Census Bureau figures reveal that, on an annual basis, revenue growth for videotape and disc rental stores declined during the early 2000s. While sales increased nearly 10 percent from 1998 to 1999, annual growth was about 3 percent from 1999 to 2000. In 2001, the industry's revenues declined more than 4 percent, falling from approximately \$9 billion to \$8.6 billion. The rising popularity of DVD hindered rental revenues somewhat, as many consumers opted to purchase attractively priced DVD titles—both classic favorites and newer titles—from discount retailers like Best Buy and Wal-Mart for their home libraries instead of renting them.

By the early 2000s, digital technology was beginning to change how consumers obtained movies for viewing. In late 2002, Warner Brothers forged an agreement with CinemaNow in which, for \$3 to \$4, consumers could download movies to their personal computer for a period of 30 days. By the spring of 2003, 20th Century Fox had entered into an online distribution with CinemaNow. In November of 2002, a competing online movie service called Movielink—a joint venture between Paramount Pictures, Metro-Goldwyn-Mayer Studios, Warner Bros., Universal, and Sony Pictures Entertainment—began serving customers. According to *The Online Reporter*, by 2005 feature films delivered via the Internet were expected to result in revenues of \$882 million. However, by early 2003 roughly 10 percent of homes were outfitted with the high-speed Internet connectivity required to download films in this way. Therefore, some industry observers argued that discounted DVDs were more of a threat to the rental industry than such video-on-demand services.

Although consumers purchased DVD titles in growing numbers, a great many also were inspired to rent them, which boded well for the industry. This led to a subsequent decline in videocassette rentals. These trends are evident in figures from Alexander & Associates, which show VHS rentals falling from 3.7 million in 2000 to 3.3 million in 2001, and then dropping to 2.6 billion in 2002. Spending on VHS rentals mirrored this decline, dropping from \$11.6 billion in 2000 to \$10.8 billion in 2001, and then falling sharply to \$8.8 billion in 2002. Alexander & Associates reports that while total DVD rentals were a mere 246 million in 2000, they quickly jumped to 616 million in 2001 and then skyrocketed to about 1.2 billion in 2002. Spending on DVD rentals during this timeframe also increased, reaching \$781 million in 2000, \$2.2 billion in 2001, and \$4.3 billion in 2002.

In early 2003, the video rental industry appeared to be recovering. Consumer spending on rentals reached record levels in the first quarter that year, with combined revenues for both DVD and VHS reaching \$2.3 billion,

according to the Video Software Dealers Association. During the month of March, DVD rental sales surpassed VHS on two occasions. This was an industry milestone and, according to some players, marked a pivotal point for the DVD format, which was expected to eclipse VHS overall in 2003 and subsequent years.

As DVD became a hit with consumers, a variety of companies—including cable operators that were disappointed with consumer response to pay-per-view services—expressed an interest in DVD rental schemes that would generate additional revenues. Although earlier services that offered Internet-based video rental—including Kozmo.com—failed, Netflix was one company that successfully took the DVD rental model to the Web. In April 2003 the company allowed consumers to rent more than 13,500 different titles via the Internet, including the latest blockbusters, as well as documentaries and independent films that were hard to find in traditional rental outlets. For a monthly subscription fee of \$19.95, Netflix offered free one to three day shipping both ways and allowed customers to rent up to three titles at a time with no due date, thus eliminating the late fees charged by traditional stores. The company accomplished this via 18 shipping centers, a number that was increasing during 2003. By the end of that year, Netflix indicated that 75 percent of its customers would enjoy overnight movie delivery.

INDUSTRY LEADERS

Blockbuster. The undisputed leader of the video store industry is Blockbuster, Inc., owned since 1994 by the media conglomerate Viacom. Despite its dominance, Blockbuster's corporate performance has been spotty. From 1997 to 1999, although its revenue grew significantly, it ran net losses and racked up heavy debt. Blockbuster's weakness was also an ongoing source of friction with its parent, Viacom, which was under pressure from investors to spin the video unit off as a separate entity. After long delays, the first steps were taken in 1999 with a public offering of part of Blockbuster's stock. When they finally came, however, the new shares were not warmly received by the market, and in following months Blockbuster's shares largely hovered below their offering price. In 2002 Blockbuster pulled in \$5.6 billion in worldwide sales, but the company posted a loss of \$1.6 billion. The video leader operated 8,500 stores throughout the world, including approximately 5,900 domestic outlets.

Hollywood Video. The second-largest U.S. video store operator during the early 2000s was Oregon-based Hollywood Video. Owned by Hollywood Entertainment Corp., the chain consisted of 1,800 outlets in early 2003. The company operates Game Crazy videogame outlets in six states within select video stores. In 1999 Hollywood and Blockbuster engaged in talks about merging their online

offerings to better compete in the emerging electronic film delivery business. Those talks mushroomed into full-blown merger discussions, but the Federal Trade Commission quickly doused any such plans by expressing antitrust concerns. Hollywood Entertainment owns one of the Internet's most popular film sites, Reel.com. In 2002 it forged a partnership with Amazon.com in which Reel.com visitors who wish to purchase movies were linked to the Amazon.com Web site. Hollywood Entertainment achieved sales of \$1.5 billion in 2002, at which time it planned to increase its store count to 1,841 locations.

Movie Gallery. With 1,800 stores, Movie Gallery was the third-leading video rental business in the early 2000s. Focusing on smaller cities and rural areas, Movie Gallery recorded sales of \$529 million in 2002. That figure was up more than 43 percent from the previous year. In 2002, the company saw its net income increase more than 46 percent, reaching nearly \$21 million. The firm purchased BlowOut Entertainment in 1999, and Video Update, Inc. in December 2001. Video Update formerly was the fourth-leading video store business.

DANCE STUDIOS, SCHOOLS, AND HALLS

Establishments in this industry are primarily engaged in operating dance studios, schools, and public dance halls or ballrooms. Establishments primarily engaged in renting facilities used as dance halls or ballrooms are classified in **SIC 6512: Operators of Nonresidential Buildings**. This category includes ballroom operation, children's dancing schools, dance hall operation, dance instructors, dance studios and schools, discotheques (except those serving alcoholic beverages), and professional dancing schools.

NAICS CODE(S)

713990 (All Other Amusement and Recreation Industries)

611610 (Fine Arts Schools)

This approximately \$500 million industry constitutes a very small portion of the overall recreation category. It is dominated by small, independent schools run by sole proprietors, usually owner-operators. The two major nationwide dance school chains, Arthur Murray International and Fred Astaire Dance Studios, cater to adults. Independent studios, which are primarily involved in teaching ballet and tap dancing to children, outnumber other franchises by about six to one.

The dance school industry in America has had an uneven history. Dancing as a leisure activity was forced underground by the dominant Protestant culture that de-

clared dancing socially unacceptable and linked it with drinking and lewdness. Even when European immigrants brought traditional dances to America during the nineteenth century, they were limited to celebrations at ethnic social halls.

Dancing became more mainstream after the turn of the century, when music and more organized bands earned enthusiastic followings. The advent of prohibition in 1920 separated dancing and drinking to a certain extent, and made dancing more socially respectable. Many commercial dance palaces were set up during this period, and in New York City alone, dance halls had revenues of \$8 million in 1920.

Arthur Murray and Fred Astaire, the namesakes of the twentieth century's two largest dance schools, got their starts during this period. Murray opened his first dance studio when he was just 18 years old. Murray's career reflected the fortunes of the dance school and hall industry, crescendoing in the 1940s, when the song, "Arthur Murray Taught Me Dancing in a Hurry" was penned by Johnny Mercer. A request by a hotel manager to have Arthur Murray dance instructors in all Statler Hotels was just the beginning. Headquartered in Coral Gables, Florida, the company has around 180 studios in nine countries. In 1964, Murray and his wife Kathryn sold the studios to Philip Masters and president and CEO George Theiss, who retain ownership. Arthur Murray International reported revenues of \$55 million in 2001 and \$60 million in 2002.

Fred Astaire and Ginger Rogers inspired young men and women to emulate their moves in such popular films as *Top Hat*, *Swing Time*, and *Shall We Dance*. The Fred Astaire Dance Studios, headquartered in Boca Raton, Florida, were established in 1947 and have locations throughout North America. Fred Astaire Dance Studios reported revenues of \$40 million in 2001.

A combination of social, economic, and demographic factors contributed to the decline of ballroom dancing and the dance school industry in the 1950s and 1960s. Fewer extravagant, romantic movie musicals were filmed. The advent of counter-culture rock-and-roll music was accompanied by alcohol use, transferring much social dancing into another industrial category. Moreover, the mass exodus to suburbia during this period resulted in a decreasing number of couples visiting urban dance halls. During the 1960s and 1970s, improvised singles dancing grew increasingly popular, and organized couples dancing became reserved for weddings and other special occasions.

Ballroom dancing regained popularity in the 1980s, spurred by a modest revival of music from the first half of the century. As the decade of conspicuous consumption progressed, ballroom dancing provided an outlet for pros-

perous men and women to dress up and spend money. Dance studios and halls also benefited from the fitness craze, as people danced for exercise and to relieve tension. Some observers even cited the increasing fear of both AIDS and romantic commitment as reasons for the industry's upswing, noting that individuals could get to know each other without having a formal date. The return of traditional formal weddings also contributed to this industry's growth in the 1980s. Dance teachers also credited the Public Broadcasting Service, which carried major ballroom dance competitions beginning in 1981, for promoting the activity. Dance studios began to coordinate more competitions, which encouraged students to take more lessons in preparation for competition.

The International Dancesport Federation (IDSF, formerly the International Council of Amateur Dancers) spent the latter half of the twentieth century working toward the acceptance of ballroom dancing as an Olympic event. In 1987, IDSF designated the United States Amateur Ballroom Dancers Association as the sole governing body for amateur ballroom dancing in the United States. Ten years later, the International Olympic Committee gave full recognition to the IDSF and its affiliates. As the twenty-first century began, the dancesport community was awaiting inclusion as a medal sport.

The growing popularity of recreational dance was evidenced by the number of Web sites devoted to ballroom, folk, Latin, swing, and country/western dancing. These sites offer directories of schools, dance halls, and competitions.

As popular dance boomed, however, professional dance lagged. Rehearsal space in New York City, always rare, has been taken away from professional dancers and college students and used for more lucrative activities. A sizable number of professional dancers supplemented their incomes by working as aerobic instructors. In addition, dance companies were licensing fitness centers to use their names, choreography and techniques.

Although college dance students were being urged by their professors to prepare for alternative careers, dance schools at the University of Utah, University of Hartford, Rutgers University, University of Iowa, and Hunter College of the City University of New York still provided professional dancers for smaller companies. A growing concern for dancers' health was responsible for the inclusion of nutrition classes in these curriculums. The National Association of Schools of Dance (NASD), founded in 1981, has 57 institutional members, all of whom offer programs in dance. As an accrediting agency, the NASD serves to delineate and improve practices and professional standards in dance education and training.

Music copyright collections was a prominent issue for dance schools. Schools are required to pay fees for the

use of music registered with ASCAP, BMI, and SESAC. Although there appeared to be agreement in the dance community that composers should receive royalties when their music is used during public performances, the status of many schools as non-profit institutions was a cause for controversy.

According to the U.S. Department of Labor, Bureau of Labor Statistics, 33,630 people were employed by dance schools, studios, and halls in 2001. Management occupations accounted for just over 3.5 percent with general and operations managers accounting for 910 of the 1,240 total management positions and reported a mean annual salary of \$46,140. For the mere 40 chief executive officers listed, the mean annual salary was \$61,460. Self-enrichment education teachers, with a mean annual salary of \$33,180, accounted for nearly 30 percent of the industry's jobs, and choreographers, with a mean annual salary of \$32,080, accounted for another third of jobs. Dancers numbered 2,360, or 7 percent of the jobs, with a mean annual salary of \$27,040. Office and administrative support positions totaled 12.5 percent of the industry's jobs.

INDUSTRY SNAPSHOT

New York City, particularly Manhattan, has always been the undisputed center of the U.S. theater scene. The late 1990s did nothing to change this, though developments somewhat altered the internal dynamics of New York's theater market. At all levels, the theater industry was characterized by rising production costs, which have focused efforts on more tested and proven productions that can more readily assure profits. This trend is most pronounced among the large Broadway theaters with the most to lose—one reason for the proliferation of revivals on Broadway, which are more reliable than new productions.

The scope of theater nationwide is so broad and varied that a snapshot of its size, as measured by revenues, does not currently exist. Broadway productions are fairly well documented; off-Broadway and off-off-Broadway are significantly less so. Regional touring companies, community theaters, summer stock (where one ensemble performs several plays each season), and their contributing entities such as agencies and scenery design and building are so fragmented as to render a comprehensive overall picture nearly impossible to draw.

SIC 7922

THEATRICAL PRODUCERS (EXCEPT MOTION PICTURE) AND MISCELLANEOUS THEATRICAL SERVICES

This category includes companies engaged in providing live theatrical presentations, including road companies and summer theaters. This industry also includes

Throughout the nineteenth and early twentieth centuries, the New York theater district along Broadway kept moving north as new theaters were built and old ones were abandoned or torn down. After World War II, as construction of new theaters became rare, "Broadway" stabilized in an area that can be roughly defined as the section of Broadway between Times Square and 53rd Street. Most of Broadway's 32 theaters are not actually on Broadway but clustered on side streets.

The New York theater market surged in the late 1990s at all levels, generating about \$1.6 billion in ticket sales. Although Broadway enjoyed record box office returns, the biggest gains, both in attendance and in prestige, occurred at off- and off-off-Broadway venues, most of which have theater capacities of 75 to 400 seats.

Broadway. The 1998-99 New York Broadway attendance reached a record 11.7 million, according to information provided by the League of American Theaters and Producers, Inc. This represented a 23 percent increase from the 9.45 million Broadway attendees in 1996. Box office receipts also achieved unprecedented heights in 1999, totaling \$588.5 million, up 5.5 percent from the year before. Thirty-nine Broadway productions opened in New York, four more than in 1998. However, the total playing weeks of Broadway shows fell slightly to 1,440. Major successes of the late 1990s included "Art," which turned a profit of \$4.5 million from its 600 performances; Disney's "The Lion King," a box office smash indicative of Broadway's heightened attempts to draw young and other non-traditional audiences in, as well as the revivals of "Cabaret" and "Chicago."

Although the numbers seem encouraging, there is serious concern about Broadway's future. Ticket prices have gone up with the cost of production. In 1957, top price orchestra seats at a Broadway musical could be had for \$8.05. By 1970, the price nearly doubled to \$15.00, and by the early 1980s soared to \$45.00. In 1999, orchestra seats were going for \$75.00. According to the League of American Theaters and Producers, Inc., the average paid admission to a Broadway production was \$50.30, up from \$48.58 in 1998, and could reach as high as \$85.00. In 1987, the average stood at \$28.66. Ticket prices for Broadway road companies follow a similar pattern. The rising costs are attributed to a strong U.S. economy, the increasing wealth of the typical theater audience, and, most particularly, rising production costs. Unless production costs diminish, it seems unlikely that ticket prices at commercial theaters will decrease.

In the mid and late 1990s, the minimum cost of mounting a Broadway production was \$750,000 for a play, and \$3.5 to \$6 million for a musical. Some musicals have had budgets in the \$10 million range. Increased costs have made turning a profit more difficult, and shows

can run for well over a year without moving to the plus side financially. Investors are increasingly reluctant to back risky ventures — those which do not have the potential for a lengthy run. This situation has led to a preponderance of revivals of past successes, especially musicals. *Carousel*, *Damn Yankees*, *Show Boat*, *The King and I*, and *How to Succeed in Business Without Really Trying*, are just a few of the older works that have returned to Broadway in the 1990s. According to the *New York Times*, about half of the productions that opened on Broadway in the 1995-96 season were revivals. Though revivals are a normal and necessary part of the theater, such a large number of them is unprecedented and problematic. Meanwhile, one of the lynchpins of the late 1990s Broadway market, "The Lion King," had already proven itself as a fantastically successful animated Disney motion picture, thus constituting another relatively safe investment.

Soaring production costs further sparked increased focus on marketing campaigns as a competitive field for Broadway producers. A typical Broadway production spends between \$300,000 and \$1 million on pre-opening marketing campaigns and maintains publicity with about \$50,000 per week after the production hits the theater. Meanwhile, the League of American Theaters and Producers has entered into a number of promotional contracts with major companies, including Schweppes, which agreed to launch a Broadway sweepstakes campaign advertised on its beverage bottles. Similarly, the First USA Bank-Broadway credit card features Broadway-related consumer incentives. Broadway shows have advertised on McDonald's French fries containers, while youth-oriented productions such as "Rent" and Disney productions have placed products such as coloring books in schools.

An extension of Broadway are road companies, which bring streamlined, though still often extremely elaborate, versions of Broadway productions to major cities around the United States and Canada. In the 1998-99 theater season, 14.8 million people attended Broadway shows outside of New York, down 20 percent from 1996. The box office take equaled \$716 million, also down from \$721 million. The declining number of touring productions largely accounts for sagging receipts; only 25 Broadway shows took to the road in 1999, down 30 percent from 1996.

Off-Broadway. Re-staging of material that has already proven itself Off-Broadway or in London is also a current feature of Broadway. The conservative reluctance to exhibit new and untested work has somewhat diminished Broadway's status as the center of the American theater. The pressure to come up with a long running crowd pleaser has also turned away creative personnel. Off-Broadway, a term applied to a wide variety of smaller theaters in New York located away from the major theatrical district, is

becoming more important as a place to showcase original material. Once considered a training ground for Broadway, Off-Broadway is now accorded as much prestige as Broadway, as a venue in which audiences can glimpse the latest, most innovative works before they explode on the commercial scene, as was the case with the late 1990s hit "Bring in 'da Noise, Bring in 'da Funk." Having a success Off-Broadway has even come to be seen as an end in itself. Many playwrights and theater composers, including well-established ones such as Stephen Sondheim, Neil Simon, and Edward Albee, have taken some of their works Off-Broadway in the 1990s.

Eight million people attended non-Broadway shows in New York during the 1997-98 season, representing an increase of 8 percent from the previous year. The commercial possibilities of Off-Broadway have increased along with its prestige. Although the vast sums brought in by "megahit" Broadway shows are not possible in Off-Broadway's small to moderate size theaters and lower profile atmosphere, handsome profits are still being made. Some long-running Off-Broadway successes, such as *Tony and Tina's Wedding*, have franchised lucrative duplicate productions in other cities. Off-Broadway's appeal has increased so much that, by the mid 1990s, there was a clamor for space in its handful of larger size theaters. Some analysts view the increased status and popularity of off-Broadway productions with some caution; the trend spurred theater construction at a pace of nearly one-and-a-half new theaters per month in 1999, sparking fears of a possible glut in coming years—especially should the newfound success of off-Broadway prove only a fad.

Demographics. The League of American Theaters and Producers notes that the average theater attendee belongs to a household with more than \$80,000 in annual income. Moreover, about 88 percent of audiences are white, though that figure diminishes among the growing youth audience.

The increase in ticket sales enjoyed by theaters in recent years is often attributed to an overall increase in the adult population due to the post World War II "baby boom," rather than increased interest in the theater. Though the number of tickets sold has gone up, the percentage of Americans who say they have attended a theatrical production in the last year has declined steadily to about 11 percent in 1999. Various reasons have been put forth for the waning popularity of theatergoing, including the greater availability of home entertainment; high ticket prices; and the trend towards late-in-life parenthood, which has left many people with child care obligations well into middle age.

For many years, the theater industry was most disturbed by the strikingly low attendance rates among

younger audiences, suggesting that the theater's future lifeline was sorely thin as younger people showed little interest in theater shows as an entertainment form. Toward the end of the 1990s, that long-standing trend began to change somewhat. The percentage of Broadway audiences composed of people younger than 18 years of age grew from 1.3 percent in 1990 to 4.7 percent in 1998. The 18-24 sector, meanwhile grew from 3.6 percent to 5.9 percent over that period. While in the late 1990s, many attributed this sudden turnaround to the massive popularity of youth-directed productions, such as the Generation-X-angst production "Rent," some analysts suspected that long-running intensive marketing efforts geared toward younger audiences were finally paying off.

Notable developments on the road included a considerable gender gap in Broadway audiences, particularly among younger attendees. Women comprise 70 percent of the touring Broadway audience; moreover, they purchase 75 percent of the tickets for those shows. A demographic study by the League of American Theaters and Producers concluded that approximately 30 percent of theatergoers are "apparently dragged to the theater by their wives or girlfriends."

Tourists constituted an increasing proportion of Broadway audiences through the 1990s, equaling roughly 60 percent of Broadway attendees at the end of the decade, up from 50 percent just three years earlier. For long running hits such as *Les Miserables* and *Cats*, the percentage of tourists can be as much as 80 percent. There is great concern that the theater in New York, and elsewhere, is losing its base of regular patrons whose interests go beyond an occasional visit to a hit show. Observers surmise that tourists tend to be drawn to the traditional glamour and mystique of Broadway, while more hardened New York locals have grown weary of its increasing conservatism and reliance on lavish revivals.

BACKGROUND AND DEVELOPMENT

Theater in America dates back to the Revolutionary War period, which saw the formation of the first professional company in Williamsburg, Virginia, in 1752. The company was led by Lewis Hallam and was a profit-sharing venture. This financial structure called upon the actors to pay a percentage of company expenses and to receive a share of the profits. This organizational structure was adopted from Elizabethan England and also existed in the first known company in the Americas, which began in Peru in 1599. The general manager of the company was also generally a leading actor and would both invest more, and receive a greater share of the profits, than the other performers in the company. Playwrights and musicians would also participate in this type of ensemble. Not only did the performers often make a meager living from this arrangement, but they also faced

the barrier of resistance from Quaker and Puritan colonists. But theaters began to open in the late 1700s and were well established by the turn of the century.

The era of profit-sharing theater companies gave way to one of independent stock companies, which lasted through the 1870s. The independent stock company would instead have a fairly permanent stable of actors and a fixed supply of scenery and props. These companies would stage a variety of current works and classics, and would either tour or present shows in a fixed venue. Most actors remained relatively obscure, although audiences made tours of celebrity performers from England popular during this time.

The impetus for the next major change in the structure of theater was the development of the railroad system, which led to the “combination company”—the ensemble that toured by train from one major city to another, stagehands, scenery, and the like in tow. Most combination productions were organized in New York, and this led to centralization of the American theater in that city (Philadelphia and Boston had offered some rivalry to New York in earlier decades). The combination system required a complicated booking system to insure that large ensembles of performers and scenery would move smoothly through lengthy tours. As a result, theater ownership became centralized into a small number of circuits, which monopolized booking rights in various geographical areas. In 1896, three theater owning circuits joined forces to create the “Theatrical Syndicate,” which dominated the theater for the next two decades. Producers who wanted to use a Syndicate-owned theater in a certain city were forced to book their entire tours in Syndicate theaters. Thus, theaters owned by non-Syndicate members languished and competition was minimal. Syndicate members, most notably Charles Frohman, were also producers and reserved the best routes and best theaters for their own productions. Theatrical offerings of this era focused on star performers in vehicles suited to their talents, such as Maude Adams in *Peter Pan* and David Warfield in *The Music Master*. Road tours, which made one-night stops in small cities as well as playing for lengthier engagements in large cities, were more profitable than playing in New York and only a handful of major successes ran on Broadway for more than two or three months. Eventually, the Theatrical Syndicate declined, and the chain of theaters owned by the Shubert brothers became the nation’s most powerful theatrical landlord. The Shubert Organization still thrives, owning sixteen of Broadway’s thirty-two theaters, with a half interest in a 17th, the Music Box. Theater owners hold an important position in the commercial theater since they control what goes in their venues.

In the 1920s, the once lucrative road dissolved as many theaters were converted into movie houses which

are inherently more profitable than legitimate theaters since operating costs are lower. Theatergoers in many medium and small cities were left with no theater to attend. According to Jack Poggi in *Theater in America*, the number of legitimate theaters outside major metropolitan centers dropped from 1,549 in 1910 to 400 in 1928. Motion pictures had begun to capture the imagination of the public, especially that segment that had patronized second tier theatrical comedies and melodramas. This left the theater with a smaller but more sophisticated clientele.

The stock market crash of 1929 and subsequent Great Depression hurt the theater but, unlike in other industries, improvement in the economy did not bring a recovery. The level of Broadway activity in the prosperous post-World War II era, sometimes considered Broadway’s heyday since so many works from that period still enjoy popularity, was actually no higher than during the depths of the Depression.

A burgeoning number of non-profit resident theaters, or repertory companies, began operating in cities outside New York in the 1970s, though a number of them, such as the Pasadena Playhouse in California and the Arena Stage in Washington, D.C., have existed for much longer. These companies, which have lower ticket prices and a wider range of offerings than the commercial theater, depend to a great extent on government grants and private sector donations. Reduced levels of support from these sources imperil many resident companies. The budget of the National Endowment for the Arts was slashed by 40 percent in fiscal 1996, and while its budget was squeezed tightly throughout the remainder of the decade, debate raged on Capitol Hill and elsewhere often calling for the endowment’s dissolution altogether.

Even more important, in the opinion of some analysts, is the dramatic drop in private philanthropy. Younger people are patronizing art organizations at a decreasing rate and, consequently, they are not supporting such organizations with generous donations. Charitable donations to the arts declined by about half between the mid 1980s and mid 1990s, and registered a further 2.5-percent drop in 1998, despite a booming U.S. economy and increased income among the largest traditional arts-patronage demographic. To deal with this situation, many resident theaters are restructuring their finances, making longer range economic plans, and producing works that appeal to a wider audience. There is also greater acceptance of the idea that some resident theaters, especially those that cannot put themselves on a stronger financial footing, will have to be disbanded. This situation is troubling to many people since producing highly commercial material is not viewed as the purpose of non-profit theater, and companies with sound finances are not necessarily those of the greatest artistic merit.

the top performers in popular music in the late 1990s included genre stalwarts The Rolling Stones, who raked in \$89.2 million in 1999; Bruce Springsteen, whose reunion tour with the E-Street Band generated \$53 million in box office receipts; hip hop stars Master P and Sean Puffy Combs, who in 1998 earned \$56.5 million and \$53.5 million, respectively; the Dave Matthews Band, whose concerts brought in sales of \$44.5 million; pop diva Celine Dion, with \$55.5 million in 1998; and 'N Sync, the top new act in 1999, earning \$44.3 million to edge out their boy-band competitors, The Backstreet Boys, who made \$24.5 million. Barbara Streisand, meanwhile, broke the box-office record for a single show with her New Year's Eve, 1999, performance in Las Vegas, which generated ticket sales of \$14.7 million, topping the Three Tenors' New Jersey show in 1996, in which Luciano Pavarotti, Placido Domingo, and Jose Carneras raked in \$13.4 million.

Festivals continued to play a vital role as a way to excite concert goers, with touring shows such as the Lilith Fair designed to showcase a particular niche market, in this case the female pop singer/songwriter genre, in a forum that draws greater numbers than promoters surmise the artists could draw on their own, while fetching a higher ticket price in the meantime. Following the same logic while drawing on pop culture mystique, the Woodstock '99 concert in upstate New York drew 186,963 fans to its three-day festival, generating ticket sales of \$28.86 million. The show managed to arouse controversy, a staple of the rock and roll scene, as the kids took to destroying the venue and, disturbingly, committing over a dozen sexual assaults. From a financial standpoint, however, the show was indicative of the year's success in rock and pop music. Gimmickry was also alive and well on the concert scene. The Christian rock band, The Newsboys, planned a U.S. tour in 2000 featuring their own portable arena, a 3,500-seat blow-up model that could be set up in 90 minutes and transported from city to city.

Country music, however, failed to enjoy such good news; attendance was down about 20 percent in 1999 after dramatic growth through the mid 1990s. Total receipts for country music shows fell 16 percent to \$116 million, with two acts, Shania Twain and George Strait, accounting for more than half of that total, at \$36.6 million and \$32.0 million, respectively. Observers attributed a large share of this decline to the absence of country star Garth Brooks from the concert scene in 1999. Long the brightest star in country music, Brooks was among the top entertainers in 1998 with concert sales totaling \$54 million.

One of the most notable popular-music trends at the close of the 1990s was the voracious market for teen pop acts. The boy-band craze of 1999, featuring acts such as

SIC 7929**BANDS, ORCHESTRAS, ACTORS, AND OTHER ENTERTAINERS AND ENTERTAINMENT GROUPS**

This category covers establishments primarily engaged in providing entertainment other than live theatrical presentations; these establishments include bands, orchestras, and entertainers.

NAICS CODE(S)

711190 (Other Performing Arts Companies)

Music. The pop music concert circuit reached record levels in the late 1990s, deriving its success from seasoned veterans as well as trendy new acts. The top ten acts managed to bring in \$414.3 million, up substantially from sagging mid 1990s receipts. Internationally, concert receipts totaled \$1.3 billion in 1999, up 12 percent from 1998, while in North America revenues reached \$1.23 billion, representing an increase of 11 percent. Some of

The Backstreet Boys, 'N Sync, and 98 Degrees, along with other artists such as Britney Spears, jumped on the youth fan base stirred up in preceding years by The Spice Girls to create the most visible and lucrative niche market in popular music. Despite the notorious track record of here-today, gone-tomorrow youth acts such as New Kids on the Block, some record executives were banking on such artists for the long haul; in 1999 Jive Records signed The Backstreet Boys to a five-album, \$60 million contract, one of the biggest music deals ever.

Other trends in popular music relied less on teen innocence and more on parental shock. Acts such as Marilyn Manson and Insane Clown Posse incorporated explicit lyrics and often-graphic sexual or gory imagery into their live performances, arousing parental ire and even leading to talks in state and local legislatures of implementing a ratings system for live shows. Analysts estimated that about 25 percent of pop-music concert revenues were generated by acts that engage in some type of obscenity on stage. By including warning labels on tickets or rating shows in the manner of motion pictures, proponents hoped to keep children away from such concerts unless accompanied by an adult. Some artists, however, considered these proposals an act of censorship; high-powered acts such as Pearl Jam and R.E.M. announced that they would refuse to play in any state that passed a concert-rating law.

Another musical genre making an unexpected surge in the mid and late 1990s was opera, which *Forbes* labeled "one of the hottest sectors in the entertainment business." In the 18- to 24-year-old crowd, attendance grew by 15 percent between 1989 and 1999, while the number of opera companies has gone from 60 in the late 1970s to 170 in 1998. Opera's popularity rested on its traditional styles as well as on cross-over collaborations between opera stars like Luciano Pavarotti with pop acts such as U2. Meanwhile, some corporations paid as much as \$75,000 for an opera star to sing for as little as half an hour at a company event, quite a bit higher than the \$15,000 top fee for singing at the New York Metropolitan Opera.

Symphony orchestras continued to struggle in the 1990s, often going to great lengths to court younger audiences. The Philharmonic Society of Orange County, California, for instance, devised a multimedia performance for their concerts incorporating video footage and live theater in accompaniment with the musical performance. The Dallas Symphony Orchestra (DSO), meanwhile, invested in a World Wide Web site to showcase both technological and symphonic music, often in hybrid form, and to transmit live Web-casts of DSO performances.

One reason cited for frustrating sales figures is the high price of tickets for symphonic performances, which

averaged \$112 in 1999. Personnel costs made up nearly half of an orchestra's budget. Minimum starting salaries for new orchestra members in "major orchestras" (orchestras with a \$5 million or higher budget) were approximately \$74,360 annually, with highs of \$130,000 reported by the New York Philharmonic and the Chicago Symphony. Salaries in most orchestras range from \$25,000 to \$100,000. There were more than 800 symphony orchestras in the United States in the late 1990s.

Magic Shows. Other live entertainment that has recently regained popularity has been the age-old industry of magic. Some of the highest paid entertainers are magicians, or illusionists. David Copperfield, long the reigning illusionist, generated sales of \$49.5 million in 1999. Las Vegas has been the hot spot for the rebirth of the illusionist, with all the major casinos touting their own acts. The business community has also tapped into illusionists, using them at trade shows and sales meetings, with fees running as high as \$2 million for Siegfried & Roy to appear at a German theme park opening.

Comedians. Comedians were also laughing their way to the bank, with comedy clubs cropping up around the country. Jerry Seinfeld topped the 1998 *Forbes* list of the highest-paid performers, taking in \$225 million. Meanwhile, comedy records registered a huge upsurge in the mid and late 1990s, with comedians such as Seinfeld and George Carlin releasing highly successful recordings of their live performances.

Actors. Although musicians and actors have differing talents, the most successful ones end up looking rather similar. They are wealthy and powerful, and have national, if not international, name recognition. Talk-show host Oprah Winfrey continued her reign as the highest-paid television performer, raking in \$125 million in 1999; Tim Allen followed with \$77 million. Winfrey's syndicated talk show faced challenges in this period from Jerry Springer's notoriously volatile program.

Screen actors are generally the most high-profile and glamorous personalities in entertainment. Leading actors include Harrison Ford, who pulled in more than \$58 million in 1998; Robin Williams, with \$56 million; and Mel Gibson, with \$55 million.

The lingering wage disparity between actors and actresses was a growing concern to the acting community in the late 1990s. The Screen Actors Guild (SAG) noted that men typically earn about twice as much as women in the profession, while leading actresses could not command anywhere near the top-dollar salaries of their male counterparts. Furthermore, SAG reported in 1999 that 63 percent of all movie roles are written for men, a gap that has held steady since 1992. Most of the difference is accounted for in the heavily male-dominated supporting role field. When combined with age demographics, the

disparity was even more pronounced. While about two-thirds of all acting roles were awarded to people under 40 years of age, only 27 percent of all female roles went to women over 40, compared with 37 percent for men.

Meanwhile, the television and film industries fell under scrutiny in 1999 as disproportionately few roles were awarded to minorities. According to SAG reports, only 19 percent of all roles were awarded to minority actors in 1998. Latinos were the most under-represented, accounting for only 3 percent of all roles despite constituting 10 percent of the U.S. population.

Many actors and actresses spend the majority of their careers in live theatrical productions. Many reasons can be found for this interest in the theater. The stage is regarded by many actors as a demanding, exhilarating venue from which to practice their craft. In 1997, the minimum weekly salary for Broadway actors was about \$1,040, while off-Broadway actors commanded about \$600 per week. The uncertain future of governmental arts subsidies could have dramatic consequences for actors and actresses in this field.

BOWLING CENTERS

This industry includes establishments known to the public as bowling centers or bowling alleys. Such establishments frequently sell meals and refreshments.

NAICS CODE(S)

713950 (Bowling Centers)

INDUSTRY SNAPSHOT

Approximately 53.3 million Americans visited a bowling alley at least once in 1997, making tenpin bowling the most popular indoor participation sport in the United States, based on participation of once or more per year. There were also 8 million “frequent bowlers,” or those who bowled more than 25 times per year.

Bowling boomed following the invention of the automatic pin setter in the early 1950s. By the mid 1960s, approximately 12,000 bowling centers were built in mostly blue-collar, urban areas of the United States. Due to demographic and lifestyle changes, however, the bowling market collapsed during the 1970s. As of 1998, there were only 6,542 certified bowling centers in the United States, the lowest total since 1954. In response, the bowling industry tried to redefine its image, with the hopes of attracting the affluent middle class and their children. New centers have been built in better market locations with state-of-the-art facilities. Operators renovated their existing centers to include computerized scoring, upscale dining, entertainment, and even child care.

ORGANIZATION AND STRUCTURE

Many forms of bowling existed, but tenpins became the most widely played version in the United States and throughout most of the world. According to rules specified by the American Bowling Congress (ABC), tenpin bowling is played indoors with 15-inch pins arranged in a triangle at the end of a wooden or synthetic lane. The game consists of ten frames with two rolls of the ball per frame. The goal is to knock down all ten pins with the first ball, which earns a strike. If pins are left standing after the first roll, the fallen pins are removed and a second delivery attempted. Knocking over all the remaining pins earns a spare. A perfect game totals a score of 300 and consists of 12 strikes in a row (two additional rolls are granted on the final frame).

The traditional strength of the bowling center industry was its highly organized, competitive league structure. Men’s and women’s leagues consisted of teams with up to five players each. The total number of teams per league depended upon the number of lanes per bowling center. Three bowling associations determined the rules of league play. They also handled the prize money collected from bowlers’ entry fees.

Most bowling alleys relied upon the steady revenue of league bowling instead of walk-in traffic. Approximately two-thirds of revenues came from bowling fees, so it was critical for centers to attract large numbers of customers to their lanes. Demographic and lifestyle changes triggered a decline in bowling leagues. In re-

sponse, some operators instituted flexible leagues, while others shortened their seasons to 20 weeks, or offered league play every other week.

BACKGROUND AND DEVELOPMENT

The modern game of bowling probably originated in ancient Germany as a religious ceremony. As early as the third or fourth century, most Germans had kegels, or clubs, that they used for both sport and self-defense. Some Germans would take their kegels to church in an attempt to rid themselves of sin. They would place the kegels at the end of a long lane, similar to the modern bowling alley, and roll a stone toward them. If the kegels were knocked over, the owners were absolved of sin.

Dutch settlers brought ninepin bowling to the United States in the seventeenth century. The game quickly grew in popularity but was soon taken over by gambling interests. So strong was gambling's hold on bowling, some states outlawed the game altogether. In fact, some sources claimed that the tenth pin was added to the game in the early eighteenth century to circumvent the prohibition of bowling, which applied only to the ninepin game.

The popularity of tenpin bowling spread as German immigrants moved to Chicago, Milwaukee, St. Louis, Cincinnati, and Detroit. However, the lack of uniform rules and equipment stunted the development of the sport. In 1875, intending to establish standardized rules and regulations, nine bowling clubs in New York City and Brooklyn organized the National Bowling Association.

Despite this initial attempt, disagreement over game rules persisted. In 1895, a second group, the American Bowling Congress (ABC), was organized in New York City. ABC succeeded in establishing standard regulations and became the governing body for men's bowling, sponsoring its first national tournament in 1901.

ABC's counterpart, the Women's International Bowling Congress (WIBC), was founded in 1916 and began its annual national championship in 1917. Although they remained separate organizations, these two groups shared equipment testing and research facilities. In an attempt to attract a younger audience, the Young American Bowling Alliance (YABA) was established in 1982. This group worked with bowlers from childhood through college age. All three organizations combined to serve about 4.5 million members.

The invention of the automatic pin setter in the early 1950s revolutionized bowling and acted as a catalyst for the growth of alleys and league play. Between 1955 and 1963, the number of bowling alleys in the United States grew from 6,600 to 11,000, while the number of organized league bowlers jumped from less than 3 million to 7 million.

During the same time period, the Professional Bowlers Association of America (PBA) was established. Similar to professional golf, the PBA quickly developed a star system complete with professional tournaments. With the advent of television, PBA members became household names and earned millions in prize money.

Following its boom in the 1950s and 1960s, bowling centers were overbuilt in the 1970s. During the same time period, bowling's primary clientele — blue-collar workers — moved from the inner city to the suburbs. While demographics and lifestyles changed, the industry failed to adapt.

Since the late 1970s, the bowling industry has participated in a collective reconstruction and repositioning campaign. Many operators shut down their inner-city facilities while renovating suburban locations. Companies invested in computerized lane operations and added other recreational activities and eating establishments, turning bowling alleys into entertainment centers. One consequence of this regeneration was the demise of small, family-owned bowling alleys, especially those located within inner cities.

Despite a 25 percent drop in league bowling from 1980 to 1987, bowling remained one of the largest indoor participation sports in the United States in the early 1990s. However, the growth of the industry continued to be slow. In 1998, the total membership in the American Bowling Congress, Women's International Bowling Congress, and Young American Bowling Alliance decreased 5.7 percent, the twenty-second consecutive year it had decreased. There has also been a 28 percent decline in "frequency" of play since 1987.

Demographic data indicated that bowlers gradually increased in income level and were predominantly male. Between 1987 and 1995, the number of male bowlers grew 13 percent to represent about 53 percent of the total, while the number of female bowlers increased only 8 percent. In addition, the number of bowlers with an annual household income above \$50,000 increased 52 percent over the same time period, while those with incomes under \$25,000 fell 15 percent.

CURRENT CONDITIONS

Despite downward trends through the mid 1990s, some industry analysts said the bowling industry was poised for a comeback. In 1998, bowling manufacturers sales' were up 3 to 5 percent on average. To take advantage of this trend, bowling center operators continued to diversify their image by renovating their alleys into entertainment centers and marketing to upscale adults as well as their children. Operators began to attract younger customers by including video games in their centers and promoting programs such as "rock and roll bowling" and Brunswick Corp.'s Cosmic Bowling, which inte-

grated music, laser lights, and fog machines. As of 1998, teenagers accounted for only 15.9 percent of current bowlers, but those in the bowling industry looked for an increase in this figure over the next decade, as the teenage population itself was expected to grow 15 percent. For small children, bowling operators began offering "bumper bowling," in which the gutters were filled with plastic tubes to keep balls on the lane. In 1996, American Recreation Centers (ARC) introduced the "Family Entertainment Center" (FEC) concept with Fun Fest, a 49,000-square-foot facility in Addison, Texas. Many bowling proprietors viewed this kind of facility as the prototype for the future of the industry.

INDUSTRY LEADERS

As of 1997, AMF Bowling Centers, Inc. was the largest owner and operator of bowling centers in the world. It has been a leader in the bowling industry consolidation, acquiring Bowling Corp. of America in 1996 and American Recreation Centers, Inc. in 1997. As of 1998, AMF Bowling Worldwide owned and operated 490 bowling centers, with more than 100 in the United States. It also was buying more of them, at a rate of 13 a month. After aggressively researching new prototype designs for its centers, AMF conducted a \$1.6-million renovation job at its East Meadow Bowl on Long Island. The establishment included an AMF automated scoring system, an updated color scheme, and a 20-foot outdoor sign. Another AMF project was a \$10-million recreational complex in Franklin, New Jersey. This property included a bowling center, movie house with ten screens, video arcade, billiard parlor, and restaurant. AMF Bowling Worldwide conducted approximately 60 percent of its business in 70 international markets.

Brunswick Recreation Centers owned and operated more than 125 "fun centers" in the United States, Canada, and Europe, featuring bowling, billiards, and restaurants. Brunswick introduced Glow-in-the-Dark Cosmic Bowling in the mid 1990s, which increased open play revenues in more than 20 of its locations. In 1996, Brunswick began offering Cosmic Bowling to other proprietors. Brunswick Corp. is a major manufacturer of bowling equipment, from balls and bags to computerized scoring systems and pin setters. Brunswick Corp. also manufactures fitness equipment, camping and fishing equipment, boats, marine engines, and bicycles.

Alexandria, Virginia-based Bowl America operates more than 20 bowling centers (15 in the Baltimore-Washington, D.C. area, 3 in Richmond, Virginia, and 4 in Jacksonville and Orlando, Florida). Unlike other operators that also manufactured bowling equipment, Bowl America's principal source of revenue was bowling fees and the sale of food and beverages consumed on premise. The company's most noteworthy property was its Gai-

thersburg, Maryland, center that opened in early 1994. Dubbed "America's most modern center," the 45,000-square-foot property featured 48 computer-controlled lanes and dining capacity for 170. Bowl America has attempted to attract younger bowlers through promotions such as "Extreme Bowling" (bowling accompanied by stereo sound and a laser show).

AMERICA AND THE WORLD

The modern game of tenpin bowling became popular in Great Britain during World War II, when lanes were installed on U.S. military bases. Since then, the business of bowling in Great Britain followed its American counterpart, peaking in the 1960s and decreasing continuously ever since. However, British companies such as First Leisure Corporation were so successful in shedding the poor image of bowling that American operators toured facilities in Great Britain looking for pointers. Bowling also became popular in Asian countries, including Japan, Hong Kong, Thailand, Singapore, and Indonesia. The Professional Bowlers Association (PBA) expanded its international presence as it held the first Korea Cup in Seoul in 1996. The PBA anticipates that this event will grow to the popularity level of the Oronamin C Japan Cup, which has had a successful annual run since the mid 1980s. The PBA also plans to expand and exploit growing markets in Europe, Mexico, and Taiwan.

In 1997, U.S. bowling exports increased by 27 percent, with sales to China accounting for almost one-third of the total sales. This generated a great deal of optimism about the possibilities of the growing Chinese market. However, the Asian financial crisis, combined with market saturation and the low average income of the Chinese population, has resulted in a halt in expansion in this area. In addition, U.S. bowling exports decreased more than 50 percent in 1998. Manufacturers will likely need to be patient in order for the international markets to grow.

RESEARCH AND TECHNOLOGY

Although technological innovations affected all aspects of bowling, some of the most dramatic changes occurred in the makeup and design of bowling balls and alleys. In addition, computerized operations brought in the use of automatic scoring and video coaching.

Modern bowling balls made from synthetic materials were completely different than their predecessors, which were made from hard rubber. In 1981, AMF took the lead by producing the first computer-designed bowling ball made from urethane. Using a computer-aided design, AMF found that urethane balls with different finishes could alter a player's performance. Likewise, bowling lanes were increasingly made from synthetic materials. These new lanes required less oil than wooden lanes and never needed resurfacing.

Computerized scoring systems were introduced in the early 1980s, making manual scoring obsolete. Most systems not only tallied the score of a game, but also kept track of handicaps and the scores of league players. Along with AMF, Brunswick Corp. was a leader in the research and development of computer systems for bowling alleys. In 1989, Brunswick introduced BowlerVision, a computer video that enabled players to set up practice shots.

Another notable attraction was the world's first bowling stadium, located in Reno, Nevada. The \$47.5-million National Bowling Stadium had 80 lanes, a pro shop, gift shops, exhibit space, meeting rooms, restaurants, a giant-screen movie theater, valet parking, general seating for about 1,000 spectators, and video monitors displaying instant replays. The American Bowling Congress used the stadium in 1995 to celebrate its one-hundredth anniversary and to house its annual championship tournament — an event with nearly 100,000 participants.

PROFESSIONAL SPORTS CLUBS AND PROMOTERS

This category covers establishments primarily engaged in operating and promoting professional and semi-professional athletic clubs. It also covers establishments engaged in promoting athletic events, including amateur athletics, and in managing individual professional athletes. Stadiums and athletic fields are included only if the operators are actually engaged in the promotion of athletic events. Otherwise, establishments engaged in operating stadiums and athletic fields are classified in **SIC 6511: Operators of Nonresidential Buildings**. Amateur sports and athletic clubs are classified in **SIC 7997: Membership Sports and Recreation Clubs**.

NAICS CODE(S)

711211 (Sports Teams and Clubs)

711410 (Agents and Managers for Artists, Athletes, Entertainers, and Other Public Figures)

711320 (Promoters of Performing Arts, Sports, and Similar Events without Facilities)

711310 (Promoters of Performing Arts, Sports, and Similar Events with Facilities)

711219 (Other Spectator Sports)

INDUSTRY SNAPSHOT

Sports is one of the fastest growing and most complex industries in the United States. According to U.S. Census Bureau figures, in recent years more than 300 professional and semiprofessional sports teams existed in the United States, with almost 20,000 employees. In 2001, companies in the spectator sports industry generated revenues of approximately \$20 billion. In addition to established sports like baseball, football, basketball, and hockey, professional clubs also were springing up across the country in sports such as volleyball, soccer, roller hockey, and lacrosse. The industry additionally supported approximately 775 sports management and promotion firms, with about 14,000 employees. In 2001, the U.S. Census Bureau revealed that promoters of arts, sports, and similar events achieved total revenues of about \$9 billion.

Some 50 cities host professional sports teams, while more than 100 cities are home to minor league franchises. Salaries paid to top professional athletes increased dramatically during the 1990s and early 2000s, even as team owners continually expressed a desire to stem the tide. For example, in 1998 National Basketball Association star Michael Jordan made in excess of \$30 million for a single season of work. In 1999, the Los Angeles Dodgers of Major League Baseball signed Kevin Brown to a seven-year, \$105-million contract. In 2002, the San Francisco Giants' Barry Bonds secured a deal worth \$90 million over five years. A decade earlier, players in both baseball leagues averaged less than \$500,000 in annual salary.

ORGANIZATION AND STRUCTURE

Most professional sports teams are organized into leagues that establish rules and regulations controlling nearly every aspect of the business—from competition to player compensation. The three most influential professional sports organizations in the United States are Major League Baseball (MLB), the National Football League (NFL), and the National Basketball Association (NBA). Another large professional sports organization, the National Hockey League (NHL), has franchises in both the United States and Canada, as do MLB and the NBA.

Major League Baseball. As of 2003, MLB consisted of 30 franchises organized into six divisions within two leagues: the National League of Professional Baseball Clubs and the American League of Professional Baseball Clubs. MLB is controlled by the team owners who ap-

point a president for each league and a commissioner of the entire sport. Bud Selig, formerly of the Milwaukee Brewers, was appointed commissioner in 1998 after acting in that role for several years. Players in the league are legally represented by the Major League Baseball Players Association. Sales for 2001 totaled an estimated \$3.5 billion, a 10 percent increase from 2000.

National Football League. As of 2003, the NFL consisted of 32 professional football teams organized into six divisions and two conferences: the American Football Conference and the National Football Conference. The NFL is controlled by the team owners and the commissioner of football, who is appointed by the owners to oversee the league's operation. The former NFL Players Association was decertified after a strike in 1987. In 2001, sales increased by nearly 17 percent from the previous year to reach an estimated \$4.2 billion.

National Basketball Association. The NBA includes 29 professional basketball teams organized into four divisions and two conferences: the Eastern Conference and the Western Conference. The NBA also is controlled by the team owners, who appoint a commissioner of basketball. The players are represented by the NBA Players Association. Two professional basketball leagues for women, one of which was affiliated with the NBA, began operations around the United States in the mid-1990s, though by 1998 the NBA-operated league was the only one still in operation.

National Hockey League. The NHL includes 30 professional teams organized into six divisions and two conferences: the Eastern Conference (Northeast, Southeast, and Atlantic Divisions) and the Western Conference (Central, Northwest, and Pacific Divisions). The NHL was formed in 1917, and the players are represented by the National Hockey League Players Association (NHLPA).

BACKGROUND AND DEVELOPMENT

Baseball. An American game that evolved in the early 1800s, baseball is thought to be a derivative of the English game "rounders." Rules for rounders, including the number of players and bases, varied widely by locale. Sports historians believe that sometime in the late 1830s or early 1840s, players in New York decided to stop throwing the ball at base runners, an aspect of the rounders game, and begin tagging them out. A commission established by Major League Baseball in 1906 gave credit to Abner Doubleday for inventing the game in Cooperstown, New York, in 1839. However, the commission's findings were most likely rooted in a patriotic desire to brand baseball as a purely American sport. Historians later disputed whether Doubleday did any more than organize a game of rounders.

During the Civil War, baseball was a favorite pastime for northern troops, who sometimes taught the game to their southern prisoners. When the war ended, the game's popularity led to rivalries between towns, and baseball clubs began enticing the best players with offers of jobs or money. James Creighton, a pitcher for the Excelsior Club of Brooklyn, purportedly became the first professional player in 1860 when his team agreed to pay his lost wages so he could join them on a road tour. When the National Association of Base Ball Players was founded in 1858, the organization had restrictions against professionalism. By 1868, however, the association had more than 300 member clubs in 17 states and officially recognized two classes of players, professional and amateur.

By the late 1860s, promoters were building enclosed ballparks and charging spectators for admission. To attract the best teams to their fields, the promoters shared a percentage of the gate receipts. In 1871, players from 10 professional baseball clubs from New York formed the National Association of Professional Base Ball Players. Nine clubs eventually paid a \$10 membership and competed for the first national baseball championship.

National League. In 1876, the Cincinnati Red Stockings and seven other teams formed the National League of Professional Base Ball Clubs. The league set ticket prices, agreed to pay umpires, and prohibited playing games on Sundays and selling alcoholic beverages in the ballparks. The league granted the Chicago-based sporting goods company of A.G. Spaulding & Brothers the exclusive right to supply baseballs to the league; the company remained the exclusive provider of baseballs to the league for 101 years. Albert G. Spaulding was a former baseball player in Boston and Chicago who broke ranks with the players' association because he believed baseball needed to be run by businessmen. He later became league president.

In 1878, the National League created the League Alliance to cover minor league baseball. For a \$10 membership fee, the National League would recognize a minor league's territorial rights and player contracts. It was the first working agreement between Major League Baseball and the minor leagues. The most controversial act by the young league, however, was its adoption of the "reserve rule" in 1879. The reserve rule, at first a secret agreement among team owners, gave each club the exclusive right to re-sign players from one season to the next. Only if a club gave up that right could a player be signed by another team. In Spaulding's words, the rule was "to prevent competition for the best players." The reserve clause was challenged many times before baseball players won the right of limited free agency in 1976.

American League. Hard hit by the depression of 1893, the National League struggled along with 12 teams until

1900, when the owners voted to eliminate financially weak franchises in Baltimore, Washington, Louisville, and Cleveland. The Western League, a minor league that actually operated in the Midwest, saw this as an opportunity to expand. Changing its name to the American League, it claimed major league status and established teams in Boston, Philadelphia, Chicago, and the four cities abandoned by the National League.

The American League received support from the newly formed Ball Players Protective Association, which urged its members not to sign contracts with National League teams unless the salary cap was lifted. The American League signed several top National League players and in its second season in 1901, surpassed the National League in attendance. When the American League then set its sights on expanding into New York, the National League capitulated by acknowledging the American League as a second major league. The two leagues agreed to honor each other's contracts, enforce the reserve clause, and respect each other's playing territories. The American League was also allowed to establish a franchise in New York that eventually became the Yankees.

In 1903, the National and American Leagues signed another agreement that established a three-member commission consisting of the league presidents and a chairman elected by the club owners to set policy. The two-year-old National Association of Professional Baseball Leagues, which then represented 13 minor leagues, also signed the agreement. Under the agreement, major league baseball clubs, which had been created, moved, reorganized, sold, and disbanded with regularity for the past 20 years, achieved some stability.

Labor Movement. Major League Baseball players were without a labor organization from the time the Ball Players Protective Association folded in the early 1900s until 1946, when the eight-year-old Congress of Industrial Organizations convinced the players to form the American Baseball Guild. In August 1946, the Pittsburgh Pirates debated on striking for better pay and working conditions. Although there was no strike, the threat was sufficient to win some concessions for the players from the owners, including a \$5,000 minimum salary, a limit of 25 percent on pay cuts from year to year, and a pension plan.

Decline of the Minor Leagues. The 1950s and early 1960s were turbulent years for organized baseball. Although the minor leagues enjoyed record crowds in the early 1950s, major league attendance fell 25 percent between 1948 and 1952. By the mid-1950s, the minor leagues were also having financial trouble, which was blamed on the emergence of television. Television provided plenty of entertainment at home, which kept people away from both major league and minor league ballparks. Major league teams compensated by negotiating broad-

cast rights with local television stations, although the results were mixed. In 1959, for example, the New York Yankees received \$1 million in television rights fees. In contrast, the Washington Senators received only \$150,000; the minor league teams, however, received nothing.

At first, organized baseball tried to protect the minor leagues from the effects of television by restricting broadcasts to within 50 miles of the home ball park, as it had done for many years with radio. But a Congressional investigation prompted organized baseball to lift the restrictions in 1953, and millions of Americans saw their first major league baseball game. When given this choice of watching baseball on television or going to a ballpark, the fans chose television. Although national television exposure gave baseball a boost in the late 1950s and early 1960s, the sport began to slump again in the mid-1960s when interest in professional football rose dramatically. By 1965 baseball games were among the least watched programs on television, and to attract fans to the stadiums, team owners resorted to rule changes, colorful uniforms, exploding scoreboards, and offbeat promotions that were reminiscent of minor-league ballparks.

Labor Relations. Labor relations between the owners and the players also came to the forefront in the mid-1960s. In 1966, Sandy Koufax and Don Drysdale, then all-star pitchers for the Los Angeles Dodgers, presented salary demands to owner Walter O'Malley and forced him to negotiate with their agent, attorney J. William Hayes. Hayes negotiated \$60,000 raises for both players, more than doubling Koufax's salary and tripling Drysdale's.

Also that year, the Major League Baseball Players Association (MLBPA), which had carried little influence since it was created in 1954, hired Marvin Miller, a former United Steelworkers of America union official, as its first full-time executive director. Within a year, Miller had negotiated an agreement with the owners that increased the players' minimum salary by more than 50 percent, from \$6,000 to \$10,000, and increased the owners' contributions to the players' pension plan. When the first agreement expired in 1969, the MLBPA used the threat of a strike to force the owners to recognize the union as the sole bargaining unit for all major league players in everything but salaries. For the first time, the owners also agreed to deal with the players' agents on matters of salary.

The first strike in organized baseball occurred after the second agreement expired in 1972 and the players voted 663 to 10 to walk out of spring training camps. The strike lasted one week past the scheduled opening day and cost club owners about \$5 million in lost ticket revenues. The players lost about \$1 million in salary. The

strike ended when the owners agreed to contribute another \$500,000 to the players' pension fund; however, the two sides did not reach a new labor agreement until the next year.

In 1973, the owners agreed that players with 10 years of major league experience and five years with the same team could veto trades. They also agreed to binding arbitration in contract disputes involving players who had been in the majors at least two years—a concession that was to cost the owners millions of dollars in later years. The reserve clause, however, remained intact, especially after the Supreme Court reaffirmed baseball's antitrust exemption in 1972 by ruling against former St. Louis Cardinal outfielder, Curt Flood.

Free Agency. Baseball regained favor with sports fans during the 1970s. The dramatic World Series between the Boston Red Sox and the Cincinnati Reds in 1975 was the most watched sporting event in history. However, the most crucial event for baseball that year came after the season ended. On the advice of their agents, pitchers Andy Messersmith and Dave McNally had played the entire 1975 season without signing their contracts. When the season ended, the two pitchers claimed that the reserve clause, which had guaranteed clubs the right to re-sign players since 1879, did not apply to them because they were not under contract. They were, they said, free agents.

The issue went to arbitration, and Messersmith and McNally's position was upheld by a professional arbiter, Peter Seitz, who was promptly fired by Major League Baseball. The decision, however, forced the owners to face the question of free agency. In the spring of 1976, the owners shut down training camps and threatened to cancel the season until the MLBPA agreed to restrictions on the movement of players between teams, but commissioner Bowie Kuhn interceded and the season began on time. That summer the MLBPA and the league ownership signed their fourth contract, in which they agreed that players could become free agents after six years in the major leagues. Technically, the players became part of a re-entry draft, and the clubs who lost players were entitled to compensation in the form of an additional pick in the amateur draft.

With free agency, players' salaries began to escalate rapidly. The average professional baseball player's salary more than doubled in a short period of time, from \$45,000 in 1976 to more than \$100,000 in 1979. The owners also began to issue dire predictions that wealthy teams would prosper, while less affluent teams, especially teams in small urban markets without large local television contracts, risked bankruptcy. The MLBPA's response was that television revenues would more than cover rising costs.

In 1979, baseball club owners decided that any team losing a player to free agency should be entitled to compensation in the form of a player from the free agent's new team. Teams would be allowed to protect either 15 or 18 players, depending on the quality of the free agent, but all other players would be at risk. The MLBPA objected and when negotiations between the owners and the union broke off in April 1980, the players again walked out of camp. The season, however, started on time when the negotiations resumed. When the two sides ultimately failed to reach an agreement, the owners unilaterally declared that the compensation plan would become effective in 1981. That led to the most damaging strike in major league history. The players struck on June 11, 1981, shutting down a baseball season that was already in progress. The strike lasted 50 days. It cost the owners an estimated \$116 million and the players an estimated \$30 million. Polls taken during the strike showed that fans supported the owners over the players, whose average annual salary had by then climbed to \$130,000. Eventually, the players and owners compromised on a player-compensation plan. Despite the labor problems, baseball enjoyed a renaissance throughout the 1980s, with record-setting attendance at major league ballparks. Salary levels rose as well, as did debate about the economics of the game.

By the time the players' average annual salary reached almost \$1.2 million in 1994, things had taken a serious turn for the worse. "Realizing they are unable to control themselves, or each other, in holding the line on players' salaries, the owners . . . asked the players to split all revenue 50-50 and accept a salary cap," according to the *Detroit Free Press*. The relationship between owners and the players' union continued deteriorating in an escalating war of words until August 12, 1994, when players who had refused to accept a new collective bargaining agreement with the salary cap provision walked out of the nation's ball parks and went on strike. They did not return to work for 234 days, which canceled the 1994 World Series for the first time in 90 years and delayed the start of the 1995 season. They went back when forced to by a federal judge. Fan interest was initially slow to rebound, and average salaries declined for the first time in 30 years. MLB responded by adding new franchises (in Tampa and Phoenix), scheduling regular-season interleague play, and embarking on various marketing and public relations efforts designed to boost interest and attendance. In November 1996, owners and players brought the unrest to an official end by finally ratifying a collective bargaining agreement that held into the next century. Significant recovery was evident by 1997, when both attendance and salary figures again began to climb. The recovery was further fueled in 1998 by a chase of the single season home run record, held by Roger Maris. St. Louis Cardinal Mark McGwire and Chicago Cub Sammy

Sosa were able to break the record and draw fans back to the ballparks in record numbers.

Football. American football evolved from rugby in the late 1800s. In 1874, Harvard University, whose students played a form of soccer, accepted a challenge from McGill University, a Canadian school that played rugby. The schools played one game of each sport. Afterwards, Harvard switched to playing rugby and introduced the sport to other Eastern colleges in the United States. Walter Camp, who played on and later coached the rugby team at Yale University, is credited with developing many of the rules in the early 1880s that eventually made American football a sport distinct from rugby. For example, he created the center snap and the system of yards and downs. The first professional football game was played in 1895.

National Football League. Professional football remained generally disorganized until the American Professional Football Association was founded in 1920, with the Chicago Cardinals and the Staleys of Decatur, Illinois, as the original charter members. The Green Bay Packers joined the league a year later. In 1922, George Halas and Dutch Sternaman purchased the Staleys for \$100 and moved the team to Chicago where it was renamed the Bears. The American Professional Football League also changed its name in 1922 to the National Football League (NFL). The New York Giants made it a three-team league in 1925. Additional clubs joined the NFL throughout the 1930s and 1940s, but, as is the case with many young leagues, the early years of the NFL were characterized by the rise and fall and relocation of many of these franchises.

Rival Leagues. The first of several leagues formed to challenge the NFL was the All-America Football Conference. Founded in 1944, the league played four seasons and folded in 1950. The next challenger was the American Football League (AFL), formed in 1960, which proved to have greater staying power and fan appeal. The AFL began play with teams in New York (Titans), Dallas (Texans), Los Angeles (Chargers), Denver (Broncos), and Houston (Oilers). The Buffalo Bills, Boston Patriots, Oakland Raiders, and Miami Dolphins joined the league over the next five years. The Chargers would move to San Diego after only a year in Los Angeles, and the Texans moved to Kansas City in 1963, where they became the Chiefs, but none of the original AFL teams folded.

The NFL and AFL battled over fans, players, and television revenues for six years before agreeing to merge in 1966 under the banner of the NFL. The first Super Bowl, pitting the AFL champion against the NFL champion, was played in 1967. Regular season play between the realigned National Football Conference and the American Football Conference began in 1970.

There have been two other challenges to the NFL since the American Football League, although neither has lasted long. The World Football League was formed in 1974 and played only a season and a half before folding. The United States Football League (USFL) was organized in 1983 and enjoyed a brief, three-season existence. The USFL played its first two seasons as a spring and early summer league and enjoyed modest acceptance from football fans, even though all of its teams lost money. However, in 1985, the league switched its schedule to the fall and went head-to-head with the NFL, a strategy that proved faulty. Still, the USFL did have a significant impact on the NFL. In 1983, the average NFL salary was \$126,000. With the USFL bidding for top college players, the NFL average increased to \$205,000 by the 1986 season.

The USFL also filed an antitrust suit in 1984, charging the NFL with conspiring to block a national television contract, deliberately expanding its rosters to prevent the USFL from signing players, tampering with players under contract to the USFL, and refusing to allow USFL teams to play in stadiums that were either owned or controlled by NFL teams. The USFL won the lawsuit, although by then the league had ceased to field any teams. In addition, instead of the \$400 million the league had asked for in damages, which would have been increased to \$1.2 billion under antitrust laws, the jury awarded only \$1.

Union Representation. The NFL Players Association was formed in 1956, and even though the NFL owners refused to acknowledge the organization as a union, the first basic agreement was negotiated in 1957. It covered minimum wages, preseason pay, and medical care and salaries for injured players. The owners formally recognized the union in 1968.

When a contract negotiated with the NFL in 1982 after a 57-day strike expired, the players called another strike during the 1987 season. The owners, however, hired replacement players from the ranks of semipro and former NFL players and continued play. The strike ended after 24 days. Afterwards, in a strategic move, the union voluntarily decertified itself as the players' collective bargaining unit and became a self-described trade association. The move opened the door to antitrust suits by individual players because technically there was no longer a collective bargaining agreement or ongoing negotiations with a union. The union was recertified to represent NFL players in 1993.

Free Agency. Like baseball and basketball players, professional football players achieved a degree of free agency only after a lengthy series of legal challenges. The first significant case involved William Radovich, a former Detroit Lion who jumped to the All-America Football Conference in 1946. The NFL blacklisted Radovich

and, in 1948, the NFL prevented him from playing for a team in the Pacific Coast League. Radovich sued and, in 1957, the Supreme Court ruled that unlike baseball, football was subject to antitrust laws. The court awarded damages to Radovich.

Then in 1971, John Mackey, president of the NFL Players Association, and 15 other players challenged the Rozelle Rule, named for the late NFL commissioner Pete Rozelle. The Rozelle Rule gave the commissioner absolute authority to order teams that signed free agents to give up other players in compensation, effectively stopping almost all free-agent signings. In 1976, a Federal District Court in the Mackey case ruled that the Rozelle Rule was unreasonable and had been unfairly forced on the players during labor negotiations.

The NFL draft of college players was also challenged in the 1970s as a violation of antitrust laws. In the key case, James "Yazoo" Smith, who had been drafted by the Washington Redskins, suffered a career-ending injury in the last game of the season. Smith, who did not have a guaranteed contract with the Redskins, claimed that the draft, which limited him to dealing with a single team, prevented him from negotiating a better contract. The court ruled that the draft was unreasonable restrictive and awarded Smith \$276,000 in damages.

Armed with favorable decisions in these and other cases, the players association signed a new agreement with the NFL in 1977 that sanctioned the draft and allowed for some restrictions on player movements in return for financial incentives for the players. In another antitrust case that went to court in 1978, the court ruled that antitrust trust laws did not apply because the players had voluntarily given up certain rights when they agreed to the contract with the NFL.

After an abortive strike in 1987, the players association claimed in 1989 that it was no longer a union, and therefore, the expired labor agreement no longer protected the NFL from antitrust suits. The association also claimed that all players would become free agents as their individual contracts expired. NFL team owners argued that the players association was continuing to operate as a union despite its self-decertification.

In the absence of a negotiated contract, team owners also unilaterally instituted a free-agency plan in 1989 that came to be known as "Plan B," as in "let's go to Plan B" when the initial plan fails. Plan B allowed teams to "protect" 37 of their 47 players after each season. The remaining 10 unprotected players were free to negotiate with whatever team they wished. A protected player whose contract had expired could also enter the free agent market; however, his former team had the right to match any offers or to receive draft picks as compensation. Several players challenged Plan B in court, and late in

1992, an eight-member Federal District Court jury in Minneapolis found Plan B was overly restrictive and, therefore, in violation of federal antitrust laws. However, the jury also agreed with the NFL that some restrictions on free agency were necessary.

Finally, observed the *Monthly Labor Review*, "the National Football League and the National Football League Players Association reached a collective bargaining settlement in 1993 that the parties hoped would auger a more progressive, cooperative relationship, instead of the contentious and litigious one that had existed since the 1980s. In the end, the parties had a seven-year agreement with free agency, and the union was recertified to represent National Football League players." Salary cap figures and free agency restrictions were included in the agreement, and in 1999 the cap was increased to \$58 million.

Basketball. The game of basketball was invented by James A. Naismith, a physical education instructor at the former International YMCA Training School in Springfield, Massachusetts, who needed a game that would keep the school's rugby and football players occupied during the winter months. Naismith's game became so popular that professional basketball teams were formed by 1895, although modern fans would hardly recognize the game.

National Basketball Association. Most early professional teams were touring squads that would challenge a local community's best players for a share of the gate receipts. There were, however, early attempts to organize professional basketball into leagues. The first league was probably the National League. Founded in 1898, it lasted only until 1903. The next major attempt to organize professional basketball was the American Basketball League (ABL). Players on most NBL teams worked for their corporate sponsors during the day and played basketball at night. Teams were often named for their sponsors' products, such as the Zollner Pistons of Fort Wayne, which later became the Detroit Pistons. In 1946, the owners of several professional hockey teams formed the Basketball Association of America (BAA) to help keep their arenas filled during hockey's off-season. The more established NBL boasted better players and more competitive play, but the East Coast-based BAA played in larger cities and better facilities. In 1948, the two strongest teams in the NBL, the Minneapolis Lakers and the Rochester, New York, Royals, bolted to the BAA.

The loss of its two best teams and its fiercest rivalry nearly devastated the NBL. In a desperate attempt to survive, the NBL signed all the graduating starters from the NCAA champion University of Kentucky team and assigned them to a new franchise in Indianapolis. The college stars had all played on the Gold-medal winning U.S. Olympic team in 1948, and the franchise was named

the Olympians. The team gave the NBL enough leverage to force a merger with the BAA in 1949. The combined league, which sported 17 teams, was named the National Basketball Association.

Modern Basketball. Professional basketball in the early 1950s was a plodding game characterized more by pushing and shoving than by scoring. In 1954, the NBA instituted two rule changes designed to speed up the game and increase fan interest. The first was to award free throws after a team had accumulated five personal fouls in a quarter. This eliminated much of the rough play and intentional fouling that had bogged down the games. The second rule change had an even greater impact. Stalling occurred when one club held possession of the ball for long periods of time without attempting a shot, and it was a common tactic in basketball. But Danny Biasone, owner of the Syracuse Nationals, proposed giving teams 24 seconds to shoot or lose the ball to the other team. Biasone chose 24 seconds because that would allow each team about 60 shots a game, which was considered an optimum pace. In addition to raising scores so that 100-point games became common, the 24-second clock also had a dramatic impact where it counted most—at the box office. Basketball closed out the 1950s as the fastest growing professional sport in the United States.

Union Representation. The NBA Players Association (NBAPA) was formed in the early 1950s, but it operated more as a fraternal organization than a labor union until the early 1960s. In 1964, however, the union threatened to boycott the All-Star Game unless the owners agreed to improve pensions. The players literally refused to leave the locker rooms until the owners capitulated. In 1967, the union negotiated the first basic labor agreement in professional basketball.

American Basketball Association. The American Basketball Association (ABA) was formed in 1967 and introduced several innovations, such as the three-point shot. Billing itself as “the Lively League,” the ABA also drove up salaries by competing with the NBA for the best players. However, the league never achieved financial stability. After a decade of playing with its signature red, white, and blue basketball, the ABA was merged into the NBA in 1976. ABA franchises in Denver, New York, San Antonio, and Indiana each paid \$3.2 million for the privilege of joining the NBA. The three remaining ABA franchises in Kentucky, St. Louis, and Virginia folded.

Free Agency. The NBAPA attempted to stop the league from merging with the ABA by filing an antitrust suit in U.S. District Court. The union also challenged the NBA’s option clause, which, like baseball’s reserve clause, gave teams the exclusive right to re-sign players when their contracts expired. Although the players failed to stop the merger, they did receive a preliminary ruling that cast

doubt on many of the NBA’s labor practices. Armed with the ruling, the NBA Players Association negotiated an agreement in 1976 that did away with the option clause and league rules, which provided for compensation for teams that lost players to free agency.

The players negotiated further concessions on free agency in 1987. Under the old agreement, players became free agents when their contracts expired, but their old teams had the right to match any offers they received. Because teams were seldom willing to lose star players, bidding on free agents drove up salaries, but few quality players actually changed teams. In 1987, the owners agreed to give up the right of first refusal for veteran players whose contracts had expired. In the first year of the agreement, the liberalized rules applied to players with seven years of experience, but that dropped to four years in 1989.

Salary Cap. The merger between the NBA and ABA eased the pressure of escalating salaries, but the long fight for players, a series of drug scandals, and sagging attendance left professional basketball with serious financial problems. Pro basketball was then the least-watched sport on television, trailing even golf, and the NBA was the only major professional sports league without a national television contract.

By the early 1980s, 16 of the 23 NBA teams were losing money, and four teams were on the verge of bankruptcy. To save the league, the NBAPA agreed to a limit on the total amount that teams could pay in salaries. In return, the owners promised that team payrolls would never fall below 53 percent of the leagues’ gross revenues. Although NBA teams were still free to offer multimillion-dollar contracts to their superstars, the salary cap slowed the overall growth of salaries and helped put the league back on firm financial footing. These fiscal steps, coupled with the emergence of a number of particularly popular star players and an upswing in marketing savvy, enabled the NBA to reverse its fortunes. By 1987, almost every NBA club was profitable.

The growth of the league continued unabated into the mid-1990s, as evidenced by increasingly lucrative television contracts and attendance records. Player salaries surged as well. By 1994, the average NBA player made \$1.4 million. In 1998, the NBA owners put a stop to the salary surge by putting a cap on the amount that could be paid to individual players. This amount increased based on a player’s experience in the league. It is felt that this system may well be a model for other professional leagues to follow.

Hockey. Ice hockey was originally known as ice hurley in the early 1800s and was started in northern Europe. By 1950, it was commonly called hockey. In 1873, J.G.A. Creighton became known as the father of organized

hockey after he introduced the sport in Montreal. In 1892, the English Governor General of Canada, Lord Stanley of Preston, bought a trophy that was given to the best amateur team in Canada. By the 1900s, the game was rapidly expanding across the United States and Canada and professional leagues were created in 1904 and 1910. In 1914, two leagues were in existence, the National Hockey Association (NHA) and the Pacific Coast League (PCL). The NHL opened in 1917 with five teams, and the winner played the PCL champion for the Stanley Cup. The PCL folded in 1926 and the NHL was the only remaining professional league.

Approximately 700 players are represented by the National Hockey League Players Association (NHLPA), which is headed by Trevor Linden. The association even had its own television show in the late 1990s—"Be a Player! The Hockey Show," which profiled players and presented trivia challenges. The Stanley Cup is now awarded to the best professional team in the NHL.

Professional sports have assumed ever greater economic importance over the past three decades and the rise of mega-dollar contracts, powerful sports agents, dominant player organizations, fashionable superstar personalities, rewarding product endorsements, and lucrative broadcast deals has mirrored their growing popularity. In the early 1990s, professional sports were arguably more popular than ever before. The NFL and NBA were selling more than 90 percent of all available seats for their games, while MLB was enjoying record attendance. The NHL was steadily increasing in popularity. Television networks were willing to spend billions of dollars to broadcast sports events. Cities were willing to spend millions of dollars to build new stadiums or provide incentives to keep or attract professional sports teams. Sports franchises were escalating in value. In 1997, 52 public companies owned part of the 113 MLB, NBA, or NHL franchises; they were being viewed as "brands" that could be used in many profitable ways.

But in the midst of plenty, most professional teams also faced serious financial challenges due to operating costs, most of it tied up in spiraling player salaries that were rising far more rapidly than revenues. In many instances, teams were faced with declining revenues without any expectation that the incredible growth in salaries would slow.

Revenues. Heady bidding among the major broadcast and cable television networks, plus the sale of local broadcast rights, provided professional sports with steadily increasing revenues throughout the 1980s. Each NFL team, for example, received about \$5.9 million from national broadcast rights in 1980; by 1990 that amount had increased to more than \$26 million per team. Television revenues for MLB increased from about \$3.3 million per

team to \$14 million. The NBA saw television revenues increase from \$1.2 million per team to \$5 million. In 1997, football brought in revenues of more than \$160 million; basketball garnered close to \$120 million; baseball brought in approximately \$110 million; and hockey garnered more than \$70 million.

In the 1990s, however, fees for sports broadcast rights began to reflect a glut of TV programming and a dearth of advertising revenue. The NBA, the only major sports league with increasing television viewership, signed a four-year, \$750 million contract with NBC in 1993 that represented a 25 percent increase over its previous contract. But two years later and with many of its teams already operating at a loss, MLB accepted an unusual \$516 million joint contract with NBC and ABC that paid each team only \$4.6 million—about one-half of what they received in the final year of the previous deal with CBS. MLB's continuing rebound was reflected in a new national deal in 1996 that put total broadcast revenue at \$730 million. Around the same time, the upstart Fox network jumped into the picture and helped up the ante by paying \$395 million to broadcast NFL games and \$31 million to bring NHL contests to a national audience. The NHL now has a \$600 million television deal with ABC and ESPN, and the NFL has a \$2.2 billion television contract with four networks through 2006.

The broadcast issue has been more complicated for MLB than for other sports, because its teams also negotiate individual fees with local outlets. Owing to their location in the nation's top media market, the New York Yankees reportedly received almost \$60 million in 1997 in total broadcast revenues—more than every other franchise and about three times the league average of \$20 million. Baseball teams in smaller markets generally fare far worse, which was one of the prime rationales for the rich team/poor team revenue-sharing program included in the long-delayed collective bargaining agreement accepted in late 1996.

With traditional revenue sources no longer guaranteed, sports franchises in the late 1990s were developing new income sources. Chief among these were new or renovated stadiums with more seats, higher ticket prices, private "skyboxes" and "club sections" that commanded premium prices, and a widening array of commercial licensing opportunities that ranged from jumbo electronic scoreboard advertisements to naming rights for the stadiums themselves. Some teams also struck previously unheard-of endorsement deals with major sponsors; others were purchased outright by corporations that also controlled broadcasting properties or other avenues for peripheral profit. Additionally, in the late 1990s all of the major professional leagues were looking to increase their international operations.

Salaries. The greatest cost involved in operating a sports franchise is the salaries paid to the professional athletes. In the 1980s, free agency, player unions, and seemingly unlimited television revenues combined to drive salaries ever higher. In 1995, according to *Financial World*, they represented 68 percent of revenues in the NFL, 62 percent in MLB, 49 percent in the NBA, and 41 percent in the NHL. All of the major leagues have tried to reign in these escalating salaries, with different results.

During the late 1990s, the NBA system achieved some initial success in limiting salaries. The NFL-implemented salary cap has been somewhat successful, although it has increased from \$37 million in 1995 to \$57 million in 1999. An average increase in salaries of \$5 million per year per team is not what NFL owners hoped for.

Baseball owners initially tried to stem the rising tide of player salaries by simply agreeing among themselves in the late 1980s not to bid on free-agent talent. But the MLBPA filed suit against the owners, charging collusion. The owners lost the court battle, were ordered to pay \$280 million in damages, and saw salaries begin to rise again. In 1992, the average salary for a major league baseball player was slightly more than \$1 million and at least 30 players earned more than \$3 million annually; in 1997, according to Associated Press figures, the average had climbed to nearly \$1.4 million and about 130 players were in the \$3 million club.

CURRENT CONDITIONS

By the early 2000s, weak economic conditions led to decreased levels of consumer and corporate spending. This ultimately had a negative impact on cash flow and revenues for professional sports teams, as ticket buyers were less likely to invest in skyboxes and premium club seating. In addition, some observers noted that many of the revenue sources professional teams rely on—including sponsorships, corporate stadium naming deals, advertising, Web sites, and sales of premium seating—were more or less exhausted. As TV ratings declined—much to the dismay of broadcast networks like Fox, ABC, and CBS, which were losing money on long-term contracts—leading sports leagues effectively saw the value of their broadcast rights fall.

By early 2003, challenging conditions within the industry had forced some teams into bankruptcy. Many owners subsequently put their teams on the market. According to *Business Week*, across the four major professional sports, some 20 teams were for sale in early 2003. Conditions were particularly bleak in the NHL, where analysts indicated that approximately one-third of the league's teams were for sale. Making matters worse, sellers were faced with a limited universe of potential buyers. Interested investors had the advantage of

choosing from a wide variety of cash-strapped teams in a number of different markets.

Among the owners seeking to exit the industry were corporations and entertainment companies, which began to view sports teams as not fitting into their core business offerings. For example, Fox Entertainment Group, Inc. sought to rid itself of the Los Angeles Dodgers; the Walt Disney Co. sought to sell the California Angels; and entertainment giant AOL Time Warner sought to divest its Turner Sports subsidiary. Turner Sports owned three Atlanta-based professional sports teams, including the NHL's Atlanta Thrashers, MLB's Atlanta Braves, and the NBA's Atlanta Hawks, among other sports interests. In response, banks stepped in with creative financing arrangements to accommodate such high-stakes deals. *American Banker* reported that by the early 2000s a number of leading banks, including J.P. Morgan Chase & Co., Bank of America Corp., and FleetBoston Financial Corp., had established teams of bankers who were dedicated to working on deals involving sports teams. This was in stark contrast to the early 1990s, when such ventures were not of interest to many bankers. As the publication explained, "With player salaries and stadium costs skyrocketing, teams are increasingly relying on banks to arrange financing and negotiate franchise sales."

Although the number of new stadiums being constructed was slowing during the early 2000s, the influence of corporate naming had been significant within the industry. According to *Advertising Age*, across the four major professional sports leagues, more than 50 stadiums had corporate names by late 2002. These collectively represented some \$3 billion in revenue for sports teams. In addition, *Forbes* indicated that in 2002 alone, such deals were responsible in garnering about \$500 million for sports teams. In an industry climate where revenue new streams are increasingly scarce, such deals are almost certain to continue.

INDUSTRY LEADERS

Driven by multimillion-dollar television contracts, the value of professional sports franchises ballooned in the 1980s, increasing an average of 20 percent per year. However, as television contracts and other revenues became less certain in the early 1990s, franchise values began to fall.

In early 2003, *Forbes* reported that the top professional baseball teams by value were the New York Yankees (\$849 million); the New York Mets (\$498 million); the Boston Red Sox (\$488 million); the Los Angeles Dodgers (\$449 million); and the Atlanta Braves (\$423 million). The most valuable NFL franchises were the Washington Redskins (\$845 million); the Dallas Cowboys (\$784 million); the Cleveland Browns (\$618 million); the Carolina Panthers (\$609 million); and the Balti-

more Ravens (\$607 million). The most valuable NBA franchises were the Los Angeles Lakers (\$426 million); the New York Knicks (\$398 million); the Chicago Bulls (\$323 million); the Dallas Mavericks (\$304 million); and the Philadelphia 76ers (\$298 million).

Gaining entry into the world of professional sports ownership has consistently become more expensive. In 1996, *Financial World* said it would cost at least \$150 million to start up a new baseball or football team and \$100 million for a team in basketball or hockey. By the early 2000s, the cost for new professional teams had surpassed \$500 million.

RACING, INCLUDING TRACK OPERATION

This classification covers promoters and participants in racing activities, including racetrack operators, operators of racing stables, jockeys, racehorse trainers, and race car owners and operators.

NAICS CODE(S)

711212 (Race Tracks)

711219 (Other Spectator Sports)

INDUSTRY SNAPSHOT

The thrill of competition and the overall excitement of racing drew millions of American spectators to the wide variety of events in the racing industry, including horse races, dog races (greyhound), automobile races, and motorcycle races. The industry generated close to \$5 billion in revenue in 1995.

Thoroughbred horse racing alone attracted 60 million spectators to racetracks in 36 states. On a total of 8,000 racing dates, visitors bet more than \$13 billion at the tracks and at off-site locations. In the late 1980s, however, the horse racing industry began to fall behind more publicized and simplistic forms of legalized gambling, particularly the state lotteries. Unprepared for the influx of competition, track operators scrambled to make their courses more inviting to spectators in order to attract new and younger customers.

ORGANIZATION AND STRUCTURE

Horse Racing. In the horse racing sector of the industry, most U.S. racetracks were privately owned, and racing operations were governed by state commissions where the tracks were located. Most tracks were operated for a profit, as were the horses, while the trainers and jockeys worked as independent contractors. Some U.S. tracks, such as the ones operated by the New York Racing Association, were non-profit organizations. By contrast, racetracks in some other countries were owned and operated by the national government.

All horse racing, except quarter horse racing, involved thoroughbreds, usually three-year-olds. A racehorse achieves peak ability at age five, but few races included horses older than four due to increases in purses, breeding fees, and sale prices. Owners of thoroughbreds tried to produce superior horses through complex mating

strategies, with the most desirable horse being one that performed well during long races. But as Patrick Cunningham, a professor of animal genetics at Trinity College in Dublin, claimed in *Fortune*, “only 35 percent of the differences between horses is attributable to genetic factors; the other 65 percent reflects diet, training, and random health-affecting events around the barn.”

Early horse races featured a simple system of wagering in which spectators tried to pick the winner. In modern horse racing, however, spectators placed their bets on the first three horses, and most of the purse money was provided by the stakes fees of the horse owners. This practice, called pari-mutuel betting, created a common betting pool and paid off numerous winners. Those who wagered on horses finishing in the first three places (win, place, or show) shared the total amount betted, minus a percentage for the track management. Most purses allocated 60 percent to the winner, 20 percent to second place, 10 percent to third place, and 5 percent to fourth place. The system always provided the operator a profit and allowed any number of bettors to win.

Racetrack management began to offer pari-mutuel betting with the invention of the totalizator in the 1920s. The totalizator collected all bets and provided an instantaneous picture of the betting pools, displaying the approximate odds to win on each horse. Computerized totalizators at modern tracks flashed these totals to spectators at regular intervals, as well as displayed race results, payoff amounts, and running times.

Dog Racing. The dog racing sector of the industry consisted of events featuring a group of greyhounds chasing a mechanical rabbit around an enclosed track. Based upon an older sport where dogs hunted by sight rather than scent, the first greyhound race was held in Emeryville, California, in 1919. In U.S. races, eight dogs competed per run, with up to 11 quarter-mile races per program. Similar to horse racing, dog racing in the United States included wagering and was governed by state commissions. The 1990s saw animal rights groups start wide spread lobbying efforts to secure homes for retired greyhounds.

Car Racing. In the 1900s, many cities and states began banning car racing on public roads, which led to the advent of closed circuit courses built specifically for the purpose of auto racing. The automobile racing sector of the industry included several different types of events. Stock cars — American production cars with some modifications to their bodies and engines — generally raced on oval tracks with banked corners. Stock car racing was governed by the National Association of Stock Car Auto Racing, or NASCAR. Formula One or Grand Prix cars — open-wheeled, race-prepared cars — competed at a number of tracks and street courses in the United States and

around the world. Formula One racing was governed by an international authority. The American version, often called Indy cars, raced on both oval and road courses around the country. Indy car racing was governed by the United States Auto Club (USAC) at the Indianapolis 500 and by Championship Auto Racing Teams (CART) at all other venues. Dragsters — which included a wide variety of cars with significant modifications to their tires and engines — generally raced for a quarter mile in a straight line. Drag racing was governed by the National Hot Rod Association (NHRA). Various other professional and amateur auto racing series existed, including sports cars, dirt-track racers, and go-carts.

The Daytona International Speedway, known as the “World Center of Racing,” became one of the best known racetracks in the United States and featured stock car, sports car, and motorcycle events. The track’s most popular race, the Daytona 500, began in 1959 and remained the premier event and opening race of the NASCAR Winston Cup Series. The Daytona 500 was started in February of 1959, when prize monies totaled \$67,000. By 1999, that figure had jumped to over \$3.6 million.

The Indianapolis 500 became the main event of the 12-race USAC drivers’ championship. For many years following its inaugural running in 1911, the race took place on a surface of paving brick, which gave rise to the speedway’s nickname, “the Brickyard.” The modern track, however, featured an all-asphalt surface except for a 36-inch strip of the original brick at the starting line. The 500 was the only annual race at the speedway until 1994, when the first Brickyard 400 race for NASCAR Winston Cup stock cars was held. In 1999, the combined winnings for the Indianapolis 500 was more than \$9 million.

Motorcycle Racing. The motorcycle racing sector of the industry included two main types of events, road-bike races and dirt-bike races. In road-bike races, professionals and amateurs rode low, sleek racing motorcycles on asphalt tracks. In dirt bike racing, participants rode all-terrain motorcycles with knobby tires and special shock absorbers on dirt tracks. Street and off road racing has become more and more popular, with regular appearances on the popular sporting television channels such as ESPN and ESPN2.

BACKGROUND AND DEVELOPMENT

Horse racing was one of the oldest sports known to mankind. Some of the earliest races, both chariot and bareback, were held at the Olympic Games in Greece from 700 B.C. to 40 B.C.. England’s King Charles II, who ruled from 1660 to 1685, inaugurated the first races that offered prizes to winners, which were called the “King’s Plates.” The original King’s Plates were standardized four-mile heat races for six-year-old horses

carrying 168 pounds. A horse had to win two heats to be declared the winner. Although heat racing continued in the United States well into the 1860s, dash racing took over in Europe. A dash was any race decided by one heat, regardless of distance.

Thoroughbred breeding began in the 1700s, and all of the 500,000 Thoroughbreds born since that time were said to have descended from the same small group of Arabian and English horses. In fact, Cunningham proved that modern Thoroughbreds drew half of their genes from only ten horses. A famous horse known as the Godolphin Arabian, born about 1725, contributed 14.6 percent of the genes.

In North America, horse racing began in 1665 at Hampton Plains, Long Island. Richard Nicolls, governor of the colony of New York, offered a silver cup as the prize — the first known North American racing trophy. During the modern era, horse racing evolved from an activity to amuse the leisure class into an enormous business providing public entertainment. The three best known American races were the Belmont Stakes, inaugurated in 1867, the Preakness Stakes, first run in 1873, and the Kentucky Derby, which began in 1875; these races together were dubbed the Triple Crown.

Americans began racing automobiles virtually as soon as they were invented in the late 1800s. The first racetracks generally formed either where people gathered to race their cars — like on the flat sand beaches at Daytona — or where manufacturers tested their new products — like the facility in Indianapolis. Speeds increased dramatically over the years, as did the stakes. Prize money for the Indianapolis 500 topped \$9 million in 1999, and the race was won by driver Kenny Brack.

CURRENT CONDITIONS

While the gambling industry in general soared 67 percent from 1982 to 1988 to reach \$253 billion, the annual amount betted on horse racing climbed barely 17 percent during the same period to \$13.7 billion a year, according to *Business Week*. Horse racing faced intense competition from other forms of legalized wagering, including riverboat gambling, casinos, and state lotteries — which alone drained about 11 percent of potential bettors from horse races. Many analysts claimed that racetracks became complacent in their marketing efforts and were unprepared for this new competition. Because illegal horse racing bets are still taken throughout the country, the exact amount of money wagered on such events is hard to pinpoint.

Even off-track betting (OTB) shops presented a threat to the racetracks. Although the tracks received a percentage of OTB commissions, customers watched simulcasts of live races at off-track sites rather than coming to the racetrack. So while total wagering on thoroughbred

racing nationwide increased, paid admissions fell. According to *Business Week*, “From 1986 to 1990, nationwide betting from off-track sites soared 86 percent, to \$4.1 billion, while on-track wagering fell 36 percent to \$6.1 billion.” The drain caused by simulcast races magnified the need for track management to attract new spectators to their venues. By the early 1990s, many tracks began to market themselves more diligently, adding customer relations departments and special services.

However, several industry analysts felt that the horse racing industry suffered from a more fundamental problem: Many Americans simply did not understand the sport. For example, Ken Alhadeff, executive vice-president of Longacres Race Course near Seattle, told *Business Week*, “Kids grow up with football, but horse racing remains a mystery to most of us. The savior of racing will be our ability to attract new fans by ripping down the intimidation factor.” Longacres’ attempts to retain spectators included handing out “First Timer’s Kits,” which explained how to read the Daily Racing Form, and offering a “New Comer’s Corner,” which taught betting techniques.

Several track operators also began hedging their bets by adding other gambling venues, like video poker machines. Hollywood Park in Los Angeles, for example, opened a card club, and Louisiana Downs planned to run a riverboat casino. Moreover, some racetracks began adding non-racing entertainment, such as restaurants, video arcades, music theaters, and parks.

By the late 1990s, there were finally signs that horse racing was making a comeback. The average purchase price for horses of all ages increased, with an impressive 35 percent increase in the sale price of yearling horses, the most popular age. Television ratings were up as well, thanks in no small part to the near Triple Crown performance of the horse Real Quiet. A strong 1999 season by the horse Charismatic continued this trend. Though the horse racing industry is still not where it once was, it is now making positive strides.

INDUSTRY LEADERS

The leading companies in the racing industry included: New York Racing Association, Inc. of Jamaica, New York; Hollywood Park Inc. of Inglewood, California; Anita Operating Company of Arcadia, California; International Speedway Corp. of Daytona Beach, Florida; Los Angeles Turf Club, Inc. of Arcadia, California; and Churchill Downs Inc. of Louisville, Kentucky.

A non-profit organization, the New York Racing Association (NYRA) owned and operated the three largest racetracks in New York — Aqueduct, Belmont Park, and Saratoga. Established in 1955, the NYRA was a non-dividend-paying corporation governed by a board of trustees.

Races at NYRA's tracks brought in the highest on-track attendance and daily wagers throughout the United States. NYRA tracks averaged 9,800 fans per race day, with nearly 130,000 more watching at OTB shops or at inter-track simulcast facilities. Approximately 2.5 million people attended the races at NYRA tracks in 1998. The Saratoga track led the country in on-track attendance. The average amount bet on NYRA races, including OTB wagering, of more than \$9 million per day, far exceeds any other racing organization in the United States.

Hollywood Park Inc. was the ninth-largest organization in the racing industry. Accommodating more than 50,000 spectators at facilities that opened in 1938, Hollywood Park was the site of the Breeder's Cup and the Hollywood Gold Cup. After losing \$30 million in four years, the shareholders of Hollywood Park elected a new CEO, R. D. Hubbard, in early 1991. As a result, Hollywood Park showed a profit that year and more than tripled its earnings in 1992.

Most recently, the company operated eight riverboat and land-based casinos in the states of Louisiana, Mississippi, and Nevada, as well as the country of Argentina. In 1998, Hollywood Park, Inc. reported \$408 million in sales. In 1999, the company sold its namesake, Hollywood Park, to Churchill Downs, Inc.

WORKFORCE

The labor pool in the horse racing sector of the industry included jockeys, grooms, and exercise riders, along with other skilled and unskilled workers. Approximately 2,800 jockeys were licensed throughout the country, nearly 20 percent of whom were women. Approximately 53,900 horse owners and 4,440 trainers were registered with the national office of the Horsemen's Benevolent and Protective Association (HBPA). The group also posted nearly 5,400 combined owners and trainers.

The number of other workers at U.S. racetracks was difficult to determine because the work was seasonal. Moreover, illegal aliens were often used for labor at the tracks. In fact, in 1985, more than 400 illegal aliens were seized at Southern California tracks. When track management complained that they could not find U.S. citizens willing to perform such work, the U.S. Immigration and Naturalization Service granted H-2 visas that permitted temporary work status for skilled employment. Certification for unskilled workers was declined.

AMERICA AND THE WORLD

As of 1997, Japan had 40 racetracks, 30 public courses and 10 owned by the Japan Racing Association (JRA). The JRA is the sports governing body in Japan, and is a non-profit organization that operates on a 15

percent share of betting turnover. This organization severely restricts Japan's horse racing industry to outsiders.

As Karen Lowry Miller explained in *Business Week*, "Only 114 of Japan's 6,000 registered thoroughbreds are foreign-born. Just two annual races, the Japan Cup and the Fuji Stakes, allow foreign horses that have raced before. And just 35 percent of the 6,000 races held by the JRA allow foreign-born horses at all, even if they're trained in Japan." Representatives of both the United States and Great Britain urged Japan to reduce its trade restrictions, especially to lower its barriers against imported racehorses. Since the U.S. industry had declined, foreign markets like Japan became increasingly important. American horse owners were especially interested in the Japanese market because of its bettors. The Japanese eventually conceded to a plan to allow foreign-born horses to run in 65 percent of JRA-sanctioned races by the mid 1990s and to open 15 more events to foreign owners.

Horse racing also became wildly successful in Hong Kong, with an average racing day bringing 50,000 spectators to the tracks. These spectators, along with 1.5 million off-track bettors, wagered \$170 million per racing day. And due to its ever-increasing purse size, Hong Kong's races began attracting more international entries.

RESEARCH AND TECHNOLOGY

The United States began moving toward high-tech horse racing in the 1990s. As with simulcasting, these technological advances were expected to bring additional bettors to the racing world, but not necessarily to the tracks. One program was interactive betting, a system used at home via a "black box" cable program. Wagering via telephone also appeared to be destined for the future of racing.

The NYRA set up computerized personal betting accounts for its patrons. Using a special debit card, a user could place a bet at terminals located throughout the track. Money was added or subtracted from the account as the bettor won or lost. The bettor could wager over the phone and even electronically transfer funds from a MasterCard or Visa credit line to their account. Following a test run at Belmont, the system moved into full operation at all three NYRA racecourses in late 1991.

In the automobile racing sector of the industry, research centered around increasing speed and driver safety. Often, technological advances originating in race cars became standard equipment for passenger cars within a few years. Some early examples included four-wheel brakes, turbo charged engines, and aerodynamic designs.

SIC 7991

PHYSICAL FITNESS FACILITIES

Establishments in this industry are primarily engaged in operating reducing and other health clubs, spas, and similar facilities featuring exercise and other active physical fitness conditioning, whether or not on a membership basis. Also included in this industry are establishments providing aerobic dance and exercise classes. Sports and recreation clubs are classified in **SIC 7997: Membership Sports and Recreation Clubs** if operated on a membership basis, and in **SIC 7992: Public Golf Courses** or **SIC 7999: Amusement and Recreation Services, Not Elsewhere Classified** if open to the general public. Health resorts and spas providing lodging are classified in **SIC 7011: Hotels and Motels** and **SIC 7041: Organizational Hotels and Lodging Houses, on Membership Basis**. Establishments that promote physical fitness through diet control are classified in **SIC 7299: Miscellaneous Personal Services, Not Elsewhere Classified**.

NAICS CODE(S)

713940 (Fitness and Recreational Sports Centers)

INDUSTRY SNAPSHOT

According to the International Health, Racquet & Sportsclub Association, the number of health clubs in the United States grew by 5.1 percent during 2001 to 17,807 facilities at the beginning of 2002, up from 16,938 in January 2001. Despite the slow economy that characterized the first years of the 2000s, health club expansion continued at a quick pace. In 2001 fitness and health centers in the United States generated combined revenues of more than \$12.2 billion.

Health clubs emphasize three aspects of physical fitness: cardiovascular conditioning, strength, and flexibility. Some even add nonprofessional mental health

services like stress reduction and counseling programs. Full-service health clubs featured aerobic conditioning equipment, resistance equipment, dance and exercise classes, swimming pools and spa areas, and sometimes even tanning and massage. As the U.S. population ages, the over 50 population is becoming increasingly important to the health club industry, and some clubs are responding by adding health maintenance and monitoring programs to their offerings, including checks for bone density, blood sugar, and blood pressure.

In 2002 membership and enrollment (or initiation) fees from the industry's 33.8 million members constituted the vast majority of club revenues. Although these fees have long been the mainstay of industry income, other revenue sources like children's programs, personal training, exercise classes, physical therapy, and aquatic programs started contributing a growing proportion of health club revenues.

ORGANIZATION AND STRUCTURE

The fitness center industry is self-regulated through several professional organizations that were formed in the mid-1970s. The two most influential of these are the Association of Physical Fitness Centers (APFC) and the International Racquet Sports Association (IRSA). The APFC was founded in 1975 to provide the burgeoning industry with information, education, and public relations advice. This organization is concerned with the public's perception of the fitness industry, and it has led the way in self-regulation. The APFC's *Code of Ethical Practices* was one of the first and until the early 1990s the only attempt to establish and enforce industry guidelines. Member facilities had to agree to honor the *Code*, but the APFC had no legal authority over its members. IRSA, which later changed its name to the International Health, Racquet & Sportsclub (IHRSA), was formed when the National Tennis Association and the National Court Club Association consolidated in 1981. As its name indicates, the majority of IHRSA's membership (about two-thirds) consists of multipurpose clubs that combine fitness and racquet facilities. IHRSA's most valuable contributions to the fitness industry include its statistical surveys and its professional journal, *Fitness Management*. Fitness centers are geographically concentrated in high population areas. Consequently, California leads the nation, followed by New York, Texas, and Florida. The vast majority of these businesses were privately held, with notable exceptions being industry leaders Bally Total Fitness Corp., Sports Club Company Inc., and Health Fitness Physical Therapy Inc.

BACKGROUND AND DEVELOPMENT

Health Spas. Known early in their history as health spas, fitness centers sprung up in the early 1960s, by which time increasing automation had negated the need

for most people to perform daily physical labor. At the time, some experts predicted that physical health in the United States in general would deteriorate, but some Americans made a concerted effort to encourage physical fitness. This “fringe movement” of enthusiasts and entrepreneurs started a trend that led to a fitness boom.

Spas were the first establishments of the fitness center industry. They emphasized relaxation with a European flavor, featuring whirlpools, steam rooms, and massage services. The following were the most prominent of these spas: Europa, European, Scandinavian, Grecian, and Olympic. These early facilities also had some fitness equipment, including manual joggers, stationary bicycles, standard resistance machines for men, and passive resistance equipment for women. Most spas focused on a single sex and had only one locker room. Some clubs tried to maximize their facilities by alternating women and men on particular days of the week. In 1972, however, the New York Health and Racquet Club ushered in co-ed fitness when it built its first facility that had both a men’s and a women’s locker room. The vast majority of fitness clubs constructed since that time also have locker rooms for both men and women.

Self-regulation. An appreciation of professionalism was also spawned in the early 1970s. In the decade prior to that time, health spas were largely isolated from one another and were characterized by “inexperienced, inefficient and insincere” management, according to *The Complete Health Club Handbook*. Rising concerns about providing consistent quality led to the creation of affiliate organizations such as the APFC and, later, the IHRSA.

But these early attempts at professionalization were not sufficient to stem the rising tide of consumer complaints that precipitated public Federal Trade Commission (FTC) hearings in the late 1970s. The government’s investigation identified several industry-wide problems, including false, deceptive, and misleading advertising and sales presentations; high-pressure sales tactics; bait advertising; deceptive pricing; misrepresentation of membership benefits and staff qualifications; and unfair cancellation and refund policies. Despite the large number of complaints, Dr. Jimmy Johnson, then executive director of the APFC, convinced the FTC that the industry was “well on its way to being self-policing.” Johnson’s protestations and his association’s laudable efforts at self-regulation prevented the FTC from bringing the industry under government regulation. Although the problems cited in the 1970s continued to crop up over the next two decades, the fitness center industry managed to avoid government control throughout the 1980s and early 1990s by steadily increasing self-regulation.

Nevertheless, abuses continued. In 1994 Bally’s Health & Tennis (later Bally Total Fitness Corp.) was

fined \$120,000 and ordered by the FTC to refund thousands in membership fees in connection with charges of improper billing and collections practices.

Certification of individual employees began in the mid-1980s, but stringent evaluation and certification of facilities were not undertaken until 1989, when the American College of Sports Medicine (ACSM) began a feasibility study of the proposition. After determining that facility certification was necessary “to elevate the credibility of the health and fitness industry to the purchasing public, as well as to ensure the safety of the public when exercising at a facility,” the ACSM laid out three phases for the project. They first developed standards and guidelines for facilities, then published a 16-page booklet targeted to the public titled, *The ACSM Guide to Selecting a Health and Fitness Facility*. Released in 1992, the publication helped educate potential fitness facility members in their efforts to determine which facilities offered safe, high-quality services. The ACSM started its third phase, actual certification, in mid-1993.

The Fitness Boom. An enormous number of adult exercisers generated a sport and fitness boom in the 1970s and 1980s, which caused rapid growth in the fitness center industry. In 1961 less than one-fourth of Americans, when asked, said that they did something aside from work to promote their own physical fitness. But throughout the 1970s and 1980s, more than 45 percent responded affirmatively to that question.

It was during this period that many of the best-known fitness center chains (including Bally’s, Holiday Universal, Inc.; President’s Health & Racquet Clubs, Inc.; Vic Tanny International, Inc.; and Scandinavian Health Spa) experienced dramatic growth. The aerobics and running craze of the late 1970s and early 1980s launched a general fitness boom, and by the early 1990s more than two-thirds of Americans claimed to participate in some form of exercise. Health clubs were even celebrated as smart singles spots in the 1980s, but this social orientation faded in the 1990s.

Legal Aspects. The fitness center industry has not been able to escape the tidal wave of litigation that has overwhelmed the United States. Fitness center managers have needed to employ waivers and releases, risk management services, and liability insurance to protect themselves from financial disaster at the hands of an unhappy member and his or her lawyer. The most exacting claims seemed to occur in three categories: slip-and-fall or wet area accidents, injury to participants engaged in athletic activity, and claims involving health center employees.

David L. Herbert asserted in *Fitness Management* magazine that “one who merely rents space for a particular activity owes no duty to those utilizing the space to supervise its use.” But as fitness centers in the 1990s

offered more services like health and fitness appraisals, weight training, smoking cessation programs, and stress management, they incurred more liability. Herbert emphasized that “once a facility does more than merely rent space, it is likely that it will be required to exercise due care to protect users from unreasonable risk of harm or to insure compliance with safety-related game rules.” Fitness centers and their employees who did not properly screen or test participants before exercise, improperly prescribed activities, and improperly or negligently supervised activities opened themselves to lawsuits, according to Herbert.

The Americans with Disabilities Act (Public Law 101-336), which went into effect in January 1992, added another legal challenge to fitness center management. The law, which prohibited discrimination by places of public accommodation against those with disabilities, compelled architectural and program changes, such as the addition of ramps and changing screening systems, for example. Again, Herbert warned that “Health and fitness facilities that presently utilize screening systems to admit or exclude individuals to particular exercise or recreation programs may have to modify their policies to accommodate the provisions of the law.” On the other hand, prospective members whose medical histories forbade particular activities would not be able to gain access to those programs, regardless of the law’s stipulations.

Top Challenges. In 1993 IHRSAs members claimed that the following issues were the five most pressing external challenges to the industry: local economy, price sensitivity of the market, competition from clubs, taxes, and unfair competition from non-profit establishments like YMCAs. The same survey respondents specified member retention, personnel management, advertising and marketing, cost control, and sales management as their top five internal priorities. Although home exercise was farther down the list of external threats, some industry analysts have noted that “the boom in home fitness is cutting into the health club business.” The National Sporting Goods Association reported that sales of home fitness equipment in the United States more than tripled over the course of the 1980s, from \$54.17 million in 1980 to \$1.79 billion in 1990. Home exercisers cited convenience and privacy as advantages, but most consumers conceded that they could not recreate the variety of activities possible in a multipurpose fitness center.

America’s recessionary economy of the late 1980s and early 1990s challenged fitness centers. Conventional wisdom predicted that consumers who had less discretionary income would eliminate health club memberships from their personal budgets. But performance of the fitness industry in past economic downturns showed that people often focused more on their health during stressful economic periods. Membership in virtually every age

group rose continuously throughout the 1990s. Memberships for those over the age of 55 and those under the age of 18 were particularly active areas of growth during this time. Women constituted another major area of growth for the industry. By 1997 women made up 57 percent of health club patrons, almost triple the number in 1981.

During the economic downturn, fitness centers that were already weak or questionable were “shaken out.” One analyst said, “Recessions are grand opportunities for the strong,” because the healthy businesses would be able to capture their failing competitors’ members. Industry statistics supported that commentator’s view: the total number of commercial clubs decreased for the first time in the history of the industry, from about 13,500 in 1990 to 12,000 in 1991 and remained at that level through 1995. By 1997, though, the number had climbed again, to more than 13,000.

The fitness center industry continued to grow throughout the decade. The number of adult users of clubs increased from 18 million in 1995 to 22.5 million by 1998. Despite dire predictions, there was no “credit crunch,” and, in fact, low interest rates helped boost the average pretax net income of fitness centers by 41.2 percent. This increase was due in large part to debt restructuring. Great potential for increased membership remained—only 8.5 percent of the population belonged to health clubs in 1998.

CURRENT CONDITIONS

Despite a sluggish economy, health clubs fared well in the early 2000s. According to *Bank Loan Report*, 17 of the country’s largest health clubs increased revenues by almost 15 percent during the first quarter of 2002. The day spa industry in the United States generated approximately \$7.3 billion in 2001. Over 12 percent of Americans, 80 percent of whom were women, attended a day spa between 1999 and 2001.

The vitality of the health club industry can be at least partially attributed to the changing demographics of the U.S. population and the industry’s response. Traditionally, health club membership was dominated by the 18- to 34-year-old age group; however, in 2002, the 35- to 50-year-old group became the largest age segment of health club membership with 37 percent, whereas the 18- to 34-year olds held a 34-percent share. The largest percentage jump came in the category of oldest members, those over 55 years old, which grew from just 9 percent of all health club members in 1987 to 23 percent in 2001. Health clubs also began catering to the youngest crowd, those who were 6 to 18 years old, a category that also saw significant growth.

Although most clubs continue to offer traditional workout equipment and programs that focus on aerobic and strength training, clubs are responding to their changing clientele base by offering more activities for children

and teenagers as well as catering to the older crowd by focusing on wellness, not just exercise. For example, during the early 2000s, yoga became the latest health club fad. Emphasizing stretching and mental relaxation, yoga classes became very popular. Health clubs also tapped into programs and services that appeal to women. As a result of these changes, the health club industry is working to provide a well-balanced program with something for everyone.

INDUSTRY LEADERS

With more than four million members and 360 clubs in 27 States and Canada, Chicago-based Bally Total Fitness Holding Corp. (BFIT) was by far the nation's largest fitness chain. In fact, BFIT was more than three times larger than the next nine competitors combined. BFIT was the fitness-center division of parent company Bally Manufacturing Corporation. In 2002, Bally Total Fitness had revenues of \$968.1 million. The fitness centers were spun off from their parent company in 1996 and had a public stock offering in 1997. Two other fitness center chains followed Bally into the public realm in the 1990s: Los Angeles-based Sports Club Company Inc. (\$122.5 million in 2002 sales) and Minnesota's Health Fitness Corporation (\$27.9 million). Both of these companies have been successful, but on a much smaller scale than Bally.

WORKFORCE

Composition. The fitness center industry employs more than 600,000 full- and part-time workers, and part-time employees outnumbered full-timers by a ratio of five-to-one in the late 1990s. The workforce was predominantly composed of fitness and dance instructors, who are paid hourly, by the session, or per student. According to the U.S. Department of Labor, Bureau of Labor Statistics, in 2001 the industry employed 4,520 athletic trainers. More than 80 percent of aerobics instructors have some college education, and most clubs require certification of instructors. Front desk employees made up the second largest segment of industry workers. These unskilled, entry-level workers were paid an hourly wage. Owners constituted the third largest group of fitness center workers. Fitness centers also employed maintenance engineers, tennis instructors, racquetball/squash instructors, sales and marketing personnel, and administrators. An increasing number of clubs hired independent contractors as sports trainers, physicians, and physical therapists. Approximately 85 percent of the industry's clubs provided some level of employee health benefits for full- and/or part-time workers. An across-the-industry hiring and pay freeze in the 1990s helped hold down operating expenses.

Certification. Throughout most of the history of the fitness center industry, employees were not required to have any formal training. The only exceptions were life-

guards, who were required by law to be certified. Several public and private universities had health, physical education, and recreation programs, but most employees of physical fitness centers were not required to have such training. That changed in the early 1980s, when knowledgeable consumers began to demand more than just enthusiasm from fitness instructors.

Certification tests and programs proliferated in the 1980s from such professional organizations as the American College of Sports Medicine (ACSM), the American Council on Exercise (ACE), the Association for Fitness in Business (AFB), the National Strength and Conditioning Association (NSCA), and IDEA-The Association For Fitness Professionals (formerly the International Dance-Exercise Association). IDEA's certification examination for aerobic dance instructors, first administered in 1986, is a good example of such tests. It consisted of 175 multiple choice questions on exercise physiology, anatomy, kinesiology, programming skills, leadership techniques, nutrition, weight loss and control, emergency training, health screening, and legal issues. Those seeking certification were required to be at least 18 years old and have current CPR certification. Notwithstanding the prevalence of certification, there were no national or state accrediting standards in the late 1990s.

AMERICA AND THE WORLD

The American fitness center industry is generally regarded as being a decade ahead of its European counterpart. Reasons cited for the disparity focus on costs and professionalization. For example, high-energy costs make standard swimming pools very expensive for European businesses to operate. Consequently, they have tried to compensate with expanded whirlpool and sauna areas. Moreover, high real estate costs have forced most fitness center owners to lease their facilities. As far as professionalism is concerned, the European industry appeared to be in a "pre-association" state in the 1990s: club owners did not share information and, consequently, many of their management practices, promotional ideas, and marketing tactics were accomplished by trial and error. The "pay-as-you-play system" that characterized America's fitness industry in its early years was the norm in European clubs of the 1990s.

RESEARCH AND TECHNOLOGY

Research and technology have played an important, but sometimes dubious, role in the fitness center industry. Fleeting trends have sometimes brought sweeping transformations in equipment and training methods at fitness centers. In the late 1980s and early 1990s, everything from stationary bicycles to resistance equipment became computerized. Much of the technologically advanced equipment simulated other sports, like downhill and cross-country skiing, rowing, and even rock climbing.

And while some practitioners, like Augie Nieto (president of Life Fitness, Inc.), predicted increasing computerization, other observers, like Douglas Garfield (of Bodyguard, Inc.), foresaw “less high-tech and more high-touch” activities in health clubs of the future.

Demographics Influence Trends. As a mass of “baby boomers” entered middle age, the health and fitness center industry rushed to meet their needs. The industry had to make a critical transition from an almost exclusive focus on the young adult market, toward the “40-somethings” and their families. Some club owners asserted that “family-oriented health programs are the fastest-growing segment of the health club industry.” Programming gained popularity as a source of member recruitment and retention and increased revenue. Convenience-oriented services included food service, salons, childcare, laundry facilities, car washes, ATMs, and sporting goods shops. Bally even began offering a line of vitamins and nutritional supplements.

Enrollment fees, long considered a powerful inducement to member retention, were proven to have no power to ensure member longevity. More and more clubs have dropped enrollment fees, partly in response to consumer demands. This trend was predicted to continue. Although some industry observers decried the return to old-fashioned “pay-as-you-play,” fitness services, other entrepreneurs viewed them as “a valuable option for wooing customers into joining.”

Other trends included the growth of more all-female health clubs, the development of “ultraluxe fitness centers,” and a continuing focus on attracting more baby boomers. As of 1997, only 5 percent of health clubs were single-sex, and the industry felt it could capitalize on women who did not want to “mingle” while they were working out. “Ultraluxe” clubs feature services as varied as plush surroundings, gourmet meals, business centers, and dry cleaning. They have sprung up in major cities such as Chicago and New York and cater to an extremely wealthy clientele. As baby boomers approach retirement, they will have more free time, and the industry hopes to capitalize on this extra time by drawing them in as new customers.

SIC 7992

PUBLIC GOLF COURSES

This industry includes establishments primarily engaged in the operation of golf courses open to the general public on a contract or fee basis. Membership golf and country clubs are classified in **SIC 7997: Membership Sports and Recreation Clubs**. Miniature golf courses and golf driving ranges are classified in **SIC 7999: Amusement and Recreation Services, Not Elsewhere Classified**.

NAICS CODE(S)

713910 (Golf Courses and Country Clubs)

By definition, public golf courses are open to the public on a contract or fee basis. According to The National Golf Foundation, there were 16,365 golf courses in the United States as of December 31, 1998. Of those, only 4,708 were private facilities. The remaining 11,657 courses were privately-owned facilities open to the public or city-owned municipal courses. In 1999, 387 more courses in the United States were finished with construction. Florida, California, Michigan, New York, and Texas boast the greatest number of total courses in America; in all of those states, the number of daily fee and municipal courses available far outnumber those of private club courses.

During the 1990s, the game of golf continued to enjoy a steady growth in popularity that spanned the last few decades. In 1970, most estimations placed the number of golfers in the United States at approximately 11 million. By 1980, that number had increased to more than 15 million. According to the National Golf Foundation, however, the number of golfers in the United States peaked at 27.8 million in 1990 and settled at 25 million in 1995. By the close of 1997, the number climbed to 26.5 million, with Americans playing a total of 547 million rounds of golf during that year.

Although the number of golfers had gone flat, the number of golf courses in the United States continued to grow. In the past, the game of golf was practiced predominantly at country clubs and other membership and recreation clubs. Over time, however, that has changed: the number of private courses increased by only ten in 1998, while 86 percent of the courses built that year were open to the public. All of this growth had some adverse effects on the industry as a whole: what some believe may have been overbuilding has forced many real estate developers and municipalities nationwide to grapple with unexpectedly high debt burdens.

Still, the often expensive fees and dues associated with membership clubs has led many of the sport's practitioners away from traditional country clubs to public golf facilities. Moreover, with the growing number of courses offered and continued enthusiasm to build, many golfers are finding public courses rivaling private clubs in terms of aesthetics and level of skill.

SIC 7993

COIN-OPERATED AMUSEMENT DEVICES

This industry includes establishments primarily engaged in operating coin-operated amusement devices, either in their own or in other places of business. Such amusement devices include jukeboxes, pinball machines, mechanical games, electronic games, pool tables, shuffle alleys, electronic darts, video games, kiddie rides, prize dispensing machines, and slot machines. Amusement

(including video game) arcades and parlors are also included in this industry.

NAICS CODE(S)

713120 (Amusement Arcades)

713290 (Other Gambling Industries)

713990 (All Other Amusement and Recreation Industries)

Coin-operated amusement devices can be found in a variety of locations. Primary locales include taverns and bars, restaurants, retail stores, and shopping malls, which often include one or more video arcade establishments. Other locales in which coin-operated amusement devices can be found include bus terminals, hotels, grocery stores, and truck stops. In 1997, there were 2,737 amusement arcades across the country, with another 2,668 operators of coin-operated, non-gambling, amusement devices.

The 1990s have seen a dramatic proliferation of indoor amusement facilities, known as "family fun centers," which vary greatly in size and in the activities they offer. The indoor facilities often include bumper car rides, bumper boats, basketball machines, and a variety of video arcade equipment. Many of the family fun centers start small — often with an outdoor miniature golf course — and when they develop inside, sometimes bumper cars become a new attraction, and almost invariably some type of "video arcade" devices are introduced.

The International Association of Family Entertainment Centers (IAFEC) reported 350 members in 1999. Although this group owned establishments at nearly 2,800 locations, 70 percent of their membership owned only one site. These locally-owned establishments faced competition from chains. One of the most ambitious chains to emerge in the late 1990s was Gameworks, a joint venture between Dreamworks, Universal Studios, and the video-game giant Sega. When the first Gameworks opened in 1997, the company announced plans to have 100 locations within five years.

The proliferation of legalized gambling has produced dramatic growth for some participants in another segment of the coin-operated amusements industry. Slot machines have become so popular that they provide 75 percent of casino revenues. Besides the more than 700 casinos operating in the United States in 1997, there were another 328 operators of slot machines. Based on an average cost of roughly \$5,000 each, slot machines provide a huge return on investment.

Slot machines have not changed much since the 1980s when electronic mechanisms were added inside the machines. In the United States alone, players fed an estimated \$16 billion per year into the machines. Slot

machines were the fastest growing segment of legalized gambling.

Another popular coin-operated gambling device is the video lottery terminal (VLT). VLTs are slot machines that display video games, such as video poker and bingo, for low-stakes gambling. In states where these machines are operated, they are part of the state lottery system. The VLT terminals are the same as the video poker machines in Las Vegas, Nevada, except for the payment devices. Money is fed into the machine, and winnings and losses are electronically calculated and printed out for the player. State lottery revenues have slacked off, and the video lottery is a means for states to increase revenues. Video lottery terminal machines offer the gambler the opportunity to play video poker, blackjack, keno, or bingo for a nickel to \$2.50 a bet.

With the increase in slot machines and the easy access to VLTs, another gambling industry — horse racing — has felt the affects of competition. In response, racetracks have lobbied for permission to operate slots on their premises. States such as Delaware, Iowa, and West Virginia, among others, have passed laws allowing such operations. Many of these laws contain regulations to ensure that the primary focus stays on the races and does not shift to slot machines at these establishments.

The leader in the gambling segment of the industry is International Game Technology (IGT), the world's largest manufacturer and designer of gaming machines and software. IGT currently controls more than 75 percent of the U.S. slot machine market and had 1998 revenues of \$824 million. Its products include progressive slot machine systems like Fabulous Fifties, High Rollers, and Megabucks; reel-type slot machines like S-Plus; video gaming products; and video gaming terminals for government-sponsored state run lotteries. IGT has benefited from the legalization of gambling on riverboats and Indian reservations and is betting on an increased consumer interest in gambling for future profits. IGT also has an international presence, with nearly 25 percent of its revenue coming from sales to other countries.

State regulation of coin-operated amusement devices varies from state to state. Some are very strict regarding every aspect of the industry, including use and location of the machines. For instance, in the state of Texas, regulations determine the percentage operators may pay to the owner of the establishment in which their machine is located. Operators must also keep records of income from individual machines. By contrast, some other states regulate less strictly and allow operators wider parameters.

SIC 7996

AMUSEMENT PARKS

This category covers theme parks, kiddie parks, amusement piers, centers, and parks, and other establishments (excluding fairs, circuses, and carnivals) that operate in part or whole such attractions as mechanical rides, amusement devices, refreshment stands, and picnic grounds. Amusement concessionaires operating within these establishments are generally covered in **SIC 7999: Amusement and Recreation Services, Not Elsewhere Classified**.

NAICS CODE(S)

713110 (Amusement and Theme Parks)

According to *The Great American Amusement Parks*, the earliest amusement parks were the European pleasure gardens of the seventeenth and eighteenth centuries. But only with the technological advances of the Industrial Revolution did the mechanical rides of the modern amusement park come into being. In this area of development, American parks led the way.

Jones's Wood in New York City, established in the early nineteenth century, was probably the first major U.S. amusement park. But its humble attractions — including billiards, bowling, and donkey rides — were soon eclipsed by Coney Island. This legendary resort first began to expand dramatically in the 1870s when a railway line to it was constructed. In 1920, the extension of the New York subway system to Coney Island put city residents a nickel away from the resort's attractions. Indeed, before the advent of the automobile, ease of travel played a crucial role — "trolley parks" acquired their name from the system of transport that brought customers to them.

Mechanized rides of the kind taken for granted in modern amusement parks reached Coney Island in 1884, with the advent of LaMarcus Adna Thompson's Switchback Railway, the first roller coaster. From their inception, roller coasters proved the most popular attractions, as well as the largest and most expensive to build and maintain.

The first ferris wheel — named for George Ferris, not because he invented the concept, but because his engineering talents produced the first such ride made of steel rather than wood and built on a huge scale — made its appearance at the 1893 Chicago World's Fair Columbian Exposition. Coney Island, and the many other amusement parks that sprang into being in response to its success, faced hazards from fire and water. Rainy weather discouraged attendance because most of the attractions were outdoors. Initial reliance for construction on such cheap but highly flammable materials as lath and staff — a combination of plaster of Paris and hemp fiber — meant that fires were frequent and caused great damage.

Other problems such as noise, dirt, and criminality often found in the early amusement parks became more apparent as larger numbers of middle- and upper-class Americans owning cars gained the freedom to seek their entertainment elsewhere. The formation of the International Association of Amusement Parks and Attractions in 1920 was motivated in part by the industry's concern over its reputation. Individual parks, such as Cincinnati's Coney Island and Playland, in Rye, New York, also sought to create a more family-oriented image by making sure that structural damage, litter, and graffiti were swiftly removed from sight.

Disney was the most significant creator of wholesome amusement in its innovative theme parks. The first of these, Disneyland, opened its doors in 1955. An instant success, the park initially proved hard to imitate. But Six Flags Over Texas, opened in 1961, found another winning formula, leading to the construction of additional Six Flags complexes. Other Disney competitors also began to find new angles on the theme park concept.

CURRENT CONDITIONS

American Demographics estimated that more than 50 million people over the age of 18 visited one of North America's theme parks in 1998. This obviously does not account for the large number of children who visit these parks as well. The magazine further projected a 4.5 percent increase in this attendance by 2005 and a 10.4 percent increase by 2008. Motion picture tie-ins and high-tech rides were the big draws, with simulator rides growing in popularity. Start-up costs for a new theme park were estimated at \$500 million on the low end, with a single simulator ride costing upwards of \$40 million.

According to *Amusement Business*, Disney properties continued to lead the present-day amusement park industry. Disney World's Magic Kingdom, Epcot Center, and Disney-MGM Studios Theme Park, both located in Lake Buena Vista, Florida, brought in more than 35.7 million customers in 1998. Disney's newest park in the Florida region, Animal Kingdom, attracted 6 million further visitors in 1998. Tokyo Disneyland and Disneyland Paris have also become popular tourist attractions, resulting in Disney's plan for further international expansion.

Six Flags parks, which are partly owned by Time Warner, uses Warner movie tie-ins to boost their attendance. The fact that there are currently 25 Six Flags theme parks across the United States makes location another important strategy for the company. Paramount Entertainment also uses the movie strategy in operating its six theme parks, including Paramount's Great America in Santa Clara, California, and Paramount's Kings Island in Cincinnati, Ohio. More than 13 million people visited one of these parks in 1998. The amusement parks of MCA/Universal Studios, located in Orlando, Florida, and Hollywood, California, combined to serve 8.9 million in 1998. Anheuser-Busch operates parks such as Busch Gardens and Sea World. These parks attracted 20 million guests in 1998 and generated \$116 million for the company.

Just as the tourist appeal of California and Florida aided Disney in the development of its domestic amusement parks, so location offered a crucial advantage to competitors in Las Vegas, where Circus Circus Enterprises, MGM Grand, and Mirage Resorts were developing a line of casinos angled toward the family, with kiddie parks to keep children happy while parents gambled. Other operators looked to complexes combining amusement parks with retail outlets, such as the Mall of America in Bloomington, Minnesota — the largest mall in America. The mall's anchor attraction is Knott's Camp Snoopy Indoor Theme Park.

Europe and Asia were the new growth areas for amusement and theme parks. With old parks being renewed and new parks opening up, Europe has seen a 10 percent increase in attendance, as reported in *Newsweek*. In Asia, according to *The Economist*, more free time and increased income was spurring a leisure revolution. Shopping malls have become theme parks, with more than 40 opened in China alone during the past decade. Unlike their American counterparts, these often tend toward a cultural, historical, or environmental theme. Bangkok, Singapore, and Kuala Lumpur all would like to become hubs of tourism, and theme parks have figured into that future.

Future industry challenges will be devising ways of bringing out the aging populations. Viacom Inc. has started opening adult playgrounds featuring virtual real-

ity games, while Disney has started marketing ads to retired couples.

SIC 7997

MEMBERSHIP SPORTS AND RECREATION CLUBS

This industry classification covers sports and recreation clubs that are restricted to use by members and their guests. Country, golf, tennis, yacht, and amateur sports and recreation clubs are included in this industry. Health clubs and other fitness facilities are classified in **SIC 7991: Physical Fitness Facilities**.

NAICS CODE(S)

713910 (Golf Courses and Country Clubs)

713940 (Fitness and Recreational Sports Centers)

713990 (All Other Amusement and Recreation Industries)

An estimated 15,100 membership sports and recreation clubs were in operation in 1998, generating revenues of more than \$7.5 billion. These numbers represent a 15.5 percent growth in the number of clubs and a whopping 61 percent increase in revenues from 1990. Employment grew nearly 23 percent since 1990, totaling about 297,300 in 1998.

American country clubs were born in the late 1880s — a creation of the wealthy upper class as an exclusive social setting in which to enjoy various athletic and recreational endeavors. The clubs flourished until the late 1920s, when the Depression forced many of them to close. A renaissance took place in the late 1940s and 1950s, spawned by post-war affluence and the increased interest in golf (a sport that has enjoyed a tremendous amount of growth across the nation for the past several decades); and, as a direct result of this heightened popularity, many country clubs were built during this period.

In the late 1990s, private country clubs have become a major pastime for many Americans, with nearly 12,000 such facilities in operation.

Golf Clubs. The National Golf Foundation estimated that more than 26 million golfers played roughly 520 million rounds of golf in 1998, up about 6 percent from the 490 million rounds played in 1994. The United States boasted nearly 16,400 golf courses by the end of 1998, the majority of which were either municipal or private courses that were open to the public. Many private golf courses offered a variety of different memberships, with the most sought-after and expensive membership being a full-equity membership, in which members have full use of the golf course and share of stock in the club and with which they are able to share with any approved member. Other, more restricted memberships included dining room privileges only, while some full memberships gave members use of all facilities except the golf course.

Because of new tax laws passed in 1994 eliminating the business deduction for club dues and reducing deductions on business meals, many of which were eaten in private clubhouse dining rooms, clubs struggled in the mid 1990s to retain current members and to attract new members.

Club Corp International, headquartered in Dallas, Texas, is the world’s largest private club and resort operator. In 1999, Club Corp owned or managed approximately 230 clubs, resorts, public fee golf courses, and real estate developments worldwide. In 1998, the company garnered revenues of more than \$850 million.

Other Membership Sports and Recreation Clubs.

Americans support a wide array of athletic and recreational clubs offering a variety of sports and recreational activities, such as yachting, archery, and tennis. Many of these establishments are independent clubs with no other affiliations, privately owned by the club membership. Others operate as subsidiaries of larger corporations.

In the late 1990s, other major players in the industry included American Golf Corp., the world’s largest golf management company, and Golf Trust of America. American Golf, based in Santa Monica, California, operates more than 250 public and private golf courses and country clubs. The company reported 1998 sales of more than \$575 million. Golf Trust, headquartered in Charleston, South Carolina, has a stake in more than 30 upscale U.S. golf courses, the bulk of them located in the Sunbelt. It posted 1998 revenues of \$44.5 million.

SIC 7999

AMUSEMENT AND RECREATION SERVICES, NOT ELSEWHERE CLASSIFIED

This industry covers establishments primarily engaged in the operation of sports, amusement, and recreation services, not elsewhere classified, such as bathing beaches, swimming pools, lottery operations, riding academies and schools, gaming establishments, carnival operations, exposition operations, horse shows, picnic grounds operation, ski resorts, and shooting galleries. Establishments primarily engaged in showing or handling animals at shows or exhibitions are classified in **SIC 0752: Animal Specialty Services, Except Veterinary**.

NAICS CODE(S)

- 561599 (All Other Travel Arrangement and Reservation Services)
- 487990 (Scenic and Sightseeing Transportation, Other)
- 711190 (Other Performing Arts Companies)
- 711219 (Other Spectator Sports)
- 713920 (Skiing Facilities)
- 713940 (Fitness and Recreational Sports Centers)
- 713210 (Casinos (except Casino Hotels))
- 713290 (Other Gambling Industries)
- 712190 (Nature Parks and Other Similar Institutions)
- 611620 (Sports and Recreation Instruction)
- 532292 (Recreational Goods Rental)
- 487110 (Scenic and Sightseeing Transportation, Land)
- 487210 (Scenic and Sightseeing Transportation, Water)
- 713990 (All Other Amusement and Recreation Industries)

Americans entertain themselves with a broad spectrum of amusements and recreations that include participatory and spectator sports, tourism, and other activities. Members of this broad industry range from athletes to bowling instructors and from fortune tellers to fireworks operators. The U.S. population's traditional interest in a rich and varied range of recreational activities has supported the growth of an enormous, sprawling industry to capitalize on the continued popularity of such activities.

Spending on recreational activities has grown dramatically since 1990, even in the absence of more free time. It was projected that spending by Americans on recreational activities would increase more than 30 percent between 2000 and 2005. Entertainment spending was dramatically higher in affluent and well-educated households.

While this industry classification covers many establishments, several areas of the industry have particular economic significance in the United States.

Ski Resorts. Skiing is one of America's favorite recreational sports, but with the number of skiers leveling off and operational costs such as snowmaking and workers' compensation rising, resorts were forced to hike prices and even explore consolidation opportunities. Many younger outdoor enthusiasts were taking up snowboarding, further contributing to the downhill skiing slump. In 1996, flashy new ski designs were introduced to appeal to skiers over 35, who make up an increasing share of the market. The new skis claim to allow ordinary skiers to cut smooth turns at slow speeds and with little effort.

Vail Resorts Inc., the nation's largest ski resort operator, currently owns the nation's three most popular resorts: Vail Mountain, Breckenridge Mountain Resort, and Keystone Mountain. Vail Resorts Inc. has been an active participant in the consolidation trend.

Tourism. The tourism industry includes such items as air, bus, cruise ship, and rail travel; hotel and motel accommodations; camping; food and drink; retail purchases; and amusement and recreation service. Across the United States, cities and counties have found success by using tourism to attract industry. The tourism industry ranks among the top 3 employers in a majority of the 50 states. Travel spending in the United States is responsible for millions of jobs generating hundreds of billions of dollars in wages and salaries.

As concern for the environment has grown, the so-called "eco-trip" or adventure travel, has become a popular vacation alternative. These eco-tours, which include such excursions as white water rafting, watching sea lions, or visiting a rain forest, are not new, but they have become a growth area of the travel industry.

Gaming Establishments. Until the late 1980s, only Nevada and New Jersey permitted casinos. But with states and localities hard-pressed to generate jobs, tourism, and tax dollars, the gaming industry has increasingly been viewed as a vehicle for economic growth. Today, some form of legal gambling is available in 47 states and the District of Columbia. In 1996, 56 percent of Americans gambled at least once, generating more than \$50 billion in gross revenues.

Based on revenue, Las Vegas and Atlantic City remain the two largest centers of the U.S. gaming market. In 1995, Nevada's total wagerings grew almost 6 percent to \$112 billion, the smallest gain in 6 years. While Las Vegas has been enormously successful at attracting new visitors, they are gawking more and gambling less. The amount of money and time spent gambling has decreased in recent years, while spending on shows, sightseeing, and other activities outside the casinos has more than tripled.

In contrast to Las Vegas, which is more of a resort and business convention destination, about 30 percent of the visitors to Atlantic City arrive by charter bus and stay for less than a full day. Ten of Atlantic City's gaming facilities are located on or near the Boardwalk.

During the early 1990s, casino-type activity become increasingly accessible to U.S. consumers. The geographic expansion of legalized gaming broadened the industry's customer base. People who had never traveled to Las Vegas or Atlantic City were being lured to local riverboats or Native American casinos. As of 1996, there were approximately 65 riverboat casinos open in Iowa, Illinois, Mississippi, Louisiana, Missouri, and Indiana. In addition, a number of states had authorized video gaming terminals (VGTs), which resembled slot machines.

The 1990s also witnessed the expansion of Native American gaming facilities. Under the Indian Gaming Regulatory Act of 1988 (IGRA), Native Americans can operate whatever form of gambling legally exists in a given state. Typically, a tribe seeks an agreement, or compact, with the state, detailing the gambling activity for which it seeks approval. Currently 24 states have permitted Native American gaming sites, with the most active being Connecticut, Minnesota, and Michigan.

More recently, however, there has been a slowdown in the number of new jurisdictions adopting legalized gambling. Concerns about social and moral issues may continue to restrict the spread of legalized gambling, and Congress established the Gaming Impact and Policy Commission in 1996 to study the effects of the industry on the public. The Commission found that while the gambling industry has entertained and provided decent jobs for some, it does have significant problems. The main problems cited were the effect on those with a pathological gambling problem and their families, and the fact that in many cases, the revenues from gambling that were supposed to go into causes like education or the environment, have simply not gone there. The Commission recommended that a "pause" was necessary before further legalization of gambling was allowed.

INDUSTRY LEADERS

Mirage Resorts is one of the largest casino operators in Las Vegas. Its major U.S. properties include the Mi-

rage, a tropically-themed 95,000 square-foot casino and 3,000 room hotel; Treasure Island, a pirate-themed 75,000 square-foot casino and 2,900 room resort; and the Golden Nugget, a 38,000 square-foot casino with 300 hotel rooms located in downtown Las Vegas. In 1998, Mirage opened the \$1.6 billion Bellagio casino/hotel in Las Vegas. Future plans included resorts in Atlantic City.

Hilton Hotels owns, manages, and/or franchises more than 260 hotels around the globe. With its \$2 billion purchase of Bally Entertainment in 1996, Hilton became the nation's largest gambling business. Its U.S. gaming assets include casino hotels in Las Vegas and Atlantic City, a riverboat casino in New Orleans, and an interest in a Canadian casino. Among the most well known Hilton properties are The Waldorf-Astoria, Hilton Hawaiian Village, and Palmer House Hilton.

SIC 8011

OFFICES, CLINICS OF DOCTORS OF MEDICINE

This industry consists of offices and clinics of licensed medical doctors, excluding doctors of osteopathic medicine (covered in **SIC 8031: Clinics of Doctors of Osteopathy**). These establishments are engaged in general or specialized medicine or surgery. This category includes the offices of the following types of medical specialists: anesthesiologists, dermatologists, gynecologists, neurologists, obstetricians, oculists, ophthalmologists, orthopedic physicians, pathologists, pediatricians, plastic surgeons, psychiatrists, psychoanalysts, radiologists, medical surgeons, and urologists. Clinics covered in this category are free-standing—not associated with hospitals—such as ambulatory surgical centers, free-standing emergency medical centers, primary care medical clinics, and outpatient psychotherapy and women's health clinics.

NAICS CODE(S)

621493 (Freestanding Ambulatory Surgical and Emergency Centers)

621491 (HMO Medical Centers)

621112 (Offices of Physicians, Mental Health Specialists)

621111 (Offices of Physicians (except Mental Health))

INDUSTRY SNAPSHOT

According to the U.S. Department of Labor, Bureau of Labor Statistics, in 2001 there were 856,350 people serving as healthcare practitioners and technicians, including 66,700 family and general physicians; 42,420 surgeons; 41,370 general internists; 19,500 anesthesiologists; 18,200 general pediatricians; and 13,970 obstetricians and gynecologists. On average, a physician sees over 100 patients each week, with general and family physicians averaging slightly more than specialists.

The operation of office- and clinic-based physician practices has been strongly influenced by ongoing changes in the entire healthcare industry. Increased healthcare costs, coupled with decreased federal funding, has pushed practitioners to closely evaluate their practices and patient base. At the turn of the twenty-first century, physicians were also adjusting to new options in technology that could finally convert multiple filing tasks into automated computerized systems that, although expensive to install, were expected to provide better quality-of-care and overall cost savings.

ORGANIZATION AND STRUCTURE

This industry is organized mainly according to the type of practice or medical specialty performed at an establishment. The 1980s introduced another classification within this industry based on whether a doctor was working completely independently or through a group, such as a health maintenance organization (HMO) or a preferred provider organization (PPO). Managed care also cultivated the increase of practice consolidation by putting added pressure on solo and small group practices. Smaller practices did not have the ability to negotiate sufficiently favorable managed care contracts to keep them in business. The proportion of physicians with managed care contracts increased from 56 percent in 1986 to 83 percent in 1995, with little variation between specialties.

In the past, most physicians were self-employed and ran their offices in a partnership or group, sharing office help and medical assistants. During the 1980s, some physicians started to franchise, which involved paying a franchiser to handle administration, such as billing and insurance claims. The number of self-employed, patient-care physicians in solo practices dropped from 40.5 percent in 1983 to 26.3 percent in 1995. The number of self-employed physicians in group practices fell from 35.3 percent in 1983 to 28.3 percent in 1995. The number of physicians employed by a health care company, however, rose from 24.2 percent in 1983 to 45.4 percent in 1995.

Of those physicians employed by an outside agency in 1995, 31 percent worked for physician groups and 8 percent for staff-model HMOs. Many staff-model HMOs were quite large in 1996, with as many as several thousand physicians. By the late 1990s, many physicians either merged with larger medical groups or sold their practices to hospitals. This trend led to the development of physician-hospital organizations (PHOs) and management services organizations (MSOs).

PHOs far outnumbered MSOs in 1995, creating a partnership between physicians and hospitals with equal management weight to each. Also a hospital partnership, MSOs require physicians to purchase shares in the MSO, which provided management services and equitable management to both hospitals and physicians. In MSOs, physicians could later sell their shares in the organization for profit.

Physicians who sold their practice in 1995 received generous compensation. Specialty and multi-specialty practices had the highest median value per physician at \$244,000, plus a base salary. More than 80 percent of the physicians who sold their practices could also receive bonuses in future years. The largest number of physicians who sold their practices in 1995 were primary care physicians, especially family physicians and internists.

Doctors' offices and clinics play an important role in the overall operation of the health care industry. Doctors usually work with one hospital and refer patients to that hospital for tests and treatment. For this reason, the relationship between doctors and hospitals is often regarded as a buyer-seller relationship, in which hospitals approach local doctors for their patients. In addition, doctors are also buyers in their relationship with pharmaceutical companies.

BACKGROUND AND DEVELOPMENT

While the convention of doctors working in some institutional or hospital-like establishment dates back to ancient Egypt, doctors' offices as independent establishments emerged in the Middle Ages with barber-surgeons. These independently employed doctors worked in their offices or in patients' homes and received payment for their services as they were provided. Doctors who cared for patients in hospitals received no payment from their patients or the hospital. In the nineteenth century, however, hospitals began paying doctors, and the profession grew rapidly.

During the twentieth century, the role of the physician changed with economic, government, and societal pressures, along with technological advances. In the early part of the century, doctors in the United States were a highly autonomous group, which was held accountable to the standards defined by the profession itself and not the

general public, according to Harold M. Swartz and Ann Barry Flood in *Money, Power, and Health Care*.

The gap in salaries between primary care physicians and specialists grew significantly in the twentieth century. As a result, there was a general shift from primary care physicians to specialists. The use of HMOs and provider networks to cut medical costs also changed this profession from wholly self-employed doctors to those working on salaries for hospitals, HMOs, and provider networks. By 1995 the average share of physicians' revenues from managed care rose from 11 to 27 percent, with a higher proportion going to primary care physicians.

Technical advances in this industry were abundant during the twentieth century. From 1900 to the 1950s, the development of antibiotics and public health initiatives—such as water treatment—increased physician effectiveness in many parts of the country and simultaneously decreased the need for doctors in many respects. Wars and increases in population and fatal crimes offset this pattern, however.

During the second half of the twentieth century, technical developments increased doctors' roles in health care; many diseases, such as Hodgkin's disease and leukemia, were now treated with chemotherapy. Moreover, detecting disease became more practiced with new technologies for diagnosis. The development and use of these technologies, however, was regulated by governmental bodies and insurance companies.

The second half of the twentieth century also witnessed a growth in freestanding clinics. By the end of the 1980s, there were 23,000 licensed clinics in the United States, according to the General Accounting Office (GAO). These included outpatient ambulatory care facilities, outpatient surgical centers, psychiatric and psychotherapy clinics, and obstetric/gynecological clinics.

The rapid proliferation of clinics posed problems for state regulators of these facilities. According to a 1989 GAO report, state health regulators were concerned about the complex appeals systems between patients and clinics and were disturbed to find that roughly one-half of the states did not have any means of resolving patient complaints against clinics.

The government acknowledged the growing need for psychiatric outpatient care in 1989 when it increased its coverage for such care under Medicare. The program opted to provide more types of psychiatric and psychotherapy care and to increase the caps on payments.

In the 1980s physicians broke with a long-held tradition by advertising their services. This new practice was the focus of much debate within the profession and was initially regarded by many physicians and other health care providers as unprofessional. By the end of the 1980s, however, advertising in newspapers, television, and radio

became common. By 1992 doctors' offices and clinics spent roughly \$50 million annually in advertising, with a 13.7 percent growth rate in advertising expenditures.

Plastic surgeons spent an estimated \$30 million on advertising in 1990; this amount was a 400 percent increase from 1985. In large part the increase was due to societal changes that made plastic surgery in general more acceptable. According to the American Society of Plastic and Reconstructive Surgeons, in 1987 nearly 50 percent of all Americans found plastic surgery acceptable, compared with 35 percent in 1982. In addition, advertising by plastic surgeons increased because a larger number of doctors went into plastic surgery and had consequently increased competition.

Due to increased health care costs and rising competition among doctors seeking business, the late 1980s witnessed a surge in consumers seeking medical information outside doctors' offices. Nurse-call lines, self-help medical books, and educational videotapes started to compete with doctors' offices. Some offices and clinics, however, adapted to this trend by showing videotaped programs as a way of educating patients about procedures and the treatment options available.

Company Clinics. By the end of the 1980s, large companies across a variety of businesses greatly expanded their company clinics in response to rising health care costs. By 1990 about 12 employers sponsored clinics for their employees. Many of these clinics were operated by the companies themselves and others were operated by medical management companies. One of the primary ways in which these clinics brought down medical costs was through the hiring of doctors on salaries on the assumption that salaried physicians did not have incentives to perform unnecessary tests, according to Jerry Geisel in *Business Insurance*.

In 1992 John Deere was the first company in the United States to set up a primary care clinic for its employees in conjunction with a third-party hospital, the Mayo Clinic of Rochester, Minnesota. The largest company clinic in the country was operated by Southern California Edison Company, which had 10 medical clinics and first-aid stations, employed a staff of 70 and facilitated more than 100,000 patient visits annually. Similarly, the Gillette Company and Goodyear Tire & Rubber Company sponsored corporate primary care clinics and offered incentives for employees to use them.

Medicare and Medicaid. Medicare and Medicaid are government programs providing financial assistance for medical treatment. The Medicare program is designed for individuals at least 65 years old and for the disabled, while Medicaid helps families with low incomes. Government funds for these programs come from both federal

and state sources and primarily through Social Security payroll taxes.

In 1997 more than 55 million people received Medicare and Medicaid payments. Medicare payments for doctors, clinics, laboratory services, end-stage renal disease treatments, and continuous-use medical equipment—such as wheelchairs—totaled \$51.7 billion in 1997, with \$38.2 billion going to physicians. Medicaid payments going to both hospitals and doctors and other health care facilities and providers totaled \$123.6 billion in 1997.

Though Medicaid expenditures nearly doubled between 1990 and 1997, growth dropped to 2.8 percent from 1995 to 1997. In 1997 Medicare paid for 20.7 percent of the 787.4 million patient-visits to office-based physicians, while Medicaid financed another 8.1 percent of total visits. Private insurance covered 53.1 percent of 1997 visits to office-based physicians.

Medicare and Medicaid greatly affected this industry by increasing administrative duties involved in handling paperwork and by setting costs for medical services. Since the late 1980s lawmakers have tried to reduce Medicare and Medicaid financing by shifting coverage to promote outpatient treatment over extended hospital care.

In 1991 the Medicare program was reduced by \$43 billion as part of the federal government's economic budget changes. In 1992 the Health Care Financing Administration, which managed Medicare, started a plan to change how doctors were paid by the government. Under the new plan, doctors' fees were based on resources and the doctors' time in consultations, rather than on procedures performed by the physicians. This arrangement was set up to attract primary care physicians who felt the old system was unfair. The American Medical Association (AMA) opposed total use of this system, pointing out that some unfairness to specialty doctors needed to be worked out of the system before private insurers adopted it for their payment plans. At the end of the 1990s the cost of Medicare was still a hot topic for political debate pertaining to the goal to balance the budget and create health care reform.

Malpractice. The Insurance Information Institute (III) reported that the number of medical malpractice claims filed against doctors peaked in 1985 at 17.8 per 100 doctors and then fell for the rest of the decade, dropping to 8 claims per 100 doctors by 1989. During the 1990s the rate of increase in the number and size of claims tended to fluctuate, according to the III. The malpractice insurance market attracted new entrants in many states, increasing competition and holding down rates.

Due to the proliferation of malpractice suits, the practice of defensive medicine increased considerably. Defensive medicine refers to excessive precautions doc-

tors take in order to safeguard themselves against possible malpractice suits. Precautions that doctors often took in treating patients included ordering duplicate tests, requesting additional diagnostic procedures, and using consultants. According to the AMA, in 1992, defensive medicine added \$15 billion to the cost of health care nationwide. In 1991 medical malpractice represented \$9.1 billion of total tort costs in the United States; of that total, 58 percent was incurred by physicians. In 1993 the number of malpractice claims had been reduced by state health regulators imposing caps on suit awards and by the insurance industry and medical profession—represented by more than 30 medical associations—together advocating tort system reforms.

Obstetricians and gynecologists were among the doctors most commonly sued for medical malpractice in the early 1990s. According to a study conducted by the American College of Obstetricians and Gynecologists, in 1992 about 27 percent of all claims against gynecologists were for failure to diagnose a medical condition, usually breast cancer. The average payment for claims won against gynecologists was reported at \$92,500 in 1990. Approximately 33 percent of all obstetric complaints were for infant brain damage. The average payment for obstetric claims was \$311,400 in 1990. Given the frequency and costs of these claims against obstetricians and gynecologists, their average insurance premiums were \$36,946 in 1991, while the average for all physicians was \$15,900. Insurance payments and claims awards, however, varied considerably from state to state.

Malpractice cases also strained the relationship between physicians and hospitals. Hospitals had higher insurance coverage and more general funds to cover malpractice cases; consequently, many claims involving doctors were directed at hospitals in order to receive higher awards.

According to a 1993 study by the Health Research Group of Public Citizens, the most common complaints against doctors were for negligence, misprescribing drugs, and substance abuse by the physicians. The study also showed that 150,000 to 300,000 medical negligence cases were not disciplined by such measures as revoking or suspending licenses. The AMA responded to this study by pointing out that physicians as a group acted as a self-correcting organization, whereby doctors did not refer patients to doctors with reputations for such practices. Moreover, as pointed out at the time of the study, many states did not have the funds to investigate the many claims against doctors.

One measure taken to protect patients from consulting with negligent doctors began in 1990 with the establishment of the National Practitioners Data Bank. Owned by the federal government, this computer data bank stored and provided information about physicians who

had their licenses suspended or who faced disciplinary action for negligence and helped to prevent these physicians from setting up new offices.

Other ways of dealing with malpractice cases and the costs they placed on health care included placing caps on the size of awards for personal suffering; this system has been used in California since the late 1970s. Under health care reform programs discussed at the federal level in 1993, most of the cost of malpractice awards would be paid by HMOs and other health management organizations.

Self-Referrals. In the mid-1980s, consumer groups drew attention to physicians who referred patients to laboratories totally or partially owned by the doctors, a practice known as “self-referrals.” In 1992 a study conducted by the Health Care Financing Administration estimated that at least 25 percent of independent laboratories were financially tied to individual physicians. The same study reported that Medicare patients who were referred by physicians to laboratories they owned received 45 percent more lab tests than other Medicare patients. Some sources estimated that the annual excess in costs as a result of self-referrals was roughly \$140 million; others estimated the costs in the tens of billions.

Federal legislation was expected to be drafted to prohibit physicians from making self-referrals for Medicare patients. State legislators had been adopting similar laws to cover patients on private insurance.

Doctors’ Offices Dispensing Medicine. Since the early 1900s, when licensed physicians gained the legal right to prescribe drugs, doctors’ offices and clinics had dispensed drugs in limited numbers to patients. Originally, this practice was not done for profit; during the 1980s and into the 1990s, however, drug dispensation began to increase rapidly. This increase was prompted by high profits and persuasive marketing by the pharmaceutical repackaging industry. Pharmaceutical repackagers purchase drugs in bulk and repackage them in small units, allowing doctors to maintain a stock of a large variety of drugs at their offices. In 1987 about 5 percent of doctors’ offices and clinics routinely dispensed these repackaged drugs; by 1993, nearly 50 percent of doctors’ offices and clinics were dispensing repackaged drugs.

The dispensing of drugs out of doctors’ offices and clinics caused friction between the medical doctors and the pharmaceutical industry. Moreover, this practice raised ethical issues within the medical community. Health care professionals disagreed as to whether doctors should engage in competition with pharmacists and whether doctors, who were generally not as well trained in medicines as pharmacists were, had the qualifications to routinely dispense drugs.

In 1988 the federal government tried to amend the Food, Drug, and Cosmetic Act to restrict doctors from

selling drugs out of their offices, with the exceptions of emergencies or cases in which patients would have difficulties getting to a pharmacist. The amendment did not pass, and the federal government has since prohibited states from passing similar laws that restrict doctors from dispensing drugs.

According to the National Center for Health Statistics, the number of people who used the services of doctors’ offices and clinics gradually increased throughout the 1980s, with the largest increases occurring in cities. This industry also benefited from the aging population, which was reflected in the growth in geriatric medicine and the offices of ophthalmologists—where technical innovations provided eye surgery for the elderly.

In the 1990s this industry faced challenges to its organizational structure and its means of making a profit. The economic needs of employers and the expected government reforms have changed the industry’s structure from individual practices to group care. The rising costs of health care also introduced new ways of pricing services provided by doctors. In addition to the new system adopted by Medicare, which attempted to establish salary parity between primary care doctors and specialists, private insurers and health provider networks imposed caps on the costs of doctors’ services. Government efforts at health care reform were also expected to reduce the time doctors’ offices spent in handling paperwork; according to the Lewin-VHI health consulting firm, 20 percent of health dollars spent in 1993 went to administrative costs.

Organizational changes also occurred in this industry as health care moved from inpatient to outpatient surgery. Ambulatory surgical centers, ophthalmology clinics, and gynecology clinics were the fastest growing of these outpatient centers, estimated at nearly 1,500 in 1991. The growth of managed care has promoted the trend toward practice consolidation and significantly reduced the number of self-employed, solo practice physicians.

This industry experienced a shortage of primary care physicians, particularly in rural areas. The more lucrative specialists’ salaries drove medical students away from primary care. Rural areas were even less desirable for primary care physicians because salaries were generally smaller than those offered in cities, and physicians preferred to live in metropolitan areas. From 1985 to 1994, the number of physicians in relation to the population increased 11 percent in nonmetropolitan areas compared to 16 percent in large metropolitan areas (populations over one million) and 19 percent in small metropolitan areas. Rural hospitals attempted to attract more primary care physicians by offering income guarantees for doctors who joined local practices, and state governments helped rural practices in recruiting new doctors.

CURRENT CONDITIONS

As in the entire health care industry, changing government regulations and funding made a deep impact on the manner in which office- and clinic-based physicians practice and conduct business. According to a 2002 study by the American Academy of Family Physicians, nearly 22 percent of family physicians surveyed said they no longer accept new Medicare patients, a 28-percent increase from a similar study done the previous year. The paperwork hassles combined with a decreasing pay schedule, which dropped 5.4 percent in 2002 and another 4.4 percent in 2003, mean that Medicare patients are too much work for too little return. Of those physicians who are not outright refusing Medicare patients, nearly 25 percent have placed limits on the number of Medicare patients they will retain on their books. According to doctors, reimbursements simply do not cover their overhead, making Medicare billing for many a money-losing endeavor.

In 2003, physicians were also working to keep ahead of the technology learning curve as computer-based programming and Internet-related technology began to transform the way doctors conducted their businesses. In the 1980s few physicians' offices had a computer, and all offices kept track of the paperwork associated with their patients and a handful of insurance companies in a manual filing system. Twenty years later, a doctor's office may have over a thousand insurance company claims on file, each with specific rules for filing and reimbursement. New programming and technology was expected to begin to allow for computerized patient records as well as online insurance claims. These anticipated changes should result better care as patients' files become more quickly accessible and updateable. Doctors should also benefit from cost-savings related to increased efficiency and quicker reimbursement. According to a *Modern Physician* survey conducted in 2000, over 63 percent of physicians surveyed said that they would be using computer-based medical records systems within three years, up from just 21 percent in 2000.

INDUSTRY LEADERS

Since many doctors were self-employed or in small group practices, this industry's leaders during the 1990s were companies that owned and managed large groups of doctors' offices and clinics. In 1996 there were 166 of these physician practice management companies, employing more than 40,800 medical and nonmedical personnel. Most of these companies were privately held, while a handful were publicly traded and a few others were subsidiaries of hospitals. As the decade ended, however, this segment of the industry found itself under increasing financial pressure, and a number of companies bailed out of the business. Originally set up to relieve

physicians of such nonmedical concerns as mushrooming paperwork, capitated payments, and the rise of managed care, the practice management companies began foundering because of ineffective cost controls.

When MedPartners, headquartered in Nashville, Tennessee, went public in 1995, it had 6,000 physicians under its banner. However, after posting continuing annual losses, culminating in a \$1.2 billion loss in 1998, MedPartners filed chapter 11 bankruptcy, reorganizing as Caremark, a pharmacy benefits company. In a similar vein, Phycor went public in 1992 with 3,800 physicians on its rolls. After reporting earnings of \$81 million in 1994, the company reported a net loss of \$444 million, and stock prices plummeted from a high of \$40 per share to \$0.10 per share. The company followed MedPartners into bankruptcy and reemerged in July 2002 as Aveta Health, which focuses on health care risk management. PhyAmerica Physician Group, another leader in the field, also ended up in bankruptcy court in 2001.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, doctors' offices and clinics employed a total 2,046,760 people in 2001. Of that total, 42 percent, or 856,350 people, were healthcare practitioners and technicians, including 66,700 family and general physicians; 42,420 surgeons; 41,370 general internists; 19,500 anesthesiologists; 18,200 general pediatricians; and 13,970 obstetricians and gynecologists. Registered nurses and licensed practical and vocational nurses accounted for 216,880 and 91,340 jobs, respectively. Radiologic technologists and technicians held 41,140 jobs, and medical records and health information technicians held 43,370 jobs. The median annual salary of a family practitioner in 2001 was \$123,070; general internist, \$130,880; obstetricians and gynecologists, \$137,230; anesthesiologists, \$138,120; and surgeons, \$139,020.

Healthcare support occupations totaled 285,640, or nearly 14 percent, of the industry's workforce. Of that total, medical assistants accounted for 202,810 jobs. Office and administrative support occupations accounted for 751,200 jobs in doctors' offices and clinics. Medical secretaries numbered 152,190, and receptionists and information clerks totaled 153,510. Other significant in-category positions include office managers and administrative support workers (65,620), billing and posting clerks (89,600), file clerks (35,570), and bookkeeping, accounting, and auditing clerks (29,750). The median annual salary for the healthcare support occupations in 2001 was \$25,580.

Registered nurses working in doctors' offices and clinics assist physicians by administering medications and treatments and by performing routine laboratory and office work. They receive their training through bachelor

and associate degree programs in nursing or through three-year diploma programs in hospitals. They must pass a licensing examination to obtain a nursing license. Nurses working in doctors' offices and clinics reported annual salaries of roughly \$47,560 in 2001. As of 2001, the entire healthcare industry continued to suffer from an overall lack of registered nurses.

Physician assistants support physicians and provide routine diagnostic, therapeutic, and preventive health care services under the supervision of a physician. Physician assistants take medical histories, examine patients, order and interpret laboratory tests and X-rays, make preliminary diagnoses, and treat minor injuries. Physician assistants must complete an accredited, formal education program. Most states require physician assistants to pass a certifying exam. In 2001 the 28,820 physician assistants working in doctors' offices and clinics earned a median annual salary of \$63,800.

Medical laboratory technologists work under the direction of a pathologist. There are three types of medical laboratory technologists with different levels of training: medical technologists, with four years of specialized training; medical laboratory technicians, with two years of training; and medical laboratory assistants, with one year of training. Of these three, only the medical technologist carries out supervisory and administrative duties. In 2001 the median salary for medical technologists was \$42,960, while medical laboratory technicians earned an average of \$29,520 annually.

Jobs for physicians and other positions in doctors' offices and clinics were generally expected to grow through the 2000s, along with the overall growth in the health care industry and the aging population. Government reforms, however, were expected to address the shortage of medical doctors in primary care by reducing the demand for and income of specialists. Moreover, due to cost controls enforced by HMOs and government programs, physicians' incomes began to level off at the end of the century, curtailing their considerable annual growth rate. Under government reforms, the need for medical support staff such as nurses and medical assistants was expected to increase, while the number of secretaries would be reduced as reforms reduced paperwork and doctors left their individual practices to join HMOs and other group practices.

AMERICA AND THE WORLD

American doctors and health care companies faced an expanding market for their services outside the United States—in places such as Western Europe, Mexico, and Japan—where aging populations grew. In addition, these countries began developing HMO services for non-state-run care.

In order for foreign doctors to practice medicine in the United States, they had to be licensed in the United States. Given that American doctors earned more than their foreign counterparts—in 1990, German doctors earned \$120,000 a year; Japanese doctors earned \$78,000; and British doctors earned \$65,000—practicing medicine in the United States was highly desirable for foreigners entering this profession. As a result, however, of an influential study by the U.S. Department of Health and Human Services, which predicted a large surplus of doctors by the end of the century, the U.S. government passed legislation in 1976 restricting foreign doctors from practicing in the United States. The laws prohibited foreign doctors who had completed their residency programs in the United States from practicing in the United States for two years after obtaining their degrees.

The laws restricting the practices of foreign doctors in the United States had a strong impact on Canadian doctors in particular. Prior to these laws, Canadian doctors could easily obtain five-year permits using their Canadian credentials. The 1976 laws required Canadian doctors to have a full-time resident's green card if they wanted to practice in the United States. The card was often difficult to acquire, though, and greatly reduced the number of Canadian doctors working in the country.

RESEARCH AND TECHNOLOGY

Upon entering the twenty-first century, new technology fueled the shift from inpatient hospital care to outpatient surgical clinics. Technologies, such as laser surgery, decreased the invasiveness of many medical procedures, allowing them to be performed in outpatient facilities. Technological advances also decreased complications related to the administering of anesthesia, which often required overnight hospitalization.

The trend away from prolonged hospitalization also gave rise to the development of in-home monitoring devices. These devices were used by patients who left hospitals for financial reasons but who also had conditions requiring observation, such as congestive heart failure. The monitoring devices electronically linked the patient's home and a doctor's office or health care agency.

Advances in information technology were slowly used in this industry, particularly by self-employed doctors but became important to the operation of these establishments by the 1990s. In order to reduce office paperwork and maintain more accurate patient records, doctors started using desktop systems for such routine functions as accessing patients' medical histories and insurance records and placing prescriptions with pharmacists.

Doctors also began using information technology to assist them in making diagnoses. Computers provided doctors with sorted information and success ratios on

treatments and procedures. This type of information was especially valuable to doctors who needed data on rare diseases and conditions. Researchers in this area were continuing to develop software able to handle the massive amounts of information required by doctors.

OFFICES AND CLINICS OF DENTISTS

This industry consists of offices and clinics of licensed practitioners of dentistry with the degree of D.M.D., D.D.S., or D.D.Sc. Included in this industry are the offices of dentists, dental surgeons, pediatric dentists, endodontists (root canal specialists), oral pathologists (specialists in mouth diseases), orthodontists (specialists in straightening the teeth), periodontists (gum specialists), and prosthodontists (artificial teeth and denture specialists).

NAICS CODE(S)

621210 (Offices of Dentists)

INDUSTRY SNAPSHOT

During much of the 1990s, the number of professionally active dentists was on the decline. By 2000, there were 154,459 professionally active dentists in the United States. Approximately 4,000 new dentists graduate in a typical year, whereas 6,000 retire. Throughout much of the 1980s, there was a perceived oversupply of dentists, which gave insurers the upper hand—providing patients for dentists in exchange for discounts. Due to the perceived decline in the number of dentists in the early 2000s, insurers had to compete for doctors with services and information they could provide. Approximately half of U.S. citizens had some form of dental coverage in 2001, steadily rising over the last two decades. Self-pay and private prepayment each accounted for about 47 percent of payments for dental care, with government-financed care making up 4 percent and other private funds accounting for 2 percent.

Total dental revenue in 2001 was approximately \$65.5 billion, up 8. percent from an estimated \$60 billion in 2000. Revenue also grew in 2000, up 7.7 percent from \$56.3 billion in 1999. Growth has been slightly less than the growth rate of the Gross Domestic Product (GDP). Dental costs were on the rise, climbing an estimated 6 percent in 2001, which was about two or three times higher than the growth in the consumer price index.

Employer funding of dental benefits is an area that is expected to experience major changes in the coming years. Medical costs will continue to rise, and health benefits will continue to compete with dental benefits for employer dollars. More employers will be expected to play a bigger role in cost sharing, and contribution programs will become more defined. These factors will affect dental services and the types of services provided. A growing number of patients are frustrated with increasing restrictions from their insurance companies, service limitations, larger co-payments, and annual caps on benefits. Some dentists are similarly frustrated with dealing with the bureaucracy and complicated paperwork of dental benefits companies and have been moving toward “insurance free” services. If this trend continues, dental insurance could be negatively affected.

ORGANIZATION AND STRUCTURE

The dental profession is divided into eight types of practices carried out at dental offices and clinics: general dentistry, oral and maxillofacial surgery, endodontics, orthodontics, pediatric dentistry, periodontics, oral pathology, and dental public health.

Prior to the 1980s, establishments in this industry that were owned by self-employed dentists were operated by the dentist and a small staff. During the 1980s, dentists began running their offices like small businesses, employing the outside services of managerial consultants

and dental office advisers. These organizational changes continued throughout the industry in the 1990s. With the health care industry moving toward managed care, dental maintenance organizations (DMOs) grew rapidly; at these organizations, participating dentists were paid fixed monthly rates. In 1989, only 10 percent of dentists worked with DMOs. By 1992, 15 percent of all dentists participated in these organizations, and analysts forecasted that 40 percent would be participating in such plans by the year 2000. Another reason that DMOs were seen as necessary was because the dental inflation rate had started to exceed the medical inflation rate in the mid-1990s. In 1995, approximately 18 percent of Americans were enrolled in a DMO. In fact, a total of 100 million people (including 52 percent of adults) were in a dental plan that covered part or all of their dental expenses.

BACKGROUND AND DEVELOPMENT

Modern dentistry began in the sixteenth century with the European revival of arts and sciences. According to dental historians, dentistry was being practiced independently from general medicine and surgery as early as 1544. Dentistry and medicine had been united for centuries because both sciences were practiced by barbers. The sixteenth century saw the important developments of dental instruments designed for cleaning and filling teeth.

In the seventeenth century, dentistry developed into an area of scientific inquiry in the way medicine had for many centuries. In Europe and America, academic and scientific articles began to appear on dentistry topics. During this time, the occupation of the barber-dentist evolved into that of tooth puller, while a separate practice of dental surgeons began to develop. The practices of periodontics and dental pathology began to develop during the eighteenth century.

Dentistry saw tremendous growth in the twentieth century. Preventive dentistry and public education on the importance of dental health and hygiene paid off for this industry. The number of patient visits rose significantly, especially for preventive measures. Moreover, elderly patients, unlike previous generations, did not lose their teeth and therefore went to dentists regularly.

Advances in fluoride treatments and dental technology have decreased the number of cavities Americans have. In 1990 Americans had 151 million fillings, only half the number of fillings in 1959, even though the population had doubled during that time. The number of root canals, however, tripled.

Income levels play a significant role in the number of times a person visits the dentist. In 1997, approximately 59 percent of people with household incomes between \$10,000 and \$19,999 indicated they had visited a dentist within the past 12 months, whereas 84.9 percent of

people with annual household incomes of \$55,000 or more said they had been to a dentist.

Technological Advances. The expansion of this industry during the twentieth century was also due to numerous technological advances. During the 1940s and 1950s, new methods of anesthetics greatly reduced pain during clinical procedures. The 1960s saw the development of bonding, whereby a liquid resin is applied to a tooth, then shaped as it hardens, providing a better fitting and more attractive cap, or crown.

In the late 1980s, orthodontists' offices increased as new types of braces and appliances were developed that were suitable for adults. Clear plastic braces and more cosmetically appealing appliances that fit inside the mouth were marketed toward adults undergoing orthodontic treatment. Similarly, dental surgeons provided services for an increasing number of adults wanting to have their jaws realigned for both medical and cosmetic reasons.

Perhaps the most significant technological development for modern dentistry has been the surgical laser, which came into common use at the end of the 1980s. In 1997 the International Academy of Laser Dentistry estimated that across the world 5,000 lasers were in use, often shared by several dentists.

The Nd:YAG laser has been the laser most commonly used by dentists. This laser is used for soft-tissue procedures to heal inflammation and reduce bleeding. Since 1987, Nd:YAG has been studied for its use in hard-tissue cutting procedures, such as working with enamel and metal for orthodontic dentistry. The CO₂ laser was the first to be approved by the Food and Drug Administration (FDA) and is the second most widely used laser in dentistry. It is employed for soft-tissue surgery, such as removing lesions and, like Nd:YAG, has been experimented with for hard-tissue applications. The third major type of laser is the argon laser, which has been used for soft-tissue procedures, such as curing tissue. All three lasers also have uses for sterilizing dental instruments and are expected to undergo further developments.

Other significant technological innovations for this industry have been in intra-oral television and T-Scan devices; both have been utilized to educate patients on the condition of their teeth and the work involved in various procedures. Intra-oral television, as its name indicates, shows patients an enlarged view of their teeth and gums on a television screen. T-Scan uses a computer screen to show patients the static and dynamic contacts on their teeth. Both of these types of visual aids have helped dentists explain procedures to their patients and make them feel more comfortable.

Dental Office Hazards. Working with nitrous oxide (commonly known as "laughing gas") has long been a

concern of dental office workers. In 1993 this gas was used by nearly 50 percent of all dentists in the United States, primarily by general dentists. Although the government recommends that dentists take in under 25 parts per million of this gas, most dentists get 250 times this amount, according to Elise Tanouye in the *Wall Street Journal*. Realizing possible health hazards, this industry has tried to lower the amounts that escape by using special types of masks, known as "scavenging systems," that are worn by the patient.

Although the risks of nitrous-oxide exposure are not fully known, the increase in the number of female dentists, dental assistants, and hygienists has drawn attention to reduced fertility among women working in dentists' offices and clinics. A 1992 study showed that women exposed to high levels of nitrous oxide were 60 percent less fertile than women who had not been exposed to the gas, according to Tanouye in the *Wall Street Journal*. The Dental Assistants Association suggested that nitrous oxide exposure could be linked to miscarriages, liver disease, and neurological problems. As the twentieth century drew to a close, the topic was still being hotly debated.

Another cause of concern in dental offices has arisen with the frequent use of lasers. Lasers can be harmful to both patient and staff if misdirected to the wrong tissue, especially toward the eyes. Given the risks, dentists have taken precautions, such as the use of eye protection and surgical masks specially developed for laser surgery.

Costs of Infection Control. In 1990 a Florida dentist who had AIDS had allegedly transmitted the HIV virus that leads to AIDS to at least three of his patients. Although it is not certain that the patients contracted the virus from their dentist, these cases received much public attention and national publicity. As a result of this, dentists' offices and associations received thousands of inquiries from concerned patients. Throughout the industry, dentists responded to these new concerns by investing in more infection-control measures. Moreover, the Occupational Safety and Health Administration has enforced additional regulations for the safety of dental office workers, who are believed to be at greater risk of getting AIDS from their patients than vice versa.

Infection control includes the use of more disposable items, disinfectants, sterilizers, and ultrasonic cleaners. According to a 1993 study by Clinical Research Associates, infection control cost an average of nine dollars per patient visit, adding more than \$30,000 annually to a dentist's overhead costs, according to Gordon J. and Rella P. Christensen in the *Journal of the American Dental Association*. These costs have been handed down to patients, with some dentists adding an extra fee to their bills and labeling it "infection control."

Dental Fraud. With an overall increase in dental benefits insurance plans starting in the 1980s, this industry was noted for significant amounts of billing fraud. Though exact numbers are not available, according to Nancy Coe Bailey in *Business and Health*, one large insurer reported 88 dental fraud cases in 1989, whereas another insurer was investigating claims of \$300,000 in billing fraud from one dental group alone.

There are basically three types of dental fraud: double-billing, where dentists charge both a patient's insurer and the insurer of the patient's spouse for the same procedure; billing for services not rendered; and manipulating billing codes by "unbundling" a procedure and billing it under several codes. Partially in response to the growing amount of billing fraud in the health care field in general, the Department of Health and Human Services enacted the Health Insurance Portability and Accountability Act of 1996. This act established a national bank to take reports of fraud and abuse and issue regular reports on the issue.

A related problem for this industry has been the concern that insurance companies have been "downcoding" dentists' bills. In downcoding, insurance companies price a procedure based on less complex and lower-cost procedures than that reported by the dentist. This is part of a larger problem facing dentists' offices and clinics, where insurance companies have started to play an important role.

Marketing. According to the American Dental Association (ADA), less than 1 percent of income from dentists' offices and clinics was spent on advertising in 1993. Traditionally, this industry has taken a nonaggressive approach to advertising because most patients go to a dentist who has been referred to them by other patients or to the dentist their parents sent them to as children. This industry has benefited, however, from indirect advertising. The ADA recognizes that public health programs, as well as toothpaste and mouthwash advertisements, promote preventive dentistry and indirectly advertise for dentists' offices and clinics.

In 1997 Americans spent almost \$51 billion on dental services from the nation's 150,090 professionally active dentists, more than 138,000 of whom worked in private practice in an independent office or through a group practice or clinic. Nearly 20 percent of all active dentists in the United States were specialists, with the two largest groups made up of orthodontists and oral surgeons. The total number of board-certified dentists in 1997 exceeded 150,090, but many of those not actively practicing were involved in dental education or research projects.

According to the 1997 Survey of Consumer Attitudes and Behaviors Regarding Dental Issues, conducted

by the American Dental Association (ADA), most American adults reported that they had visited a dentist within the past year. Nearly 60 percent of adult Americans reported that they had visited a dentist in the previous 6 months, while another 16 percent said they had seen a dentist between 6 and 11 months ago. For most Americans, the factor most influential in making a decision to visit a dentist was the elimination of pain, according to the ADA survey.

The industry has expanded to meet the needs of two growing sectors of the population: the aged and babies. Pediatric dentistry is one of the fastest-growing sectors of the industry. Additional growth has occurred as an increasing number of Americans have acquired dental insurance.

Throughout the 1990s, dentists' offices and clinics were faced with new challenges related to industry reforms and the rise of managed care. Dentists sought changes in managerial practices and human resources to bring down high overhead costs. With inflation rates for dental care exceeding those for medical care, DMOs were becoming more popular. Growth in DMOs, however, has been slow, with only about 25 percent of people enrolled in one by the end of the 1990s.

CURRENT CONDITIONS

Health in America is continually improving, with more people aware of the positive effects of hygiene, exercise, and a generally healthy lifestyle. Oral health has also been on the rise in recent times, with an increasing number of children and adolescents from 5 to 17 who have never experienced dental caries in their permanent teeth. Adults from 18 to 34 years also have fewer fillings and less decay than ever. There has been a dramatic decline in people who lose all their teeth. Oral cancer rates are also down. Due to these reasons, dental services continue to shift based on demand for services. Basic services, such as fillings, have slowed, whereas cosmetic dentistry has become an increasingly important trend, albeit one that is not covered by insurance companies. Americans spent about \$1.3 billion in 2000 on professional teeth-whitening procedures, with analysts predicting a 24 percent growth annually. Cosmetic procedures more than tripled between 1996 and 2000. This gave rise to BriteSmile Professional Teeth Whitening Centers in the early 2000s, a Walnut Creek, California-based company that offers one-hour professional tooth whitening via laser. The "dental spa" came about in the early 2000s, offering clients a retreat with traditional spa services, including facials, foot massage, and limo service, along with dental treatments. Traditional dentists even began to add spa treatments to their services to attract clients.

Another trend in the field was the significant rise in dental visits by uninsured people, although still far less than the percentage of people seeing a dentist with private insurance, according to an ADA news release. The percentage of people with private dental insurance who visited a dentist in 1999 was 75.2 percent, up 5 percent from 71.4 percent in 1989. Among those without dental insurance, the percentage rose to 58.1 percent in 1999, up 22 percent from 47.6 percent in 1987. In total, the percentage of Americans who reported a dental visit jumped to 64.1 percent in 1999, from 57.2 percent in 1989. The percentage of people with private dental insurance dropped, however, to 35.2 percent in 1999, from 40.5 percent in 1989.

In 2003, the ADA and two member dentists filed a class-action suit against some of the largest insurance companies in the United States. The ADA claimed those insurers—which included CIGNA Corporation; CIGNA Dental Health, Inc.; MetLife, Inc.; Mutual of Omaha Insurance Company; Metropolitan Life Insurance Company; and Connecticut General Life Insurance Company—violated the federal Racketeer Influenced and Corrupt Organization Act (RICO) and supported state law for insurance abuses against dentists contracted under the insurers' managed-care plans. Among the charges were that the insurers illegally paid their in-network dental providers less than their charges for provided dental services and with late payments in states with prompt-pay status; downcoding, or changing the procedure code to a less expensive code; and bundling, or combining codes of two or more performed procedures into one billed procedure.

INDUSTRY LEADERS

By the close of the 1990s, the industry boasted more than 109,000 dental offices and clinics. A 1996 report by *Inc.* magazine listed dental offices as the third-highest category of start-up businesses that were likely to survive. The industry leaders were companies that owned several dental clinics and/or group offices. In the late 1990s, the industry leader was SafeGuard Health Enterprises, Inc., a publicly held company headquartered in Anaheim, California. In 1999 the company provided dental services to well over 1 million employees in both the private and public sectors, as well as multiple-employer trusts. SafeGuard offered dental care through a force of about 16,000 dentists practicing in some 14,000 independent offices. The states in which SafeGuard did the most business included California, Florida, Texas, Missouri, and Colorado. In 1998 the company posted revenues of \$97.4 million, a 2 percent increase over its sales in 1997.

WORKFORCE

In 2000, there were approximately 154,459 professionally active dentists. The average annual salary for

dentists in 2000 was \$129,000. Almost all dentists work in private practice, with about 80 percent of dentists in private practice sole proprietorships and 13 percent belonging to partnerships. Additionally, the industry in the 2000s employed about 247,000 dental assistants. Companies operating large dental offices and clinics employ additional office personnel, including insurance claims specialists and managers.

Although dental assistants may begin their career without a college degree, dentists increasingly are looking for assistants with at least some college education. Most dental assistants are employed by dentists in general practice, although dental specialists, including endodontists and periodontists, employ assistants as well. The average hourly wage for dental assistants was \$12.49 in 2000. The employment outlook for dental assistants was bright in the early 2000s and beyond. Employment was expected grow significantly faster than the average for all occupations through 2010.

Even though the need for dental health was expected to grow substantially in the twenty-first century, most of the increase in the workforce is expected to come from dental hygienists and assistants. The number of dentists in the field was expected to grow more slowly than the average of all occupations through 2010.

AMERICA AND THE WORLD

According to the American Dental Association, this industry is not characterized by its international market. Although foreign dentists come to the United States to study procedures related to the latest technology, American dentists tend to practice and perform research in the United States.

As information technology grew in the late 1990s and early 2000s, however, health care and dental health became an increasingly global concern. New scientific findings could be researched over the Internet while microbes could be transported worldwide in a short amount of time.

RESEARCH AND TECHNOLOGY

In the realm of dental health, periodontal (gum) disease remained the biggest concern among dentists in 1998, according to the American Dental Association (ADA)/Colgate Oral Health Trend Survey. More than half of the dentists surveyed reported that periodontal disease was the one area of dental health about which their patients seemed inadequately concerned. Nearly three-quarters of the dentists surveyed reported they planned to step up educational efforts about the dangers of periodontal disease, particularly in view of the recently discovered links between gum disease and heart problems. According to Dr. Timothy Rose, president of the ADA, "it's possible to have periodontal disease and not

recognize the warning signs. That is why regular dental check-ups and periodontal examinations are important."

According to Howard Glazer, president of the Academy of General Dentistry and associate clinical professor at the Albert Einstein College of Dentistry, new techniques being considered in the dental industry included "digitized x-rays, laser techniques for painless drilling, osseo-integrated implants to replace bridges and other nonpermanent artificial teeth, and synthetic tooth enamel."

Other advances in research were predicted in the development of new procedures and materials, such as techniques used to perform tooth implants and substances used for bonding and repairing teeth.

Scientific and technological advances were growing rapidly in the early 2000s, a trend expected to continue in the coming decade and beyond. As social, biological, and physical sciences begin to merge and evolve, a greater understanding of human health is emerging. The mapping of the human genome was a large step toward understanding the organisms associated with dental conditions, including oral candidiasis, dental caries, and periodontal disease. Genetic engineering has produced new and altered animals and foods with applications that could make new tissues, organs, and drugs. Of course, new ethical, legal, and social issues have arisen due to these advancements. Dental tools continue to advance via miniaturization and nanotechnology. Optical laser systems and computer-assisted informatics are in the forefront of new technological applications. In addition, information technology has also revolutionized this industry, via information dissemination through the Internet to both medical professionals and consumers alike.

SIC 8031

OFFICES AND CLINICS OF DOCTORS OF OSTEOPATHY

This industry consists of offices and clinics of licensed doctors of osteopathic medicine (D.O.) and engaged in the practice of general or specialized osteopathic medicine and surgery. Establishments operating as clinics of osteopathic physicians are included in this industry. Like medical doctors, doctors of osteopathic medicine are complete physicians with at least four years of medical school training; however, they differ from medical doctors by focusing on structural derangement, especially that of the spinal cord, as the chief cause of disease.

NAICS CODE(S)

621111 (Offices of Physicians (except Mental Health Specialists))

621112 (Offices of Physicians, Mental Health Specialists)

According to the American Osteopathic Association (AOA), in 1998 there were 44,000 doctors of osteopathy (DOs) in the United States, making up about 5.5 percent of all physicians in the United States. Of these doctors, nearly 60 percent practice in the primary care fields. Although DOs represent less than 6 percent of all physicians, they account for 15 percent of all physicians practicing in rural areas with populations of 2,500 or less. Their fields of specialty include surgery, obstetrics and gynecology, pediatrics, psychiatry and neurology, and internal medicine.

This branch of medicine has grown considerably since 1970, when there were just over 14,300 DOs practicing in the United States. Ten years later, that number had jumped to 18,800, and by 1990, the number of osteopathic doctors practicing had climbed to 30,000, with only 2 percent of those DOs working in hospitals and another 2 percent teaching. By 1998, the total number of DOs had grown to 44,000 and is expected to top 45,000 by the turn of the twenty-first century. The AOA estimates that DOs receive some 100 million patient visits annually. The greatest demand in the future for DOs will be in rural and suburban areas. Employment is expected to grow faster than average, with the best prospects being

in primary care fields such as family practice, geriatrics, and preventive care specialist.

While exact figures on the revenues in osteopathy as a whole are not available, doctors of osteopathic medicine in private or group practice earned annual salaries of roughly \$85,000 to \$150,000 in the late 1990s, depending on whether they were general practitioners or specialists. Beginning osteopathic physicians who practice in Veterans Hospitals earn an average of \$47,500 a year.

There has been a sharp jump in the number of students pursuing studies in osteopathic medicine, according to the AOA: enrollment increased nearly 41 percent between 1990 and 1998. The National Center for Health Statistics projected that the 19 U.S. colleges of osteopathic medicine would graduate nearly 2,000 DOs in the year 2000. The 1980s and 1990s have also seen a sharp jump in the number of minority and female students enrolling in programs of osteopathic study. Between 1980 and 1996, minority students and female students in osteopathic programs increased 15 percent and 17 percent, respectively.

In 1996, there were more than 500 approved osteopathic sites, offering more than 3,800 residency programs. There were also more than 200 osteopathic health care systems in the United States, and that number was expected to grow.

In 1995, three out of four DOs practiced in twelve states, each state being one with osteopathic schools and hospitals. Michigan had the greatest number of DOs, followed by Pennsylvania, Ohio, Florida, New Jersey, and Texas.

Overseas, American doctors of osteopathic medicine have operated clinics and trained staff, but typically have not set up private practices for themselves, as salaries are not as high as those in the United States. The United States is the only country in the world that has osteopathic medicine integrated with a physician's degree. In other countries, practitioners generally earn certification after one to two years of schooling and hold less prestige than their American counterparts.

In 1998, about 60 percent of all DOs were involved in primary care, providing about 9 percent of all primary care available in the United States; primary care physicians, including both family and general practitioners, are the first to see a patient. More importantly for this branch of medicine, DOs' services account for 15 percent of primary care in rural areas, where primary care physicians have been in increasing demand since the 1980s, when more and more physicians (MDs and DOs) either went into specialized medicine or preferred to work in the cities. Given this expanding niche in the health care market, doctors of osteopathic medicine are expected to

become more recognized and earn higher revenues in the future.

SIC 8041

OFFICES AND CLINICS OF CHIROPRACTORS

This category includes establishments of licensed practitioners having the degree of doctor of chiropractic and engaged in the practice of chiropractic medicine. Operations serving as clinics of chiropractors are also covered in this industry.

NAICS CODE(S)

621310 (Offices of Chiropractors)

INDUSTRY SNAPSHOT

The central element of chiropractic is the practitioner's belief that the nervous system holds the key to maintenance of a healthy balance in the body. Practitioners believe that their manipulations of the spine can prevent disease and promote well-being. Doctors of chiropractic (DCs) believe that a patient's susceptibility to disease increases when homeostasis, or a healthy balance, in the body is disrupted by the misalignment of vertebrae. Chiropractors use gentle manual pressure to correct such misalignments, or subluxations. Chiropractors also use muscle massage and ultrasound stimulation of deep tissue.

Although doctors of medicine, as represented by the American Medical Association (AMA), long have suggested that chiropractic is something that falls far short of medicine, in recent years, antichiropractic rhetoric from the AMA has diminished significantly. Indeed, some medical doctors today grudgingly acknowledge that there definitely is a place for chiropractic, particularly in the

treatment of chronic back and neck pain and headaches. For their part, most chiropractors unhesitatingly refer certain patients to medical doctors if they feel the latter are best equipped to deal with those patients' ailments.

According to the U.S. Bureau of Labor Statistics' *Occupational Outlook Handbook 2002-2003*, there were approximately 50,000 active chiropractic licenses in the United States in 2000. Some of the DCs not currently in active practice on their own may teach, conduct research for chiropractic colleges, or work in hospitals. Chiropractors may be self-employed or salaried, with those self-employed usually earning more. According to the American Chiropractic Association (ACA), the average income in 2000 for all chiropractors, including self-employed, was about \$81,500 after expenses. Median annual earnings of salaried chiropractors were \$67,030 in 2000. A chiropractor's income may be influenced by a number of factors, including experience, characteristics, qualifications, and geographic location.

Based on a poll conducted by the Gallup organization in the early 1990s, the ACA estimates that about 10 percent of the adult American population visits a chiropractor every year. Assuming that this figure has remained relatively static, that would mean that 27 to 28 million Americans use chiropractic services each year.

ORGANIZATION AND STRUCTURE

Chiropractors must have a license to practice and can practice only in the states where they have licenses. According to the *Occupational Outlook Handbook*, all states recognize chiropractors trained by colleges accredited by the Council on Chiropractic Education. The majority of state licensing boards require at least two years of undergraduate college education, followed by the four-year training course at a chiropractic college, while others require a bachelor's degree.

Most states accept part or all of the National Board of Chiropractic Examiners' three-part test. Some states ask chiropractors to take an additional basic science proficiency exam. Those who complete a chiropractic education are awarded a doctor of chiropractic degree. Almost all states require chiropractors to complete a specific number of hours of continuing education every year to keep their licenses current. Some chiropractic associations provide courses to obtain specialty certification, called "diplomate" certification. Areas of specialty include: orthopedics, sports injuries, nutrition, radiology, thermography, neurology, internal disorders, and occupational and industrial health.

About 70 percent of licensed chiropractors open solo private practices. Some join established practices on a salary basis to earn enough money to open their own clinics. Although many chiropractors are self-employed, most work about a 40-hour work week and vary sched-

ules to accommodate patients' needs. Chiropractors on average employ about three office staff, and their salaries constitute a practitioner's largest operating expense. The geographical location ratios of chiropractors are imbalanced, because many open their practices near chiropractic colleges.

Financial Structure. Average gross revenue for chiropractors totaled about \$230,000 in 1999, down about 2 percent from 1990. Chiropractors had about 132 patient visits per week in 1999, up from 128 per week in 1990, and received 40 percent of their payments from private insurance; 29 percent from cash; 15 percent from worker's compensation (the lowest level since 1987); 8 percent from Medicare; 7 percent from personal injury, auto, no-fault insurance; and 1 percent from Medicaid.

BACKGROUND AND DEVELOPMENT

The chiropractic method was first developed in America in 1895 by Daniel David Palmer, a teacher, spiritualist, and magnetic healer from Davenport, Iowa. Magnetic healing was based on a theory by Austrian physician Anton Mesmer. Mesmer believed that the body had magnetic poles that facilitated a natural flow of fluid. Any obstacle that interrupted this flow resulted in sickness. Healing could thus be obtained by massaging the body's poles to restore this natural flow.

In search of an alternative to traditional medicine, Palmer made his first discovery by manipulating the spine of Harvey Lillard, a deaf janitor who worked in his Davenport office building. Palmer had learned that Lillard had become deaf upon wrenching his back. An examination later demonstrated that Lillard's vertebra had moved. By "racking his spine into position" Palmer was able to eventually restore Lillard's hearing. It was from this "first adjustment" in 1895 that the field of chiropractic medicine was born.

Palmer, however, was soon dismissed as a heretic and a charlatan for his belief in healing through magnetism and spinal manipulation. According to J. Stuart Moore in *Chiropractic in America*, "Palmer was determined that his new brainchild, chiropractic, would acquire the scientific respectability that his earlier career in spiritualism and magnetic healing had lacked."

Palmer based chiropractic on the theory that a misaligned spine (subluxation) caused illness. By readjusting the spine and thus restoring full nervous system function, all illness could be prevented and or cured. By 1897, Palmer had founded the Palmer Infirmary and Chiropractic Institute (the Palmer School of Chiropractic) in Davenport. Palmer in 1910 became affiliated with the Pacific College of Chiropractic in Portland, Oregon. It was there that he wrote the textbook and primer for beginning chiropractors, *The Chiropractor's Adjuster: A Textbook*

of the Science, Art, and Philosophy of Chiropractic for Students and Practitioners. His son, Bartlett Joshua (B.J.), became a practitioner. B.J. Palmer founded the first chiropractic association and helped establish chiropractic colleges nationwide. Early practitioners of chiropractic were defiant in the face of skepticism from the established medical community.

Theories of chiropractors often put them in direct conflict with medical doctors. The practice of chiropractic was often entwined in mysticism and unorthodox religious beliefs during the profession's early development. Some chiropractors were even jailed for practicing 'medicine' without a license.

Other practitioners would eventually refine spinal adjustments and use X-rays to make better diagnoses. But the development of the industry was often clouded. Chiropractors of the latter twentieth century come from a wide range of beliefs and theories, and many do not base their practices on a single chiropractic doctrine. For example, chiropractors who use chiropractic with other theories such as iridology, hair analysis, and colonic irrigation are termed "mixers" and are represented by the ACA. "Straights," represented by the International Chiropractic Association, base their practices solely on correcting subluxation in the tradition of Palmer. Then there are chiropractors who believe in manipulating a certain area of vertebrae (National Upper Cervical Chiropractic Association) instead of merely readjusting the spine at the site of pain.

By the mid-1990s, chiropractors followed a standard routine to diagnose and determine the treatment necessary. The data includes: the patient's medical history; results of physical, neurological, and orthopedic exams; posture and spine analysis; and sometimes X-rays and other laboratory tests. Chiropractic treatment had expanded so much that some practitioners specialized in select areas, such as sports injuries, neurology, orthopedics, nutrition, internal disorders, and diagnostic imaging.

Chiropractors of any kind, however, encountered fierce resistance to the profession in America throughout the mid-1990s. While chiropractic enjoyed increased recognition in many regions of the world at this time, the AMA was adamant in its opposition to the practice. Nonetheless, chiropractic care was included under Medicare coverage in 1973, and in 1974 Mississippi became the last state to establish a review board for licensing chiropractors.

Growth of Chiropractic. Current statistical surveys, including a Gallup poll commissioned by the ACA, indicate that roughly 10 percent of adult Americans visit chiropractors annually. The profession is gaining in popularity. With just 30 percent of back care patients using chiropractic treatment, the potential for growth is enor-

mous. Chiropractors in the 1990s are the third largest medical profession behind dentists and medical doctors. Although chiropractors cannot administer or prescribe drugs or perform surgery, they may counsel patients about nutrition, exercise, and stress management.

One avenue that the chiropractic profession has pursued to secure acceptance in the medical community has been the legal system. In 1976 a lawsuit was filed by four chiropractors against the AMA for antitrust violations. The chiropractors in *Wilk v AMA* alleged that the AMA and other health providers conspired to put them out of business. The AMA said it was trying to protect patients from methods it saw as “unscientific and deleterious,” reported the *University of California Wellness Letter*. In the 1960s, the AMA had told its members that it was unethical to associate with chiropractors.

The AMA dropped its ethical ban in 1980 after modifying it years earlier. In 1981, charges were dismissed against all defendants, but the federal appellate court ordered a new trial. In 1987 the Federal Court of Appeals ruled in favor of the chiropractors by issuing a permanent injunction against the AMA, the American College of Surgeons, and the American College of Radiology that prevented them from denying chiropractors entry to labs and hospitals and access to insurance reimbursement. The court dismissed charges against several other defendants.

Another lawsuit ensued in December of 1993, when three New York chiropractors again sued the AMA, along with state and county medical societies, four national insurance trade groups, and a dozen insurers and managed care plans. In this suit, the plaintiffs claimed that “physicians and insurers have conspired to keep them from taking part in New York managed care panels,” and that many of the defendant plans do not cover chiropractic services, according to *American Medical News*. The AMA intended to file a request to have the case dismissed for lack of merit in 1994. According to a study in 1995, nearly half of all HMOs covered chiropractic treatments. In June of 1995, the AMA and two other medical societies were dismissed as defendants in the case, but the plaintiffs continued the suit against the remaining defendants.

In a report from *The Back Letter* in 1995, many hospitals began giving clinical privileges to chiropractors across the country. Hospitals recognized chiropractic treatment as more cost-effective than surgery in some cases, and the chiropractors would provide another source of revenue. The number of chiropractors reporting to chiropractic departments in hospitals doubled from 1993 to 1995, according to the ACA.

Recent studies have suggested that chiropractic care may even be more effective for back and neck pain than

regular medical care. Treating back pain is estimated to cost from \$8 billion to \$24 billion annually in the United States. A report by the RAND Corporation found that chiropractic care is “effective in treating acute back pain when no serious neurological symptoms are present,” and that patients with low-back pain did better with chiropractic treatment, often at less cost than medical treatment. The *British Medical Journal* found that “spinal manipulation was more effective for relieving low-back aches for up to three years after diagnosis.” However, those with nerve disorders, sciatica, and chronic low back pain did not benefit as much from chiropractic treatment.

Industry Reform and Renewal. According to Robin Kamen in *Crain's New York Business*, chiropractors are increasingly turning to modern marketing techniques to maintain their businesses, using advertising and sales promotional literature to educate the public about the benefits of chiropractic.

A renewed interest in alternative medicine has contributed to an increasing public interest in chiropractic theory. Slowly, medical doctors are discovering they can benefit from referring their patients to chiropractors because they request “natural treatment” and noninvasive techniques. Chiropractors, in turn, refer patients who need medical treatment they cannot provide.

However, chiropractors nationwide are finding that they are losing patients because their insurance or worker's compensation either restricts visits to chiropractors or does not cover chiropractic at all. Medicare does cover some services but is limited. Trade and state chiropractic associations in Oregon, New York, and Colorado have conducted extensive lobbying efforts to garner more extensive insurance benefits for chiropractic patients, although without much success. For example, New York lawmakers in 1993 approved a bill requiring unlimited insurance coverage for chiropractic clients but withdrew the legislation after Governor Mario Cuomo threatened to veto it.

Efforts also are underway to provide cost-containment strategies to reduce chiropractic costs, as reported in *Risk Management*. Excessive treatment, at times because of criminal motives, has been cited as a key factor in the price of chiropractic care. *Risk Management* magazine cited a study by National Medical Audit, Inc., where a four-part chiropractic review program was used and helped reduce chiropractic costs by 25 percent. The ACA in 1992 issued guidelines to set parameters on the frequency and duration of care and “more appropriate and realistic reimbursement systems,” reported *National Underwriter Life & Health*.

Chiropractors won an important victory in November 1999 when President Bill Clinton signed into law legislation that makes chiropractic care more accessible to U.S. veterans. The Veterans Millennium Health Care

Act (H.R. 2116) requires the Veterans Administration to develop a policy covering the use of chiropractic treatment within the Veteran Administration's (VA) health care system. Successfully lobbying for the chiropractic provision were the ACA and the Association of Chiropractic Colleges. The legislation gave the VA 120 days to develop a chiropractic care policy.

CURRENT CONDITIONS

The complementary and alternative medicine market grew 12 percent in 2001, reaching \$30 billion. Chiropractic medicine accounted for half of that total, or \$15 billion. According to the National Market Measures for Landmark Health, two-thirds of HMOs (67 percent) offered at least one type of alternative care to their members by 2000. Chiropractic care was the most common type of alternative care. More and more HMOs were also allowing members to choose a chiropractic doctor as their primary care physician.

In 2000, the ACA, along with other national and state chiropractic groups, doctors, and patients filed a lawsuit against Blue Cross/Blue Shield Association and Trigon Healthcare Inc. The suits alleged that Trigon, the Blue Cross/Blue Shield insurer in Virginia, put unreasonable caps on spinal manipulation and paid chiropractors less than physicians for the same services. They alleged discriminatory practices were aimed at steering patients away from chiropractors to medical physicians.

The chiropractic field is expected to grow faster than the average for all occupations through 2010. The field has become more accepted in the United States, and more Americans are turning to alternative health care to avoid drugs or costly surgery.

WORKFORCE

The job outlook appeared very favorable for chiropractors in the late 1990s. The number of chiropractic graduates increased "fourfold since the early 1970s," according to *U.S. Occupational Outlook Handbook*. In 2000, there were approximately 50,000 chiropractors practicing in the United States, according to the ACA. Employment growth will depend on the need to replace retired chiropractors, the continued popularity of the practice, and the ability of patients to pay for services under health insurance plans. In addition, as the population of elderly people increases, so will the need for treatment of mechanical and structural difficulties. The growth of chiropractors is expected to accelerate faster than the average for all occupations through 2010.

SIC 8042

OFFICES AND CLINICS OF OPTOMETRISTS

This category covers establishments of licensed practitioners having the degree of O.D. (Doctor of Optometry) and engaged in the practice of optometry. Establishments operating as clinics of optometrists also are included in this industry.

NAICS CODE(S)

621320 (Offices of Optometrists)

INDUSTRY SNAPSHOT

According to the Association of Schools and Colleges of Optometry (ASCO), there were nearly 30,000 full-time equivalent practicing doctors of optometry in the United States during the late 1990s. These optometrists served in 7,084 communities across the country and in more than 4,300 of those communities were the only primary eye-care providers. Doctors of optometry examine, diagnose, and treat a variety of diseases and disorders of the vision system, the eye, and associated structures. Services rendered by optometrists include the prescription of glasses and contact lenses, rehabilitation of the visually impaired, and the diagnosis and treatment of ocular disease. According to ASCO data, the mean net income for optometrists in the late 1990s was \$88,690.

Figures supplied by the American Optometric Association indicated that approximately \$17.5 billion was spent in 1995 on vision care and prescription eyewear. That figure did not include costs for eye surgery or treatment for eye injuries and disease. ASCO statistics showed that in 1995 some 86 million Americans had their eyes examined and more than half of all Americans wore either glasses or contact lenses.

ORGANIZATION AND STRUCTURE

Sixty-eight percent of optometrists worked out of their own clinics or offices and were self-employed. They, unlike ophthalmologists, are not medical doctors. Optometrists examine the eyes to evaluate eye health and visual acuity and to diagnose eye diseases and eye conditions. Optometrists are not qualified to perform eye surgery, but they can prescribe corrective treatment: glasses, contact lenses, vision therapy, and low-vision aids. As of June 1996, 48 states had passed legislation that authorized optometrists to use drugs to treat diseases of the eye, allowing them to compete with ophthalmologists who have traditionally performed this service. Industry experts predicted that all doctors of optometry (ODs) would soon be given this right. Optometrists are also lobbying for the right to perform photorefractive keratectomies. Most states require that a licensed doctor perform the surgery, but Idaho allows optometrists to do the procedure.

Some optometrists held more than one job or worked out of more than one office or clinic. Commercial vision-care centers serve as another option for optometrists establishing their practices. According to the *Occupational Outlook Handbook*, optometrists were increasingly buying franchises from large retail optical chains and operating them as independent businesses. Younger optometrists also tended to join partners or form group practices. The *Handbook* noted that working optometrists also earned salaries as employees of health maintenance organizations (HMOs), health centers and eye clinics, public and private health agencies, insurance companies, or schools of optometry. The majority of optometric practitioners worked full time.

Like others in the health care profession, some optometrists worked in a general practice, while others chose to specialize. Some areas of specialty in the field of optometry include geriatrics, contact lenses, low-vision services, occupational vision, pediatrics, sports vision, and vision therapy. Still other doctors of optometry chose to devote their careers to teaching or scientific research.

All 50 states and the District of Columbia require optometrists to be licensed upon obtaining a doctor of optometry degree from an accredited school or college. Doctors of Optometry must either pass a state board examination or the National Board of Examiners in Optometry exam. There is some reciprocity between states concerning licenses; 46 states, however, require that optometrists complete a specified number of continuing education hours to renew their licenses.

Training consists of a four-year undergraduate degree and two-to-three years of pre-optometric study at an accredited school. As of the late 1990s, there were 17 colleges of optometry in the United States and Puerto Rico accredited by the Council on Optometric Education

of the American Optometric Association. Those applying to an optometric program must take the Optometry Admission Test, which measures academic ability and scientific comprehension. Competition to gain admittance to these schools is fierce.

Optometrists wishing to teach or do research may study for master's or Ph.D. degrees in visual science, physiological optics, neurophysiology, public health, health administration, health information and communication, or health education. One-year postgraduate clinical residency programs are available for optometrists who wish to specialize in family practice optometry, pediatric optometry, geriatric optometry, vision therapy, contact lenses, hospital based optometry, primary care optometry, or ocular disease.

BACKGROUND AND DEVELOPMENT

The practice of optometry began with the invention and subsequent refinement of eyeglasses in the early nineteenth century. Optometry guilds were formed at this time, and the practice eventually was regulated under statutory law. Jewelers were actually some of the first professionals to use eye charts and sell glasses to the public.

The industry in the United States expanded during the Civil War when the government purchased large quantities of binoculars and microscopes for the war effort. Eyeglasses became plentiful and, by the end of the nineteenth century, schools were teaching the science of optics, often in combination with instruction in watch repair.

Door-to-door peddlers, jewelers, and optometrists all sold eyeglasses in the late 1800s. At the beginning of the twentieth century, however, physicians conducted most of the eye examinations. "Refracting opticians," who provided the same service, later became known as the present-day optometrists. In some fairly fundamental ways, optometry practices have operated the same way for decades. That is, clients still visit optometry offices to secure eyeglass prescriptions, which are sent to an optical laboratory. The lab makes the glasses according to specifications and sends the frames to the officiating optometrist, who subsequently fits them to the client.

In the late 1960s, however, mass marketing of optical products and services changed some optometry practices. Vision-care chain stores emerged, but many states prohibited doctors from working in them. Some chain stores such as Sears and Kmart circumvented these restrictions by leasing space to optometrists, who worked independently but were able to lease space at below market rates. Doctors often profited from discounted rent and equipment. This partnership enabled chain stores to advertise that they provided full-service vision care at their facilities.

Competitive Structure. The advent of vision-care chain stores contributed to a loss of market share for private doctors of optometry. Private practitioners sell their businesses on the quality care and services they provide and emphasize personal service and attention. Often this is communicated by word of mouth and not through the aggressive marketing techniques that chain stores use. According to the *Journal of Commercial Lending*, "Repeated surveys have also shown that people feel they get a 'better' examination from a private OD compared with one received in a 'commercial environment.'"

The *Journal* also cited a study conducted by Robert R. Nathan Associates, Inc., a Washington, D.C.-area private economics consulting firm that found that "vision problems other than routine nearsightedness were detected almost twice as frequently by noncommercial ODs than commercial ODs." Optometrists in the study also spent an average of 30 minutes per exam compared to their commercial counterparts, who spent an average of 15 minutes in examining a patient.

Vision-care chain stores have resorted to coupons and other special deals to attract customers. Some also promoted their quick turnaround time in filling eyeglass and contact lens prescriptions. Private practitioners also began to reduce the waiting time for glasses and contacts, in an effort to remain competitive. They also expanded their private practices to include lab services, which enabled them to fill prescriptions in a shorter time.

Financial Structure. Overhead costs for maintaining an optometric practice increased since the mid 1980s. According to the "State of the Profession 1996" in *Optometric Economics*, the ratio of net income to gross income declined. Expenses for staff totaled 14.7 percent of gross income, while total laboratory expenses made up 28.9 percent. Other costs included rent and utilities (6.6 percent), contributions to retirement plans (1.7 percent), and miscellaneous office expenses (15.9 percent). The average net percentage for a practitioner was only 32.2 percent of the gross income. As a whole, expenses took a higher percentage (77 percent) of gross revenues of optometrists practicing in the eastern region of the United States; expenses were lowest in the South (63 percent).

INDUSTRY LEADERS

The leading U.S. vision-care services chains as of the late 1990s were Cole National; LensCrafters, a wholly owned subsidiary of Italy's Luxottica; and Vista Eyecare. Cole operated some 2,800 retail locations under the brand names of Pearle Vision, Sears Optical, Target Optical, and B.J.'s Optical. With 13,100 employees, Cole National reported revenue of nearly \$1.1 billion in 1998. LensCrafters, as of March 31, 1999, operated 853 retail outlets throughout the United States and Canada. Lens-

Crafters' 1998 revenue was estimated at \$1.1 billion. Vista Eyecare, headquartered in Lawrenceville, Georgia, was a relative newcomer to the field, but it moved quickly to establish a foothold in the market. As of late 1999, it operated some 300 retail outlets under the Vista Optical trade name as well as 600 leased vision-care centers inside Wal-Mart and other major retail stores. Vista's 1998 revenue topped \$245 million.

WORKFORCE

Optometrists earned an average of about \$27,000 in their first full year of practice in 1984. By the mid 1990s, the mean net income for optometrists had risen to almost \$89,000. Optometrists who were self-employed earned an average of \$95,707 in 1994. That same year female ODs reported a median net income of \$59,500, while male ODs reported \$83,500. This discrepancy was partly due to the length of time in the field, but even accounting for that, females, in general, earned 16 percent less than males. The *Occupational Outlook Handbook*, however, noted that salaries were also dependent upon specialization and location of the practice.

Increasingly, more optometrists joined HMOs and managed-care organizations. In 1996, more than two-thirds of optometrists were providers for some managed-care program. Medicare, too, began to cover examinations, treatment of eye diseases, and postoperative eye care services provided by optometrists to cataract surgery patients.

The American Optometric Association (AOA) was the largest trade association in the industry, representing more than 32,000 optometrists, students of optometry, and optometric technicians in the United States. Founded in 1898, the association aimed to make available and improve the quality of eye and vision care for all. The group focused on helping their members achieve the highest standards of efficiency and patient care. It also represented the industry to government and other health care organizations.

Future Expectations. As the AOA pointed out, 54 percent (145 million people) of all Americans needed prescription eyewear. Employment of optometrists was expected to grow about as fast as the average for all occupations through the year 2005 in response to the vision-care needs of a growing and aging population. By the year 2000, estimates suggested that there would be 32,000 optometrists in the United States (2,000 more than in 1998). The maturing of the baby-boom generation, together with rapid growth in the oldest age group would drive this growth. As baby boomers reached the age of 45 they would be more likely to visit optometrists and ophthalmologists because of the onset of vision problems in middle age. The demand for optometric services would also increase because of growth in the oldest age group,

with their increased likelihood of cataracts, glaucoma, diabetes, and hypertension. Employment of optometrists would also grow due to greater recognition of the importance of vision care, rising personal incomes, and growth in employee vision-care plans.

Employment of optometrists would grow more rapidly were it not for anticipated productivity gains that will allow each optometrist to see more patients. These gains would result from greater use of optometric assistants and other support personnel, and the introduction of new equipment and procedures.

Replacement needs were low. In this occupation, replacement needs arose almost entirely from retirements. Optometrists generally remained in practice until they retired; few transferred to other occupations.

SIC 8043

OFFICES AND CLINICS OF PODIATRISTS

This category pertains to establishments of licensed practitioners having the degree of D.P. (Doctor of Podiatry) and engaged in the practice of podiatry. Establishments operating as clinics of podiatrists are included in this industry.

NAICS CODE(S)

621391 (Offices of Podiatrists)

The podiatry industry is gaining increasing public recognition as a health profession. Podiatrists work at

private or group practices, health maintenance organizations (HMOs), hospitals, public health services and departments, and podiatric schools of medicine. The majority of podiatrists work in their own private practices and set their hours of business accordingly.

Approximately 14,000 podiatrists practiced in the United States in 1997, up from 11,000 in 1996. These doctors averaged a 42.5-hour workweek, primarily occupied with patient visitation. Their income ranged from \$56,000 for most inexperienced, to \$138,000 for experienced doctors with over 30 years of practice. While the majority of podiatrists work in major metropolitan areas, they are not evenly distributed geographically. Since the 1970s, the northeastern United States has been the site of the highest concentration of podiatrists. Many podiatrists set up practices near the seven colleges of podiatric medicine — in California, Florida, Illinois, Iowa, New York, Pennsylvania, and Ohio. There are also two podiatric hospitals — in Pittsburgh and San Francisco. The south and southwestern portions of the United States and nonurban areas have fewer podiatrists. Less than 200 podiatrists practice in Washington State, where doctors report a saturated market.

The U.S. Bureau of Labor Statistics (BLS) maintains that podiatry is a well-paid profession, with projected growth at a par with the average growth rate for all occupations through the year 2006. In 1997, the American Podiatric Medical Association (APMA) estimated that 5 percent of the population visited podiatrists, and according to the California College of Podiatric Medicine, demand for podiatrists is projected to reach 80 million visits per year in the twenty-first century. BLS further advises that opportunities for this profession are most lucrative in group practices or within medical networks, as opposed to individual private practice.

Podiatry involves the study of movement and medical care of the foot and ankle. Doctors of podiatry diagnose and treat diseases and disorders of the foot, but they also can diagnose other maladies such as arthritis, diabetes, and heart disease because the foot is often the first part of the body to manifest the signs of serious illness. Orthopedists specialize in foot surgery, orthopedics, children's problems (podopediatrics), or foot problems of the elderly. The major focus of a podiatrist's practice, however, is the treatment of corns, bunions, calluses, ingrown toenails, and nail diseases, along with *palliative* care (to ease pain). Women of middle age comprise as much as 80 percent of some podiatrists' clientele, a situation attributed to the poor design of women's shoes.

The industry has experienced steady growth in the number of trained podiatrists who establish practices. Younger podiatrists, though, saddled with college-aid debt, often elect to work in partnerships to earn enough money and experience to open their own practices.

To gain admission into one of the seven colleges of podiatric medicine, prospective students must first complete at least 3 years or 90 semester hours of college credit at an accredited undergraduate institution, according to the American Podiatric Medical Association. Over 90 percent of the students entering a college of podiatric medicine have bachelor's degrees. Applicants must take the Medical College Admissions Test (MCAT). Podiatrists must be licensed to practice podiatric medicine after earning a doctor of podiatric medicine (DPM) degree from an accredited college of podiatry. Training for the DPM degree requires study in the basic and clinical sciences — anatomy, chemistry, pathology, physiology, pharmacology — and inpatient care. Graduate study entails a residency of one to three years in length after the DPM degree. All states and the District of Columbia require licensure, and another 32 require completion of an accredited residency program. Thirty-eight states require some form of continuing education in order to renew a license.

Podiatrists, like other alternative health care service providers such as chiropractors, optometrists, nurses, midwives, and acupuncturists are fighting to establish themselves in the medical community. They hope that national health care reform legislation will eventually become reality and will enable greater numbers of patients to gain access to “nontraditional” medical treatments. Medicare and private health insurance do not normally cover routine foot care. As a result, podiatric care is dependent on disposable income to a greater degree than other medical care. As the number of elderly in the U.S. population grows, demand for podiatric care also should rise, since this population has a high incidence of ailments in the leg and foot area.

Managed care also has raised serious concerns within the profession. In early 1997, an investor-owned Florida company, Consolidated Health Corporation, purchased the Podiatry Hospital of Pittsburgh, one of only two such hospitals in the United States. The hospital, which has about 70 affiliated podiatrists, had seen dwindling admissions in the era of managed care. It was converted to for-profit status, and a private management firm was hired by Consolidated. In the mid 1990s, faced with such developments, podiatrists organized the first national labor union for doctors, the First National Guild for Health Care Providers of the Lower Extremities, which will be affiliated with the AFL-CIO. Among the issues of concern to podiatrists is the change in podiatrist fee schedules associated with managed care, whereby services are reimbursed only, to the exclusion of supplies.

SIC 8049

OFFICES AND CLINICS OF HEALTH PRACTITIONERS, NOT ELSEWHERE CLASSIFIED

This industry consists of establishments of health care practitioners engaged in the practice of health fields not elsewhere classified. Practitioners may or may not be licensed or certified, depending on the state in which they practice. Establishments operating as clinics of health practitioners, not elsewhere classified, are included in this industry. Specific health care practitioners included in this industry include: acupuncturists (except M.D.s), audiologists, Christian Science practitioners, dental hygienists, hypnotists, respiratory therapists, midwives, naturopaths, nurses (except home health service nurses), nutritionists, occupational therapists, paramedics, physical therapists, physician's assistants, psychiatric social workers, clinical psychologists, psychotherapists (except M.D.s), speech clinicians, and speech pathologists.

NAICS CODE(S)

- 621330 (Offices of Mental Health Practitioners (except Physicians))
- 621340 (Offices of Physical, Occupational, and Speech Therapists and Audiologists)
- 621399 (Offices of All Other Miscellaneous Health Practitioners)

INDUSTRY SNAPSHOT

The offices and clinics of health care providers in this industry are characterized by their contrast and competition with offices and clinics of medical doctors. In America, many sectors of this industry have not enjoyed the public acceptance given to medical doctors. As a whole, this industry has become more accepted during the latter part of the twentieth century as a result of various social and economic factors.

This industry earns income from the tens of thousands of health providers in private practice who are either self-employed or employed through health maintenance organizations (HMOs).

Since the mid 1980s, the “graying” of America has helped to fuel the growth of offices and clinics of respiratory therapists, physical therapists, and nurses, with a substantial number employed by home health care services.

ORGANIZATION AND STRUCTURE

Offices and clinics in this industry belong to either hospitals, where the practitioners may be employed by the hospital or those that work independently of hospitals. Occupational and physical therapists, psychologists, and acupuncturists often work, to some extent, with hospitals. Occupational and physical therapists are frequently employed by general and rehabilitation hospitals, and many psychotherapists work at psychiatric hospitals treating the mentally ill.

Unlike the offices of medical doctors and dentists, establishments in this industry do not rely on payments made through insurance companies or government programs like Medicare and Medicaid as their main source of income. However, occupational and physical therapists receive the largest portion of their incomes from employee compensation plans. Practitioners in this industry use referral services, such as those of profession associations, as a tool to ensure a steady flow of self-funded patients.

BACKGROUND AND DEVELOPMENT

Common to the background of many of the professions represented by this industry, such as acupuncturists, is their long global history. Many of these practices, however, have gained acceptance in the United States only during the twentieth century. Another common feature of these professions has been their rapid growth since the 1970s, when “natural” and Eastern medicine gained popularity; at the same time, the rising costs of traditional health care spurred patients to seek new approaches to health care.

Acupuncturists. Acupuncture is a system of medicine that uses needles on nerve and “energy” points to cure disease and modify certain behaviors. Developed in ancient China, acupuncture was not widely practiced in America, outside Chinese communities, until the 1960s. Today acupuncture and other forms of Oriental medicine are among the fastest growing segments of health care in America. According to the National Acupuncture and Oriental Medicine Alliance, at the end of the 1990s, thirty-eight states and the District of Columbia had recognized the practice of acupuncture, and legislation had been introduced in eight additional states. The number of

licensed acupuncturists in the United States rose from 5,525 in 1992 to 10,512 in 1998. Nearly all full-time acupuncturists in the United States are self-employed. Others, mostly medical doctors, have been trained in acupuncture and use the technique mostly as a form of anesthesia.

Audiologists and Speech-language Pathologists.

Audiologists work in the diagnosis and treatment of hearing problems; in addition, these practitioners work in public health, providing instruction and counseling for the hard of hearing. By 2005, a doctoral degree may be required to enter audiology practice. This sector of the health care industry has grown steadily since the 1970s, in part because of a maturing patient base and in part because of technological advances that allow increasingly effective treatment of patients with hearing difficulties.

Speech-language pathologists treat and counsel people with communication disorders caused from hearing loss, brain injury, learning disability, mental retardation, or emotional problems. These practitioners are mostly self-employed and work at rehabilitation hospitals and clinics and out of private offices. In 1993, the American Speech-Language-Hearing Association reported that nearly 58,000 speech-language pathologists were established in the United States. In 1992, it was estimated that nearly eight million Americans sought treatment from speech-language pathologists. Of those, more than three million were children undergoing therapy for speech impairments, primarily stuttering.

In 1997, there were about 87,000 speech-language pathologists and audiologists practicing in America. The median annual salary in 1997 for speech-language pathologists was \$44,000 and \$43,000 for audiologists. One half provided services in preschool, elementary, secondary schools or in colleges and universities; 10 percent worked in hospitals. Both of these fields are expected to grow because of the aging population and also federal laws that guarantee special education for all eligible children.

Christian Science Practitioners. These practitioners, in following the Christian Science faith, use spiritual healing to cure ailments. This form of healing, which relies on prayer and Bible reading, dates back to the start of the Christian Science religion, founded by Mary Baker Eddy in 1866. Throughout this profession’s history, efforts have been made, mostly by governing bodies, to prohibit this form of health care; however, laws guaranteeing the right to religious practices have continually fought this opposition. Some states have passed laws specifically designed to protect the rights of this profession.

Nationally, this profession suffered negative publicity in the 1980s following several incidents where children died under the care of a Christian Science practi-

tioner; in these cases, medical experts testified that the children would not have perished under the care of a medical doctor. These incidents were highlighted by legislation brought about in 1983 that drew the public's attention to spiritual healing. That year the federal government defined a parent's failure to provide medical care—which excludes spiritual healing—for a child as child neglect. Additionally, the government had the right to intervene if a parent's actions prohibited medical treatment. Consequently, the parents of children who died under the care of Christian Science practitioners faced criminal charges.

Most of these cases were dismissed on the basis of lack of due process, while another case was dismissed due to freedom of religion acts; other cases remain in the appeals system. In 1993, however, a landmark decision was made against the Christian Science Church itself that returned a \$5.2 million wrongful death judgment to the biological father of a diabetic boy who died under a Christian Science practitioner's care. This decision was important to this industry as it placed the blame upon the practitioners and not the parents. Legal battles continue in this area, which involves issues ranging from children's rights to religious rights.

Dental Hygienists. Dental hygienists provide treatment and education for oral hygiene and prevention of gum disease. The offices and clinics of dental hygienists, independent from employment by a dentist, involve working for public health agencies, industrial plants, and independent dental clinics. In 1996, there were approximately 133,000 dental hygienists working in America, of which the majority worked for general dentists.

Hypnotists. The practice of putting a person into a trance, or sleep-like state, in order to influence their actions and behaviors, was long regarded as a form of trickery. Its origins are unclear, although the first reliable form of hypnotic induction was reported in the eighteenth century. Research continued during the nineteenth century and the hypnotic state came to be increasingly attributed to physiological and psychological factors. By 1893, the British Medical Association “officially recognized hypnotism in a report that found the hypnotic state to be real and of value in relieving pain and alleviating certain functional ailments. The report was not approved by the American Medical Association until 1958, and acceptance of it among medical doctors continues to be slow,” noted the *New Age Encyclopedia*. Modern hypnosis is used for treating smoking, alcoholism, weight control, disorders related to stress, and many phobias.

According to the American Association for Professional Hypnotherapy, in 1997 nearly all of the 13,300 hypnotists practicing in America were self-employed, and a considerable number were licensed in other health

fields, such as psychotherapy or medicine; hypnotherapy has been developing as a treatment used in conjunction with more traditional health practices. However, even when hypnosis is used by a medical doctor, it is rarely covered by insurance; this factor has hindered the growth of this profession within the medical community.

Midwives. Midwifery, the profession providing care and assistance for delivering babies, has a long history. The dominance of obstetrics in America, however, has significantly diminished this profession from the role it enjoyed earlier in the country's history. However, the practice enjoyed something of a revival in the late 1980s and 1990s. Midwives delivered 3.7 percent of all births in 1989, but eight years later, in 1997, that figure had nearly doubled to 7 percent. As of 1999, the American College of Nurse-Midwives reported its membership had topped 6,700, of whom about 5,700 were in clinical practice. Of these, less than 500 were self-employed, while the majority of midwives worked at birth centers or clinics or as nurses to medical doctors.

Historically, midwives were not licensed to use instruments, such as forceps, and they had to call upon a medical doctor if there were any complications with a birth. Despite these restrictions, prior to the seventeenth century midwifery was a lucrative profession for women. In Europe during the seventeenth century, a male-dominated medical profession sought to include childbirth as part of their practice. Since then, the scientific advances available to women through the established medical profession has kept pregnant women away from the natural methods of childbirth usually employed by a midwife.

In colonial America, midwifery was still a prosperous profession and remained so until the expansion of medical schools and specialties in the nineteenth century, and the consequent development of the field of obstetrics. It was also during this time that European immigration to America had a negative impact on the midwives' profession. In Europe, midwives usually belonged to the middle classes, and since the Europeans who immigrated to America belonged mostly to the lower classes, midwives were left behind. According to the 1910 census, after a wave of European immigration, 50 percent of births in America were carried out by midwives, a precipitous drop from an estimated 90 percent during colonial times.

Midwifery in America was to see another major setback during the 1920s and 1930s, as medical procedures for childbirth in hospitals improved dramatically, as did medical training in the field of obstetrics. It was also during this time that some states decided to prohibit the practice of midwifery, while many other states enforced strict supervision. Many historians (of medicine and women's studies) have explained this change from

midwifery to obstetrics as a male takeover of the profession of assisting childbirth.

Midwives practicing in America cared for less than 10 percent of childbirths by 1960. However, during the 1960s and 1970s, interest in women's rights and the women's liberation movement brought renewed interest in natural childbirth and the services of a midwife. Between 1975 and 1980, the number of American babies delivered by midwives doubled. In 1993, CNMs attended 188,370 deliveries, which accounted for 4.5 percent of all U.S. births. By 1997, midwife-assisted births had climbed to 7 percent of total U.S. births.

Naturopathic Physicians. Naturopathic physicians specialize in the use of natural therapeutics and are primarily concerned with overall health instead of alleviating specific symptoms or illnesses. The types of treatments and medical practices used by these physicians include herbology, acupuncture, natural childbirth, and homeopathy (which employs drugs that reproduce the symptoms of a disease as a way of canceling it out). Naturopathic physicians are only licensed in eleven states: Alaska, Arizona, Connecticut, Hawaii, Maine, Montana, New Hampshire, Oregon, Utah, Vermont, and Washington.

Their offices and clinics are operated in ways similar to those of primary care physicians, with the assistance of medical secretaries and medical assistants. These health care providers routinely perform physical examinations, lab tests, and minor surgery. In 1997, there were an estimated 2,300 offices and clinics of naturopathic physicians in the United States.

Nurses. The offices and clinics of nurses, independent from medical doctors, have had long histories in institutions and large industrial sites where first aid facilities are needed. This role has evolved since the 1960s into the job of occupational health nurse. In addition to administering first aid, occupational health nurses develop health promotion programs related to fitness and well-being, as well as safety regulations for the work site. Regulations passed by the Occupational Safety and Health Administration (OSHA) during the 1980s have greatly expanded the roles of occupational health nurses, whose responsibility it is to see that regulatory standards are met.

Establishments of nurse practitioners outside of institutions and industrial work sites have also evolved into new, more challenging roles. With the rise in health care costs and the shortage of family doctors, nurses have been providing primary care previously serviced by medical doctors. According to *Business Week*, registered nurses with advance training can provide 60 to 80 percent of all primary care. Given that nurses' salaries are considerably less than those of doctors, these services are provided at a savings and are filling a niche in the health care

industry. A study by the American Nurses Association found that primary care provided by a nurse practitioner costs an average of 60 percent less than that provided by a medical doctor. For these reasons, nurses are expected to benefit from government-imposed health care reform designed to expand primary care and cut costs.

However, the move into primary care for nurses has been challenged by the medical profession and state governments. These groups have expressed concern over the qualifications of nurses seeking to expand their roles into primary care. Moreover, in some states, such as California, controversy has arisen over whether nurses should legally be allowed to fill prescriptions.

In 1994, there were about 1.97 million registered nurses practicing in the United States. Of those, nearly two-thirds worked in hospitals, while the remaining third worked in nursing homes, home health care agencies, schools, government agencies, and the offices and clinics of physicians. The median annual salary for a RN was \$36,240. In 1996, there were roughly 700,000 licensed practical nurses (LPNs) with a median annual salary of \$24,336.

Nutritionists and Dietitians. Nutritionists plan and supervise meals in state and government health departments, social service agencies, residential care facilities, and at schools. They may also counsel individuals on aspects of nutrition and ways to prevent diseases. In 1996, there were 58,000 dietitians and nutritionists. According to a Hay Group survey of acute care hospitals, their median annual salary was \$34,400 in early 1997.

Occupational Therapists. Occupational therapists treat people with physical or emotional illnesses that affect their abilities in a day-to-day work or home environment; this type of therapy emphasizes treatment of work-related behaviors and skills. According to the American Occupational Therapy Association, the most common problems among patients of occupational therapy in the 1990s were strokes, developmental disabilities, arthritis, hand injuries, depression and schizophrenia. In 1996, there were roughly 57,000 occupational therapists practicing in the United States, earning a median base salary of \$40,560 a year. Most occupational therapists worked in hospitals, with school systems being the second largest employer. A small but rapidly growing segment works in private practice.

The offices and clinics of occupational therapists originated in Europe and America after World War I with the emergence of rehabilitation hospitals for the long-term disabled. By 1925, the Council on Physical Therapy was created by the United States federal government. This governing body reviewed occupational therapy programs and established accreditation standards for therapists and their assistants.

This sector of the health care industry witnessed steady growth from the 1930s through the 1970s. Since the 1980s, growth in occupational therapy has accelerated with the aging population and increased efforts to integrate more disabled people into the work force.

The profession has changed in recent years in the types of services offered. Fewer occupational therapists have been working with mental health patients and patients with cerebral palsy and arteriosclerosis; these trends can be explained in part by the increase in the number of psychotherapists and psychiatric social workers and by the development of better medications. At the same time, following increased public awareness of learning disabilities (such as dyslexia and slow cognitive processing), occupational therapists have increasingly turned to patients with learning disabilities.

Paramedics and Emergency Medical Technicians (EMTs). Paramedics and EMTs are medical technicians who give on-site medical treatment in place of a physician. These health care practitioners provide treatment most commonly for heart attack and accident victims. Paramedic services were introduced in the United States in the 1960s. During the late 1990s, there were about 150,000 paramedics and EMTs working in the United States. One-third of them worked with police, fire, and rescue squad departments; two-fifths worked for private ambulance companies and one-fourth in hospitals. The average salary of a paramedic was \$30,407, while an EMT made \$25,051. Many work on a voluntary basis.

Physical Therapists. Similar to the work of occupational therapists, physical therapists provide treatment for the physically or developmentally disabled; their patients include victims of strokes and accidents and the elderly. These practitioners carry out programs of testing, massage, exercise, and other therapeutic treatments to increase their patients' muscular strength and range of motion and to relieve pain.

In 1996, there were roughly 115,000 physical therapists working in the United States, earning a median base salary of \$39,364 a year. Most of these therapists worked in general hospitals, rehabilitation hospitals, and nursing homes. Since the mid 1980s, the aging population has resulted in an increase in the number of physical therapists working in patients' homes or out of their own private practices.

Psychotherapists and Clinical Psychologists. The offices and clinics of psychotherapists and clinical psychologists began with the emergence of psychotherapy in the late 1800s in Europe. Like psychiatrists, psychotherapists and clinical psychologists treat patients with mental disorders and emotional problems. According to *American Demographics*, 76 percent of the patients of psychotherapists (including clinical psychologists who practice psy-

chotherapy) were being treated for emotional conditions such as anxiety disorders, neuroses, and relationship problems. However, unlike psychiatrists, psychotherapists and clinical psychologists do not prescribe medication and are not licensed as medical doctors. Another notable difference between these two related professions is that psychoanalysis requires more frequent patient visits and treatment outcomes are less predictable than those of psychiatric treatment.

These differences have made it more difficult for psychotherapists and clinical psychologists to gain wide acceptance in America. The insurance industry traditionally limited its coverage for mental health patients not under a psychiatrist's care. The role of the insurance industry has played a large part in the growth of this industry. It was not until after World War II that this industry was given a boost by commercial insurance companies offering coverage of mental healthcare for the first time. At first such insurance coverage provided for psychiatric and nonpsychiatric care; however, by the 1970s, insurers started restricting coverage of non-psychiatric mental health care, mainly because of the difficulty of diagnosing such ailments and the uncertain amount of time needed to treat disorders. In 1989, federally-funded insurance provided through Medicare expanded its coverage policy to include treatment by psychotherapists and clinical psychologists; this prompted private insurers to offer wider coverage again—a key factor in the industry's recent economic improvement.

In addition to increased insurance coverage, this sector of this industry has been aided by employers' increased awareness of work-related psychological disorders such as stress and fatigue. Many companies have set up Employee Assistance Programs (EAP). The involvement of psychotherapists and clinical psychologists in treating such problems in corporate environments has seen rapid growth since the mid 1980s. Many government agencies also mandated the set up of EAP programs for their employees.

The offices and clinics of psychotherapists and clinical psychologists compete for business with the establishments of psychiatrists, psychiatric social workers, and primary care physicians who counsel their patients. In 1989, there were a considerably greater number of clinical psychologists than psychiatrists; however, psychiatrists held a considerably larger portion of the mental health market.

In 1997, there were about 143,000 psychologists employed in the United States. Nearly 40 percent of them worked in educational institutions while 30 percent were employed in health services, and one-sixth worked in government agencies. The U.S. Department of Veterans Affairs and the Department of Defense used 80 percent of the federally employed psychologists.

Respiratory Therapists. Respiratory therapists treat patients with cardiopulmonary (heart and lung) problems that obstruct breathing. These health care practitioners work primarily in hospitals and nursing homes, but have also filled a growing need in home health services. Out of the 82,000 respiratory therapists working in 1996, more than 9 out of 10 worked in hospitals.

CURRENT CONDITIONS

Like other sectors of the health care industry, establishments in this industry entered the 1990s expecting growth due primarily to the maturing American population, but at the same time held concerns about health care costs and government reforms affecting the management and insurance coverage of their services.

The needs of the aging population of the United States have contributed to the rapid growth of home health services, which primarily employ physical and occupational therapists, respiratory therapists, and nurses. Other sectors of this industry which entered the 1990s to service the needs of the elderly include audiologists and paramedics.

According to *Business Insurance*, the changes expected with more managed care have been of particular concern to psychologists and psychotherapists, as these professions have been negatively affected by existing managed care systems; which have favored the use of psychiatric social workers over psychotherapists and clinical psychologists as the least expensive outpatient mental health provider. By 1996, some managed care organizations were beginning to cover certain alternative treatments, including acupuncture and hypnosis.

With cost-cutting changes in health care moving the health care industry away from inpatient treatment and toward more outpatient treatment, the offices and clinics of occupational and physical therapists have increasingly moved from hospital settings to more private offices and outpatient clinics.

INDUSTRY LEADERS

Some of the leaders in this industry in the late 1990s included HEALTHSOUTH Corp., NovaCare Inc., Comprehensive Care Corp., and Tenet Healthcare Corp.

HEALTHSOUTH, headquartered in Birmingham, Alabama, is the largest provider of outpatient surgery services and rehabilitative health care in the United States, operating nearly 2,000 health care facilities in this country, Australia, and the United Kingdom. With more than 51,000 employees worldwide, HEALTHSOUTH posted 1998 net income of \$46.5 million on sales of \$4 billion. Although the company's sales were up more than 32 percent from 1997, net earnings were nearly 86 percent below the level achieved the previous year.

NovaCare, one of HEALTHSOUTH's leading competitors in the field of rehabilitative health care, was in the process of extricating itself from the business in late 1999. The company suffered a net loss of \$189.5 million on revenue of \$1.48 billion in fiscal 1999, the 12 months ending on June 30, 1999. NovaCare, which provided rehabilitation services to nearly 3,000 hospitals and nursing homes, employed 54,800 worldwide as of late 1999.

Comprehensive Care Corporation provides inpatient and outpatient mental health and substance abuse therapy and counseling. It contracts with hospitals and also operates free-standing facilities. Its subsidiary, Comprehensive Behavioral Care Inc., provides the same care for employers, HMOs, PPS, government organizations, third party administrators, and other group purchasers of healthcare. Headquartered in Tampa, Florida, the company posted net income of \$42.0 million on revenue of \$46.1 million in fiscal 1998, the 12 months ending on May 31, 1999.

Although its main business is the operation of hospitals, Tenet Healthcare Corp. also runs a number of outpatient surgery centers and rehabilitation centers. With more than 125,000 employees worldwide, Tenet posted net income of \$249 million on revenue of \$10.9 billion in fiscal 1999, the 12 months ending on May 31, 1999.

WORKFORCE

The various professions represented by this industry are on the whole expected to grow well into the end of the century. The fields that involve home health care and health care conducive to managed care systems are expected to do best; nurses and physical and occupational therapists represent three of the fastest growing areas of the health care industry. According to the U.S. Bureau of Labor Statistics, by the year 2005, there will be a 55 percent increase in the number of self-employed nurses and occupational therapists; the job market for physical therapists is expected to grow by more than 25 percent.

During the latter half of the 1990s, the average salaries for practitioners in this industry were as follows: audiologists and speech-language pathologists, \$43,000 and \$44,000, respectively; dental hygienists, \$39,468; registered nurses, \$36,244; licensed practical nurses, \$24,336; occupational therapists, \$40,560; occupational therapy assistants, \$27,442; paramedics, \$30,407; physical therapists, \$39,364; psychiatric social workers, \$35,000; psychotherapists, hospital/clinic, \$51,000; psychotherapist, government, \$62,120; and respiratory therapists, \$32,500.

With the exceptions of midwives and occupational therapist assistants, the occupations listed above require at least four years of training, usually in conjunction with a bachelor's degree. Midwives can practice with two

years of training and certification in the state they work. Occupational therapist assistants undergo two years of training through an associate's degree program and have to be certified by the American Occupational Therapy Association.

AMERICA AND THE WORLD

Many of the professions represented by this industry have had larger and often more profitable markets overseas, especially practitioners of "alternative medicine," such as acupuncture and natural therapies. Acupuncture is not only a standard form of medicine in China, but is also widely practiced all over the world. In Great Britain and Germany, acupuncture is covered by the government-run health programs. Hypnosis, naturopathy, and various forms of spiritual healing have also been more widely accepted overseas than in the United States.

America's approach to midwifery has also been significantly different from approaches overseas. In most other industrialized countries, midwifery has been blended into the medical profession, while in the United States, the use of obstetricians and gynecologists has taken precedence. Midwives from overseas, unlike many other nurse-practitioners in the health care industry, do not tend to seek employment or set up practices in the United States.

However, the better salaries offered in the United States for nurses and physical and occupational therapists have brought many practitioners in these professions to the United States. Nursing professionals, in particular, are apt to secure work overseas because their credentials are easily transferable and because of the worldwide shortage of nurses.

RESEARCH AND TECHNOLOGY

Like other sectors of the health care industry, establishments in this industry are greatly affected by medical research and technology. Technological developments since the mid 1980s such as computerized infusion therapy and smaller physical therapy apparatus have helped home health care services grow. In addition, at-home monitoring devices for the elderly have increased the efficiency and use of paramedics.

Information technology has brought about new developments in computer-assisted healthcare, including psychotherapy. Computer systems, such as the Therapeutic Learning Program, developed by a California psychiatrist, provide therapeutic advice to employees at their work site, meeting the concerns of employers over employees' psychological well-being. Such systems can be operated by the patient, although mental health practitioners see such systems as working in conjunction with services provided by a practitioner for personalized diagnoses.

The National Institutes of Health have also begun research on alternative therapies, such as naturopathy and hypnotism. The institute is offering grants for private studies on such therapies. The outcome of these studies will either help promote or reduce the number of people interested in using these kinds of healing methods.

SKILLED NURSING CARE FACILITIES

This industry contains establishments primarily engaged in providing inpatient nursing and rehabilitative services to patients who require continuous health care but not hospital services. Care must be ordered by and under the direction of a physician. The staff must include a licensed nurse on duty continuously with a minimum of one full-time registered nurse on duty during each day shift. Included are establishments certified to deliver skilled nursing care under Medicare and Medicaid programs. Skilled care facilities include the following: convalescent homes with continuous nursing care, extended care facilities, mental retardation hospitals, and skilled nursing homes.

NAICS CODE(S)

623311 (Continuing Care Retirement Communities)
623210 (Residential Mental Retardation Facilities)
623110 (Nursing Care Facilities)

INDUSTRY SNAPSHOT

According to the Centers for Medicare and Medicaid Services (previously known as the Health Care Financing

Administration), U.S. citizens spent \$92.2 billion on nursing home care in 2001.

Skilled nursing care facilities serve the nation's fastest growing population segment—those 65 years and older. An estimated 1.5 million people resided in nursing facilities in 2000. The most common reason the elderly enter a residential facility is circulatory problems (22 percent). Injuries and respiratory diseases account for 14 percent and 11 percent of admissions, respectively. In 2001, 13 percent of the U.S. population was over 65, a number that was expected to increase to 20 percent by 2020. An estimated 5.8 percent of all persons aged 65 and over resided in nursing homes in 1999. This number is also expected to increase, reaching approximately 8.4 percent, or 6.6 million people, by 2050.

In 2000, at the age of 65, men were expected to live an additional 16.3 years; women, an additional 19.2 years. Life expectancy was projected to continue to rise, with life expectancy at age 65 reaching 17 years and 20 years for men and women, respectively, by 2020. In other words by 2020, a 65-year-old man could be expected to live to the age of 82 and a woman could be expected to live to the age of 85. For those over the age of 65, there is a 41 percent chance that they will spend an average of 2.5 years in a skilled nursing facility. A one-year stay in a nursing home can cost between \$30,000 and \$80,000.

Longer life spans, coupled with the trend toward smaller families with fewer children to share responsibilities for the aged, will mean a greater need for medical health companies. As a result, the nursing home and long-term care industry will continue to grow, but it is unlikely that it will be able to keep pace with the growing demand for quality skilled nursing care. Funding will also be a dilemma as reduced or stagnated government spending is a widespread concern.

Essentially, these figures sketch the scope and populations served by the skilled care nursing industry. Over the course of the past decade, innovative reallocation of resources has expanded options for long-term care, but few, however, match the optimum level of skilled nursing care provided for populations with chronic and multiple disablement. Skilled nursing care, similar to custodial or convalescent care conceptually, represents a long-term vehicle for meeting the comprehensive medical, personal, and social service needs of chronically disabled persons.

Skilled nursing care services differ in terms of the levels of services provided, patient admission criteria, staffing, and reimbursement mechanisms. Each aspect of the skilled nursing care environment reflects the high level of intensive care. All skilled care facilities provide continuous 24-hour care that is prescribed, directed, and executed under the supervision of a medical doctor. Pro-

fessional performance and supervision by licensed personnel also apply to the provision of ancillary services such as physical therapy and other such prescribed services.

One of the trends affecting health care is integration or integrated delivery systems—a system that tracks patients over time and spans all levels of care and fosters alliances among the various care givers. Nursing home regulations, the need for new managers, standards, and managed care contracts are among some of the challenges facing the industry.

ORGANIZATION AND STRUCTURE

Skilled nursing care facilities primarily operate under three categories of ownership: for-profit, nonprofit, and government. For-profit skilled care nursing encompasses tax-paying structures operating under proprietary or investor/shareholder ownership by licensed administrators or as a subsidiary of a corporation. Nonprofit ownership includes non-secular, church-related nonprofit organizations and secular, fraternal or other membership group, ownership. Government, or public ownership, includes establishments operated by city, state, or federal governments.

In 1999 and 2000, 67 percent of nursing home facilities were for-profit; 26 percent, nonprofit; and 7 percent, government-owned. Fifty-five percent were owned by a multifacility chain, and the remainder was under single ownership. Nearly 80 percent of all facilities were dually certified for Medicaid and Medicare, with 7 percent Medicare-only certified and 13 percent Medicaid-only certified.

In the mid-1990s, nonprofit nursing homes, which were either self-financed via retained earnings or through tax-exempt debt, began facing a bigger challenge from the for-profit sector. For-profit organizations could raise funds through stock offerings and retain managers through stock option plans. The non-profit sector was challenged to manage as efficiently and effectively as the for-profit group. Seventy-three percent of nursing homes were investor-owned in the early 1990s. Although the nonprofit sector was relatively stable, larger companies continued to acquire smaller long-term care facilities.

At the same time, there were 296 associations concerned with nursing homes and 59 associations devoted to nursing home administration. The Association of Health Facility Survey Agencies was concerned with facility licensing and certification programs. The American College of Health Care Administrators certified members' ability to meet and maintain standards of competence. Its affiliated Foundation of American College of Health Care Administrators was concerned with scholarship to improve long-term care and nursing home administration. The National Association of Boards of Exam-

iners for Nursing Home Administrators produced the competence testing exam. Another relevant association was the National Subacute Care Association.

Sources of Skilled Care Revenue. According to the American Health Care Society, of the nearly \$88 billion spent nationally for private sector nursing home care in 1998 (up to over \$92 billion by 2001), 46.3 percent of nursing home care was covered by Medicaid, 11.9 percent by Medicare, and 32.5 percent by out-of-pocket. The remaining 9.3 percent came from other sources such as private health insurance, Veterans Administration, and private philanthropy. Analysis of revenue trends based on facility ownership also reveals that, for government and for-profit homes, Medicaid accounted for more than 60 percent of revenues. Private pay revenue was highest for church-related and secular homes.

Medicaid. Medicaid is the largest insurer of long-term care for all Americans. Medicaid payments for skilled nursing facility care totaled almost 24 percent, or \$44.4 billion, of the entire Medicaid budget in 2000, down from 25 percent in 1997.

Medicaid is a federal/state funded program administered by individual states. Originally designed for poverty-level women, children, and the elderly, increased utilization by the elderly has converted long-term care to a majority component of Medicaid. All long-term care patients, however, are not automatically eligible for Medicaid assistance. Ineligibility may be decided either because a prospective patient's assets exceed the normal \$2,000 limit or the patient's monthly income exceeds state limitations.

Several legislative changes in Medicaid reimbursements have created tensions between the state government officials and nursing home providers. Specifically, the Boren Amendment enacted in 1980 and the broad nursing home reform provisions mandated by the Omnibus Budget Reconciliation Act (OBRA) of 1987 have been problematic for providers.

Prior to the Boren Amendment, nursing homes were reimbursed on the basis of reasonable, cost-based expenses. The Boren Amendment changed the system by granting the states greater freedom and latitude in determining the amount of Medicaid reimbursements considered to be "reasonable and adequate." Because of budgetary and other fiscal problems, the amount of Medicaid reimbursement paid by states to nursing home providers frequently did not cover basic costs of patient care. Understandably, nursing home operators objected.

Nursing home operators were also concerned with the effects of OBRA. Among other things, OBRA regulated the purpose, nature, and use of restraints in long-term care facilities to ensure they were for the patient's benefit and not the provider's convenience. Nursing

homes, however, did receive some relief from governmental actions. A 1990 Supreme Court ruling gave providers the right to challenge states regarding reimbursement levels. As a result of this ruling, states had to adjust Medicaid payments sufficiently to assist providers to meet compliance costs associated with OBRA.

Still another integrity issue surrounding Medicaid emerged from a U.S. Census Bureau report that claimed Medicaid, as the principal payer for almost two-thirds of nursing facility resident days, was plagued by fraudulent claims from ineligible applicants who did not meet poverty guidelines. To curb these practices, which potentially threaten Medicaid's fiscal base, the American Health Care Association (AHCA) called for action designed to enforce existing statutory prohibitions against transferring or otherwise disposing of assets used in determining Medicaid eligibility and identify and amend statutory provisions encouraging implementation of Medicaid Estate Planning.

Medicare. Only 7.3 percent of facilities are solely certified by Medicare, and this number accounts for only 3.4 percent of all available beds. The late 1990s trend was for Medicaid-certified facilities to become dually certified. In 2000, nearly 80 percent of all skilled care facilities were certified for both Medicare and Medicaid, up from 63 percent in 1993.

Medicare Hospital Insurance, under Part A, assists in covering costs for skilled nursing home care, excluding convalescent or custodial homes. Skilled nursing facilities generally are reluctant to utilize Medicare reimbursement for several reasons. First, complexities associated with Medicare reporting guidelines frequently result in losses because of disallowance of patient and patient-related skilled care costs. Second, under the reimbursement system, hospitals received a higher rate of compensation than nursing facilities for providing the same type of skilled care nursing services. As a result of this inequitable system, the higher rates allowed hospitals a significant competitive edge. One proposed solution for payment equity called for hospitals and nursing facilities to receive the same rate for providing the same type of skilled nursing care.

Another contentious issue between skilled nursing facilities and Medicare focused on the three-day hospital stay requirement for admission to skilled care facilities. Though it was intended to function as a measure to protect against unnecessary admissions, skilled nursing care facilities argued that the ruling led to unnecessary hospital stays resulting in further delays of essentially needed skilled nursing care for patients. Providers preferred total elimination of a pre-hospital stay admission requirement. Based on the government's analysis, elimination of this requirement would increase Medicare

spending by an estimated \$3 billion over five years. Based on the AHCA's analysis, however, elimination of the three-day requirement would save \$1 billion over five years because savings in Medicare hospital expenditures would more than offset expenditures of skilled nursing facilities.

In the 1990s, the conversion of beds into "subacute" care beds emerged as one trend in the nursing home industry, in part because the latter offered much greater levels of Medicare revenue. For example, the average Medicare payment per diem in the nursing home setting was \$98 in 1990, as compared to \$249 in 1998, about half the cost of daily expenses, which averaged \$508.

Under this payment system for skilled nursing facilities, Medicare would pay for up to 100 days of nursing home care, subsequent to an acute care hospital stay of at least three days. Rates were determined in terms of "reasonable" costs, which fall into three categories: routine costs (including daily expenses that a skilled nursing facility incurs); ancillary service costs (including rehabilitation therapy, nonroutine medical care, and radiology services); and capital costs (including depreciation, amortization, and interest).

Over 90 percent of all nursing home facilities depend on Medicaid for at least part of their revenues. The Kassenbaum-Kennedy health insurance portability law makes long-term care expenses and premiums tax deductible. State governments were concerned about their one-third share of spending on Medicaid, which they felt was going to the middle class rather than the poor.

Respiratory therapy was provided in approximately 35 to 40 percent of all nursing homes but was not a reimbursable cost in skilled care facilities unless certain conditions were met. One condition for Medicare reimbursement for respiratory therapy required a transfer agreement that specified that the hospital provide respiratory care personnel to the skilled nursing facility. As it was, patients transferring from hospitals to skilled nursing facilities were likely to discover Medicare disallowance of respiratory therapy payment.

Reimbursement for Medicare and Medicaid required certification of nursing facilities by the funding agencies. The certification process, normally accomplished via inspection, assessed the total spectrum of the facility's capacity to provide optimum skilled care. The certification process represented a challenge for nursing facilities and proved to be a significant hurdle for a significant number of facilities. The 1987 Omnibus Budget Reconciliation Act's (OBRA) impact changed the course of nursing home enforcement. This federal law created in response to increasing concern about the industry in the 1980s that arose out of a series of well-publicized accounts of neglect and ill treatment at nursing care facili-

ties. As a committee of the Institute of Medicine noted, "a stronger federal leadership is essential because not all state governments have been willing to regulate nursing homes adequately unless required to do so by the federal government." OBRA provided new federal regulations that were implemented "to improve nursing home conditions by giving patients a stronger voice in their care, requiring facilities to document treatment and specifying how surveyors should inspect nursing homes to see whether the new standards are being met," according to the *New York Times*.

One major change affected by OBRA was the survey inspection procedure. Pursuant to OBRA, the Department of Health and Human Services was directed to enter agreements with state survey agencies for assessing nursing facilities' compliance with OBRA's requirements. The results of on-site inspections subsequently determined whether to enter into, deny, renew, or terminate a facility's Medicare/Medicaid participation agreement. To implement this requirement, the Health Care Financing Administration (HCFA), Medicare's operational arm, called a meeting of nursing home industry representatives; they agreed to use an inspection rating instrument featuring a "scope and severity scale." HCFA later revised the plan, deleted the scale, and added fines of as much as \$10,000 per day for inspection violations endangering a patient's life. A ruling was also added allowing state takeover of facilities judged as repeat offenders. The industry objected to HCFA's new regulations. Though infrequently applied, ouster from the Medicare program could cripple a facility. An even more punitive aspect of the measures, however, in the nursing industry's opinion, was the absence in HCFA revisions of a dispute resolution process whereby providers could explain, clarify, or contest a survey finding. In 1995, HCFA implemented the 1987 Omnibus Budget Reconciliation Act by providing sanctions for nursing home violations. Support surfaces that were previously considered routine costs, such as mattress replacements, became considered ancillary costs.

OBRA also granted nursing homes funds for correcting inspection violations. Rectification of inspection deficiencies would be completed in adherence to a state designed timetable. If facilities did not rectify deficiencies, then federal law required the state to repay the federal government the amount of funds given to the nursing facility. Rather than be saddled with such repayment obligations, states sometimes chose to decertify facilities deemed noncompliant.

While the other 49 states implemented the 1987 Omnibus Budget Reconciliation Act, California openly and blatantly rebelled. California refused to adhere to federal guidelines for inspections on the basis that federal requirements would impose an additional \$500 million

annual cost to the Medicaid program. Tit-for-tat actions ensued. California sued the federal government. The government withheld \$24 million of \$5 billion in Medicaid contributions. After a few months of bitter controversy, a satisfactory resolution was finally reached when the federal government attributed problems to a misunderstanding and accepted California's proposed inspection changes. Several other issues regarding compliance with OBRA remained in various discussion stages. Some felt that OBRA was an overregulation that harmed those it was intended to protect.

Nursing homes were also governed by Occupational Safety and Health Administration (OSHA) regulations, with fines of up to \$2,000 per violation. Most frequent violations were lack of a written program, lack of employee training, lack of proper labels for containers, and failure to make material safety data sheets available.

Rehabilitation Skilled Nursing Homes. Patients in these homes include accident victims who enter for shorter extended stays needing care and rehabilitation services connected to head injuries, strokes, spinal cord injuries, amputation, orthopedic and neurological impairment, arthritis, or war-related trauma. The proliferation of highly specialized trauma centers concentrated on services for single injury-related rehabilitation such as head, spinal cord, or other types of disablement. Growth of the rehabilitation industry could in part be attributed to medical science advances. Because of these advances, the potential of rehabilitation expanded options for all ages of patients.

Skilled Nursing Care Facilities for AIDS Patients. AIDS morbidity, as with escalating group of nursing home patients, created yet another challenge for the nursing home industry. Skilled care needs of AIDS patients differ from those of other nursing home patients. Provision of optimum care means comprehensive reallocation of nursing home staffing and other resources. One study found that 20 percent of AIDS patients experienced difficulty with placement in skilled nursing facilities. A survey of 54 Illinois homes related the most salient reasons for this difficulty related to cost, staff abilities, or resistance due to concerns regarding mixing AIDS patients with other patients.

Skilled Nursing Care Facilities for Children. Children under the age of six who are victims of traumatic accidents, congenital defects, and chronic diseases such as cystic fibrosis and other ailments, were a fast-growing long-term care group in the United States. The combined total of children's facilities in the United States included 47 freestanding or independently operated children's hospitals, with the remainder affiliated with other types of institutions. Although many children's facilities were backed by large endowments, several conditions

contributed to extreme financial conditions. Because these facilities often cared for seriously ill patients, about one-third of their beds were allocated for intensive care, comparable to skilled nursing care. Many admissions consist of transfers from community hospitals that were unable to provide the prescribed level of intensive care. Despite the fact that Medicaid reimbursement covered an average of more than 80 percent of the care cost and disproportionate share payments covered the difference, children's facilities frequently faced financial crises. One reason stemmed from frequent delays of Medicaid reimbursements. This state of affairs could impose significant financial strain and conceivably threaten the survival of children's facilities. More problems could be anticipated if future payment rate allowances failed to consider the high numbers of Medicaid and uninsured patients served by children's hospitals.

Subacute Skilled Care Nursing Facilities. For the most fragile patients, many long-term care facilities developed a subacute level of care, described by the American Health Care Association as intensive, licensed, skilled nursing care provided in a distinct part/skilled nursing facility. Many subacute level patients are "heavy care" elderly with respiratory ailments requiring ventilator or intravenous therapy. Because of inadequate Medicare reimbursement for this type of treatment, nursing homes were unwilling to accept these patients.

BACKGROUND AND DEVELOPMENT

The cost of one year of care in a nursing home in 2001 was between \$30,000 and \$80,000 annually. Although costs were expected to continue increasing at about 7.5 percent per year, the industry's fiscal status was regarded as somewhat flat. While expansion capital might not be readily available to the industry, neither was the concept of expansion an overwhelming objective for most of the industry. Nursing home chains recalled the heady conditions of an expansive period during the 1980s. Ballooning profits and expansions contributed to an enthusiastic appraisal of the industry's future.

As companies felt the impact of Medicare price changes, however, members of the industry scaled back expectations. Precariously slim profit margins, due in part to an overload of unprofitable and unnecessary relics from the expansion period, forced companies to scale back to survive. What followed was an austerity phase characterized by budget cutting and dumping of unprofitable entities. Many of the innovative strategies of restructuring, diversification, and other cost-saving measures continued as industry foundations into the early 2000s. Humana, one of the larger chains, added an insurance entity that proved to be a profitable strategy. Other organizations diversified by adding specialized services as well, and a 1995 association—The Health Resources

Alliance—was established to act as a contact point for long-term care clients needing a variety of specialized care facilities.

Although nursing homes may be designated as skilled care nursing care facilities, occupancy patterns for most facilities combined a mix of patients needing skilled and unskilled care. To meet federal and state requirements for skilled nursing care, facilities thus maintained distinctly separate beds, staffing, records, and other services. Statistically, this organizational pattern, in addition to other factors, determined the demographic approach for documenting the skilled nursing care industry. First, more accurate indicators regarding the skilled care nursing industry emerged from enumeration of the number of beds rather than the number of facilities. Second, because Medicare or Medicaid reimbursement of skilled nursing care depended on certification by these mechanisms, this method allowed still another means of documentation. Finally, while the predominant elderly population of skilled care nursing homes formulated a valid sample, the universe of skilled care nursing included all ages of adults, children, and even infants suffering from chronic illness. The National Governors' Association approved a compromise in nursing home coverage for the poor and disabled elderly that would give states greater authority of payments and eligibility.

Non-profit nursing homes, self-financed via retained earnings or tax exempt debt, faced challenges from the for-profit sector, which could raise funds via stock offerings or use stock-option plans to retain managers or staff. This created a growing challenge to manage effectively and efficiently. Small providers were banding together to compete for managed care business. The for-profit sector threatened to provide nursing facilities at lower costs and with more services, including assisted living and home care, than nonprofit sectors. According to the National Center for Assisted Living, in the late 1990s, about 13 percent of all assisted living residents were in nursing facilities.

Continuing Care Retirement Communities (CCRCs) nursing homes sometimes lose residents to HMOs when they are discharged from the hospital and told they must go to an HMO provider. In the middle and late 1990s, CCRCs were seeking their own contracts with HMOs.

The under-age-65 nursing home population totaled about 173,100 in the mid-1990s, with admissions due to disablement by reason of mental retardation, chronic disease, or illness incidental to congenital defects, trauma, or accident. With the exception of purely age-related conditions, manifestations of chronic illness and disability are practically the same for both the elderly and younger groups.

Future nursing homes resources will need to be expanded to accommodate the projected volume increase of

elderly patients presenting these manifestations. Advances in medical science have enabled people to live longer, but higher costs trail longevity. U.S. Census reports projected that by the year 2025, the number of people over age 85 would climb to seven million—nearly double the 3.4 million in the mid-1990s. Because frailty and deterioration intensify with age, future nursing homes will find a majority of patients in need of more intensive care. Preparing to offer no less than optimum care for this patient segment means expansion of industry resources with accentuation on intensive care exclusively offered by skilled nursing systems.

There is a growing interest in substituting skilled nursing facilities for extended hospital care among the managed care plans. In 1996, 12 percent of all Medicare beneficiaries, 4.5 million persons, were enrolled in managed care plans. Major cost savings were achieved by switching patients from hospitals to skilled nursing facilities for convalescing.

The new trend toward expansion was expected to require new financing that was becoming increasingly easier to obtain because of the excellent profit potential. It served the fastest growing segment of the population. Nursing homes were among the most cost-effective providers of health care services. Honesty and accuracy in reporting fiscal, regulatory, management, and marketing portions of a home would improve loan approval.

As of 2000, about 1,500 of the 17,000 nursing homes were financed or owned by real estate investment trusts (REITs). Thirteen REITs invested exclusively in health care, with Meditrust's 1.8 billion portfolio being the largest. Advantages of REIT financing included long-term loans, better rates than banks, and the potential for operators to have a sales/leaseback option.

Late 1990s Changes. The Balanced Budget Act of 1997 (BBA) mandated the phase-in of a prospective payment system (PPS) for nursing homes over a four-year period starting on January 1, 1999. Under PPS, which went into effect in July 1998, Medicare paid nursing homes a fixed per patient-day based on the acuity level of the patient. Traditionally, the "cost-plus" reimbursement approach reimbursed nursing homes for actual service cost, in addition to a percentage based on capital expenditures and other operating expenses.

In this transitional period, the nursing home industry faced many difficulties in coping with the new changes. Small nursing homes, in particular, suffered because attempts to control costs below the per-diem rates resulted in operating margin erosion. Generally, nursing facilities with relatively more numerous, sicker residents operated less profitably, a situation that potentially threatened their ability to provide patients with adequate care.

The nursing home PPS legislation contributed to a significant decline in many service areas, especially rehabilitation and respiratory therapies and pharmaceutical services.

Consolidated revenues and profits did not rebound in the late 1990s and were not anticipated to do so in the early 2000s. Reflecting these changes, the *Standard & Poor's Health Care (Long-Term Care) Index* decreased 31 percent in the first four months of 1999, following a 54 percent freefall in 1998.

CURRENT CONDITIONS

In 2002 over 17,000 skilled care facilities were in operation in the United States. Over the course of one year, an estimated 3.5 million of the nation's elderly would spend some amount of time in a nursing home, meaning that 15 percent of the nation's population would have a relative who was living in a long-term care facility.

Despite a relative boon in government spending and potential customer base, the nursing home industry had growing concerns over the gradual, yet significant, shift in the makeup of its residents. With the advent of assisted-living facilities, which provide support services but not extensive medical services and attract the more able elderly, nursing homes were finding that their residents were in poorer health and in need of more advanced, expensive medical care. This situation was aggravated by hospitals, which in their own attempt to cut costs, discharged patients quicker and sicker than ever before.

Concerns also remained regarding the ongoing quality of nursing home care. Despite short-term increased government funding in the late 1990s, staffing did not increase. In fact, the total daily interaction time between staff and patients fell since 1998. A study by researchers at the University of California reported the most significant decrease was among nurse assistants, which fell 16 percent, from 3.1 hours per patient per day to 2.6 hours. Staffing remained a problem for the nursing home industry, which continued to struggle with high rates of turnover and poor pay, particularly for its nursing assistants. This situation, in turn, tied into the ongoing struggle to ensure quality of care.

An estimated 78 million Americans will need skilled care or assisted living arrangements in the early 2000s. Because government funding will not be able to keep pace with the influx of baby boomers into the long-term care system, nursing homes face a future of a rapidly increasing customer base but a decreasing amount of financial support per resident from the federal government. During 2002 the bulk of increase in federal assistance came in the form of temporary payment add-ons

that, when expired, would decrease governmental funds for skilled nursing facilities by over \$1 billion.

INDUSTRY LEADERS

For-Profit Homes. Approximately two-thirds of nursing homes operated for profit. About 55 percent of those for-profit homes were part of a chain. Beverly Enterprises, which operated its Arkansas-based, for-profit nursing home chain under its subsidiary Beverly Healthcare, was the industry leader in ownership of about 500 facilities in 30 states and the District of Columbia. In 2002 Beverly Enterprises, including all its business interests, reported a net loss of \$146.1 million on revenues of \$2.4 billion. Long-term care providers were experiencing pressure to revamp the delivery of services and broaden their range of services. Beverly Enterprises was one of seven nursing home chains to receive a multistate contract for veterans care as part of the Veterans Affairs' (VA) attempt to cut administrative costs. Other chains receiving contracts were Kindred Healthcare (then known as Vencor), Sun Healthcare Group, Genesis Health Ventures, Integrated Health Services, Unicare Health Finances, and Harmony.

Kindred Healthcare operated approximately 300 nursing homes as well as 55 long-term, acute care hospitals. In 2001 Kindred reported a net income of \$56.1 million on \$2.3 billion in revenues. The company, which employed 52,800, filed Chapter 11 bankruptcy in 2002 and underwent restructuring. Manor Care, which operated approximately 300 nursing homes under the names of Heartland and ManorCare, reported a net profit of \$130.6 million on \$2.9 billion in sales in 2002. Sun HealthCare Group, another industry leader, also went through Chapter 11 bankruptcy in 2002 after posting a net loss of \$69.1 million in 2001. The company owned and operated 240 long-term and subacute care facilities.

Non-Profit Nursing Homes. According to an Agency for Health Care Policy and Research (AHCPR) survey, nonprofit nursing homes were more apt than for-profit homes to be affiliated with non-nursing units, such as personal care or independent living. Nonprofit nursing homes were more likely to be hospital-based than for-profit nursing homes.

Rehabilitation Skilled Nursing Homes. Rehabilitation facilities, similar to other industries, faced the usual cost strategies involving restructuring, takeovers, and other measures. Although rehabilitation operations enjoyed a lucrative investor status in the 1990s, public officials viewed its growth status with less enthusiasm. Public health officials charged that these facilities shunned the indigent and made treatment decisions in deference to the patient's ability to pay. Several other problems surrounding rehabilitation facilities have dented the industry's integrity.

Public or Government Owned/Leased Skilled Care Facilities. Sixty-seven percent of nursing homes were operated for profit, about 26 percent were nonprofit facilities, and the remaining 7 percent were government-owned. Nonprofit and government-owned nursing facilities were more apt to be a part of a hospital-based nursing home than were for-profit nursing homes. The United States Department of Veterans Affairs was the largest of the government-owned facilities. In some instances, Veterans Affairs delivered long-term care services via service contracts with other nursing homes, as mentioned previously.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, there were 1,861,800 workers employed by nursing and personal care facilities in 2001. Healthcare support occupations, including nursing aides, orderlies, and attendants, accounted for nearly 40 percent of all jobs, with a mean annual salary of \$19,440. Healthcare practitioners and technicians accounted for nearly 23 percent of the workforce, with the largest single in-category groups being registered nurses (8 percent, mean annual salary, \$43,920) and licensed nurse practitioners (11 percent, mean annual salary, \$31,850). Food preparation and serving occupations accounted for 12 percent of jobs, with a mean annual salary of \$19,790. On the high end of the category, head chefs made a mean annual salary \$33,550; on the low end, dishwashers made \$15,360.

Statistically, the highest number of employees per set-up beds characterized nonprofit, Medicare-certified facilities. For-profit homes consistently maintained the fewest number of employees per bed.

Compared to other industries, nursing homes bore an unusually weighted portion of labor problems emanating from high turnover, staff shortages, and volumes of unskilled workers. Scattered stories of physical and sexual abuse, fraud, injuries, drug abuse, mistreatment of patients, and incompetence in the 1980s and 1990s marred the image of nursing homes as havens of care and security for the disabled. Through the late 1990s, particularly post-OBRA, labor conditions were beginning to change. In addition to mandating reimbursement changes, OBRA also mandated comprehensive changes in staff training. Evidence of these changes stimulated a work environment that, proponents say, encouraged more creative recruitment and retention strategies. Most of the more than two-thirds of all nursing homes with OBRA violations in July 1995 had complied by October 1995. In 1996, a seven-state initiative to help 1.6 million nursing home workers in over 5,000 nursing homes reduce injuries and illnesses through focusing on common hazards was initiated by then-Labor Secretary Robert Reich.

Skilled nursing home staffing patterns primarily divide into three categories: administrative, nursing, and patient and facility maintenance. All skilled nursing care was supervised or under the direction of a medical director. Patients had the option of selecting their primary physician. Most nursing home patients, however, chose their personal physician rather than the medical director as a primary physician.

Skilled Nursing Home Administrators. Management of daily facility operations was directed by the skilled home administrator. According to the Bureau of Labor Statistics, the median annual base salary of full-time general and operational managers was \$65,640.

One study constructed a profile of a typical long-term administrator by sampling 226 administrators in Oklahoma. Given that the administrator probably functioned as owner, president, or director of nursing, of the total sample, the study indicated that the 19 administrators of skilled and intermediate care nursing homes earned the highest salaries, ranging from \$28,000 to \$80,000 with a mean of \$43,000. Although a majority of skilled care administrators were college graduates, 111 of the total sample had only a high school education, and only 66 had a bachelor or master's. Implementation of OBRA would address the educational needs of administrators through development of standards of education, additional training requirements, and licensure.

Skilled Care Nursing Staff. Within the nursing staff, turnover rates remained relatively stable in the early and middle 1990s. Turnover rates for RNs and LPNs remained at a constant low rate of around 21 percent in the mid-1990s. The industry did suffer from tremendously high turnover rates for nursing aides, particularly in church-related and Medicare-certified facilities.

Starting salaries for nurses in this industry vary a great deal geographically. For example, in 1995, the median salary of a registered nurse in Atlanta, Georgia, with little or no experience was about \$27,560; whereas one in similar circumstances in New York was about \$38,584. A much dimmer picture characterized nurses' aides' starting salaries, which were often less than those of half of their RN and LPN colleagues.

Prior to OBRA, little attention was given to the training or career needs of nurses' aides. For the first time ever, OBRA introduced a requirement for newly-hired nurse assistants in long-term care facilities to receive at least 75 hours of state-approved training and competency testing. The statute also required that Medicare and/or Medicaid reimburse nursing facilities for the costs of conducting nurses' aide training programs. The American Health Care Association went a step further in proposing legislation that would create and fund career ladders for nurses' aides under a "pay back system."

AMERICA AND THE WORLD

In 2000, national health expenditures nearly reached \$1.3 trillion, with per capita spending of approximately \$4,480. In this context, most major countries such as Sweden, Canada, France, and the United Kingdom, had a higher ratio of government to private spending.

In Canada, public and private health care spending totaled about \$55 billion in 1996, with an additional \$1 billion used to purchase health care services in the United States. With the Canadian government depending more on the private sector for health care needs, there were more opportunities for U.S. firms specializing in medical matters.

Latin America provided more opportunities for U.S. health care businesses. Many Latin American companies in the late 1990s were beginning to incorporate parts of a managed care system, including capitation and salaried medical specialists. Such Latin American countries as Columbia demonstrated the desire for better health care; in 1993, health care spending there represented about 2 percent of the gross domestic product (GDP), and in 1998 it was 5 percent.

RESEARCH AND TECHNOLOGY

The health industry embraced computerized health care systems at a rapid rate. The estimated market in the early 2000s of \$15 billion for health care systems was expected to grow to \$50 billion by the year 2000. Computerization would facilitate quantification of data and comparison of nursing home services. Health Outcomes Management, Inc. began developing a shared database for it—Assurance Long-Term Care System software.

SIC 8052

INTERMEDIATE CARE FACILITIES

This industry includes establishments that provide inpatient nursing and rehabilitative services, but not on a continuous basis. Designated in particular are facilities certified under the Medicaid program to deliver intermediate care to the developmentally disabled.

NAICS CODE(S)

623311 (Continuing Care Retirement Communities)

623210 (Residential Mental Retardation Facilities)

623110 (Nursing Care Facilities)

INDUSTRY SNAPSHOT

The *Code of Federal Regulations* (4-1-93 Edition) has defined an intermediate care facility (ICF) as “a proprietary facility or a facility of a private nonprofit corporation or association licensed or regulated by the State . . . for the accommodation of persons, who, because of incapacitating infirmities, require minimum but continuous care but are not in need of continuous medical or nursing services. The term also includes additional facilities for the nonresident care of elderly individuals and others who are able to live independently but who require care during the day.”

ICFs provide inpatient nursing and rehabilitative services, predominantly to individuals with developmental disabilities. Though they operate 24 hours a day, services are not provided on a continuous basis. Personnel in ICFs must include 24-hour staff in addition to a licensed nurse on duty full-time each day. The term “developmental disabilities” generally refers to mental retardation. Therefore, ICFs often are designated as ICF/MRs—

Medicaid-funded facilities that provide residential care and services for individuals with developmental disabilities. ICF/MR services were used primarily by the aged (34.9 percent) and the disabled (6.9 percent), and not by low-income children or low-income adults.

Approximately 2.5 percent of the national population can be classified as mentally retarded. Although the majority of individuals with mental retardation or related conditions are able to live with their families or other adults in ordinary homes, other individuals with developmental disabilities are cared for in ICFs. Alternatively, individuals with developmental disabilities who require continuous medical or nursing care can be placed in nursing facilities. Many patients reside in ICF/MRs from youth until old age.

ICFs also can provide care to individuals with cerebral palsy, epilepsy, or other severe impairments of the central nervous system, not attributable to mental illness, that result in physical, mental, and behavioral disabilities comparable to those caused by mental retardation.

The individuals with developmental disabilities in ICFs typically require both health care and special services due to limited capabilities for self-care—housekeeping, language, social, and vocational skills. The health care offered by ICFs must include a consultation by a registered nurse at least once a week on the delivery of health care to individual inpatients and a licensed nurse on full-time duty for each day shift. Other services that ICFs provide include habilitation (training) in daily living, self-help, socialization, prevocational skills (such as focusing on tasks and observing time schedules), and vocational skills. Some ICF programs sponsor sheltered workshops, whereby disabled individuals receive less than minimum wages, calibrated to individual productivity, for economic output; and supported employment, whereby disabled individuals join nondisabled persons in work settings. ICFs sometimes provide recreational activity centers for inpatients and respite care (temporary care of individuals with developmental disabilities who generally reside with and are cared for by their families).

ORGANIZATION AND STRUCTURE

Licensed ICFs are categorized into three types by the California Department of Developmental Services (CDDS): larger facilities (more than 16 beds) that provide developmental, training, habilitative, and supportive health services to adults and children who have a primary need for developmental services but intermittent need for skilled nursing services; smaller, habilitative units with 4 to 15 beds that provide the aforementioned services, plus personal care in the least restrictive community setting to the above, who also have an ongoing but predictable need for intermediate care for skilled nursing services; and

finally, smaller units that provide the same services outlined above, except that they include nursing supervision and require recurring but intermittent nursing services not available above.

The Medicaid program, which is federally supported but state administered, is the primary source of economic aid for the ICF population, although other funds are available. In general, individuals with developmental disabilities qualify for Medicaid benefits by meeting the disability and financial criteria established for the Supplemental Security Income (SSI) funding. ICFs must meet federal standards intended to ensure that residents live in a safe environment, are supervised by qualified staff, and receive appropriate habilitation and medical treatment. Individuals who meet the disability criteria for Medicaid funding generally must be both mentally impaired (with an IQ of 50 or less) and functionally disabled (incapable of performing the ordinary activities appropriate for persons of their age). Financial eligibility is based upon the economic resources of the developmentally disabled individual and, if the developmentally disabled individual is a child less than 21 years old and living in the family household, on the economic resources of that individual's parents. Once a developmentally disabled child has been institutionalized for a month or more in an ICF or a comparable Medicaid institution, only income actually provided by the parents is considered in determining that child's financial eligibility for Medicaid.

BACKGROUND AND DEVELOPMENT

Prior to the development of ICFs, care of individuals with developmental disabilities had been the responsibility of individual states. Most individuals with developmental disabilities who did not live with their families were placed in large state facilities, generally in rural and isolated locations, that emphasized custodial care rather than treatment. By the 1950s, parents and advocates of individuals with developmental disabilities began to push for the reform of such large state institutions and for the development of community-based services, whereby individuals with developmental disabilities could receive special services but continue to live at home. In 1962, a panel appointed by President Kennedy recommended that only developmentally disabled individuals whose specific needs were appropriately met by institutional services should be placed within state facilities. This panel also recommended that federal and state agencies and local communities cooperate in the establishment of community services for individuals with developmental disabilities. In the 1960s and 1970s, with the press reporting on the often harsh conditions to which institutionalized individuals with developmental disabilities were subjected, the movement to reform and provide alternatives to large custodial facilities gained momentum.

Until the 1970s, individual states bore the economic burden of providing for individuals with developmental disabilities. In that decade, however, Congress began enacting legislation to provide federal funds for the treatment of developmentally disabled individuals. In 1971, Congress authorized the use of federal Medicaid funding for the services to be provided by ICFs. The purpose of Congress' substituting federal for state funding was to encourage reform by imposing federal standards on state facilities. Throughout the 1970s, federal expenditures on ICFs rose rapidly, initially due to an increase in the enrollment of individuals with developmental disabilities who qualified for Medicaid benefits. In 1981, the congressional Omnibus Budget Reconciliation Act authorized home- and community-based waivers whereby states could apply Medicaid funding for individuals with developmental disabilities to services provided in non-institutional settings. Since that time, increasing numbers of individuals who otherwise would have been directed to ICFs are being treated within their homes and communities.

Medicaid spent \$8.3 billion or 7.7 percent of its \$108.3 billion budget for ICFs for the mentally retarded in 1994, according to the *Health Care Financing Review* statistical supplement published in October 1996. ICF/MR costs rose \$6 per aged person from \$13 to \$19 during the period 1987 to 1994. In 1994, Medicaid served 159,000 ICF/MR persons, up an average of 4.5 percent per year for each year during the previous decade. In 1995 there were 200,000 ICF/MR recipients for whom \$10.4 billion was paid by Medicaid to vendors. This amount represented 9 percent of the total payments to all Medicaid vendors for all Medicaid services. By 1996 the total of Medicaid recipients in ICFs/MR had receded to 100,000.

CURRENT CONDITIONS

The nursing and residential care facilities market, of which ICFs are a part, took in an estimated \$116 billion in 2001, up 6.8 percent from \$108.6 billion the previous year. Medicaid spent \$9.3 billion, or 6.1 percent of its \$152.6 billion budget, for ICFs for the mentally retarded in 1999. All 50 states have at least one ICF/MR facility. Of the 40.4 million enrollees in Medicaid in 2003, 4.3 million were aged and 7.7 million were blind or disabled. ICF/MR benefits served approximately 129,000 people with mental retardation and other related conditions in 2003. Medicaid spending on intermediate care facilities has continued to rise over the last several years, as ICF facilities continue to decline.

The trend of mergers in this sector in the late 1990s continued into the new millennium. In 2001, Universal American Financial Corp. and its CHCS Services acquired the assets of Living Strategies Inc., an employer-

sponsored elder-care programs provider. Sun Prairie company purchased 12 assisted living centers from Alterra Healthcare Corp. in 2001. Res-Care Inc., offering services to the mentally disabled, was also purchased in 2000 by an investment group for a reported \$700 million.

INDUSTRY LEADERS

National leaders in sales among companies with interests in ICFs were Genesis Health Ventures, Multicare Companies Inc., Carondelet Health Corp., United Health Services Inc., RehabCare Corp., and Turtle Creek Health. Others included Eger Lutheran, Charter Care Corp., Peninsula United Methodist, Waterfront Health Care Center, and Dover Nursing.

Genesis Health Ventures Inc. provides basic and specialty health care services for the elderly. Under the Genesis ElderCare name, the company owns or manages 250 geriatric care facilities, including primary care physician clinics, pharmacies, medical supply distribution centers, rehabilitation clinics, and infusion therapy services. Revenues for fiscal year 2002 were \$2.6 billion, up 2.1 percent from 2001.

RehabCare Group Inc., a major provider of contract rehabilitation services, provides services for more than 3,000 hospitals, long-term care units, and outpatient facilities across the United States. RehabCare's subsidiary Health Care Staffing Solutions provides temporary therapist and nurse staffing services to nursing homes and hospitals. RehabCare had revenues of \$562.6 million in 2002.

United Health installed a private ATM and Sonet network to increase communications efficiency among its hospitals, corporate headquarters, and 25 physicians throughout its region. United Health evolved rapidly into a comprehensive delivery system by using a variety of methods to bring about real integration between physician and nonphysician leaders.

WORKFORCE

ICF employees include administrators and managers; nursing aides, orderlies, and attendants; licensed practical nurses and registered nurses; food service workers; cleaning supervisors, janitors, maids, and housekeepers; laundry and dry cleaning workers; maintenance personnel; and recreation workers.

In 1992, the average number of employees per establishment was 45 (compared to 13 employees per establishment for service industries as a whole). In proprietary establishments, the average number of employees was 50; in tax-exempt establishments, the average number was 46. In 1995, ICFs accounted for a total of 212,800 employees, of which 191,400 worked in nonsupervisory positions. The states with the greatest concentration of ICF employees were Ohio (23,402 employees, or 9.3

percent of the national total), Illinois (20,656 employees, or 8.2 percent of the national total), and New York (16,789 employees, or 6.6 percent of the national total).

In 1996, ICFs employed 220,700 persons who earned an average of \$8.51 an hour and worked an average of 31.8 hours a week. By 1999, ICFs in the United States employed 202,200 people.

SIC 8059

NURSING AND PERSONAL CARE FACILITIES, NOT ELSEWHERE CLASSIFIED

This classification covers establishments primarily engaged in providing limited nursing and health-related or personal care to individuals who do not need the degree of care and treatment that a skilled or intermediate care facility provides.

NAICS CODE(S)

623311 (Continuing Care Retirement Communities)

623110 (Nursing Care Facilities)

INDUSTRY SNAPSHOT

Facilities in this category are used mainly by the elderly and to a much lesser extent by psychiatric patients and the mentally retarded. These individuals may be healthy or require only a minimum of nursing care such as the administration of medicine or supervision of self-administered medications prescribed by a physician.

These live-in facilities run the gamut from nursing homes and board-and-care facilities to affluent retirement villages. Convalescent homes for psychiatric patients and group homes for the mentally retarded also fall in this category. Nursing homes in this category are classified as residential care facilities, but some are housed in skilled or intermediate nursing homes. Assisted living, congregate care, domiciliary care, and other arrangements also are in this classification.

Residential care facilities represent the second largest component of health services in this country because of the need to provide care for the growing number of elderly, but the concept of the nursing home is becoming outdated as a place for residential care. It has "become out of sync with the needs and expectations of our elderly population who require long term care," wrote Martins S. Valins in *Nursing Homes*. Valins is an architect specializing in the design of long-term care. He adds that "the root cause of the problem is that nursing homes were originally conceived out of a hospital model of care—an environment best suited to short-term medical treatment. Only recently did the nation begin to distinguish old age from illness. Becoming old does not necessarily imply that one will become ill or need constant medical supervision."

One of the most significant associations in the industry, the Assisted Living Federation of America, was founded in 1991 as the Assisted Living Facilities Association of America. The non-profit organization is a trade association devoted to the assisted living industry and the population it serves, and is comprised of more than 6,000 members, including providers of assisted living; state associations of providers; and others interested in promoting awareness, standards, and the interests of the industry. The American College of Health Care Administrators (ACHCA) is a professional society for 6,300 administrators in long-term care, assisted living, and sub-acute care. The ACHCA's mission to be "the premier organization serving as a catalyst to empower administrators who will define professionalism throughout the continuum of care." The American Health Care Association (AHCA) is a federation of 50 state health organizations and represents nearly 12,000 non-profit and for-profit assisted living facilities, nursing facilities, and sub-acute care providers.

ORGANIZATION AND STRUCTURE

While this category consists of group homes for the mentally retarded and convalescent homes for psychiatric patients, the largest segment and fastest growing area was the assisted living component. "Nursing and personal care" are frequently lumped together in statistical charts under nursing homes in general. This broader category was a \$11.1 billion industry in 1996, up from \$2.8 billion

in 1990. As a bundled group, it contained 1.75 million workers in November 1996, an increase of about 46,000 from November 1995.

The projected population of those 65 and older was expected to increase to 35 million by the turn of the twenty-first century, and to 40 million by 2010. More than 6,000 Americans turn 65 each day. The increase in the 85-plus population was predicted to grow by 94 percent in the next 25 years compared to a general population growth of 25 percent, according to Jonathan Goldman in a special supplement on health care in the *Institutional Investor*. Life expectancy for those who have reached 85 has increased 24 percent from 1960 to 1990 and was expected to increase another 44 percent by 2040. A growing percentage of those over 65 were employed from 1990 to 1995, and there was an increase in those 75 and over who were living alone.

More than 1.5 million persons spend between \$10 billion and \$15 billion annually to live in 40,000 assisted living communities in the United States. The assisted living industry was expected to grow from \$8 billion to nearly \$25 billion by the new millennium.

Assisted-living free-standing residences are easy to build and less risky than other entries into the retirement market, according to 80 percent of the respondents to a survey of 326 senior housing executives published in *Commercial Investment Real Estate* in 1995. They also require less capital investment and lower operating costs.

It was estimated that between one-fourth and one-half of nursing home residents could be in assisted-living at substantially less cost. With 90 percent of assisted-living funds coming from private individuals, nursing homes could house only Medicare/Medicaid patients. Average costs for assisted living are \$60 per day versus \$80 to \$100 for nursing homes. Nearly all assisted-living expenses are funded privately. However, 46 percent of all persons leaving assisted care do enter a skilled nursing facility.

Assisted living can provide a sense of independence and dignity. One of the problems is that Medicare or Medicaid funds nursing home stays, but does not cover assisted living. In some cases, this may foster upgrading or overstating a condition to become a nursing home resident. Oregon passed legislation allowing unlicensed staff to perform selected nursing duties. This has cut assisted-living costs to two-thirds of those for nursing homes. The primary objective of managed care is to move patients to the most appropriate and least expensive level.

During the first half of 1994, more than 25 assisted living retirement facilities with a total value of \$400 million were financed by Real Estate Investment Trusts

(REITs). The evolution of national assisted living chains have accelerated the role of REITs.

In the past, residential nursing care for the elderly was not reimbursed by payments from Medicaid, the federal and state health care insurance for low-income individuals. However, many states are seeking waivers so that Medicaid can fund a variety of residential care settings.

Residential care units often exist in skilled or intermediate nursing facilities that are funded primarily by the government. Every state has its own licensing regulations and its own methods of enforcing regulations. About 68 percent of total nursing home expenditures in 1997 were funded by Medicaid. Private insurers paid for 23 percent of costs. Assisted living facilities have higher operating margins because they are developed with private capital and their clients pay privately, allowing them to adjust charges accordingly.

Total nursing home industry revenues were estimated at \$74.3 billion in 1993, most of it from government reimbursement for patients requiring skilled or intermediate level nursing care. During 1997, there were approximately 17,000 nursing facilities with 1.8 million beds. The industry was projected to increase to 2.2 million beds by the turn of the new century. According to Social Security Administration projections, the number of individuals 75 and older will increase by 31 percent between 1991 and 2010.

There is a continuum of care among the types of facilities in this category, ranging from retirement villages and assisted living arrangements to nursing homes. Retirement villages offer gracious living in private homes or town houses, often with hotel-type services and recreation. Many of these developments offer medical backup, medical alert systems, and sometimes a connection to a nursing home. The most expensive retirement villages offer continuing care and a guarantee of increasing nursing care as needed for life. Less expensive retirement communities provide only short-term nursing care. More and more facilities offer a choice of care in a campus setting or in different wings of the same building.

Assisted living is based on the European model of residential long-term care. Residences are in homes, apartment buildings, or studio or one-bedroom apartments. Transportation, housekeeping, meals, personal care, and often other services such as adult day care, vision clinics, rehabilitation programs, and health promotion centers are provided. The number of such communities nationwide increased during the 1990s from 277 to 1,000.

Congregate-care facilities offer residents considerably more independence than nursing homes and board-and-care homes. Congregate-care arrangements provide

residents with small, private-living quarters, access to a shared kitchen and/or prepared meals served in a common dining room, but offer less medical and health related assistance assisted-living care.

Some elderly individuals live in subsidized housing units built by nursing homes, on the nursing home grounds, through a U.S. Department of Housing and Urban Development program. Though these arrangements offer access to some nursing home services such as medical screenings and meals, they often do not include nursing care.

Residential-care nursing offers a supportive and protective living environment for ambulatory residents, usually those older than 50, who have difficulty taking care of themselves but who do not require skilled nursing on a routine basis. Medicare has not paid for those in residential care, nor has Medicaid, though attempts are underway to change this. Medicaid traditionally has gone to licensed nursing homes providing skilled or intermediate care.

Increasingly, many facilities are choosing to offer a combination of all of these services, enabling residents to move through the system as needed. At the Ida Cuber House in the state of Washington, many options are available and there is considerable movement within the facility. Some residents want a permanent home and the option of progressing through levels of care as needed. Others are admitted for short-term stays and are expected to return to their homes.

At the Ida Cuber House, the nursing care center and assisted living program accommodate short-term care, with supportive therapies to return residents to the lightest level of care possible. Other residents who have initially come to the facility's nursing care center from the general community have been discharged to assisted living or to an independent living facility. On the other hand, as some residents become more functionally or cognitively impaired, they move to assisted living or to the nursing care center.

Board-and-care facilities, sometimes known as rest homes, provide little more than housing and meals. These facilities can house as few as four or five residents boarding in someone's house, to several hundred residents. In 1989, the U.S. General Accounting Office (GAO) estimated that there were 41,000 licensed homes of this type with 563,000 beds and additional unlicensed beds. The GAO also found that many failed to provide medical care, hygiene, and nutrition.

New York was among the first states to expose such abuse and fraud. It created a permanent special prosecutor to investigate such matters. In 1974, information was uncovered that millions of Medicaid dollars earmarked for the care of elderly indigent patients was instead going

into the pockets of certain New York nursing home owners and operators. By 1977, with the federal government spending \$16 billion a year on Medicaid, a Senate investigating committee found a substantial portion of the total was the result of "rampant fraud and abuse," brought about by state indifference. In 1977, Congress passed legislation establishing the State Medicaid Fraud Control Unit Program, which enabled qualifying states to become eligible for reimbursement of 90 percent of their expenses for fraud control expenditures.

BACKGROUND AND DEVELOPMENT

By the turn of the twenty-first century, the assisted living revenue was expected to grow from \$8 billion to \$25 billion—an annual rate of 25 percent.

Continuing-care retirement communities' (CCRCs) assisted living beds rose 12.8 percent to a total of 13,584. In 1994, 526 CCRCs had 68,895 independent living units, 12,369 assisted-living beds and 20,360 nursing beds.

CURRENT CONDITIONS

Despite increasing demands for residential care, fewer people are winding up in nursing homes than had been predicted. Healthier lifestyles and improved medical technology are allowing seniors to recover from strokes, broken hips, and other pitfalls of the aging process so that they do not need to live in a skilled nursing facility.

For that reason, the days of the skilled nursing home as the preferred model of long-term care may be numbered, as nursing home industry leaders warned their colleagues. They recommended that nursing homes either be converted to apartment-like facilities providing assisted living or to sub-acute institutions caring for the seriously ill, as part of a managed care network. Since the proposed health reforms in the mid 1990s were calling for moving health care delivery away from hospitals and into community-based satellite health care facilities, nursing home leaders suggest that homes serve the needs of non-resident seniors in their community as well as residents. Assisted living units built in conjunction with single-family homes and condominiums in a planned unit development or adjacent to a health center, are a newer concept that would allow older persons the opportunity to mingle with their children, relatives, or other young people in a neighborhood.

In the meantime, nursing homes continued to search for revenue and ways to reduce costs, hoping to become integrated into health care networks of hospitals and clinics. Medicaid was the fastest growing state expenditure. At a time when the states were in financial distress, many tried to hold down expenses by not issuing permits for the construction of new nursing homes. In 1997,

changes in the nation's health care system cut back on Medicaid reimbursement for elder care providers. By the late 1990s, some of the leading providers of care had filed for bankruptcy protection.

Prejudices about the elderly among health care professionals and other staff, plus attitudes that favor high-tech over low-tech treatment, may also interfere with advances in residential care. Worse than prejudices are the repeated instances of neglect among residential facilities caring for the elderly, leading to complaints that the residents are merely being "warehoused." Reports of such instances have continued to prompt investigations. Nursing home inspections have become more stringent, leading to the discovery of more abuses. In 1996, there were investigations of nursing homes nationwide. Nursing home abuse has led states such as New York to propose criminal checks on nursing aides and stringent penalties for convicted abusers. Nursing homes continued to be plagued by accusations of mistreatment into the new century.

The "hottest niche for the future," according to Sandy Lutz in *Modern Healthcare*, appears to be assisted living and low-intensity medical services housing. Residential care was number one on the U.S. Small Business Administration's list of fast growing markets, with most of the growth coming from assisted-living facilities.

INDUSTRY LEADERS

Leaders were not without challenges in the late 1990s and into the twenty-first century, facing bankruptcies and a continuing stigma toward the nursing home industry. Many organizations sought to change the public's concept of nursing homes from dull, sterile places to elegant manors with delicious food, fun activities, and home or resort-like atmospheres.

At the end of the 1990s, leading public companies were: Sun Healthcare Group Inc., Beverly Enterprises Inc., Assisted Living Concepts Inc., Manor Care Inc., Marriott Senior Living Services, and Mariner Post-Acute Network Inc.

Changes are rapidly occurring in the insurance industry to provide for long-term care coverage. TIAA, a major retirement fund for college teachers, began to offer such insurance for family, including parents, in 1997. Other retirement systems and private insurers will most likely follow. There also is a movement to obtain federal assistance for assisted living as a lesser-cost alternative to nursing homes.

WORKFORCE

Personnel at residential care facilities will vary according to the number of residents and services provided. Staff may be employed by the facility or in cooperation with an outside agency. In nursing and convalescent

homes, there is a manager or administrator, plus personal care attendants on staff who assist residents with personal needs (such as feeding, dressing, and bathing), nurses who assist residents with education and the administration and supervision of medication, physical therapists, activities coordinators, food service managers, and maintenance staff.

Many states require the administrator or manager of nursing homes to complete a state-approved certification program within one year of being hired and require them to take continuing education courses annually from a state board of nursing, social work, or other such agency.

Employment in residential care facilities in general represents 18 percent of the jobs in the health services. Jobs in this sector increased by 3.9 percent during the 1980s, adding a 550,000 employee increase to the industry. Early in the twenty-first century, nursing homes and personal care facilities employed about 1.6 million workers at approximately 21,000 work sites. By 2005, this figure is expected to rise to 2.4 million workers. Employment in this industry has been affected little by the changes in the economy.

One new and possible trend is the movement toward a holistic or universal work attending to all the daily needs of a resident. The same person will assist with meal services, light housekeeping, and laundry. Retraining staff from task orientation to resident orientation is a major challenge. Employment strictly in this industry was 229,000 in 1995, an increase of 7,000 from 1994. If the average workweek and wage is the same as that for the broader category of nursing and personal care, it is 32 hours and \$9.06 per hour, respectively.

SIC 8062

GENERAL MEDICAL AND SURGICAL HOSPITALS

This industry consists of establishments primarily providing general medical and surgical services and other hospital services in a hospital setting. This grouping excludes specialty hospitals classified in **SIC 8069: Specialty Hospital, Except Psychiatric** and psychiatric hospitals covered in **SIC 8063: Psychiatric Hospitals**.

NAICS CODE(S)

622110 (General Medical and Surgical Hospitals)

INDUSTRY SNAPSHOT

According to the 2002 *Statistical Abstract of the United States*, the United States had 5,810 general and surgical hospitals in 2000, down from 6,965 in 1980. Of the total facilities in 2000, approximately 3,000 hospitals had more than 100 beds. Made up of both non-profit and profit-making establishments, they employed slightly more than 5 million workers and took in about \$412 billion in annual gross revenues. This amount accounted for nearly one-half of the nation's total annual health care employment and health care expenditures, placing hospitals at the center of the health care industry. Although hospital revenues have increased substantially every year, from \$102 billion in 1980 to \$412 billion in 2000, or 404 percent, costs incurred by hospitals have also increased, from nearly \$92 billion in 1980 to over \$395 billion in 2000, or 429 percent.

In recent years, hospitals in the United States have been increasingly under pressure by government and businesses to provide higher quality service at lower costs while increasing access and preserving patient choice. A move to emphasize outpatient over inpatient care and efforts to use health maintenance organizations (HMOs) and other cost-cutting measures implemented by employers dramatically altered the business in the 1980s and 1990s. One result was a trend toward more academic medical centers, more ambulatory surgery, and fewer community hospitals, which declined in total number by 17 percent after 1981. As pressure to enact such changes continued, general medical and surgical hospitals approached the end of the twentieth century with persistent uncertainty about the direction and shape of their industry's future.

ORGANIZATION AND STRUCTURE

General and surgical hospitals are generally categorized as non-profit, profit-making, and both state and local government establishments. The 2002 *Statistical Abstract of the United States* reported 3,003 nonprofit,

749 profit-making, and 1,163 government hospitals in the United States. Nonfederal community hospitals, which included short-stay, general care hospitals and excluded federal, long-term, and psychiatric facilities, accounted for about 84 percent of the 932,000 available beds, providing 2.9 beds for every 1,000 U.S. residents. Beds available in federal hospitals were cut by more than half after 1980, from 117,000 to just 53,000. During the 1990s, community hospitals increasingly became part of multihospital systems, where one owner or an ownership group owned more than one hospital. The Public Citizen Health Research Group found that 1 in 12 community hospitals across the United States was involved in merger activity in 1995 alone.

Hospitals receive their revenues from different sources for the services they provide to patients. In the early 2000s the largest source of income to community hospitals came from Medicare and Medicaid programs. Of the \$1.4 trillion spent on health care in 2001, governmental funds provided 46 percent, or \$648 billion. Private insurance paid 35 percent, or nearly \$487 billion, and out-of-pocket expenses accounted for 15 percent, or \$210 billion. The remaining 4 percent came from other sources of revenue.

Hospital expenses are strongly affected by legislation, costs of medical technology, and trends in medical practice. As these expenses rose throughout the 1990s and into the 2000s, on-site administrative, food service, maintenance, and laundry support often were streamlined or contracted out in response. To counteract rising costs, many hospitals also attempted to expand their revenues by increasing their role in community health maintenance efforts beyond traditional emergency, obstetrics, and inpatient care to include disease prevention and patient education programs such as weight reduction, drug rehabilitation, prenatal care, and pediatric wellness.

Internally, hospitals are structured around an administrative staff that oversees nursing and administrative functions and separately operated medical staff and ancillary services—such as a pharmacy and the services of various therapists.

BACKGROUND AND DEVELOPMENT

Early hospitals were established by governments and religious groups for care of special segments of the population, such as the poor, the military, and slaves. In Europe, doctors and other medical staff were not paid for their services in hospitals as such services were regarded as Christian charitable work. Records show that during the Middle Ages, medical staffs of charity workers were divided into two groups that rotated their work each month.

Starting in the thirteenth century, hospitals greatly increased in number throughout Europe. With this, hospitals gradually became more secular and began paying

their medical staffs. At this time, and up until the eighteenth century, private patients in a hospital ward were virtually nonexistent. Hospitals were still regarded as places for the poor, while wealthy patients were usually treated in their homes by hired physicians.

By the late eighteenth and early nineteenth century, another form of hospital emerged. “Voluntary” institutions were developed with the idea of providing charitable treatment for all segments of the population. These hospitals grew into the “non-profit” U.S. establishments of the twentieth century.

Early hospitals in the United States followed the pattern of their European predecessors; most hospitals developed out of houses and treatment centers for special groups of the population. Many of these early U.S. hospitals were often quickly built in order to confine the spread of contagious diseases. The first hospitals in the United States were Bellevue Hospital founded in New York in 1658, and Philadelphia Hospital, founded in 1713. Both institutions were originally intended for the insane, the aged, and the poor.

In 1752, the Pennsylvania Hospital was founded as a voluntary hospital to serve both the poor in large public wards and other patients in private rooms; these affluent patients paid both the physician and the hospital for their services. However, hospitals in Europe and the United States were still viewed as places for the poor until the nineteenth century, when medical technology made large advances. During this period, hospitals became equipped with anesthesia (considered by experts to represent a turning point for hospitals), new medicines, and more sterile environments, making hospitals safer places for treatment.

The nineteenth century brought about other significant developments for hospitals. Hospitals became the centers of medical education and research. In addition to doctors, other medical staff, most notably nurses, became professionals in their own right, developing their own professional standards and certifications. It was also during this century that the health insurance industry started. Patient insurance began in Germany in 1883 and was operated and paid for by the German government; in the United States the idea was taken over by private insurance companies.

The twentieth century witnessed remarkable changes in this industry. Technological advances in radiology meant earlier diagnosis of many fatal ailments—in particular cancers—and treatment of those conditions. As many fields in medicine have developed, such as obstetrics, pediatrics, and transplant surgery, so too have departments providing these services in hospitals.

In response to the post-war baby boom, the 1950s saw a large growth in the number of hospitals throughout the country. At this time, medical schools and teaching

hospitals grew to meet the demands of the new generation. From 1970 until 1990, the role of hospitals in U.S. society and their function within the larger health care industry changed significantly. During this period, the number of U.S. hospitals began to decline from 7,123 with 1.6 million beds, to 6,400 with 992,000 beds. Additionally, the rate of occupancy in hospitals also dropped from 80 percent in 1970 to 66.1 percent in 1994. The following year, the *Journal of the American Medical Association* projected hospital admissions would decline an additional 26 percent and average length of stay would dip another 11 percent by the end of the century.

This ongoing reduction in the number of hospitals and the drop in occupancy rates reflected a general trend away from traditional inpatient care to procedures that could be done just as effectively but even more economically on an outpatient basis. Outpatient visits at all U.S. hospitals accordingly rose from 181 million in 1970 to 454 million in 1994. Much of this movement resulted from government legislation and health insurance plans offering more coverage for less costly treatments that did not require overnight stays. Additional growth was spurred by technical advances in outpatient surgical procedures, which permitted the number of all surgeries performed outside a traditional hospital setting to rise from 24 percent in 1983 to 55 percent in 1993.

Since the 1970s the industry has also seen proprietorship of hospitals shift from a climate in which the ownership of individual establishments was predominant to one in which chains of hospitals prevailed. This situation enabled hospitals to share technology and management resources across their chains of establishments and cut costs due to economies of scale. Moreover, it allowed hospital owners to begin specializing their ownership services by dividing hospitals into the three main industry groups: general medical and surgical, psychiatric, and other specialties. The consolidation was not without problems, however, especially as it changed some non-profit institutions into for-profit enterprises, which do not always stand in high regard.

Services Offered by Hospitals. General medical and surgical hospitals provide a variety of hospital-based health services. According to the 1996 *Statistical Abstract of the United States*, more than 92 percent of hospitals in the United States had emergency departments. For AIDS sufferers, nearly 74 percent of hospitals offered general inpatient care (up from 61 percent in 1992), while 6.7 percent offered specialized outpatient AIDS programs. Therapy services also made up a large portion of services provided by general medical and surgical hospitals: 91.2 percent of these hospitals offered respiratory therapy services, 85.5 percent had physical therapy programs, and 55.5 percent assisted with occupational therapy. Addressing the needs of the aging popula-

tion, U.S. hospitals increased their geriatric services during the 1980s and 1990s. By the mid-1980s, nearly two-thirds of all hospitals offered one or more geriatric services. These included geriatric response, which monitors elderly patients in their homes and links them with hospitals in case of emergency; respite care facilities; and geriatric acute care units. A small number of hospitals developed Alzheimer's diagnostic and assessment services and adult day care facilities. However, the fastest growing field within geriatric care is psychiatric services; in 1992, 27 percent of general hospitals offered geriatric mental health programs. According to Paula Eubanks in *Hospitals*, the majority of geriatric mental health programs were only available at non-community hospitals like large university hospitals and hospitals run by the Department of Veteran Affairs.

According to the American Hospital Association, 87 percent of general medical and surgical hospitals in the United States had an official outpatient department in 1993, while almost 94 percent offered at least some outpatient surgery services. That year, outpatient surgical procedures accounted for 55 percent of all surgeries performed in community hospitals. About 85 percent of all hospitals had blood banks, more than 66 percent had birthing rooms, and nearly 85 percent had ultrasound. Approximately 21 percent offered alcohol/chemical dependency care, and 23 percent had psychiatric services. In the 1990s, many hospitals also opened outpatient centers that specialized in the treatment of pain. These outpatient pain clinics varied in size and the specific types of treatments offered. With the growth in managed care and patients seeking alternatives to costly inpatient stays, these clinics were expected to increase in the late 1990s. Another significant growth area for outpatient services was in home health care; in 1993, 41.5 percent of all community hospitals offered home health care services.

In the 1990s, community hospitals also provided a growing array of health promotion services. In 1993, the American Hospital Association reported that more than 88 percent had patient education programs. Approximately 60 percent of all hospitals offered worksite health promotion programs.

Medicare and Medicaid. Medicare and Medicaid are federally funded health insurance programs that provide assistance to patients over 65 years of age and patients with low incomes or end-stage kidney disease or disabilities. In 1993, Medicare paid for 51 percent of all inpatient hospital visits and 8 percent of outpatient hospital costs; Medicaid paid for 27 percent of inpatient stays and 6 percent of outpatient charges. The Hospital Insurance (HI) program within Medicare pays for care given at hospitals, home health agencies, hospices, and skilled nursing facilities. In 1997, HI payments totaled \$137.8 billion for 38 million enrollees.

The introduction of Medicare and Medicaid programs in the early 1970s significantly impacted this industry. In 1970, Medicare and Medicaid accounted for just over 6 million patient admissions to general medical and surgical hospitals and paid for \$5 billion of their hospital charges; by 1993, Medicare alone paid \$76.3 billion in inpatient hospital charges. Between 1980 and 1990, the number of Medicaid recipients receiving inpatient treatment rose by 913,000 annually, while the number of Medicaid patients receiving outpatient care rose by 2.6 million annually. By 1995 Medicare was the largest single insurer in the United States, covering about 14 percent of the entire population. As the population continued aging and additional advances were made in medicine and technology, Medicare funds for people over 65 years of age became the largest portion of all hospitals' government-funded health coverage.

Medicare and Medicaid programs also affected hospital management, requiring greater training in non-medical matters in order to deal with paperwork regulations and various service requirements. But cutbacks and changes in the payment systems in Medicare and Medicaid during the 1980s and early 1990s had their largest impact on the industry's bottom line. In 1991 alone, \$43 billion was cut from the Medicare budget, and in 1996 President Clinton vetoed a Republican balanced budget plan that would have mandated Medicare cuts of \$270 billion and Medicaid cuts of \$163 billion by the year 2000; the president's own alternative called for \$124 billion in Medicare reductions, so even though no compromise was immediately reached, the hospital industry readied itself for even more changes.

As part of the overall realignment, the Health Care Financing Administration (HCFA), which managed Medicare, proposed fixed-rate pricing on many medical services. This new pricing system was projected to bridge the gap between the salaries of specialist physicians and general or family practitioners and was expected to improve the accounting involved in ambulatory care services.

Mergers. Mergers and joint ventures played important roles in this industry as a way of sharing the costs of needed technology and trimming redundant costs. Moreover, as the occupancy rate increased in hospitals across the country, joint ventures opened means of sharing liabilities to reduce the impact of financial downturns on individual hospitals.

In the late 1980s, the federal government imposed antitrust rulings in two highly publicized cases prohibiting the merger of certain hospitals. Following this action, a few mergers per year were investigated by federal agencies. As a result, the American Hospital Association ran a campaign to have antitrust laws relaxed, believing such laws hindered mergers and joint ventures

between hospitals. As of the early 2000s, the government had not reversed any of its rulings concerning antitrust laws over hospital mergers. However, this issue remained important to this industry as it moved into the twenty-first century.

Malpractice. By the 1990s, the American Medical Association was estimating that \$15 billion of the nation's health costs went towards "defensive medicine," that is, additional tests and diagnostic procedures carried out to protect doctors from malpractice claims. For this reason, the increase in malpractice cases, particularly during the mid-1980s, increased the use of hospital laboratory facilities. However, malpractice cases were more noted for negatively affecting this industry. Because hospitals have more insurance and larger revenues than individual doctors, they are often the targets of such suits. In the early 1990s, hospitals responded to malpractice cases by increasing medical staff decisions and reviews of doctors' procedures. Hospitals also started protecting their assets by placing them in separate corporations or endowments.

Hospitals and Pollution. Establishments in this industry have long dealt with the problem of waste disposal. Hospitals generate large amounts of general waste, such as paper and food; and they also have to dispose of chemical and pathogen waste. The AIDS epidemic has increased concern over waste containing live pathogens, which could be contaminated with the AIDS virus.

Until the late 1980s, hospitals in United States disposed of medical wastes by using on-site incinerators, which were effective in burning wastes, but polluted the air. In 1988, nine states passed medical-waste disposal legislation, and in 1989 an additional 22 states passed these types of laws. By 1990, new government standards, mostly at the state level, affected an estimated 6,000 hospital incinerators. Complying with the new standards imposed costs of between \$500,000 and \$1 million on each hospital.

To avoid the direct financial burden of upgrading incinerators, small hospitals, especially those in rural areas, banded together to share regional incinerators which met the new air pollution standards. However, this approach introduced new costs related to hauling waste to the incinerator.

As a result of overexpansion of facilities in the 1970s and the economic recession at the beginning of the 1990s, hospitals struggled without easy access to capital and charitable funding. Between 1985 and 1995, according to *Modern Healthcare*, approximately 600 acute care hospitals closed and eliminated about 180,000 beds. Even so, some believed that with the ongoing fiscal belt-tightening as many as 447,000 unnecessary beds still remained—enough to fill almost 2,500 hospitals.

In order to deal with the various financial problems they faced some companies in this industry increased their psychiatric units and rehabilitation clinics, both of which were high-profit facilities. Nearly all hospitals expanded their outpatient services, which generally brought in lower profits than inpatient units but yielded continuous revenues. Many were automating routine administrative tasks.

According to *Hospitals*, this industry also entered the 1990s suffering from a public image problem that affected the non-profit status of most U.S. hospitals. This situation resulted from public criticisms of hospital pricing practices, the growing number of malpractice cases, and the way in which hospitals took on a more business-like approach to managing their establishments. The decision by 447 formerly single-unit community hospitals to merge with larger corporations in 1995, along with the conversion that year of 58 non-profit hospitals to for-profit status, did not help the industry's overall public image.

The business-like approach that generally marked the entire industry was characterized by "quality management." Instead of leaving the quality of care in the hands of individual practitioners, hospitals instituted measures to prevent faulty processes from occurring. According to Julia Flynn Siler and Sandra Atchison in *Business Week*, quality management was originally adopted by hospitals to improve food service and lower the length of patient stays; however, in the 1990s this approach was also used for clinical decisions and processes.

The shift towards more outpatient care also affected hospital management. Although hospitals accounted for outpatient care separately from inpatient treatment, management of the two types of services was traditionally under one supervisor. However, in the 1990s hospitals started moving towards specialized management, which would unite the various types of outpatient services while keeping them separate from inpatient care.

CURRENT CONDITIONS

At the end of 2002 hospital industry advocates were calling for increased provider payment relief for 2003, noting that more than half of the members of the American Hospital Association (AHA) reported losing money on Medicare in 2000. In addition, around 60 percent lost money in the Medicaid program, and about one out of every three hospitals reported a year-end loss. They also noted that profit margins in 2001 were at the lowest they had been since 1993. The annual profit margin for 2001 was 4.2 percent, down from 4.6 percent the previous year. Total revenue for U.S. hospitals grew 7 percent, to \$400.6 billion in 2001, up from \$373.5 billion in 2000. However, costs also increased 7 percent, from \$356.5 billion in 2000 to \$383.7 billion in 2001. The AHA listed higher costs for labor, new technology, and medical liability

insurance, as well as bioterrorism preparedness, as factors in the increase in expenses.

Hospitals can anticipate a growing customer base as the average age of Americans continues to rise. However, ongoing cuts in Medicare and Medicaid, rising insurance premiums, and increased costs of medical technology, as well as a new focus on emergency preparedness in the wake of the terrorist attacks of September 2001, could simply leave hospitals with more patients on which to lose money.

INDUSTRY LEADERS

In 2002, industry leaders were HCA Corporation, Tenet Healthcare Corporation, and Ascension Health.

Columbia/HCA Healthcare Corp., created by the 1994 merger of Columbia Healthcare Corp. and Hospital Corp. of America, became the largest hospital company when it merged again with Healthtrust in 1995. The new \$17.7 billion-enterprise controlled 318 hospitals, staffed 62,277 acute care beds, and employed 240,000 workers. *Standard & Poor's* reported that the 1994 merger enabled the company to save \$130 million annually through consolidation and lower purchasing costs; the 1995 merger, it predicted, would lead to an additional \$125 million in savings each year.

In 1993, before the mergers, Hospital Corp. of America (HCA) owned 96 hospitals in 21 states. Despite sales of over \$4 billion in 1991, this company recorded a loss in that year of \$5.4 million. However, in 1992, it rebounded with earnings of \$28.2 million on \$5.13 billion in sales revenues.

The following year, it received public attention as part of the Government Accounting Office (GAO) report on hospitals found to be overbilling Medicare. According to the report, in 1991, Hospital Corp. of America sought Medicare payments for over \$1.1 million in questionable non-medical costs. The company's account for these overbillings was \$75,000, pointing out that it was a small fraction of the \$114 million the hospital received from Medicare in 1991.

Columbia/HCA Healthcare Corp. sought to reinvent itself in the late 1990's by halting its expansion plans and trimming operations. By 2002, after several name changes that eventually became simply HCA and after the sale of 137 hospitals—nearly half of its 347 facilities—and its prescription benefit unit, HCA owned and operated 172 general, acute care hospitals and 79 ambulatory surgery centers, and employed 178,000. HCA reported \$833 million in net income on \$19.7 billion in sales in 2002.

In the early 2000s Tenet Healthcare Corporation was the second largest hospital chain in the United States, owning or operating 116 hospitals in 16 states and an

additional hospital in Barcelona, Spain. Tenet, which operated a vast regional health care delivery system, recorded \$785 million in earnings on \$13.9 billion in sales in 2002. Ascension Health, the number one Catholic hospital system as well as the largest not-for-profit healthcare system in the United States, operated a network of 60 Catholic hospitals, as well as nursing homes, psychiatric wards, and other facilities in 15 states and the District of Columbia. Ascension was formed in 1999 by the merger of Daughters of Charity National Health System and the Sisters of St. Joseph Health System. Ascension reported a net income of \$111 million on revenues of \$7.7 billion in 2002.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, the hospital industry accounted for 5,054,820 jobs in 2001. Mean annual salaries ranged from \$128,390 (surgeons) to cafeteria help (\$16,900). Healthcare practitioners and technical occupations, including doctors, nurses and therapists, accounted for over half of all jobs. Nurses made up approximately one quarter of the hospital industry workforce, with an annual mean salary of \$49,140. Office and administrative support accounted for just over 15 percent of the workforce, with a mean annual salary of \$25,750. Health support occupations, including health aides, orderlies, and attendants, represented nearly 13 percent of jobs, with a mean annual salary of \$22,680.

The overall job outlook for people working in hospitals was not as good as in the early 2000s as it was at the start of the 1990s when community and non-community hospitals were experiencing severe worker shortages. According to James C. Franklin in *Monthly Labor Review*, hospital staffs are expected to expand but at the slowest pace of all industries in the health care sector through 2005 as consolidations and cost-cutting efforts continue.

Since the 1980s, the number of hospitals has declined nationwide; nonetheless, up to the beginning of the twenty-first century there was a shortage of nurses. As job prospects for nurses level out in the 2000s, most areas of growth will be in home health, long-term, and ambulatory care facilities. Whereas RNs earned a mean annual salary of over \$49,000, licensed nurse practitioners, which accounted for almost 4 percent of all hospital jobs, earned a mean annual salary of \$30,470.

Job prospects for physician's assistants (PAs) are expected to be high through 2006. Due to an emphasis in the industry on cost containment, PAs will be looked upon as a favorable alternative to hiring more expensive physicians. PAs can assist in medical and surgical procedures as well as provide primary care to patients. In 2001, the median income for full-time physician assistants in clinical practice was \$63,080.

The increase in hospital paperwork generated by private insurance companies and government insurance programs created growth for specialized occupations, such as medical record technicians. These workers are responsible for patient records and for providing statistical reports to insurers and hospital administrators. In 2001, medical records technicians held about 54,400 jobs in hospitals and had median annual salaries of \$26,170.

AMERICA AND THE WORLD

This industry as part of the larger health care industry is expected to experience considerable growth in overseas markets as countries in western Europe expand their privatized services and countries in eastern Europe seek to fill shortages in general medical services. Only since the late 1970s have American hospitals sought business overseas, and at first they opened only a few hospitals in Canada, Great Britain, and Spain. *Business America* reported that American health care providers were increasingly looking toward countries in Europe and Asia, as well as in the Middle East, for expansion opportunities in 1996. U.S. enterprises also had established more than 12 arrangements with local providers in the former Soviet Union and Eastern Europe.

RESEARCH AND TECHNOLOGY

Technological advances since the 1970s largely contributed to the number of outpatient surgeries available in hospitals. Less invasive procedures were made possible by radiology and new surgical instruments and techniques.

In inpatient treatment, the last half of the twentieth century witnessed tremendous advances in transplant surgery. In 1990, over 10 percent of community hospitals performed organ transplants. With over 20,000 patients on waiting lists for transplants, continued research and technological developments were expected to address the increasing needs. AIDS treatment and research was another area in which growth was expected to continue. Services for AIDS patients were likely to change with advances in drug treatments, such as AZT and Pentamidine. Moreover, research continued in specialized physical and respiratory therapy for AIDS sufferers.

Larger hospitals have traditionally had an easier time investing in sophisticated medical technologies and gathering the expertise necessary to utilize them.

SIC 8063

PSYCHIATRIC HOSPITALS

This industry consists of establishments primarily engaged in medical services for the mentally ill. Hospital establishments primarily engaged in providing health care for the mentally retarded are classified in **SIC 8051: Skilled Nursing Care Facilities**.

NAICS CODE(S)

622210 (Psychiatric and Substance Abuse Hospitals)

INDUSTRY SNAPSHOT

Psychiatric hospitals are primarily inpatient, acute care units. A growing public awareness of mental disorders between 1970 and 1992 led to a significant increase in the number of these establishments and in the range of services they provided. U.S. Census Bureau figures revealed the total number of psychiatric hospitals in the United States peaked by 1992, with 919 establishments in operation—an increase of nearly 17 percent over the 1987 figure. Between 1984 and 1991 individual hospital admissions rose by 27 percent until the number of psychiatric hospital beds reached approximately 121,000 in the United States, according to the American Hospital Association.

The trend toward desinstitutionalization took over in the late 1990s and early 2000s, drastically reducing the number of state hospital beds for persons with severe mental illnesses and greatly changing the mental health services system. Excluding government-owned facilities, in 1995 there were 433 psychiatric hospitals compared to 315 in 1999. The number of beds shrank from 43,497 in 1995 to 29,937 in 1999. As nursing homes took over a bigger role in the delivery of mental health services, controversy arose as to the appropriateness of care for the mentally ill living in and seeking treatment in nursing

homes. The situation worsened for the mentally ill during the recession in 2002 and 2003, when many mental health programs were being targeted for cuts statewide. Private insurers were not filling the gap left by government programs, with one study noting that the amount of resources devoted to psychiatric care among private insurers had dropped 54 percent in the 10-year period ending in 1998. Due to these reasons, several state mental hospitals were closing and private hospitals were filing for bankruptcy protection in mid-2002. Community mental health centers, a less costly alternative to inpatient psychiatric care, were overrun and more hospital emergency rooms began taking on the care of patients with no other alternatives. When a psychiatric patient enters an emergency room, often uninsured and unable to pay out-of-pocket costs, he or she must be held until the hospital can find a bed in a psychiatric facility, taking hours or even days. As a result, many hospitals and universities began to expand their mental health facilities.

ORGANIZATION AND STRUCTURE

Psychiatric hospitals fall into one of two categories: nonprofit or profit making. Nonprofit entities include government-administered facilities and charitable institutions. In the mid-1990s, nearly one-half of the nation's psychiatric hospitals were either nonprofit or government entities. In keeping with this configuration, the standards and revenues of the industry are largely shaped by government legislation.

BACKGROUND AND DEVELOPMENT

Historical Evolution. The first psychiatric hospital founded in the United States was the Eastern Lunatic Asylum in Williamsburg, Virginia in 1772. It was around this time that Dr. Benjamin Rush had introduced a medical and humanistic approach to mental illness in the United States. However, mental illness was regarded, as it had been for centuries, as the result of physiological disorders. Connecting neurotic or hysterical behaviors with the mind did not develop until the late nineteenth century, with the origin of psychoanalysis.

The development of psychoanalysis altered the patient treatment at psychiatric hospitals as the psychoanalytical methods better explained diseases and offered more cures. However, psychoanalysis programs took years for patients to complete and were not suitable for most hospital settings. Eventually, psychoanalysis began to take place mostly in doctors' offices and clinics.

The 1920s marked significant change for psychiatric hospitals in the United States, as a result of developments in psychiatric medicine. In the 1920s, the connections between bacterial infection and brain functions were identified. Moreover, techniques for treating neurosis symptoms and deep-seated psychoses were also devel-

oped. In 1938, a neuropsychiatrist in Italy began using electronic shocks for the treatment of many severe mental disorders. Previous techniques used toxic chemicals, which often produced dangerous side effects. Shock treatment soon became commonly used at psychiatric hospitals in the United States.

It was also during the 1930s that psychosurgery became a popular technique for altering behavior. The first lobotomy was performed in 1935; however, public opinion was against the use of lobotomies because results were irreversible and were generally worse than the original illnesses. In response to public opinion and with the development of more medications to treat severe cases, the number of lobotomies performed at psychiatric hospitals in the United States started to drop at the end of the 1940s.

In the 1950s psychiatric hospitals began to use stimulants, tranquilizers, and vitamin therapies to treat patients. The number of patients confined to hospitals dropped considerably, because these therapies allowed patients to control their disorders on an outpatient basis or through services provided at psychiatrists' offices and clinics.

After 1970 the use of psychotherapy grew substantially, a move that shifted outpatient care toward more group-oriented psychotherapy programs, either with family or other individuals. Psychiatric hospital care shifted from emphasizing a cure to helping patients cope with their mental illnesses and disorders. Drug therapy augmented psychotherapy as a standard means for dealing with the majority of mental illnesses and disorders. Along with psychotherapy, drug treatment programs played a major role in the overall services offered by psychiatric hospitals.

Modern Services. By the late 1900s, psychiatric hospitals in the United States expanded services and offered a variety of inpatient and outpatient services. The nature of mental illnesses and its treatment dictated that inpatient care at psychiatric hospitals be linked to routine outpatient treatments, which typically continued after the patient's release from inpatient care. Follow-up treatment habitually involved psychosocial services in addition to medical treatment. Over 50 percent of psychiatric hospitals offered outpatient services. In addition to psychotherapy conducted as part of patient treatment, other therapy programs were incorporated into the services provided at psychiatric hospitals after 1970.

Most prevalent among the outpatient services offered at psychiatric hospitals was substance abuse treatment, or dependency outpatient clinics, with over 40 percent of all psychiatric hospitals having such clinics. Also, by the 1990s 67 percent of psychiatric hospitals in America offered occupational therapy to help patients maintain daily living and work skills. Nearly 90 percent of psychiatric hospitals used recreational therapy as an

integral part of treatment; physical therapy and speech therapy were both employed in over 25 percent of psychiatric hospitals. In contrast to other types of hospitals, psychiatric hospitals do not perform many surgeries; during the peak facility year of 1992, psychiatric hospitals performed less than 10,000 surgeries.

Some industry growth was attributed to increases in patient insurance coverage for mental health care and came as a result of changing social attitudes during the 1980s when the image of mental health care lost much of its stigma. Demand for many services increased, and insurance companies expanded coverage of these services in response to public pressure. Consequently, many people who previously avoided psychiatric treatment for financial reasons sought to obtain assistance. Between 1985 and 1990, the number of insurance providers for mental health care increased 500 percent, a trend projected to continue into the twenty-first century.

Psychiatric hospitals in the United States also developed comprehensive health promotion services. In the 1990s, more than 62 percent of psychiatric hospitals offered patient education services. Outside of the hospital establishments, 35 percent of psychiatric hospitals were engaged in community health promotion and an additional 37 percent in work-site health promotion.

Key among the expanded service roster developed by psychiatric hospitals were programs that addressed the psychiatric and psychological problems of children and adolescents. In 1986, more than 20 percent of the patients in psychiatric hospitals were under 18 years old, and by the 1990s more than 70 percent of psychiatric hospitals offered programs specially designed for this age group. Such programs emphasized outpatient care, in an effort to encourage teens to seek treatment without the fear of inpatient hospitalization.

Modern psychiatric hospitals implemented specialized services for geriatric patients as well. In the 1990s, nearly 20 percent of psychiatric hospitals in America had comprehensive geriatric psychiatric assessment facilities. More than 12 percent had Alzheimer's diagnostic programs and 11 percent offered geriatric acute care units. Psychiatric hospitals met the needs of the aging population with adult day care programs and geriatric clinics.

Since the discovery of the AIDS virus in the mid-1980s, psychiatric hospitals strived to meet the needs of the growing number of AIDS victims with special psychiatric ailments. By 1992, nearly 13 percent of psychiatric hospitals in America offered special inpatient services for AIDS patients.

Industry Setback from Fraud. In the early 1990s eight insurance companies sued National Medical Enterprises, Inc. (NME; now a part of Tenet Health Care) for providing unnecessary hospitalization and costly treatments. In addi-

tion, the company was accused of admitting patients based on health care coverage and not genuine need. Over 130 lawsuits were filed against NME by patients. In 1994, the company paid almost \$375 million in fines to the Justice Department for violations. As a result of this case, similar reports surfaced concerning other private psychiatric hospitals. Some hospitals allegedly sought to acquire new patients by paying police, student counselors, and probation officers for referrals. Other accusations maintained that certain hospitals altered patient fees to collect inflated insurance reimbursements. Government investigations ensued. Some of the charges were adjudged to be true, and the resultant negative publicity affected hospitals that were not involved in the scandals. According to *Employee Benefit Plan Review*, other private hospitals suffered from drops in occupancy rates and diminished stock prices as a result of the scandal.

The Citizens Commission on Human Rights accused the industry of further collecting \$600,000 to \$900,000 a year on nonexistent or bogus treatments. Additional charges held that the industry employed “patient brokers” who accepted finder’s fees—payments as high as \$3,000—for the successful solicitation of prospective patients. Statistics revealed that psychiatrists comprised a disproportionately high percentage of the health care practitioners banned from the Medicare program for reasons of fraud. According to Gary Null, Ph.D., an investigative reporter and author of several books, “Last year [1995], \$411 million was paid to the government in fines and penalties for health care fraud and 90 percent of that was paid by psychiatrists or psychiatric institutions.”

Social Obligations. The rapid reduction in psychiatric hospital accommodations after 1992 raised concern over the continued funding and profitability of these institutions. The issue loomed as a crucial factor in the preservation of these mental health resources for the American public.

In 1999 the U.S. Surgeon General released a report wherein it directed criticism toward the private insurance sector for its failure to provide adequate coverage for inpatient care at psychiatric hospitals. The *Washington Post* in reporting the matter refuted the charges and chastised instead the government bureaucracy for its own latent failure to provide hospitalization benefits for psychiatric disorders under the Medicaid system. The *Post* cited the hundreds of thousands of mentally ill people in the United States who fall within the jurisdiction of the Medicaid system for reasons of incarceration or homelessness yet fail to receive appropriate medical attention for their psychiatric problems due to government failure to provide coverage.

Economic Viability. Restrictions imposed by the Health Care Financing Administration (HCFA)—a government

body that manages Medicare—placed potentially detrimental restraint on the profitability of the mental health care industry. In 1992 HCFA undertook the implementation of a system to impose caps on the amount that health care providers could charge patients. Anticipation that similar systems would spread beyond Medicare as the federal government assumed a larger role in the nation’s health care system generated new concerns over government reform of the mental health care industry.

Despite cutbacks and restrictive governmental action, the annual cost of psychiatric care reached \$12.3 billion by the mid-1990s. The cost increase more than doubled the 1980 total of \$5.8 billion, yet the producer price index for the psychiatric hospital industry increased at a rate that was generally slower than other medical industries. Following a 0.1 percent growth in 1995, the supplier index rose by 5 percent in 1996 but fell by 6.7 percent in 1997. In 1998 the rise of 0.5 percent was low in comparison to 1.3 percent for general medical and surgical hospitals and 2.3 percent for other specialty hospitals. Ellen Paris in *Forbes* suggested that future cost controls for psychiatric hospitals might focus on inpatient services, where the highest profit margins endured.

In conformance with a prevailing trend among many types of hospitals during the 1990s, psychiatric hospitals reduced inpatient facilities and increased outpatient services in their stead. The inpatient count at state hospitals fell from 470,000 in 1965 to fewer than 60,000 by the end of the century. Due to the reduction in facilities, the average occupancy rate in all psychiatric hospitals remained consistently high and declined by less than 5 percent during the 1980s and into the 1990s. By the mid-1990s the occupancy rate for psychiatric hospitals continued in excess of 80 percent. General hospitals in comparison reported only 60 percent occupancy, and lower rates were reported in other specialty hospitals.

CURRENT CONDITIONS

With so many psychiatric patients uninsured and unable to pay, Congress was being pressured to pass mental health parity legislation, requiring insurers to pay for mental health treatment in the same manner as other health care. The American Hospital Association and the National Association of Psychiatric Health Systems asked the House in March 2002 to pass the Mental Health Equitable Treatment Act, which was previously passed by the Senate. Currently, 34 states have parity laws requiring all health plans participating in the Federal Employees Health Benefit Plan to abide by the parity, as part of an order issued by former President Clinton. State lawmakers also began focusing on Medicaid, which plays a large part in the treatment of behavioral health issues and had stopped reimbursing behavioral health facilities for non-medical services in some states. In 2002, 28

states attempted to find more resources to improve access to residential facilities; 28 states prioritized strengthening mental health services for children; 28 states were making an effort to implement treatment programs over jail; and 23 states were considering enacting or amending mental health parity laws.

According to an article published in the November 6, 2000, issue of *Modern Healthcare*, psychiatric hospitals, as well as other behavioral health care providers, instead began seeing a trend in increased outpatient visits, which also meant higher outpatient revenue. The average number of outpatient visits per year for psychiatric hospitals and behavioral units in acute care hospitals was 20,332, an increase of 6.8 percent from 1997. Average net revenue per day from outpatient services was \$105 in 1999, an increase of 19.3 percent from 1997 and 59 percent since 1994. This revenue partially offset the amount of increasing bad debt and charity care. Charity care and bad debt rose to 10.7 percent in 1999, from 7.6 percent in 1997. Insurers were blamed for much of that by imposing treatment limits or random caps. Outpatient care was the only classification of care to rise between 1994 and 1999. Net revenue per day sunk 6.5 percent for inpatient care, decreased 6.4 percent for residential treatment, and decreased 10.9 percent for partial hospitalization over the same time period. The average inpatient length of stay in 1999 was 9.2 days, a decrease of 30.3 percent from 13.2 days in 1994.

Although most in-patient psychiatric hospitals have been coed since 1970 when patients began to be treated in units by disease instead of gender, at least one hospital, the 25-bed Women's Program at the Westchester Division of the Weill Cornell Westchester Hospital, a division of New York-Presbyterian Hospital, began to cater to women only in 2002. With a majority of women patients experiencing some type of abuse, hospitals that treat women only offer advantages. Additionally, the hospital encourages a home-like environment, and patients are allowed to wear their own pajamas instead of hospital gowns.

INDUSTRY LEADERS

In 1999, according to *Service Industries USA*, the two leading providers of psychiatric hospital services in the United States were publicly traded companies: HCA Inc. (formerly HCA-The Healthcare Company) and Tenet Healthcare Corporation, respectively. The third largest, Intermountain Health Care, Inc., was a not-for-profit establishment.

HCA Inc. HCA Inc., headquartered in Nashville, Tennessee, was listed at number 69 among the *Fortune 500* in 1999. Several major acquisitions and mergers in the 1990s allowed the company to grow overall, despite internal upheaval in the wake of an investigation into the company's

potentially unethical referral procedures and possible Medicare fraud. HCA, with operations in the United States, Switzerland, and the United Kingdom, reported sales revenues of \$19.7 billion for a revenue growth of 9.9 percent in 2002. The corporation operated a total of 260 hospitals and freestanding surgery centers in 2002.

Tenet Healthcare. As the second-largest hospital chain in the United States, Tenet Healthcare Corporation of Santa Barbara, California, operates about 115 hospitals and offers general hospital, psychiatric, surgery, and neonatal services. Tenet's subsidiaries and holdings include home health care centers, a health maintenance organization, and a managed care insurance company. The Tenet employee count in 2002 totaled 113,877 workers, an increase of 6.5 percent for the year. Tenet reported sales of \$8.74 billion in 2002.

Intermountain Health Care. Intermountain Health Care of Salt Lake City, Utah, ranked third in size in 1999. Intermountain is a not-for-profit organization established in 1975 as the result of donations to local communities on behalf of the Mormon Church. The organization serviced over 425,000 members in the western states of Utah, Idaho, and Wyoming and reported total patient services and nonpatient activities of nearly \$2.85 billion in 2002, up from \$2.65 billion in 2001.

SIC 8069

SPECIALTY HOSPITALS, EXCEPT PSYCHIATRIC

This industry consists of establishments primarily engaged in providing hospital services for specialized

categories of patients, except for the mentally ill (see **SIC 8051: Skilled Nursing Care Facilities** and **SIC 8063: Psychiatric Hospitals**). Hospitals in this industry classification include facilities that treat alcoholism and drug addiction, cancer, children's illnesses, chronic disease, maternity, orthopedic, and tuberculosis.

NAICS CODE(S)

622110 (General Medical and Surgical Hospitals)
622210 (Psychiatric and Substance Abuse Hospitals)
622310 (Specialty (except Psychiatric and Substance Abuse) Hospitals)

INDUSTRY SNAPSHOT

Establishments in this industry provide hospital services for patients who have usually already seen a physician at a general hospital or medical office. Specialty hospitals appear most densely in the mid-Atlantic United States, including New York and Pennsylvania, with the second greatest concentration in Texas, Oklahoma, and Louisiana. Many are located along the southern Atlantic seaboard as well. This industry, as part of the broader health care industry, saw overall growth throughout the 20th century, with certain areas experiencing distinct growth in the final years of the century. Specific specialty hospitals, such as those treating tuberculosis and cancer, grew as a response to the increase in the number of people diagnosed with these ailments. Maternity hospitals conversely decreased in number as technology and social change brought about an increase in birthing facilities at general hospitals.

Throughout the 1990s, these hospitals, like other establishments in the larger health care industry, were faced with cost-cutting measures imposed by economic factors and anticipated government reforms targeted at health care. *Service Industries USA* reported 577 specialty hospitals in the United States in 1992, up from 505 in 1987, an increase of 14.3 percent; yet viable projections suggested a continued revenue decline beginning in the mid 1990s.

ORGANIZATION AND STRUCTURE

Several distinct types of hospitals are classified in this industry group—each with a unique history and status. Like other hospitals, specialty hospitals are either non-profit or profit making and have competition from government-owned hospitals. In 1990, the U.S. government owned the vast majority of tuberculosis and chronic disease hospitals in the United States. Alcohol and drug abuse rehabilitation hospitals and cancer hospitals tended to fall under private ownership. Of the total number of specialty hospitals in the 1990s, 64 percent fell into the category of non-taxed (government operated or non-profit) institutions.

Specialty hospitals include both long-term and acute (short-term) facilities. Long-term specialty hospitals (where patients usually stay for 30 days or more) include alcohol and drug abuse rehabilitation hospitals, (physical) rehabilitation hospitals, chronic disease hospitals, and cancer hospitals. Short-term specialty hospitals (where patients usually stay for 30 days or less) include maternity (obstetric) hospitals and children's hospitals.

BACKGROUND AND DEVELOPMENT

The evolution of specialty hospitals is best understood through an examination of the diverse histories and services offered by each respective hospital type.

Tuberculosis Hospitals. Tuberculosis, an infectious disease that usually affects the lungs, was the leading killer of Americans at the turn of the century. This disease, also referred to as consumption, gave rise to hundreds of sanitariums in the early 1900s. It was thought that rest and isolation, along with treatments using temperature extremes, were ways of curing the disease. It was not until the 1940s that antibiotics were used successfully to cure the disease, turning many of the sanitariums into tuberculosis hospitals. Preventive treatments were developed and, during the 1950s, hundreds of tuberculosis hospitals in the United States closed.

In 1985, the federal government reduced funding for preventive treatments, thinking that tuberculosis was under control. In the 1990s, however, documented cases of tuberculosis began to rise again for the first time in more than 50 years. At that time, there were reportedly only four tuberculosis hospitals in the United States. The total of these facilities included 470 beds at 66.4 percent occupancy rate. Additionally, the hospitals provided services for more than 16,800 non-emergency outpatient visits. (These hospitals did not provide emergency services.) Observers forecasted the conversion of selected general hospitals into tuberculosis hospitals to meet the potential demand.

Maternity Hospitals. In the early 1990s, there were 12 maternity hospitals, with a total of 1,894 beds, in operation in the United States. During that time, these hospitals had a 57.4 percent occupancy rate and performed duties for more than 55,000 births. In addition, maternity hospitals serviced more than 60,000 surgeries, 58,000 emergency outpatient visits, and 223,000 non-emergency outpatient visits. By the mid 1990s, approximately 135 licensed birth centers invaded the market in 34 states, with 90 additional centers slated to open before the end of the century.

Eye, Ear, Nose, and Throat Hospitals. There were 12 eye, ear, nose, and throat (otolaryngology) hospitals in the United States in the mid 1990s. These facilities together offered 669 beds and a 32 percent occupancy rate.

During that time, they performed more than 79,000 surgeries, and provided services for more than 78,000 emergency outpatient visits and 458,000 non-emergency outpatient visits.

Rehabilitation Hospitals. Rehabilitation hospitals provide medical services for patients suffering from physically debilitating ailments, usually as a result of an injury. In the 1990s, most patients admitted to these establishments suffered from head or traumatic spinal cord injuries. More than 140 rehabilitation hospitals maintained operation in the United States, with a total of 19,079 beds and an average 73.6 percent occupancy rate. These facilities performed more than 5,300 surgeries, and serviced more than 29,000 emergency outpatient visits and more than 2.2 million non-emergency outpatient visits.

Rehabilitation centers dedicated to the treatment of addiction encountered a serious challenge in the mid 1990s with the rise of managed care insurance programs. Managed care plans in general afforded their members little or no coverage in the area of substance abuse and addiction treatment, and hospitals that specialized in the treatment of these ailments suffered subsequent loss of revenue. "The number of inpatient treatment programs has declined precipitously," Monica Oss, editor of the behavioral health industry newsletter, *Open Minds*, told *Time*. "Between 1988 and 1993, the average number of patient bed days dropped from 35 to 17." Rehabilitation facilities countered the circumstance by offering a variety of treatment options, including outpatient therapy.

Orthopedic Hospitals. In the 1990s, there were approximately 30 orthopedic hospitals in operation in the United States. These facilities treated patients with physical deformities; often these patients are children. These hospitals had a total of more than 2,000 beds and a 55.5 percent occupancy rate. They performed more than 58,000 surgeries and serviced nearly 40,000 emergency outpatient visits and more than 570,000 non-emergency outpatient visits.

Chronic Disease Hospitals. More than 30 chronic disease hospitals operated in the United States in the 1990s. These hospitals most commonly provide long-term inpatient care facilities for patients with chronic illnesses, such as chronic respiratory infections. Chronic disease hospitals had a total of 10,870 beds and a 90.3 percent occupancy rate. During that time, they performed just over 1,000 surgeries and provided services for more than 4,500 emergency outpatient cases and 118,000 non-emergency outpatient cases. Chronic disease hospitals do not treat cancer and tuberculosis patients.

Children's Hospitals. Among other specialty hospitals in the United States, the leading establishments are children's hospitals and cancer hospitals. In the mid 1990s, children's hospitals were in high demand, and adminis-

trators commonly resorted to the use of waiting lists as a method of prioritizing admittance into the facilities. One crucial factor that contributed to the growing need for children's hospitals was the increase in the number of children in the United States who required care for illnesses related to poverty.

The demand for cancer hospitals increased during the 1990s. *Hospitals* noted that, "The American Cancer Society . . . estimates that one in three Americans now living will develop cancer at some point in their lives. Each year of this decade, more than 1.1 million people will be diagnosed with the disease." Accredited cancer programs proliferated at general hospitals across the country in response to the need, even as cancer treatment specialty hospitals increased in number.

Prognosis. In 1998, HCIA, Incorporated reported that a renewed upsurge of specialty hospitals in certain geographic areas stimulated cooperative efforts between those hospitals and the physicians of the region. The collaborations resulted in the formation of mutual partnerships between the two factions. Survey results suggest that the entry of a specialty hospital into any given market place might potentially drain as much as 35 percent of revenues from traditional programs within the respective locale. Findings were based on a study that focused on effects of cardiac specialty facilities on the disbursement of Medicare dollars within a given area.

INDUSTRY LEADERS

According to *Service Industries USA*, in 1999 the three industry leaders for specialty hospitals in the United States were Columbia/HCA Healthcare, with \$18.7 billion in revenue in 1998; Tenet Healthcare Corporation, with 1999 revenue of \$10.9 billion; and Beverly Enterprises, Incorporated, reporting \$2.8 billion in revenue.

In 1994, Columbia Healthcare Corp. of Kentucky, merged with Hospital Corporation of America. In April of 1995, Columbia/HCA formed yet another merger — with Health Trust Incorporated, of Tennessee. The 1995 merger was the largest hospital chain merger in U.S. history. The \$5.6 billion merger resulted in a huge chain of 318 hospitals. In the mid 1990s, Columbia/HCA Healthcare owned and operated approximately 220 facilities. Tenet Healthcare involved more than 120 facilities across 18 United States, plus operations overseas in Barcelona, Spain.

Another merger in this field combined the next two leaders in the industry in March of 1995. National Medical Enterprises merged with American Medical International to form Tenet Healthcare Corporation, of California. In 1997, Tenet challenged Columbia/HCA Healthcare as the largest hospital operator when it acquired OrNda HealthCorp for \$3.1 billion. According to

Modern Healthcare, Tenet Healthcare anticipated the new acquisition would add \$2 billion to its \$9 billion annual revenues in 1997. American Medical International owned and operated 8,853 beds in 36 facilities; National Medical Enterprises had 6,671 beds in 33 facilities; and OrNda had 8,423 beds in 47 facilities. However not all facilities were strictly specialty hospitals. Already impressive, Tenet reported revenue growth of 10 percent in 1999, as compared to Columbia/HCA which grew by only 0.7 percent in 1998.

Industry leaders among the non-profit segment of the industry in 1999 were City of Hope National Medical Center in Duarte, California; Spaulding Rehabilitation Hospital Corporation in Boston, Massachusetts; and Bethesda Hospital Association of Zanesville, Ohio—each with more than \$50 million in reported earnings. Greenery Rehabilitation Group, Inc., which operated rehabilitation hospitals for young adults with neurological impairments was next in earnings, followed by Children's Hospital of Orange County, and Women and Infants Hospital of Rhode Island.

WORKFORCE

In the mid 1990s, approximately 270,000 people were employed in specialty hospitals in the United States. The distribution of the work force included registered nurses (RNs) comprising 25 percent of the total, aides and orderlies made up 6.2 percent, and licensed practical nurses (LPNs) comprised 4.6 percent. Non-medical personnel, such as maintenance and clerical workers, totaled 11.6 percent of the work force, while professionals, administrators, and physicians comprised 8.1 percent, not including 5.1 percent categorized as technicians. Other professions included therapists, social workers, psychiatric staff, and medical secretaries.

RESEARCH AND TECHNOLOGY

This industry, which can be regarded as primarily one for specialists, relies strongly on developments in research and technology. Research in biotechnology is expected to have a tremendous impact on cancer treatments provided by cancer hospitals and general hospitals. *Hospitals* noted that such research advances could mean that "biotech will shift the site for treatment from inside to outside—from external, systemic treatments like radiation and chemotherapy, to targeted, tumor-specific drugs that strengthen and then deploy the body's immune system to destroy cancer cells." The Pharmaceutical Manufacturers Association cited numerous cancer-treating biotechnology drugs under development, and biotech drugs may replace radiation and chemotherapy, which have been the main forms of cancer treatment since the 1970s. Additionally, the emerging field of gene therapy holds promise in the field of cancer research. Researchers at the Karolinska Institutet in Stockholm,

Sweden announced advancements in 1999 of the development of enhanced methods of delivering tumor-killing genes. Investigators observed that the technology performed effectively in vitro (in test tubes) and expressed promise for the potential of a genetically-based offensive against cancer.

Another significant development in cancer treatment, which will also expand the use of outpatient services, has been in bone marrow transplants. Traditionally, bone marrow transplants have required long hospital stays ranging from a few weeks to a month, and from the hospitals' viewpoint, extensive staffing for the follow-up care and related administrative duties. In the early 1990s, advances in the use of laser technology and other less-invasive procedures allowed many types of bone marrow transplants to be performed on an outpatient basis. New changes in cancer treatment clearly hold the potential to effect the nature and duration of treatment at cancer hospitals. Advanced technologies hold the promise of shifting emphasis from long-term inpatient facilities such as those required for radiation and chemotherapy treatment to minimized inpatient care and outpatient care of shorter duration. Indeed a trend in the direction of expanded outpatient care for cancer patients was underway by the end of the 20th century, independent of molecular biological research, as a result of cost cutting by many hospitals.

Research in the 1990s has led to the development of a number of prosthetic and other devices related to orthopedics. Developments in biotechnology and biomaterials, as well as research and development with carbon composite prostheses and thermoplastic prostheses will also affect orthopedics.

Technological advances in computer systems have also assisted many specialty hospitals by providing networks of information, which can be linked among hospitals throughout the country. Throughout the 1990s, these hospitals increasingly shared information on treatments through the use of treatment registries available on computer networks.

SIC 8071

MEDICAL LABORATORIES

This category covers establishments that provide professional analytic or diagnostic services to the medical profession or to patients upon prescription of their physicians.

NAICS CODE(S)

621511 (Medical Laboratories)

INDUSTRY SNAPSHOT

The laboratories in this classification are independent, commercial enterprises that provide bacteriological, biological, histological, blood, chemical, and pathological analysis; urinalysis; and medical and dental x-rays. While demand is high due to the increased health care needs of the country’s aging population and the outbreak of new and serious diseases, intense competition, cost-cutting measures implemented by managed care organizations, and a lack of skilled workers presented challenges to the industry’s continued growth in the twenty-first century.

Laboratory companies have met these challenges by growing through mergers and acquisitions and by continually developing faster, cheaper, and less invasive testing procedures. One significant trend is toward more point-of-care testing, in which tests are performed in a doctor’s office—or in the case of home health care, at home—with testing, diagnosis, and treatment consolidated to one location. By 2001, over half of all simple medical testing was completed in doctors’ offices.

BACKGROUND AND DEVELOPMENT

Medical laboratories are governed by the Clinical Laboratory Improvement Act of 1988 (CLIA ’88). These regulations, implemented in 1992, increased requirements for proficiency testing, thereby raising costs. The cost of proficiency materials tests went up by 67 percent in the first eight months of 1992. While the new regulations caused the cost of materials to go up, the regulations also simplified administrative costs by unifying separate rules that had been established under previous programs.

National health care expenses more than doubled between 1980 and 1990, from \$250 billion to \$696 billion per year, and nearly doubled again by 2000, reaching \$1.3 trillion. Because of these huge increases, employers and insurers sought to control costs. They took steps to substitute outpatient treatment for hospitalization when possible. Insurers and employers wanted to see laboratory tests and x-rays to determine if hospitalization recommended by physicians was really necessary. Hospitals also had a stake in making sure that unnecessary hospitalizations were not occurring. After 1983, hospitals were reimbursed for Medicare patients at a modest rate as determined by federal “diagnostic related groups (DRG)” —standard rates determined by a patient’s diagnosis, age, sex, treatment modality, and discharge status. If costs exceeded DRG prices, the hospitals were required to absorb the cost. Ironically, the new emphasis on tests caused the cost of diagnostic procedures to skyrocket. Insurers and employers sought to hold down costs for these as well.

One of the most vigorous debates in medicine in the mid-1990s centered on clinical laboratories owned by doctors. In 1989, the federal government passed a law prohibiting doctors from referring Medicare or Medicaid patients to clinical laboratories in which they had invested, but critics wanted to ban doctors from referring *any* patients to such laboratories. Self-referral, they argued, leads to unnecessary diagnostic procedures. Government studies indicated that 10 percent of the nation’s doctors had invested in a business to which they sent their patients and that these doctors made more such referrals than doctors who had not invested in the facilities to which they referred patients.

Other legal issues that haunted the industry during the early 1990s included fraud and charges of unsafe practices. In 1993 state and federal officials subpoenaed the Medicaid and Medicare records of at least five of the country’s largest medical labs in an effort to stop suspected fraud, such as unallowable overhead Medicare charges, overcharging, and false claims. The owner and president of Diagnostic Technology Inc. and New York Blood Components was convicted of a felony and misdemeanors and fined \$25,000 for sending lab test kits containing HIV- and hepatitis B-contaminated blood through

the mail. In the late 1990s, industry observers were concerned with the future direction of EPA rulings governing lab waste disposal.

Total revenues for all clinical laboratory services in the United States in 1999 were \$39.2 billion. Commercial laboratories of the sort represented in this industry sector were responsible for more than one-third of those totals, with 1999 revenues of \$14.9 billion. Other providers of clinical laboratory services were hospitals and physicians' offices. Of these types of laboratories, commercial labs showed the most growth, with a compound growth rate of 5.4 percent, compared to 2.5 percent for hospitals and 1.2 percent for physicians' offices. Hospitals continued to reduce the number of laboratories they operate.

The increasing presence of managed care in the health care industry has been a major influence on the continued consolidation of medical laboratories. As in other sectors of the economy, large national chains dominated and often drove out independent laboratories. While there were fewer large chains in the late 1990s, those chains in existence increased dramatically in size. Some analysts suggest that only large chains—or laboratories that join to form “purchasing groups”—can afford to provide services at the extremely low costs managed care firms demand. Some managed care groups have also negotiated a “subscription” rate with laboratories so that they pay one total annual fee for all services instead of paying for each test individually. The trend toward managed care has also compelled physicians to order fewer tests to cut costs and to take fewer samples for testing.

CURRENT CONDITIONS

According to the 2002 *U.S. Statistical Abstract*, in 2000 the medical and diagnostic laboratory industry took in nearly \$23.2 billion in revenues, up from \$19.2 billion in 1998. Employment statistics also grew steadily reaching 216,000 in 2001, up from 166,000 in 1990. During the early 2000s the industry was struggling with a shortage of qualified laboratorians, and laboratories were thus turning more to automated systems for simpler tests.

The diagnostic laboratory industry was undergoing a significant trend toward point-of-care testing, in which patients enter a doctor's office for “test-and-treat” care. Physicians' testing facilities was the fastest growing sector of the medical laboratory industry. S. Wayne Kay, chief executive officer of Quidel Corporation, which specializes in point-of-care diagnostic tools, told *Medical Laboratory Observer*, “The movement towards decentralization of the laboratory and the need for more accessible diagnostic testing where the physician can test and treat will contribute to this demand curve. This speed of service—fast turnaround times—combined with a medically important need to diagnose and treat as quickly as possible, makes our mission exciting.” In 2001, approxi-

mately 58 percent of the nation's 170,000 medical laboratories were located in doctors' offices.

Another trend in the industry was the rapid growth of molecular diagnostic testing. Diagnostic laboratories were also on the cutting edge in developing tests and solutions in anticipation of any bioterrorism attacks on the United States, following the terrorist attacks of September 11, 2001.

INDUSTRY LEADERS

The medical laboratories industry underwent significant reorganization during the late 1990s. In February 1999 SmithKline Beecham announced an agreement to sell its laboratory division to Quest Diagnostics (formerly MetPath/Corning Clinical Laboratories, until Corning sold it off in 1997). The division was sold for \$1.02 billion and a 29 percent equity interest in Quest (estimated worth, \$245 million). In 2002 Quest reported net income of \$322.2 million on revenues of \$4.1 billion, making it the largest medical laboratory company in the United States. Its acquisition of SmithKline Beecham's lab operations in 1999 also made it the industry leader in drug testing services for employers. In early 2000, Quest announced a joint venture with online health services provider Caresoft Incorporated to make patients' lab results available through Caresoft's Web site.

For 2002, Laboratory Corporation of America Holdings (LabCorp), another industry leader, reported earnings of \$254.6 million on \$2.5 billion in sales. Despite its high sales ranking, LabCorp also faced serious difficulties in the second half of the 1990s, starting with its guilty plea to accusations of criminal fraud in 1996. The company lost \$166 million between 1996 and 1997. Some company officials, as well as some industry observers, suggested that the government was partially to blame for the fraudulent billing because it lacked clear billing guidelines. Nonetheless, LabCorp retained a good position for growth, rebounding in the 2000s to post a profit. LabCorp owns DynaCare, which also provides diagnostic testing services.

WORKFORCE

Employment in this industry grew steadily through the last thirty years of the twentieth century. According to the U.S. Department of Labor, Bureau of Labor Statistics, in 2001 the medical and dental laboratory industry accounted for 224,110 workers. Medical and clinical laboratory technologists and technicians held nearly 20 percent of the industry's workforce. Technologists had a mean annual salary of \$42,790; technicians, \$28,360.

Clinical laboratory technologists have a bachelor's degree in medical technology or in another life science. They can perform a variety of complex tests. In larger laboratories, they generally specialize in a particular area,

such as microbiology or immunology. Technicians have associate degrees or a diploma from a vocational or technical school and perform more routine tests. Some states require lab personnel to obtain licenses. Certification is another way that individuals in this field prove their competence. Because technicians are cheaper to employ than better-educated technologists, many labs began to use more technicians; at some companies, technicians constituted up to 75 percent of the staff.

Developments that may affect the workforce in the twenty-first century include increasing automation, a growing number of products that allow patients to self-test at home, and more “point-of-care” testing (testing that does not need to be performed at a central laboratory site). In 1999, the Medical Automation Research Center reported that 50 percent of tests performed at central laboratories could be performed at the point of care using only existing technology. The center predicted that by 2004, 80 percent of tests would be performed “at the patient’s bedside.” Others suggest, however, that the need for manually obtained specimens and the increasing number of lab tests available will ensure continued job growth in this field.

RESEARCH AND DEVELOPMENT

An important trend in the development of new clinical testing procedures is the increase in early-stage testing procedures that can find disease much sooner than tests used in the past could. These procedures are often less invasive and quicker than older methods. Examples include a test that more accurately determines one’s risk of heart disease by “listening” to fats in the blood, thus allowing a more precise reading of cholesterol levels. Researchers have also developed an instrument that analyzes the breath to detect diseases, including kidney problems and diabetes. This device was expected to be available by 2005.

Testing for cancer was another growth area—early testing could mean thousands of lives saved each year. New technologies in 1999 included a less invasive test for prostate cancer that more precisely measured the amount of prostate-specific antigens. A test that detected unusually high amounts of certain DNA elements in the urine—a potential sign of cancer—was in the early trial stage. Genetic testing was also a major area of research for the detection and prevention of cancer, but as of 1999, over 90 percent of this type of testing was performed in university hospitals—an indication that this technology was still at a very early stage of development.

Other areas of expected development included the miniaturization of laboratory devices, allowing them to fit in the hand, and molecular biotechnology, an example of which is applying knowledge gained from the se-

quencing of the human genome, a project expected to be completed by 2003.

SIC 8072

DENTAL LABORATORIES

This classification comprises establishments primarily engaged in making dentures, artificial teeth, and orthodontic appliances to order for the dental profession. Those establishments primarily engaged in manufacturing artificial teeth, except to order, are classified in **SIC 3843: Dental Equipment and Supplies**, and those providing dental x-ray laboratory services are classified in **SIC 8071: Medical Laboratories**.

NAICS CODE(S)

339116 (Dental Laboratories)

INDUSTRY SNAPSHOT

According to the U.S. Census Bureau, there were approximately 7,500 dental laboratories providing almost \$3 billion worth of services in 1997. These businesses produced custom-made prosthetic appliances for the dental profession. By 1997, this fragmented industry employed roughly 41,000 people domestically. Entering the mid 1990s, the industry had been expected to experience some growth based on continuing "advances in dental techniques, increased cosmetic dentistry, and increased dental insurance coverage." Advances in preventive dental care, however, were also predicted to have a negative impact on the pace of that anticipated growth. In fact, the number of businesses declined during the mid 1990s while the dollar value of sales increased. Computer technology played an increasing role among dental laboratories, from the standpoint of both research and business management. Advances in computer technology weeded out businesses that were unable to keep up, and may have accounted for the decline in the number of employees. But technological advances also accounted for the rise in sales and profitability for businesses on the leading technological edge.

ORGANIZATION AND STRUCTURE

About half of all individual dental laboratories are owned by corporate bodies, while the balance are owned and operated through sole proprietorship and partnerships. The Census figure of nearly \$3 billion in revenues for 1997 agrees with data from economic conditions surveys sponsored by the National Association of Dental Laboratories. According to the survey, "dental laboratory sales represented only about two-tenths of a percent of the nation's total expenditures on health care" for 1994. The survey also indicated that 77.4 percent of dental labs with sales of no more than \$50,000 were sole proprietorships; conversely, 82.3 percent of dental labs with sales volumes exceeding \$1 million were owned by "regular corporations." National Dented Corporation, considered the largest operator of dental laboratories in the United States, experienced sales of over \$44 million for fiscal 1995 alone, while Senate Corporation—the second largest owner of dental laboratories domestically—posted sales of \$43 million for the same year.

Most of the country's dental laboratories are found in large metropolitan areas. Dental laboratories are spread throughout the United States; in 1997, each state contained at least 34 establishments. California was the leader, containing almost twice as many labs as any other state. With about 1,100 laboratories in 1997, California employed a work force of 6,000 people in this industry, and accounted for over \$400 million of the industry's sales. Ranking directly behind California were Florida, with over 600 establishments, and New York, with almost 500.

Customarily, in creating an actual dental prosthesis (for example, full or partial dentures, a bridge, or a crown), laboratories follow instructions provided by the individual dentist and use a wax or plastic impression of the patient's mouth that had been made in the dentist's office. In some cases, dental laboratory technicians work directly for dentists and are present in the dental office setting itself to facilitate such procedures. Dental laboratory technicians working in actual laboratories may also have contact with patients in preparing and fitting the individual prostheses, but more commonly have no contact with patients at all. Dental laboratories typically purchase their materials from companies that manufactured products specifically for the health care industry (see **SIC 3843, Dental Equipment Manufacturers**).

By the mid 1990s, dental laboratories were expected to comply with certain standards as set forth by the federal Occupational Safety and Health Administration (OSHA) and were subject to inspection by that body. According to the National Association of Dental Laboratories in 1996, a relatively small percentage of laboratories was actually inspected by the OSHA and the manner in which OSHA standards were applied to the industry's specific procedures and instruments was considered problematic due to inconsistency.

Qualifying dental laboratories were eligible to apply for certification from the National Board for Certification of Dental Laboratories (CDL), which had established specific standards for "personnel skills, laboratory facilities, and infection control in dental laboratories." According to the CDL, certification was potentially "invaluable in establishing credibility with outside third parties, including courts of law, insurance companies, and government." To receive certification, a laboratory is required to employ certified dental technicians in supervisory positions, document facility compliance with accepted health and safety standards, and maintain high levels of training and practice in infection control.

BACKGROUND AND DEVELOPMENT

Restorative dentistry, as outlined by Bonnie L. Kendall in *Opportunities in Dental Care*, traced its beginnings to the Etruscan people of central Italy, who made bridges and crowns. In the Roman Empire, numerous processes were developed for the restoration of teeth by artificial means. Few dental advances were made in the Middle Ages, when the main antidote to toothache was extraction of the offending tooth. It was not until at least the sixteenth century that anatomical study led to new discoveries about teeth.

Restorative dentistry in the American colonies consisted of tooth transplants, false teeth, and a hygienic dentifrice. Such items were generally fashioned by the same individuals who treated toothaches. As the popula-

tion of the United States grew, “dentists” began to establish permanent rather than itinerant practices. According to Kendall, silversmiths and goldsmiths periodically assisted in the creation of artificial teeth, working either independently or with dentists. By the nineteenth century, the majority of dentists made such prostheses themselves or employed apprentices to assist in their production. With the 1840 opening of America’s first dental college in Baltimore, students began to receive training not only in dental procedures but also in the preparation and setting of artificial teeth; nationally, by 1986, there were 58 accredited training programs for the education of dental lab technicians. The precise date when independent laboratories first appeared is not known; by 1920, approximately 2,000 laboratories were in operation in the United States.

In 1933, according to Kendall, the government ruled that the dental laboratory industry should be operated by “a code of fair practices,” and a group was established to formulate these guidelines. In 1951, the American Dental Laboratory merged with the Dental Laboratory Institute to form the National Association of Dental Laboratories (NADL). In 1952, the NADL opened its offices in Washington, D.C., and by 1958 had set up its Certified Dental Technician (CDT) program. The NADL’s voluntary national program for laboratory certification (the National Board for Certification of Dental Laboratories) was instituted in 1977.

One of the most significant developments in the course of the dental laboratory industry’s existence, aside from a gradual movement toward an increased emphasis on dental care, was the utilization of orthodontic appliances in a widespread fashion. Attributable in part to the growing affluence of the nation as a whole during the 1960s, this increase in use was also a result of technological advances made in the same decade. Prior to that period, in an era when only the most financially secure could afford orthodontia, dental surgeons had to adhere each metal band to individual teeth, one at a time, pinching the band around a tooth, then soldering it permanently in place—an arduous and time-consuming task. By the 1960s, however, significant advances had been achieved in the manufacture of metal braces, taking orthodontics into mass-production and eliminating the need for the piecemeal application of braces.

With these developments, the number of patients opting for orthodontia increased, eventually creating one of the primary market segments that would support dental laboratories in years to follow.

In the mid 1990s, health-related issues were of particular importance to the dental laboratory industry as a whole. Topics of concern included such items as infection control guidelines, occupational risk of exposure to HIV and other blood-borne diseases, and occupational

lung diseases. There was a significant increase among all areas of dentistry in the hygienic precautions regularly taken to reduce the risk of exposure to blood.

Infection control guidelines from the U.S. Centers for Disease Control and Prevention applied not only to workers in dental offices, but to employees in dental laboratories as well. Occupational lung diseases, caused by exposure to a variety of dusts, also presented a risk to dental technicians, according to *Infection Control Weekly*. According to a study by French researcher D. Choudat, several respiratory and non-respiratory ailments were identified as being possibly related to the inhalation of dusts present in dental laboratories, specifically silica, alloys, and acrylic plastics. Although this was more of a concern in small independent labs than in large establishments, and more of a problem abroad than domestically, dental laboratories were encouraged to install and maintain adequate ventilation systems to reduce potential exposures for all employees. Choudat noted that these risks appeared cumulative, manifesting themselves to a greater degree and at a higher incidence among employees who had worked in dental laboratories for many years. Additionally, employees who smoked were considered at greater risk of contracting these occupational illnesses.

CURRENT CONDITIONS

The dental laboratory industry makes about three-fourths of its income from the production of artificial teeth, dentures, and other orthodontic appliances specifically based on prescriptions and orders from dentists. Laboratories provide record-keeping services that account for the remainder of its income. The industry’s finished products add over \$2 billion to the materials, energy, and other consumables used in manufacture.

INDUSTRY LEADERS

According to revenue figures posted by the individual companies, the following companies lead the dental laboratory industry: National Dentex Corp. of Wayland, Massachusetts, with sales exceeding \$63.8 million in 1998, 1,211 employees, and a dollar value in sales per employee of \$52,684; Recigno Laboratories, Inc., of Willow Grove, Pennsylvania, with sales of \$39 million in 1995, 500 employees, and sales per employee of \$78,000 for 1995; Sentage Corp., with sales of \$43 million, and 1,000 employees; James R. Glidewell Dental Ceramics, with sales of \$26.5 million, and 400 employees; Americus Dental Labs LP, with sales of \$14 million, and 200 employees; Dentalcare Partners Inc., with sales of \$12 million, and 125 employees; and Dental Arts Laboratory Inc., with sales of \$10.4 million, and 250 employees. As of 1996, National Dentex served an active customer base of 8,000 dentists via 24 full-service and five branch

dental labs in 20 states and offered a full range of dental prostheses.

WORKFORCE

The industry employed about 41,000 people in the late 1990s, down from roughly 44,000 people in the mid 1990s and from 49,000 in the early 1980s. Employment opportunities were expected to remain fair through the year 2005, according to *Career Information Center*. According to the 1997 Census, over 6,000 labs employed less than 10 people. Only the four largest labs employed more than 250 people.

The formal training of many dental laboratory technicians may begin as early as high school, through specific vocational courses, or via apprenticeship. Trainees normally work under the guidance of experienced practicing technicians, and generally gain skills over a period of at least three years. Individual technicians seeking to gain professional credentials as a Certified Dental Technician apply to the NADL's appropriate governing board for certification.

According to the U.S. Department of Labor, dental lab technicians, in the course of their daily work, may engage in the following sorts of tasks: employing a variety of hand tools for extremely detailed work; reading dentists' prescriptions and examining dental impressions and models; displaying expertise in grinding, polishing, and soldering of dental appliances; attempting to resolve problems in the design and setup of dentures; consulting with individual dentists for problem resolution, when necessary; and fabricating full or partial dentures and crowns.

Trainees in dental laboratories, according to the 1995 NADL survey, may have earned between \$5.50 and \$7.00 per hour to start. Wages for technicians with at least 10 years of experience earned at least \$12 an hour, with \$19 capping the hourly range.

RESEARCH AND TECHNOLOGY

As one example of technological advances in the field, in 1995, Dr. Anthony Chillura wrote in *Newsweek* magazine that "technological breakthroughs promise to revolutionize the way . . . crowns . . . are created and fitted." Chillura noted that crown production in the past was a "time consuming multi-step process that began with alginate impressions of the tooth and continued through fabrication in a dental laboratory and subsequent fitting (and adjustment) to the patient in the chair." Using the new computerized crown manufacturing machine "the prototype system rapidly scans the tooth image and then computer-guided cutting hardware creates the crown." Gold or porcelain crowns that once took hours to prepare could henceforth be fashioned in about half an hour.

According to *Business Wire* in November 1996, Automated Products Incorporated (API), a Texas-based developer of such technology, indicated that by using this type of system one technician could "produce up to one hundred or more crown copings per day." Planned enhancements to API's system were expected to include "the ability to produce multi-unit bridges, inlays, onlays and laminates."

SIC 8082

HOME HEALTH CARE SERVICES

This industry consists of establishments primarily engaged in providing skilled nursing or medical care in the home under the supervision of a physician. It includes home healthcare services and visiting nurse associations that provide care to recovering, disabled, and chronically or terminally ill people.

NAICS CODE(S)

621610 (Home Health Care Services)

INDUSTRY SNAPSHOT

Home healthcare services provide a wide array of short-term and ongoing services. Ongoing treatments include respiratory therapy programs, which provide complete air support for patients suffering from many respiratory ailments such as asthma, bronchitis, and cystic fibrosis. Other homecare services include delivery of nutrients intravenously or through feeding tubes; the intravenous infusion of antibiotics to treat infectious diseases; and infusion therapies for patients with fully or partially dysfunctional digestive tracts. Home healthcare

services also provide short-term therapy and home care for post-operative and recovering patients.

In 2001 the National Association for Home Care (NAHC) counted more than 20,000 providers of homecare services to 7.6 million people suffering from acute illness, long-term health problems, disabilities, or terminal illness. This number represents a phenomenal increase since 1963, when only 1,100 homecare providers were in operation. Annual estimated expenditures for home health care in 2001 were \$41.3 billion

The home healthcare industry blossomed after the 1965 enactment of the Medicare program, which provided federal funding for in-home care of the chronically ill. According to the HCFA, of the \$36.6 billion spent on home health care in 2000, out-of-pocket expenses accounted for 28.1 percent, or \$10.9 billion of all homecare expenses. Medicare paid provided 26 percent, or \$26 billion, of all payments. Private insurance paid 6.9 percent, or \$18.9 billion, with Medicaid and state and local governments accounting for smaller contributions.

ORGANIZATION AND STRUCTURE

Home healthcare services are categorized by ownership: government, hospitals, privately owned companies, and nonprofit organization or visiting nurse associations, all of which provide these services. In 1998, nearly private companies owned 46 percent of all home healthcare agencies in the United States. In the same year, around 12 percent were owned by nonprofit organizations or visiting nurse associations, hospitals owned more than 27 percent, and the government owned 12 percent. Local healthcare providers owned roughly 75 percent of establishments not owned by the government as franchises.

While there continued to be a trend toward consolidation, the home healthcare industry was still somewhat fragmented in the late 1990s. The total number of home healthcare agencies operated by the 38 largest homecare chains increased from 3,649 offices in 1996 to 3,984 offices in 1997, an increase of 9.2 percent. These chains represented about 26 percent of the homecare industry in 1997.

The impact of The 1997 Balanced Budget Act (BBA) on home care cannot be underestimated. In addition to capping the amount of annual reimbursement that a homecare agency could receive per patient, the act required home healthcare agencies to obtain surety bonds. Regulated by the HCFA, only certain types of surety bonds qualified, complicating the process for many homecare agencies.

BACKGROUND AND DEVELOPMENT

The first homecare agencies were established in the 1880s, and by 1963 more than 1,100 such agencies existed. The dramatic increase in home healthcare providers

between 1965 and 1999 was propelled by the 1965 Medicare enactment making homecare services available to the elderly as long as the services were for "nursing and therapy of a curative or restorative nature," according to the NAHC. In 1973, these benefits were also made available to the younger population. Between 1967 and 1985 the number of Medicare-certified agencies participating in the Medicare program rose from 1,753 to 5,983. The industry leveled off temporarily in 1985 as Medicare paperwork and policies made regulatory compliance difficult and payments were not made reliably. In 1987, consumer groups, the NAHC, and members of Congress successfully sued the HCFA. Medicare homecare policies were rewritten, annual Medicare outlays were increased, and the number of Medicare-certified agencies again rose, this time to 10,000. That number later declined (9,655 at the end of 1998), this time as a result of the Balanced Budget Act's changes in Medicare home health reimbursement.

Home health care has increasingly been regarded as one of the essential components of comprehensive health care. The high costs of hospital and nursing home care have helped this industry to become one of the fastest growing sectors of the larger healthcare industry in the United States.

Home health care services provide a variety of services for patients in the home. The three most common services offered by home health agencies are skilled nursing, personal care for the elderly and disabled, and home infusion therapy. Of patients using home health services, 30 percent have diseases of the circulatory system, while 20 percent have some form of heart disease. Other services include administering antibiotics, providing rehabilitation services, and aiding chemotherapy. Generally, these services are provided by a team of healthcare professionals.

Home infusion therapy has been one of the fastest growing services offered by companies in this industry. Home infusion therapy provides initial patient evaluation; compounds and dispenses drugs, solutions, and nutrients; and provides ongoing clinical monitoring. According to the National Alliance for Infusion Therapy, in 1995, the most common treatment given through home infusion therapy was antibiotic therapy, relying mostly on pumps for drug delivery. This therapy was followed by enteral nutrition, chemotherapy, and pain management. In the same year, the most common diagnoses of patients using home infusion therapy were AIDS, Lyme disease, and colon cancer.

Medicare, the federally funded health insurance providing assistance to the elderly and disabled, has played an important role in the growth of this industry. It was the largest single payer of home care services, accounting for

more than one-third of total home care expenditures in 1995.

In 1997, Medicare financed \$214.6 billion in spending for 39 million aged and disabled enrollees, according to HCFA. By spending category, the largest one was hospital care (57.6 percent of total expenditures), as compared to home health care at 6 percent. In 1996, roughly 3.9 million of the 37 million Medicare enrollees received home healthcare services, about twice the number of people who received such services in 1990. However, annual growth in Medicare spending decreased from 12.2 percent in 1994 to 7.2 percent in 1997. Home healthcare growth has also decreased, mostly due to the public sector's desire to restrain the boom in home healthcare services in the middle and late 1990s.

During the 1990s, this industry was marked by mergers among industry leaders. In 1993, Abbey Healthcare Group, which specialized in rehabilitation and respiratory therapy equipment, purchased Total Pharmaceutical, which dealt mainly in intravenous drug and nutritional therapy. In the same year, Olsten Corporation, which owned Olsten Health Care Services, purchased Lifetime Corp., along with its subsidiary, Kimberly Quality Care. This merger ended a highly publicized takeover battle between Abbey Healthcare and Olsten Corporation; Abbey offered to purchase Lifetime for \$220 million, yet this offer was rejected for Olsen's offer of \$449 million.

In 1995, Abbey and Homedco, two of the largest home healthcare providers in the United States, merged to form Apria Healthcare Group, Inc., making it the largest provider in this field.

Also in the early 1990s, the public's attention was drawn to the ethical practices of home infusion therapy services. One ethical issue arose when some home infusion agencies paid physicians a weekly stipend for each patient they referred to the agency. Concerns were raised over whether the payment of such stipends would influence physicians' judgments in using home infusion services. Another ethical controversy for home infusion therapy companies arose when these companies bought a practice from a physician and later hired the physician as an employee; this action suggested that the physician was bought to write prescriptions for the company. Both of these ethical issues were addressed by legislators at the state and national levels, and by the mid-1990s, a few states had already enacted legislation prohibiting physicians from being financially linked to clinics or certain types of home health services.

CURRENT CONDITIONS

Home health care is at once a blossoming and struggling industry. As the population of the nation ages rapidly, there is an increasing demand for services provided by homecare agencies. New technologies that al-

low for on-site diagnostic testing and treatment allow more elderly or ill individuals to remain at home rather than enter a nursing home. At the same time, the industry had not yet recovered from the financial effects of the Balanced Budget Act of 1997, which, according to the NAHC, cut Medicare reimbursements for home health care by \$69 billion—more than four times the amount intended by Congress. For example, Rhode Island alone, which provides homecare serves to approximately 2,000 residents, lost \$56 million in Medicare reimbursements between 1997 and 2001.

Another chronic problem for the home healthcare industry was the shortage of registered nurses and home-health aides, as well as a high rate of turnover. According to the Visiting Nurse Associations of America, the nation turnover rate was 21 percent for registered nurses in home health and 28 percent for home-health aides. Once again, the industry pointed a finger at the federal government for its woes, noting that cumbersome paperwork was the result of too many federal regulations, adding stress and additional hours to nurses' workdays. Nurses were also under pressure to balance their commitment to providing quality care with the need to also provide cost-effective care.

The home health care industry was undergoing a development process during the early 2000s, in which industry experts believed that the growing demand coupled with financial instability would ultimately lead to a more streamlined industry that would sift out those who cannot cope with the increasing federal regulation and decreasing federal financial support. For example, according to the American Association for Homecare, in 2002 the percentage of home healthcare businesses owned by hospitals fell to 25 percent, down from 35 percent in 2001. Medicare and Medicaid accounted for 46 percent of home health revenues, and private-sector managed-care plans picked up an increasing portion of the bill.

In an ongoing effort to balance quality care with cost control, the home healthcare industry began to experiment with telehomecare. By using telephone- and Internet-based communication, medical care professionals could stay in touch with patients without travel. The Veterans' Affairs (VA) in Connecticut tested telehomecare over a six-month period and discovered that the program reduced emergency room, clinic, and home health visits by over 20 percent, resulting in a per-patient savings of \$200. As the medical device industry continued to develop simple-to-use, at-home vital signs testing equipment, such as the oximeter, EKG, stethoscope, and fingerstick glucometer, the potential for providing a medically significant link between a case manager and patient via the Internet was expected to become an important development in the home healthcare industry.

INDUSTRY LEADERS

Apria Healthcare Group, Inc. Apria Healthcare Group, Inc. was formed in 1995 when Homedco and Abbey Healthcare merged. These two companies showed a combined revenue of \$1 billion in 1994. This merger created the largest home healthcare company in the United States. The bulk of its revenues (53 percent) came from its respiratory therapy. By 2002, Apria (headquartered in Costa Mesa, California) operated approximately 400 branches across the country. The company earned a net profit of \$115.6 million on sales of \$1.25 billion during 2002 and employed nearly 9,700 people.

Coram Healthcare Corporation. Based in Denver, Colorado, Coram Healthcare Corporation was formed in 1994 by a four-way merger of Curaflex Health Services, HealthInfusion, Medisys, and T2 Medical. Coram acquired HMSS in 1994 and Caremark International in 1995. (Note above that Caremark was sold in 1996 to MedPartners). In the early 2000s, Coram provided services ranging from infusion to anti-infective chemotherapy, clinical research, and medical informatics services. Coram filed for Chapter 11 bankruptcy in 2001 and underwent restructuring. It continued to operate 70 branches in 40 states.

Lincare. Lincare, with headquarters in Clearwater, Florida, was one of the nation's largest providers of oxygen and other respiratory therapy services. It reported more than 180,000 customers in 42 states. Lincare earned a net profit of \$190.4 million in 2002 on sales of \$960.9 million and employed 6,100.

American HomePatient, Inc. American HomePatient, Inc. of Brentwood, Tennessee, is one of the largest home care companies in the United States. In August 1997 it acquired five companies with combined annualized revenues of \$10.3 million. Those companies were Central Home Medical Supply, located in Enid, Oklahoma; Ameriquipt Corporation Inc., in Leesburg, Florida; Homecare Medical Equipment, Inc., in Whitely City, Kentucky; Downeast Medical Shoppe, in Bangor, Maine; and the reparatory and medical equipment divisions of Headley Home Care Medical Services, based in Fransville, Wisconsin. The company provided healthcare services and medical equipment through its 300 branches in 40 states. In 2002, American HomePatient posted a net loss of \$11.5 million on revenues of \$352.6 million and employed 3,300, down from over 4,750 people in 1998.

WORKFORCE

In 2001, the U.S. Department of Labor, Bureau of Labor Statistics counted 658,110 employees in home healthcare agencies, excluding hospitals and public agencies. Healthcare practitioners and technical occupations accounted for nearly one-third of all jobs. Registered nurses,

the largest in-category occupation, had a mean annual salary of \$47,560; occupational therapists had a mean annual salary of \$64,930; and licensed practical and licensed vocational nurses had a mean annual salary of \$33,030.

Healthcare support occupations—primarily home health aides and nursing aides—accounted for 36 percent of the industry's jobs, with a mean annual salary of \$17,880. Personal and homecare occupations held 18 percent of the industry's jobs. Homecare aides had a mean annual salary of \$14,650.

RESEARCH AND TECHNOLOGY

New drugs, drug pumps, and home infusion equipment helped the home healthcare industry to expand by offering more at-home services, previously only available in hospitals or nursing homes. Future technological developments could only be expected to benefit this industry, which has grown in the wake of soaring healthcare costs in the beginning years of the twenty-first century.

SIC 8092

KIDNEY DIALYSIS CENTERS

This industry consists of establishments primarily engaged in providing kidney or renal dialysis services. Establishments operating as clinics of physicians are covered in **SIC 8011: Offices and Clinics of Doctors of Medicine**.

NAICS CODE(S)

621492 (Kidney Dialysis Centers)

INDUSTRY SNAPSHOT

An aging population and a growing health care sector were reflected in the continued growth of the dialysis center industry, which is composed of approved independent and hospital-based or affiliated facilities. All kidney dialysis centers are regulated and subsidized by the federal government, which grants exclusive licenses to providers to supply long-term dialysis within a designated territory. The facilities are reimbursed through the Health Care Financing Administration (HCFA) with Medicare funds.

As in many other sectors of the economy, trends toward mergers, acquisitions, and nationwide chains influenced the growth of this industry. Investors have grown increasingly interested in this area, attracted by an increase in revenues of nearly 190 percent during the 1990s.

BACKGROUND AND DEVELOPMENT

The process of dialysis was invented about 1854 by a Scottish chemist named Thomas Graham, who would later become the first to employ dialysis to prolong life. The procedure was not widely used until after 1945, when Dr. Wilhelm Kolff used it to save the life of a patient in active renal failure, demonstrating that the process not only could prolong life for a short time, but could actually increase survival rates for renal failure.

Most users of dialysis in the late twentieth century were victims of end-stage renal disease, which requires either dialysis or transplant for survival and is not reversible. Two kinds of dialysis are used: hemodialysis and peritoneal dialysis. Hemodialysis is generally performed three times a week in two- to four- hour sessions, remov-

ing waste through an artificial kidney machine outside of the patient's body. Peritoneal dialysis uses the peritoneum, a membrane in the abdomen, to remove the waste, using a procedure that can be performed at home by the patient. The amount of patients receiving peritoneal dialysis is expected to increase, as it is a cost-saving measure that keeps patients out of the hospital. By the end of the 1990s, however, the technology for peritoneal dialysis was not sufficiently advanced to allow all patients to use it, particularly those with severely impaired renal function. In 1999, less than 15 percent of kidney patients were treated at home.

Since 1972, the number of chronic dialysis patients has increased a hundredfold. In 1996, an estimated 214,000 Americans received dialysis. The HCFA predicted that the number of these patients will increase by at least 9 percent per year. HCFA reimbursements accounted for the majority of payments to kidney dialysis centers. Scarcity of funds caused the federal government to cut back on its reimbursement rates, making it difficult for many hospital-based centers to keep operating. Some hospitals have responded by referring patients to free-standing centers.

In the mid 1990s, however, that cost-cutting proved deadly. A National Kidney Foundation report published in 1995 found that American dialysis patients faced a much higher mortality rate than dialysis patients in other countries. Figures for 1992 showed that nearly 24 percent of U.S. dialysis patients died, compared with a mortality rate of 9.7 percent in Japan, 10 percent in Germany, and 11 percent in France. Because cost incentives built into the system may have limited dialysis treatment times and frequency, and the reuse of supplies, the number of end-stage renal disease patients — and mortality rates — went up. The for-profit nature of dialysis centers seemed only partially to blame. The National Kidney Foundation study found that cost-cutting in the form of poorly trained staff and inefficient use of dialysis machines also seemed to be a factor in the 45,000 American deaths. As Dr. Neil Kurtzman told the *Journal of the American Medical Association*, "The government pays for visits to a facility. We believe it should change this and pay for the actual care a patient receives."

A campaign was launched in 1995 by the National Kidney Foundation to improve patient care at dialysis centers and decrease deaths. The licensing of a new, relatively lightweight, and easy to use home-dialysis machine was also expected to bring changes to the industry.

CURRENT CONDITIONS

The number of patients receiving kidney dialysis in the United States was expected by some analysts to hold steady at close to 214,000, given the increasing number of kidney transplants being performed and the expecta-

tion of improved transplant success in the future. The HCFA, however, predicted in 1996 that the number of patients would continue to grow at the rate of 9 percent annually until at least 2001, and possibly until 2006. The aging of the American population was also expected to contribute to an increase in patients. In 1999, the United States was the world's largest market for kidney dialysis, followed by Japan, the rest of Asia, and Latin America.

A treatment trend of the late 1990s was daily hemodialysis. Estimates suggest that in 1998, 12 centers worldwide were providing daily treatments for more than 100 individuals with renal failure. This treatment plan was not for the general public, however; at that time, such frequent treatments were not covered by Medicare, which paid for any patient with end-stage renal disease.

As an industry, kidney dialysis centers grew steadily throughout the 1990s, from revenues of \$1.45 billion in 1990 to \$3.38 billion in 1996. Projected revenues for 1998 were \$4.19 billion, reflecting a growth of nearly 190 percent. Employment in this industry, like many other health care industries, was also forecast to increase significantly. Most positions—such as nurses, physicians, and lab technicians—were expected to increase by close to 50 percent by the year 2006. Rapid increases in employment opportunities have made adequate training a problem for the work force in this industry.

Growth of individual businesses has been limited in some areas by the requirement for a Certificate of Need (CON). The certificate demonstrates that “the communities they’re targeting for additional dialysis services need more service, that their proposed projects are the best way to meet those needs, that they’re financially feasible and that they will deliver high-quality service,” according to a 1997 article in the *Puget Sound Business Journal*. This system has tended to favor smaller, local, or non-profit businesses already in place at the expense of national or worldwide firms seeking to expand their territory. Larger companies have complained that the regulation is anticompetitive. Some states have phased out this requirement. In Ohio, prior to the elimination of the CON rule, the state foresaw a need for 40 new dialysis stations. Once the rule was lifted, 571 new ones were added. Current dialysis providers in Washington fear the frenzied competition created by lifting the CON rule will drive several existing companies out of business, particularly independent providers.

INDUSTRY LEADERS

As of 1998, the largest companies in this industry, ranked by sales and number of employees, were Fresenius National Medical Care, Gambro Healthcare Inc. (with its subsidiaries COBE Laboratories Inc., Vivra Inc., and REN Corporation), and Total Renal Care.

Fresenius National is the U.S. subsidiary of Fresenius Medical Care, based in Germany. In 1998, Fresenius National reported \$2.2 billion in sales—a figure that also reflects its interests in home health care service and other medical products, although in mid 1998 the company sold off its U.S. holdings not related to its core business of kidney dialysis. In 1999, Fresenius claimed to serve 23 percent of dialysis patients in the United States. In the late 1990s, Fresenius was the subject of two major lawsuits charging false claims; the company settled in both cases without acknowledging any wrongdoing.

Gambro Healthcare posted \$1 billion in sales in 1998, and its subsidiaries also did well: COBE Laboratories reported \$1.7 billion in sales; Vivra, \$517 million, and REN, \$132 million. Gambro acquired Vivra in 1997, making the company second only to Fresenius as a worldwide provider of dialysis products and services. In 1999, Gambro announced plans for a joint venture with Baxter Healthcare, a pioneer in hemodialysis technology. Baxter created the first commercial artificial kidney machine in 1956 and was also a leader in developing home-based dialysis products. Gambro also announced plans to reorganize the company significantly in 1999, possibly selling COBE Labs and consolidating worldwide operations by moving offices from Sweden into its Colorado headquarters.

Gambro's closest competitor for second place was California-based Total Renal Care, which acquired Renal Treatment Centers Inc. in 1997. Total Renal Care Holdings Inc. claimed \$1.2 billion in revenues for 1998. Total Renal Care stock was popular with investors until mid 1999, when its CEO and chief financial officer both stepped down and the company posted a second-quarter loss of \$21 million. The interim CEO blamed a billing backlog—uncollected moneys from both patients and hospitals—for the financial setback.

SIC 8093

SPECIALTY OUTPATIENT FACILITIES, NOT ELSEWHERE CLASSIFIED

This grouping covers establishments primarily engaged in outpatient care of a specialized nature with permanent facilities and with medical staff to provide diagnosis, treatment, or both for patients who are ambulatory and do not require inpatient care. Offices and clinics of health practitioners are classified according to their primary health care activity.

NAICS CODE(S)

621410 (Family Planning Centers)

621420 (Outpatient Mental Health and Substance Abuse Centers)

621498 (All Other Outpatient Care Facilities)

INDUSTRY SNAPSHOT

Facilities in this category are diverse and include outpatient centers offering alcohol or drug treatment, bio-feedback, family planning, mental health services, rehabilitation centers, outpatient surgery, kidney dialysis, lithotripsy (therapy that reduces kidney stones into small pieces so that they can be voided), and diagnostic imaging environments. Efforts to cut huge medical costs starting in the 1980s led to a movement away from inpatient treatment that continued to the 1990s, resulting in a number of different outpatient services. Growth was expected to continue into 2006 in new areas, most of which are less than 10 years old because of technology that further reduced the cost of providing these services and allowed them to be offered in outpatient facilities.

In the early 1990s, these outpatient and office locations were less regulated and utilized third-party reimbursement. Many were owned by physicians or physician groups and were not subjected to the same oversight as inpatient proce-

dures. This changed in the middle of the decade with the introduction of government legislation to reduce abuses by physicians referring patients to self-owned laboratory services. The Stark Amendment created a list of 11 designated services to which physician owners could not refer Medicare or Medicaid patients. Combined with pressures from managed care companies, many physicians sold their interests in facilities, resulting in many publicly owned companies entering this specialized marketplace offering multiple services at a lower cost.

ORGANIZATION AND STRUCTURE

Drug and Alcohol Treatment. The trend of using specialized outpatient facilities is especially evident in substance abuse treatment. Drug and alcohol treatment is increasingly being done on an outpatient basis. The 17 percent growth rate for the service market for inpatient drug and alcohol treatment centers was at its height in 1989, bringing in \$3.9 billion in revenues. This area has remained at this economic level through the 1990s.

The industry had been built on inpatient care. But in a cost-cutting environment, reimbursement requests for substance abuse treatment were being subjected to greater scrutiny by insurance companies. More co-payments were required, and lifetime caps were set on reimbursement. Outpatient care was less costly as well, and treatment methodologies changed as a result of all these factors. Now patients are typically treated for only a brief period in a hospital before moving on to outpatient centers, where treatment typically lasts four weeks.

The shift to outpatient care is apparent in the declining numbers of days that patients receive inpatient substance abuse treatment. Formerly the length of stay was 28 days. In the 1990s, inpatient stays averaged 15 to 19 days. The number of treatment beds was also down and, according to industry statistics, substance abuse facilities were operating at about 65 percent capacity, a decline from 80 to 90 percent capacity levels posted in the late 1980s.

Increased regard for civil liberties has also decreased compulsory inpatient treatment. In addition, community-based support groups have become an integral part of drug and alcohol abuse treatment enabling drug abuse patients to avoid hospitalization. Another factor discouraging the use of inpatient facilities for substance abuse is the increasing number of young people with alcohol abuse problems who are seeking treatment. These clients typically have fewer medical problems related to their addiction and are less in need of hospitalization to treat such related problems.

Psychiatric Outpatient Care. Insurance companies and other third-party payers are also taking a harder look at claims for inpatient psychiatric care today, prompting

hospitals and other health care providers to set up less expensive outpatient facilities. According to a survey from the National Association of Psychiatric Health Systems (NAPHS), nearly 67 percent of psychiatric centers provided outpatient services. The average length of an inpatient psychiatric stay has gone down, according to the Health Care Institute of America, a health care consulting firm. The average stay in a psychiatric hospital went down to 11.5 days in the late 1990s from 25.7 days in 1987, while total patient rates increased. The number of outpatient admissions rose nearly 21 percent to over 1,200. The number of each patient's visits declined during that time.

Family Planning Clinics. These free-standing centers practice measures designed to assist pregnant women (and families) in making various decisions regarding their condition. Such clinics have a unique history and are at the center of a controversial ethical debate. Abortions are one of the services provided by these clinics since the Supreme Court's *Roe v. Wade* decision that legalized abortion in the United States. Since that decision, however, debate has raged about the practice. Protests outside family planning clinics of abortion services have grown increasingly frequent. The fortunes of such clinics have thus changed with shifts in political power at the national level. Under the Bush administration, which did not favor abortion rights, regulations were passed preventing federally-funded family planning centers from providing abortion counseling. That regulation was rescinded by the Clinton administration.

Family planning clinics not only provide contraceptive methods but also offer screening services to contraceptive clients since the services are required for prescribing birth control pills. Almost all such establishments provide pelvic examinations, blood pressure tests, PAP smears, and breast examinations.

Planned Parenthood-World Population, formerly the Planned Parenthood Association, is a leading family-planning network, and one which brought organized family planning to the United States. It was founded in 1921 and has centers throughout the United States. Many Planned Parenthood affiliates also offer services such as colposcopy (examination of the vagina and cervix) and HIV testing.

Prospective Payment System In the 1980s, a movement away from retrospective payment for inpatient care began. When Medicare was initiated in 1965, it reimbursed hospitals and physicians based on bills submitted after treatment. But in 1983, that type of payment for hospital inpatient treatment was replaced with the Prospective Payment System. Yet charges for physicians and outpatient services continued to be reimbursed retrospectively, encouraging a shift to outpatient therapy.

The Prospective Payment System for the first time rewarded hospitals for holding down costs and allowed hospital administrators to know before treatment how much a hospital would be reimbursed for illness at rates determined by geographic region as well as by specific procedures and medical problems.

CURRENT CONDITIONS

At the beginning of the twenty-first century, each medical problem was classified by a specialized group of health professionals into a Diagnostic Related Group. If a hospital spends less than is allotted under prospective payment it makes a profit, but if it spends more, the hospital must make up the difference. As a result many believe that doctors may be admitting fewer patients and referring more to outpatient settings not subject to peer review or prospective payment. Indeed, the incidence of outpatient treatment rose dramatically following introduction of the Prospective Payment System.

Many Clinton administration officials expressed determination to eliminate what they viewed as the insurance industry's discrimination against the mentally ill. Both Medicaid and private insurance policies severely restrict coverage of mental health care. Generally the elderly and disabled beneficiaries must pay 50 percent of the bills for outpatient mental health services, a stark contrast with the 20 percent contribution generally required for treatment of physical ailments. Currently the federal government pays for a quarter of the \$67 billion spent annually for mental health care, with private insurers and patients paying the balance. Proposed plans for alleviating this problem included the creation of incentives for community-based care and outpatient services rather than hospitalization.

Yet there have been problems with treating the mentally ill as outpatients. During the 1980s, in an effort to cut costs, several states deinstitutionalized mental patients and made plans for them to continue their treatment in outpatient settings. New York hospitals, for instance, made elaborate plans for treatment of mentally ill patients after their release, but those plans fell through. According to a 1993 study of the New York State Commission on the Quality of Care for the Mentally Disabled, 40 percent of the discharged mental patients whose cases were reviewed ended up being rehospitalized within six months of their discharge because they were unable to make their way through the complicated government and health care bureaucracies they needed to help them. The released patients were rehospitalized at an average cost of \$30,750. Nine of ten patients had abused drugs or alcohol and received no services for the mental illness or addiction.

In 1998, total industry revenue was reported to be nearly \$5.9 billion, with expenses of \$5.5 billion. This

represented a 1.4 percent decrease in revenue, and a 1.1 percent decrease in expenses from the previous year.

Family Planning. Financial strains on family planning facilities have increased in recent years. There has been less public funding, while expenses have gone up. New contraceptive methods such as the contraceptive implant are expensive. To meet these expenses many agencies have had to raise fees. While the Clinton administration was friendly to these clinics, in contrast to the previous administration, clinics faced long-term economic insecurity. Without public funds, family planning leaders said, their clinics would have to merge with managed care organizations or offer primary care to remain financially viable—and providing primary care would force these clinics to narrow the range of contraceptive care they offer.

Hospital Outpatient Treatment. Outpatient facilities are also being set up by hospitals. Anxious to preserve their traditional centrality in health care, hospitals are establishing health care networks with a variety of outpatient services in addition to the traditional inpatient care. The Berlin Memorial Hospital in central Wisconsin, for example, links women's health clinics in three separate towns with anesthesiology centers, internal-medicine centers, an extended-care facility, and a nursing home. Information systems in such cases are integrated for ease of handling by insurers and participating physicians. The effort by hospitals nationwide to assume a more important role for outpatient centers is part of the overall trend advancing outpatient care at a time when the nation is taking a critical look at its traditional health care system.

WORKFORCE

The employment pattern for miscellaneous outpatient services underwent accelerated growth during the period from the 1980s through the 1990s and proved to be basically immune to recessionary pressures. This is due, in part, to the large increase in the numbers of middle-aged and elderly in the population. An aging population typically brings an increased incidence of disease and need for outpatient services. For example, employment of radiology technologists is expected to grow faster than average through 2006 because of the vast clinical potential of diagnostic imaging and therapeutic technology. In the late 1990s, the average starting salary was just under \$29,000. Department heads' salaries were \$68,500.

SIC 8099

HEALTH AND ALLIED SERVICES, NOT ELSEWHERE CLASSIFIED

This classification is comprised of establishments primarily engaged in providing health and allied services, not described under other classifications.

NAICS CODE(S)

- 621991 (Blood and Organ Banks)
- 541430 (Graphic Design Services)
- 541922 (Commercial Photography)
- 621410 (Family Planning Centers)
- 621999 (All Other Miscellaneous Ambulatory Health Care Services)

INDUSTRY SNAPSHOT

This segment of the health services industry includes an array of services and occupations that most often do not involve the provision of direct care. Rather they provide diagnostic services or facilitate the work of physicians and other health care providers.

Despite the extreme diversity of establishments in this classification, all enjoy the economic advantages of offering services that are in great demand regardless of economic climate. The establishments include blood banks; hearing testing services; childbirth preparation classes; health screening centers, except by physicians; sperm banks; osteoporosis centers; medical illustration; oxygen tent services; and plasmapheresis centers. In 1997, the industry had total revenues of just under \$23 billion; by 1998 the industry employed 339,000 people.

The classification contains a notable mix of profit and non-profit organizations. Blood banking, for example, is a multi-billion dollar industry in which the purified products, though donated, command a high price if sold. Hearing testing services may be available for free at schools or for a fee at private commercial establishments. Most hearing testing is done in schools and colleges, with

10 percent in hospitals and the rest in private offices and speech, language, and hearing centers. Similarly, childbirth preparation classes are often available through schools, community groups, and other nonprofit organizations, but they are also available from commercial childbirth preparation centers. Health screenings are done by municipal health departments as well as independent commercial establishments. Unlike the rest of the activities on this list, medical equipment like oxygen tents are profit-making ventures, while medical art and photography may be provided by independent entrepreneurs contracted by medical textbook publishers or others engaged in medical education.

The state of the nation's health has had a great impact on two of the health services in this group — the collection and production of blood. Combined, this sector, the most lucrative in this classification, has been much affected over the last decade by the need to test for hepatitis and AIDS. The same concerns hold true for sperm banks.

ORGANIZATION AND STRUCTURE

Since there is such a diversity of activities within the health and allied services group, there is no overall industry structure. Rather, different structures govern each activity. For example, in the case of blood banks, three nonprofit organizations preside over the \$3 billion U.S. whole blood market.

At the end of the 1990s, the leading blood market organization was the Red Cross, which had 38 regional blood centers that collected blood from more than 4.5 million donors, and supplied more than half of the nation's blood supply. The number of blood centers the previous year was 45, however, the organization was forced to restructure their blood bank operations after questions arose regarding their quality standards. The 1996 restructuring cost approximately \$162 million.

The Red Cross was estimated to have \$1.9 billion in revenue in 1997. A majority came from biomedical services (the collection, testing, and distribution of blood and blood components); revenue derived solely from these activities accounted for \$1.1 billion.

Second to the Red Cross is America's Blood Centers (ABC), a nation-wide network of independent blood centers in 46 states at over 450 sites. Their mission also included blood diagnostic and therapeutic services. In 1999, ABC collected approximately 47 percent of the blood used in the United States.

Industry Divisions. The miscellaneous services provided in the health and allied services industry can be subsumed into two general groupings: first, services provided to physicians and hospitals; and second, services provided to health care consumers.

The services provided to physicians and hospitals include medical photography and art and blood and blood products from blood and plasmapheresis centers. Medical or biological subjects may be illustrated for teaching purposes through photography, graphics, paintings, and three-dimensional models. Medical art and photography appears in books, films, videotapes, and computer graphics. Blood banks provide whole blood and some derived components that are processed, typed, and stored until needed for transfusion. Blood should be used as soon as possible since the number of red blood cells decline significantly after 14 days. At plasmapheresis centers, blood is removed from the body, centrifuged, and the red cells suspended in a solution. They may be re-injected into the donor or into a patient who requires red cells rather than whole blood.

Examples of services provided to health consumers include health screening, hearing testing, child birth preparation classes, sperm banks, and osteoporosis centers.

Health screening centers, whether private or public, are likely to focus on particular problems such as cancer detection; sexually transmitted diseases; or nutrition, diet, and weight control.

Hearing centers diagnose hearing problems and prescribe treatment. An audiologist uses an audiometer and other testing devices to measure the loudest sound at which a person begins to hear. The audiologist also measures the ability to tell the difference between sounds and the extent of any hearing loss. The results of the tests may be correlated with other medical, psychological, and education test results and a course of treatment determined.

Childbirth preparation classes often follow the principles of the French obstetrician Fernand Lamaze, who advocated avoiding highly medicated childbirth. The method stresses the active participation of the mother through muscle control and breathing, with encouragement and massage given to her by her husband. In this method, also known as psycho-prophylaxis, the husband is prepared to act as his wife's labor coach.

The fact that sperm can be kept alive for long periods of time in cold temperatures has enabled banks of human semen to be maintained for use in artificial insemination. Licensed sperm banks are members of the American Fertility Society. The society has revised its guidelines for therapeutic donor insemination of sperm several times in recent years to improve selection of donors and decrease the potential hazard for transmitting infectious agents.

CURRENT CONDITIONS

As in general medical professions, there are controversies within this classification regarding the right of

physicians to refer patients to establishments in which they have invested. In 1993, the Federal Trade Commission used antitrust legislation to challenge two oxygen and oxygen equipment businesses owned by doctors who referred their patients to them. According to the Federal Trade Commission, 60 percent of the lung specialists in two California counties, Contra Costa and Alameda, had invested in the medical equipment companies. The Commission stated that such "self-referrals," as they are called, exclude competitors from the market in violation of the law since the doctors can control the referral of patients who need these services. Since other home oxygen companies may not be able to get referrals from doctors, they were unable to compete in the market regardless of the quality or prices. The commission and the companies agreed on a settlement, stipulating that some of the lung specialists would have to sell their shares in the company so that no more than 25 percent of the lung specialists in the area would have a connection with the company.

The need to protect the blood supply against hepatitis and AIDS has made the work of blood banks and plasmapheresis centers increasingly complex. To screen against the two diseases, blood centers have added five tests since 1985. Commercial companies and nonprofit blood centers have acquired computer systems to track donors throughout the country. The American Blood Resources Association is setting up a nationwide donor referral registry, so that a blood center can call an 800 number to find out if the donor has ever tested positive for the AIDS virus or another condition that would rule them out as a donor. Aware of public concern over the safety of the blood supply, the American Association of Blood Banks in 1993 mounted a public relations program designed to increase public awareness about the general safety of the blood supply.

Plasma, in particular, is the fastest growing sector of the blood products industry. There is a worldwide market for blood plasma. A pint of whole blood has a \$100 price tag, but its components add up to \$190 a pint. Plasma lasts longer than blood and \$55 worth of plasma can be extracted from a pint of blood. The technology and training for processing plasma requires a significant investment. Obtaining plasma may often involve paying donors. Plasma can be separated into albumin, which is necessary to keep blood vessels from collapsing after an injury; factor VIII, an important blood clotting agent; and immune globulins, which can protect against several diseases.

With 30 percent market share, the leader in the industry is Armour Pharmaceutical Company (of Bluebell, Pennsylvania), a subsidiary of Rhone-Pulenc Rorer, the French government-owned pharmaceutical company. Next, with 25 percent of the market, is Hyland Therapeu-

tics (of Glendale, California), a subsidiary of Baxter International Inc. The Red Cross became involved in the commercial market in 1978 when it took donated plasma from its supplies and used the Hyland manufacturing facilities to turn it into its marketable components. That move brought the Red Cross approximately \$100 million of tax-exempt revenue in 1990. By 1996, the Red Cross had become a \$1.9 billion organization.

The blood and blood products sector is the most highly regulated sector within this classification. The U.S. Food and Drug Administration (FDA) licenses plasmapheresis firms as well as the firms that ship their products from state to state. The problems that were uncovered at a Tacoma, Washington plasmapheresis center illustrate the risks involved when this type of firm does not adhere to regulations. The firm, AVRE Plasma, received a four-month suspension of its establishment and product licenses in 1992 as a result of operating practices that the FDA termed "dangerous." AVRE sells source plasma to pharmaceutical firms for processing into serum albumin, immune globulins, and other medical products.

WORKFORCE

The training required to carry out the duties of the health and allied services listed here varies greatly. Medical illustrators generally have a four-year bachelor's degree, and often from one of the six accredited schools in the United States that offer a degree in medical illustration. Audiologists also have four years of training, but with a master's degree, may acquire the Certificate of Clinical Competence offered by the American Speech and Hearing Association. They must also have 300 hours of supervised clinical experience in a 9-month, post-graduate internship, and pass an examination. In contrast to the extensive training required by others in this category, phlebotomists can be trained to draw blood in from one to three months. However, much more extensive training is required for the technicians who analyze blood to determine if there are abnormalities; hence, the medical director of a blood bank is often a pathologist with a full medical degree.

RESEARCH AND TECHNOLOGY

The blood industry will require huge infusions of money early in the twenty-first century to purchase new equipment for research and employ more staff. The commercial blood products companies have invested \$50 million for research into new blood products; the Red Cross has invested \$7 million alone.

The advent of the AIDS epidemic has also resulted in people storing their own blood in preparation for operations or emergencies. The first autologous blood storage was done by a sperm bank owned by the Daxor Corpora-

tion, based in New York. The blood can be stored for 10 years, and storage charges vary from \$12 a month for a pint of fragile red cells to \$8 for plasma. Autologous blood banks have not been a good investment, according to Dr. Joseph Feldschu, who founded Daxor. Acceptance of this approach has been slow. Traditional blood banks also consider that autologous blood threatens the system of voluntary blood donations for others.

Reports at the 1994 American Association of Blood Banks Conference showed how new technologies could reduce or even replace the need for blood transfusions. One such technology involves the transplantation of purified peripheral blood progenitor cells, which are collected through an immuno-absorption system. In tests at the University of Colorado Cancer Center in Denver, patients showed improvements in their recovery rate. "Patients are recovering faster, doing better, and getting out of the hospital more quickly, which translates into reduced costs," Shelly Heimfeld, director of biological research at CellPro in Washington, told *JAMA*. "Peripheral blood also dramatically reduced the number of red blood cell and platelet transfusions needed."

In 1999, under the auspices of the Federal Drug Administration's Investigational New Drug (IND) application process, the blood community began Nucleic Acid Amplification Testing (NAT). This new technology specifically sought increased protection of the nation's blood supply by detecting genetic material that marked HCV and HIV viruses.

The medical illustration industry benefited greatly from computer technology innovations in the mid to late 1990s. By 1997, illustrators had access to more techniques, such as three-dimensional scientific imaging, surface modeling, and animation. In addition, medical illustrators could use laser scanners and digitizers to enhance detail and accuracy. Illustrators could also manipulate three-dimensional information using the virtual reality modeling language (VRML) to put biological models and data on the World Wide Web for examination by medical students, patients, and consultants.

SIC 8111

LEGAL SERVICES

This industry consists of establishments that are headed by members of the bar and are primarily engaged in offering legal advice and/or services. Such establishments include attorneys, counselors at law, law offices, lawyers, legal aid services, legal services, patent solicitors' offices, and referees in bankruptcy.

NAICS CODE(S)

541110 (Offices of Lawyers)

INDUSTRY SNAPSHOT

The legal service industry is the second largest professional service industry in the nation, second only to health services. At the beginning of the twenty-first century, the industry collected more than \$132 billion in annual revenue—more than five times the annual revenue collected by advertising firms, almost three times the revenue collected by accounting and auditing firms, and approximately one-third less than the amount of revenue generated by the automobile industry. The legal services industry employed more than one million people, with nearly half of the workforce consisting of practicing attorneys.

The economic recession of the early 2000s slowed the growth of the legal industry but did not squelch it completely. Multi-lawyer practices adjusted to the slow economy primarily by cutting back on the number of vested partners in firms. Rather than stepping into a firm right out of law school and immediately onto the fast track to partnership, young lawyers were finding the traditional process by which they would come to share in the wealth of the firm's business stymied. Two-tiered partnerships were being put in place and fewer full partnerships were being offered. Despite the changes, however, job placement following law school was 90 percent in 2001, but—reflecting another trend to use legal skills in new fields—only 58 percent of law graduates were employed by law firms.

ORGANIZATION AND STRUCTURE

An attorney, also known as a lawyer, is an agent, that is, a person appointed to act on behalf of another. As indicated by noted attorney Karl Llewellyn in the *ABA Journal* in 1942, “the essence of our craftsmanship lies in skills and wisdom; in practical, effective, persuasive, inventive skills for getting things done. . . . We are the trouble-shooters.” The right to assume this agency relationship is granted by state statutes dictating admission to the state bar. Admission to the bar confers the authority or license to practice law. Requirements for admission usually include three years of college, graduation from an American Bar Association (ABA) accredited law school, residency requirements, and successful completion of the bar examination. In the early 2000s, some states such as California had varying practices regarding study requirements and allowed apprenticeships in lieu of academic study. In addition, some states relied entirely upon their own bar examinations while others used a “multistate” examination. Attorneys admitted to the bar in one state might not practice in another without permission of the other state’s authority. Practicing law without proper accreditation is a punishable and sometimes criminal offense. While there has never been a nationwide bar exam, 46 states required in the early 2000s that applicants pass the multi-state bar exam (MBE) as part of the admission process.

Lawyers are admitted to the bar for life; however, misconduct can bring suspension or disbarment as well as other appropriate punishment. As a general axiom, any conduct that would have prevented admission to the bar also would be sufficient to suspend or disbar an attorney. The general criterion is whether the attorney is deemed fit for the confidence and trust required in the attorney-client relationship.

The bar review industry is an extremely concentrated and competitive industry wherein five firms control most of the market. The five major players in the industry—Bar/Bri, PMBR, SMH, Barpassers, and Reed—aggressively pursue the limited market of 58,000 annual exam takers, which generates \$50 million in revenues. Founded in 1967, Bar/Bri was the early 2000s leader among such reviewers, with more than 600,000 students having taken its course.

Categories of Legal Service. Four broad categories of legal service providers in the United States, each having subcategories of their own, are public legal assistance, government, nonprofit, and private.

Public Legal Assistance. According to the Sixth Amendment to the U.S. Constitution and affirmed by the landmark Supreme Court case *Gideon v. Wainwright*, all individuals are entitled to legal services regardless of ability to pay. Due to the high cost of legal counsel,

public legal assistance programs have been established for people who cannot afford legal services.

In 1963, Clarence Earl Gideon, an uneducated gambler and petty thief, insisted on his right to legal counsel. The Supreme Court and Justice Hugo Black upheld this right: “Any person hauled into court who is too poor to hire a lawyer cannot be assured a fair trial unless counsel is provided for him. . . . This seems to us to be an obvious truth.” The courts have expanded the ruling in *Gideon* to apply to all criminal cases, which has led to the establishment of two types of public legal offices: public defenders and legal aid offices.

Public defenders represent criminal defendants. A criminal case is distinguished from a civil case by two primary elements. First, in a civil suit, someone has sustained a loss or harm as the result of some act (or failure to act) by another. The individual filing the act is seeking compensation (either monetary or performance) rather than seeking punishment, as in a criminal case. Second, an individual party usually files against another in a civil case; a criminal case is filed by the state against an individual. In the early 2000s, the state of public defense was enormously strained by caseloads that overwhelmed defense attorneys, as well as a paucity of funds. Legal aid offices represented the civil counterpart of public defenders. These organizations represented those who could not afford legal counsel in civil matters such as tort litigation (i.e. lawsuits resulting from negligence, etc.). Eligibility guidelines for access to public legal services varied depending on location, family size, and household income.

Government Lawyers. Supported by tax dollars, hundreds of attorneys work for the government at each of the three levels: local, state, and federal. Government attorneys are primarily engaged in legal problems concerning government service (e.g., Bureau of Consumer Protection, Human Relations Commission, or Department of Environmental Resources) or government-regulated industries (e.g. Public Utilities Commission).

Nonprofit Organizations. These types of organizations provide free representation to individual cases that relate to the organization’s unique interests. Special interest organizations such as the Environmental Defense Fund, the National Association for the Advancement of Colored People (NAACP), and the American Civil Liberties Union (ACLU) are engaged in the provision of legal services.

In addition to career nonprofit lawyers, charitable legal services or pro bono work is becoming increasingly prevalent as a mandatory part of legal education. Several law schools have public service requirements for graduating students. As of the early 2000s, Tulane University School of Law, for example, required that graduating

students perform at least 20 hours of public service law. Beginning with the class of 1996, Columbia University School of Law required its students to complete 40 hours of pro bono work over a period of two years. At other schools, nonprofit work was voluntary—New York University's entering class pledged to perform 95 hours of community service work apiece during the students' three-year tenure. In addition, more than 50 law schools had initiated programs to ease the debt burden of graduates who go into nonprofit practice.

Private Lawyers. The most prevalent form of legal service provider is the private attorney. There are two basic types of private attorney: individual or sole practitioners and group practitioners or law firms. Group practices fall into three primary categories: informal arrangements in which two or more lawyers share office space and support services, partnerships, and legal corporations. Partnerships and legal corporations are designated as law firms. An ABA survey indicated that practices with five or fewer attorneys represent 25 percent of the industry. Approximately 31 percent of lawyers engage in practice as partners or as associates of law firms with 20 or more practitioners. Law firms range in size from two practitioners to large, multidivisional firms engaging more than 100 associates. Large corporations employ an additional category of private lawyers as house counsel.

A survey of ABA membership indicated that 4 out of 5 (80 percent) attorneys worked in private practice with law firms and another 10 percent worked in corporate law departments. Thus, approximately 90 percent worked in private practice. The remainder was divided between government, judiciary, and academia.

Economic Structure. Most of the \$132 billion annually collected by lawyers and law firms is collected through direct billing of legal fees. There are four fee arrangements generally used within the industry: contingent fees, hourly rates, retainers, and fixed fees.

Contingent Fees. A large percentage of civil case fee arrangements are structured so that attorneys are only compensated if they are successful in obtaining a settlement on their client's behalf. The fee usually is a percentage of the amount of the settlement. Some contingent fees can range as high as 60 percent of an eventual settlement, with the industry standard hovering around 30 to 35 percent of the amount of the settlement.

Contingent fee arrangements also require the client to cover the expenses accrued in filing a complaint, engaging in discovery, and either negotiating a settlement or trying the case in court. These expenses are the responsibility of the client, whatever the outcome. There are two basic contingent fee arrangements: expenses off the top and expenses after the deduction of fee.

Hourly Rates. An hourly rate is assessed based on the amount of time attorneys invest in a case. However, trends within the industry toward increased client accountability have led to modifications in the traditional practice of "billable hours." Consulting firms that advise both law firms and clients about billing practices have become more common. These firms have assisted law firms in assessing their service provision costs and investments and allocating these costs to clients in the form of equitable fee setting. Fee-consulting firms also have been able to save clients from 10 to 30 percent on their legal bills.

Retainers. A retainer is an advance payment estimated to cover the cost of legal services. Retainers are based on an estimate of the time spent by the lawyer, the complexity of the legal issues in question, and the potential amount of money involved in the action.

Fixed Fees. Fixed fees usually are assessed for simple legal tasks, such as deed preparation, no contest divorce, and consumer bankruptcy. Fixed fees are those in which the client pays in advance a fixed amount for a certain legal service—for example, \$100 for preparation of a deed—regardless of the length of time it takes the attorney to complete the task.

BACKGROUND AND DEVELOPMENT

The legal industry in the United States is facing a number of contemporary issues regarding internal firm structure, external competition, and diversified growth.

Career Progression. Fueled by increased competition between law firms, the traditional "partnership track" is changing within the industry. Previously, there was an unspoken promise among major law firms that a summer job between the second and third year of law school was a practical guarantee of a permanent position after graduation, with a relatively safe period of tenure as an associate for at least one year and up to five years. Those attorneys completing the five years as an associate usually were offered a partnership position. However, the partnership path has become more arduous, with the apprenticeship period prior to "making partner" lasting 10 years or longer. Further, employers simply have rejected many candidates with partnership potential.

To keep revenues ahead of costs, law firms have had to increase the ratio of associates to partners from a one-to-one ratio to five partners for every six associates, according to an *ABA Journal* report.

This change in the dynamics of legal career progression has led to two internal innovations within the industry. The first is an increased use of paralegals to do the work now assigned to associates. The second strategy is to develop a new position, the "career attorney." Law firms offer those individuals who have little or no chance

of making partner a higher salary than other associates make for staying with the firm.

Firm Size. Another structural innovation to maintain competitiveness is the increased use of branch offices and acquisitions. According to a report in the *ABA Journal*, 30 percent of the lawyers in the nation's 250 largest firms practice in branch offices. The *ABA Journal* noted that "branches have become a major weapon in many law firm's arsenal to fight for new business and increased market share." Many large U.S. law firms are looking overseas to international opportunities as well. As Ward Bower, a consultant with the Philadelphia office of Altman, Weil and Pensa, said, "The costs of overseas expansion are very heavy, so the downside can be great, but so is the potential."

Small firms will continue to handle issues such as landlord-tenant disputes, traffic violations, and a variety of criminal matters that have been the traditional province of the small firm. However, increased competition from legal chains such as Hyatt Legal Services, coupled with spiraling overhead costs, will force the small or solo practitioners to be better organized and more efficient.

Professional Management. The trend toward increased size in law firms has led to an increasing need for professional management. The law firm is faced with dual pressures: the need for increased responsiveness to client needs and demands counterbalanced by the need to generate revenue. Furthermore, increased size is creating an additional impediment to effective management; firms with 200 or more partners cannot run a firm as a democracy. The trend is toward creating a new position, an executive director, who will function as a chief operating officer. This individual will have minimal legal responsibility and perhaps will not even be a lawyer. In fact, non-lawyers may be established as partners at even the most prestigious law firms.

In addition to professional management, law firms are (and will continue) adopting other accouterments of more traditional business organizations. These include practice managers (similar to product managers) who augment service delivery and expedite performance appraisal in diverse sub-disciplines (e.g. tax, litigation, etc.) within the profession.

External Competition Issues. Lawyers are facing increased competitive pressure from paralegal firms offering low-cost legal services. Independent paralegals increased from approximately 200 individuals in 1985 to an estimated 6,000 in the mid-1990s. These nonlawyer practitioners are offering legal services in such areas as will and living trust preparation and child-support arrangements. Concerns expressed by the ABA regarding the ancillary businesses include creating a danger of loss of confidentiality and conflict of interest and distracting

lawyers from their duties of law practice and their professional responsibilities. In contrast, members of the legal community indicate that full-service law firms allow attorneys the opportunity to better serve their clients. Furthermore, proponents of ancillary businesses indicate that professional diversification already is practiced by accounting firms that do tax law and banks that engage in estate planning. Diversification, supporters argue, allows law firms to remain competitive.

CURRENT CONDITIONS

According to the *National Law Journal's* annual survey of the 250 largest law firms in the country, the firms grew just 3.7 percent between October 2001 through September 2002, down from a 8.2 percent increase the previous year. Considering the overall economy, most in the industry view any growth—albeit small—as a positive sign. Another trend, likely prompted by the nation's slumping economy, was toward fewer partners but an increase in senior counselors or nonequity partners—those with partnership status who are not provided a share of the firm's overall profits. Twelve U.S.-based firms employed more than 1,000 lawyers, and eight of the 10 fastest-growing firms were grown through acquisitions and mergers. During the 15-year span from 1987 to 2001 the number of total lawyers in the nation's top 250 firms grew 85 percent, from 58,533 to 108,361.

In the early 2000s, continued global expansion was also on the increase. United Kingdom-based Clifford Chance, the world's largest law firm, expanded its presence in the United States by acquiring a group of California firms, adding to its New York operations. While the British moved in, the U.S. legal industry continued to move out, expanding around the world. The number of lawyers working abroad grew by 12.8 percent, and between 1997 and 2001, 70 firms opened branches in London, a common first stop in international expansion. From 1987 to 2001, in the nation's largest 250 firms, the number of lawyers practicing abroad increased six-fold, from 1,401 to 9,573.

The increasing presence of multi-disciplinary practices (MDPs) remained on the horizon for the legal industry, which would introduce the significant financial power of the world's largest accounting firms into competition with traditional law firms. As of early 2003, accounting firm lawyers were not allowed to practice law in the United States; however, the MDP system was already in full swing in Europe, where accounting giant Arthur Andersen was also Europe's biggest law firm.

INDUSTRY LEADERS

The legal industry is highly atomistic, with the top 10 law firms accounting for only 3.5 percent of total industry revenues. Baker & McKenzie of Chicago, the largest firm

in the nation with nearly 3,300 lawyers and \$1.6 billion in revenues in 2002, was the leading firm (in terms of revenue) in the industry, but it controlled only 0.5 percent of the market. Skadden, Arps, Slate, Meagher & Flom, in New York, another industry leader, had 652 lawyers and \$440 million in revenues. Although only 4.5 percent of the nation's attorneys worked for the largest 100 law firms, those firms took in 16 percent of the industry's revenue.

Chicago's Baker & McKenzie firm built its position in the industry in a different fashion. The firm engaged in legal practice for more than a century. The growth of the firm primarily was attributed to expertise and growth in international law, with a substantial portion of the firm's almost 1,600 lawyers located in overseas branch offices. The firm had 66 offices in 36 countries, including the People's Republic of China (Beijing, Guangzhou, and Shanghai), Russia (Moscow), and Saudi Arabia (Riyadh). In 2002 the firm opened branches in Shanghai and Vienna and, in 2003, in Bologna and Antwerp.

According to the *National Law Journal*, Skadden, Arps, Slate, Meagher & Flom of New York tied with Jones, Day, Reavis & Pogue of Cleveland for second place in the industry, based on number of lawyers, both with 1,822 full-time (and full-time-equivalent) attorneys on staff. Skadden, Arps' ascension to the top of the profession primarily was a function of the diligence and expertise of partner Joseph Flom. Flom joined the five-lawyer firm in 1948 after graduating from Harvard law School. He developed an expertise in helping shareholders challenge the management of their companies. In 1974 Flom successfully represented International Nickel Corporation (INCO) and won control of a target company, ESB Inc., in a takeover attempt that was to set the tone for the merger and acquisition activity prevalent in the 1980s. In 1975 Flom represented Chicago's Marshall Field's and saved it from a takeover attempt by Carter Hawley Hale. Flom employed a unique strategy—he encouraged Marshall Field's to begin building stores in towns where Carter Hawley Hale already had outlets. The strategy created such complicated antitrust implications that Carter simply dropped the takeover attempt.

By the mid-1980s, Skadden, Arps was a part of many major deals. According to Kim Eisler's book *Shark Tank*, Flom's instinct for acquisition and defense skills were so expertly developed that many active players in the mergers and acquisitions market paid Flom a retainer to ensure that a potential raider could not use his skill against them.

WORKFORCE

According to the U.S. Department of Labor Bureau of Labor Statistics, the legal services industry accounted for 1,043,680 jobs in 2001. Occupations specifically legal

in nature (i.e., lawyers, law clerks, paralegals, etc.) totaled 496,710. The mean annual salary for a lawyer was \$95,250; a paralegal, \$37,940; and a law clerk, \$30,880. Office and administrative support positions accounted for the majority of the remainder of the legal workforce.

Wages in the industry continued to rise at a rate above that set by most other industries. In the early 1990s the average beginning lawyer earned \$36,600 per year, and top graduates from top law schools started out at around \$80,000 per year. Since then, the economic climate induced law firms to take a more conservative approach to hiring. Despite this "soft" market for law school graduates, average starting salaries continued to accelerate. In the mid-1990s, graduates from prestigious law schools, such as Yale University, Columbia University, New York University, and Georgetown University Law Center, received average starting salaries in excess of \$70,000. This demand for higher salaries was fueled in part by rising tuition costs at major law schools and heavy student loan burdens faced by recent graduates. Average associate salaries for young New York attorneys exceeded \$82,000.

Lawyers on salary received increases as they assumed greater responsibility. Lawyers starting their own practice might need to work part time in other occupations during the first years to supplement their income. Their incomes usually grew as their practices develop.

Lawyers who were partners in law firms generally earned more than those who practiced alone, although a majority of associates and others polled considered partnership to be a less necessary step toward career advancement. According to the National Association for Law Placement, only about half of all associates (56 percent) perceived partnership as an incentive for their careers in private practice.

The field of law made a difference, too. Several areas of the legal profession were currently regarded as "hot" practice areas. These included bankruptcy and corporate reorganization, environmental law, alternative dispute resolution, and technology law. Environmental and technology practices were expected to remain strong practice areas. These areas were fueled by growing concerns and increasing legislation in regards to the environment and ubiquitous high-technology issues such as computer fraud and electronic funds transfer. In addition, firms operating in the increasingly competitive pharmaceutical and biotechnology businesses were seeking to protect their innovations through patents, accelerating the demand for patent attorneys and attorneys with technical training. Patent lawyers generally were among the highest paid attorneys. Finally, the litigious nature of modern U.S. society was expected to ensure a continued emphasis on legal mediation and arbitration.

In support services, paralegal work represented the area with the greatest employment potential. Law firms, rather than pay top salaries to law school graduates, were using increasing numbers of paralegals to do routine work traditionally performed by new associates.

Although there was a marked fall-off in merger and acquisition and real estate practice, New York remained the strongest job market, according to the National Association for Law Placement. The next largest legal job market was Washington, D.C.

RESEARCH AND TECHNOLOGY

The practice of law has and will continue to become increasingly automated. Law office automation was becoming a necessity for improving office productivity and efficiency, for maintaining cost controls and competitiveness, and for meeting minimum standards of professional practice.

The evolution of the personal computer and the phenomenal growth of the Internet beginning in 1998 represent the primary focal points of automation and instant communication in the legal industry. "On-line" databases made available through vendor services such as Lexis/Nexis or Westlaw allowed the practitioner to expedite research. The Lexis/Nexis service featured both legal reference sources and news publications, from *The American Lawyer* to *USA Today* to transcripts of CNN and the PBS Lehrer Report. A report issued by the ABA Legal Technology Research Center in Chicago predicted that individual law firms would create their own in-house databases to draw on their past work and handle new matters more expeditiously. Furthermore, firms would create "expert" software that allowed the entire firm to tap into a specialist's knowledge.

ELEMENTARY AND SECONDARY SCHOOLS

This category includes elementary and secondary schools furnishing academic courses, ordinarily for kindergarten through grade 12. It includes both public and private institutions and encompasses parochial schools, boarding schools, vocational high schools, and schools providing special services for physically and mentally handicapped students.

NAICS CODE(S)

611110 (Elementary and Secondary Schools)

INDUSTRY SNAPSHOT

By the early 2000s, elementary and secondary education in the United States was characterized by the growing emphasis on technological access and education in order to boost the educational quality and attainment levels of U.S. students and to prepare them for a future in a rapidly evolving technological work environment. As the public school system continued to receive its share of criticism, alternatives such as charter schools were enjoying increased popularity.

About 53 million students attended elementary and secondary schools in the United States during the early 2000s. In 1999-2000, these students attended 92,012 public schools and 27,223 private schools. Of these, some 80,661 were elementary and 24,903 were secondary. According to the National Center for Education Statistics (NCES), enrollment in public elementary and secondary schools was 46.9 million in 1999. Levels were projected to reach 47.4 million by 2002, and record growth was expected to continue for public schools through 2005. The fastest growth is occurring in the secondary grades, fueled by strong elementary school enrollment levels during the late 1990s. Enrollment in elementary and middle schools increased from 29.9 million in 1990 to approximately 33.6 million in 2001. Public high schools grew from 11.3 million in 1990 to 13.6 million in 2001. High schools account for 24.3 percent of all public schools and 28.5 percent of enrollment.

About 6.2 million students participated in programs for the disabled in 1999-2000. This represented some 13 percent of students, an increase from 1990-91 when students with disabilities constituted 11 percent of the population. About 60 percent of all public elementary and secondary schools students are white, whereas Hispanic students account for 18 percent, and African Americans make up 17 percent. Only a fraction of the student population was Asian American or Native American.

Approximately 6 million students attended private elementary or secondary schools in the early 2000s, representing 11 percent all students. The total number of such schools was 27,223 in 1999-2000, up from 24,690 in 1990-91. Catholic schools accounted for 48.6 percent of these students (though only 29.8 percent of those schools); other religious schools accounted for 35.7 percent, and nonsectarian schools claimed a 15.7 percent share. The proportion of students in private schools has changed little in recent years.

The expenditures of public schools in the elementary and secondary grades were estimated to total \$358 billion for the 2002 fiscal year, up from \$338 billion in 2001. In recent years local authorities provided approximately 45 percent of school revenues, state governments provided about 48 percent, and the federal government supplied some 7 percent. Average per pupil expenditures amounted to \$7,524 in the 2001-02 school year, up from an estimated \$7,079 the previous year and \$6,409 in 1990-91.

All 50 states have compulsory education statutes requiring children to attend school. Although such regulations vary state by state, in general attendance is mandated to begin by a specified age (typically between 5 and 8 years old) and children are required to remain in school until a specified age (typically between 14 and 18 years old) or until high school graduation is achieved.

Enrollment trends observed during the early 1990s led to projections of increased enrollment through the mid-2000s. The increase in elementary school enrollment will continue to be the most pronounced for several years but will taper off relative to secondary schools as those students reach high-school age. By 2009, an estimated 54.5 million students are expected to be enrolled in elementary and secondary schools in the United States, a figure analysts claim will necessitate about 6,000 new schools. Between fall 1996 and fall 2006, public enrollment was projected to grow by 2 percent, while public secondary school enrollment was expected to rise by 15 percent.

ORGANIZATION AND STRUCTURE

In the United States, schools are arranged into districts. Regular school districts are defined as those providing free public elementary and secondary education for the children living within them. Each school district functions under the auspices of a state-level regulatory agency and is responsible for the oversight and operation of the schools within its geographic boundaries. According to figures compiled by the National Center for Education Statistics, there were 14,928 regular school districts within the United States during the 1999 to 2000 school year, down from 15,358 in 1990 to 1991. This decrease reflects school district consolidation and reorganization

in order to achieve greater efficiency in delivery of public school services. Over the long term, this trend is dramatically more pronounced; in 1930 there were more than 262,000 public elementary and secondary schools.

During the early 2000s, the nation's five largest districts were New York City; Los Angeles Unified; City of Chicago Schools; Dade County, Florida; and Broward County, Florida. In recent years, large metropolitan cities were home to about one out of every eight elementary schools, but one out of six students. Districts with student populations of more than 25,000 accounted for only 1.1 percent of the nation's school districts but served 30 percent of the nation's public school students. California and Texas led the nation with respect to the number of school districts, each reporting more than 1,000 districts. From 1970 through the 1990s, the percentage distribution of public elementary and secondary school enrollment increased in the South and the West but declined in both the Midwest and Northeast.

Different types of schools were established to serve students with different needs. According to U.S. Department of Education, in recent years approximately 98 percent of the nation's public schools were regular schools. The remaining schools offered special services such as vocational, alternative, or special education. Alternative schools were often operated in conjunction with regular schools and provided options for students whose needs were unmet in regular classroom settings. Special education schools provided adapted curriculum to meet the needs of students with specific disabilities such as physical, emotional, or mental impairments. The nation's vocational schools focused on providing education and training in semiskilled or technical occupations. Regular schools, moreover, often provide programs such as those offered at these different types of institutions in addition to their standard course load.

BACKGROUND AND DEVELOPMENT

Education involves the process of transferring information from one generation to the next. Its origins are inseparable from the origins of civilization. Throughout history humankind has been concerned with the process of maintaining culture, preserving mores, and stimulating minds. The ancients passed on religious information; early science instruction took the form of indoctrination in the magical arts; and oral literary traditions developed before words were ever written down.

The roots of Western education can be traced to the ancient Greeks. Historians credited the Greeks with developing the study of science, art, literature, philosophy, ethics, and politics. Greek schools were designed to prepare the sons of Greek citizens for citizenship. This purpose represented a departure from older forms of education that focused on specialized instruction, such as the

training of skilled craftsmen, priests, or government officials.

The expansion of the ensuing Roman Empire paved the way for the development of education throughout Europe. Roman schools consisted of three levels: elementary, secondary, and higher. Elementary schools taught reading, writing, morality, conduct, counting, and calculating. Secondary schools taught literature, language, astronomy, geometry, and ethics. Students in higher education learned rhetoric, mathematics, music, history, and law. The study of these subjects enabled students to lead effective public lives.

Christian schools, dating back to the second century, were developed to teach new believers about the doctrines, discipline, and morals of the church. Other religious schools were developed to teach theology, philosophy, and science. As early as the fourth century, controversy arose concerning the conflict between the pagan influence in Roman schools and the teachings of the Christian church. Gradually, the pagan schools closed and the center of learning shifted to monasteries. Monastic schools were devoted to preparing students for careers with the church. Pupils were taught discipline, and they received instruction in subjects such as Latin, music, grammar, composition, record keeping, law, logic, arithmetic, geometry, and astronomy. Advanced students also studied higher mathematics and science. The emperor Charlemagne (742 to 814) was credited with revitalizing education. He opened schools for common children and ordered priests to offer free instruction to anyone who came to learn letters.

Following the Middle Ages, Europe saw a rise in universities where students could receive instruction in the arts, law, medicine, and theology. The Renaissance brought a revival of classical studies combined with Christian ideals. Formal education focused on cultivating the mind and the body. In the New World, colonists copied the European model but lacked established institutions and had to build a structure for education. Early opportunities were limited to apprenticeships, schools for practical instruction in mathematics and surveying, and instruction in reading and religion. College-bound students could arrange for training in Latin grammar.

Private schools in America developed during the eighteenth century, and, following the Revolutionary War, the nation turned its attention to the idea of public education. Legislation in 1785 required new townships to set aside land for public education. Massachusetts was the first state to pass a compulsory education statute. Enacted in 1852, the law required that children between the ages of 8 and 14 attend school 12 weeks per year and that 6 of the 12 weeks had to be consecutive. As the complexity of public education grew, states created positions for superintendents. By 1861, 30 of the existing

states and organized territories had state-level school officials. During the Reconstruction era following the Civil War, education reform spread from the North into the South. During the 1869-70 school year, 6.9 million students were enrolled in the nation's public elementary and secondary schools. The average school year was 132.2 days long, and the average number of days attended per pupil was 78.4 days. The system employed 201,000 people as supervisors, principals, teachers, and other nonsupervisory instructional staff. The average annual salary was \$189.

At the end of the nineteenth century, primary education focused on the fundamentals of reading and mathematics and on the development of specific character qualities such as honesty and patriotism. Industrial expansion and growing middle-class ambition brought with them increased interest in expanding participation in the educational process.

Fundamental changes in educational philosophy occurred with the dawning of the twentieth century. A new attitude emerged, characterized by the challenging of long-established traditions. The early years of the 1900s saw educational expansion in the sciences, modern languages, and history. The process of scientific inquiry ushered in an era of questioning that included the close examination of ideas and customs. John Dewey made a significant impact on the development of educational philosophy in the United States. Dewey's many written works included *The School and Society* and *Democracy & Education*. Dewey espoused the notion that the purpose of education was not to prepare students for future life but that it was part of an ongoing experience leading to social progress and reform. A Deweyan teacher was not one who merely educated a child, but one who changed society. Dewey's principles were promoted by the Progressive Education Association (PEA), which was founded in 1919. The PEA dissolved in the mid-1950s because its aims had largely been adopted by mainstream educators.

During the time between World War I and World War II, American educational establishments focused on expanding and providing universal secondary education. As a result, high school attendance increased from 915,000 during the 1909-10 school year to more than 4.4 million in 1929-30, and to 6.6 million by 1939-40. The increasing numbers of students involved in secondary education during the 1930s led to an expansion in course offerings. High schools, which had traditionally offered classes intended to prepare students for higher education, added courses in general education, commercial and industrial arts, and home economics.

Following World War II and through the 1950s, the American educational system was characterized by many changes. Rapid increases in enrollment occurred as chil-

dren born in the post World War II era began entering elementary schools. In 1954 the Supreme Court's *Brown v Board of Education* decision opened the way for racial integration. Curriculum changes reflected the intensified competition between Communist and Western nations, placing a heavy emphasis on scientific investigation and innovation. As a result, in 1958 Congress passed the National Defense Education Act to encourage the study of science, mathematics, foreign languages, and technology.

During the 1960s, school enrollment continued to climb. As mainstream education centered on programmed instruction, alternate programs based on the Montessori method experienced a revival. This educational philosophy was based on the work of Maria Montessori (1870 to 1952), an Italian educator. Montessori believed that education should encourage spontaneity and activity and that children needed freedom to develop. Legislative initiatives also impacted education during the decade. In 1964 the National Defense Education Act was expanded to include English, social sciences, and reading. Congress also passed the Economic Opportunity Act in 1964, intended to expand the availability of educational opportunities in disadvantaged areas. In 1965, the Elementary and Secondary Education Act (ESEA) was enacted as part of President Lyndon Johnson's War on Poverty. The purpose of ESEA was to give federal support to schools located in low-income communities. ESEA made provisions for the funding of counseling, remedial education, and experimental classes. In subsequent years, ESEA was expanded to include help for migrant, neglected, delinquent, non-English speaking, and other children with special needs. The education establishment also saw a shift back to classes focused on preparing students for life experiences during the 1960s. Courses were provided in areas such as community involvement, job performance, citizenship, and family life.

Educators of the 1970s were challenged by rapid changes in society and technology. The prevailing educational philosophy was characterized by a "back to basics" attitude. Critics charged that such an emphasis forced educators to focus on low-level skills and test children in accordance with minimum standards rather than striving to achieve excellence. Another challenge of the decade was the expansion of special services for handicapped children. In 1975 Congress passed the Education for All Handicapped Children Act. The act required school districts to identify students with special needs and provide educational opportunities for them. The four most commonly identified dysfunctions were learning disabilities, speech and language impairments, mental handicaps, and emotional disturbances. In the 1976-77 school year, 8.3 percent of the nation's children were served by special programs. By 1993-94, the most

recent tabulation, the number had increased to 12 percent. The most significant increases were among children identified as learning disabled.

Although the Education for All Handicapped Children Act was intended to help foster educational opportunities for all students, it drew criticism during the late 1980s and early 1990s as courts interpreted its provisions to mean that school districts were required to pay for educational and support services irrespective of a child's ability to benefit from any education provided. Critics of the courts' actions claimed, without success, that the decisions placed an undue burden on school districts and that the cost of providing services for the severely disabled should be transferred to health care agencies.

During the early 1980s, a federal report titled *A Nation at Risk* analyzed the education system and concluded that schools were not doing an adequate job. The report led to the development of school reform efforts that continued into the 1990s. As a result, between 1982 and the early 1990s, 47 states instituted more stringent student testing practices, 42 implemented higher graduation requirements, and 39 established programs to test teachers. Changes were also made in vocational education philosophy. The Carl D. Perkins Vocational and Applied Technology Education Act of 1990 (Perkins Act) was aimed at restructuring vocational education through the integration of broad-based academic requirements. Because only 27 percent of secondary students completing high school with a major in a technical area ever worked in a related field, and because American workers generally changed occupations four to six times during a lifetime, the narrow training given to students in vocational programs was judged inadequate. Critics claimed it provided only obsolete skills that were not transferable. Under the provisions of the Perkins Act, vocational programs were required to help students experience and understand all aspects of an industry with the aim that graduating students be prepared to take an active role in community development.

Problems with vocational education were also raised by critics who claimed that a shortage of skilled workers would render the United States unable to remain competitive in the global economy. Some educators advocated the development of a high-tech preparatory program that would include provisions for transition into the work world through apprenticeships or would prepare students for further study at two-year community or technical colleges.

In addition to the problems associated with low academic achievement, schools continued to face challenges related to drug abuse and violence. According to the U.S. Department of Health and Human Services, the proportion of public and private high school seniors who reported ever using an illicit drug rose from 55 percent in

1975 to 66 percent in 1981. After 1981, that proportion fell to 41 percent in 1992 but rose again to 48 percent in 1995. The proportion of high school seniors who had ever used cocaine fell from 17 percent in 1985 to 6 percent in 1995. Alcohol remained the most often used drug with the proportion of seniors who had used alcohol within the past 30 days declining from 72 percent in 1980 to 51 percent in 1995. Cigarette and smokeless tobacco use increased from ninth to twelfth grades for all categories. However, alcohol, marijuana, and illegal drug use on school property increased for boys while it declined for girls.

As the education establishment entered the 1990s, efforts aimed at improving learning opportunities for all of America's children intensified. The number of high school graduates in 1997 and 1998 totaled about 2.7 million. Americans 25 years old and older holding high school diplomas or GED credentials increased from 69 percent to 82 percent between 1990 and 1977. The dropout rate at U.S. high schools fell from 14 percent in 1977 to 11 percent 20 years later.

The 1990s were plagued by negative public perceptions about schools and inconsistent measurements of student achievement. For example, school records indicated that an increasing number of students were taking college preparatory classes in math, English, science, and social studies—up from 37.9 percent in 1982 to almost 50 percent in 1996. Moreover, state governments placed a great deal of emphasis on increasing standards, indicative of the heightened primacy of scholastic assessment tests, both in evaluating school performance and for students entering colleges and advanced learning programs. But educators argued about the effect of these measures. SAT scores remained flat through the 1990s, still far below their mid-1960s peak, despite the fact that students taking advanced-placement courses in high school grew from 5 percent of seniors in 1984 to 13.1 percent in 1997. Geography and history performance among students at all levels remain dismal by international standards. In mathematics, 9- and 13-year-olds demonstrated improved skills in numeric operations between 1977 and 1997, whereas performance remained flat for the remainder of the 1990s. Meanwhile, more complex mathematical skills among 17-year-olds continued their 20-year disappointment through 1997, by which time complex procedures and reasoning were only proficiently tackled by 59 percent of high-school 17-year-olds, while adequacy in multistep algebra was beyond the grasp of 93 percent of that age group.

Attempts aimed at increasing the quality of science education focused on curriculum changes. One program, sponsored by the National Science Foundation, provided obligatory units of science in each grade progressing from basic measurements in ninth grade to abstract and

theoretical studies in the higher grades. This proposal was intended to replace traditional science studies in which students, on an elective basis, enrolled in biology in tenth grade, chemistry in eleventh grade, and physics in twelfth grade. Under traditional science programs, statistics for 1994 graduates revealed that although 94 percent had taken biology, only 56 percent had taken chemistry and only 24 percent had taken physics, though the average number of science courses completed in high school rose from 2.2 in 1980 to 3 in 1994.

Reading proficiency was another area of concern. The reading level among 9- and 13-year-olds improved markedly between 1970 and 1995, but little of the change occurred after 1980. By 1996, the reading level of high-school 17-year-olds was unchanged since 1971, and writing levels declined gradually over that period. A Department of Education Study in the late 1990s reported that only 1 in 4 students sampled across fourth, eighth, and twelfth grades met the Department's standards of writing proficiency for those levels.

Despite improvements made by African Americans and other minorities over the last 30 years, minority students continued to score below white students in many standardized tests and educational assessments. In 1996, National Assessment of Educational Progress (NAEP) results in reading suggested that minority groups were beginning to lose some of the earlier gains they had made relative to whites. The problem was heightened by the fact that minority students were statistically in the majority at 22 of the nation's largest 25 school districts. In such schools, classroom sizes tended to be larger and the level of economic prosperity markedly lower. Moreover, studies have revealed a positive correlation between students' levels of educational performance and the level of parents' educational attainment. According to statements made by the U.S. Department of Education, school reforms made under the Elementary and Secondary Education Act "seldom triggered the kinds of transforming that our schools need—particularly in economically disadvantaged communities."

Many school problems were associated with economically disadvantaged students. According to statistics, tenth-grade students from districts with high rates of poverty were found to have dropout rates twice as high as those from schools in districts with little poverty. The U.S. Department of Education estimates that more than 50 percent of the students in schools containing the nation's highest concentrations of poverty were judged to be low achievers. In schools with the least poverty, only about 10 percent of the students were judged to be low achievers. Because of the ramifications of poverty on education, 30 states were involved in lawsuits over disparities in education spending created by differences in local property taxes during the mid-1990s. In two states,

Alabama and Massachusetts, the courts ruled that disparities in school funding violated the states' constitutions.

In an effort to increase the quality of education for the economically disadvantaged, the Clinton Administration in 1994 reauthorized the Elementary and Secondary Education Act (ESEA) of 1965 and passed the Goals 2000: Educate America Act, aimed at setting exacting standards for poorer students that matched those for their more advantaged counterparts. Federal resources were thus directed toward helping states implement these performance standards. Texas, for instance, achieved among the highest gains in National Assessment of Educational Progress performance and further closed achievement levels between minority and white students.

Such measures were not without detractors, however. Critics of such educational spending proposals argued that states with the highest per-pupil spending had the lowest test scores. Instead of increasing financial assistance to schools, these analysts recommended core changes in school structure and curricula. Social scientists attribute much of the white-minority differences in achievement not only to poverty but also to the lower average educational levels of their parents. Although it is difficult for schools to compensate for such disadvantages, there is evidence that extraordinary schools and teachers make a difference in how all students perform. Research on early intervention and one-to-one tutoring suggests that at-risk students can achieve far higher levels and that taking more challenging courses is related to higher performance and achievement.

Other tools influencing student achievement are electronic computers and Internet access. By 1998, 89 percent of public schools were plugged into the Internet, an increase of 11 percent from a year earlier; only 35 percent of public schools were connected in 1994. Thus the elementary and secondary school systems were closing in on the Clinton administration's goal of connecting all schools to the Internet by 2000. Nonetheless, schools in impoverished areas remained the least likely to maintain Internet access. In other technological developments, more than 90 percent of all elementary and secondary schools utilized computers in classrooms (as opposed to only in a separate computer room), whereas the number of students per computer dropped from 45.3 in the 1985-86 school year to 7.4 in 1996-97. A growing number of schools also maintained local area networks (LANs), CD-ROMs, and even satellite dishes. The Department of Education further maintained the Star Schools Program, which provided education at a distance by utilizing telecommunications to transmit video and interactive instruction, reaching about 1.6 million students.

School districts entered into periods of restructuring through the 1990s. Some individual schools were

stepping up efforts to make the educational process more efficient and more profitable to students. For example, some schools experimented with having teachers move up with students so that students did not have to lose instruction time during the beginning of the school year as they adjusted to new teachers.

In addition to efforts to make the educational system more profitable to students, a growing movement was geared toward generating profits for the schools themselves. More than 200 for-profit schools were in operation in 1999, enrolling about 100,000 students. Edison Schools, based in New York, generated \$217 million in revenues. Edison is also an expansion franchise, growing from four schools in 1995 to 79 schools across 16 states in 2000. By 2006 the company expected to operate 423 schools and enroll 260,000 students, for revenues of \$1.8 billion in sales. Overall, a Merrill Lynch and Company analyst predicted that U.S. for-profit schools could maintain 10 percent of the elementary-school market by 2009.

Unsurprisingly, the trend toward profitability in the school system met with ethical concerns. While proponents of the trend argued that financial competitiveness would force schools to increase their efficiency and standards, essentially to offer a more superior product than their competitors, critics feared that the profit motive inherent in such moves would drastically alter the type of education students received, inviting companies to gear learning toward their economic interests and advertising.

The influence of commercialism in U.S. elementary and secondary schools is hardly limited to for-profit institutions, however. In order to garner increased funding to compensate for tight budgets and to gain a competitive edge, schools have sought investment from companies looking to peddle their products inside the schools. Zapme! Corp., for instance, donated computer equipment and software to schools in exchange for information about students that the company could use in marketing campaigns; meanwhile, the computers themselves displayed advertisements in the corner of the screen for companies such as PCGames.com, Amazon.com, and Lego. Channel One, a commercial-supported education channel introduced in 1991 and received in 12,000 U.S. schools, included advertisements for acne medicine, breakfast cereals, candy, and other youth-oriented products in addition to shoe and apparel brands such as Nike and Gap.

The cola wars, meanwhile, shifted their battle ground to U.S. schools. Coca-Cola and Pepsi increasingly enjoyed "official drink" status at schools, in which the companies installed soda-dispenser machines in exchange for investing funds. This trend achieved a degree of notoriety in 1998 when an Atlanta high school student was suspended from school for wearing a Pepsi t-shirt on "Coca-Cola Day." Such reports raised the eyebrows of

many educators, claiming that the influence of commercial enterprises had extended too far. The city of San Francisco prohibited its schools from contracting with beverage and snack companies.

Public schools also investigated the concept of charter schools. Charter schools are public schools set up to function independently of state regulation (except in regard to civil rights, health and safety, and financial accountability). Proponents of charter schools claimed that the concept provides administrators with the freedom to offer the types of programs best suited to their students. The nation's first state-sanctioned charter school, City Academy, opened in St. Paul, Minnesota, in September 1992. Cleveland joined Milwaukee's six-year-old program of 1,700 students. In this program, the private schools are not allowed to choose their students, however. By 1999 more than 30 states had passed charter-school legislation, and 160,000 students were educated in about 720 such schools. Nearly 35 percent of all charter-school students lived in California, followed by Arizona, with 15 percent, although Arizona had the highest proportion of its population enrolled in charter schools. According to studies, about 70 percent of charter schools were created to realize a vision of education that was alternative to that provided by the public-school system.

Home schooling, likewise, became increasingly attractive during the 1990s. The growth of home schooling follows years of negative perception of the public-school system. While home schooling traditionally was relegated to fringe religious groups, the practice has become increasingly common and mainstream. Strong performance results as measured by SAT scores and other standardized test have gained wide recognition. A precise figure is difficult to come by, but most observers agree that the total number of home-schooled students in 1999 lay somewhere between the Department of Education's estimate of 750,000 and home-schooling advocates' figure of 1.5 million.

School safety achieved a high priority in the late 1990s after a string of high-profile school shootings involving juvenile assailants. Public schools reported 6,093 expulsions for possession of firearms during 1996-97, whereas 57 percent of public elementary schools reported at least one incident of crime or violence that required reporting to officials (including police officers) outside the school. Moreover, 10 percent of public schools reported at least one serious crime, a classification that includes murder, rape, sexual battery, suicide, physical attack, fighting with a weapon, and robbery. Urban schools were twice as likely to experience incidences of violent crime. Particularly following the large-scale shooting at a high school in Littleton, Colorado, legislators debated fiercely over a range of issues relating to juvenile violence and schooling, ranging from gun con-

trol, enhanced punishment of juvenile offenders, and heightened disciplinary measures. Most broadly, the issue has triggered a wave of zero-tolerance rules, including sharp disciplinary action by school administrators for incidences, both inside and outside of the school, of dress and speech deemed inappropriate.

Educators came under criticism by some who claimed that by focusing on the needs of disadvantaged students they were failing to provide for the nation's brightest students. Proponents of special programming for gifted and talented students offered statistical evidence that the top-performing students in the United States were behind their peers in other countries, particularly in mathematics and science. In response, legislatures in 45 states passed laws either mandating gifted and talented programs or making provisions for state support of programs serving gifted and talented students. Not all people, however, accepted the premise that special programs should be provided for bright children. Critics claimed the programs were elitist. As a result, although only 2 percent of the funds spent on K-12 education were spent on gifted and talented programs, funding in many states was in danger of being cut.

Debate over the implementation of school-choice programs grew increasingly heated since the late 1980s. Many parents and politicians demanded public subsidies, such as school vouchers, to provide financial assistance to parents choosing private education. Proponents argued that such programs would afford parents greater freedom to provide their children with the highest-caliber education. Opponents, however, countered that vouchers and similar programs would not be able to cover the total costs of private education, and thus would afford greater leverage to the more economically advantaged while simultaneously gutting the public school system that the disadvantaged would have to rely on. There were three types of school-choice programs in the late 1990s: intra-district, interdistrict, and magnet. Magnet schools, sometimes in conjunction with one of the other types, offer specialized programs aimed at drawing students with particular interests, abilities, or characteristics.

CURRENT CONDITIONS

By the early 2000s, weak economic conditions had resulted in business closures, massive workforce reductions, and decreasing tax bases throughout the United States, leading to state budget shortfalls. During the prosperous years of the 1990s, a number of states began funding schools through income taxes instead of property taxes. Ultimately, this trend hurt many of the nation's school districts. According to the January 19, 2003 *Chicago Tribune*, "The lingering national economic downturn, which last year resulted in trims to administrative expenses and loss of extracurricular activities, now is

forcing districts to make severe cuts that directly affect the classroom.” The newspaper cited figures from the National Conference of States Legislatures showing U.S. school districts were short \$49 billion at the start of the 2002-03 academic year. By January, the deficit had increased by another \$18 billion.

Amidst these conditions, some school districts sought ways to reduce costs and maintain operations. For example, by early 2003 nearly 28 percent of the school districts in Oregon were considering reducing the number of school days on their academic calendars. Among these, schools in Portland were moving toward four-day school weeks. This also was the case in some areas of New York State, where Governor George Pataki proposed education budget cuts of 8.5 percent. The *New York Times* reported that this would result in potentially devastating cutbacks of \$1.24 billion for the state’s elementary and secondary schools. In some states, districts were limited by the fact that four-day school weeks were not legal, or could jeopardize already falling levels of state funding.

In addition to considering shorter academic years, schools implemented other cost-cutting measures. In Oklahoma, teachers and students cleaned their own classrooms after custodians were eliminated from the payroll. Janitorial budget cutbacks in Hawaii resulted in potential toilet paper shortfalls, effectively causing schools to choose between basic essentials and needed educational resources like textbooks. Nationwide, schools also were looking to decrease energy costs in both new and existing facilities. In March 2003, *Buildings* reported that, according to estimates from the U.S. Department of Energy, school energy expenditures exceed \$6 billion annually. The publication indicated that schools could save \$1.5 billion of this amount each year by improving operations, designing better buildings, and relying on renewable technologies that were more efficient.

Although resources were increasingly strained, the nation’s elementary and secondary schools faced unprecedented challenges in providing quality educations. In July of 2002, the Associated Press reported that 9 percent of U.S. schools did not meet established state academic standards. In January of that year, President George W. Bush signed the No Child Left Behind Act of 2001. According to the U.S. Department of Education, “The Act is the most sweeping reform of the Elementary and Secondary Education Act (ESEA) since ESEA was enacted in 1965. It redefines the federal role in K-12 education and will help close the achievement gap between disadvantaged and minority students and their peers. It is based on four basic principles: stronger accountability for results, increased flexibility and local control, expanded options for parents, and an emphasis on teaching methods that have been proven to work.”

The act allows children in schools that fail to meet academic standards established by their state to move to another public school without incurring excessive transportation costs.

WORKFORCE

During the 2001-02 school year, a total of three million teachers worked at U.S. elementary and secondary schools. This figure was the same in 2000-01, but higher than 1999-2000 when 2.9 million teachers were employed. The growth in public school teachers through the 1990s mirrored the escalating enrollment figures, maintaining a ratio of about 17 students per every teacher. By 2001-02, the national ratio stood at 15.9.

Almost all teachers held at least a bachelor’s degree by the early 2000s, while roughly 45 percent held a master’s degree. According to the U.S. Department of Labor, in 2001 education, training, and library workers at elementary and secondary schools earned an average annual salary of \$36,899.

Most teachers work a 10-month schedule, with two months off during the summer. However, in addition to classroom duties, teachers’ responsibilities include devising lesson plans, grading assignments and tests, and meeting with faculty, administrators, parents, and students. The combination of these tasks generally translates into significantly more than 40 hours of work per week.

Examples of nonteaching staff include principals and assistant principals, guidance counselors, librarians, teacher aides, and noninstructional staff. In private schools, the pupil/teacher ratio is 15:1.

AMERICA AND THE WORLD

The U.S. elementary and secondary school system has long met with sharp criticism from those who feel its success in transmitting basic knowledge to its students was falling behind other nations. Scholastic tests repeatedly reveal that U.S. students tend to be toward the bottom of the list of industrialized countries in mathematics and science, while history and geography scores remain, for many educators, embarrassingly low. Although an ever-increasing number of Americans are completing high school, literacy levels remain below many developed nations, including Sweden, Germany, and Japan.

Only France and Germany spend a higher percentage of annual gross domestic product on education, whereas Sweden, Switzerland, and the United States spend the most per pupil. Schools in the United States, however, are structured differently from many schools overseas and offer wider educational opportunities to a more diverse student population. In the United States, elementary schools are structured to prepare students for secondary school, and secondary schools are structured to prepare students for higher education. In many other places, the

progression of educational opportunity is less unified. Primary schools provide a basic education for the masses, and separate preparatory schools train children of the higher social classes for a secondary or higher education. Once committed to either a primary school or a preparatory school, very few students can move to the other system.

Despite these differences, critics of the American system claim that even European and Japanese students in non-college bound courses of study receive better academic training and higher skills via apprenticeships and school-to-work transition programs than do their American counterparts. In Germany, beginning with the fifth grade, children are enrolled in vocational, technical, or college-prep schools. In the tenth grade, students in vocational and technical schools begin paid apprenticeship programs in which they work for approximately three years while completing their academic and skill-building schooling. Students in college-prep schools, called *Gymnasien*, prepare for stringent university entrance exams.

COLLEGES, UNIVERSITIES, AND PROFESSIONAL SCHOOLS

This classification covers colleges, universities, seminaries, and professional schools offering academic courses and granting academic degrees. The minimum requirement for admission is a high school diploma or equivalent general academic training.

NAICS CODE(S)

611310 (Colleges, Universities, and Professional Schools)

INDUSTRY SNAPSHOT

The U.S. higher educational system has long been the envy of the developed world. It plays a critical role in U.S. social and economic life and is a cornerstone of the nation's competitiveness on the world stage. By the twenty-first century, U.S. colleges and universities were increasingly coming to resemble traditional business entities by streamlining operations and aggressively competing for students and finances as a way of maintaining their vitality.

Colleges and universities are institutions of higher learning that admit postsecondary students for education and training in a vast number of disciplines. No central governing body oversees the administration of these institutions, although governments do contribute financial aid in the form of loans and grants to both students and schools. Private corporations donate substantial sums of money to colleges, universities, seminaries, and professional schools in the United States, supplementing public subsidies as a way of investing in research and development, and traditionally recruit employees from these institutions. Although primarily mandated to impart skills

and knowledge to students, many colleges and universities are also major research institutions and have made significant contributions to medicine, technology, engineering, and a number of other fields.

Almost 12 million students were enrolled in public colleges and universities during the 2000-01 school year. In addition, nearly four million attended private schools. There were a total of 4,182 postsecondary schools in the United States, of which community, junior, and technical colleges accounted for 1,732. About 1.8 million students were enrolled in graduate programs in 1999, a figure that escalated rapidly in the early and mid-1990s after holding steady around 1.3 million for more than a decade. Students tended to gravitate toward very large or very small schools. While 40 percent of institutions had a student body of less than 1,000 students in 1999, they represented only 4 percent of all postsecondary students. Conversely, whereas only 10 percent of colleges and universities had more than 10,000 students, they enrolled about half of the nation's total student population.

U.S. colleges and universities enjoy significant endowment funding. In 2000, the greatest beneficiaries included prestigious research universities such as Harvard University, with assets of \$18.8 billion; Yale University, with \$10.1 billion; the University of Texas System, with \$10 billion; Stanford University, with \$8.6 billion; and Princeton University, with \$8.4 billion.

Federal studies show that the nation's public colleges and universities recorded more than \$170 billion in expenditures in 2000-01, whereas expenditures for private schools were nearly \$110 billion. In recent years, approximately 1 percent of all postsecondary institutions were under federal control; state governments were responsible for about 28 percent, independent religious institutions for 25 percent, and independent nonprofit organizations for 20 percent. The majority of college campuses are located in small towns, closely followed by urban settings and suburban areas, with the fewest located in rural areas.

Tuition rose steadily throughout the 1990s and early 2000s. Private four-year colleges and universities demand the highest annual tuition, followed by independent two-year institutes; public four-year institutions come next, and two-year public schools charge the lowest tuition. In the early 2000s average tuition ranged from \$1,338 at public community colleges to \$15,531 at private four-year universities. Moreover, private universities have experienced the fastest rise in prices, growing 27 percent between 1991 and 2001. Tuition at public universities increased 23 percent over the same period.

In 1999 about 28 percent of all college and university students were minorities, a substantial increase over the 16 percent in 1976. This trend is most notable among

Hispanic and Asian students; Asian and Pacific students tripled their presence over this period, accounting for 6 percent of the student body in 1999, whereas Hispanic students more than doubled their proportion to 9 percent. African American students accounted for about 11 percent of all students. Native Americans were the least represented minority group with enrollments averaging 1 percent on all campuses. Meanwhile, the number of women enrolled in higher education rose 13 percent between 1989 and 1999, whereas male enrollment increased 5 percent over that period. By 1999, female enrollment totaled 8.3 million and male enrollment had reached 6.5 million.

ORGANIZATION AND STRUCTURE

Colleges and universities are either public or private. Public institutions are able to secure funding from government sources, whereas private institutions rely on tuition and private donations to operate. Universities are different from colleges in that they provide a greater number of areas of study, are larger in size, and are more involved in research activities. Universities also grant graduate, doctoral, and professional degrees in addition to undergraduate degrees, which colleges may or may not bestow.

The way a college or university is structured is in large part determined by the needs of the population it serves. Underscoring the objectives and operating strategies of every U.S. institution of higher learning is the fundamental belief that every interested and capable high school graduate should have the opportunity to attend postsecondary school. This philosophy has distinguished higher education in the United States and serves as a central tenet of its structure and organization.

Population growth, particularly the significant growth of the college-age population in the 1960s and 1970s, put increased pressure on institutions of higher learning. Private and public donations also increased the number and diversity of programs offered, as did the quality of teachers and technology available. In all, the landscape of the industry is remarkable for its sheer diversity and its ability to meet the needs of students, whether they seek a well-rounded liberal arts education or hands-on training in the most advanced computer sciences.

In terms of broad structure, coordinating boards are the primary feature in most colleges and universities. These boards, some elected, others appointed, may govern only senior institutions; others may govern all of the institutions in a state; still others are charged with compiling and analyzing data that is related to enrollment, curricula, staff appointments, institution investments and disbursements, and other issues related to the administration and management of the schools. Some states employ

statewide governing boards charged with overseeing specific or all institutions of higher learning. An additional administrative arm of colleges and universities is voluntary consortia, both public and private. These advisory and governing bodies address such areas as faculty composition, teaching facilities, and library materials.

BACKGROUND AND DEVELOPMENT

The development of higher education in America had its genesis as far back as 1636, when the first colleges in the colonies began to take shape. These institutions had close ties to religious organizations, a condition that remained prevalent until early in the twentieth century when a number of these universities were secularized in administration and curriculum. (Many American colleges and universities, however, continue to cultivate a relationship with religious bodies.) During the latter stages of the eighteenth century, professional studies were first incorporated into these schools.

Harvard, the first institution of higher learning in America, was founded in 1636. The first colonial colleges attempted to foster the advancement of learning and the training of clergymen. These colleges offered curricula that featured classical studies such as rhetoric, mathematics, and logic. It was not until the emergence of the university that emphasis was placed on the total education of the individual, and the liberal arts education, with its emphasis on diversity of subject matter, took a prominent role in higher learning.

Professional schools, often referred to as technical or polytechnical schools, emerged alongside the growing popularity of liberal arts colleges. Professional schools were intended to provide students with "practical skills" that would prepare them for employment in a specialized field when they graduated. Prototypes of these applied science institutions included the Polytechnic Institute of Brooklyn and Cooper Union and agricultural schools in Maryland, Pennsylvania, and Michigan. So successful were the experimental professional schools that traditional institutions that had ignored practical skills training began incorporating them into their programs. The federal government also recognized the utility of such training and indicated its approval by requiring institutions participating in the Morrill Land-Grant College Act of 1862 to include agriculture and the mechanic arts in their curricula.

A key piece of legislation in the history of American higher education was the passage of the Morrill Act in 1862, which permitted public lands to be appropriated by individual states in order to establish state agricultural and mechanical schools, forerunners of the modern state university.

The Land-Grant College Act of 1862 granted to each state 30,000 acres of land (or its equivalent) for each

senator and representative in Congress. This allowed colleges and universities, particularly those that specialized in training students in agriculture and mechanical arts, enormous growth potential. The land-grant colleges and universities benefited the curriculum and overall structure of higher education in America in general; most notably, states realized the practical and long-term benefit of continued underwriting of institutions of higher learning. Equally as important, the breadth of subject matter available at these schools became increasingly diverse and wide-ranging as the institutions improved and expanded their faculties.

Normal schools, which traditionally trained teachers, came into existence around 1840. As the training of elementary and secondary instructors became more specialized, teachers' colleges emerged and eventually became a vibrant part of the industry.

It was during the mid-1800s that the states began to exert more influence on colleges and universities and promote them as private, nonsectarian institutions of learning. State funding and development of colleges and universities heralded the end of the era of the public college and ushered in the industry of colleges and universities in its present form. The Universities of Georgia (1785), North Carolina (1789), and Vermont (1791) were the first state-chartered schools. This trend escalated dramatically around the time of the Civil War, until state colleges and universities became the standard route to higher education across the nation. It was not until late in the nineteenth century, however, that states began to assume financial responsibility on an ongoing basis for colleges and universities. It was also at this time that the municipal college or university came into being. These institutions were managed by city governments and partially funded by municipal taxes.

So specialized had the industry become that special colleges for women and for black Americans began operating in the nineteenth century. The overall trend in higher education, however, has been toward coeducation. Today, of course, admittance discrimination based on gender, race, or religion is outlawed. Still, there are about 130 single-sex colleges (men- or women-only) in the United States today, and there are more than 100 historically black colleges.

Universities, as institutions of higher learning and scholarship, became fully entrenched after the founding of Johns Hopkins in 1876. Truly the renaissance in higher education in America, it was during this period as well that Yale, Columbia, Harvard, and the Universities of Michigan, Wisconsin, Minnesota, and California opened their doors. Endowments and grants from major corporations also established these institutions as the focus of corporate investment. With such fiscal leverage at their disposal, these universities quickly became forces to be

reckoned with, both in the academic arena as well as in the overall economy. Research and the training of highly specialized professionals positioned the nation's universities as one of the primary resources big business and government relied on for a constant supply of technology and skilled labor. In addition, communities where colleges and universities were located became increasingly dependent on those institutions for the community's economic health and well-being.

Higher education became an even more dominant part of the American experience after World War II. Virtually anyone who qualified for the G.I. Bill of Rights and was armed with the necessary academic requirements could gain entrance to a college or university. Financial subsidies from the government increased attendance enormously, and postsecondary institutions realized substantial growth in revenues. The surge in the popularity and fiscal growth of these institutions can be appreciated by comparing enrollment statistics: The enrollment in the fall semester of 1950 for all students in institutions of higher education was 2.6 million; in 1990 that number had increased to 13.8 million. Industry analysts predict this trend will continue.

The exponential growth of two-year trade schools, or junior or community colleges, is indicative of the diversity that characterizes higher education in the 20th century. Staggeringly popular since the middle of this century, these two-year programs, according to *American Universities and Colleges*, enrolled 217,572 students in 527 institutions in 1950-51; by the 1998-99 academic year, enrollment totaled approximately 5.4 million in more than 1,600 institutions.

As the twenty-first century approached, colleges and universities emphasized imparting practical skills and knowledge to as wide and diverse a population as possible. The technological and computer revolution supplanted the traditional liberal arts education, stressing the importance of skills and knowledge that make students marketable in a computerized age. There has also been a strong emphasis placed on removing financial and racial barriers to a higher education. Government loan programs and equal opportunity initiatives have been very successful in these areas.

The higher educational system faced the twenty-first century with a wide range of challenges and some significant transformations in the works. Many colleges and universities were financially troubled. Operating costs continued to soar in all areas—scholarships, administration, student services, faculty, research, and maintenance. As a result, tuition and room and board costs grew, typically higher than the rate of overall inflation. Throughout the 1970s and 1980s, most universities attempted to mitigate these pressures by cutting expenses at the margins, such as maintenance and staff cuts, while

raising tuition prices and boosting fund-raising efforts. An increasingly competitive industry, colleges and universities found that in order to maintain a competitive edge in this crowded field, they would need to begin thinking strategically in the manner of a typical corporation.

Appropriately, then, the presence of corporate America has grown highly visible on United States campuses. Marketing contracts, research funding, and other such deals between schools and powerful business skyrocketed in the mid- and late 1990s. Pennsylvania State University, for example, entered into a contract with Pepsi-Cola Co. whereby Pepsi agreed to donate \$14 million to the university over a 10-year period in exchange for granting the soft drink company exclusive rights to market and sell its products on the school's campuses. Coca-Cola, Nike Inc., Rite Aid Corp., and a host of other firms have made similar deals with colleges and universities across the country. Other corporations have donated money to build academic facilities on campuses in exchange for the right to occupy parts of the buildings for their own operations.

Moreover, as businesses invested more heavily in colleges and universities, curricula became increasingly tailored to gear students toward careers with the firms donating the money. The National Science Foundation in 1998 facilitated more than 20 partnerships between businesses and community colleges designed to ready students for jobs in the high-technology sector. As schools compete to retain top-notch programs to draw the highest caliber of students, they are expected to rely more on corporate investment to propel their research programs.

As postsecondary education came to adopt the traditional business model, institutions met with inflated pressures to streamline their operations and eliminate bureaucracies. By the end of the 1990s, one of the most notable examples of cost cutting was in the realm of faculty. Whereas traditionally colleges and universities prized the tenure status of professors, which guarantees permanent employment, thereby allowing professors to concentrate on research, by the late 1990s tenure itself was under attack. Critics complained that tenure encouraged professors to diminish productivity and lose sight of their teaching responsibilities. However, cost pressures were the most widely recognized explanation for the decreased emphasis on tenured faculty. The temptation to register savings by filling vacancies with part-time faculty proved very powerful through the mid- and late 1990s.

The proliferation of qualified teachers has made the transition toward part-time, or adjunct, faculty especially attractive. The large potential employment pool from which departments and administrators can draw has resulted in a tremendous market for low-cost part-time teachers. The tendency toward fiscal austerity is most

marked in the humanities and other liberal arts programs. These conditions do not bode well for the current record numbers of students enrolled in graduate programs in these areas. The number of adjunct faculty members leaped 30 percent between 1991 and 1995; over the longer term, the use of part-time teachers escalated 266 percent between 1970 and 1995, during which time the number of full-time faculty members declined 49 percent. A total of 10,732 new full-time faculty appointments were made in 1996, down 25 percent from 1989. By 1998, 45 percent of all faculty at U.S. postsecondary schools were part-time; among community colleges, that figure jumped to 63 percent.

By the late 1990s, efforts to organize adjunct faculty members were intensifying in an effort to gain some leverage throughout the higher education system, including demand for health benefits. Adjuncts typically were remunerated according to the number of credit hours they taught each semester, usually amounting to between \$1,200 and \$2,000 for a regular three-credit course. This usually translated into annual earnings of less than \$12,000 per year. About 70 percent of part-time teachers, therefore, supplemented their income with other employment, which they had to balance with recurrent job-application filings for their next teaching position. It was not uncommon for adjunct faculty to commute between positions at two or even three schools in a localized region.

Tuition. As a whole, tuition rose twice the rate of inflation in the 1980s and 1990s. In the late 1990s, tuition costs rose about 4 percent annually. This trend held true for all types of postsecondary institutions. For instance, the average annual at a four-year private institution was \$13,664 during the 1997-98 academic year, compared to \$10,994 in 1993-94 and \$8,120 during 1984-85. Likewise, four-year public institutions cost \$3,111 in 1997-98, up from \$2,543 in 1993-94 and \$1,748 in 1984-85. When combined with room and board prices, the total basic expenses at private schools reached \$18,745 in 1997-98, compared with \$6,788 at public institutions. These costs do not include books and supplies, health insurance, and personal expenses, which includes traveling between school and home. At public community colleges, tuition averaged \$1,501 in 1997-98, up from \$1,114 in 1993-94.

According to a March 1997 *Time* magazine special investigation by Erik Larson, tuition hikes can be attributed to high growth and expansion in the 1950s and 1960s, the slowing of federal funding in the mid-1970s, the rising energy costs of the late 1970s, high inflation in the 1970s and 1980s, and a phenomenon called the "Chivas Regal effect" in the 1980s, in which universities and parents began to equate higher tuition with higher educational quality, especially among the very competi-

tive Ivy League schools. In the 1990s, financial aid and the expense of keeping up with technological advances were among the reasons for rising costs.

Pressure caused tuition hikes to slow down. Indeed, some Ivy League schools may have lost many top-notch students who were unable to afford or unwilling to pay exorbitant tuition costs. In addition, the financial-aid process grew increasingly convoluted. Still, since the 1980s a college education has been perceived to be a necessity, due to the significantly increased value an employee commands on the job market if in possession of a college degree. By the late 1990s, a college diploma translated into an average of 52 percent in additional wages when compared with an applicant with only a high school diploma. Moreover, real wages in some sectors, such as certain manufacturing fields, were actually lower than their 1960 level for those with only a high school education. Those with professional degrees, such as legal, medical, or business certificates, tend to garner the highest salaries, followed by doctoral and master degrees. As job security diminishes throughout the economy, moreover, a degree from a prestigious university is increasingly valued as an insurance policy against downsizing layoffs.

During the late 1990s, the federal government underwrote about 72 percent of the approximately \$60 billion in financial aid benefits offered annually by federal, state, institutional, and private bodies. Lower-income students and families received assistance in paying for higher education through Pell Grants and Hope Scholarship tax credits. For adult students, moreover, the Lifelong Learning tax credit supplemented employment income while they retrained to upgrade their skills.

The Student Body. The composition of the student body has changed dramatically. In 1970 women made up 41 percent of the college and university student body. By 1998 this figure had increased to more than 53 percent. Minority enrollment has escalated as well. Moreover, an increasing number of minority high school students were pursuing college degrees by enrolling in college preparatory classes in secondary schools. Observers note that individuals with parents who attended colleges were far more likely to attend college themselves.

Racial and ethnic demographics underwent some interesting shifts in the 1990s. Although African Americans have come to enjoy nearly proportional enrollment in postsecondary education, the National Association for Equal Opportunity in Higher Education reported that enrollment at historically black colleges and universities (HBCUs) rose 11 percent between 1990 and 1998; notably, however, white enrollment at these institutions increased 16 percent during this period, whereas African American enrollment rose 6 percent. Most of this growth, analysts surmised, was due to the schools' lower average

tuition cost (\$6,600) when compared to other private schools, as well as the expanding number of degree offerings at HBCUs. Those schools, meanwhile, have greatly intensified their recruitment efforts in an effort to more readily meet their financial needs and, of course, to attract the best students.

Diversity has become key to the college curriculum. With the rising presence of minority students on college campuses has come the demand for more ethnic studies and foreign-language courses, as well as minority instructors. According to the National Center for Education Statistics and the Asian-American Studies Program at Cornell University, in 1996 about 90 of 2,200 four-year colleges in the United States offered majors in African American studies, 20 in Latino studies, 17 in Asian American studies, and 12 in Native American studies. Some conservatives challenge the academic legitimacy of these courses, fearing they will de-emphasize the core curriculum, whereas supporters question the assumptions that kept such studies out of the traditional curriculum and note that students can only benefit by diversifying their range of knowledge. At any rate, students of all races find ethnic studies popular, and often these classes have long waiting lists. Moreover, many businesses emphasize the growing need for greater cultural awareness as the business community grows more international in character.

Most institutions of higher learning attempted to tailor their programs according to the needs of students who would be job hunting into the twenty-first century. Land-grant universities in particular were being urged to combine vocational training with general education. Throughout the country, in fact, institutions are finding that applications for admission increase proportionate to their ability to offer instruction in areas such as advanced business training, computer sciences, health sciences, engineering, and other professions that will be looking for qualified graduates in the near future.

Indicative of the situation facing college students who will be seeking employment in an environment where many blue-collar and white-collar skills are becoming obsolete, vocational colleges and two-year trade schools have enjoyed increasing enrollments for a number of years. Since the 1960s and 1970s, these institutions have become a staple in most communities and show every indication of thriving well into the next century.

An important and increasingly popular component of the training these schools offer is upgrading and remedial education, which appeals to an American population that is discovering the value of re-education. Remedial skills training, taught in a wide variety of evening, weekend, summer, and other adult education programs, are appealing to students who might have enrolled in a liberal arts college 15 or 20 years ago.

Government Financial Assistance. Retraining and educational upgrading have become priorities of both federal and local governments in the United States. Both the technical revolution, particularly related to the computer industry, and the obsolescence of many white-collar, middle- and upper-management jobs have engendered a revolution in retraining in America. The public sector has been committing substantial amounts of money to the re-education of Americans who possess minimal training in the skills that are required in today's market. In 1998 federal funds for education and related activities amounted to contributions of more than \$60 billion. Education analysts believe government will continue to support such efforts.

CURRENT CONDITIONS

By the early 2000s, weak economic conditions had resulted in business closures, massive workforce reductions, and decreasing tax bases throughout the United States. This led to state budget shortfalls, which in turn affected funding for colleges and universities. During the boom years of the late 1990s, state appropriations for higher education averaged 7 to 8 percent. However, according to *Educational Marketer*, the Center for Higher Education at Illinois State University reported that funding for higher education at the state level increased a mere 1.2 percent in 2002-03, reaching almost \$64 billion. Fourteen states cut funding, whereas another eight kept funding at the previous year's level or increased appropriations less than 1 percent. The most significant reductions occurred in Oregon, which implemented cuts of 11 percent, followed by 10 percent cutbacks in Missouri.

As government funding decreased, colleges and universities increased tuition. On average, tuition increased 10 percent in 2001-02 at public four-year institutions. At private schools, tuition and fee increases averaged about 6 percent. Tuition increases varied considerably from state to state. For example, *Education Daily* revealed that Massachusetts ramped up tuition by 24 percent, whereas New York only increased tuition by 2 percent. In all, some 16 states increased tuition more than 10 percent. In addition to paying higher tuition, students also faced financial aid cutbacks, with 17 states spending less on aid in 2002 than they did the previous year. Just as Massachusetts increased tuition by 24 percent, student aid levels also declined by that percentage in 2002. In addition to tuition hikes and less assistance, the stock market took its toll on college savings plans, putting increased strain on families with students near or of college age. According to *Money*, Morningstar indicated that funds in college savings plans fell 9 percent in 2002.

Looking ahead to the 2003-04 school year and beyond, experts were not hopeful for a quick turnaround. In its February 12, 2003, issue, *Education Daily* provided

information from *College Affordability in Jeopardy*, a study conducted by the National Center for Public Policy and Higher Education (NCPPE). Calling the state budget situation the “worst fiscal news for public higher education institutions and their students in at least a decade,” the NCPPE commented that widespread economic uncertainty, recessions in nearly every state, and “the need to provide adequate funding for K-12 education and Medicaid before fretting about higher education” were all factors that foretold of more bad news for U.S. colleges and universities.

WORKFORCE

Approximately 2.7 million people are employed in U.S. colleges and universities. Faculty members, by far the largest and most visible component of the workforce, assume a number of diverse roles in higher education. Duties typically include teaching, appointment and promotion of colleagues, conferring tenure, curriculum planning, and student admission evaluations. Faculty usually operate within specific academic or administrative departments and are represented in faculties, senates, committees, and, in some cases, bargaining or arbitration units. Gender disparity continues to haunt the coveted tenure position; about 72 percent of male faculty had tenure in the late 1990s, compared with 52 percent of women. Only 13 percent of faculty members belonged to an ethnic minority.

The average academic year salary for a full-ranking professor at a public university in 1999-2000 was \$76,200. An associate professor earned an average of \$55,300; assistant professors brought in \$45,600; and instructors earned \$34,700. Salaries are dependent on expertise and standing. For all positions, faculty at private schools tend to earn higher salaries. The highest paying fields include medicine, law, and engineering, whereas the lowest salaries are earned by those in the humanities and education.

AMERICA AND THE WORLD

Higher education in the United States continues to enjoy a great deal of prestige around the world. In recent years, record numbers of foreign students have enrolled in U.S. colleges and universities. Foreign students continue to value an American business education above all other forms of learning available in this country. Until recently, engineering was the most popular subject among foreigners. This discipline, though, has fallen behind programs such as the master's of business administration.

The foreign student population in American universities and colleges is largely composed of students from China, Japan, Korea, and Taiwan. Overall, Asians have constituted approximately two-thirds of all foreign stu-

dents attending U.S. colleges and universities, whereas Europeans have accounted for 15 percent. There has also been a relatively recent increase in the number of students coming from Latin America, Africa, and the Middle East. In the late 1990s, approximately 45 percent of graduate students in American colleges and universities were foreign students, whereas foreigners accounted for one-fourth of all doctorates awarded in the United States. Observers feel that this trend will continue and that foreign students will continue to represent a significant percentage of the population of colleges and universities.

SIC 8222

JUNIOR COLLEGES AND TECHNICAL INSTITUTES

This classification includes junior colleges and technical institutes offering academic or technical courses and granting Associate degrees, certificates, or diplomas. The minimum requirement for admission is a high school diploma or equivalent general academic training. Schools having junior college grades in conjunction with secondary grades are classified in **SIC 8211: Elementary and Secondary Schools**.

NAICS CODE(S)

611210 (Junior Colleges)

INDUSTRY SNAPSHOT

By the late 1990s, more than 1,500 institutions in the United States offered courses at the junior, community, or technical college level to more than 6 million students. This type of institution is often referred to as a two-year college, though this designation only pertains to establishments that provide students with an Associate's degree. Students at these institutions pay relatively low tuition rates compared to amounts charged by colleges and universities. Federal, state, and local appropriations and grants support public community colleges, which account for the majority of these schools, while private community colleges receive funds from a variety of sources.

Community and technical colleges are considered more convenient for students because they offer options for full-time, part-time, day, evening, weekend, and co-op Associate degree programs, which are especially helpful to those with full-time employment and family obligations. In fact, the majority of students at these institutions are enrolled part-time. The open-door policy of these colleges (admission is open to individuals with a high school diploma or equivalent) provides higher education to people whose circumstances might otherwise prevent them from obtaining a degree. In addition to the comparably lower tuition fees, two-year college students' expenses are usually lower due to savings on room and board costs, since many students live at home rather than on campus.

ORGANIZATION AND STRUCTURE

Community colleges and technical institutes are either private or public. Among private schools, many are administered by religious groups. There are also independent nonprofit institutions and proprietary institutes that are owned by individuals or groups. Since the funding for these schools does not come from public funds, they are relatively free to set their own priorities and form their own curricula. If they wish to receive accreditation from the American Association of Community and Junior Colleges (AACJC), however, they must fulfill specific requirements.

Most community colleges are public. Federal funding for community colleges comes in the form of either appropriations or grants. The Vocational Education Act of 1963, Title III of the Higher Education Act of 1965, and the Comprehensive Employment and Training Act of 1973 established appropriations to be awarded to schools. Federal grants are awarded to students for tuition and other needs. Forms and amounts of state and local funding vary widely. The amount of money the federal, state, or local community provides is a constant matter of controversy, along with the degree to which programming decisions are tied to funding. Members of a local school board may believe that they possess the greatest understanding of student needs and interests in their community, but when the state provides funding there is often a state board of education that exercises authority.

There are at least five functions performed by community colleges: academic transfer preparation, vocational education, continuing education, remedial education, and community service. Academic transfer preparation programs are designed for students whose academic performance in high school did not meet four-year college admission standards. These programs offer students an opportunity to prove their academic abilities and develop in a particular field of study, with the goal of gaining admission and transferring to a four-year college to earn a Baccalaureate degree. Some schools have established honors programs within academic transfer programs for those students who demonstrate high academic potential.

Vocational or technical education is designed for students who have a particular career goal in mind; subjects ranging from cosmetology to word processing are taught in these programs. Usually, the two-year degree offered by the community college will be the culmination of a vocational student's educational career.

Continuing education is designed for adults who are interested in taking courses for career or academic reasons. Continuing education students often maintain full-time jobs while attending community college. Remedial education is designed for students with developmental or learning disabilities, or students who received an inadequate

secondary education. Community service programs consist of short courses, workshops, and non-credit courses.

BACKGROUND AND DEVELOPMENT

The community college is a strictly American phenomenon. It is the most substantial element of the nation's educational system that is not based on an European model. The first junior college was established in 1896 as a division of the University of Chicago by William Rainey Harper, the result of an idea that first emerged from the frustration of many university administrators who were concerned with devoting valuable class time to freshman and sophomores. Subsequent development of the junior college, however, occurred more at the grassroots level than within the university community. During the first decade of the twentieth century, some high schools began offering courses for graduates who remained in the area instead of attending college. As the idea spread from state to state, private junior colleges predominated over public ones and, depending on the region, certain colleges emphasized agricultural or industrial education. The two years after high school were regarded as the final stage in the transition into adulthood and, for that reason, many educators felt these years were best spent in the home and in the community.

The democratic ideal that education should be available to all who seek it fueled what became known as "The Junior College Movement." After World War II, many veterans took advantage of the GI Bill by pursuing a government-sponsored education without leaving their communities. As baby boomers reached the ages of 19 and 20 during the 1960s, they filled junior colleges beyond their capacity, which resulted in a simultaneous growth in the budgets and staffs at these institutions. With this growth, public junior colleges overtook private ones in number and size. California became the first state in the nation to establish a statewide junior college system. By the 1976-77 school year, there were 1,030 public junior colleges in the United States, compared to 203 private ones. By this time, the schools saturated almost every region of the country. Subsequent growth, however, became considerably slower. Many of the two-year colleges that opened were designated "community college" rather than "junior college," and administrators began to stress the change in focus that accompanied this change in name.

Two-year colleges tend to be much more diverse than their four-year counterparts because they comprise students of all ages, races, and economic backgrounds. Almost 50 percent of all undergraduates in the United States attend two-year institutions, and more than 50 percent of first-time freshmen begin their higher education at a community college.

The issue of funding for community colleges was hotly debated during the economic recession of the early

1990s. Because this community concern has national ramifications, all three of the major presidential candidates visited community colleges during the campaign of 1992, pledging to uphold the institutions with tax dollars. Ross Perot, a former student in the community college system himself, was an especially vociferous supporter. Nevertheless, community colleges suffered along with all other recipients of federal dollars. In order to cope, many schools established fund-raising campaigns targeting former students, local businesses, and businesses with traditions of supporting educational growth.

Curriculum was another issue that divided community colleges, with student diversity presenting a key challenge. With such diversity came distinct and sometimes conflicting expectations of post-secondary education. Some students and faculty pushed for a new balance between vocational training and liberal education, which has always been an issue of debate for community college administrators.

As efforts to curtail government spending increased in the 1980s and early 1990s, funds for public community colleges began to fall short of their needs, and the schools began to turn to other sources for funding. Corporate donations became more common, especially at technical institutes. Some schools had success with fund-raising campaigns styled after those of colleges and universities. As financial woes continued, administrators began debating the possibility of increasing tuition or restricting admission. While both options would save money, they went against the principles of affordability and accessibility, upon which community colleges have rested since their creation early in the twentieth century. Other schools considered eliminating their special education divisions and facilities for students with learning disabilities, but again, it was feared that such decisions would undermine the intentions of the institutions.

With the proliferation of computer and video technology, some community colleges began experimenting with nontraditional teaching methods, including 24-hour learning laboratories; lectures delivered on closed-circuit, cable, or public television; and computer conferences. Such programs were aimed at meeting the needs of students whose work schedules conflicted with course schedules, as well as students who were unable to commute to school for a variety of other reasons. Such innovations were seen as a way of keeping pace with technological developments, especially in the field of computers.

Community colleges have reevaluated their curricula. In the early 1990s, it was determined that fewer students were earning Associate degrees and less than a quarter were transferring to four-year colleges. The pattern that many students seemed to be following was horizontal rather than vertical. This behavior was attributed to student scheduling conflicts and career considerations, rather

than a lack of ambition or inability to pursue a goal. Community colleges have tried to address these problems by providing alternative means of participating in class — often through the use of modern technology. For instance, community college libraries are being transformed into “resource centers.”

While funding was readily available for computer and video equipment in the early 1980s, the recession of the late 1980s and early 1990s resulted in limited resources for community colleges. Consequently, community colleges have often been unable to maintain a constant investment in rapidly developing technology. Heavy investment in the area of computer software, for example, was seen as a risky endeavor since nobody could predict which systems would endure. In order to remain current, some colleges have initiated partnerships with local software companies or companies that target the offices and work places of their community. This allows community college students to develop computer literacy on the equipment of a particular company, often in a setting that resembles an office.

Mutual use of network communications technology, such as e-mail and the Internet, is another partnership with the corporate world that has been an effective way for community colleges to obtain expensive technology without relying on government funds.

Because community colleges have a large number of minority students, especially in urban areas, the question of changing curriculum—such as including an ethnic studies program—was raised starting in the late 1980s and early 1990s. The debate over curriculum was comparable to the question of revising the canon of literary classics at colleges and universities. Community colleges, however, did not prove to be a radical force for change in the academic curriculum. Students interested in vocational training were naturally not as insistent about bringing nontraditional works into the classroom, and students aiming at transferring to four-year institutions feared that the study of anything other than the established curriculum might jeopardize their chances. Students at many four-year universities, however, have demanded ethnic-studies programs and many institutions have implemented such programs.

In regard to growth in the community college industry, at least one expert, Arthur M. Cohen, long-time director of the Educational Resources Information Center (ERIC) Clearinghouse for Junior Colleges, believes that community colleges have reached a saturation point in the United States. Because these institutions are within easy access to virtually every community, no further dramatic growth is expected. According to Cohen, “Few new institutions will open in the years ahead because a community college is now within commuting distance of most of the nation’s population. There will be very little

contraction in enrollment. . . . Funding for various programs will continue to be provided. . . . The colleges are here to stay in their current form.”

CURRENT CONDITIONS

Between 1971 and 1997, the percentage of high school graduates who had completed at least some college rose from 44 to 65 percent. The number of Associate degrees awarded during 1997-1998 was approximately 514,000. The 18- to 24-year-old population is expected to increase by 16 percent by the year 2007. However, the 25- to 29-year-old population was expected to decrease by 10 percent until 2002, when it would commensurately increase again. As junior college populations tend to carry large numbers of students in these age groups, total college enrollments are expected to increase at a more modest annual rate of between 1.1 and 1.3 percent. The number of associate degrees awarded annually is expected to increase to 587,000 by 2006-07. All in all, these statistical trends reflect America’s growing emphasis on education as a means to better one’s job opportunities, earnings, and community stature.

WORKFORCE

Community college faculty and administrators have long had to cope with the impression that their schools are somehow less legitimate or consequential than four-year institutions. According to Dale Parnell, a former chief executive officer of the AACJC, for too many educators, “the highest calling in teaching is an Ivy League university. If you can’t teach there, then in a state college or another four-year institution. If you can’t do that, teach in a community college. If not there, then teach in high school.” Frustration with this pecking order is often formidable. Along with being accorded less respect, teachers receive lower salaries than their counterparts at four-year colleges and universities. The level of aggravation, however, among two-year instructors is a great deal higher. The faculty at community colleges is often composed of younger teachers who, like their students, are looking to transfer to four-year institutions. Teachers complain that their students have not been adequately prepared during their secondary education to handle college material, that high student-to-teacher ratios make it extremely difficult to perform their classroom duties and still keep abreast of developments in their field, and that their reputation as second-rate professionals hampers their performance. To boost morale among teachers, some community colleges have established programs for recognizing and rewarding excellence.

SIC 8231

LIBRARIES

This category encompasses establishments primarily engaged in providing library services, including the circulation of books and other materials for reading, study, and reference. Establishments primarily engaged in operating motion picture film libraries are classified in **SIC 7829: Services Allied to Motion Picture Distribution**.

NAICS CODE(S)

514120 (Libraries and Archives)

INDUSTRY SNAPSHOT

During the early 2000s, 117,418 libraries provided services to the public and to specialized audiences. Libraries offer printed matter, electronic services, audio and video recordings, CD-ROM, lectures and similar adult programming, concerts, puppet shows, as well as reading hours for children, bookmobiles, and many other services.

In addition to public libraries (9,074), there are academic libraries at colleges and universities (3,658), school libraries (93,861), special libraries (9,170), armed forces libraries (329), government libraries (1,326), as well as corporate libraries and collections tailored to specific needs like hospitals, religious organizations, and museums.

Probably the most visible libraries are the public facilities located in communities across the country. Americans borrow more than 1.7 billion items each year from such libraries, which total 16,298 including branch libraries. In addition to books, Americans borrow magazines, sound recordings (both tape and CD-ROM), videotapes, DVDs, games, artwork, computer software, and other materials.

Of all adults over the age of 17, some 64 percent use public libraries. Similarly, almost 75 percent of children between the ages of three and nine visit a public library each year, and more than 40 million elementary and

secondary school students use their school libraries each week.

Public library circulation in fiscal year 2000 reached 1.7 billion items, a per capita total of 6.4 per year. Total visits numbered 1.1 billion. According to a study commissioned by the American Library Association (ALA), a majority of the population (84 percent) is satisfied with public libraries. In addition, more than half believe funding in support of libraries should be increased.

Public, academic, and special libraries alike face great challenges. Libraries usually are the first to bear the brunt of budget cuts, whether in the public domain, at universities, or in corporations, despite their importance to users. Struggling to keep up with rapidly evolving, costly, yet necessary technology, while striving to operate within budgets, libraries find themselves walking an increasingly fine line.

In recent years, library budget cuts have received widespread press coverage. Libraries also have begun purchasing greater proportions of new content in digital format. Nonetheless, overall these institutions remain an attractive market to book publishers. Libraries continue to purchase more diversified materials in order to keep up with the demand for information. In an effort to economize and make the most of existing funds, many institutions participate in cooperative arrangements known as interlibrary loan systems. Such programs enable school, public, and academic libraries to borrow materials from other libraries nationwide. As more libraries computerize their holdings, these arrangements will increase and sharing will become faster, economically workable, and more practical, enhancing efforts to reduce costs and increase library offerings and services.

ORGANIZATION AND STRUCTURE

The American Library Association (ALA) divides the country's libraries into several main categories. These include government, public, academic, school, and special libraries.

The nation's largest library is the Library of Congress, which contains more than 83 million items, including approximately 24 million volumes, pamphlets, and other printed materials. Created in 1800, beginning with Thomas Jefferson's collection of some 6,000 volumes, the library's first priority is to serve the U.S. Congress; it also provides many services to the nation's other libraries as well as to the general public. The Library of Congress publishes the *National Union Catalog*, a guide to the location of books in more than 1,200 libraries across North America. In addition, the library compiles bibliographic data for published books that is made available to other libraries on magnetic tape or machine-readable cataloging (MARC) for use in their cataloging processes.

The National Archives houses documents and records of the nation's history to be used for research and study. In addition to textual documents, such items include photographs, audio and video recordings, and maps. Since about 1770, the archives has housed all aspects of the federal government, encompassing domestic and military activities as well as foreign relations. The National Archives is also responsible for organizing and preserving the items and making them available to the country's citizens.

The National Library of Medicine holds the distinction of being the world's largest research library devoted to a single scientific area, although material on such topics as physics, chemistry, botany, and zoology are also collected. The library developed an online network available to major libraries across the country that allows virtually instantaneous searches of more than 5 million bibliographic citations from current journals in the health sciences.

The National Agricultural Library has been at the forefront of librarianship since it was founded in 1862 as part of the Department of Agriculture. The institution began printing a card catalog in 1899. A photocopier was developed in order to provide fast and inexpensive copies of materials, and it was the first library to test the feasibility of automated information storage and retrieval.

Establishing libraries in other countries is just one aspect of the United States Information Agency's objectives in promoting mutual understanding between Americans and citizens of foreign countries. The collections of such libraries introduce patrons to U.S. history, culture, and technology as well as American literary classics. Such libraries also serve as an example of the value of public libraries and free access to information.

School libraries play an expanded role in education by offering enhanced methods of learning via audio and videotapes, printed materials, CD-ROM, the Internet, and reference volumes formerly unavailable in more remote areas. Automation of libraries continues to make these services more widely available.

Academic libraries provide more specialized information for the benefit of scholars. Typically, a group of libraries focusing on various disciplines is linked together within a college or university setting to provide materials to students seeking specific information. The Harvard University Library, the second largest library in the United States (founded in 1638), contains more than 14 million volumes. Harvard's library system includes branches specializing in topics ranging from music to divinity, as well as a renowned law library.

The United States began the practice of providing all of its citizens access to public libraries and still strives to ensure that library services are made available to every-

one. This goal was made more attainable by the Library Services and Construction Act, which made money available for the purpose of establishing libraries in smaller towns and rural areas. Similarly, branch libraries provide library service to neighborhoods in larger cities. Public libraries provide a myriad of services to their community of users. In addition to making books, periodicals, and audiovisual materials available, these libraries offer information and referral services. Voter registration, tax, employment, health and family services, and other assistance is also available, and librarians guide citizens to various agencies.

As the largest public library in the United States, the New York Public Library has a total of 85 branches. It was established in 1895 when the Astor and Lenox libraries and the Tilden Trust were consolidated. The library contains more than 42 million catalog items, including 14 million books and a large number of manuscripts, microfilm, CD-ROMs, DVD, video, audio recordings, and sheet music.

BACKGROUND AND DEVELOPMENT

Libraries have played an important role in preserving the history of civilization since the invention of writing. Alexandria, Egypt, was the site of the most comprehensive ancient library, where scholars could study manuscripts in Greek, Ethiopian, Persian, Hebrew, and Hindi. In Rome, educated citizens maintained personal libraries, and there were 28 public libraries in Rome by the beginning of the fourth century A.D.

During the Middle Ages, the libraries of monasteries preserved copies of Greek and Latin classics. During the Renaissance, collectors, kings, and noblemen preserved many works of literature and philosophy in their personal libraries. These collections became the foundations of some of Europe's great scholarly libraries.

Books received a larger circulation after Johannes Gutenberg invented the printing press in the mid-1440s. Prior to this invention, manuscripts were written by hand, an inefficient method. In addition, few members of the public were literate or had the leisure time to read books until the Industrial Revolution and other social changes in the eighteenth and nineteenth centuries. Because of these advances, libraries changed from institutions that preserved valuable works with a limited sphere of elite users to educational facilities for the common people.

In 1731, Benjamin Franklin and some of his friends organized the Library Company of Philadelphia, the earliest library of its kind in the American colonies. The first free public library supported by public funds opened in Peterborough, New Hampshire, in 1833. Additional libraries were soon opened in many other cities in the United States and Great Britain. By 1876, there were 342

public libraries in the United States, and by 1920, the number had grown to more than 6,500 institutions.

As the twentieth century came to a close, libraries were being used by record numbers of American citizens. However, funding from government at the local, state, and federal levels was becoming increasingly difficult to secure, especially in certain geographic regions. In some places libraries have closed; in others, new libraries are being built, stocked with print materials and connected to the Internet.

Electronic information services began to play an increasing role in serving library users. Massive amounts of information were contained on database systems, and people used the library as their primary source for health, employment, financial, educational, as well as entertainment needs.

In markets serving populations of 100,000 or more, the following computer-related services were available to the public in a majority of the centers: CD-ROM databases (71 percent), remote database searching (71 percent), microcomputers (62 percent), software (57 percent), and online public access catalogs (OPACs). Increasingly, libraries offered access to the Internet, enabling libraries to serve those who do not otherwise have computer access—by providing information as well as instruction in the use of computers and other equipment.

The Internet. The biggest change in libraries during the 1990s was the rapidly increasing availability of access to computers generally, and to the Internet in particular. Nowhere was the change more dramatic than in the nation's schools. Through the efforts of local communities and upon the urging of the President, "Net Days" made possible wiring and connections to the Internet for many of the nation's schools and especially school libraries. By 1998, 89 percent of public schools were connected to the Internet.

As of 1997, the American Library Association (ALA) reported that library staff had access to the Internet in virtually all academic libraries. Users had access to the Internet from terminals in the libraries of 93 percent of doctorate-granting institutions, 82 percent of master's colleges, 76 percent of baccalaureate colleges, and 61 percent of associate of arts colleges.

The World Wide Web became a significant vehicle for distributing information. By the late 1990s, Web home pages had been developed by 87 percent baccalaureate-granting universities, 62 percent of master's colleges, 51 percent of baccalaureate colleges, and 26 percent of associate of arts colleges.

According to the ALA, 74 percent of public libraries offered public access to the Internet during the late 1990s.

Of libraries serving populations greater than 100,000 people, 85 percent provided Internet access.

Of the 461 public libraries that served populations of 100,000 or more in 1998 (the libraries that served 57 percent of the U.S. population), 99.4 percent offered Internet access to library staff; 65 percent offered Internet access for their patrons with a staff member in attendance; 85.4 percent offered direct Internet access to their patrons; and 31.1 percent offered modem access to the Internet from outside the library.

In "A Digital Metropolis," a *New York Times* Internet edition column by Jason Chervokas and Tom Watson, the New York Public Library was used as an example of the "Quiet Revolution" taking place in libraries. Eighty-three branch libraries were equipped with 220 Internet-ready computers; the most (17) were located in the Mid-Manhattan branch. In the four research centers the library maintained, there were 110 Internet-equipped computers; the most (95) were in the Science, Industry, and Business Library. The New York Public Library's extensive catalogue was available online through the Library Entrance Online (LEO) system. The system was made available in November of 1995 and by June of 1996 was recording nearly 30,000 visits a day.

Electronic media owners, seeking to protect their rights to the information in their databases, tried to control access to data by selling the use of the material, unlike the one-time sale of a book or periodical. This forced some libraries to charge users for access to this information—despite the basic tenets of the public library ensuring free and equal access to its patrons—based on relatively arbitrary fee structures.

Public libraries' budgets rose by 4.4 percent in 1998, for the fifth straight year. Funding for these libraries was provided by local tax dollars (78 percent), state sources (12 percent), and donations (9 percent). Less than 1 percent of funding came from federal tax dollars.

CURRENT CONDITIONS

The United States has the most extensive public library system in the world, with almost 16,300 outlets, including branches. Weak economic conditions—made worse by the terrorist attacks against the United States on September 11, 2001—presented grave challenges to these institutions during the early 2000s. While many libraries saw their budgets fall, some were forced to periodically close their doors to reduce expenses. Among the less fortunate were the Seattle Public Library, which closed down for two one-week periods during 2002. Academic libraries also fell victim to state budget cuts. In its December 2002 issue, *Library Journal* proclaimed that more challenging times were ahead in 2003 and that libraries would need to employ creativity and decisiveness when administering their budgets.

Despite the challenging times, *Library Journal* reported that more than 100 new libraries were constructed in 2002, along with another 111 addition and renovation projects. Together these projects cost in excess of \$788 million, the majority of which came from local sources (87 percent). Included were some truly spectacular buildings, including the 330,000-square-foot Central Library of the Memphis & Shelby County Public Library and Information Center, constructed at the cost of more than \$65 million. Although these figures are encouraging, the publication explained that 2002's project count tied for the third lowest in 14 years.

As the economy struggled, libraries saw utilization levels rise. In order to substantiate a long-held belief that an inverse relationship exists between these two variables, the ALA conducted a study in conjunction with the University of Illinois Library Research Center (LRC). According to the ALA, the study evaluated "library use over the last five years at the 25 U.S. public libraries serving populations of one million or more. Using data from 18 of those large libraries, the study found that circulation has increased significantly since March 2001, when the National Bureau of Economic Research pegged the beginning of the latest recession. Using statistical analysis, the LRC found that circulation in March 2001 was 8.3 percent higher than would be expected from the trend observed since January 1997. Following the events of September 11, circulation in October 2001 exceeded the trend by 11.3 percent."

As libraries headed toward the mid-2000s, an increasing amount of attention was being given to the so-called "library of the future." The growing universe of digital content was at the heart of discussions about how libraries would change as they became increasingly virtual, offering content to a larger, more geographically dispersed user base that demanded instant access to information. In early 2003, *Online* reported that 52 percent of the content purchased by libraries was digital. This figure was expected to soon increase to 58 percent. In response, many leading book publishers began offering their content in both print and electronic versions. Some observers argued that libraries increasingly would become centers of collaboration, as opposed to serving mainly as depositories of printed matter. In this scenario, librarians' roles would become more consultative and advisory than ever before.

WORKFORCE

There were approximately 136,000 librarians employed in the United States in the early 2000s, the vast majority of whom were required to have a master's degree in library and/or information science. About 66,471 worked in school libraries; 29,519 in public libraries; 24,815 in college and university libraries; and

15,307 in special libraries. More than 272,000 technical and clerical staff members supported the librarians' labors.

The number of jobs is expected to increase more slowly through the first decade of the 2000s than the average for all occupations. The number of new positions decreased somewhat in the 1980s and is on the rise as information becomes a more valuable and vital commodity. Librarians who have special qualifications such as expertise in computerized systems, data searching, foreign languages, or children's services may expect an optimistic forecast for employment opportunities. Numerous career opportunities exist in libraries, including positions as library administrators; public service, reference, and acquisitions librarians; and catalogers, online data entry, information designers, and systems planners.

There are also many technical and clerical positions available that do not require library school training. For those who choose to pursue a career as a librarian, a background in liberal arts serves as a strong base for library science. So too, is an undergraduate degree in computer science as libraries become an aspect of the information available to users of the World Wide Web. After completing undergraduate studies, library science students study for at least a year in one of the approximately 56 schools in the United States that are accredited by the American Library Association.

RESEARCH AND TECHNOLOGY

Computers are increasingly important in the library as networks linking public, college and university, school, and special libraries are expanded. Librarians maintain records on computers, and card catalogs are now nearly all replaced by computer terminals that allow online access to the library's holdings, as well as data, abstracts, and texts contained in periodicals and journals. The electronic network enables libraries to economically facilitate interlibrary loans, thus expanding their collections, controlling cost, and improving service to users.

New software allows research to be completed and followed with a request for an interlibrary loan. David Churbuck predicted in *Forbes* that a system consisting of thousands of main libraries and branches will become obsolete with the advent of more sophisticated computer programs that allow users to obtain full-text versions of the volumes they need. In addition, Churbuck believes that librarians will be replaced by programmers and database experts. The use of libraries as a prime source of access to the Internet for those who otherwise do not have access continues to grow.

In order for such complex networks of the future to become reality, printed books must be digitized through the technique of scanning—an electronic procedure that translates material into a digitized format. Project Guten-

berg, a program for digitizing books, is the creation of Michael Hart, professor of electronic text at Illinois Benedictine College in Lisle, Illinois. The Library of Congress is also digitizing its collection, and much is now currently available on the Internet. In addition, many periodicals have online editions.

Electronic resources will continue to enhance the information available to library users. Online mediated searching, CD-ROM, and various databases provide references that were previously unavailable. Online searching is the most common electronic option and was the first electronic reference service to be offered by research librarians in the 1970s.

SIC 8243

DATA PROCESSING SCHOOLS

The data processing schools category encompasses establishments primarily engaged in offering data processing courses or training in computer programming and computer peripheral equipment operation, maintenance, and repair. Schools offering an academic degree in computer sciences are classified in **SIC 8221: Colleges, Universities, and Professional Schools**.

NAICS CODE(S)

611420 (Computer Training)

611519 (Other Technical and Trade Schools)

INDUSTRY SNAPSHOT

Data processing schools are profit-making institutions that teach specific skills required for computer-related jobs. The types of schools range from residential vocational training schools to correspondence school programs. The U.S. Census Bureau showed that there were 10 exclusive establishments in the data processing schools industry in 1992. By 1997, 2,785 establishments were listed as offering computer training, but not all were data processing schools exclusively. Most were headquartered in California, Connecticut, Illinois, New Jersey, New York, Pennsylvania, and Wisconsin. Several schools were subsidiaries of larger corporations.

Computer consulting and training is a multi-billion dollar industry. The growth of this industry, however, does not necessarily translate to the data processing schools industry, which is limited by competition from computer-related training in secondary and other post-secondary schools and the availability of self-tutorials. On the other hand, the market for data processing schools could increase as employers demand specialized skills from their workers and other post-secondary education becomes more expensive. Successful marketing of data processing schools as a less expensive and more job-specific alternative to college and university education is essential for growth.

INDUSTRY LEADERS

The National Education Training Group (NETG), a subsidiary of National Education Corporation, which was acquired by Sylvan Learning Systems in March, 1997, is the global leader in information technology and interactive media-based learning. Its broad area of training ranges from programming to networking. NETG has been successful due to its diversified offerings, including multimedia products to train information technology professionals and end-user clients. NETG courses also include training to prepare professionals for vendor certification exams. NETG students may choose to combine media-based courses with classroom instruction. In February, 1997, NETG was selected by Microsoft Corporation to provide computer-based training to its employees.

WORKFORCE

Most instructional staff members of data processing schools hold bachelor's degrees and have worked in the data processing field prior to becoming instructors. According to U.S. Census Bureau information released in 1999, employment in the industry in 1997 was listed as 28,848 people—from 8,200 in 1987. Industry payroll

increased as well, from \$165.3 million in 1987 to \$970.2 million in 1997.

AMERICA AND THE WORLD

The U.S. data processing network is among the world's largest, and much of the industry's growth potential exists in foreign markets. *U.S. Industrial Outlook* estimates that more than 28 percent of computer education and consulting revenues will come from foreign countries.

Data processing schools must continue to work closely with the computer industry to train workers adequately. Computer hardware and software change frequently, and the schools must strive to utilize state-of-the-art equipment to prepare students for employment in an increasingly computer-reliant business world.

SIC 8244

BUSINESS AND SECRETARIAL SCHOOLS

This category includes establishments offering courses in business machine operation, office procedures, and secretarial and stenographic skills. Schools offering academic degrees are classified in Industry Groups 821 and 822.

NAICS CODE(S)

611410 (Business and Secretarial Schools)

INDUSTRY SNAPSHOT

Independent business and secretarial schools, once widespread, have steadily decreased in number since the 1950s as business education has migrated to colleges and universities and secretarial training has undergone a transformation. Where secretaries were once responsible for typing, filing, and taking dictation, their tasks have grown to encompass computerized business systems. Secretarial training is typically part of vocational training offered at technical and community colleges, which have

the financial resources to purchase business equipment for students. The term "secretarial school" itself has become antiquated in the United States; today most business and secretarial schools leave the word "secretarial" out of their name.

In the mid 1990s, there were 581 business and secretarial schools operating in the United States, employing 10,900 people and earning \$554 million in revenues.

BACKGROUND AND DEVELOPMENT

For centuries the profession of secretary was dominated by educated, economically lower-class males. Because there was no specialized equipment, a liberal arts education was considered adequate for a secretary's schooling. When the English gunsmith firm E. Remington and Sons began to produce typewriters in 1873, they employed young women to demonstrate the machines. As a result, the secretarial profession became associated with females. Remington and other companies established schools that offered typing instruction. These schools later evolved into secretarial schools. The Katharine Gibbs School—founded in 1911 in Providence, Rhode Island—became one of the most noteworthy names in the industry, branching into 11 separate locations by 1985. In the 1990s, Gibbs offered a one-year program, a two-year program, an Entre program for college graduates, and an Options program for those who were returning to work and wanted to improve particular skills.

Because some American executives believed that British secretaries were a status symbol, firms such as England's Brook Street Bureau of Mayfair, Ltd. trained secretaries and placed them in U.S. companies. Changes in immigration laws in the 1960s restricted such placement, and Brook Street established its own secretarial schools in the United States. The 1960s also saw the return of men into the American secretarial work force. Men trained in secretarial schools were often hired by female executives who were eager to reverse conventional gender roles.

Secretarial training became a common facet of community college systems as these institutions grew in number and stature during the 1960s and 1970s. Government funding for community colleges provided all members of the community the opportunity to acquire valuable skills. As Charles Myers wrote in 1970 of a secretarial training program at the Southern Nevada Vocational Technical Center, "The secretarial student who completes her course at the Las Vegas Vocational Center is entering the business world better equipped to handle today's modern business equipment than were any of her predecessors. . . . Thus, the community which has invested in her training gets its return at a higher interest rate than ever before."

The 1980s brought sweeping changes to business and secretarial schools as new or refined technologies—photocopiers, fax machines, and personal computers—entered business offices. While technology eliminated or improved many secretarial tasks, they also required that secretaries receive new types of training. In 1981, Katharine Gibbs School Inc., then a subsidiary of Macmillan Inc., announced the formation of Gibbs Consulting Group, whose role included office-automation training. Recognizing that the role of secretaries had changed, Gibbs also focused on training managers to utilize their secretaries most effectively. In 1985, the publishing magnate Robert Maxwell acquired Macmillan and proceeded to rid the company of all non-publishing operations, including the Katharine Gibbs Schools.

CURRENT CONDITIONS

E-commerce was the buzz word at business schools during the late 1990s, and those that offered courses in e-commerce and Internet business strategies had students lined up to register. Overall, technology courses such as MIS and computer science were most in demand, causing business schools to continue to move away from secretarial skills and move toward office automation and computer technology, accounting programs, court reporting programs, paralegal training, administrative training, legal (secretarial) programs, medical (secretarial) programs, and travel agent training in their curricula. Institutes offering these curricula include the Academy of Court Reporting, Michigan-based Dorsey Business Schools, and the renowned Wharton Business School.

According to a study completed by the Babson School of Executive Training in Massachusetts and the London School of Economics, in 1999, one in 12 persons in the United States was engaged in an entrepreneurial activity, compared to one in 30 in Britain. Consultants Ernst & Young believe that entrepreneurial activity in America will be the “defining economic event” of the millennium’s first decade.

By catering to the needs of entrepreneurs in their curricular development, business schools may be able to create a niche for themselves in a market of educational services clamoring to gain the competitive edge over traditional institutions for the training of business and corporate skills.

INDUSTRY LEADERS

Dale Carnegie & Associates Inc., headquartered in Garden City, New York, is the provider of the well-known Dale Carnegie Courses. Founded in 1912 by Dale Carnegie, the company offers eight courses that have been translated in 20 different languages and made available in 70 countries. The firm has an annual average of more than 150,000 participants taught by approximately

2,700 instructors. Dale Carnegie Courses provide a unique type of business skills training that can be targeted to any employee at a business, management or non-management. Training is available at either a Dale Carnegie facility or on-site. The company offers courses that are designed to improve management and employee performance in areas such as sales presentation, public speaking, organizational planning, goal setting, working in teams, customer relations, and problem-solving.

DeVry Inc., headquartered in Oakbrook Terrace, Illinois, is another industry leader. It offers courses in electronics, data processing, accounting, telecommunications, and business. DeVry has 30 schools in seven states, an enrollment of 30,000 students, and 850 faculty members. It owns DeVry Institute, Keller Graduate School of Management, and Corporate Educational Services. In 1998, DeVry had sales of \$308 million.

VOCATIONAL SCHOOLS, NOT ELSEWHERE CLASSIFIED

This classification covers establishments primarily engaged in offering specialized vocational courses, not elsewhere classified. Also included in this industry are establishments primarily engaged in offering educational courses by mail. Offices maintained by such schools for the sale of correspondence courses are included. Excluded from this classification are beauty schools, barber schools, schools offering flight instruction, and schools offering academic training.

NAICS CODE(S)

611513 (Apprenticeship Training)

611512 (Flight Training)

611519 (Other Technical and Trade Schools)

INDUSTRY SNAPSHOT

Thousands of students have learned a new vocation, explored an avocation, or earned a certificate or degree from the establishments operating in this industry. Students can enroll in schools or correspondence courses that provide training in fields as varied as banking, commercial art, construction equipment operation, electronics, practical nursing, real estate, restaurant operation, and truck driving.

Vocational schools have existed for more than 200 years in the United States. Initially, a vocational education program was part of a high school education, but independent schools were established after the 1972 Education Amendments recognized technical education as part of post-secondary education.

ORGANIZATION AND STRUCTURE

Vocational schools train students in hundreds of occupations, ranging from automobile mechanic to practical nurse. Programs emphasize hands-on training and use modern equipment and professional teaching techniques. Some schools maintain a variety of industrial contacts in order to keep up with the latest technology and better match the curriculum to job demands. Programs usually take between six months to two years to complete, and students who successfully complete a program typically receive diplomas or certificates. Almost all privately owned post-secondary training schools are approved by an accreditation agency.

Post-secondary training schools usually qualify for federal and state financial aid programs, and a large percentage of the students who participate in specialized trade programs receive financial aid.

Many institutions offer home study or correspondence courses. Various called “distance learning,” “alternative,” “nontraditional,” “external,” and “off-campus” education, the field began to grow rapidly beginning in the mid 1970s. Home study provides an alternative for people who want to pursue an educational goal but do not want to sit in a classroom. The programs are particularly popular with the disabled, parents of young children, and people living too far away from an educational institution’s campus to attend regular classes.

Approximately 3 million students pursue their educational objectives each year through independent study. Students can usually enroll at any time of the year and sometimes have as long as a year to complete a course. While students may enroll simply to learn about a particular subject, most often they take courses in order to improve their employability or upgrade their skills. Courses vary greatly in subject matter, skill level, and duration. These courses offer students the advantages of studying at their own pace and with a reduction in ex-

pense — there are no room and board or transportation costs.

In the not-too-distant past, correspondence courses were solely delivered through postal mail. Technology has changed this practice. Improved and less expensive telecommunications technologies have contributed to increasing interest in distance learning education. Today, distance learning provides educational programs and course materials to off-site students via interactive telecommunications networks, such as a computer modem (Internet or Intranet) or computer and video conferencing. Some are provided by cable or satellite television, videotapes and audiotapes, fax machine, or other modes of electronic delivery. Courses are offered for credit, non-credit, or professional certification.

Privately owned and operated home study schools offer vocational correspondence programs, and U.S. colleges and universities offer numerous correspondence and distance learning classes. Private foundations, nonprofit organizations, and the U.S. military also operate correspondence schools. Students who complete correspondence or distance learning programs generally receive diplomas or certificates. Depending on the course, an institution may grant credits transferable to a formal degree program, an external degree, a certificate, or Continuing Education Units (CEUs). Continuing Education Units is a nationally recognized system that provides a standard measure for acknowledging, accumulating, and transferring credit in continuing education programs. One CEU is considered ten hours of participation in an organized continuing education course taught under qualified instruction.

The U.S. Department of Education recognizes several organizations that accredit institutions offering correspondence or distance learning programs. The National Home Study Council, six Regional Accrediting Commissions, and nationally recognized accrediting associations are among these organizations.

CURRENT CONDITIONS

One of the most interesting aspects of vocational education has been its ability to keep pace with demographic and socio-economic trends. As the booming economy in the latter 1990s gave Americans more leisure time and money to spend, vocational education in home improvement and culinary arts soared — so also did massage therapy, herbal medicine, landscaping, and gardening programs. One of the newest programs to enter the certification forum was in outdoor power equipment operation. By the late 1990s, 18 schools were either certified or had certification pending by the Equipment & Engine Training Council (EETC) for the outdoor power equipment industry. “Industry certification” of programs have helped to bridge the gap between completing a vocational program and finding related employment.

The 1997 statistics released by the Bureau of the Census for business and industry indicate that there were 253 establishments in the United States that offered programs in apprenticeship training and more than 2,500 trade and technical schools. About as many establishments offered vocational rehabilitation services.

INDUSTRY LEADERS

The top vocational school company is National Education Corporation's subsidiary ICS Learning Systems, the world's largest provider of distance education in vocational, academic, and professional studies. In March 1997, National Education Corp. was acquired by educational services giant Sylvan Learning Systems, Inc. In the future, executives speculate that certain ICS courses could be migrated to technology platforms for learning center-based or Internet-based delivery.

Among technical institutes, DeVry Inc. headquartered in Oakbrook, Illinois, is an industry leader. In 1996, the institute earned \$260 million in revenues. DeVry Inc. was founded in 1973 and owns and operates the DeVry Institutes of Technology, the Keller Graduate School of Management, Corporate Educational Services, and the Becker CPA Review. In 1996, 28,150 full- and part-time students were enrolled in the DeVry Institutes' Associate and Bachelor's degree day and evening programs in electronics, electronics engineering technology, computer information systems, technical management, telecommunications management, accounting, and business operations. DeVry's 1998 revenues were \$308 million, with earnings of \$24.2 million.

SIC 8299

SCHOOLS AND EDUCATIONAL SERVICES, NOT ELSEWHERE CLASSIFIED

This classification covers establishments primarily engaged in offering educational courses and services not elsewhere classified. Included in this industry are music schools, drama schools, language schools, short-term ex-

amination preparatory schools, student exchange programs, curriculum development, and vocational counseling, except rehabilitation counseling. Establishments primarily engaged in operating dance schools are classified in **SIC 7911: Dance Studios, Schools, and Halls**; and those providing rehabilitation counseling are classified in **SIC 8331: Job Training and Vocational Rehabilitation Services**.

NAICS CODE(S)

- 611512 (Flight Training)
- 611692 (Automobile Driving Schools)
- 611710 (Educational Support Services)
- 611691 (Exam Preparation and Tutoring)
- 611610 (Fine Arts Schools)
- 611630 (Language Schools)
- 611430 (Professional and Management Development Training Schools)
- 611699 (All other Miscellaneous Schools and Instruction)

INDUSTRY SNAPSHOT

Somewhere between traditional education at colleges or universities and adult enrichment classes at the local high school, there lies a vast array of schools, programs and educational services intended to educate students in areas where other schools may have left them out. Specialty schools and classes, often turning interests into careers, have enjoyed a steady following through the 1990s and into the new millennium. In the periphery is a broad stratum of support services, all intended to assist the prospective student with informational, directional, or financial resources. This industry is segmented into three broad groupings: enrichment and avocational instruction, career development programs, and educational services.

ORGANIZATION AND STRUCTURE

The enrichment and avocational group is the largest in the industry. It encompasses art, ceramics, and cooking schools; baton, drama, and music schools; charm, diction, finishing, modeling, personal development, public speaking, and speed reading schools; as well as schools for those who want to learn to drive an automobile, fly an airplane, study the Bible, speak foreign languages, or survive in the wilderness. The depth of instruction varies and may range from appreciation of a subject all the way to mastery of that subject.

Career development programs include continuing education programs and civil service schools. Continuing education programs provide students with opportunities to learn or improve job and professional skills through participation in seminars and workshops. Civil service schools prepare students to successfully take the examinations required for employment in government positions. Other preparatory schools offer courses intended to

enhance a prospective student's chances of being accepted into graduate or post-graduate schools.

Educational services organizations develop educational curricula, offer tutoring, or provide vocational counseling. Some also operate student exchange programs or provide other networking resources to facilitate a correct match between student and school.

CURRENT CONDITIONS

According to the most recent statistics available from the Business & Economics Department within the Bureau of the Census, there were 33,784 establishments listed in the educational services industry in 1997, employing more than 250,000 persons. The number of establishments did not include schools and educational institutions offering traditional diploma or degree programs, excepting those incidental to educational services.

Interest in private specialty schools has remained high. In 1997, *U.S. News & World Report* ranked leading music, drama, and fine arts (among other specialty) schools in the nation. Competing against their university counterparts, The Julliard School (New York), the Curtis Institute of Music (Pennsylvania), and the New England Conservatory of Music (Massachusetts) were three among the top six schools of music nationally. Independent drama schools also ranked successfully against competing universities offering comparable programs. In fact, during the spring of 1998, New York City drama schools had an unusually high number of applicants for the 1998-99 school year. The 1998 Tanglewood Festival in Lenox, Massachusetts, was also particularly crowded, and prospective students clamored to gain advice and lessons from celebrity performers and musicians.

Federal funds remained generally accessible for student loan financing through 1999. However, in 1998, a federal appeals court upheld the U.S. Department of Education's criteria for determining student loan default rates, which had been challenged by the American Association of Cosmetology Schools of Phoenix. The decision could adversely affect other small specialty schools because their smaller student bodies contribute to statistical anomalies when compared to larger student bodies from two- and four-year colleges. The challenged policy cuts federally guaranteed loans to any school which has a 25 percent default rate on loans for three straight years. In small specialty schools, a mere dozen students could represent a 25 percent default rate, for example, if that school has an enrollment of 50 per program.

INDUSTRY LEADERS

Leading companies offering enrichment and avocational classes include the Braille Institute, Comair Aviation Academy, and Skip Barber Racing School. New

York-based Barbizon International Inc., established in 1939, leads the modeling school industry. Barbizon schools serve more than 200 markets located around the world, and many of its graduates become professional models, actors, and actresses.

Of all the specialized instructional institutions, language schools are among the fastest growing. Berlitz International leads the field in teaching foreign languages to business executives and travelers around the world. The company's enrollment has increased significantly in the 1990s as corporations recognize the importance of foreign language skills when competing in global markets.

Some establishments in the industry offer job training. Career Track Inc. and Development Dimensions International are among the companies providing services in the area of career development programs.

Leading companies offering post-secondary educational services include Wilson Learning Corporation and Sylvan Learning Systems Inc., the world's leading educational services company. Sylvan, which acquired National Education Center in March, 1997, holds chief market positions in supplemental education services for children, computer-based testing, adult professional education and training, and distance learning. In 1998, Sylvan bought out the stock of a German tutorial business and the Universidad Europea in Madrid, Spain. By the second quarter of 1999, Sylvan's earnings were up 49 percent, increasing its quarterly earnings from \$99 million to \$148 million.

DeVry Inc., another fast-growing post-secondary education specialist, owns and operates Corporate Educational Services, a provider of on-site technical education and training services to businesses and government agencies, and Becker CPA Review prepares candidates to pass the Certified Public Accountant and Certified Management Accountant professional certification examinations. The company's revenues for fiscal year 1998 were \$308 million, with earnings of \$24.2 million. In the late 1990s, DeVry planned to open three new DeVry Institutes—in San Francisco, New York, and Los Angeles. To mark its twenty-fifth anniversary, the successful company offered stock options to reward its employees.

SIC 8322

INDIVIDUAL AND FAMILY SOCIAL SERVICES

This industry includes establishments primarily engaged in providing one or more of a wide variety of individual and family social, counseling, welfare, or referral services, including refugee, disaster, and temporary relief services. This industry includes offices of specialists providing counseling, referral, and other social services. Government offices directly concerned with the delivery of social services to individuals and families, such as issuing of welfare aid, rent supplements, food stamps, and eligibility casework, are included here, but central office administration of these programs is classified in **SIC 9441: Administration of Social, Human Resource and Income Maintenance Programs**.

NAICS CODE(S)

- 624110 (Child and Youth Services)
- 624210 (Community Food Services)
- 624229 (Other Community Housing Services)
- 624230 (Emergency and Other Relief Services)
- 624120 (Services for the Elderly and Persons with Disabilities)
- 624221 (Temporary Shelter)
- 922150 (Parole Offices and Probation Offices)
- 624190 (Other Individual and Family Services)

INDUSTRY SNAPSHOT

The services within this industry can be classified as either public assistance programs or social service programs. These include individual and family service establishments that provide counseling and social services such as refugee, disaster, and temporary relief. Also included are state and local offices that distribute welfare benefits. Some private and public agencies offer adult day care, home-delivered meals, homemaking services, and in-home nursing. Other programs concentrate on children and youth, such as big brother/big sister organizations and protective and adoption services. The industry covers

crisis centers, self-help organizations, parole offices, and probation services.

The shape of U.S. social services underwent a transformation in 1996 with the introduction of Temporary Assistance for Needy Families (TANF), which replaced the long-standing Aid to Families with Dependent Children (AFDC). Welfare roles dramatically declined, from 5 million AFDC recipients in January 1995 to 2.2 million families on TANF in June 2001. The future of both private and public social services hinged largely on the future shape of TANF, set to be revamped during 2003. Since TANF is the dominant provider of U.S. welfare services, its successes and failures directly affect the ongoing services of other support agencies.

ORGANIZATION AND STRUCTURE

Public welfare programs fall under one of three general categories: social insurance, public assistance, or social services. Funded by mandatory contributions from employers and employees, social insurance programs are designed to protect people who experience a sudden loss of income due to the disability, temporary employment, retirement, or death of a wage earner.

Public assistance programs are designed to help the financially needy with services commonly known as welfare, particularly through the Temporary Assistance for Needy Families (TANF) and the Food Stamp program. Financed by federal, state, and local tax dollars, these programs provide benefits to people who show financial need and meet specific program qualifications.

Public social services were developed to meet needs through services such as counseling, day care, emergency youth shelters, alcohol and drug abuse services, and foster care. These programs are operated by state, county, and/or city governments, along with public and private agencies.

The availability of these services, as well as the sources for their funding, vary greatly. Some programs are open to all people, while others are available for a fee. Some are accessible only to those already receiving assistance from other public assistance programs.

Federal Agencies. Until the passage of the Personal Responsibility and Work Opportunity Act of 1996, which transferred public assistance programs from federal agencies to state jurisdiction, many locally administered individual and family social services were under the jurisdiction of both state and federal agencies. Several public welfare programs were under the direction of the U.S. Department of Health and Human Services, including TANF, the largest social welfare program in the United States.

TANF is a bipartisan creation that encourages welfare recipients to find jobs and become self-sufficient,

while at the same time promoting strong family units. The program allocates a block grant of \$16.8 billion to states and U.S. territories, which covers benefits, administrative expenses, and services. Individual states have a vast amount of power in determining their own programs, with the exception of a few federal mandates on eligibility. Under its original rules, recipients of aid must work after two years of assistance; families can only receive aid for five cumulative years; and food stamps can only be received for three consecutive months out of every 36.

Other Agencies. More than 100,000 social service organizations operate at the state, county, and local levels. For nearly 20 years, money from the private sector has made possible the activities and services of many of these groups. With the passage of the Personal Responsibility and Work Opportunity Act of 1996, most public assistance programs were operated at state, county, and local government levels.

BACKGROUND AND DEVELOPMENT

Social welfare in the United States began with the Social Security Act of 1935. The Great Depression, brought on many economic events culminating with the 1929 stock market crash, led Americans to realize that unforeseen circumstances could lead anyone into poverty. The Social Security Act was established to circumvent this eventuality. The act provided protection against the loss of income due to old age, involuntary unemployment, and blindness; in 1956 it was amended to include disability. The act also established Aid to Dependent Children, a financial support program for children who had lost one or both parents.

The next major change in U.S. policy toward social welfare came during the 1960s and was known as the “War on Poverty.” Precipitated by the civil rights movement that began in the 1950s, national social policy was changed during the 1960s to improve the standard of living for the poor. The federal government expanded existing programs such as AFDC and established new ones such as the Food Stamp Program.

During the 1970s, the federal government attempted to improve management and control over these public assistance programs. To eliminate variations of coverage among the states, uniform national standards were set for programs where the federal government and the states shared responsibility. Programs serving similar needs were consolidated into block grants to the states, in which federal money was strictly limited in return for increased discretion in state spending.

Realizing that the current welfare system has been producing generations of recipients, both the state and federal governments began looking at welfare reform during the 1980s. President Reagan cut federally funded

social spending by \$20 billion in 1981. The Family Support Act of 1988 forced AFDC recipients into job training or education. But by the 1990s, state governments, whose federal funding was slashed during the 1980s, looked at more drastic measures, like cutting AFDC payments for mothers who have additional children while on welfare.

AFDC was a federally funded program that provided cash and noncash services to families with needy children. Available in all 50 states, the District of Columbia, the Virgin Islands, Guam, and Puerto Rico, AFDC aided children in families where need was brought by parental unemployment, disability, death, or continued absence. Financed by federal and state funds, payments usually were made directly to AFDC recipients. The federal government’s share of AFDC payments was based on the need of each state. The government provided a higher percentage of federal matching funds to states with lower per capita incomes and a lower percentage to states with higher per capita incomes. The federal government also paid a certain percentage of costs related to program administration and training and the costs for acquiring and implementing management information systems. This public assistance program was later handled by individual state governments.

In August 1996, President Clinton made good on his 1992 presidential campaign promise to “end welfare as we know it,” by passing the Personal Responsibility and Work Opportunity Act of 1996, effectively replacing AFDC with TANF. The legislation ended the 61-year federal guarantee of aid to the poor and children, giving states broad power to design their own welfare programs, imposing a five-year lifetime limit on receiving welfare, and requiring recipients to begin working within two years after receiving benefits. President Clinton stated that the reform “gives us a chance we haven’t had before, to break the cycle of dependency” that affects millions of Americans.

TANF supplies an annual block grant to states to run their own programs. A five-year lifetime limit on receiving welfare requires recipients to work within two years, and half of all welfare recipients would eventually have to be working 30 hours a week. States that already have welfare programs in place under federal waivers would not have to comply with some federal work rules. The bill allowed childless, able-bodied individuals ages 18 to 50 to receive Food Stamp benefits for only three months in any three-year period unless they were working part-time and undergoing job training. These people could receive food stamps for another three months in that time frame if they were laid off from a job.

From 1993 to 1998, welfare recipients decreased by more than 41 percent—a total of 5.7 million people. The number of recipients reduced by approximately 2 percent

monthly. In fact, 1998 saw the lowest total number of welfare recipients (8.7 million) since 1970, the lowest number of families receiving aid (3.2 million) since 1972, and the lowest percentage of the population (3.2 percent) since 1968. In addition to the new legislation, these results were attributed to the nation's strong economy.

CURRENT CONDITIONS

According to TANF's annual report, released in February 2003 and reflecting 2001 statistics, 92 percent of approximately \$81 billion in TANF funds distributed to the states since the program's inception had been spent. Seventy-six percent went directly through states' TANF programs, 10 percent was allocated to the Child Care and Development Fund, and 6 percent went to the Social Services Block Grant. During fiscal year 2002, TANF caseloads declined for the sixth straight year to 4,995,719, down 6.2 percent from the previous year and down 59.2 percent from the program's inception in 1996. Over the same period, the number of families receiving TANF support declined 54.1 percent, to 2,024,691.

TANF law expired in October 2002 but continued to operate under an extension while Congress considered revisions and renewal. Debate was heated regarding the future form of TANF, and the issues surrounding the future of program were complex and highly political in nature. For example, proponents pointed to TANF's success by noting that welfare rolls declined at rates that even surprised TANF advocates. On the other hand, opponents questioned whether removal from TANF rolls equaled economic self-sufficient status. A 1998 study by the National Governor's Association reported that the majority of former welfare recipients earned between \$5.50 and \$7.00 per hour, leaving them well below the national poverty level. According to another study, three-fourths of women who left welfare in 1997 held low-paying, below-poverty-level jobs.

INDUSTRY LEADERS

Other than TANF, the largest programs in this industry are the Food Stamp Program, disaster relief services, eldercare, adoption services, and self-help organizations.

Food Stamps. Established by the Food Stamp Act of 1964, the Food Stamp Program was available in all 50 states, the District of Columbia, Guam, and the Virgin Islands. The Food Stamp Program assisted more than 10 million households and 25 million individuals. Under this program, low-income individuals living in households meeting nationwide standards for income and assets might receive coupons redeemable at most grocery stores for food. As a result of the Personal Responsibility and Work Opportunity Act of 1996, the caseload for the Food Stamp Program was reduced dramatically. From March 1994, a peak caseload year, the number of participants in

the program fell to two-thirds by 1998. Moreover, the number of beneficiaries in the Food Stamp Program dropped by 36 percent (five million people). The U.S. Department of Agriculture administered the Food Stamp Program at the federal level through its Food and Consumer Service (FCS). State welfare agencies administered the program at the state and local levels. In 2002, the number of average monthly individual recipients totaled just over 19 million. After three consecutive years of decline, the number of participating families grew to nearly 8.2 million in 2002, an increase from 7.4 million in 2001.

Disaster Relief. Founded in 1881 by Clara Barton, the American Red Cross responded to thousands of tornadoes, hurricanes, floods, earthquakes, fires, hazardous materials spills, transportation accidents, and other calamities that occur in the United States each year by providing emergency and disaster assistance through their trained paid and volunteer staff.

After a major disaster, the Red Cross supplied basic emergency shelter, food, medicine, and first aid to victims and distributed home clean-up items throughout affected areas. Red Cross disaster relief also included feeding emergency workers; referring disaster victims to other available resources; handling inquiries from concerned family members outside the affected area; and supplying blood and blood products, as well as disaster-related counseling to victims.

The Red Cross enabled disaster victims to resume independent living by assisting with the payment of groceries, clothing, basic household items, medicine, temporary housing, emergency home repairs, transportation, and tools. The American Red Cross provided all of its disaster assistance for free.

The Red Cross also offered assistance when other resources, such as insurance benefits and government assistance, were unavailable or inadequate in meeting disaster-related needs. All Red Cross assistance was provided on an individual basis, based on verified disaster-caused needs, and free of charge. American Red Cross chapters also worked within their communities to help the public prepare for, prevent, and cope with disasters and emergency situations.

Just hours after the terrorist attacks of September 11, 2001, the American Red Cross was on the scene in Pennsylvania, Washington, D.C., and New York, providing emergency relief services. In the aftermath, the Red Cross was flooded with donations from around the nation. There was an immediate influx of blood donations—unfortunately not immediately needed because there were so few survivors—and by June 30, 2002, the agency's fiscal year-end, the Red Cross had received over \$1 billion in monetary and in-kind dona-

tions. Of that total \$618 million was spent during the year in support of September 11 victims and their families. Another nearly \$420 million was left unspent at fiscal year-end but was earmarked for Liberty Fund, set up to funnel donations to victims of the terrorist attacks.

Eldercare. According to demographers, population trends predicted that the needs of the rapidly growing elderly population would equal, if not exceed the needs for child care. U.S. workers were left primarily to their own resources for finding elderly care services. In fact, as the 1990s began, a Bureau of Labor Statistics' survey of medium and large firms indicated that only 3 percent of the 32.4 million employees contacted had an eldercare benefit program that included employer subsidies for day care or time off to handle eldercare needs. Although numerous private and public agencies existed that provide elder care, neither employers nor employees often knew where to get assistance. Coordinated efforts began between employers and social service providers, however, to address the needs of those with eldercare responsibilities.

One option for eldercare was senior citizen day care centers. A practical alternative to costly in-home care, day care centers provided social interaction and activities that improved the livelihood of the aged. According to the National Adult Day Services Association, more than 4,000 elderly day care centers existed in the United States at the beginning of the twenty-first century—almost three times the number of centers in 1991.

Adoption Services. Thousands of social service agencies worked with adoption services, but only 250 handled most of the caseload. Traditional agencies, such as Catholic Charities, managed about 70 percent of the business, while other intermediaries, usually attorneys, handled the remainder. According to the National Committee for Adoption, which represented over 100 non-profit agencies, nearly 1 million couples sought to adopt every year. Based on the information available in the early 2000s, the number of adoptions varied by decade—in 1951, unrelated adoptions rose from 33,800 in 1951 to an all-time high in 1970 of 89,200 children. From 1975, numbers dropped dramatically and averaged 49,000 yearly for the next ten years. Numbers rose to 61,600 in 1996. In general, the number of available babies affected the number of adoptions. Less than two-thirds of those were infants. The combined effects of legalized abortion and the declining social stigma of unwed mothers were possible reasons for the shortage of available babies.

Self-help Organizations. The self-help movement, which began in 1935 with Alcoholics Anonymous (AA), has turned into a modern-day, low-cost alternative to expensive mental health services. Since self-help organizations have been inexpensive to operate, these popular

organizations have become appealing to lawmakers concerned with rising health care costs.

The AA formula of strict anonymity and its 12-step recovery program have proven to be quite successful. In 2003, over 100,000 AA chapters could be found in 150 countries with an estimated worldwide membership of over 2 million people. Moreover, between 12 and 15 million Americans were estimated to have become involved in nonprofit self-help groups like AA.

Certain studies show that self-help membership was increasing annually. Growth may be attributed to the anonymous nature of these groups, although anonymity has made accurate counting impossible. Most self-help participants have been white, middle-class baby boomers, but the movement itself has encompassed all kinds of Americans. The roster of groups includes Overeaters Anonymous, Gamblers Anonymous, and Debtors Anonymous.

WORKFORCE

According to the Census Bureau, in 2001 taxable and tax-exempt individual and family social services establishments in the United States, employed 821,890 workers, down from 923,300 in 1998. (Almost half of all nongovernmental social service employees worked for individual and miscellaneous social service organizations.) In 2001 mean hourly wage was \$12.14, with an annual mean of \$24,250. Management positions had a mean annual salary of \$45,990; chief executives averaged \$77,090. Community and social service organization positions, such as substance abuse counselors, family therapists, and social workers, were paid a mean annual salary of \$26,600.

Nearly two-thirds of all social service establishments have fewer than ten employees. However, half of all workers have been employed by larger establishments, those with 50 employees or more. The industry also has employed a high percentage of older workers, 36 percent being 45 years old or older.

One-third of nongovernmental jobs in social services have been in service occupations, such as homemaker/home health aides, food preparation workers, nurse aides, and child care or elderly care workers, according to the Department of Labor. These jobs usually have required little formal training in social services or an education beyond high school.

One-fourth of nongovernmental social service jobs have been professional specialty occupations, such as social workers, human services workers, adult education teachers, and counselors. These jobs usually have specific entrance requirements, similar to most professional specialty occupations. Some jobs required specific clinical knowledge, such as the duties of a licensed nurse.

Some of the fastest growing occupations in the United States can be found in the field of social services. By the year 2005, the number of homemaker/home health care aides in all industries has been projected to grow 88 percent, human service workers by 71 percent, and social workers by 34 percent, according to the Department of Labor. The anticipated growth in social service work has been based on the expanding needs of the elderly, disabled, mentally ill, mentally retarded, and families in crisis.

RESEARCH AND TECHNOLOGY

The federal government has been actively involved in researching technological options available for use in an electronic system to deliver public assistance benefits. Targeted for implementation sometime within the first two decades of the twenty-first century, the program would provide greater efficiency to the welfare system, especially in detecting fraud, waste, and abuse. The electronic delivery system would also reduce the costs associated with a paper-based, manual issuance, and redemption public assistance program.

JOB TRAINING AND VOCATIONAL REHABILITATION SERVICES

This category encompasses establishments primarily engaged in providing manpower training and vocational rehabilitation services for the unemployed, the underemployed, the disabled, and persons who have a job market disadvantage because of lack of education, job skills, or experience. Included in this industry are upgrading and job-development services, skill training, world-of-work orientation, and vocational rehabilitation counseling. This industry also includes offices of specialists providing rehabilitation and job counseling. Establishments primarily engaged in providing work experience for rehabilitates are also classified in this industry.

NAICS CODE(S)

624310 (Vocational Rehabilitation Services)

INDUSTRY SNAPSHOT

American industry spent tens of billions of dollars to train its employees each year. As industry becomes increasingly global and technology becomes more sophisticated, employers demand that workers sharpen their analytical, decision-making, and communication skills. In order to remain competitive, businesses need to provide their employees with continuous training. Likewise, to become employed and remain employable, individuals must be, at the minimum, literate and skilled. For many individuals—including those with vocational disadvantages such as illiteracy, a criminal record, former substance abuse, or physical and mental disabilities—education and training is received through job training and vocational rehabilitation centers.

According to the U.S. Census Bureau, there were an estimated 9,707 job training and vocational establishments operating in the United States in 1998, with combined operating revenues of almost \$2.9 billion for taxable firms. These establishments employed 336,800 workers. The U.S. Department of Commerce, Bureau of Economic Analysis, estimated that there were about 4,000 non-tax-exempt private vocational schools in operation, which posted about \$7.4 billion in revenues. Estimates of the cost of private-sector training vary widely, due to differences in the methods used and the difficulty of collecting cost data.

Job rehabilitation and training were expected to remain an important component of industry well into the twenty-first century as technological advances necessitated enhanced skills from new and current employees. Corporate downsizing and rapid technological change in the workplace promised to focus more attention on building and retaining a skilled workforce. Training was a key element in that process.

Workers once considered to have sufficient skills for lifetime employment found themselves learning new skills and processes to sustain their employment in an increasingly technological work environment. According to the U.S. Department of Education, in 1997, 76 percent of students in grades 1-12 used a computer at school (up from 62 percent in 1993), and 45 percent used one at home (up significantly from 25 percent in 1993). By the beginning of the twenty-first century, a consequential number of both high school and college graduates used computers in their jobs. Technological growth raised the level of training required for the workforce in nearly all industries.

Based on the educational background of the unemployed and labor-market projections, the U.S. Office of Technology Assessment (OTA) found that a large segment of the U.S. labor force was fast becoming more prepared for employment in an increasingly high-tech workplace. Yet other groups, including the immigrants who made up 26 percent of the labor force growth in the 1980s and early 1990s, still had a need for more job training.

Additionally, employers and post-secondary institutions found that a number of high school graduates and college students needed remedial work in grammar, mathematics, and basic problem-solving skills before they could be ready for employment or college. As a result, efforts redoubled throughout the 1990s to ensure academic accountability through minimum proficiency requirements students had to pass to graduate. However, for those who had already been through the system and whose educational skills remained sub-par, job training and vocational rehabilitation services were designed to address needs for education and skill development and

provide rehabilitative help and training for students and workers with insufficient knowledge and skills.

ORGANIZATION AND STRUCTURE

Nationally, the industry was composed of many small companies, a majority being non-profits and state-supported organizations. In the mid 1990s, the top 46 companies, which made up less than one percent of the total number of establishments in this industry, had sales of \$1.03 billion. This figure represented approximately 25 percent of the entire industry's sales.

During the 1990s, however, there was a decrease in the number of state-run vocational rehabilitation service centers. In 1997, the U.S. Census Bureau reported 2,549 centers, compared to 2,643 in 1992—an elimination of 94 state centers. Speculation on the reasons for this was varied. Cutbacks in individual state spending and federal subsidies accounted for some of the decline. High technology in the workplace created a much more efficient system with which workers could be trained and/or re-trained. That was a model employed by state-run program as well; many rehabilitation services were offered over the Internet and accessible from any computer.

BACKGROUND AND DEVELOPMENT

Traditionally, training programs had been implemented in response to specific problems or situations, and little regard was given to previous programs or to the implications for the future. In general, most of the money spent on training programs went to programs for professional and managerial staff, ignoring other workers whose skill development would mandate more expenditure.

The number of individuals who lacked marketable skills fueled the growth of the rehabilitative and vocational training industry. Firms in this industry were formed as a result of the lack of training available to individuals without a college degree. Many of these companies operated on the premise that people would derive greater benefits from training programs if they were able to help themselves. This idea was the genesis of Goodwill Industries of America.

Goodwill Industries was started in the early 1900s by Edgar J. Helms, a Methodist minister working in Boston. Helms began collecting unwanted household items and hiring poor men and women to repair them for resale, and he paid workers through the sale of the goods. Goodwill Industries served not only low income people but also those with other “barriers to employment including physical and mental disabilities, illiteracy, homelessness, inadequate education, and welfare dependency.” Goodwill Industries offered training in many fields, which ranged from computer programming to janitorial positions.

The passage of the Americans with Disabilities Act (ADA), which removed many employment barriers faced by physically disabled individuals, was expected to increase the number of clients served by training centers. Implementation of the ADA met with some resistance from employers who feared that they would be required to meet hiring quotas, and by employees who believed that physically disabled workers would receive preferential treatment in the workplace. The training and development industry worked to resolve these issues by helping to create and sustain supportive work environments for all workers. Training was well received when the trainers were sensitive to employee attitudes and encouraged open discussion.

Passage of the ADA represented significant growth potential for the training industry. In addition to providing training to employees, professionals in this industry found a market in corporations making changes to meet the federal regulations and needing insights about hiring and training physically challenged employees.

CURRENT CONDITIONS

In August 1996, President Clinton signed and Congress passed the Personal Responsibility and Work Opportunity Act of 1996. The legislation ended a 61-year federal guarantee of aid to the poor, giving states the power to design their own welfare programs, imposing a five-year lifetime limit on receiving welfare, and requiring recipients to begin working within two years after receiving benefits. Childless, able-bodied people, aged 18 to 50, were limited to three months of welfare every three months. They were eligible to continue receiving food stamps on the condition that they secure a 20-hour per week job and participate in job training or volunteer programs. President Clinton promised to encourage companies to help welfare recipients find employment. In light of this welfare reform, businesses were increasingly focusing on their roles in the education and training of adults, youth, and disadvantaged workers.

Continued corporate downsizing was another influence on the growth of the industry. As corporations continued to downsize their operations, they often demanded that remaining workers increase their performance and skill levels. More corporations required that job applicants possess high-level skills and that they cultivate these skills through on-going training. In manufacturing, for example, the tradition of using workers to perform routine, repetitive duties was being replaced by teaching employees a broader scope of skills and adding to their responsibilities. Companies were emphasizing teamwork and were cross-training their workers to make production more efficient.

The American Society for Training and Development estimated that nearly 50 million workers needed

additional training just to perform their current jobs adequately.

INDUSTRY LEADERS

Goodwill Industries of America was one of the world's largest leaders in the industry. Goodwill Industries is a nonprofit corporation that serves more than 126,000 clients annually through its vocational rehabilitation programs. Goodwill receives clients through referrals, of which the state vocational rehabilitation system and the public welfare system provide more than 50 percent. Nearly 25,000 of these clients were placed in competitive employment by Goodwill Industries in 1995. Salaries and wages earned by clients in that year totaled \$261 million. These people had previously depended upon some form of public assistance, but with their newly achieved employment, they became contributors to their local economies and returned about \$32 million in tax revenues to government at federal, state, and local levels. In 1996, Goodwill Industries encompassed more than 185 independent member organizations in the United States, Canada, and the Pacific Basin. In addition, the company worked with more than 50 affiliated International Goodwill organizations.

Goodwill's largest client group included people with such vocational disadvantages as illiteracy, past substance abuse, a record of criminal behavior, physical and mental disabilities, and a lack of work experience. People with mental retardation made up the second-largest group of Goodwill's clients. Goodwill Industries divided its vocational services into four categories: vocational evaluation, vocational adjustment, job-seeking skills and placement, and sheltered employment for those who could not realistically expect to succeed in a competitive environment. Goodwill also assisted clients with social adjustment training, and many of its facilities provided rehabilitation for persons with industrial injuries. In late 1999, The U.S. Department of Labor awarded Goodwill Industries International Inc. a \$20 million grant to provide training and support to place men and women on welfare in career-building Census 2000 jobs. The grant was the result of Goodwill's partnership with the Census Bureau; their goal was to recruit and hire 850,000 employees to conduct the census, and to place Goodwill graduates in jobs.

Goodwill Industries funded its job training programs through store, salvage, and contract sales; rehabilitation fees and grants; and public support funds. This revenue went directly to job-training services, vocational rehabilitation, and equipment required by people with disabilities and other special needs. An average of 84 percent of all revenue raised by Goodwill Industries from the sale of donated goods supported job-training and rehabilitation programs. The other 16 percent went toward overhead costs.

Another industry giant was Lions World Services for the Blind (LWSB), sponsored by various Lions Clubs. LWSB was formed to teach people who are blind or visually impaired independent living skills or job training skills. In the United States, 1.3 million Americans age 25 and older have severe visual impairments, causing them to make adjustments in areas of careers and everyday living situations. Since its founding in Little Rock, Arkansas, in 1947, LWSB has served more than 10,000 individuals in the United States and 54 other countries. LWSB offers a variety of vocational training programs to prepare individuals who are blind or visually impaired for careers in both white and blue-collar jobs. By the turn of the century, LWSB offered 13 vocational programs, which included several courses that train students to work for the Internal Revenue Service. LWSB also provided a variety of other services, including a college preparatory program to prepare people for college work, job-seeking skills training, employer education workshops, job placement assistance on a selected basis, and in-service training for rehabilitation professionals.

WORKFORCE

According to the U.S. Census Bureau, the salary difference in taxed and tax-exempt establishments in this industry was significant in the 1990s. Workers in taxed organizations typically earned more than their counterparts employed by tax-exempt organizations. Based on limited information, starting salaries for these human services workers ranged from \$13,000 to \$20,000 a year in 1994. Experienced workers generally earned between \$18,000 and \$27,000 annually.

The industry relied on various instructors and workers to provide job training assistance to its diverse client base. Teachers and instructors in vocational education programs comprised a significant percentage of this industry's workforce, but other workers included counselors, social workers, and secretaries.

According to the U.S. Department of Labor, employment in this industry was expected to increase significantly by 2008. In 1998, job training and related services industry accounted for almost 370,000 workers; a 31 percent increase to over 483,000 workers was expected by 2008. When the 20th century ended, job training programs began to require more workers as the U.S. economy continued to grow at an unprecedented rate. Companies changed their mode of production more frequently, thus more workers needed to be retrained.

AMERICA AND THE WORLD

In addition to simply making corporations more efficient, job training is key to keeping the United States competitive in world markets. Skills training will enable American companies to exploit the benefits of available

technology. Enhanced skills will be necessary to run advanced computers, including interactive software. Training will help close the gap between non-skilled workers and sophisticated technology.

With the exception of Goodwill Industries and Lions World Services for the Blind, most companies in this industry do not operate internationally. In general, training needs for vocational jobs vary widely from country to country. Many other countries have advanced systems of job training and apprenticeship. The United States relies heavily on on-the-job training, while European countries, particularly Germany, have more focused post-secondary education programs. Industry analysts expect that the United States will begin to follow Europe's example by establishing job-training programs in high schools and instituting a nationwide program of youth apprenticeship. Despite the attractiveness of a U.S. higher education to foreign students, the competitiveness of U.S. workers has declined compared with workers in some Asian and European countries because of weaker support for training and vocational education. These countries have used better-trained workers to shorten the production cycle and make incremental improvements in existing products, giving them a competitive edge over the United States.

RESEARCH AND TECHNOLOGY

The industry did not rely on technology to function, but rather trained its clients to make use of existing technology. Advances in computer software and systems were fast becoming a primary focus of the job training industry, as corporations demanded that their employees improve their computer literacy.

SIC 8351

CHILD DAY CARE SERVICES

This industry includes establishments primarily engaged in the care of infants or children or in providing pre-kindergarten education where medical care or delinquency correction is not a major element. These establishments may or may not have substantial educational

programs. These establishments generally care for pre-kindergarten or preschool children but may also care for older children when they are not in school. Establishments providing baby-sitting services are classified in **SIC 7299: Miscellaneous Personal Services, Not Elsewhere Classified**. Head Start centers operating in conjunction with elementary schools are classified in **SIC 8211: Elementary and Secondary Schools**.

NAICS CODE(S)

624310 (Child Daycare Services)

INDUSTRY SNAPSHOT

In 2002, two-thirds of women with preschool-aged children worked outside the home, up from 39 percent in 1975. At the beginning of the twentieth-first century, the daycare business had become, by some estimates, a \$30 billion dollar industry and was poised to grow even further over the next several years. Between 1980 and 2000, the number of children in center-based child care quadrupled. According to the U.S. Census Bureau, in 1999, 22.1 percent of all preschool-aged children of working mothers were provided care in center-based childcare facilities; 21.5 percent were in parental care; 28.8 percent in the care of a relative; 16 percent were in 20.3 non-relative care, including family-based care; and 7.4 percent were regularly cared for by an in-home babysitter or had no regular arrangements for care.

ORGANIZATION AND STRUCTURE

Daycare services can be broadly divided into two groups: family daycare homes and daycare centers. Family day care occurs in a private residence and typically serves four to six children. Most such providers operate unofficially, however, either because (1) they take care of four or fewer non-related children and thus in many states are not required to register, or (2) they are subject to state regulation but are wittingly or unwittingly operating underground. Estimates of these facilities naturally vary widely: a report of the National Association for the Education of Young Children places their number at anywhere from 500,000 to a million.

Daycare centers, in contrast, operate outside homes and typically enroll more children, perhaps 50 to 100. The centers can be divided into for-profit and nonprofit facilities. For-profit centers comprise the large national or regional chains with hundreds of centers, such as KinderCare and Children's World Learning Centers, as well as thousands of smaller businesses. Nonprofit centers may be operated by churches, parent cooperatives, public schools, community centers, Head Start, YMCAs, and so forth; some may be operated by businesses for the benefit of their employees or by the employees themselves.

During the late 1990s thousands of mothers entered the workforce under the guidelines of the Clinton administration's welfare-to-work program, causing an overloading of already limited availability of adequate child care. Parents called upon employers and state and local government to provide assistance with child care, in the form of subsidies, training, better monitoring and regulations, and greater flexibility. As the labor shortage worsened, more and more employers found that child care was an important benefit for both employee retention and increased productivity. But because of the labor shortage, qualified childcare workers became even more difficult to find.

Several studies during the late 1990s and early 2000s caused frazzled parents even more worries. For example, a study of 1,000 families in 10 cities conducted by three researchers from Columbia University in 2002 found that 3-year-old children scored significantly lower on basic assessment tests if their mothers worked more than 30 hours a week by the time the child was nine months old. Although studies were mixed on the long-term effects of high quality child care versus staying home with a parent, surveys examining the standards of U.S. child care were unanimous: the majority of children in day care received mediocre to poor care.

As in most other sectors of the economy, major growth in the industry was achieved by mergers and acquisitions. Although large chains made up a very small portion of childcare services in the 1990s, many were rapidly purchasing local chains and independent centers to expand operations, while others consolidated to increase their clout in the marketplace.

BACKGROUND AND DEVELOPMENT

During the seventeenth and eighteenth centuries, parents in the United States rarely had to face the problems of child-rearing alone because they could usually expect support from their extended families, many of whom lived and worked close by. Urbanization and changing social conditions in the nineteenth century created a need for child care for poor mothers who had to work. To this end, in 1828 a group of evangelical women established the Boston Infant School, often considered the first daycare center in the United States. Similar schools were soon set up in New York and Philadelphia. As these centers were usually established under religious auspices, part of their care entailed instructing their charges in moral and religious belief.

Throughout the nineteenth century and the early 1900s, such centers generally provided care only for poor children. More affluent mothers rarely worked, and, if they did, they hired nannies to look after their children. Thus, until the Great Depression, day care was generally seen as an issue confined to a relatively small segment of

the population. The enormous rise in unemployment and the subsequent creation of the New Deal afforded a vast expansion of daycare facilities through the Works Progress Administration. One of the primary objectives of these centers was to give jobs to the unemployed, especially laid-off schoolteachers.

Despite the dramatic social changes brought on by the Great Depression and World War II, most communities did not have full-day childcare programs until the late 1960s. In the 1970s and 1980s the number of daycare centers grew dramatically. The rise in the number of women working outside the home explains much of the story: in 1987, 67 percent of women in the United States were in the out-of-home workforce, compared with 39 percent in 1970. According to government estimates, in 1991 employed mothers had almost 10 million children under the age of five. Nearly one quarter of these children received care in an organized facility such as a nursery school or a daycare center. Forecasts indicated that women would account for 62 percent of the growth in the labor force through the year 2005, thus indicating a continued need for child daycare services.

Demand also depends on local social conditions, including the strength of family ties. For example, a unit of KinderCare, the largest of the daycare chains, surveyed 4,000 employees of an Ohio company and found that only 42 said they would use a corporate daycare center. A stunning contrast was provided within the skyscrapers of New York, where children of investment bankers might be making bird feeders from milk cartons as their moms and dads closed billion-dollar merger deals down the hall.

Regulation. State and local regulations, primarily enforced by state human services agencies and, to a lesser degree, local building departments, were a major challenge for daycare operators. Daycare regulation presented a particularly difficult dilemma for governments and legislators—and parents. While tough rules might increase the quality of care, they could also curtail supply and raise costs. Moreover, stringent requirements often drove providers, especially those with small family daycare homes, to operate underground.

Thus what began as a valiant attempt to offer maximum protection to children had the effect of creating facilities that had little or no regulatory oversight. Indeed, there was little doubt that some underground providers were not only skirting extraneous regulation but basic safety requirements as well. In early 1993, for example, the bodies of two children caught in a fire in a New York daycare home were found in the cellar, next to a pile of mattresses and a nonworking smoke detector.

Some observers noted that often the rules might be sufficient, but the staff that enforces them could be small and inadequate, with a single inspector responsible for as

many as 150 facilities. Providers complained that there were so many requirements that they were unable to discern which were essential and which were merely recommended. Directors were often frustrated by having to compete with programs that were exempt from licensing, which often included centers run by churches, local governments, or public schools.

The biggest regulatory hurdle for many daycare centers was meeting child-to-staff ratio requirements, since wages usually accounted for well over half of all operating costs. To ensure that children received proper supervision, state regulations required certain ratios of workers to children. The ratio varied with the age of the children. Child development experts generally recommended that a single caregiver be responsible for no more than three or four infants (less than one year old), five or six toddlers (one to two years old), or 10 preschool-age children (between two and five years old).

Health and Safety. During the mid-1980s, the insurance market for childcare centers was in a crisis. Legal costs were climbing; insurers feared huge tort settlements; reports of child sex abuse, most notably at the McMartin Preschool, were on the rise; and a major insurer of childcare services, Mission Insurance Co., became insolvent. By 1992, however, the Child Care Action Campaign was able to list 25 insurers that offered coverage, up from just a few providers available several years earlier.

Some daycare centers were criticized for unsafe conditions identified on playgrounds, where climbing equipment was often too high or equipment was poorly maintained. While children did occasionally sustain injuries at centers, most of them were minor and resulted in only small claims. Indeed, it appeared only 5 percent of accidents at centers led to liability claims, versus 10 to 15 percent for accidents in general. On the downside, however, policies became more expensive and insurers excluded some important risks. Most refused to cover legal costs to defend against physical or sexual abuse charges.

Without attempting to minimize the horror of any instance of child abuse in a daycare setting, some observers noted that these incidents represented a very small fraction of all child abuse cases. Indeed, statistically speaking, children were less likely to suffer abuse in a daycare facility than they were in their own homes. Other commentators noted that a child in day care is, again on a statistical basis, safer than a home because someone is always supervising the children, poisons are locked up, and there are no guns.

Whether small children are more likely to catch infectious diseases in a daycare facility than in their own homes was a source of controversy. Some noted the literature in medical journals that suggested several seri-

ous diseases, as well as less dangerous maladies, were more common among children in day care than those at home with a parent. A 1995 study found that an unsettling number of childcare centers, both for-profit and nonprofit, were unhealthy for children. The study showed that one in eight centers was unhealthy, primarily because of unsanitary conditions that promote the spread of infectious diseases. According to researchers, the underlying cause of many child daycare problems could be attributed to the low training of personnel and the high worker-to-child ratios.

Welfare to Work. The welfare reforms of the Clinton administration during the 1990s raised new concerns about the quality and quantity of day care, as many women previously staying home to care for their children were compelled to work outside of the home. One company addressed the problem by hiring women recently off welfare to provide childcare. In 1997, Philadelphia-based Childspace Management Group employed such women at an hourly wage of \$7 an hour—25 percent higher than the industry average. Employees paid a reduced rate to enroll their own children, and after one year were offered stock options in the company. The turnover rate for the company was more than 50 percent lower than the industry average. Another program, based in Chicago, which came about due to welfare reform efforts, helped women getting off welfare to obtain licenses for running daycare centers out of their homes.

For many of the working poor, mainly single mothers, help was not so forthcoming. Although some states offered childcare assistance to working women, for some women their wages were too high to get public assistance but too low to pay for childcare bills as high as \$600 per month for one child in the Seattle area—or up to \$1,000 monthly for two. Some women requested lower wages or part-time work; others took lower paying jobs. Actually finding child care also presented challenges. Although women leaving welfare received priority, they still faced waiting lists nearing 400 families.

An additional hurdle facing workers starting in entry-level jobs was the difficulty of finding child care that matched their working hours. According to a survey by the National Association for the Education of Young Children, in the early 1990s only 10 percent of childcare centers had weekend hours, and just 3 percent offered their services at night. According to the U.S. Census Bureau, less than one-third of workers hold 9-to-5 jobs, and that proportion is much higher in entry-level positions. Cities working to move parents off welfare initiated programs and lessened restrictions to increase the number of hours child care was offered. In 1998, for example, the Chicago City Council rescinded a regulation requiring childcare centers to close before 9:00 p.m. Rolling

Meadows, a Chicago suburb, announced plans to open a center operating 24 hours a day, seven days a week.

Employer Support. Employer support might take several forms, which included providing referral and information services; reimbursing employees, in varying degrees, through a benefits package; using a vendor system (the company buys places at daycare centers, and then the employee pays all or part of the costs); contributing to local daycare facilities; or opening a corporate childcare center, as was the case with some corporations in the United States that have on-site facilities. Opening a daycare center often yields much goodwill both within the firm, as well as favorable press. A 1997 study by Coopers & Lybrand L.L.P. reported that 43 percent of employers offered child care benefits, up from 30 percent the year before.

The study also reported that as many as 73 percent of companies with \$1 billion or more in revenue provided some kind of childcare benefits, while only 18 percent of companies with revenues under \$10 million did the same. But as small business grew throughout the 1990s, so did their childcare concerns. Tightening labor markets made retention of employees at all levels a crucial issue, more so in smaller firms, where losing one employee—either for a day or permanently—meant losing a substantial portion of the workforce. Smaller firms lacking the resources for on-site child care often offered employees a payroll deduction permitting them to use pretax earnings for day care, through the federal Dependent Care Assistance Program. Union-based movements were also pushing state governments and individual employers to improve childcare benefits.

A growing trend for employers was the provision of backup child care, allowing parents to work when their regular babysitter was not available: on weekends and evenings or in case of an emergency. ChildrenFirst Inc. operated 14 backup care centers in major metropolitan areas in 1998. “Sick day care,” child care for children too ill to attend regular day care, was also subsidized by some major employers. Often, employers “subscribed” to the program by paying a flat annual fee; employees who used the service made a low co-payment for the days they used. Both types of providers relied primarily on corporate clients for support, rather than individual parents. According to benefits consultants, this sector of the industry was growing faster than on-site care.

Quality vs. Quantity. As more mothers entered the workforce throughout the 1990s, concerns about the effects of day care on children also increased. Several studies released in the late 1990s offered mixed reports. Widely publicized studies in 1997 reported that the most brain development happens prior to age three and that it is highly dependent upon environmental factors including

attachment to caregivers and mental stimulation. In 1999, the National Institute of Child Health and Human Development released another installment of a study of 1,300 children from birth to age three. The results suggested that using child care during the first year of life, particularly the first four months, disrupts “the process of attachment, when mother and child learn to read one another’s signals and expressions.” Early reports from the National Institute’s study provided parents better news. Findings released in 1998 indicated that “toddlers in day care have fewer behavioral problems, like tantrums and hitting, than do those cared for alone with a nanny or in small groups.” A 1997 report from that study claimed that children in high-quality day care begin school with enhanced language and social skills. A 27-year study at the University of North Carolina supported these findings by concluding that children in “quality childcare programs” could maintain that advantage into adulthood.

With extreme shortages in affordable child care getting worse, however, quality was hard to come by. In 1999, the Consumer Products Safety Commission (CPSC) released the results of a study revealing unsafe practices and products in a majority of daycare centers. Of the 200 licensed centers the CPSC examined, over two-thirds had a least one major safety hazard. The findings, reported in *U.S. News and World Report*, listed several common safety hazards: “At 38 percent of the centers, children were wearing clothing with neck drawstrings, which can become caught in playground equipment and can lead to strangulation. Twenty-four percent of the centers had unsafe playground surfacing, and 19 percent had cribs that contained soft bedding, which can smother children. Other dangers included poorly maintained playground surfaces, loops on the cords of window blinds, and failure to use child safety gates where necessary.” The study offered no count of how many injuries were caused by these hazards, but the CPSC reported 56 deaths since 1990. A broader nationwide study, however, counted at least 76 deaths in the year 1996 alone.

Apart from safety concerns, many centers did not offer high quality care. A report published in 1996 by Suzanne Helburn and Carollee Howes found that 86 percent of childcare centers were below average to bad. Home-based day care was not substantially better: the study found 35 percent to be inadequate and 56 percent to be no more than adequate. A 1999 article in *Time* cited a federal study with similar findings: “85 percent of preschoolers who are cared for outside the home get poor or mediocre care, delivered by a hodgepodge of mostly unregulated providers.”

Other Programs. As private nursery schools began to proliferate in the postwar years, educators began to note that children were entering kindergarten with widely differing abilities. Project Head Start was conceived to

give poorer children a “head start” on their education. The program was distinguished by its commitment to the total child: it included nutrition and health care assistance and supported parents in their job searches. Unlike many of the programs initially funded during by the Johnson administration’s War on Poverty campaign of the 1960s, Head Start continued to receive strong support from the government and the public.

In 1999, there were approximately 1,500 Head Start programs nationwide—some of which covered multiple sites—at an annual cost of \$4.6 billion to the federal government. In the mid-1990s, the government became concerned with the quality of Head Start programs in many communities. According to the *National Journal*, “Over time, many Head Start organizations became stale, entrenched bureaucracies, protected by local politics and politicians, with little accountability to anyone or close examination of their record in helping kids.” Another challenge to the program was its strong affiliation with African-American communities, as the population of children being served by Head Start became more diverse and more heavily Hispanic. In a Clinton administration initiative, hundreds of the poorest performing Head Start programs were closed down, and many others were reformed.

Child care for older children also became a bigger issue, as more parents sought structured after-school programs. Proposals included keeping schools open as late as 6 p.m., although conservatives have argued that such programs give government too much power. As a compromise, some suggest using public school facilities for community-based programs. As of 1999, 30 percent of public elementary schools offered after-school programs; 3.4 percent of eligible children made use of them. One publicly held childcare provider sought to corner this market: Nobel Education Dynamics offered programs for children through the eight grade. The company announced in early 2000 that its net earnings for the six months ended December 31 1999, increased by over 153 percent from the same period of the previous year.

CURRENT CONDITIONS

According to the Children’s Foundation, in 2002 there were 113,298 regulated childcare centers in the United States, up from 86,212 in 1988. Family childcare homes totaled 306,802. Of that total, 262,329 were family-based childcare homes and 44,473 were group (large) childcare homes. This number represented a significant increase from 1988, when the Children’s Foundation listed 193,044 total family childcare homes—181,662 family-based and 11,382 group.

The trend toward children living in households where both parents work continued to provoke discussion in the childcare industry on how best to serve the needs of

these children. Although two-thirds of mothers with young children work outside the home, a report issued by Public Agenda reported that 70 percent of mothers with children under the age of five preferred to stay at home and 80 percent believed that their children would fair better in terms of attention and affection under the care of a parent than in a well-run, quality childcare facility. Whereas 67 percent of parents surveyed supported tax cuts to help families allow one parent to stay at home, only 27 percent of child advocate groups agree. Organizations such as the Children's Defense Fund and National Association of Child Advocates believe that the answer to the nation's childcare needs lies in developing more affordable and quality daycare centers.

As a result of the ongoing debate regarding the future direction of satisfying childcare needs, the direction of future trends is fragmented and without consensus. While childcare advocates push for increased funding to improve the quality of care available to low-income families who cannot afford to place their children in private daycares, families themselves have opted for changing to stay-at-home careers and jobs with flexible work hours. Ideally for many would be a trend toward on-site childcare facilities, but nearly 80 percent of companies surveyed by Public Agenda did not believe they had lost good employees due to lack of childcare benefits, making unlikely the hope that corporate America would lead a full-scale charge into innovative child care.

INDUSTRY LEADERS

In the early 2000s, KinderCare Learning Centers was the nation's largest for-profit childcare organization; it cared for over 129,000 children, ages 6 weeks to 12 years old, in 39 states as well as two sites in the United Kingdom. The average weekly tuition was approximately \$135. Along with its KinderCare Learning Centers and Mulberry Child Care Centers, KinderCare also operated on-site at nearly 50 corporate sites under the banner KinderCare at Work. In 2002 the company reported a net income of \$16.5 million on sales of \$829.4 million.

With an enrollment of some 74,600 children, La Petite was the second largest for-profit provider of childcare services, with approximately 720 centers in 36 states and Washington, D.C. J.P. Morgan Partners owned a controlling share of the organization. In fiscal year 2002 (ending in June) La Petite reported revenues of \$384.8 million, resulting in a net loss of \$6.3 million.

Bright Horizons was another large childcare center chain, specializing in on-site child care. It operated centers over 400 centers for more than 300 employers. Some of its clients were Allstate Insurance, Apple Computer, AT&T, Dunkin' Donuts, DuPont Company, Ernst & Young, Fidelity Investments, Hewlett Packard, IBM, Mattel Toys, MCA/Universal City Studios Inc., Merck &

Co., Motorola Inc., Paramount Pictures, Procter & Gamble, Prudential Insurance Co., Sony Pictures Entertainment, Time Warner, United Nations, Women & Infants Hospital, and Xerox. In 2002 the company posted earnings of \$15.3 million on sales of \$407.5 million.

As the industry grew, these large firms became targets for acquisition by other companies. In March of 1998, Knowledge Universe—an education investment concern organized by Michael Milken—purchased Children's Discovery Center for \$82 million, which then became known as the Knowledge Learning Corporation. In 1997, Chase Manhattan purchased La Petite Academy. The large chains also began going public as investor interest grew. In 1998, New Horizons Kid Quest, Childtime Learning Centers, Bright Horizons, and Corporate Family Solutions were publicly traded; Childcare Network—the nation's fourteenth largest firm—held an initial public offering and began trading on the NASDAQ.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, in 2000 childcare workers, who provide care for children up to the age of 12, including preschool teachers, accounted for 1.2 million jobs, up from 1 million in 1994, and 500,000 in 1988. However, because of the inherent problems in identifying all childcare arrangements, other studies place the figures much higher. According to a 2002 report from the Center for the Child Care Workforce (CCCW) and Human Services Policy Center (HSPC), paid caregivers of children ages one day to 5 years old totaled more than 2.3 million. Of this total the CCCW and the HSPC estimated that 24 percent worked in center-based settings, 28 percent provided family child care, 35 percent were paid relative caregivers, and 16 percent were nonrelative caregivers in the home (i.e., nannies and babysitters).

The U.S. Bureau of Labor Statistics projected that the category of "child care workers" would be one of the fastest growing occupations from 1998 to 2008, which it estimated would grow by over 25 percent during that time frame. This projection marked another cause for concern in an industry that was marked by high turnover rates and historically low wages.

The majority of the workers in the industry were female, and about one-third of the workforce was composed of women of color. Many childcare workers worked part time and about 4 out of 10 preschool teachers and childcare workers were self-employed, most of whom were family daycare providers. More than 60 percent of all salaried preschool teachers and childcare personnel were found in child daycare centers and preschools, and about 15 percent worked for a religious institution. Others worked in service organizations and in government.

Despite the increase in employment, childcare wages remained among the lowest of all industries. In 2001, median hourly wage for childcare workers was \$8.16. The average yearly salary was \$16,030, ranging from a low of \$12,110 to a high of \$23,290. Preschool teachers in privately funded childcare centers generally earn much lower salaries than other comparably educated workers. Earnings of self-employed childcare workers varied depending on the hours worked, number and ages of the children, and the location. The benefits for preschool teachers and childcare workers also varied. Many employers offered free or discounted child care to employees. Some employers offered a full benefits package, including health insurance and paid vacations, but other employers offered no benefits at all. Some employers offered seminars and workshops to help workers improve upon or learn new skills.

Many childcare employees made a salary that was below the poverty level—causing over 40 percent to leave their jobs every year. According to the National Center for the Early Childhood workforce, one reason for the low U.S. wages was dismally low—compared to other industrialized nations—government or corporate subsidies for working parents to pay for child care.

The training and qualifications required of preschool teachers and childcare workers varies widely. Each state had licensing requirements that regulated caregiver training—ranging from a high school diploma, to community college courses, to a college degree in child development or early childhood education. Some states required continuing education for workers in this field. The state of Virginia, for example, required that all daycare center personnel receive eight hours of child care related courses each year. Formal education requirements in some private preschools and daycare centers were often lower than in public programs since they were not bound by state requirements. Some states preferred preschool teachers and childcare workers to have a Child Development Associate (CDA) credential, which was offered by the Council for Early Childhood Professional Recognition. The CDA credential was recognized as a qualification for teachers and directors in 46 states and the District of Columbia. The credential required 120 hours of training, a high school diploma, and 480 hours of experience.

AMERICA AND THE WORLD

Provisions for childcare services were often part of the state insurance schemes of many European nations. As of 1990 the Swedish government provided day care for most children over 18 months. In Denmark about 50 percent of children under the age of three and nearly 90 percent of children between the ages of three and six were in publicly financed day care. Initially prompted by fears

that the population would not produce enough soldiers, France has had state childcare policies since the eighteenth century. Roughly 25 percent of French children under three years of age are in programs wholly or partly subsidized by the government, while 95 percent of three- to five-year-olds are in preschools. Belgium offers about the same level of state-sponsored care.

Britain, on the other hand, has few childcare centers. Upper-income families employ nannies, while less affluent families rely on family members and so-called “child minders.” As the cost of domestic help rises, however, there has been increasing pressure on companies and the government to offer better care. Nevertheless, in 1990 there were only 120 daycare centers operating in British workplaces.

SIC 8361

RESIDENTIAL CARE

This industry classification consists of establishments that provide residential social and personal care for children, senior citizens, and special categories of individuals with some limits on ability for self-care, but where medical care is not a major element. Included are group foster homes; halfway group homes; homes for the physically and mentally disabled; homes for the elderly; juvenile correctional homes; rehabilitation or residential centers; and children’s boarding homes. Boarding schools providing elementary and secondary education are classified in **SIC 8211: Elementary and Secondary Schools**. Nursing homes and other providers of health-related personal care are classified in **SIC 8051: Skilled Nursing Care Facilities**, **SIC 8052: Intermediate Care Facilities**, and **SIC 8059: Nursing and Personal Care Facilities, Not Elsewhere Classified**.

NAICS CODE(S)

623312 (Homes for the Elderly)

623220 (Residential Mental Health and Substance Abuse Facilities)

623990 (Other Residential Care Facilities)

INDUSTRY SNAPSHOT

Facilities of many different types fall into the general category called residential care. The types of establishments in this classification include children’s homes, rehabilitation facilities, group homes for people with a variety of limitations, halfway houses, and rest homes for the aged. For some segments of this industry, business has been booming in recent years. The market for space in retirement homes, for example, has expanded greatly due to the aging of the American population. Residential drug and alcohol treatment centers are overflowing. Orphanages have also been experiencing increased residency over the last several years. According to the U.S. Census Bureau, 10,869 establishments generated \$9.4 billion in revenue in 1997.

Collectively, long-term care (LTC) facilities make up a multi-billion dollar industry in the United States. Long-term care industry forecasts are difficult to make because of continuing changes in federal and state legislation. In recent years, more than a dozen major long-

term care companies and nursing facilities (containing more than 2,000 beds each) have been purchased by larger operators.

There are millions of people living in the various types of nursing homes and retirement communities that provide residential care for the elderly in the United States. The number of facilities continue to grow as America’s population ages.

ORGANIZATION AND STRUCTURE

A broad range of residential care options exists for the elderly, making it possible for a client to choose a facility that is well-suited to his or her needs, both physical and financial. Traditional nursing homes provide continual shelter and 24-hour medical care for their elderly residents, who are unable to independently care for themselves. Nursing homes provide their residents with on-site meals and constant physical care, including assistance with bathing, grooming, and dressing. Nursing homes also often provide their residents with on-site social activities.

Retirement centers, increasingly referred to as assisted living communities, are designed for persons who are unable to function in an independent living setting, but do not need daily nursing care. In the late 1990s, there were approximately 10,000 assisted living communities housing more than a million residents. Assisted living communities generally assist with bathing, dressing, housekeeping, and meals. The amount of help provided depends on individual need. Retirement homes offering assisted living can be considerably more affordable than nursing homes, primarily because 24-hour medical care is not required. The cost can range from \$1,000 to more than \$4,000 a month, about 30 percent less than the range for licensed nursing home care. Unlike nursing homes, however, most assisted living is not covered by private or government insurance. Independent operators and corporations in related industries such as hotel management are prevalent in assisted living.

Continuing-care retirement communities (CCRCs) are apartment complexes designed to meet the specific needs of the elderly, providing meals, social services, health care access, and sometimes housekeeping. CCRCs provide a somewhat higher degree of care than retirement centers, though health care is still secondary in these facilities. In the United States, there are about 700 CCRCs, housing more than 200,000 residents. Continuing care retirement communities offer seniors long-term contracts that ensure lifelong shelter and access to certain health care services. CCRC residents are able to enjoy an independent lifestyle with the knowledge that if they become sick or disabled, their needs will continue to be met. Residents usually pay an entrance fee and regular monthly payments for this service. Depending on the

contract, the entrance fee may or may not be refundable. Most CCRCs enact requirements for incoming residents based on age, income level, financial assets, and physical health and mobility. Generally, residents are expected to move into the community while they are still fully able to care for themselves. Not-for-profit organizations, such as hospitals and religious groups, sponsor about 95 percent of the CCRCs in the United States.

Nearly two-thirds of drug and alcohol rehabilitation facilities, including outpatient and hospital programs not primarily engaged in the residential care industry, are privately owned, nonprofit operations. These institutions treat about 60 percent of the industry's substance abuse clients. The next largest segment consists of facilities run by state or local governments. These account for about 16 percent of rehabilitation operations, but treat nearly 25 percent of the industry's clients. The remainder of facilities are either privately-owned for profit (16.5 percent) or run by the federal government. The largest share of financial support for treatment services came from private third-party payers, such as HMOs and Blue Cross/Blue Shield. State governments contribute about one fourth of the industry's total funding. Only about 12 percent of funding comes from fees paid by clients.

Juvenile facilities make up another large block of institutions providing residential care. A steady rise in youth crime has led to an increasing demand for juvenile treatment services and providers who are qualified and experienced in serving troubled youth. The juvenile facilities segment of the industry, however, includes not only detention centers for delinquents, but also shelters, training schools, camps, ranches, and group homes.

Residential care for the mentally retarded and developmentally disabled has undergone a qualitative change since the 1970s. The shift has been away from large state institutions toward smaller, more flexible community-based group home settings. The number of residents in large state-operated institutions has shrunk by more than half since the late 1960s. Meanwhile, the number of people in facilities with less than 15 residents tripled during the 1980s and continues to rise. Numerous mental health professionals now consider group homes to be the most favorable residential environment for the mentally retarded. Throughout the 1990s, group homes had more than 100,000 residents nationwide, plus waiting lists with tens of thousands of additional names.

BACKGROUND AND DEVELOPMENT

Orphanages. Each type of facility that is a part of the residential care industry has a distinct history. Orphanages, for example, have a history that is centuries old, as well as a brutal reputation based on Dickensian tales of squalor and abuse. By the 1970s, a large percentage of the bigger group homes had closed amid a flood of lawsuits

and allegations of abuse and neglect. By the 1990s, however, orphanages began to reappear, as the need began to outdistance the availability of home-based foster care. The Hollywood-generated reputation of facilities such as Boys Town is somewhat more positive than that of the ordinary orphanage. Boys Town, which went co-ed in 1979, was founded by the legendary Father Flanagan in 1917. Located outside of Omaha, Nebraska, Boys Town covers 1,300 acres and has its own school, fire department, and zip code.

Residential Care for the Mentally Retarded. A history of poor conditions has also led to great changes in the residential care of the mentally retarded. Historically, these individuals were not distinguished from insane or violent people, and therefore residential care resembled incarceration more than housing. The shift toward group homes began in the early 1970s as a reaction to growing dissatisfaction with the care that was being received in large institutions for the mentally retarded and developmentally disabled. Around 1972, lawsuits were brought in more than a dozen states, including New York, Illinois, Pennsylvania, and Texas, to protest the lack of adequate care in these facilities. As a result, scores of large institutions have since closed. The strongest resistance to the group home concept has come from the residents of neighborhoods that have been proposed sites for group homes. Some labor unions have also expressed concern, since many group home programs include vocational training that puts residents into competition with the unions for jobs.

Residential Care for the Elderly. The emergence of different levels of residential care for the elderly is a relatively recent phenomenon. Until the last few decades, nursing homes were the only option for those who could no longer care for themselves completely independently. CCRCs began to appear around 1960; however, they did not become common until the mid 1980s. In fact, about 80 percent of the CCRCs currently in existence opened between 1985 and 1989. Not surprisingly, this rapid expansion did meet with some resistance from nursing home organizations. Among the states, Oregon has been at the forefront of the movement for alternative housing for the elderly. In Oregon, several group homes, whose funding is aided by the state, house more than a thousand residents who might otherwise be in nursing homes. Most of these group homes are privately owned and licensed by the state.

CURRENT CONDITIONS

The current conditions of the residential care industry reflect the differing funding sources of its various segments. Although the demand for residential care seems to be increasing across the board, only those facilities funded through private investment seem able to

meet the demand. Those relying on government funding are struggling with ways to meet the needs of their clients with the limited resources available to them.

Rehabilitation Facilities. Since the early 1990s, rehabilitation centers have been experiencing particularly strong growth. A number of large, multi-unit, investor-owned facilities have emerged. Several of the most successful rehabilitation chains have expanded through joint ventures with hospitals and nursing homes. At the same time, drug rehabilitation facilities run by public agencies are in crisis. Funding for public agencies has been frozen, and in some cases is being decreased, while the number of people seeking treatment in these facilities continues to increase.

Facilities for Children. Orphanages and other residential care for children is another area in which demand is skyrocketing, although very few of these facilities are run for profit. The main reason for the increase in this type of facility is the lack of space in foster homes. At the turn of the twenty-first century, an estimated 520,000 children were in foster care, 117,000 of whom were eligible for adoption. That year, there were about 1,000 group homes for children in operation. The AIDS epidemic has created a special need for abandoned children who have AIDS or HIV, or are born with a drug addiction. Residential care for parentless children can take a variety of forms, from the sprawling Boys Town, to home-like settings that house an average of eight children.

Facilities for the Elderly. Residential care for the elderly is an area that is expanding through the diversification of services offered. Advocacy groups estimate that as many as half of the residents in nursing homes could function adequately in facilities that placed less emphasis on medical attention. This fact, combined with the more rigid restrictions created by the National Nursing Home Reform Act of 1987 (passed to address the alarming increase in abuse cases), has led the emergence of a broad range of facilities that offer less intensive care. Residential care for the elderly is one segment of the industry in which both nonprofit and for-profit operations are well represented. As the elderly population is the fastest-growing segment of the American population, the need for residential care facilities is expected to grow. In 1997, 2,669 of these establishments generated \$2 billion in revenue.

INDUSTRY LEADERS

Res-Care, Inc. is the leader among facilities that provide residential care and vocational training for mentally retarded and developmentally disabled people, as well as at-risk youths. Res-Care was founded in 1974 and is located in Louisville, Kentucky. In 1999, the organization served more than 12,000 people with developmental disabilities and 8,400 youths in 10 states and Puerto Rico. Res-Care has more than 29,000 employees.

Five Acres, The Boys' and Girls' Aid Society of Los Angeles County is a nationally-recognized non-profit center for the prevention and therapeutic treatment of child abuse. It also serves as an educational facility for severely emotionally disturbed children. Founded in 1888 as one of Los Angeles' earliest orphanages, the Altadena, California-based agency served 1,037 children and 713 adults in 1999. Its services include residential treatment, a therapeutic school, emergency shelter, family group homes, a foster care program, in-home treatment and support for families in crisis, and deaf services programs for abused children. Their residential treatment program provides care and treatment for children ages 5 to 13 who have been removed from their homes by the courts because of severe behavior and emotional problems associated with abuse and neglect.

Sunrise Assisted Living, Inc., with 1999 sales of \$255.2 million, was also a leading provider of assisted living for the elderly. Sunrise, founded in 1981, is a privately-owned company that operates more than 120 projects in 22 states. Most of the residents in these facilities live in independent apartments where fewer services are available.

WORKFORCE

According to the U.S. Census Bureau there were more than 240,732 employees working for this industry in 1997. Approximately one-fourth of all residential care workers are employed by state and local governments, mostly in public welfare agencies and facilities for mentally disabled and developmentally delayed individuals. Another fourth work in private social or human services agencies offering a variety of services, including adult day-care, crisis intervention, counseling, and group meals. Many of these workers supervise residents of group homes and halfway houses. Others are employed in day treatment programs, detoxification units, community mental health centers, psychiatric hospitals, and sheltered workshops.

In the mid 1990s, starting salaries for residential care workers ranged from about \$13,000 to \$20,000 a year. Experienced workers generally earned between \$18,000 and \$27,000 annually.

Jobs in this industry are expected to increase significantly through the year 2005. More community-based programs, supported independent living sites, and group residences are expected to be established to shelter and assist the homeless and the chronically mentally ill, as well as provide housing and services for the elderly, disabled, and families and children in crisis.

- 813319 (Other Social Advocacy Organizations)

INDUSTRY SNAPSHOT

There were an estimated 19,600 establishments in the social services industry in 1996—an increase of more than 47 percent from 1987. The majority of establishments were in New York and California. Industry em-

ployment increased by about 38 percent since 1987, reaching approximately 39,000 individuals by 1996. By January 2000, the entire social services industry employed 2,872,000. Tremendous growth was expected in the industry, with personal and home care aides and human services workers expected to increase 155 percent and 104 percent, respectively, by the year 2005.

ORGANIZATION AND STRUCTURE

The social service organizations within this industry consist of national organizations, state and regional associations, federal government agencies, state government agencies, and clearinghouses and information centers. National organizations include voluntary associations, advocacy groups, professional organizations, and other nonprofit groups providing services at the national level. State and regional associations are generally affiliates of national groups. State and federal government agencies are government owned and operated but often influence nongovernmental organizations. Clearinghouses and information centers are a grouping of governmental and non-governmental services that collect, organize, and distribute information.

Organizations within this industry operate in many ways. For example, some establishments rely on fund-raising efforts, while others use membership dues as their primary means of support. Certain organizations conduct political lobbying on behalf of the social cause they represent.

A distinguishing factor of establishments in this industry is their use of money. Donations to establishments that primarily engage in charitable, educational, or research activities are tax-deductible to the donor. Establishments that conduct substantial lobbying activities, however, cannot receive tax-deductible donations. In addition, money collected for political election campaigns must be strictly accounted for and are heavily regulated by government bodies, such as the Federal Elections Commission.

Establishments in this industry are structured according to the types of activities they engage in, which are usually related to the services they provide. They are often referred to as social movements, improvement associations, pressure groups, citizen participation groups, or citizen action groups.

Social movements are groups that advocate changes in beliefs or practices of people within a relatively large geographical area. These establishments focus on increasing their membership and are usually managed by a paid professional staff. In addition, some social movement organizations lobby legislators, hold rallies, and promote their views through media-related activities.

Improvement associations advocate a belief or practice and foster it among their members to promote a better

state of affairs within society as a whole or to improve conditions within their professions, religions, or patriotic societies. The larger organizations have paid staff, with a central office and branches throughout the country.

Pressure groups are organizations whose main feature is their advocacy of specific-issue legislative actions. On average, they are smaller than other groups working for social change. These establishments may be sponsored by companies whose products or political ideologies are under attack. These groups are often designed to conduct political lobbying activities and fund-raising for political candidates.

Citizen participation groups basically serve as advisory committees to community councils, charitable boards, and government agencies. Their staffs are made of a small group of professionals hired to run the administrative functions, as well as uncompensated members who act as advisors.

Citizen action associations (CAAs) are organized to protect and represent the rights of the community, particularly those with low-income and welfare recipients, protecting them in matters such as housing costs and conditions and unfair business practices. These non-profit groups were created in 1964 by the Economic Opportunity Act of 1964, and are managed by a small group of professional organizers who manage volunteers. By the turn of the twenty-first century, there were almost 1,000 CAAs nationwide.

The primary source of money for CAAs comes from the Community Services Block Grant (CSBG), according to the National Association of Community Action Agencies. This block grant totals less than 10 percent of CAA funding.

BACKGROUND AND DEVELOPMENT

Social action organizations began in Victorian England when societies formed in the upper classes to give charity to people working in work houses and serving sentences in prisons. The idea soon caught on in the United States, and by the turn of the century philanthropy had developed into an industry. Social action organizations in America emerged with labor groups organizing to represent workers. At the same time, immigrant communities and new urban neighborhoods were developing groups and committees. These early groups were concerned with workers' rights and retaining a village life in newly developing cities. During the 1920s, local and community organizing expanded into social planning and fund-raising to support social agencies.

During the Great Depression, social agencies and community organizing took on new characteristics. Labor organizations became distinct political entities that elected their officers and organizers. Volunteer reform

organizations worked toward getting citizen participation on issues such as women's rights. Rather than acting as organizers, social workers were working more within and through various government agencies, providing services for the public.

INDUSTRY LEADERS

Anti-poverty organizations seek to reduce poverty and hunger in the United States and other countries. They include organizations such as the Food and Agriculture Organization (FAO), created by the United Nations to help alleviate poverty and hunger by promoting agricultural development, improved nutrition, and food security; the Institute for Research on Poverty (IRP), established in 1966 at the University of Wisconsin-Madison by the U.S. Office of Economic Opportunity as a national center created to seek ways to reduce poverty in America; and the Food Industry Crusade Against Hunger (FICAH), a voluntary initiative of the American Food Industry to relieve hunger and malnutrition in the United States and around the world. There are hundreds of other anti-poverty organizations to help the poor and hungry.

Advocacy groups represent and defend the rights of others, particularly, but not limited to, those who do not have a voice to protect themselves, such as children, the sick, the disabled, the elderly, and animals. Organizations that fall into this enormous group include Children's Protection and Advocacy Coalition, the Center for Patient Advocacy, the National Alliance for Research on Schizophrenia and Depression, the 60 Plus Association, and the United States Humane Society. Several advocacy groups support issues such as education, the arts, homosexuality, abortion (both pro-life and pro-choice), and political matters.

High-profile associations that can be considered social change organizations include Mothers Against Drunk Driving (MADD), the National Organization for Women (NOW), and the National Gay and Lesbian Task Force.

Social service information exchanges provide the public with information on a specific topic of interest. These exchanges include the Community Information Exchange, a national nonprofit information service that provides community organizations with the information needed to successfully revitalize communities; and The Adoption Information Exchange, a Washington state nonprofit volunteer organization dedicated to making adoption information available to the public.

Welfare councils are designed to support and improve human rights. Health councils promote health issues. Many local and regional communities have their own health councils to improve the way health care services are delivered, paid for, and used; to address health issues; to promote disease prevention; and support health care industry workers. The National Safety Council is a

major, nonprofit public service organization whose mission is to educate and persuade society concerning safety, health and environmental policies, and practices and procedures that prevent human suffering and economic loss.

An example of a community action group is Classical Action, an organization that uses the talents and resources of the performing arts community to raise money for AIDS-related services across the United States. A large community action group is the National Association of Community Action Agencies, a national forum for policy on poverty. Community action groups can consist of people of any age. The Youth Action Groups are comprised of young people who are supported by police, teachers, and youth workers to find solutions to community crime.

Citizen action groups are organized to protect and represent the rights of the community. The Association of Community Organizations for Reform Now (ACORN) is the nation's largest grassroots organization, acting to empower people earning low to moderate incomes. Its major concerns include housing, jobs, living wages, and banking. Citizen Action is a national federation of state citizen organizations with a combined membership of more than 2.5 million members. Citizen Action is a leading advocate for health care reform, environmental clean up, and campaign finance reform. Its state organizations consist of a coalition of community members organized in grassroots efforts to fight unfair business practices, such as high utility rates.

RESEARCH AND TECHNOLOGY

Generally, this industry has not been greatly affected by technological advances. However, computers have aided many of the office functions common to organizations in this industry, such as compiling membership databases, desktop publishing of newsletters and solicitation materials, and distributing clearinghouse mailings. In addition, technological developments in telemarketing have increased the effectiveness of calling campaigns used by lobbying groups and fund-raisers. The effect of the Internet has been felt by the industry as well. The Internet makes it far easier for organizations to disseminate information to donors, members, and the general public quickly and inexpensively. For the price of web development software or a web designer, an Internet connection, and someone to keep the site current, organizations can keep the public informed for sometimes less than the usual outreach expenses.

MUSEUMS AND ART GALLERIES

This industry classification includes establishments primarily engaged in the operation of museums and art galleries. Art galleries and dealers primarily engaged in selling to the general public are classified in **SIC 5932: Used Merchandise Stores** and **SIC 5999: Miscellaneous Retail Stores, Not Elsewhere Classified**.

NAICS CODE(S)

712110 (Museums)

712120 (Historical Sites)

INDUSTRY SNAPSHOT

The numerous U.S. museums seem as permanent and stable a part of the cultural landscape as schools and libraries, but it was not until the late nineteenth century that they attained social respectability and civic solidity. Museums had existed since the founding of the country, but they were often small collections of odd paraphernalia, housed in someone's home or carted around by circus masters such as P.T. Barnum. But American museums grew as the country grew, and, according to *Public Interest* contributor Michael Lind, "The acquisition of an art museum by a city . . . has traditionally been a source of civic pride in communities across the country."

Supported by government funding and private donations, twentieth-century museums became elaborate

storehouses of America's and the world's artistic, scientific, historical, and technological past. In the process they became very big business, attracting more than 865 million visitors a year, or 2.3 million per day, in the early 2000s. According to Richard K. Miller & Associates, nearly 50 museums and cultural attractions in the United States had more than 1 million visitors apiece in 2000. Contemporary museums are supported by billions of dollars of annual support from government sponsorship, corporate donations, and public membership, and they employ and educate a wide range of professionals.

In the early 2000s, there were more than 11,000 museums in the United States. Nine of out 10 counties in the United States have at least one museum. Slightly more than half of museums are free to the public.

ORGANIZATION AND STRUCTURE

The museum world is fragmented and hard to summarize. The most recent comprehensive study is the 1989 National Museum Survey conducted by the American Association of Museums (AAM), the findings of which were presented in the 1994 report *Museums Count*. This survey, using information from fiscal 1988, counted 8,179 museums in the United States. About three-quarters of them were founded after 1950, and less than 5 percent have origins in the nineteenth century. The AAM survey categorized American museums as follows: history museums (2,401); historic sites (2,083); art museums (1,214); general museums, or those in which two or more disciplines are equally represented (704); specialized museums, or those with a single distinct subject or for which no other category is appropriate (470); arboretum/botanical gardens (318); nature centers (297); natural history/anthropology museums (252); science museums (184); zoos (133); children's museums (64); planetariums (39); and aquariums (20). These institutions are distributed throughout the United States in roughly the same proportion as the population.

Fifty-nine percent of museums are privately run and 41 percent are run by the government, usually state or municipal authorities. Only 7 percent of the nation's museums are operated by the federal government. Government-run museums are most commonly found in southern and western states (slightly more than half of museums in these regions are public) and are least commonly found in the northeastern states (only about 27 percent of museums in the New England and Mid-Atlantic regions are public).

Museum budgets total some \$4 billion, but this money is not evenly dispersed. Just 8 percent of museums have annual budgets of \$1 million or more. Fifty-seven percent operate with \$100,000 or less, and 38 percent have \$50,000 or less to spend. Using budget size as an indicator, museums in the United States are generally

small institutions. When budget size is adjusted to the differing operation costs of museum types (for example, a science museum needs a \$5 million budget to be considered large, but a nature center requires only \$800,000), 80 percent of museums can be described as small. About one-half of museums have endowment funds, with total museum endowments valued at \$14 billion. However, 93 percent of this endowment money is held by large museums, especially art museums, which hold \$10.6 billion, or 76 percent, of all endowment money. Personnel expenses account for the largest share of museum operating expenses, taking up a median of 54 percent of museum budgets. Despite this large investment in personnel, museums are still heavily dependent on volunteer staff to accomplish both day-to-day tasks and special functions. About 377,000 people were museum volunteers in 1988, with 10 percent of them working full-time schedules of 35 hours or more per week.

In addition to serving as conservators of the nation's cultural and scientific heritage, American museums have a strong commitment to education. Sherman Lee, former director of the Cleveland Museum of Art in Ohio, claimed in *Past, Present, East and West* that "in the world of visual images . . . the museum is the primary source for education. Merely by existing—preserving and exhibiting works of art—it is educational in the broadest and best sense, though it never utters a sound or prints a word."

Most museums provide educational programs for both children and adults, including guided tours, study groups, special lectures, and demonstrations. Forty-nine million children attended a museum as part of a school group in 1988. Historic sites, history museums, and zoos were the most likely choice for school groups. Many museums have joint programs with universities or colleges to provide work experience and research opportunities for college students. The American Association of Museums (AAM), a national membership organization representing all types of museums and museum professionals, provides an ongoing series of educational programs and seminars to ensure that museum professionals are as well educated as their visitors. Their 1991 publication, *Excellence and Equity: Education and the Public Dimension of Museums*, addressed the need for museums to continue their efforts at educating the museum-going public.

According to the AAM survey, 60 percent of museums are open to the public 52 weeks per year. Weekly operating schedules vary, with arboretums and botanical gardens tending to have the longest hours, and art museums and children's museums having the shortest. As is the case with funding dollars, attendance at museums is not evenly shared by institutions. Large museums, although they make up only 7 percent of museums, attract

nearly 50 percent of all people who visit museums. Historic sites, zoos, and art museums are the types of museums most popular with the general public.

Museum attendance has increased. A 1979 survey by the AAM counted about 350 million museum visits. By 1989, that figure was up to 566 million visits. A study by the National Endowment for the Arts (NEA), which tracked participation in the arts between 1982 and 1992, concurs with the findings of the AAM survey. The NEA study, published in 1996, showed that younger Americans (those born in 1946 or after) attend art museums significantly more often than older people did when they were the same age. People born between 1951 and 1955 and 1966 and 1970 were the most likely to attend an art museum.

Increased attendance at art museums counters a general decline in arts participation among younger people, which was revealed in the NEA survey. Credit is given to art museums for doing a better job than other arts organizations in attracting new patrons. Some analysts, however, suspect that rising attendance at art museums is reflective of the decreasing interest in the arts rather than a refutation of it. "Unlike the performing arts, museum visits are an impulse buy. You don't need reservations, tickets, allocated time. You can look at what you like, or not look at anything at all. Increased museum attendance doesn't really tell us much about commitment to the fine arts," said Richard A. Peterson, one of the authors of the NEA report, to the *New York Times*.

In recent decades, many museums have greatly expanded their restaurants, gift shops, and parking facilities. Museums have also done much to shed their staid and elitist image, especially art museums, some of which are among the nation's oldest and most prestigious cultural institutions. In the late 1960s, it was considered a daring innovation for New York City's Metropolitan Museum of Art to hang a banner outside its door advertising its "Great Age of Frescoes" exhibit. The 1970s saw the advent of the "blockbuster" art museum show. The blockbuster exhibition, wrote Michael Conforti in *Art in America*, was created by Metropolitan Museum of Art director Thomas Hoving in 1971. "Museums all over the country quickly adopted the formula established at the Met for self-supported exhibitions of popular and usually artistically credible subjects like impressionism, certain archeological objects, or treasures from foreign collections. Museums expected to fund these shows through revenues from admissions, merchandise, food, and also through grants from corporations and foundations seeking more positive public images."

BACKGROUND AND DEVELOPMENT

Museums of one sort or another have played a part in the United States' cultural life from the country's incep-

tion, and they have reflected the cultural variety and democratic tendencies of the country's diverse population. European collectors had always cultivated collections of artistic and historical importance, but their collections were reserved for their own personal enjoyment. In the United States, similar collections were made available to the public as early as 1773, when the Charleston Library Association in South Carolina announced the establishment of a museum to house specimens that would allow citizens to study the natural history of their colony. In 1785 a similar desire to make educational materials available to the public prompted artist and American Revolution officer Charles Willson Peale to display his collection of art and natural history specimens from his Philadelphia home. Within a decade his collection had grown so large and his visitors so numerous that the collection was moved to the larger quarters in Philadelphia's Philosophical Hall. Peale's example was soon followed in cities throughout the growing nation with the establishment of the Tammany Society Museum of Indian Relics in New York City, the Columbian Institute for the Promotion of Arts and Sciences in Washington, D.C., and the Columbian Museum in Boston, Massachusetts.

In the eighteenth and nineteenth centuries, many Americans eager to construct for themselves a sense of national identity found scientific, historical, and artistic value in nearly all aspects of their lives. Museums sprang up across America, housing collections of everything from Indian artifacts, stuffed animals, wax figures, and later, automobiles, airplanes, and art. Karl E. Meyer, author of *The Art Museum: Power, Money, Ethics*, noted that by the mid-nineteenth century there were two kinds of museums: "One was the 'dime' museum, an emporium of curiosities operated for profit and dedicated to entertainment. The other was the impecunious but high-minded public gallery, usually an appendage of an art academy, library, historical society, college, or private club." Out of a combination of these two early progenitors, the modern museum was born.

In 1835 the U.S. government learned that it was the beneficiary of the will of British scientist James Smithson, who left slightly more than \$508,000 to found "the Smithsonian Institution, an Establishment for the increase and diffusion of knowledge among men." According to Paul H. Oehser's history, *The Smithsonian Institution*, the U.S. government hardly knew where to begin. By 1846, however, Senator John Quincy Adams had introduced legislation calling for the construction of a national museum in Washington, D.C., which would house all the objects of art and natural history belonging to the government, maintain a library, and encourage the study of science. By the mid-twentieth century, the Smithsonian Institution, with its numerous buildings

spread across Washington's mall, and with additional sites at other locations, had become the largest museum in the world. By 1996 it boasted more than 25 million visitors annually.

In 1870 corporate lawyer Joseph H. Choate convinced the city of New York to finance the construction and operation of the Metropolitan Museum of Art, which was to be governed by a board of 21 private members and civic office-holding trustees, including the mayor. The museum charter, with its unique pairing of public funding and private control, became the model for most large U.S. museums that followed. Such an organization provided unique advantages to both the city and to the wealthy Americans who sat on the museum board. The greatest benefit for the city was the status that a world-class art museum conferred: New York City's cosmopolitan reputation rested in part on its museums, and even smaller cities could brag of the sophistication of their own local arts showcases. Museums bring money and people into the cities and often serve as a focal point for other cultural activities. According to former Smithsonian Secretary Dillon Ripley in *The Sacred Grove*, "The art museum managed . . . to become a symbol of the community's rise to prominence and sophistication."

Wealthy arts patrons and businessmen were equally enthusiastic about the new American institutions, which served as a culturally sanctioned storehouse for the surplus wealth of the country's industrial leaders. "Of all the uses to which wealth can be put," wrote Lind, "surely there are few that are less antisocial than endowing a public museum." America's first art museums were filled with the art collected by America's first multimillionaires: J. Pierpont Morgan left his \$60 million art collection to the Metropolitan Museum of Art in New York City; the Rockefeller family made cultural philanthropy a family tradition; and museums across the nation became the beneficiaries of private collectors. Changes in the U.S. tax structure in 1909 and 1913 made donations of art an appealing way for the wealthy to avoid paying taxes on their assets and to mollify critics who accused corporate giants of benefiting at the expense of society at large.

Heavily advertised and often so expensive to mount that relatively small profits are common, blockbuster shows (such as those exhibiting Picasso, Van Gogh, Hopper, and Monet) draw in segments of the public who might rarely enter a museum otherwise. They can also raise a museum's status within the art world. In addition to being crowd pleasers, such shows are considered valid, scholarly endeavors. One attraction expected to attract an enormous crowd, opening at Chicago's Field Museum in the summer of 2000, was the exhibit of "Sue," the largest complete *Tyrannosaurus Rex* skeleton.

Although officially classified as privately or publicly funded, in reality most museums rely on a patchwork of

funding sources, including government and corporate grants, private donations, interest from endowments, and earned income, such as admission fees, memberships, and revenues from food service and gift shops. The number of museums charging admission, either a fixed fee or a suggested donation at the door, went up from 32 percent in 1979 to 55 percent in 1988. Zoos are the most likely type of museum to charge admission (84.8 percent), and art museums the least likely (35.8 percent). Many museums in the late 1990s had moved to a "suggested donation" instead of admission.

Even well-endowed institutions are always in need of financial assistance. Museums have been hard hit by cutbacks in government spending. The budget of the NEA, the largest source of government funds, was slashed by 40 percent in fiscal 1996. Private philanthropy is also down. To make up for this loss, museums have sought new ways of raising money. "With less government money around, we all have to be more entrepreneurial and figure out ways to stretch our advertising dollars. We are slowly learning lessons others have known for years," David A. Ross, director of New York City's Whitney Museum of American Art, told the *New York Times*.

Museums have entered into alliances with hotels, airlines, phone card companies, and credit card operations. Corporations, which once considered underwriting museum activities as primarily a gesture of goodwill, are increasingly finding their connections with museums an effective form of advertising. Also, branches of museum gift shops have opened up in many malls across the United States, with a portion of the proceeds going to the museums. On a larger scale, the cable television shopping channel QVC began a series of museum programs in 1996. In addition to being able to purchase items from the featured museum's gift shop, QVC viewers were taken on a tour of the museum's exhibits. Among the museums showcased on QVC were the Smithsonian Institution, the Philadelphia Museum of Art, Colonial Williamsburg, and the Winterthur Museum of American Decorative Arts.

CURRENT CONDITIONS

Some museums, especially in the eastern United States, saw a drop in visitors after the events of September 11, 2001, and anthrax scares in the early 2000s. With the sharp decline in travel and tourism amid terrorist fears, the Smithsonian reported a 29 percent decrease in visitors during the first seven months of 2002, with 15.1 million visits. While admission is free, gift shop sales account for a large portion of funding for the facilities and were negatively affected. The federal government provides some 70 percent of the Smithsonian's budget, which totaled \$519 million in 2002. Though most state budgets for the arts were dwindling in the early twenty-

first century across the United States, in 2003 \$2.4 billion in federal and private funds allowed plans for renovations and new museums to be established in Washington, D.C., with the largest plans undertaken by the Smithsonian, adding two new museums and revamping others. The Smithsonian was by far the most visited of all museums and cultural attractions in 2000, with 34 million visitors.

To offset losses from international visitors, which account for a large percentage of some of the major art museums and galleries, some museums and galleries turned their attention to the domestic market. The Guggenheim, with attendance down 30 percent in the fall of 2001, was down just 8 percent in fall 2002. Mounting a Norman Rockwell show, the museum appealed to Americans' sense of patriotism and drew visitors from the United States. Some museums with a large percentage of local attendees did not fare as well, however. The Brooklyn Museum of Art recorded a 25 percent drop in attendance as of 2002. The Metropolitan Museum of Art had approximately 1 million fewer visitors in 2002.

The Museum of Modern Art's new Queens location, opened to keep its business intact as its main location was being reconstructed, was banking on a blockbuster "Matisse Picasso" exhibit in February 2003, with works drawn from museums and private collections worldwide with an estimated value of \$1.5 billion. To recoup costs, the museum charged an unprecedented \$20 admission fee that caused controversy but was also speculated to be a trend-setting move. The museum rationalized the increased admission as necessary in light of increased insurance costs on art, which have tripled since 9/11. Indeed, the Guggenheim raised admission to \$15 in 2002, and the newly opened Museum of Sex in New York planned to charge \$17, the highest general admission for a museum in New York.

Another trend in this sector was the expansion of gift shop wares. Gift shops were once dominated by postcards and exhibition catalogs but now include jewelry, clothing, home furnishings, books, and toys. While perhaps increasing revenue, the retail end of museum businesses have become so large that, as of early 2003, the Museum of Fine Arts in Boston (MFA) became one of the first museums in the United States to create a separate for-profit retail operation, the MFA-owned Museum Enterprise Partners Inc. Art books have become the most important section of the new business. As new museums are designed, or redesigned, more emphasis has been placed on the amount of retail space to raise revenues. Restaurants have become increasingly important as well.

Museums grew their online presence in the new millennium. Parts of museum collections could be viewed via the Internet, whereas online gift shops provided users access to shop collections. Initially, museums feared that putting their collections online would nega-

tively affect attendance. Instead, they learned that it actually encouraged visits. The Smithsonian has 45 separate Web pages alone, filled with pictures and information. The American Museum of the Moving Image put online its Pinewood Dialogues, an archive of more than 300 film-related interviews with such artists as Mike Nichols, David Cronenberg, and David Lynch.

ARBORETA AND BOTANICAL OR ZOOLOGICAL GARDENS

This industry covers establishments primarily engaged in operating arboreta, botanical gardens, zoological gardens, and/or zoological exhibits.

NAICS CODE(S)

712130 (Zoos and Botanical Gardens)

712190 (Nature Parks and Other Similar Institutions)

INDUSTRY SNAPSHOT

In the mid 1990s, there were roughly 300 zoos and botanical gardens and aquariums and 276 nature parks in

the United States. According to the American Zoo and Aquarium Association, such wildlife facilities in North America were visited by more than 130 million people in 1998. The growth and stability of this industry depends largely on the government's surplus funds and on the ability of U.S. families to afford attendance; this industry is closely linked to family entertainment and tourism. Helped in part by both the increase in the population and in leisure time since the start of the twentieth century, the number of establishments in this industry has increased by ten percent every five years.

ORGANIZATION AND STRUCTURE

This industry is organized according to the ownership and management of its establishments. There are five types of establishments: those owned and managed by the government (usually city and community); those owned by the government but managed by a nonprofit society; those owned by the government but jointly managed with a nonprofit society; those owned and managed by a nonprofit society; and those that are privately owned by corporations and individuals. In 1995, roughly 50 percent of the establishments in this industry were owned and managed by the government; nearly 25 percent were owned privately by nonprofit societies; and 25 percent were owned privately by individuals or corporations.

Internal management at these establishments was once loosely structured, often combining volunteers with city and privately-hired employees. But during the early 1990s, the various types of owners developed new, more business-like, management styles to meet the competitive market. The San Diego Zoo, for example, went from managing 50 departments — such as animal keeping and maintenance — to managing diversified teams that claimed responsibility for one particular section of the zoo. Zoos have also modified their focus from merely allowing visitors to view animals to providing educational and hands-on opportunities.

Zoos constantly work to have more exciting, more natural habitat-like exhibits as well. Additionally, many zoos are heavily involved with the Species Survival Plan (SSP) program sponsored by the American Zoo and Aquarium Association (AZA).

The industry is served by many associations, including the AZA; the American Association of Zoo Keepers; the Consortium of Aquariums, Universities, and Zoos; and the California Association of Zoos and Aquariums (CAZA). These organizations reflect well on the industry. AZA reports that in the mid 1990s, its members supported more than 1,200 conservation efforts in approximately 60 countries. CAZA reports that its member zoos and aquariums receive more than 20 million visitors each year and contribute more than \$1.8 billion (combined) to the state's economy each year.

BACKGROUND AND DEVELOPMENT

The concept of the public zoo began in the mid 1800s. Prior to that time, zoos were the private property — and signal of power — of kings and queens. But with the growth of cities and the subsequent increase in the population's leisure time, zoos provided urban dwellers the opportunity to be closer to nature and wildlife and also served as a form of entertainment. Nearly the same can be said for botanical gardens and arboreta, but their origins as public facilities date back to Renaissance Europe. At this time, sculptured gardens were adopted as public art for the middle classes in Italy and later in England.

The first zoo in the United States was opened in 1876 by the Philadelphia Zoological Society as part of America's centennial exposition. Other major U.S. zoos also had their origins in international expositions, which often included animal exhibits from overseas. Zoos in the United States experienced considerable growth and restoration during the 1930s. Public works projects allowed new exhibits and landscaping grounds for zoos to be built. It was also during the 1930s that American zoos developed children's zoos, where children could learn about small animals through direct contact, such as petting, holding, and feeding the animals. These so-called petting zoos are now a standard feature at wildlife facilities around the world.

During the 1980s, the increase in attendance at U.S. zoos and botanical gardens was dramatic. The major wildlife facilities in the United States and Canada reported a 20 percent rise in attendance between 1980 and 1987. This increase beyond expected growth has been explained by three factors: baby-boom parents brought their children to facilities for educational reasons; establishments spent millions of dollars during the late 1970s and early 1980s upgrading their facilities (often as part of urban renewal projects); and the growth in city and suburban populations meant more attendance at local facilities.

Marketing. With increased competition within the arboreta and botanical or zoological gardens, establishments have become more involved in advertising their facilities. Each kind of facility has a different type of market. Zoos and botanical gardens are generally visited by local residents, while aquariums (which are more rare) are visited most often by tourists. Traditionally, marketing in this industry was low key. Zoological societies appealed to a small number of potential donors, and government zoos relied on a predictable portion of the government budget. However, the growth of U.S. cities limited city budgets, and an increase in competition from theme parks and other forms of family entertainment made these establishments invest considerably more in marketing starting in the late 1970s. Zoos saw their attendance increase with the birth of a new animal or the

acquisition of certain endangered species. Promoting these events became an essential part of the marketing package for zoos and aquariums. In 1995, for example, the San Diego Zoo spent roughly \$1.5 million on advertising annually.

Aquariums in the United States have advertised with the help of retail stores. Aquariums played an important part in the redevelopment of many of America's urban waterfronts where they have been placed near shopping districts and malls. In addition, these aquariums, even if privately owned, often received funding from the local governments. One of the largest aquariums in the United States, Monterey Bay National Marine Sanctuary, was built from a renovation of a sardine cannery. Zoos and aquariums have also attempted to increase their market share by expanding their facilities to include theme parks with rides and activities, such as video programs and birthday parties for the animals.

CURRENT CONDITIONS

Establishments in this industry experienced strong growth in the 1980s. Aquariums and zoo-aquariums did particularly well in attendance; according to *American Demographics*, these establishments represented more than 50 percent of all growth in this industry during the 1980s, and between 1980 and 1987 aquarium attendance increased by 50 percent and zoo-aquarium attendance by 80 percent. However, in the 1990s, attendance seems to have leveled off, while still maintaining the growth of the 1980s.

Additionally, upon entering the late 1990s, the U.S. zoos, aquariums, and botanical gardens faced new financial problems as a result of less government funding and an increase in competition from theme parks and newly built aquariums. These concerns have been addressed with an increased emphasis on fund-raising campaigns and continued marketing for sales revenues. In 1997, expenses for zoos were \$1.1 billion, while revenues were only \$127.9 million. Nature parks had revenues of \$129.4 million and expenses of only \$107.5 million.

WORKFORCE

In 1997, there were approximately 15,727 workers in this industry. Of the total number of workers in this industry, slightly more than 3 percent were animal caretakers and nearly 4 percent were gardeners. Some of the larger portions of this workforce included guards (nearly 9 percent of the total workers), cashiers (more than 8 percent), curators and restorers (more than 7 percent), marketing and sales personnel (roughly 5 percent), instructors (more than 5 percent) and administrators and office workers (10 percent). The remaining employees were maintenance and food service workers.

Animal caretakers include the occupations of zoo caretaker and zoo veterinarian. Zoo caretakers feed, water, and clean the quarters of animals and birds; they also work closely with zoo veterinarians on the diets and medications for animals. Zoo veterinarians direct and carry out the health service program at a zoo. Their responsibilities include testing all incoming animals for the prevention of diseases, providing the needed medical attention for animals, and conducting reproduction programs for endangered species.

Gardeners include horticulturists, herbarium workers, and garden workers. Horticulturists determine methods for breeding, storing, and transporting plants (including flowers and vegetables) and trees. These specialists are also responsible for the techniques used in spraying, planting, and cultivating plants and trees. Herbarium workers maintain the records of botanical gardens and arboreta by pressing and mounting plant specimens, which are then kept on card files for loans and exchanges with other establishments. Garden workers cultivate and care for floral and ornamental plant arrangements; their duties include fertilizing, watering, and transplanting flowers and plants in greenhouses and outdoor growing areas.

Job prospects predicted to grow in this industry were mainly in the area of marketing research and development and in fund raising. In related industries, engineers and architects will be needed for the building of new establishments.

AMERICA AND THE WORLD

Worldwide, there are roughly 1,500 botanical gardens and arboreta and more than 3,000 zoos and aquariums. In general, the United States has fewer gardens and arboreta and more zoos and aquariums per capita than countries overseas. The royal places of Europe and the less extreme weather have kept botanical gardens an important part of the European tourism industry. As for zoos and aquariums, the general discrepancies between the United States and other countries can be explained to a large extent by the availability of open spaces in U.S. cities and the availability of larger funds through the family entertainment industry (often working with zoo and aquarium operators to create theme parks).

In 1993, the famous London Zoo closed; its attendance had dropped from three million to slightly more than one million between 1950 and 1990. During the 1980s, the zoo experienced a financial crisis due to a lack of government funded projects and the public's decreasing interest in zoos. (The British public, including its many animal rights groups, have come to prefer safari parks, where the animals roam around freely.) The London Zoo, unlike many U.S. zoos, had not adapted to animal conser-

vationists' concerns for animals to be kept in more natural habitats.

RESEARCH AND TECHNOLOGY

Research in this industry includes the development of environmentally safe sprays and chemicals used in the soil at botanical gardens and arboreta. Aquariums are witnessing technological advances in the construction of their tanks, addressing such problems as materials resistant to salt water damage. Zoos have been investigating ways of making zoo environments more like natural habitats without posing dangers to the public. In addition, zoos are continually improving their care of animals with advances in veterinary medicine.

SIC 8611

BUSINESS ASSOCIATIONS

This industry classification includes membership organizations engaged in promoting the business interests of their members. Associations owned by their members but organized to perform a specific business function, such as common marketing of crops or joint advertising, are classified according to the function performed.

NAICS CODE(S)

813910 (Business Associations)

INDUSTRY SNAPSHOT

In the mid 1990s, approximately 100,000 business associations operated at local, state, regional, and national levels in the United States, posting over a 40 percent increase since the 1980s. Associations annually contribute over \$48 billion to the U.S. economy, provide nearly 500,000 jobs, and annually spend \$30 billion to host meetings and conventions. According to an Ameri-

can Association of Retired Persons' (AARP) study in 1998, 9 out of 10 adult Americans in the United States belonged to at least one association, and one out of four belonged to four or more associations. As many as 1,000 new groups were being formed each year.

The term "trade association" has been broadly used to describe most business associations. Trade associations are non-profit organizations representing a group of businesses within a particular segment of industry. The membership of these associations is composed primarily of individual company representatives. The oldest trade association in the United States is the New York Chamber of Commerce, which was founded in 1768. The U.S. Chamber of Commerce, headquartered in Washington, D.C. (the city with more associations than any other city), is the country's largest trade association. According to the American Society of Association Executives (ASAE), the largest national association convention in 1997 was that of the National Marine Manufacturers Association when over 170,000 members and guests attended. The Association for Manufacturing Technology was the second largest with over 100,000 attendees.

Trade association staff members perform activities that are too costly or time-consuming for an individual company to perform on its own. These activities include monitoring government regulations, conducting industry research, collecting statistical information, and producing educational programs and materials. Businesses and government depend heavily on associations for their statistical information, which is often not available elsewhere. This type of in-depth research has been spurred on by advances in computer technology, which have allowed trade associations to collect and disseminate industry information on a more timely basis and to a more targeted audience. In fact, by the late 1990s, the implementation of database programs and integrated systems became a necessity for all trade associations. Associations also publish newsletters, periodicals, and directories.

Associations rank as a major segment of the health insurance market and are the source of health insurance for more than 8 million people. They are also the originating source for codes of ethics and professional and safety standards, which govern such professions as law, medicine, banking, and manufacturing.

ORGANIZATION AND STRUCTURE

The following organizations are included under the classification of business associations: boards of trade, other than security and commodity exchanges; business associations, other than civic and social; chambers of commerce; contractors associations; growers associations, not engaged in contract buying or selling; growers marketing advisory services; industrial standards committees; junior chambers of commerce; manufacturers

institutes; merchants associations, not engaged in credit investigations; public utility associations; real estate boards; shipping and steamboat company associations; and trade associations.

Business or trade associations can be organized at the local, state, regional, national, or international level. Groups with similar interests also can belong to a federation or a collection of associations under centralized leadership, such as the National Retail Federation. Most business associations, depending upon the nature of their membership, fall under one of the following tax-exempt categories defined by the Internal Revenue Service (IRS): Section 501(c)(3) includes religious, charitable, scientific, public safety testing, literacy, and educational organizations; Section 501(c)(4) covers civic or social welfare organizations and local associations of employees; Section 501(c)(5) includes labor, agricultural, and horticultural groups; Section 501(c)(6) includes business leagues, chambers of commerce, real estate boards, and boards of trade.

The structure of an association depends upon the size of its membership and its budget. A large national organization may include hundreds of people on its staff. Usually a board of directors sets the policies of an association, and the executives and staff members are responsible for the implementation of these policies. Divisions within an association include the legislative staff, meeting planners, publications executives, public relations personnel, information and research executives, membership services personnel, and fundraisers.

The primary goal of all trade associations has been to improve the business of its members. In pursuit of this goal, trade associations have conducted research, set industry standards, and represented their members' interests before legislative and regulatory bodies. Trade associations also have provided information to many audiences, including the general public, association members, and government officials.

BACKGROUND AND DEVELOPMENT

The origins of modern trade associations can be traced to the Middle Ages, when laborers and merchants formed guilds to ensure proper wages and maintain work standards. Associations in the United States began to grow during the Industrial Revolution. Due to the social and economic hardships caused by the Revolutionary War, local organizations developed more quickly than national groups. The rapid industrial growth America experienced after the Civil War created numerous new trade associations and local chambers of commerce. The following prominent organizations were formed during this time period: the American Bankers Association (1878), the National Association of Life Underwriters

(1890), and the National Association of Manufacturers (1890).

By 1900, 100 national associations existed in the United States, and by the end of World War I that number had reached 1,000. World War II provided an opportunity for government and trade associations to work together to help meet wartime demands. Since 1945, many associations have changed, reflecting the country's evolving work environment. Those representing declining industries or technologies often merged with other organizations, became inactive, or formally dissolved.

CURRENT CONDITIONS

Two-thirds of all associations conducted research or engaged in statistical gathering in nearly all areas of public interest, including the environment, employment, and product safety. This work enabled businesses to improve their performance by comparing output to costs.

Membership education was also a primary trade association activity. Nearly 90 percent of surveyed associations offered educational programs and services to their members. More than 71 percent also disseminated industry information to the general public. By improving members' knowledge of their particular industry, associations contributed to the elevation of product and service quality and ultimately served the public interest.

Trade associations contributed greatly to setting, certifying, and meeting product safety and quality standards. Both the American Society for Testing and Materials (ASTM), and the American National Standards Institute (ANSI) have been devoted exclusively to standards testing.

One of the most visible activities of business associations in the 1990s was their legislative or lobbying efforts. Approximately 38 percent of national associations had at least one lobbyist, and 35 percent had political action committees. Business or trade associations allocated roughly 10 percent of their total annual expenditures to political education and providing industry information to Congress regarding legislative or regulatory proposals that could affect their membership. These political activities also served to provide association members with skills necessary for further political participation at the local and national level.

Other issues relevant to trade associations included the environment, energy conservation, health care costs, shifting values and attitudes in the workplace, technological innovations, declines in quality education, and a growing global economy.

INDUSTRY LEADERS

The largest trade association in the country, the United States Chamber of Commerce, is a national feder-

ation of business organizations and companies. Founded in 1912, the U.S. Chamber of Commerce maintained its headquarters in Washington, D.C., and had a staff of 1,200 and a \$70 million budget. Its membership included local chambers of commerce, trade and professional associations, and private and public companies. More than 96 percent of its members, according to the Chamber, were small businesses with 100 or fewer employees, but almost all of the largest U.S. companies were members as well.

The Chamber of Commerce represents the political interests of the U.S. business community on national issues regarding the economy. For example, in 1996, the Chamber of Commerce successfully lobbied in the House of Representatives for passage of the Working Families Flexibility Act (H.R.1), which dealt with compensatory time for workers. The Chamber also informed and trained its members to participate in policymaking at the state and local levels and in legislative and political action at the national level.

The Chamber produced *Nation's Business Today*, a daily business-oriented newscast; *Ask Washington*, a daily national television program; and *It's Your Business*, a weekly televised debate program. This business association also published an annual analysis of workers' compensation laws; the *Congressional Handbook*; *Nation's Business*, a magazine covering national issues that especially affect small business; and numerous newsletters.

The National Retail Federation (NRF) was formed in 1990 with the merger of the American Retail Federation and the National Retail Merchants Association. The largest retail trade association, the NRF had 55,000 corporate members, including department, chain, mass merchandise, and specialty stores that sell men's, women's, and children's apparel, and home furnishings. Also included were the 32 national and 50 state affiliated associations. The NRF conducted conferences and workshops and provided an extensive collection of manuals, bulletins, and promotional materials. This business association offered advisory services regarding all aspects of retailing, such as financial planning, shortage control, electronic data processing, telecommunications, merchandise management, traffic, security, store planning and construction, personnel administration, recruitment and training, and advertising.

The NRF published *Retail Control*, a journal providing retail management and financial information. It also produced *Stores Magazine*, a publication covering current trends, concepts, and promotional activities of the retail industry, as well as association news. The NRF maintained a 1,000-volume library on retail management and fashion merchandising. Headquartered in New York, the National Retail Federation had a staff of about 100

and held its annual meeting every January in New York City.

The National Restaurant Association (NRA) is a trade association for restaurants, cafeterias, clubs, contract foodservice management, drive-ins, caterers, institutional food services, and other members of the foodservice industry. The group's annual convention has become the largest association gathering in the United States. The NRA supported foodservice education and research in several educational institutions and conducted traveling management courses and seminars for restaurant personnel. This trade association also sponsored the Educational Foundation of the NRA, which provides training and education for food and equipment operators, manufacturers, and distributors.

The NRA published the bi-weekly *Foodservice Information Abstracts*; *National Restaurant Association-Washington Weekly*, a report of legislative and regulatory issues; and *Restaurants USA*, a monthly magazine covering the trends and developments in the foodservice industry. Founded in 1919, the NRA had a staff of 115, membership of 30,000, and a \$16 million budget. The association's headquarters were located in Washington, D.C., with 175,000 food service group affiliations worldwide.

The National Association of Manufacturers (NAM), also headquartered in Washington, D.C., represents manufacturers and non-manufacturers and voices the industry's political views on national and international problems. Founded in 1895, this trade also maintained the NAM National Division in Maryland, a field headquarters in Chicago, and eight regional offices throughout the United States. The NAM reviews current and proposed legislation, administrative rulings and interpretations, judicial decisions, and legal matters affecting the manufacturing industry. The organization maintained numerous policy groups including Government Regulation and Competition; Industrial Relations; International Economic Affairs; Resources and Technology; and Taxation and Fiscal Policy. The NAM was affiliated with 150 local and state trade associations of manufacturers through the National Industrial Council and 110 manufacturing associations.

The Council of Better Business Bureaus (CBBB), located in Arlington, Virginia, consisted of 250,000 businesses and professional firms from all industries and 130 local Better Business Bureaus operating autonomously in the United States, Canada, and Israel. The CBBB acted as a mouthpiece for business to consumers, assisted in expanding and upgrading local bureau capabilities, helped establish voluntary self-regulation of national advertising, provided pre-purchase information to consumers, strengthened consumer education programs, and settled consumer complaints through arbitration. Although its

inception dates back to the Better Business Bureau system (founded in 1912), the CBBB was created in 1970 with the merger of the National Better Business Bureau and the Association of Better Business Bureaus. In 1997, the CBBB reported net assets and total liabilities of almost \$6 million.

WORKFORCE

More than 500,000 people were employed in different associations throughout the United States. Staff size and responsibilities largely reflect the membership size and budget of each association. Employment positions within associations generally have been divided evenly between executive and staff positions. As associations continued to grow in size and strength, so did the possibilities for employment within these organizations. Because staff members are exposed to a wide variety of functions and responsibilities, association employment can offer tremendous advancement potential.

Entry-level employment at associations generally can be found in the positions of conference planning, public relations, or membership services. Most jobs required that employees have a liberal arts degree and strong interpersonal and communication skills. Additional education, such as an MBA, legal training, or fund-raising experience, was sometimes necessary for financial services or legislative positions. An association executive could be designated a Certified Association Executive (CAE) upon the successful completion of a daylong written test.

Although associations were located across the United States, many were found in metropolitan areas. Boasting 2,500 organizations, Washington, D.C., served as headquarters for more associations than any other city, with Chicago in second place, and New York in third. Many trade associations also were located in or near state capitals.

AMERICA AND THE WORLD

The exchange of technology and the ability to generate business in new markets led many trade associations to venture into the international arena by developing new kinds of relationships. For example, some associations engaged in international networking by creating an umbrella organization incorporating trade associations of various countries. Other international formats include foreign partnerships and working with U.S. embassies overseas.

Some business organizations have been developed for the sole purpose of fostering international trade relations. For example, the U.S. Chamber of Commerce was probably one of the world's largest business federations. At the close of the century its represented membership included not only domestic (U.S.) chapters, but 850 busi-

ness associations and 87 American Chambers of Commerce (AmChams) abroad. In addition to promoting business interests within the United States (through the auspices of AmChams), the chamber helped its members learn about the business environment and the general culture of a particular country. Membership services included supplying tax and credit information; arranging informal gatherings for foreign executives and their American counterparts; briefing U.S. employees new to the region; and counseling relocated families about schooling, housing, and health care.

In a message prepared for the general membership of AmCham Egypt, President Mohamed Hosni Mubarak opined that the beneficial function of "Private sector organizations like AmCham . . . (had) consistently shown that economic growth is a result of a partnership between business and government." Such organizations facilitated international correspondence through a range of services, such as providing access to staff members who handle international relations issues. Such individuals usually possessed specialized expertise in overcoming language barriers, finding alternative delivery systems, and forming allied private sector organizations outside the United States.

The international aspect of trade associations was expected to grow along with the continued globalization of industry, trade, and technology. Associations view internationalism as a way of thinking and doing business. Carol Kinsey Goman noted in her book *Managing in a Global Organization*, "Markets no longer stop at national boundaries, neither do corporations. . . . For organizations to flourish, let alone survive, their perspective must be global."

RESEARCH AND TECHNOLOGY

Effective information management has become a vital function for the successful business association and was the driving force for the computerization of their office operations. On an annual basis, associations spent millions of dollars on computer technology. The average association dedicated as much as \$28,500 annually to computer hardware and/or software purchases.

Most large business associations purchased mainframe systems in the 1970s to automate their record keeping. They added personal computers during the 1980s, and by the 1990s, they had amassed a collection of computers unable to communicate or interact with one another. Therefore, many associations started using local area networks (LANs) in order to share information among their departments. According to *Association Management*, "By distributing programs and processing power among microcomputers, or PCs, no one unit needs the kind of power provided by a mainframe. Executives on networked PCs can communicate electronically using

work group software applications, such as group editing, computer conferencing, project management, document design, electronic mail, and scheduling.” With the use of LANs, many associations have begun to operate database management systems and experiment with a variety of software packages and hardware products. Some of these items include legislative affairs and grassroots software; relational database software and text-based information retrieval programs; and bar coding and document scanners.

Many business organizations also ventured into the CD-ROM arena. For example, the American Hotel and Motel Association (AHMA) has stored volumes of information in its Hospitality Index database on CD-ROM. Time required to perform research was reduced to one-fifth the amount of time that was needed previously.

Associations also used new technologies in educational programs that aided in expanding their audience and delivered information in a timely and cost-efficient way. Communication throughout the world was made easier through the Internet using the World Wide Web and e-mail. Some technologies being used by the turn of the twenty-first century included online database services for up-to-date information; satellite down-links for conferencing; video recordings for standardized training; and portable computers, or laptops, for convenience when working at home or traveling. Many associations have a web page so that members and others can receive important information. As Renata Webb, ASAE executive, remarked, “Ultimately, technology adds options and alternatives.”

SIC 8621

PROFESSIONAL MEMBERSHIP ORGANIZATIONS

This industry covers membership organizations of professional persons for the advancement of the interests of their profession.

NAICS CODE(S)

813920 (Professional Organizations)

INDUSTRY SNAPSHOT

Professional membership organizations spent the mid and late 1990s stepping up efforts to attract members and remain the premier catalysts for their fields. These associations remain a vital source of information for individuals practicing in those fields, as well as for related businesses that take advantage of associations for client outreach and valuable marketing information. Among the chief concerns of associations was to establish a strong presence on the Internet, which has rapidly become one of the primary sources of the type of rapidly evolving information in which major associations specialize. Moreover, an Internet presence afforded associations the opportunity to greatly streamline their operation by cutting down printing and meeting costs.

In 1999, there were approximately 135,000 associations operating in the United States, up from 100,000 in 1995. Of these, 110,000 were local, state, or regional associations; 23,000 were national; and 1,300 were international. Associations annually contribute more than \$48 billion to the U.S. economy, provide some 295,000 jobs, and annually spend \$56 billion to host meetings and conventions. According to the American Society of Association Executives (ASAE), the national organization for association managers, 9 out of 10 adults in the United States belonged to at least one association in the mid 1990s, and one in 4 belonged to four or more associations. As many as 1,000 new associations crop up each year.

Professional membership organizations are non-profit voluntary membership associations that represent individuals with a common background in a subject or profession such as law, medicine, or accounting. Three types of professional societies exist. The first includes any group with a common personal interest such as, the International Society of Stamp Collectors. The second type is dedicated to religious, charitable, public service, or fraternal causes such, as the National Council on Aging or the American Heart Association. The third classification covers organizations dealt with in this industry classification. This category includes scientific,

engineering, and learned societies whose purpose is to advance knowledge related to their respective fields. Examples include the American Chemical Society, the Society of Automotive Engineers, and the National Association of Accountants.

The main responsibilities of professional membership organizations are to provide and enforce standards of professional practice and to conduct research. These organizations generally also provide educational programs to their members, and most supply current information and research materials to their members, governmental agencies, and the public. Since dissemination of timely information has been of the utmost importance, implementation of communications technology has become critical for effective association management.

ORGANIZATION AND STRUCTURE

Professional membership organizations include bar associations, dental associations, engineering associations, medical associations, professional standard review boards, and scientific membership associations. The memberships of professional societies are made up of individual doctors, dentists, or scientists. Membership services generally have been designed to benefit the individual members and include continued education, accreditation programs, government relations, publishing, and research.

Professional membership organizations can be organized at the local, state, regional, national, and international levels. Sometimes an individual may be a member of an organization at several different levels. For example, a doctor may belong to the local, state, and national levels of the American Medical Association. Groups with similar interests also can belong to a federation or collection of professional membership organizations, such as the American Association for the Advancement of Science.

Most professional societies, depending upon the nature of their membership, fall under one of the following tax-exempt categories defined by the Internal Revenue Service (IRS). Classification 501(c)(3) includes religious, charitable, scientific, public safety testing, literacy, and educational organizations. Section 501(c)(4) covers civic or social welfare organizations and local associations of employees. Section 501(c)(5) includes labor, agricultural, and horticultural groups.

The structure of a professional membership organization depends upon the size of its membership and its budget. A large national organization may have hundreds of people on its staff. Usually, a board of directors sets the policies of an organization, and the executives and staff members are responsible for the implementation of these policies. Divisions within a professional society include the legislative staff, meeting planners, publica-

tions executives, public relations personnel, information and research executives, membership services personnel, and fund-raisers.

BACKGROUND AND DEVELOPMENT

The formation of professional associations in the United States began during the Industrial Revolution. However, most of these groups were trade-related, not professional societies. As the United States began to develop urban areas in the mid 1800s, many professional and educational groups were established. Some organizations, such as those representing medicine, law, and accounting, were created specifically to develop and enforce standards of practice. The following organizations are among those formed during this period: the American Medical Association, founded in 1854; the American Dental Association, established in 1859; and the American Bar Association, created in 1878.

By 1900, 100 national associations existed in the United States, and by the end of World War I, that number had reached 1,000. After World War II, many trade associations changed their focus or evolved into new organizations due to technological advances in the modern business community. However, unlike trade groups, professional membership organizations maintain many of the same responsibilities as they did when they were first founded.

CURRENT CONDITIONS

By the late 1990s, associations were increasingly mirroring the behavior of the industries they represent. As merger activity sweeps across all industries, associations from different but related industries have likewise merged in order to maintain viable and effective membership. Seeking out new strategies to provide high-quality services to their members and the public, professional membership organizations have increasingly relied on non-dues income, such as fees derived from online information provision. At the same time, however, new associations have arisen quickly to serve the interests of emerging industries, particularly those related to technology. For example, twenty-five technology companies joined forces in 1999 to establish the ASP Industry Consortium to develop and implement guidelines for software service companies. Companies involved included AT&T Corp., International Business Machines Corp., and Compaq Computer Corp.

Professional societies conduct research, set professional standards, collect statistical information, produce educational programs, and represent their members' interest before legislative and regulatory bodies. They also provide information about their respective fields of study to many audiences, including the general public, association members, and government officials.

Perhaps the most important responsibility of professional societies has been the development and enforcement of standards of practice and safety as well as ethical codes. These organizations provide education and testing for certification, accreditation, and licensing of their membership. They also encourage the peer review process, offer courses that meet legal requirements, and issue standards that form the basis for disciplinary action. Approximately 30 percent of all professional societies set professional standards and 15 percent certify that these standards are met.

Membership education has also played a critical role in professional societies, since the public interest is served by the quality of members' service and standardized accreditation. About 95 percent of professional membership organizations offer such educational programs, leading to annual expenditures of more than \$3 billion on educational programs and services, while 46 percent offer scholarships. Seventy-one percent of all associations gather statistics and conduct research. For professional societies, the duty of research has been part of their very definition and purpose of existence. Research findings set important new directions and define the scope, standards, and trends within a particular field, and are often a primary source of government research and statistical compilations. This information usually is shared through some form of print or electronic journal published by the professional society. According to survey conducted by the ASAE, 62 percent of associations publish both periodicals and non-periodical literature; among these, 33 percent publish only periodicals, 82 percent publish newsletters, and 75 percent publish magazines and scholarly or research journals.

One of the most visible activities of professional membership organizations has been legislative or lobbying efforts. Approximately 40 percent of all national associations have at least one lobbyist and one-third maintain political action committees (PACs). PACs are particularly popular among smaller organizations; 52 percent of state and regional associations have political action committees. Professional societies allocate approximately 5 percent of their total annual expenditures to providing information to Congress regarding legislative or regulatory proposals that could affect the activities of their membership.

Other issues relevant to professional societies, as shown by advertising expenditures, include environmentalism, energy conservation, and health care costs. For example, in 1999 a coalition of scientific organizations pooled their resources to launch an \$8 million campaign for television, radio, and print advertisements to raise public awareness of and spark political action against global warming. Future trends likely to affect these groups include, shifting values and attitudes in the workplace,

technological innovations, decline in quality education, increased regulations, and a growing global economy.

INDUSTRY LEADERS

American Medical Association. Founded in 1854, the American Medical Association's (AMA) membership totaled 295,000 in 1998. Headquartered in Chicago, the organization maintained 54 state groups representing physicians and county medical societies. In 1962, the AMA boasted 82.1 percent of the country's physicians as members. By 1998, that figure had dropped to slightly more than 40 percent; the number of total physicians, however, nearly tripled over that period.

With an annual budget of \$190 million, the AMA disseminates a tremendous amount of information to both the public and members of the medical profession. The AMA informs members about medical and health legislation at the state and national levels, and represents its membership to legislative and regulatory bodies. It also assesses physicians' adherence to its uniform standards through the American Medical Accreditation Program and seeks to enforce ethical codes of conduct for use throughout the medical profession. In 1999, the AMA established a national labor organization, the Physicians for Responsible Negotiations, which represents practicing physicians to increase their leverage in patient-care management decisions.

With a \$60-million publishing operation, the AMA is the world's largest publisher of medical and scientific information. Two of its most well-known publications are *American Medical News*, a weekly publication covering political, social, and economic issues as they pertain to medical care, and the *Journal of the American Medical Association*, (JAMA) a weekly publication devoted to topics in general medicine. The AMA also assists in setting standards for medical schools, hospitals, residency programs, and continuing medical education courses. In addition, the organization offers physician placement services and counseling regarding practice management issues.

American Bar Association. The American Bar Association (ABA) is the world's largest voluntary professional association, with a budget of \$100 million in 1999. Founded in 1878, it is a national organization that represents all attorneys in good standing of the bar throughout the United States. The ABA is headquartered in Chicago, has 380,000 individual members, including 40,000 dues-paying associates and law students, and is affiliated with 20 other professional organizations.

The ABA addresses broad social concerns, which in the 1990s encompassed the high costs of litigation, legal services, domestic violence, and free press and fair trial issues. This organization conducts research, provides ed-

educational programs and public services, and seeks to improve the administration of civil and criminal justice. The ABA has 800 employees who operate 25 sections, including Criminal Justice, Economics of Law Practice, and Family Law. The organization's major publication is the monthly *ABA Journal*, which covers developments in law and association news.

American Dental Association. Founded in 1859, the American Dental Association (ADA) is a national professional society for dentists with 54 state or territorial and 529 local dental societies. Its membership of 141,000 gives the ADA a market share of 70 percent of all dentists in the United States. This organization promotes dental health issues to the public and dentistry issues regarding legislation, standards, and regulation. The ADA inspects and accredits dental schools and schools for dental hygienists, assistants, and laboratory technicians through its Commission on Dental Accreditation, which derives its authority from the U.S. Department of Education.

The ADA, which maintains a 50,000-volume library, conducts a vast amount of research and produces most of the dental health educational materials used in the United States. The organization also compiles statistics regarding personnel, practices, dental care needs, and attitudes of patients, as well as maintaining a biographical history of dentists in the United States. The ADA is headquartered in Chicago, operates with a staff of over 400, and has a \$57.7 million budget. Its official publication is *The Journal of the American Dental Association*, as well as the *ADA News* and the *Index to Dental Literature*.

American Association for the Advancement of Science. The American Association for the Advancement of Science (AAAS) is the largest general organization representing all areas in the field of science. Its membership includes 143,000 individuals from 130 countries, including 120,000 members in the United States, and 296 societies, professional organizations, and state and city academies. Founded in 1848, the AAAS, headquartered in Washington, D.C., has a staff of 300 people, and a \$44 million budget. It retains close links to 275 affiliated societies with more than 7 million additional members.

The goal of the AAAS is to promote the work of scientists and "improve the effectiveness of science in the promotion of human welfare." This professional membership organization conducts seminars and colloquia regarding scientific issues. The AAAS plays a role in settling crucial scientific questions and addresses issues such as population growth, environmental destruction, and viral infections. It also produces an annual report and a monograph series that provide information about proposed federal research and the development budget for the upcoming year, and maintains *Science Online* on the World Wide Web. Its highly respected

weekly journal *Science* boasts a readership of more than 500,000 people.

American Institute of Certified Public Accountants. The American Institute of Certified Public Accountants (AICPA) is a professional society of accountants certified by the states and territories. The organization was founded in 1887, and in 1999 had 330,000 individual members, with 42.0 percent composed of accountants working in industry, 41.0 percent in public practice, 2.4 percent in education, and 4.4 percent in government. Headquartered in New York, the AICPA employs 700 people. This organization has become known for its preparation and grading of the national Uniform CPA Examination for state licensing bodies. Other responsibilities of the AICPA include, establishing, auditing, and reporting standards and determining the financial accounting standards included in the financial statements of U.S. companies. The AICPA also conducts research and continuing education programs and operates more than 135 boards, committees, and subcommittees that deal with issues ranging from accounting standards and professional ethics to computer services.

The AICPA publishes a number of newsletters and journals. The most prominent of these publications include: *CPA Client Bulletin*, a monthly publication for clients of AICPA members; *CPA Examinations*, a semi-annual study package of past CPA examinations and unofficial answers; and the *Journal of Accountancy*, a monthly publication covering all aspects of accounting for practitioners and financial executives. It also produced the *CPA Client Tax Letter*, the *CPA Healthcare Client Letter*, and *Practicing CPA*.

National Society of Professional Engineers. Founded in 1934, the National Society of Professional Engineers (NSPE) is an organization representing professional engineers and engineers-in-training in all fields registered in the United States and Canada. The NSPE, headquartered in Alexandria, Virginia, has a staff of 49 and a \$6 million budget. Qualified graduate engineers, student members, and registered land surveyors are among the organization's 60,000 members, who are organized in 500 chapters.

The NSPE is concerned with the social, professional, ethical, and economic considerations of engineering as a profession. It focuses on these issues through a number of public relations programs and provides continuing education programs. The organization also monitors legislative and regulatory actions of interest to the engineering profession. The NSPE publishes the monthly *Engineering Times*.

WORKFORCE

More than 295,000 people are employed in associations throughout the United States. This figure has de-

clined gradually since the early 1990s, reflecting the consolidation forced by downsized and concentrated industries. Staff size and responsibilities largely reflect the membership size and budget of each association. Employment positions within associations generally have been divided evenly between executive and staff positions.

As associations continue to grow in size and strength, so have the possibilities for employment within these organizations. According to Ronald Krannich, author of *Jobs and Careers with Nonprofit Organizations*, all organizations need people with fund-raising skills. Professional organizations need communication specialists, researchers, writers, meeting planners, publicists, and lobbyists as well. Because staff members are exposed to a wide variety of functions and responsibilities, association employment can offer tremendous advancement potential. Executives can earn salaries nearing the \$1 million mark.

Entry-level employment at associations generally can be found in the areas of conference planning, public relations, or membership services. Most jobs require that employees have a liberal arts degree with strong interpersonal and communication skills, and some computer knowledge. Additional education, such as an M.B.A. or legal training, may be necessary for financial services or legislative positions. Association executives may earn Certified Association Executive (CAE) designation upon the successful completion of a one-day, written test.

Although associations are located across the United States, many can be found in metropolitan areas. Perhaps reflecting the growing prominence of political action committees, Washington, D.C., is home to more professional membership organizations than any other city, boasting 2,500 association headquarters. New York City followed with 1,900, and Chicago placed third with 1,500. Moreover, many professional membership organizations have chapters located in or near state capitals.

AMERICA AND THE WORLD

The emerging global community has increased the interest and the need for U.S. professional membership organizations to share their talents overseas, especially with growing business communities in emerging democracies. Many organizations have begun to develop subcommittees or international task forces to deal with these expanding needs as they pertain to their respective profession. For example, the International Relations Task Force of the Government Financial Officers Association (GFOA) has begun to work with several international professional and financial organizations. This group has been providing education and networking opportunities with foreign officials, and has been assisting U.S. and Canadian finance officers in becoming competitive in the

international economy. The GFOA has been especially active in Eastern Europe.

Staff members of professional societies who handle international relations issues usually have expertise in overcoming language barriers, finding alternative delivery systems, and forming chapters outside the United States. Most often, these people most often are contacted by members regarding international economic, social, and political issues.

RESEARCH AND TECHNOLOGY

Effective information management has become a vital function for the successful professional society, and the driving force for the computerization of their office operations. Eighty-one percent of all professional organizations incorporated networked personal computers. More and more associations were bringing their information and operations online, often to generate additional revenues. For example, the AMA has made especially aggressive moves to tap into this resource, recognizing that health information represents one of the most commonly sought topics on the World Wide Web. In conjunction with six other medical associations, the AMA invested heavily to establish Medem.com to compete with the growing number of other major online health-information services that do not promote physician-empowerment. The American Society of Association Executives, moreover, concluded an agreement with Microsoft Corp. in 1998 whereby the software giant agreed to build technological proficiency, resource access, and a model upon which associations can develop more effective networks with members. "Members only" sections on Web sites increasingly connect organization members beyond firewalls and generate additional revenue for the association from the online purchase of information materials and from advertisers. About two-thirds of the associations maintain Web sites, while more than three-fourths have e-mail.

Most large professional societies purchased mainframe systems in the 1970s to automate their record keeping. They added personal computers during the 1980s, and by the 1990s had amassed a collection of computers unable to communicate or interact with one another. Therefore, many of these organizations have begun to use local area networks (LANs) in order to share information among their departments. For instance, the AMA has been converting its legal information system from a Wang VS 300 minicomputer to microcomputer LANs with the intention of simplifying the coordination of work groups and reducing downtime. The AMA also has moved from a proprietary system to an open client/server setup, hoping to unite a divided user community and consolidate several small data centers.

With the use of LANs, many professional membership organizations have begun to operate database management systems and experiment with a variety of software packages and hardware products. Some of these items include legislative affairs and grassroots software, relational database software, text-based information retrieval programs, and bar coding and document scanners.

Many associations are now involved in some kind of Internet interaction, whether it is a World Wide Web home page or other online research capabilities. Marketing their programs and products, recruiting new members, and providing educational information and services to members and the public can be easily accomplished on the Internet or other electronic databases, making technology of the 1990s an important tool for success.

LABOR UNIONS AND SIMILAR LABOR ORGANIZATIONS

This industry includes membership organizations of workers that operate for the improvement of wages and working conditions.

NAICS CODE(S)

813930 (Labor Unions and Similar Labor Organizations)

INDUSTRY SNAPSHOT

After experiencing a slight resurgence in the late 1990s, labor unions continued to see their membership ranks diminish in the early 2000s. According to the U.S. Department of Labor, overall union membership has declined over the past two decades. The number of wage and salary workers belonging to unions fell approximately 7 percent between 1983 and 2002.

Labor unions are organized on local and national levels, usually by industry or trade. The primary function

of a labor union is to partake in collective bargaining, the negotiation process over the terms of employment between a union and management. Union officials use this procedure to determine the wages for workers of a particular industry and to settle other worker-related issues, such as health benefits, overtime compensation, and company policy and direction. Employee associations that use collective bargaining procedures have become a popular type of labor union among white-collar professionals and other workers who have shunned traditional unions. Additionally, new kinds of union membership have been offered to workers who would like to be affiliated with a union but do not work in a union shop. These workers can become associate union members or join workplace organizations.

As a whole, union vitality remains far below levels achieved in the past. In terms of membership, only 13.2 percent of the U.S. workforce was unionized in 2002, totaling 16.1 million members. Government workers were far more likely to be unionized, especially at the local level. After government, the most heavily unionized industries included transportation, in which 24 percent of the workforce was organized. Other sectors with high unionization rates included construction and manufacturing. Men belong to unions slightly more than women, with respective unionization rates of 14.7 percent and 11.6 percent. Among all employed wage and salary workers, those not represented by unions earned an average of \$587 per week, whereas union members earned \$740.

Unions faced a number of challenges in the early 2000s. Chief among these concerns was the nature of the labor union itself. The sharply diminishing ranks of unions during the previous 30 years combined with the increasingly global and mobile nature of business sparked debate as to whether the organizational structures and practices of unions were applicable to the modern economy. At the other end of the spectrum, labor activists countered that while definite improvements and re-strategizing were indeed in order, unions were never more necessary than when faced with the constant threat of strongly leveraged management afforded by the increasing mobility of trade and investment. The challenge was thus to rethink labor practices to strengthen labor’s position in the changed economic environment.

ORGANIZATION AND STRUCTURE

The American labor movement can be divided into two types of unions: craft and industrial. Craft unions were the first unions established in the United States and are comprised of workers who share a common occupation, skill, or trade. An industrial union includes all workers related to the production of a particular product, including skilled, semiskilled, and unskilled labor.

This distinction has been an important issue in the history of organized labor. The American Federation of Labor (AFL), founded by Samuel Gompers in 1886, favored craft unions. Over time and under the direction of various leaders, the Congress of Industrial Organizations (CIO) was created specifically for industrial unions. The differences between these two kinds of unions are not as apparent today because rapid changes in technology have blurred many remaining distinctions.

Probably the most recognizable name related to the American labor movement has been the AFL-CIO. This group is a “union of unions,” a federation of free and autonomous labor organizations. A voluntary membership group, the AFL-CIO includes 65 unions that represent more than 13 million workers. Membership has been limited to national unions, although a few local unions also belong to the federation directly. National unions have been the backbone of the American labor movement. Membership has been concentrated in the largest national unions, such as the Teamsters, the Auto Workers, the Steelworkers, the Carpenters, and the United Mine Workers. Regardless of AFL-CIO affiliation, these groups have been responsible for collective bargaining.

In addition to setting the price of labor in a particular market, collective bargaining allows unions to share in decision-making processes with management. Collective bargaining establishes a system of checks and balances against the authority of management. With this negotiation strategy comes a new way of making and interpreting rules, known as the “grievance procedure.” This is essentially a judicial process that ensures that the collective bargaining agreement is being properly applied and interpreted.

The 63,000 local unions in the United States have been primarily responsible for grievance procedures. Nearly 98 percent of local unions are subdivisions or chapters of national unions, although a few are affiliated directly with the AFL-CIO or are completely independent. Approximately 22,000 local unions are affiliated with six national unions that have 2,000 or more locals each.

Unlike the distant relationship between national unions and the AFL-CIO, locals typically are strictly controlled by their national leadership. The status of these locals lies entirely under the administration of the national leadership, who often disband locals deemed expendable or uneconomical to maintain. Generally, locals require permission from the national administration to call a strike, though unsanctioned “wildcard” strikes are not uncommon. National representatives are usually charged with engaging in collective bargaining on behalf of local chapters. Despite this “top-down” leadership, the local union has been a significant part of organized labor because it has been the point of contact between the member and the union. Nonetheless, recent years have witnessed heightened demand for greater direct or more

representative democracy emanating from the local chapters up to the national administration.

Employee associations, like labor unions, participate in collective bargaining, but they are less hierarchical than the unions. These groups may be the best way to organize professional and white-collar employees who are interested in collective bargaining but have reservations about being identified with a union. Approximately 2.56 million people, or 10 percent of the total U.S. union membership, belong to employee associations. The largest employee association is the National Education Association (NEA). Boasting over 2.5 million members, the NEA has surpassed the Teamsters (1.4 million members as of 2003) as the largest union in the United States. Other employee associations with over 100,000 members include the American Nurses Association, Classified School Employees, the Fraternal Order of Police, and the California State Employees.

BACKGROUND AND DEVELOPMENT

The beginnings of organized labor in the United States can be traced to the establishment of craft unions in the eighteenth century: shoemakers organized in Philadelphia in 1792, carpenters in Boston in 1793, and printers in New York in 1794. In the early nineteenth century, these groups tried to expand into other cities, with many crafts even boasting national organizations in the 1830s before being decimated by a depression later that decade. Shortly before the Civil War, many national craft unions were reestablished and, more important, survived.

By the end of the 1860s, approximately 30 national craft unions had been founded. In 1866, the National Labor Union, a national federation embracing both craft unionists and reform groups, was organized. The group lasted only six years before converting into a political party, which subsequently collapsed in 1872. The next national labor group was the Noble Order of the Knights of Labor. Founded in 1871 as a secret society, the Knights became a national organization in 1878. Their goal was to bring together in one organization all “real” producers, such as farmers, lower middle-class workers, and wage earners. The Knights were a centralized organization, which tried to prohibit national trade associations. The crafts membership of the Knights soon became disgruntled with this policy because the combination of skilled and unskilled workers weakened the craftsmen’s ability to bargain effectively. Five years into its existence, the Knights had 50,000 members. At its peak year in 1886, the group had nearly 700,000 members—an all-time high. Four years later, the group had dwindled to 100,000, as the majority of the craftsmen became aligned with a new federation.

The AFL was the first union to achieve a lasting existence. Through various economic conditions, the

AFL maintained a continuous presence from its inception until its merger with the CIO in 1955. Samuel Gompers, founder of the AFL, enforced two basic policies. National unions that belonged to the AFL were guaranteed “trade autonomy” and were to be afforded “exclusive jurisdiction” over their particular craft or other occupation.

Trade autonomy allowed decision making to be decentralized, with national unions retaining power. This was particularly important to the union’s main function of collective bargaining. With exclusive jurisdiction, the AFL recognized the sole authority of its craft union members and protected them against possible competition from other unions. The AFL assured its member groups that no other unions would be given overlapping jurisdiction, and no competitors would be recognized by the federation. These two policies proved to be extremely successful in attracting unions to the AFL. Between 1897 and 1904, the AFL issued 92 charters, doubling the number of affiliated unions to 120. By 1904, 85 percent of all national unions in the United States were affiliated with the AFL. By 1914, AFL membership exceeded 2 million. It rose briefly to 4 million before gradually declining throughout the 1920s. During the 1930s membership fell below 2.5 million.

The first two decades of the twentieth century were the period of labor radicalism, and unions’ influence registered in American political life as they have not since. Labor leader and socialist Eugene Debs made strong third-party showings in successive U.S. presidential elections, whereas militant unions such as the Industrial Workers of the World (IWW) sought to organize all workers, including those unskilled and minority workers shunned by the AFL, into “one big union” with the aim of ending the capitalist system in favor of a socialist federation of syndicated labor organizations. After World War I and the Bolshevik overthrow of the czar in Russia, the “Red Scare” in the United States produced a swift and harsh crackdown on labor militancy, and such radical unions were quickly dismantled.

In 1935, the dominance of craft unions was challenged by the establishment of a new organization that advocated a different kind of union. On 9 November 1935, John Lewis, president of the United Mine Workers, along with the presidents of seven other unions in the industrial block of the AFL, met and established the Congress of Industrial Organizations (CIO). This group promoted the collection of unorganized workers in mass-production industries on a per-industry basis. When the group was instructed by the AFL to disband the CIO or be suspended, the leaders ignored the order, broke away from the AFL, and became an independent federation.

The central legislation of U.S. labor-management relations is the National Labor Relations Act of 1935, usually referred to as the Wagner Act, which guaranteed

the right of employees to join unions and engage in collective bargaining. Immediately a thorn in the side of businesses, the act prohibited employers from firing workers for joining or trying to organize a union and from refusing to negotiate with a union that represented a majority of workers. The act further established the National Labor Relations Board (NLRB) to enforce the law’s provisions and mediate, at the federal level, broad legal disputes between labor and management. While business organizations quickly began working to amend the Wagner Act, union membership soared from 4 million in 1935 to 12 million in 1947.

Within a three-week period in early 1937, the CIO had penetrated the largest corporations in both the auto and steel industries—the core of mass production. Its first success came when General Motors, the largest automaker at that time, recognized the United Auto Workers (UAW) as the bargaining agent for its members. The CIO also made its mark on other major industries in 1937, including electrical and radio manufacturing, rubber, men’s and women’s clothing, textiles, meatpacking, petroleum, and the maritime industry. By the end of that year, 33 national unions had become affiliated with the CIO. Moreover, its total membership reached nearly 2 million, and it claimed 5 of the 10 largest unions.

Wartime activities stimulated the growth of both the CIO and the AFL. During the Korean War in 1953, CIO membership reached its all-time high of nearly 5 million workers from the auto and steel, clothing, textiles, communications, and electrical industries. The AFL also increased its membership from 3 million in 1937 to 6.8 million in 1944. Although CIO expansion leveled off in 1947, the AFL continued to grow from 8.5 million in 1947 to 10.5 million in 1955.

As strike activity skyrocketed following World War II, the U.S. business community, now recovered from the Depression, stepped up efforts to undo the Wagner Act, which was amended after President Truman intervened to settle disputes in the coal mining, railroad, and steel industries. The National Labor Relations Act of 1947, also called the Taft-Hartley Act, followed shortly thereafter, amending the controversial Section 8 by clarifying what were considered unfair labor practices by unions and employees; the Wagner Act had covered only unfair practices by employers and allowed management greater opportunity to interfere with unions’ choice of representatives for collective bargaining than had been allowed by the Wagner Act.

After a 20-year separation, the AFL and the CIO merged into a single organization, the American Federation of Labor and Congress of Industrial Organizations, on 5 December 1955. The new federation consisted of 138 unions, 108 from the AFL and 30 from the CIO, and a combined membership of 16.1 million. Two major

union movements have occurred since the 1955 merger. The first was the expulsion of the Teamsters. Embarrassed by the alleged connection of Teamsters president Jimmy Hoffa with organized crime, the AFL told Teamsters leaders to remove Hoffa from office. The Teamsters refused, and in December 1957, they were suspended from the federation; as a result, the AFL-CIO lost 1.5 million members and \$900,000 in annual dues. Ten years later, the United Auto Workers left the federation due to disagreements between then-UAW president Walter Reuther and the leadership of the AFL-CIO under George Meany. However, both groups were reinstated into the AFL-CIO, the UAW in 1981 and the Teamsters in 1987.

Union membership expanded steadily in the post-World War II years until the recession of the late 1950s, when it declined from just over 17.5 million to 16.5 million members by the early 1960s. The period from the mid-1960s to the late 1970s saw a steady and substantial growth in the number of union members, peaking at about 24 million workers in 1977. From 1978 through the mid-1990s, however, union membership plummeted, reaching lower levels than in the worst years of the early 1960s. Looking at union membership as a percentage of the private sector labor force yields less of a roller coaster, because this ratio declined in almost all years after 1955, though at an accelerated rate after the mid-1970s. In 1997, only 14.1 percent of full-time wage and salaried employees were unionized.

The decline in union membership was associated with a number of factors that led to a substantial transformation of labor-management relations in the United States. Among these factors were intensified global competition, substantially slower average growth rates for the economy as a whole, declining real wages, the deregulation of key industries, the shift in employment from the industrial to the service sector and from the union strongholds of the Midwest and Northeast to the Sunbelt states, greatly increased antiunion efforts on the part of employers, and reduced resources devoted to organizing on the part of unions.

Membership Trends. In 1999, labor unions claimed 13.9 percent of the U.S. workforce, or 16.48 million members, an increase of 265,000 over 1998 and the largest annual membership growth in more than 20 years. Moreover, of the new members, 112,000 in 1999 were in the private sector, also a 20-year high. These numbers reflected the success of an aggressive campaign waged by organized labor, particularly the AFL-CIO, to boost union membership. After John Sweeney assumed the presidency of the AFL-CIO in 1996, the union refocused its efforts and financial resources away from lobbying and electing politicians through political action committees and toward the active recruitment of new members and building grass-roots commitments to labor.

These efforts were reflected in membership and union elections. Union representative elections totaled 3,229 in 1998, up 2.2 percent from 1997; of those, unions won 51.2 percent, compared with 50.3 percent in 1997. More notably, however, the number of workers participating in such elections escalated 8 percent in 1998, while in elections won by unions, that figure was 26.2 percent, demonstrating the heightened viability of participatory democracy in organizing activities. Unionization rates are highest among African Americans, at 17.2 percent; in comparison, 13.5 percent of whites and 11.9 percent of Hispanics are unionized.

Unions also created programs to focus recruitment efforts on industries with traditionally low union representation. In addition to agricultural workers, the occupations with the lowest unionization rates were in financial, insurance, and real estate sectors, where only 2.1 percent of the workforce was unionized. Another challenge was to make unionization more attractive to the booming high-tech sector.

Although increasing union membership numbers constituted good news for labor leaders, the growing membership ranks in the late 1990s were commensurate with the expanding job market in the United States. The inability of new union membership to outpace job growth was generally attributed to mergers and acquisitions, which result in layoffs and increased leverage on the part of management and to the closing of factories as companies shift production facilities overseas. The impact of NAFTA in the mid- and late 1990s had a tremendous influence on the number of union members, with many workers losing their jobs from foreign competition and downsizing as well as plants closing. Consequently, unions no longer dominate entire industries—like automobiles, steel, and rubber—as they once did. The United Steelworkers even filed suit to have NAFTA declared unconstitutional, noting that the treaty failed to receive the two-thirds majority vote in the Senate necessary to ratify a treaty. Although NAFTA is indeed a treaty, Congress had previously stipulated that trade pacts could be passed by a mere majority in both houses. The petition was rejected, but a federal judge ruled that the union did have the standing to bring such a suit to court. While only a marginal victory, the action was indicative of labor's emboldened stance in rejecting the particular form of corporate globalization that has characterized the national and international economy in recent years.

Public vs. Private Sector. Although union membership has declined in the private sector, it has grown in the public sector. In 1958 only 12 percent of the public sector was unionized; by 1999, approximately 37.3 percent of the public sector workforce was unionized. By contrast, 35 percent of the private sector workforce belonged to a union in 1958, whereas only 9.4 percent belonged in

1999. By 1999, approximately 42 percent of all union members worked in the public sector.

Merging Unions. Technological advances have made certain trades obsolete and have led many unions to merge with others in order to boost membership and power. For example, the Retail, Wholesale and Department Store Union was combined with the United Food and Commercial Workers. The Allied Industrial Workers joined the United Paper Workers. Additionally, Communication Workers of America (CWA) merged with the National Association of Broadcast Employees and Technicians, which absorbed the International Typographical Union earlier in 1993. The CWA spent the rest of the decade on a merger and organizational tear, incorporating small machine shops, newspaper guilds, and a host of other organizations into its ranks. The United Auto Workers, meanwhile, scooped up occupations as diverse as writers, clerical employees, and farm-equipment manufacturers. As technological developments continue to squeeze out occupations and force workers to retrain, unions are likely to find it more economical to broaden their membership criteria and pool resources to cast a net over a wider area and keep pace with rapidly altering workplace conditions.

Emerging Unions. By the late 1990s, professions that traditionally found little use for unionization were beginning to see advantages in organizing. Health care workers, for example, greatly expanded their unionized ranks in 1999. The nation's largest union representing these occupations, the Service Employees International Union, doubled its rate of representation for this sector in the late 1990s, reaching 105,000 nurses, 20,000 physicians, and about 545,000 workers in health care related positions. Moreover, the American Medical Association, along with various associations representing nurses, doctors, and other health care workers, made moves toward unionizing in order to gain leverage against health care managers and insurance companies that they felt were exerting excessive influence over the health care system, thus compromising patient care. Meanwhile, unionization was being explored in the high-technology industry at such firms as AT&T and Microsoft.

Clinton Administration. Organized labor played an important role in electing Bill Clinton as president in both 1992 and in his reelection in 1996. After 12 years of strained relations with Republican administrations, initiated by President Reagan's firing of the striking air traffic controllers in 1981 and encompassing relaxed enforcement of laws against firing of organizing workers, labor unions hoped that the Democratic Clinton administration would be more sympathetic to their interests. The administration convened the Dunlop Commission to study labor-management issues in the United States. The Com-

mission's findings revealed extraordinary antiunion bias in the U.S. economy. Among its findings, the Commission reported that illegal firings occurred in one out of four union election campaigns, compared to 1 in every 20 elections in the 1950s; only two-thirds of union-certified elections were recognized by employers agreeing to negotiate contracts, whereas employers incurred no monetary penalty for refusing to engage in good faith bargaining; and, in general, recourse to legal relief through the courts was not an option for a majority of employees, whose low income levels precluded them from paying the high costs and contingency fees required by private lawyers. In response to such reports, President Clinton issued an Executive Order in 1995 banning the hiring of permanent strike replacements by certain federal contractors, later called the Workplace Fairness Act.

Although unions were generally pleased with such federal action, trade remained a sticking point between organized labor and the administration throughout the latter's terms. Clinton's strong endorsement of the North American Free Trade Agreement (NAFTA) in 1994 infuriated many union leaders, who worried about the dramatic shifting of U.S. production facilities to neighboring Mexico. Likewise, the administration's strong support of furthering the U.S. commitment to and reach of the World Trade Organization (WTO) alarmed unions, who saw in the WTO a vehicle through which businesses could force wages downward and jeopardize job security by seeking out the cheapest market worldwide in which to conduct their operations. Nonetheless, the AFL-CIO exhibited its desire for a continuation of Clinton-style policies with regard to labor, registering an early endorsement of Vice President Gore in his presidential election campaign.

Associate Membership. In an attempt to expand its member base, the AFL-CIO created a new category of worker, called an "associate member." This type of membership was created for people who do not work in a union shop but want to be affiliated with a union and participate in its benefits program. Moreover, the AFL-CIO became more like a social service organization offering credit cards, legal advice, life insurance, travel services, health benefits, and high interest-yielding saving accounts. This associate status program was particularly designed to help attract white-collar workers who have been wary of unions because of their blue-collar, industrial image. The unions also hoped to attract former members who have taken nonunion jobs, as well as other union loyalists.

Labor leaders have also created worker associations as a strategy for attracting new union members. These are union-backed organizations that have refrained from collective bargaining and confrontation. Instead, they offer assistance with a variety of workplace issues, such as pay

equity, health care, job training, and family leave. These groups also provide legal advice, language tutoring, and skills training. Unions hoped that such associations would reach unorganized segments of the workforce and give them a foot in the door at workplaces that had shut them out. By the late 1990s, these grassroots organizations had nearly 1 million members. Analysts believe that unions will have to continue with these alternative forms of membership and services if they want to keep pace with the expanding workforce.

Workers' Centers. Another form of labor organization that achieved growing popularity through the 1980s and 1990s were workers' centers. These organizations are centered on communities, rather than specific industries, and effectively bypass unions altogether to incorporate workers in trades without much established union presence. Further, these centers are especially vibrant among immigrant and ethnic-minority laborers who face particular forms of discrimination in the workplace and are often turned away from the larger unions. In the early 1980s, Korean, Chinese, Vietnamese, and Filipino women in San Francisco established the Asian Immigrant Women Advocates to conduct educational workshops on labor laws and rights for Asian women working in a variety of occupations, particularly in hotels. In New York, the Latino Workers Center conducted similar operations for workers in garment factories, groceries, health care institutions, and other occupations from the Latino community. The center also helped organize a series of protests against abusive labor practices, filed suit against employers to the Department of Labor, and even established radio and television networks to educate their community on labor and immigration issues.

The growing tendency among U.S. businesses to replace regular employees with lower-paid temporary workers has created a growing demand for organization of contingent employees. In Massachusetts, unions and community groups combined to form a Campaign on Contingent Work, establishing a workers center known as the Temporary Employees Meeting Place (TEMP) in 1996 to promote education for and solidarity among contingent workers, who have found it exceedingly difficult to organize in the past due to the unstable nature of their employment patterns.

Strikes. Strike activity generally paralleled the decline in union membership during the 1980s and 1990s. In 1997, for example, there were 29 strikes involving 1,000 or more workers, drawing a total of 339,000 workers. By way of comparison, 255 strikes of similar scale took place in 1979, involving a total of approximately 1 million workers.

The late 1990s, however, witnessed a resurgence of union militancy along with heightened emphasis on re-

cruitment. In 1998, some 5.1 million working days were lost for workers involved in all strikes, representing the first time that figure had increased since 1994. Moreover, the 34 major strikes involved an expanded 387,000 workers. Although these numbers remain low by historical standards, a series of high-profile work stoppages through the mid- and late 1990s helped garner labor unions renewed public acknowledgement as an influential force in the U.S. economy.

In the mid-1990s, amidst continued deflation of union membership and a general sense of decline in the significance of unions in general, situations emerged signaling that rumors of organized labor's demise had been premature. From 1995 to 1996, Bridgestone/Firestone Company squared off against the United Rubber Workers union in a strike that assumed symbolic import for the state of labor in the United States. The URW struck to maintain "pattern bargaining," whereby Bridgestone workers were to receive compensation and conditions on a par with workers at Goodyear, Bridgestone's more profitable competitor. Bridgestone rejected any such agreement, and the dispute evolved into a 27-month quagmire that saw the URW, by turns, nearly epitomize the death of organized labor and then symbolize its resurgence.

When Bridgestone mobilized several thousand strikebreakers in 1995, some union locals voted to return to work without any concessions, though few workers were actually rehired initially. When Bridgestone registered a significant recovery through 1995 and more strikers were called back to work, the URW regrouped and merged allied with the sympathetic United Steel Workers. Subsequent pressure on the company threatened contagion and proved embarrassing to the thriving Bridgestone. Soon all workers were rehired by the company with massive concessions.

Following this display of union vitality, the Teamsters called a strike against United Parcel Service (UPS) in 1997. After accepting a two-tier wage system at the company in the early 1980s, whereby part-time workers received significantly lower wages than full-timers, UPS drastically reorganized its workforce, boosting its reliance on part-time employees from 42 percent of all workers in 1986 to more than 60 percent in 1997. More than 10,000 workers classified as part-time, furthermore, actually worked at least a full work week. When UPS failed to sign a new contract creating more full-time jobs and subsequently proposed to assume control of the union's pension plan, the Teamsters initiated the largest U.S. strike in 20 years. The move proved extraordinarily successful for the union; although only 5 percent of all Teamsters crossed picket lines, UPS lost about \$30 million daily, and public support for the strikers was markedly high, at 55 percent, compared with only 27 percent

in favor of UPS, according to a *USA Today*-CNN-Gallup poll. After two weeks, UPS bowed to almost all the union's demands. The strike initiated dramatically heightened public concern over the trend toward contingent labor.

After the UPS victory, strikes proliferated throughout the nation. Only a small handful achieved the kind of spotlight generated at UPS, such as the 54-day strike at General Motors in the summer of 1998. But clearly strikes returned as a popular and, in the eyes of labor unions, effective strategy for winning concessions and demands from management.

Labor-Management Relations. One factor encouraging the abundance of strikes was the tight labor market of the late 1990s. With unemployment at the lowest point since the early 1960s, businesses found it difficult to hire replacement workers as the pool of available employees was fairly shallow. Companies thus reacted with greater reliance on networked production, whereby in-house operations are streamlined and downsized in favor of contracting work out to other companies both in the United States and abroad. General Motors, for example, spun off its Delphi Parts unit shortly after the 1998 strike, establishing it as a separate firm and replacing the factories with new models designed to make greater use of subcontractors, thus sidestepping its unions. Overall, companies trying to remain competitive in an ever-opening market, in which few restrictions are placed on investment and relocation of operations, sought the greatest cost-benefit efficiency and thus were relying more heavily on cheaper foreign labor or contingent domestic labor.

Indeed, competitive pressures weighing on businesses have nearly guaranteed more drastic measures taken by unions. Constantly looking for the cheapest labor markets around the world, firms who fail to exploit available cost-savings opportunities risk losing market share to shrewder competitors. Recognizing the potential confrontations this situation could force with labor, corporate lockouts became almost as numerous as employee strikes by the late 1990s, as companies wielded the power afforded by the ability to transport work elsewhere in order to stave off pressure from unions. This tactic carried the further advantage of denying unions the ability to strategize a strike in accordance with their resources.

CURRENT CONDITIONS

Union membership continued to decline in the early 2000s, continuing an overall trend that began several decades ago. According to the U.S. Department of Labor, union membership ranks decreased by 280,000 workers in 2002, reaching 16.1 million. The percentage of wage and salary workers belonging to unions fell from 13.4 percent in 2001 to 13.2 percent in 2002. According to

industry analysts, the decline in union membership mirrors a decline in the manufacturing sector. Thus, in light of this trend many unions were targeting the service industry in the early 2000s in hopes of maintaining or growing their ranks.

According to *HR Focus*, information from the National Labor Relations Board and Washington, D.C.-based BNA PLUS reveals that the number of union representation elections in the first half of 2002 numbered 1,215. This was virtually unchanged from the same period in 2001. However, in the 2002 period unions won a higher number of elections (697) than in 2001 (664). This was achieved in spite of a decrease in the number of eligible voters, which fell to 79,433—a decrease of 10,250 voters from 2001. BNA PLUS also indicated that, based on previously negotiated union contracts, the average union wage increase was expected to be 3.5 percent in 2003, up from 3.4 percent the previous year (excluding bonus payments and cost-of-living increases).

Despite their declining membership ranks, unions are still a powerful economic force. This is especially true in states like Alaska, Hawaii, Michigan, and New York, where anywhere from 20 to 25 percent of workers belong to unions. Unions continue to have considerable leverage in the transportation and automotive sectors. For example, when the International Longshore and Warehouse Union failed to come to terms with the Pacific Maritime Association in the fall of 2002, dockworkers at 29 coastal ports staged a lockout that lasted 10 days. The lockout created a number of significant problems. Hundreds of ships were stranded, leading to congestion at area seaports. In addition to losses that some industry observers estimated would cost shipping companies anywhere from \$400 to \$600 million, the lockout had a more severe impact on the larger U.S. economy. For instance, during the lockout *JoC Online* reported: “Analysts and business leaders have warned the shutdown will cause a noticeable increase in plant closings, job losses, and financial market turmoil. Already, storage facilities at beef, pork and poultry processing facilities across the country are crammed with produce that can’t be exported.” The publication revealed that the lockout’s overall impact on the U.S. economy could range in the billions of dollars.

Even smaller unions have the ability to wreak economic havoc when disagreements lead to work stoppages. In March 2003, Broadway musicians walked off the job following squabbles with theater owners about decreasing orchestra sizes. When stagehands and actors failed to cross picket lines, some 18 musicals were cancelled for four days, resulting in an estimated loss of \$10 million for New York theaters. When related business at area restaurants and shops was factored in, some estimated that the strike could have cost the city as much as \$50 million per week. To avoid such a situation, Mayor

Michael Bloomberg worked actively to resolve the dispute.

By the early 2000s, the debate continued over the necessity of labor unions. Some experts argued that unions were a negative economic force. According to *Manufacturing News*, Lowell Gallaway and Richard Vedder of Ohio State University conducted a study that indicated that, over the past 60 years, unions cost the American economy \$50 trillion. The study argued that the monopolistic hold of organized labor in a number of industry sectors—including transportation, manufacturing, construction, and mining—“decimated employment in those industries, increased the supply of employment in less unionized fields, and lowered their wage growth.” On the other hand, *Work & Family Newsbrief* cited more favorable results from a World Bank review of 1,000 studies regarding the impact of collective bargaining and unions. Entitled *Unions and Collective Bargaining: Economic Effects in a Global Environment*, the review found that under the right conditions, “high unionization rates can lead to lower unemployment and inflation rates, higher productivity and faster adjustment to economic shocks.” However, the study argued that unions also could have negative implications in certain circumstances.

INDUSTRY LEADERS

Since it was founded by Samuel Gompers in 1886, the American Federation of Labor (AFL) has been the leading voice of American organized labor. The organization’s influence was expanded when it merged with the Congress of Industrial Organizations (CIO) in 1955. Headquartered in Washington, D.C., the AFL-CIO has a staff of approximately 400 employees, and in recent years was affiliated with 68 unions throughout the United States. Membership numbered approximately 13 million in 2003, below the 1991 total of 13.9 million. During the early 2000s, the AFL-CIO embarked on a campaign to raise awareness among its members of developments and legislation relating to social security, the minimum wage, and Medicare.

The AFL-CIO reorganized extensively in the mid- and late 1990s following John J. Sweeney’s ascendancy to the presidency. Abandoning its Cold War era anticommunism efforts, the union began to actively promote international solidarity. Domestic union solidarity also assumed heightened priority, as the federation aimed to reduce competition between unions by offering matching grants for joint-organization campaigns. In an attempt to help develop a strong workforce for the future, the AFL-CIO has created programs through its Committee on the Evolution of Work, including training for a new generation of organizers. The federation also has developed Union Privilege, a benefits package that includes low-interest credit cards and home mortgage programs. In

partnerships with the government and private groups, the AFL-CIO Housing and Building Investment Trust has created jobs by building low-cost housing in urban areas. In 2003, the AFL-CIO represented more than 81 percent of the nation’s 16 million union workers.

The International Brotherhood of Teamsters, more commonly known as “the Teamsters,” was founded in 1903 and is headquartered in Washington, D.C. In 1991 the federal government forced the Teamsters’ first democratic election, in which Ronald Carey emerged as president of the organization. The Teamsters organization has been notorious for its corruption. Four of the six predecessors to Carey were indicted for embezzling union funds, and three leaders, including Jimmy Hoffa, were jailed. Jackie Presser was the fourth Teamsters leader to be indicted in 1986, but he died before his trial. In 1989 the union settled a racketeering suit, and in order to avoid government-imposed trusteeship the Teamsters agreed to open elections.

In the late 1990s, a series of presidential election disputes refocused attention on Teamsters controversy. Eventually, James P. Hoffa, son of the notorious Teamsters leader, emerged as president, and, after several years, was able to regitalize the union somewhat. The union had 1.4 million members in 2003, down from 1.6 million in late 1999. Still, the Teamsters remain one of the largest unions in North America, with 568 locals. The Teamsters continued to generate controversy during the late 1990s; the union was sued for damages caused by its strike of the Overnite Transportation Company, which the Teamsters waged for alleged illegal harassment and termination of workers. Northwest Airlines likewise sued the Teamsters for its “sick-out” strike over the 1999 holiday season, though Teamsters officials countered that the lack of passengers, not the sick-out, was the primary cause of flight cancellations.

The National Education Association (NEA) has become the largest professional organization and labor union in the United States, more than doubling its membership since 1968 to 2.7 million in more than 13,000 communities nationwide in 2003. Approximately 80 percent of NEA members are elementary or secondary schoolteachers. Another 88,000 are faculty members in institutions of higher education, and more than 160,000 are employed in such support positions as teacher assistants, bus drivers, cafeteria workers, and school custodians.

Founded as a professional association in 1857, the NEA became a labor union during the 1960s. The organization divides authority between rotating elected teachers, school employees, and permanent professional staff. The NEA also has 1,500 “UniServ” professionals to assist locals with collective bargaining. NEA dues were set at a fixed proportion of the average teacher’s salary.

The NEA political action committee donated \$1.8 million to candidates during the 2001-02 federal election cycle.

AMERICA AND THE WORLD

For years, the sagging membership of unions seemed to be a distinctly American phenomenon. However, in recent decades unions in all countries have been under increased pressure due to slowing productivity and economic growth, rapid technical change, and a shift to a free-market ideology. The United Kingdom, for example, shed its long-standing strike-prone image as its unions became among the least militant in the industrialized world.

United States labor unions have generally been more successful than their foreign counterparts in winning wage increases for their members. This has provided enormous incentive for U.S. employers to oppose trade unions and set up nonunion shops. Foreign groups have been less focused on wage increases and more concerned with worker council and plant-level decision making, a direction that some U.S. unions already have begun to take.

Foreign labor organizations have, however, begun to take aim at U.S. corporations themselves. As U.S. business investment spreads over more of the world's markets, many unions have aligned to object to what they see as unfair labor practices and failure to comply with U.S. labor laws. In 1999 Asian garment workers filed class-action suits in U.S. federal courts against U.S. clothing retailers and manufacturers such as Wal-Mart Stores, Inc.; Sears Roebuck & Co.; Gap, Inc.; and a host of others for their reliance on sweatshop labor, low wages, and excessively long work weeks in their Asian manufacturing facilities.

This growing international labor solidarity was equally evident in opposition to the World Trade Organization. While many foreign government and business officials claim that the WTO will help foster greater investment in less developed countries, thereby raising wages and spurring development, labor groups in these countries have countered that the WTO's provision would force less developed countries to compete with each other for foreign investment based on lower labor costs and relaxed labor standards. For the same reason, many U.S. unions object to the WTO's policies, which they view as facilitating the outflow of U.S. jobs to foreign countries and diminishing job security and wages at home.

RESEARCH AND TECHNOLOGY

Fearful of worker displacement caused by automation, many unions had been painfully slow to embrace the use of technology. Generally, unions have assumed that developing technology was not itself an antagonizing fac-

tor but the unequal benefits of that technology between labor and management. Unions have looked at technology in one of two ways: proactive or reactive. The reactive position has been used during contract negotiations. For example, when the UAW was making concessions in 1982, one of the trade-offs was computer training. The union began efforts in 1983 and by 1990 had three main training centers, one each at Ford, Chrysler, and General Motors.

With the notable exceptions of the Airline Pilots Association and the International Association of Machinists and Aerospace Workers, most unions offer technology training in conjunction with employers. For example, after AT&T laid off thousands of union workers during 1988 and 1989, the company established a training center with the International Brotherhood of Electrical Workers and the Communication Workers of America. The Alliance for Employee Growth and Development Inc. has provided a variety of computer and other job skills to unemployed union workers.

Instead of trying to compensate for outdated skills, unions in a proactive position have welcomed technology to further the goals of their members. The United Steelworkers of America, for instance, developed the Institute for Career Development, which provides members with up to \$2,500 in yearly tuition assistance for purposes of seeking additional technological training. The AFL-CIO, meanwhile, established an ambitious goal to provide low-cost computers with Internet access to all of its members. On a related note, the union launched a World Wide Web site called Workingfamilies.com in 1999 to help build public awareness of the union and its activities, promote union-made consumer items, and keep members informed of important economic and legislative issues.

921150 (American Indian and Alaska Native Tribal Governments)

624110 (Child and Youth Services)

Some of the most prominent civic, social, and fraternal organizations in the United States met with controversy in the late 1990s. Nonetheless, membership in such organizations increased nearly 20 percent between 1994 and 1999. This industrial classification encompasses nearly 50,000 local, national, and international nonprofit organizations, most of which are centered around a conception of altruism. It includes civic and fraternal associations, parent-teacher associations, singing societies, taxpayer's associations, veteran's organizations, youth groups, alumni associations, and booster clubs. The Internet has been instrumental in the establishment of new types of social organizations, including scores of activist groups, many devoted to social, environmental, and political causes. Their online networks facilitate organizing, letter-writing and fund-raising campaigns, and information sharing.

About 50 percent of all adults belong to civic clubs, with the percentage of women (50.5 percent) slightly outnumbering that of men (49.5 percent). However, males belong to fraternal organizations at a rate of nearly twice that of women (65.1 percent to 34.9 percent).

Civic and social associations are classified as tax-exempt corporations and are spared from federal, state, and local tax laws. They are usually not required to publish their income, expenses, or membership information. Most organizations rely primarily on volunteers to run their programs, and larger associations employ full-time administrative and management workers. About 460,000 workers were employed in the industry by the mid 1990s. The average association employee received an annual salary of approximately \$11,500, less than half the service industry average.

Nonprofit associations generate income through dues, fund-raisers, and interest from investment funds, or by managing endowments. In addition, some associations employ nonprofit fund-raising firms. These companies usually work on a flat-fee basis and utilize direct marketing techniques to raise money, such as telephone and mail solicitation.

Although the industry is comprised primarily of community groups, some of the largest organizations stand out as major American institutions. These include the Freemasons, Boy Scouts, American Legion, the YMCA, and the United Way.

Freemasonry. Freemasons were increasing efforts to boost their membership ranks in the late 1990s. There were about 2 million Freemasons in the United States; although this is a significant number, membership numbers declined dramatically between 1987 to 1997, falling

SIC 8641

CIVIC, SOCIAL, AND FRATERNAL ASSOCIATIONS

This category covers membership organizations engaged in civic, social, or fraternal activities, excluding homeowner groups primarily associated with property management and membership sports and recreation clubs, which are classified elsewhere.

NAICS CODE(S)

813410 (Civic and Social Organizations)

813990 (Other Similar Organizations)

by 750,000 to 2 million members. One of the largest fraternal organizations in the world, freemasonry promotes public service and belief in the brotherhood of all men under a single God. Its basis and membership, however, remain predominantly Christian.

The physical foundation of Freemasonry is the lodge, which exists under a charter issued by the Grand Lodge. Lodges are informally linked and offer different service and achievement programs. All lodges offer three basic degrees which are achieved through service and learning: Entered Apprentice, Fellow Craft, and Master Mason. Groups of advanced Masons confer as many as 30 additional degrees.

Freemasonry is believed to have evolved from medieval guilds of stonemasons. The first formal lodge was formed in London in 1717, and the first American lodge was created in Philadelphia in 1730. Freemasons have endured religious and political criticism from various churches. The Roman Catholic Church, for example, originally claimed that Freemasonry was a religion and secret organization and banned membership, but this was overturned in 1983. Recently the Freemasons have relaxed the aura of secrecy that has historically surrounded the organization in efforts to replenish membership ranks and to counter what they perceived as the widespread misconceptions about their organization among the general public.

In an effort to expand their social and charitable role, Freemasons have formed several other groups that are recognized among the largest U.S. civic organizations. The biggest of these is the Ancient Arabic Order of the Nobles of the Mystic Shrine—Shriners. Likewise, children's groups include De Molay for boys, and the Order of Job's Daughters and the Order of Rainbow for girls. Famous historical figures that were Freemasons include Benjamin Franklin, Wolfgang Amadeus Mozart, Henry Ford, Irving Berlin, Louis Armstrong, and Douglas MacArthur, along with George Washington and several other U.S. presidents.

Boy Scouts. One of the largest civic organizations in the world, the Boy Scouts is also the largest youth group; more than 99 million young males have been involved with the organization since its inception. Membership peaked at 4.8 million in 1972; the current membership contains 4.5 million youth and 1.2 million adult workers. The organization possesses a staff of about 1.1 million volunteers and a professional team of 4,000 scouters who provide training.

Founded in 1910, the Boy Scouts works to develop character, citizenship, and physical and mental fitness. It stresses duty to God, country, others, and self. The official Boy Scout slogan is "Do a good turn daily," and the motto is "Be prepared." Although the organization is

nonsectarian, scouts must acknowledge a duty to God in the scout oath.

A boy is admitted to scouting under the supervision of adult volunteer leaders. Scout troops consist of patrols, which are made up of five to eight boys. Patrol leaders and troop leaders are elected. As a scout progresses in age and rank, his role becomes increasingly self-governing, and he develops leadership skills through interaction with other scouts. Character and achievement are nurtured through community service, outdoor activities, and the attainment of merit badges, which are earned by studying and passing tests on certain subjects.

Many Boy Scouts are introduced to scouting through the Tiger Scouts, for boys aged 7, and the Cub Scouts, for boys between the ages of 8 and 10. In addition, the Girl Scouts acts as a sister organization and offers activities and goals similar to the Boy Scouts. The Girl Scouts of America has recently embarked on a campaign to promote itself as responsive to contemporary changes in U.S. society that affect girls, with programs focused on sports, science, and the eradication of violence toward youth. Both boys and girls can continue scouting activities through the Explorers, an organization for members aged 14 to 20.

The Boy Scouts was started in 1907 by Robert Baden-Powell, a British officer. After writing a book for adults about scouting, Powell received such a demand for his book that he decided to write *Scouting for Boys*. This manual became the primer for his Boy Scouts organization. The Boy Scouts of America was formed in 1910.

The Boy Scouts came under attack in the early 1990s for its refusal to admit atheists and homosexuals as scouts and scoutmasters. Levi Strauss, BankAmerica, and Wells Fargo halted their donations in defiance of the group's homosexual ban. President Clinton became the first U.S. president in recent history to not address the national Jamboree or send his vice president. In addition, the city of Chicago canceled its sponsorship of the group. Nevertheless, the organization prevailed in several lawsuits filed by nonmembers for refusing to admit atheists, claiming that as a private organization, it is free to establish its own membership criteria. Critics often noted, however, that the group is sponsored by public schools and municipal organizations and should be subject to anti-discrimination provisions. In other countries, the theological portion of the oath has been either eliminated or made optional. Lawsuits and controversy have continued into the late 1990s. In 1999, New Jersey struck down the ban on homosexuals after four other states had upheld it. The Supreme Court expected to rule early in the twenty-first century on whether the Boy Scouts' denial of admission to a class of people amounts to a constitutional violation.

The highest rank attainable in the Boy Scouts is Eagle Scout. Many of the nation's most successful lead-

ers hold this distinction, including astronauts, former presidents, business leaders, and creators. Gerald Ford, Sam Walton (founder of Wal-Mart), Steven Spielberg, and H. Ross Perot were examples of Eagle Scouts still living in the early 1990s. The 104th Congress of the United States has boasted 23 Eagle Scouts, with 302 members total having participated in scouting.

American Legion. The American Legion is the largest private U.S. organization for veterans. It is comprised of veterans from both world wars and the wars in Korea, Vietnam, and the Persian Gulf. The Legion is concerned primarily with the social and political interests of veterans, but it also sponsors numerous community and charitable programs, such as the Family Support Network. This program was launched in 1990 for the Persian Gulf War troops and remains active for other troops stationed around the world. Its four stated major areas of focus are: rehabilitation of veterans through medical and educational benefits; national security; child welfare; and Americanism. The organization strongly promotes respect for the U.S. flag, having drafted the U.S. Flag Code in 1923 establishing guidelines for the proper uses and treatment of the flag. The American Legion also works to fund and promote other civic associations included in this industry group, such as the Boy Scouts.

The American Legion represents 2.9 million male and female members in nearly 15,000 posts worldwide, with a full-time staff of 300. Membership is contingent upon performance of honorable service in the U.S. armed forces. The Legion's sister organization, the American Legion Auxiliary, founded in 1920, had approximately 1 million members. Its participants are women who are close relatives of Legionnaires or of deceased veterans and women who have served in the armed forces during peacetime. The Sons of the American Legion (about 180,500 members in 1995) is comprised of male descendants of Legionnaires and deceased veterans.

Because of its membership size and the percentage of its members that are registered to vote, the American Legion has constituted a powerful political block. It has served as a loud voice for veterans' rights and military preparedness. It has been a leading proponent of legislation against desecration of the American Flag since the 1960s, continuing into the 1990s. It has helped veterans receive proper medical care for illnesses that may be related to wartime environments, such as nerve gas during the Persian Gulf War in 1991. In the 1990s, the Legion campaigned to increase hospital coverage funded by the Department of Veterans' Affairs to include veterans' dependents.

YMCA. The Young Men's Christian Association (YMCA) is one of the largest associations in the world. With 2,283 YMCAs, it is also the largest non-profit

community-service organization in the United States. The YMCA is a network of nonsectarian organizations that offer athletic, recreational, cultural, educational, and health-related services to their members and local communities. YMCAs provide vocational instruction, organize sports programs, offer civic training, give night classes, and host social events. YMCAs also make their facilities available to community groups and rent cafeterias and rooms to transients and local residents.

The YMCA was founded in England in 1844, while the first YMCA in the United States was started in Boston in 1851. The World Alliance of YMCAs is headquartered in Switzerland, serving more than 30 million international members in 120 countries. There were approximately 16.9 million members in the United States in 1999, up from 14.5 million just four years earlier. They rely on more 515,720 volunteers and 20,000 full-time staff, and are funded by a combined operating budget of \$3.1 billion, drawn from fees for Y programs, membership dues, charitable contributions, and resident fees. Its sister organization, the Young Women's Christian Association (YWCA), was formed in 1855 to meet young women's physical, intellectual, and spiritual needs. But after World War II, women and girls were admitted to the YMCA, as well. By 1996, almost one-half of YMCA members and staff in the United States were women; also, one-half of all members were 18 years or under. The 326 YWCAs provide shelter for women and their families, and spearhead campaigns for domestic-violence prevention. They offer programs and services to about 700,000 women and children annually.

United Way. Another of the biggest organizations in this industry is the United Way, which is largely a fundraising organization that gives money to national and community service groups. Raising \$3.1 billion annually by their over 300,000 volunteers, it provided money to more than 50,000 agencies of health and human services needs in 1997. Fifty-two million people contribute annually to about 2,200 local United Way agencies.

Other Groups. The Knights of Columbus is a U.S. fraternal order of Roman Catholic men promoting itself as "the strong right arm of the Church." It was founded in 1882 by Michael J. McGivney, a Connecticut priest. Best known for their charity work within communities, it provides social activities, insurance, and other benefits for its members. It also sponsors athletic events, contributes to various charitable and educational projects, and works to promote Catholic interests. The group had approximately 1.6 million members in more than 12,000 local councils throughout the Americas in the late 1990s.

The Humane Society of the United States includes about 7 million supporters and established, with Salomon Brothers Asset Management, the Humane Equity Fund in

the late 1990s, which refuses to invest in firms whose practices the Humane Society considers to be detrimental to the welfare of animals. The Humane Society has contributed \$8 million to the fund.

Other organizations include university fraternities and sororities, the Elks Club, Lions Club, and the Parent-Teacher Association.

SIC 8651

POLITICAL ORGANIZATIONS

This classification includes membership organizations established to promote the interests of a national, state, or local political party or candidate. Also included are political groups organized to raise funds for a political party or individual candidates. Fund-raising organizations operating on a contract or fee basis are classified in **SIC 7389: Business Services, Not Elsewhere Classified**.

NAICS CODE(S)

813940 (Political Organizations)

INDUSTRY SNAPSHOT

The most prominent type of political organization is the political action committee, or PAC, which gradually came to replace the smaller localized political parties so prevalent in the nineteenth and early twentieth centuries. PACs are organized to pool the financial resources of a group of individuals or institutions with a common interest in order to disperse those funds toward political activities or candidates deemed by the PACs’ organizers as conducive to the ends sought. PACs are usually, but not always, organized by corporations or people within an industry, such as oil companies, dairy farmers, banking institutions, or labor organizations. PACs contribute funds to politicians in hopes of gaining their support for

legislation to advance the PACs’ interests; some of the larger PACs focus on gun control, equal rights, or abortion rights. Corporate PACs have long been the leading contributors to political campaigns. Election-campaign funding has become a hot political topic in recent years, as many questioned the political influence that PACs and other interests wield in the political process.

A 1974 law passed by Congress fueled a dramatic increase in the formation of PACs. In 1986 there were 608 PACs, but by the end of 2002 the number of PACs had grown to almost 4,600. PACs delivered \$282 million in contributions to federal candidates for the 2002 elections, up from \$259.8 million in 2000. The majority of these contributions (75 percent) went to candidates for the U.S. House of Representatives. Republican candidates enjoyed \$145.3 million in contributions, while Democrats trailed with \$136.5 million. PACs raised a total of \$685.3 million during the 2001-02 election cycle, a 13 percent increase from 1999-2000.

In recent years ideological or issue-oriented PACs have become popular. In contrast to groups that contribute directly to candidates, these PACs donate funds to organizations aligned with their interests in an effort to sway public opinion. Such organizations typically produce radio and television commercials and direct mail campaigns on controversial issues, including the right to abortion, prayer in schools, and gun control. Unlike corporate and labor union PACs, which may use money from the treasuries of their members, ideological PACs foot their own administrative costs. Because these groups are not contributing directly to candidates, they are not bound by many of the usual limitations on PACs.

ORGANIZATION AND STRUCTURE

PACs fall into five general categories: those formed by unions; trade associations and industry groups; corporations; cooperatives; and ideological PACs, which pursue specific political causes. For the most part, PACs may only solicit their own members for contributions. PACs are heavily regulated by the Federal Election Commission (FEC) and must keep accurate and detailed records of receipts and expenditures. One of the most efficient ways of collecting donations for PACs is through automatic deductions from members’ paychecks—the checkoff method. PACs may donate up to \$35,000 to a particular candidate in an election season and \$15,000 to a national party committee, as well as a maximum of \$5,000 to another PAC.

Although some commentators applaud the fact that PACs involve citizens in the political process, others argue that PACs rarely offer opportunities for people to do more than donate money. Most PACs have small boards or committees deciding how the contributions will be spent or which candidates will receive contributions.

This structure has caused some to argue that control of PAC contributions is relinquished to just a few people within the organization, which may present opportunities for abuse or misrepresentation. Another common complaint about PACs, especially in recent years, concerns the perception that they often have enjoyed too much influence in America's legislative bodies.

In an attempt to maximize their influence, most PACs channel their energy to the most powerful members of the congressional committees affecting their industry. For example, in 1986 PACs advancing the interests of banks and other financial institutions made contributions totaling more than \$3.4 million to members of the House and Senate banking committees. In 1998, the total contribution to the elections of congressional members sympathetic to financial causes was \$35.2 million. PACs are also much more likely to donate monies to incumbents, who are historically difficult to unseat. Until 1994, incumbents seeking reelection in the U.S. House of Representatives had a 98 percent victory rate; since then, election results have continued to tilt overwhelmingly in favor of incumbents.

BACKGROUND AND DEVELOPMENT

The development of modern campaign financing laws can be traced back to 1896, when scandals began to affect presidential elections. In the 1896 presidential campaign, assessments against corporations imposed by Republican National Chairman Mark Hanna filled William McKinley's campaign coffers. This was followed by the disclosure that McKinley's successor, Theodore Roosevelt, had received a secret \$50,000 contribution from a New York insurance company in 1904. This election ignited national headlines and prompted Roosevelt to call for campaign reform, urging public financing of congressional and presidential elections. Congress responded by passing the Tillman Act of 1907, which prohibited business groups from making contributions to candidates for federal office. Campaign reform was broadened with passage of the Federal Corrupt Practices Act of 1925, which placed limits on contributions and required disclosure of receipts and expenditures by federal candidates.

The modern PAC is somewhat of a newcomer to the U.S. political scene. In the 1930s, newly formed labor unions began to see the advantages of becoming involved in politics. In 1936 organized labor contributed \$750,000 to Democratic candidates, with most of the funds coming from union dues. But in 1943, Congress passed the Smith-Connally Act, which barred unions from making direct contributions in federal elections from their treasury funds. However, these laws were difficult to enforce. Both labor unions and corporations began to establish separate accounts with which to make political

contributions—such activity foreshadowed the rise of the modern PAC.

The first PAC was formed by organized labor in 1943 when the AFL and CIO merged, forming the Committee on Political Education. These labor organizations were able to operate these PACs because they used political funds rather than union dues. This laid the groundwork for other labor PACs, which began to proliferate shortly thereafter. By 1956, 17 labor PACs contributed \$2.1 million to political candidates. In 1982, the number had risen to 288 labor PACs, which contributed \$20 million to federal candidates. In 1995, there were 332 labor PACs contributing \$26 million to federal campaigns.

In the 1960s, corporations began to organize their own PACs. The first major PAC to be organized was the American Medical Political Action Committee (AM-PAC), formed in 1961 by the American Medical Association, followed by the Business Industry Political Action Committee (BIPAC), organized in 1963 by the National Association of Manufacturers. Prior to this, most political contributions were made by wealthy individuals. For example, in 1956, 199 executives from 225 corporations contributed more than \$1.9 million to federal candidates.

In 1972, Congress enacted the Federal Election Campaign Act, which superseded previous federal campaign regulations and was the catalyst for the tremendous growth of PACs in subsequent decades. The Federal Election Campaign Act (FECA) included the following key features: it limited the total amount a federal candidate could spend on media advertising to \$50,000; it required disclosure of all contributions in excess of \$100; it required committees and candidates to file reports of contributions and expenditures; and it required television stations to sell candidates time at the lowest unit cost provided to commercial advertising customers.

The most important part of the law for the PACs was the Hansen Amendment, which enabled union and corporate treasury money to be used for overhead in operating PACs. It also provided business and labor organizations with the right to solicit voluntary funds from members, employees, and stockholders. This gave PACs the power to be involved in federal elections and had the effect of institutionalizing the role of PACs within the political process. The Hansen Amendment became the springboard for the proliferation of PACs because it enabled corporate coffers to finance PACs' often considerable administrative expenses. It was estimated that in the 1984 election, some PACs spent \$75 million, roughly one-fourth of their expenditures, on administrative expenses. And as television advertisements became the primary medium for articulating their viewpoints, campaign costs rose meteorically.

Concern about large monetary gifts to candidates peaked in the aftermath of the 1972 presidential election, when it was revealed that 124 donors gave \$17 million to help reelect Richard Nixon, and several individuals contributed a combined amount of \$200,000 to George McGovern's campaign. This resulted in amendments to FECA in 1974 that established new contribution and spending limits. But in 1976, Senator James Buckley, together with Eugene McCarthy and philanthropist Stewart Mott, challenged the law, claiming that limits on campaign contributions were an infringement on the right to free speech. The U.S. Supreme Court agreed and struck down much of the law. Thereafter, groups and individuals could spend as much as they wanted to support or oppose a candidate. Later amendments to the law increased spending limits by candidates who accept public financing and required PACs and candidates to keep accurate records of receipts and expenditures.

A primary reason for the explosion of PACs was skyrocketing campaign costs. In 1974, all of the U.S. House and Senate candidates spent a combined total of \$77 million on their campaigns. By 1982, that figure had jumped to \$343 million—an increase of nearly 500 percent. And, according to the FEC, Congressional campaign spending climbed to \$626.4 million during the 1996 elections.

In 1996, PACs gave \$98.3 million to Congressional incumbents but only \$12.5 million to challengers. For many years, Democrats enjoyed the majority of PAC contributions, but that trend reversed during the 1995-96 election cycle, when Republicans received \$118.6 million compared with the Democrats' \$98.85 million. Republicans continued to outpace their Democratic rivals in contributions receipts in 1997-98. This shift is primarily attributable to the enormous Republican gains in the congressional elections of 1994, which gave them a substantial majority in both houses. Because PAC contributions flow disproportionately to incumbents, Republicans were poised to enjoy healthy contributions through the 2000 elections.

Corporate PACs contributed a total of \$78 million to candidates during the 1997-98 election cycle, of which 85 percent went to incumbents. Republicans received 68 percent of these donations, whereas Democrats received 32 percent.

Among industry groupings, contributions in 1997-98 were as follows: agribusiness contributed \$15.6 million; communications and electronics gave \$11.94 million; construction interests donated \$8.3 million; PACs representing the defense industry gave \$5.8 million; energy and natural resources concerns contributed \$14.85 million; finance and real estate bestowed \$35.2 million; health PACs supplied candidates with \$18.3 million; lawyers and lobbyists allotted \$7.7 million; transporta-

tion interests contributed \$14.4 million; and other business interests gave \$17.3 million. With the exception of lawyers and lobbyists, all groups' contributions tilted heavily in favor of Republicans.

Labor PACs maintained a strong presence during 1997-98, contributing a total of \$44.6 million. The vast majority of these donations (91 percent) went to Democrats, whereas most of the rest went to Republicans, with only a fraction left over for other candidates. Trade and membership association PACs contributed \$62.3 million, of which 81 percent was given to incumbents, 62.3 percent to Republicans, and 37.6 percent to Democrats. Cooperative PACs donated 91 percent of their \$2.4 million in total contributions to incumbents. Republicans took in 51 percent of the total, and Democrats received 48 percent. Issue-oriented PACs fortified their growing influence in 1997-98, contributing a total of \$28.15 million: 60.4 percent to Republicans and 39 percent to Democrats; 61 percent went to incumbents.

Political organizations have flourished on the World Wide Web, where a series of sites cropped up in the late 1990s devoted to mobilizing political support for issues and candidates. Furthermore, many sites, including Voter.com, Gay.com, Politicallyblack.com, and LatinoVota.com were designed specifically to raise political awareness and enhance voter turnout among specific demographic groups.

CURRENT CONDITIONS

PACs increasingly dominate Congressional elections and provide security for incumbents. In 2002, PACs gave \$213.4 million to Congressional incumbents but only \$28.5 million to challengers. Another \$40.2 million in contributions went to open seat elections. However, many legislators, including those who accept PAC contributions, regard PACs as a necessary evil because of the cost of campaigning. PACs, by their very nature, most often represent the interests of the wealthy and staunchly ideological.

Republications continued to enjoy the majority of PAC contributions in the late 1990s and early 2000s, maintaining the leadership position secured by the party in 1995-96. In 1999-2000, Republications received \$133.6 million to the Democrats' \$123.1 million. In 2001-02, Republicans received \$145.3 million to the Democrats' \$136.5 million. Of the nearly 4,600 PACs operating in 2001-02, those categorized as corporate PACs were greatest in both number (1,741) and receipts (\$191.7 million). Nonconnected PACs were the second largest category, with 1,401 committees and \$166.7 million in receipts. Trade/membership/health PACs were the next largest, with 956 committees and \$145.8 million, followed by labor PACs (337, \$167.8 million). PACs representing corporations without stock and cooperatives

rounded out the remaining 159 committees, which accounted for combined receipts of \$13.4 million.

With the explosive growth of PACs has come cries for campaign finance reform to prevent special interest money from controlling the electoral process. Critics have called for anti-PAC legislation aimed at curtailing campaign expenditures, worried that the influence of wealth would determine what candidates came to office and what policies they would support once elected. Moreover, critics contend, PAC sponsors enjoy disproportionate access to candidates, further marginalizing the general public from the political process. Opponents of such legislation have raised possible First Amendment concerns, asserting that contributing money to political campaigns amounts to free speech. Therefore, they claim, laws limiting such contributions would effectively infringe on contributors' constitutional rights.

So long as members of Congress benefit from the contributions of PACs, reform will be difficult to achieve. In recent years, many bills designed to curb the influence of political action committees have been introduced in Congress. In March of 2002, one was finally signed into law. Effective on November 6, 2002, the Bipartisan Campaign Reform Act of 2002 (BCRA) resulted in significant changes to federal campaign finance law. BCRA also is known as the McCain-Feingold Bill, because U.S. Senator John McCain (R-Arizona) and U.S. Senator Russell Feingold (D-Wisconsin) were instrumental in developing the legislation. According to a press release issued by his office, upon the bill's passage in the U.S. Senate, McCain touted: "With the stroke of the President's pen, we will eliminate hundreds of millions of dollars of unregulated soft money that has caused Americans to question the integrity of their elected representatives."

Although McCain's words were inspiring to some, who considered the law a victory, others—Democrats and Republicans alike—were critical of BCRA. These opponents filed lawsuits at the federal level, calling the law unconstitutional on First Amendment grounds. As consumer advocacy organization Public Citizen explained: "Within a month of passage of the new campaign finance law, 84 plaintiffs—ranging from Sen. Mitch McConnell (R-KY) to the AFL-CIO to the Republican party—filed 11 different lawsuits challenging every provision of the Act. The U.S. Department of Justice and the Federal Election Commission are the lead defendants in the suits, supported in their defense of BCRA by the principal congressional sponsors of the law, who intervened in the case. All the lawsuits were consolidated into one case, *McConnell v. FEC*." In May of 2003, the United States District Court for the District of Columbia issued a 1,648-page decision in *McConnell v. FEC*, and the case was appealed to the U.S. Supreme Court.

PACs continue to influence legislation and elections, and polls show that Americans view PAC lobbying as a significant problem in the current legislative process. Studies by the U.S. Public Interest Research Group show that time and again, those who receive PAC donations from a particular industry are more likely to vote in alliance with that industry. Although the issue of campaign finance reform was discussed during the 1992 Presidential and 1994 Congressional elections, only after the 1996 campaign was it seriously brought before Congress and the public by both President Clinton and Congressional leaders. By 2003, the issue was far from solved.

INDUSTRY LEADERS

The largest PACs by the early 2000s included those representing the National Association of Realtors, with contributions of \$3.65 million during the 2001-02 election cycle; the Association of Trial Lawyers of America, with \$2.81 million; the National Automobile Dealers Association (NADA), with \$2.58 million; the American Medical Association, with \$2.44 million; the American Federation of State and County Municipal Employees, with \$2.42 million; the United Auto Workers, with \$2.34 million; Democrat Republican Independent Voter Education, with \$2.33 million; Laborers' Political League-Laborers' International Union of NA, with \$2.25 million; the International Brotherhood of Electrical Workers, with \$2.21 million; and the Machinists Non-partisan Political League, with \$2.2 million.

SIC 8661

RELIGIOUS ORGANIZATIONS

This category covers organizations operated for worship, for religious training or study, for government or administration of an organized religion, or for promotion of religious activities, including religious groups reaching the public through radio or television media. Other establishments maintained by religious organizations, such as educational institutions, hospitals, publishing houses, reading rooms, social services, and secondhand stores, are classified according to their primary activity. Establishments of such religious groups that produce taped religious programming for television are covered in **SIC 7812: Motion Picture and Video Tape Production**, and those that produce live religious programs are classified in **SIC 7922: Theatrical Producers (Except Motion Picture) and Miscellaneous Theatrical Services**. Radio or television stations operated by religious organizations are classified under **SIC 4832: Radio Broadcasting Stations** or **SIC 4833: Television Broadcasting Stations**.

NAICS CODE(S)

813110 (Religious Organizations)

INDUSTRY SNAPSHOT

Religious organizations in the United States have been involved in an innumerable range of activities. In recent years, these activities have included everything

from organizing food drives for the poor, to campaigns to aid those victimized by the terrorist attacks of September 11, to grassroots measures to remove the teaching of biological evolution in U.S. science classes.

On a comparative level, the greatest number of religious organizations, and those boasting the largest membership figures, remain overwhelmingly Christian. Between the mid-1960s and the early 2000s, Catholicism and Evangelical Protestantism increased their membership as mainstream Protestant groups suffered significant losses in membership. This shift in numbers in America’s religious groups has been especially painful for the largest, most well-established denominations. With membership a paramount concern for congregations across the country, many churches have adopted active philosophies designed to attract and keep worshippers.

Near the end of the twentieth century, 70 percent of U.S. citizens age 18 or older were members of a church or synagogue, a figure that has not experienced much net change since the early 1980s. Although 62 percent of Americans were of the opinion that religion was taking on a diminished influence in national life, up from 49 percent in 1989, the proportion who place a great priority on religion in their own lives held steady at 59 percent.

BACKGROUND AND DEVELOPMENT

The United States has long prided itself on its diversity of religious expression. Numerous faiths are practiced in America, ranging from the Abrahamic religions of Judaism, Catholicism, Protestantism, and Islam to the other major world religions like Hinduism and Buddhism, as well as myriad others. The church has traditionally functioned as a major institution for vast numbers of the American populace.

Although churches do not have to pay government taxes, they still must secure income for a variety of purposes. Most churches sustain themselves financially through “tithes”—contributions made to the church by those who worship there. Tithing permits churches to meet their financial obligations in the realm of operating costs and payroll, as well as to contribute to charitable or social causes. In recent years, this primary source of income has risen in value but fallen as a proportion of the giver’s income. By 1998 the average annual family income of Catholic homes was \$43,000, but the contributions to the church was a mere 0.6 percent of their income, a fact that observers attribute to factors such as a growing tendency for worshippers to disagree with the leadership’s allocation of church resources.

The pilgrim fathers of the early seventeenth century created a powerful white Anglo-Saxon Protestant establishment. From about the mid-nineteenth century on, the nation’s majority of Protestant denominations increasingly consolidated in churches that operated the financial

aspect of their existence in a manner not unlike a corporate business.

In the 1970s and 1980s, however, Evangelical Protestant congregations increased in popularity. Long part of America but previously found among the poorest and least powerful sections of society, the numbers of Evangelical Protestants increased during this time, as did their socioeconomic status. This provided an influx of wealth that brought further conversions, together with additional power and prestige in both the religious and political halls of the United States.

During this same period, six of the seven sister denominations of mainstream Protestantism collectively suffered significant membership losses. From 1965 to 1995, the membership in the United Methodist Church dropped from 11 to 8.5 million. Losses were posted by other Protestant groups as well: Evangelical Lutheran Church in America, from 5.7 to 5.2 million; Presbyterian Church (U.S.), from 4.2 to 3.7 million; Episcopal Church, from 3.5 to 2.5 million; and the Christian Church (Disciples of Christ) from 1.9 to 1 million. The American Baptist Church, however, grew from 1.3 to 1.5 million members. The general loss of membership should have created a corresponding drop in revenue, which would force many congregations to tighten budgets and curtail community programs, but according to the 1996 *Yearbook of American & Canadian Churches*, most religious denominations showed an increase in revenue despite attendance figures. For example, the Presbyterian Church (U.S.), with one of the biggest membership losses, still had an increase of 4.8 percent in contributions/revenue, totaling \$2.1 billion.

By the late 1990s, the top five religious groups by membership size accounted for 61 percent of all memberships in religious organizations in the United States. The Catholic Church was the largest religious body in the United States with 61.2 million members and 33,000 churches; the Southern Baptist Convention had 16 million members and 41,000 churches; United Methodist Churches had 8.5 million members and 33,000 churches; the National Baptist Convention, USA, had 8.5 million members and 36,170 churches; the Church of God in Christ had 5.5 million members and 15,300 churches; and the Evangelical Lutheran Church in America had 5.2 million members and 10,900 churches.

Among those Americans older than 18, 59 percent identified themselves as Protestant; 27 percent as Catholic; and 2 percent as Jewish. In addition, there were about 530,000 Muslims, 400,000 Buddhists, and 227,000 Hindus. Only 7 percent identified themselves as atheists or agnostics. Affiliation with a religious organization was directly correlated with age; among those 65 and older, 75 percent belonged to a church, whereas the percentages

dropped among younger populations to 63 percent for those between the ages of 18 and 29.

Protestantism, the most widely practiced religion in the United States, covers more than 70 denominations. Most Protestants identify with one of the five major bodies of Protestantism: Baptist, Lutheran, Methodist, Episcopalian, and Presbyterian. The leading Protestant denomination, the Southern Baptist Convention, was expected to split sometime in 2000 along ideological grounds between the conservatives and the moderates, the latter of whom sought greater tolerance of diversity in doctrinal, ethical, and social issues. Between 400 and 3,500 churches were likely to leave the organization.

While the Baptists were separating, other Protestant organizations were striking alliances. The nation's largest Lutheran congregation, the Evangelical Lutheran Church in America, and the Episcopal Church agreed in 1999 to fully accept each other's members and sacraments. Although the two denominations maintain their respective structures and practices, the alliance allowed for an exchange of clergy and collaboration of projects and services.

Religious organizations received about 60 percent of all household charitable contributions in 1998. Among the 70 percent of U.S. households that donated money to a church or religious organization, the average contribution was \$1,022.

CURRENT CONDITIONS

According to the publication *America*, a study entitled *Religious Congregations and Membership in the United States: 2000*—issued in September 2002 by the Glenmary Research Center and the Association of Statisticians of American Religious Bodies—found that 50.2 percent of Americans were affiliated with a religious organization in 2000. This was a decrease from 1990, when affiliation levels were 55 percent.

Although the aforementioned study indicates that church affiliation declined during the 1990s, the *Yearbook of American and Canadian Churches 2003* revealed that membership in religious organizations was increasing in the early 2000s, reaching 159 million members in 2001. Among factors that benefited church attendance and membership levels during the early 2000s were the terrorist attacks against the United States on September 11, 2001, as well as the U.S.-led war with Iraq in the spring of 2003. These events increased the importance of spirituality and prayer to many Americans.

Although church membership levels increased during the early 2000s, this growth was not equally distributed among denominations. For example, strong membership increases occurred in the Catholic Church, where membership ranks increased 2.1 percent in 2000 and 2.5

percent in 2001, and the Church of Jesus Christ of Latter-Day Saints, which achieved growth of 1.9 percent and 2 percent, respectively. However, many of the largest denominations continued to see year over year memberships decline. Among these groups were the United Methodist Church and the Evangelical Lutheran Church in America.

In 2001, the top five religious groups by membership size accounted for about 69 percent of all memberships. The Catholic Church remained the largest religious body in the United States, with 65.3 million members. The Southern Baptist Convention was the next largest organization with 16.1 million; United Methodist Churches had 8.3 million members; the Church of God in Christ had 5.5 million members; the Church of Jesus Christ of Latter-Day Saints had 5.5 million members; and the Evangelical Lutheran Church in America had 5.1 million members.

Since the mid-1990s, churches have enjoyed a growing base of financial contributions. From \$15.3 billion in 1994, contributions increased steadily, reaching \$22.8 billion in 1999, \$24.5 billion in 2000, and \$26.5 billion in 2001.

WORKFORCE

Protestant ministers and diocesan priests have a wide array of duties. They read and study to prepare texts for preaching or publication, perform, offer religious instruction, and often are called upon to address various other community needs—conducting marriage and funeral services; visiting the elderly, sick, and handicapped; and responding to emergencies. Additional administrative, educational, and community service activities represent an unpredictable but typically heavy burden. Particular activities of course vary widely according to the religious group and the specific institution's mission and resources.

In recent years, there were more than 300,000 Protestant ministers leading individual congregations, as well as thousands of others with no fixed congregation. Other ministers worked in correctional institutions, universities, military, hospitals, and other establishments. Other faiths had a considerable number of religious leaders in America as well. According to the U.S. Department of Labor, Bureau of Labor Statistics, in the late 1990s approximately 4,300 rabbis were employed in America (1,000 Orthodox, 1,250 Conservative, 1,800 Reform, and 250 Reconstructionist). By 2000, there were about 45,000 priests and many more laywomen and/or nuns associated with the Catholic Church in America.

Employment prospects were considered much more favorable for Evangelical ministers than for those in the mainstream, where the number of qualified candidates seemed likely to exceed the available positions, with the

possible exception of congregations in rural areas. The Catholic Church requires that its priests remain celibate and does not allow women to serve the church in that capacity. These restrictions have been widely viewed as the primary reasons for the shortage of Catholic priests in America. By the mid-1990s, with approximately 10 percent of the Catholic Churches without a resident priest, many of them began to rely on women to act as administrative pastors, changing the participatory numbers of women greatly.

According to the *Occupational Outlook Handbook, 2002-03*, salaries for Protestant ministers vary considerably depending on factors like age, experience, denomination, the size and wealth of the congregation served, and geographic location. In recent years, the average salary (including such fringe benefits as housing and insurance), was \$30,000. Diocesan priests' salaries were typically as low as \$13,000, but were usually supplemented with a comprehensive package of benefits including a retirement plan, free room and board, a transport allowance or car, and health benefits. Diocesan priests also often supplemented their income with teaching activities within the church parish; required to take a vow of poverty, priests were reliant on the support of their religious order. In recent years, annual earnings of American rabbis generally ranged between \$45,000 and \$75,000, including benefits such as those mentioned above. Their income usually depended on the size and financial capabilities of their congregation.

SIC 8699**MEMBERSHIP ORGANIZATIONS, NOT ELSEWHERE CLASSIFIED**

This category covers membership organizations, not elsewhere classified (NEC), such as art councils, automobile owner's associations and clubs, humane societies, and reading rooms.

NAICS CODE(S)

813410 (Civic and Social Organizations)

813910 (Business Associations)

813312 (Environment, Conservation, and Wildlife Organizations)

561599 (All Other Travel Arrangement and Reservation Services)

813990 (Other Similar Organizations)

The membership organizations (NEC) group was comprised of about 11,432 establishments with 108,600 paid employees in 1998. Many organizations, however, were staffed primarily with volunteer members. Most of the groups were small, local bodies, uniting people with common interests. In fact, many associations in this classification had no full-time staff members and only few hundred, or fewer, members. In the late 1980s, the average organization had eight workers and paid about \$123,000 in payroll expenses, an average of only \$15,000 per employee.

Almost all membership organizations in this classification are tax-exempt corporations. They generate revenues through dues, sales of insurance and other products and services, fund raising events and drives, endowment funds, and investments. Larger organizations often hire professional fund-raising firms. These companies usually charge a flat-fee or a percentage of proceeds and conduct direct marketing campaigns and events. The average establishment in this group generated tax-free income of \$550,000 annually during the 1990s.

While most miscellaneous membership organizations are relatively small, there are a few large entities that warrant description. In 1998, the Boy Scouts of America (BSA) had 4.8 million members, 500 employees, and sales of \$251 million. That same year, the Girl Scouts of the USA had 3.5 million members. YWCA of the USA reported 2 million members in 1998, \$15 million in sales, and 90 employees. Rotary International reported 1.2 million members, 400 employees, and \$72 million in sales.

American Automobile Association. With more than 40 million members, 90 clubs, and 1,000 offices, the American Automobile Association (AAA) is one of the largest

and most successful enterprises in the United States. The only other organizations that compare in size to this behemoth are the U.S. Catholic Church and the American Association of Retired Persons. Unlike most organizations in this group, the AAA pays some taxes, but it still operates as a not-for-profit entity.

The AAA is a federation of 145 affiliated auto clubs. Members receive access to emergency road services, vacation and travel planning assistance, group insurance plans, and financial services. They also get periodic newsletters and magazines that keep them informed about automotive, travel, energy, environmental, and legislative topics. The AAA is the largest publisher of travel-related publications in the world. It produces more than 350 million copies of its publications each year, and consumes 22,000 tons of paper annually to produce its library of maps and books. The AAA also supports highway and road safety initiatives, and lobbies for membership interests.

The AAA was formed in 1902 when nine automobile clubs joined forces. As the automobile became a staple of American life during the twentieth century, AAA membership swelled to 20 million by 1980. During the 1980s, moreover, the AAA boosted its ranks at a rate of more than one million each year. It markets its services on a local basis, with each affiliate handling its own recruiting through direct mail and telephone sales. In-house local staffs provide individualized service. As a result, the AAA enjoys a membership renewal rate of 88 percent—much higher than the industry norm.

American Farm Bureau Federation. Another one of the largest membership organizations (NEC) is the American Farm Bureau Federation (AFBF). It represents the political interests of its members, and is recognized as a relatively powerful lobbying group in Washington. In the past, AFBF leadership has shown support for flexible price supports and minimal government interference in farming. The group has also promoted soil and water conservation, rural education programs, and rural electrification and infrastructure.

Farm bureaus emerged with the development of the county agricultural agent plan in the United States during the early 1900s. The AFBF was founded in 1919 to combine these bureaus into a single entity—to “promote, protect, and represent the business, economic, social, and educational interests of the farmers of the nation.” The AFBF had about 4 million members in 1996.

SIC 8711

ENGINEERING SERVICES

This category covers establishments engaged primarily in providing professional engineering services. Civil, mechanical, electrical and electronic, chemical, sanitary, industrial, petroleum, mining, aeronautical, and marine engineering are among the disciplines included. Establishments primarily providing and supervising their own engineering staff on temporary contract to other firms are included in this industry. Establishments providing engineering personnel, but not general supervision, are classified in **SIC 7363: Help Supply Services**. Establishments primarily providing architectural services are classified in **SIC 8712: Architectural Services**, and those providing photogrammetric engineering are classified in **SIC 8713: Surveying Services**.

NAICS CODE(S)

541330 (Engineering Services)

INDUSTRY SNAPSHOT

Engineering covers a vast array of specialties touching virtually all aspects of life. The profession is categorized into disciplines representing designated areas of interest, though not all commentators define the disciplines in the same way. Some choose many narrow descriptions while others rely on fewer, more broadly drawn classifications. By far, the most significant modern trend in the industry is computerization. Computers equipped with CAD/CAM and 3-D software largely replaced calculators and drafting boards by the end of the twentieth century.

In 2000 the top 500 engineering services design firms secured a total of \$43 billion in revenues, according to *Engineering News Record*. That year, 168 firms reported an average profit of 7.1 percent, while 10 reported a loss.

Diversification was a major trend impacting the engineering services industry at the turn of the twenty-first century. Design-build firms, those that provided both engineering and construction services, grew in number during the late 1990s and early 2000s as clients grew increasingly comfortable with the design-build concept. In fact, U.S. design-build project billings jumped more than 20 percent in 2000 to garner a 35 percent share of the nonresidential construction market, compared to 25 percent in the mid-1990s.

ORGANIZATION AND STRUCTURE

According to the Bureau of Labor Statistics (BLS), approximately 329,070 electrical and electronic engineers comprise this field, which is the largest engineering discipline. The Institute of Electrical and Electronics Engineers, Inc., with 224,658 members in the United States in the late 1990s, described itself as “the world’s largest technical professional society.”

The most populous classification of engineers after electrical and electronic engineers are computer engineers, which number 252,230, followed by mechanical engineers (209,490), civil engineers (173,690), and industrial engineers (112,400). The smallest groups of engineers are the 3,300 marine engineers and 3,440 mining engineers.

Engineering establishments serve two major classes of clients: government (representing 41.6 percent of fees charged) and industrial, commercial, and other firms (representing 35.4 percent). The remainder of engineering firm clients included architectural firms, construction companies, individuals, other engineering firms, and private institutions.

Projects undertaken by engineering establishments include industrial and processing plants and systems (19 percent); power generating and transmission facilities (18.9 percent); navel and aeronautical equipment (13.5 percent); water supply and sanitation facilities (8.1 percent); highways, roads, bridges, and streets (6.9 percent); commercial buildings (5.3 percent); and public and institutional facilities such as hospitals and educational facilities (3.3 percent).

BACKGROUND AND DEVELOPMENT

The American Society for Engineering Education defined engineering as “the profession in which a knowledge of the mathematical and natural sciences gained by study, experience and practice is applied with judgment to develop ways to utilize the materials and forces of nature economically for the benefit of mankind.” This interest in manipulating matter and power for society’s welfare has its roots in antiquity. In many ways the progress of civilization provides a record of mankind’s engineering achievements.

Throughout history, scientists have studied the world, its composition, its properties, its inhabitants, and its universe. As they discovered principles and truths, engineers applied these discoveries to construct a changed world. For example, chemists provided the information used by chemical engineers to create new building materials and pharmaceuticals. Biologists made discoveries that were put to use by engineers to increase crop production and offer improved medical services. Physical scientists contributed the knowledge needed to build pyramids and skyscrapers. Scientists identified electricity but engineers enabled the phenomenon.

Transitions from the Stone Age to the Bronze Age and then to the Iron Age were made possible by changes in mining and metallurgical engineering. When public works projects became too large for a single craftsman to accomplish, even with the help of family and apprentices, civil engineers coordinated and focused the efforts of thousands of workers. Their projects included roads, bridges, irrigation systems, government buildings, and religious structures.

Windmills and waterwheels were the work of archetypal mechanical engineers. Their progeny ushered in the Industrial Revolution during the late eighteenth and early nineteenth centuries. James Watt's invention of the steam engine in 1802 led to the development of steam locomotives, steam propelled boats, and the mechanization of agriculture.

The roots of electrical engineering extend back to the 1600s when William Gilbert, an English scientist, first described magnetism and static electricity. In 1800, Alexander Volta discovered that electric current could be made to flow. Throughout the nineteenth century, many scientists and inventors contributed to a growing body of knowledge about electricity. Some of its early applications included the telegraph (invented by Samuel Morse in 1838), the telephone (Alexander Graham Bell, 1876), the light bulb (Thomas Edison, 1878), and the electric motor (Nicholas Tesla, 1888).

As technology spread, demand for engineers increased. In time engineers specialized and founded engineering societies to facilitate the exchange of engineering knowledge. In the United States, the first officially established engineering society was the American Society of Civil Engineers (ASCE), organized in 1852. The Society of Mining Engineers was founded in 1871. The American Society of Mechanical Engineers (ASME) was established in 1880 with Thomas Edison as one of its founding members. In 1884, a group of inventors and entrepreneurs formed the American Institute of Electrical Engineers.

The era also provided rapid advances in all disciplines of engineering. Civil engineers, for example, trans-

formed bridge building technology. John Roebling, a pioneer in suspension bridge construction, designed and built an aqueduct over the Allegheny River to facilitate cargo transportation and a railway bridge over Niagara Falls Gorge. Roebling's most famous project, the Brooklyn Bridge, was completed in 1883—Roebling himself did not live to see the project finished. In addition to great landmark bridges, civil engineers erected hundreds of mass-produced metal truss bridges in many parts of the country.

Mechanical engineering, at the forefront of mass production, emerged from the domain of forges, iron smelters, and textile mills. Participants at the American Society of Mechanical Engineers' (ASME) first meeting discussed standardized sizes for screw threads, laying a necessary foundation for assembly-line technologies.

Material and metallurgical engineers also made rapid advances during the late 1800s. Innovations enabled the commercial production of aluminum, copper, zinc, and lead. Improved glass and stronger rubber products also became available. In addition, chemical engineers used scientific discoveries in the field of chemistry to produce an assortment of new materials. Some of the earliest commercial chemical products were manufactured for the nineteenth century textile dyeing industry.

In 1908, the American Institute of Chemical Engineers was founded. Throughout most of human history, people made items only with naturally occurring raw materials. Chemical engineers created new materials. They produced industrial chemicals, fertilizers, drugs, and paints. They improved stone, clay, glass, and ceramic building materials. They discovered processes to refine petroleum, preserve food, and make paper. Interest in U.S. chemical production intensified during the years preceding World War I because many industrial chemicals were imported from Germany.

During the war, an embargo of German materials led to a rapid expansion of the nation's domestic chemical industry. After the war, Arthur D. Little devised the concept of unit operations. Unit operations focused on the materials and energy undergoing changes inside a specific piece of equipment. By focusing on improving the efficiency of chemical reactions and preventing unwanted reactions, the concept enabled the development of techniques to produce chemicals in large continuous processes.

The World War I era also saw the birth of the electronic engineering field. As electrical knowledge developed, electricity was put to work in two distinct arenas. "Heavy current" was used for power and was manipulated by electrical engineers. "Light current," in contrast, was used for communication.

Electronics was born in 1907 when Lee De Forest invented the vacuum tube. Electronics engineers established the Institute of Radio Engineers in 1912 and the nation's first commercial radio stations began broadcasting during the 1920s. (The Institute of Radio Engineers and the American Institute of Electrical Engineers joined together to form the Institute of Electrical and Electronics Engineers, Inc. in 1963.)

As the machine age progressed, the need for codes and standards became apparent. To address the problem of boiler explosions, the ASME completed and published its first boiler code in 1915 and inaugurated a system for accrediting manufacturers of boiler equipment. The accrediting process involved reviewing manufacturing techniques, quality assurances, and materials. Manufacturers judged to be in compliance with the code were granted authorization to apply an ASME stamp to their products.

Three years later, in 1918, the American National Standards Institute (ANSI) was founded. ANSI, the U.S. member of the International Standards Organization, served to coordinate development of voluntary standards by the various engineering disciplines.

Engineering disciplines became increasingly interrelated. Developments by electrical engineers impacted mechanical engineers. Demands for electricity by industrial engineers necessitated the development of improved means to generate and convey electric power. The growing automotive and aeronautical industries placed heavy demands on civil engineers to build the nation's infrastructure. They also relied on petroleum and chemical engineers to produce gasoline and aviation fuel.

During World War II, chemical engineers developed materials to help replace items, such as natural rubber, which were in short supply. DuPont researchers developed Nylon, a forerunner to the development of polymer plastics. Electronics engineers, spurred by military interests, developed advanced communication technologies including radar and sonar.

Following the war, electronics engineers created the transistor. Developed during the late 1940s and introduced commercially by Bell Labs in 1951, transistors replaced more fragile vacuum tubes. In the 1960s, engineers developed ways to build transistors on small chips of silicon. These innovations helped push the electronics industry into the computer era.

The 1960s also saw an event that was described by the National Academy of Engineering as the world's greatest engineering accomplishment—landing a man on the moon. NASA's Apollo project, begun in 1961, reached its primary objective in July 1969 when Neil Armstrong set foot on the lunar surface. His step was made possible by a variety of engineers who built the

launch site; designed the spacecraft and lunar lander; generated the propulsion, guidance and life support systems; and fabricated space-durable textiles and other materials.

Another milestone in engineering history occurred in 1969 when the U.S. National Parks Service and the American Society of Civil Engineers established the Historic American Engineering Record (HAER) to chronicle America's engineering achievements. HAER's mission was to find structures of historic significance and document them, paying special attention to structures slated for demolition. HAER records were to be kept as part of the permanent collection of the Library of Congress.

David Brittan, writing for *Technology Review*, listed some of the artifacts included: blacksmith shops, bridges, canals, cider presses, coal mines, culverts, dams, electric power plants, foundries, granaries, ironworks, kilns, lighthouses, privies, sewage treatment plants, schooners, subways, tanneries, tunnels, viaducts, and waterworks.

In September 1971, ASME formed its own committee to begin a program to identify and recognize mechanical engineering artifacts. ASME noted that "machines are more likely than architecture or art to be moved, scrapped, or replaced by progressively efficient counterparts." They began a program of identifying three categories of designation: historic landmarks, heritage sites, and heritage collections. The 149 designations recognized in 34 states by 1992 included the Detroit Edison District Heating System (built in 1903), the Sikorsky VS-300 Helicopter (1939), the Experimental Breeder Reactor-1 (1951), the Shippingport Atomic Power Station (1958), the Disney Monorail System (1959), and the JFK Center's Crawler Transporters of Launch Complex 39 (1965).

Despite increased interest in preserving engineering history, engineers continued to forge the future. Advances in space technology led to improved communications. The first commercial satellite provided circuits for 240 telephone calls between the United States and Europe. By 1990, satellites provided communication systems between the United States and 40 other countries. Likewise, engineering advances made on behalf of medical providers led to the development of the computerized axial tomography (CAT) scan, based on X-ray technology that had been first used in Germany in 1895. The first CAT scanners were installed in Great Britain in 1971 and in the United States two years later. Subsequent advances led to ultrasound imaging and magnetic resonance imaging (MRI).

The increasing miniaturization of computer chips during the 1970s brought about a proliferation of electronic devices such as pocket calculators, personal computers, microwave ovens, and electronic toys. These min-

ature computer chips, no larger than a fingernail, also led to a growing sophistication of computer-controlled equipment including traffic lights, automobiles, and aircraft. More powerful computers resulted in the adoption of computer-aided design (CAD) and computer-aided manufacturing (CAM) techniques by many of the nation's major manufacturers.

Despite these accomplishments, the engineering industry faced some serious challenges during the 1980s. Some critics of modern technology blamed engineers for creating tools that wrought havoc on the environment. Others claimed that only engineering offered the potential for providing solutions to pollution. Within the arena of environmental engineering, researchers looked into ways to preserve, protect, and restore the environment. In addition, some industry watchers predicted a coming shortage of engineers. The number of male freshmen entering college with plans to earn an undergraduate degree in engineering fell from 22 percent to 17 percent between 1982 and 1987. Among women, the number dropped from 4 percent to 3 percent.

The Early 1990s. As the engineering industry entered the 1990s, the interdisciplinary nature of engineering increased. Many different types of engineering work were being done in many fields, and frequently the work done by an engineer in one discipline depended on or supplemented the work of an engineer in a different field. For example, mechanical engineering and electronic engineering combined to produce integrated machines with electronic components, and the field of robotics involved the integration of mechanical and electronic engineering.

Laser technology provided another example of an interdisciplinary expression of engineering skills. The creation of laser beams (beams of high-intensity light of one frequency, called "coherent" light) required input from electronics engineers, electrical engineers, chemical engineers, and mechanical engineers. Electronics engineers manipulated laser beams for use in office equipment. Other engineers used lasers to develop fiber optic technology. Mechanical engineers designed laser light shows. Engineers supplying the medical industry used lasers to create new types of surgical instruments.

Biochemical and biomedical chemical engineering during the 1990s also included work in genetic engineering, pharmaceutical research, and the development of agricultural chemicals. Other types of chemical engineering provided products to create advanced materials and polymer-based chemicals. In total, the chemical industry boasted sales of \$268 billion in 1990.

The development of plastics and other materials by the chemical industry resulted in decreased demand for traditional mining and metallurgical products. For example, the automotive industry turned increasingly to plas-

tics and new polymer materials to help speed production and improve fuel economy. Plastics, preferred by some manufacturers, could be injection-molded into a wider range of complex shapes with more precision than could be accomplished with metals. Ceramics were also being used with increasing frequency.

Political changes within the United States also impacted the engineering industry. As the nation shifted away from a policy of providing heavy funding for the development of defense technologies, engineers began to focus more on civilian undertakings. Research conducted in the private sector, however, typically carried more stringent economic restraints. As a result, some industry watchers predicted a slowing in the pace of technological development. Others disagreed, stating that the engineering industry would benefit from an emphasis on profitability.

In addition to the economic challenges brought about by a transforming political climate, the engineering industry faced economic difficulties as a result of global changes. The U.S. engineering establishment found itself as one of many competitors on a crowded global stage at a time when worldwide economies were in transition. According to some analysts, economies were shifting from being based on natural resources to being based on knowledge. The realization that industries involved in fast-moving technologies would be necessary to sustain a nation's future economic growth illustrated the need for continued U.S. strength in the field of engineering.

Within the United States, there were 36,086 establishments classified by the U.S. Department of Commerce as offering engineering services. In the *1987 Census of Service Industries*, their combined receipts totaled \$41.6 billion. Of this amount, \$35.3 billion represented receipts for consulting and design engineering services. Other sources of receipts included architectural and surveying services and construction management.

In the mid-1990s, engineering and design firms foresaw an end to the recession conditions that began in the early 1990s. A combination of factors such as the need for downsizing and limited resources in many industries increased the demand for engineering companies. Engineering companies were not only being sought after as consultants but as partners in day-to-day operations. The top 500 design firms garnered a collective total of \$29.4 billion in billings during 1995, up 5.2 percent over the nearly \$28 billion seen in 1994. According to *Engineering News Record*, analysts and industry executives attributed the improvement to the international market, where some \$5.2 billion in billings were seen in 1995.

Numerous opportunities arose for U.S. environmental engineering firms, both in the United States and abroad, as the 1990s came to a close. Worldwide demand

for design and construction of petrochemical plants and refineries resulted in a boom for engineering and construction firms, although subsequent unexpected decreases in the price of oil resulted in cancellation of some petrochemical expansion projects and subsequent declines in stock prices. A survey conducted by *The Oil and Gas Journal* revealed that 59 percent of 291 sites were scheduled for the Asia/Pacific region, including 60 sites in China. Local construction firms also brought world-class resources to clients by entering partnerships or by merging with global firms.

Domestically, the deregulation of the utility industry created a competitive pressure among engineering firms; many were forced to take new risks to keep revenues flowing and to survive. An unanticipated slump in construction engineering caused stock prices to plummet in the late 1990s and aggravated already slow growth. Analysts attributed the slump to premature forecasts prompted by the passage in 1998 of the Transportation Equity Act, but when sizable injections of the appropriated \$217 billion federal highway funding associated with the 1998 act entered the economy near the end of 1999, the industry regrouped. Waning stock prices recovered and the construction industry stabilized. Two additional factors driving sales were economic recovery within the United States and the implementation of the North American Free Trade Agreement (NAFTA). NAFTA suspended residency requirements for obtaining Canadian and Mexican licenses—a move intended to create a new market for American engineers in Canada and Mexico.

CURRENT CONDITIONS

Although the top 500 U.S. design firms saw their domestic billings grow approximately 8 percent to \$35 billion in 2000, international billings dropped 3 percent to \$7.6 billion. This was partially due to concerns over the instability of many markets in southeast Asia; China, however, which joined the World Trade Organization in 2001, was viewed as an potentially lucrative market.

Design-build firms gained increasing prominence in the early 2000s in the United States. Design-build revenues for the 100 largest design-build firms jumped more than 22 percent to \$39.9 billion in 2000. As a result, this group's share of the of the U.S. nonresidential construction market grew to 35 percent, compared to 25 percent in the mid-1990s. According to *Engineering News Record*, "The trend is clearly away from project-by-project management and toward management of larger construction programs for clients." The Design-Build Institute of America forecasts that design-build companies will increase their share of the U.S. nonresidential construction market to 45 percent by 2005.

The global economic recession in the early 2000s and the September 11 terrorist attacks resulted in a slowdown in many engineering sectors, as budgets for various projects dwindled. However, many environmental engineering firms saw business increase in 2001, due in part to new products resulting from the Bush Administration's focus on homeland security. The top 200 environmental engineering firms posted revenues of \$32.8 billion in 2001.

INDUSTRY LEADERS

Fluor Corporation. Fluor Corporation of Irvine, California, with sales revenue of \$8.97 billion in 2001, ranked as one of the largest companies in the industry. Design operations accounted for \$1.14 billion of sales, while contracting operations accounted for \$7.82 billion. The company's employee count totaled 44,800 in 2002. Fluor Corporation operated from offices and locations on six continents and ranked in the top 15 of *Fortune* magazine's service companies. For more than eight consecutive years, earnings from continuing operations grew an average of 15 percent.

Fluor provides a broad range of engine construction and diversified services to clients in many industries and geographic locations. The firm has also participated in several nuclear cleanup efforts.

Bechtel Group, Incorporated. Bechtel Group, Incorporated is another leading engineering services firm. The company, founded in 1898 by Warren Bechtel, remains a private, family-held firm. With headquarters in San Francisco, California, Bechtel engineers have contributed to approximately 19,000 projects in 140 countries on seven continents. In 2001 Bechtel had total sales of \$14.5 billion, \$12.3 billion of which came from contracting and \$1.9 billion of which came from design activities.

During its early years, Bechtel contracted largely with the railroad industry and later expanded into other arenas. Among Bechtel's overseas projects was its participation in the reconstruction of Kuwait's oil fields following the Persian Gulf War, a job that involved 10,000 workers from 35 nations. In the People's Republic of China, Bechtel was a key participant in the construction of the Daya Bay Nuclear Power Plant. In Europe, Bechtel participated in the construction of the Eurotunnel between England and France. In 1995, Bechtel's R&D's International Technology and Resources teamed with Southern Electric International and Arthur Andersen and Company in a consortium to assist 11 eastern European countries with energy programs under the auspices of the U.S. Agency for International Development's Regional Energy Efficiency Project. By 2001 roughly 89 percent of Bechtel's revenues were attributable to international contracts.

Specialty Disciplines. Halliburton Company was recognized as the largest oil field services provider worldwide. The firm's revenues of \$17.4 billion in 1998 constituted a 96.8 percent growth in the wake of a merger with Dresser Industries Incorporated that was finalized on September 29, 1998. Eventually, however, Halliburton sold off its Dresser unit, a move reflected in its 2002 sales, which totaled \$12.4 billion.

Additionally, United States Steel Corporation reported sales of \$6.9 billion in 2002 and was the largest steel maker in the United States according to Hoover's, with services ranging from engineering consulting resource management and value-added product production. In November of 1999 U.S. Steel Gary Works, Indiana, received the Association of Iron and Steel Engineers' (AISE) Project Excellence Award. The award was in recognition of a *turnkey* (prefabricated) energy co-generation plant that was designed, constructed, and managed by Duke/Fluor Daniel through an ongoing alliance with Primary Energy Incorporated. The plant, for converting coke oven and blast furnace emissions into energy, had commenced commercial operation in 1997.

WORKFORCE

BLS statistics released for 1999 reported an estimated 2.5 million workers in engineering and related occupations including technicians, technologists, estimators, and drafters. Of those employed, 209,100 were civil engineers; 202,901 were mechanical engineers; 155,910 were industrial engineers; 149,201 were electrical engineers; and 51,450 were environmental engineers.

Salaries for engineers varied according to discipline and education. Highest paid among the engineering disciplines were nuclear and petroleum engineers with a mean salary of \$72,000 per year in 2000, according to the BLS. Marine engineers ranked lowest in compensation, with a mean salary of \$47,770 per year. Civil engineers earned an average of \$52,650 in 2000.

Despite national industrial decreases overall, employment fluctuations within the top performing engineering companies reflected a pattern of growth. Industry leader Fluor Corporation increased its employee count by 6.3 percent in the late 1990s, and U.S. Steel gained 5 percent. Although Bechtel reported no growth in that area, neither did the company experience a loss of employees. Halliburton Corporation meanwhile reported employee growth of 52.4 percent in the late 1990s as the result of its merger with Dresser Industries; however this number decreased when Halliburton divested its Dresser unit in the early 2000s.

Electronic News reported late in 1999 that the Department of Labor projected a need for nearly one-half million skilled scientists and technicians, including engineers, by 2006. The American Electronic Association at

that same time reported a low 1.6 unemployment rate for engineers coupled with a significant drop in engineering graduates during the course of the 1990s. A report in *Crain's Cleveland Business* reiterated the need for greater numbers of engineering professionals. The article indicated further that a dearth of skilled technicians and machinists also loomed heavily against the industry, in the absence of programs geared to elementary and secondary students to publicize the advantages of such careers. In an effort to meet future demand for engineers, the Cleveland Engineering Society developed the Internet-based "TOP RATE" program to encourage elementary and secondary students to enter the field of engineering. The Internet site was designed to provide links to database listings of scholarships, educational programs, and other career development resources.

AMERICA AND THE WORLD

Demand for U.S. engineer services is closely tied to conditions in other countries. Increased competition from foreign nations pressured U.S. companies to expand productivity and reduce the cost of high-tech engineering services during the 1980s and 1990s. By 1999 IEEE reported 67.1 percent of its total membership came from non-U.S. citizens.

Additionally, U.S. construction engineers faced increased competition in the global marketplace. Asian factories suffered severely from a massive layoff of 8,000 employees by Seagate Technology in 1999. The cutbacks, attributed to automation, reflected a need for fewer assembly line workers in deference to greater numbers of skilled laborers at Seagate factories in Singapore, Thailand, Malaysia, and China. Elsewhere in Asia, electronics and electrical production constituted the biggest U.S. industry in Hong Kong, with \$1.13 billion invested in that arena, totaling more than 5 percent of U.S. direct investment. Recent relaxation of restrictions prohibiting the employment of women in more dangerous trades, according to the U.S. Department of State, facilitated the escalation of heavier industries on the part of U.S. enterprises. The largest segment of the worldwide construction market—estimated at \$3 trillion by the U.S. Department of Commerce in the 1990s—was in Japan. Yet the lucrative market, hindered by cartel-style pricing structures in the construction industry, remained largely closed to non-Japanese firms. Lee Chang-bok, president of Korea's Dong Ah Construction, cited his own company's ranking at the top of a Japanese governmental listing of the best foreign contractors, but noted that exclusionary government standards and restrictive business practices impeded what he termed an "impregnable" construction market. U.S.-based Bechtel Corporation ranked at number two on the listing.

Developing Nations. Overseas markets with the most growth potential for construction engineers were located in the Middle East where developing nations were expected to turn to foreign firms for help in developing their infrastructure and industrial base. Chang-bok focused on the Arabian markets as his company restructured in a rebound from the Asian monetary crisis of 1997. Among Dong Ah's largest projects, the firm held a 25 percent interest on the \$1.2 billion Phase III of Libya's "Great Man-Made River Authority." In order to compete, Dong Ah initiated a joint venture with local contractor, Al Hahr Company. Chang-bok noted that restrictive conditions in the Middle East precluded contractors from working in the absence of a joint venture agreement with another contractor local to the area. The government of Bahrain additionally required private contractors to register with the Ministry of Works and Agriculture. According to the *Herald*, Libyan leader Muammar Qaddafi announced an intent to assemble the nations of Northern Africa into a union modeled after the European Union, to be headquartered at Sirt, in the vicinity of Tripoli. Such a project would open major new markets in that part of the world.

In the late 1990s construction accounted for 10 percent of the \$47.6 billion gross domestic product of Algeria; U.S. aid accounted for \$209 million of that country's income. Thus, an untapped potential market for contractors existed in that country, where a housing shortage persisted according to the U.S. Department of State Report on Economic Policy and Trade Practices. According to consulting engineer Rodney Nohr, business opportunities abounded in developing nations. Nohr, cited by Jackie Elowsky in *Resource: Engineering & Technology for a Sustainable World*, faulted American engineering firms who ". . . often fail to see profit in projects with non-U.S. companies. This leaves the global market open to smaller agencies . . ." Nohr noted that improved communications technology had improved working conditions for American contractors working in developing nations. The ability to collaborate on a joint venture with local firms, often critical to such ventures, eliminated the restriction on foreign service industries. Such restrictions, common to Asian nations and others where significant barriers to trade were continually relaxed, were further augmented in Indonesia. There, according to law, foreign contractors must purchase local products as much as is feasible, except for goods purchased through financial aid resources.

South America. Substantial barriers preclude significant export of engineering services to Brazil. Among these, government contracting restraints prohibited contracting in technical service arenas unless domestic Brazilian contractors were unable to provide adequate facilities and services. Conspicuously complex registration

procedures for foreign contractors applied in particular to the architectural and engineering industries.

RESEARCH AND TECHNOLOGY

Projects under development during the late 1990s and early 2000s by U.S. engineering teams involved superconductors, robotics, fuel cells, particle beams, magnetic levitation trains, radioactive waste storage, and advanced computer-integrated manufacturing. Chemical engineers continued investigating new materials for advanced information and communications, studying environmental issues, and contributing to public health technologies.

SIC 8712

ARCHITECTURAL SERVICES

This classification covers establishments primarily engaged in providing professional architectural services. Establishments primarily engaged in providing landscape architecture services are classified in **SIC 078: Landscape Counseling and Planning**. Those primarily engaged in providing graphic arts and related design services are classified in **SIC 7336: Commercial Art and Graphic Design**, and those providing drafting services are classified in **SIC 7389: Business Services, Not Elsewhere Classified**.

NAICS CODE(S)

541310 (Architectural Services)

INDUSTRY SNAPSHOT

Design firms primarily engaged in providing professional construction-related design services constitute the architectural services industry. This industry includes companies that offer engineering design services related to architectural work, but does not include civil engineering or ship and boat design companies. Landscape architecture, graphic arts, and drafting disciplines are covered in separate classifications.

Aside from actually designing structures, architects typically are employed throughout all phases of the building process—from conceptual planning through client construction. In the late 1990s an estimated 18,994 establishments employing 138,800 people existed in this in-

dustry. The Accounting Industry Association estimated that 91,000 licensed architects were operating in the United States in 2000. Licensure is the highest form of industry regulation, and all 50 states require architects to be licensed.

After suffering from a deep recession in the late 1980s and the early 1990s, the architectural services industry began a steady rise into the 1990s. Consumer confidence mounted throughout the late 1990s, and the economy boomed. Annual revenue growth in the industry averaged 10.2 percent in the late 1990s, and totaled 9.2 percent in 2000. Home and office construction skyrocketed during the late 1990s. When weakening economic conditions began to slow consumer spending, falling interest rates bolstered the home construction sector in the early 2000s, although the office construction sector began to slow at that time.

ORGANIZATION AND STRUCTURE

Architecture firms design a multitude of different structures for all sectors of the market. Office and apartment buildings, schools, military installations, churches, factories, hospitals, houses, and airport terminals are but a few of the facilities that they design for commercial, government, and private nonprofit organizations. While some firms specialize in serving one niche or a few related segments of the market, others are highly diversified and offer a variety of design services to all types of clients.

The Design Process. Building design can be a complex, detailed, and painstaking endeavor. In addition to the important consideration of appearance, architects must also stress functionality, safety, and economy in the design process. Even one minuscule flaw in a volume of construction drawings can result in costly litigation and the erosion, or destruction, of a firm's reputation. More important than pleasing the potential users of any structure or satisfying personal design aspirations, architects must accommodate the client that commissions and funds a project.

Design programming is the first stage of the building process. Architects are often called upon at this point to determine what type of structure to erect. Marketing research, demographic analyses, regulatory constraints, and other factors all help to determine economically viable development options. Site selection and acquisition follow the design programming stage. The architect analyzes factors such as soils, drainage, utility availability, tax rates, and traffic patterns to determine where to build a project. If the client already has a parcel of land, the firm can help determine the financial and physical feasibility of developing the site.

After the client decides to build, the architect begins the conceptual design process. Schematic drawings and relational diagrams, prepared by the architect, allow the

client to study possible options for developing the site. Crude models are often used to represent ideas in three dimensions. The conceptual design process eventually results in a hypothetical plan that is used to generate cost estimates and guide the development of more detailed elevations, cross-sections, models, and perspectives.

After developing a detailed design, the architect begins the bulk of the design work—detailed construction drawings. These highly-detailed drawings determine accurate construction cost estimates and bids by contractors. They also dictate the quality of craftsmanship and materials to be used by contractors. Architects cooperate with engineers and other professionals to insure that the design is technically appropriate and complies with legal guidelines. When the working drawings are complete, the architect usually takes bids on the project from contractors, awards a contract, and supervises construction to ensure that the contractor properly executes design details.

Although rates vary, most architects bill clients on a per-hour basis. The total bill for architecture and engineering design services is often in the range of 2 to 4 percent of the total construction cost of a project, but can be much more or less depending on the type of project or the level of involvement by the architect.

Types of Firms and Projects. Three types of companies are primarily engaged in providing architectural services: engineer/architecture (E/A) firms; architecture/engineer (A/E) companies; and architecture firms. Typically it is only an estimated 15 percent of the total billings by architectural firms that are rendered by firms in the architectural services industry. Engineering and construction firms and other companies that offer services related to architectural work such as surveying services consume the bulk of the revenues.

Purely architectural firms bill strictly for architectural design work. They do not have engineers on staff and often offer limited construction management expertise. *Building Design & Construction* reported in July of 1997 that the top 10 firms of this type accounted for \$327 million of industry billings in the prior year. Furthermore, this segment supplied only a small percentage of all architectural services rendered by U.S. companies.

A/E firms, while still emphasizing architectural skills, have engineers on staff with expertise related to architectural building design. Firms in this category typically account for 5 percent of all industry billings, as they service only a small percentage of the entire U.S. market for architectural services.

E/A firms maintain architects on staff but emphasize engineering design services that are related to construction work. These firms capture slightly more than half (approximately 54 percent) of all industry billings and

furnish the highest percentage of all architectural services rendered by U.S. firms.

BACKGROUND AND DEVELOPMENT

Architects have been designing structures in return for compensation for more than 3,000 years. Although several famous architects designed well-known projects during America's early history, such as Thomas Jefferson's Monticello in the early nineteenth century, an organized architectural profession did not exist in the United States until the 1850s. In fact, formal educational programs for architects were unavailable until the 1860s, with the establishment of the Massachusetts Institute of Technology, Cornell University, and the University of Illinois.

Prominent works which sprang from the fledgling architectural services industry in the middle and late nineteenth century included the Marshall Field & Company building in Chicago, the Wainright Building in St. Louis, St. Patrick's Cathedral in New York, and the Harvard Museum of Comparative Zoology in Cambridge. Prominent architects of the period who owned firms included James Renwick, Louis Agassiz, H. H. Richardson, and Louis H. Sullivan. Between 1900 and 1940, Frank Lloyd Wright, Mies van der Rohe, and Le Corbusier, among others, designed significant projects and had enormous influence on the profession. Famous works of this time included many office buildings, such as the Empire State Building and Rockefeller Center in New York.

It was not until after World War II that the U.S. architectural industry began to experience rapid growth and to become closely affiliated with building and construction industries. During that time, large corporations developed massive structures that projected wealth and distinction, and government expenditures for infrastructure and public works grew at an unprecedented rate. This development boom gave birth to many large architecture firms, like Hellmuth, Obata & Kassabaum and Perkins & Will, that employed hundreds of architects. Skidmore, Owings & Merrill, one of the larger firms in the post-war period, designed such projects as the Connecticut General Life and Inland Steel Buildings. The General Motors Technical Center and Frank Lloyd Wright's Guggenheim Museum were other prominent landmarks that characterized the progression of the industry from the 1950s through the 1970s.

By 1983, however, new development activity was leading the architectural services industry into an era of unprecedented profit and growth. Deregulation of lending institutions, an influx of foreign investment dollars, and new tax laws all combined to generate a massive injection of capital into the commercial development industry. Between 1982 and 1985 the total amount of commercial space designed by architects ballooned from less than 700 million square feet per year to over 1.3 billion. At the

same time, residential markets were also booming and the demand for new public construction increased. As a result, the total number of establishments in the architectural services industry jumped over 20 percent, from 14,089 in 1985 to a peak of 17,777 by 1987. During the same period revenues leapt from \$5.9 billion to over \$9.8 billion and industry employment shot up to nearly 140,000 from only 105,000.

In the late 1980s the flow of capital for new design projects waned. The Tax Reform Act of 1986, which discouraged new construction, and a shortage of savings and loan capital were two of the various factors contributing to a slowdown in 1987. Architecture firms saw a significant decline in the number of design jobs available in many commercial and residential markets. In fact, by 1989 it was clear that their industry had fallen into a severe, and potentially sustainable, recession. Total new commercial development plunged to about 1 billion square feet in 1988, and fell to under 800 million square feet in 1989.

By the end of 1989, the market for architectural services appeared to many analysts to have bottomed out. But, while most firms were on the ropes and struggling to survive the industry shake-out, the development market continued to plummet in 1990 and 1991. In fact, many office buildings that architects had designed in the late 1980s opened in the early 1990s without a single tenant; these became known as "see-through buildings." The total demand for new construction continued to fall from only \$410 billion in 1989 to about \$358 billion in 1991. The market for residential design services was also hit hard, as new construction in that sector fell 14 percent in the same three-year period. Although many firms were able to stay afloat by emphasizing public works projects, which experienced expenditure increases of 9 percent between 1989 and 1991, most firms lost revenue.

In response to dour market conditions, the architectural services industry became increasingly competitive in the early 1990s. As hundreds of firms closed their doors, most remaining companies took sharp measures to increase their market share and to maintain profits. In some cities, about 50 percent of all architects were laid-off. Those hit hardest were young, inexperienced workers and older, highly paid employees. Firms were also reducing fees in an effort to undercut competitors. Most importantly, however, architecture firms were looking to new growth markets and technology to give them an edge in the 1990s.

Market conditions improved slightly from 1991 to 1992, indicating that the development drought was easing. The total value of new construction increased about 4 percent to about \$423 billion. Although work in commercial markets, especially office building design, continued to decline, housing and public works design projects increased. Furthermore, spending in some com-

mercial niche markets, such as health care, improved by as much as 5 percent. Importantly, remodeling, retrofit, and repair construction for all sectors reached record levels in 1992, allowing many firms to boost billings on small maintenance jobs.

A survey of 100 design firms by *Architectural Record* in 1992 revealed that nearly half the respondents had realized a reduction in the construction-dollar value of their commissions since 1990. The average decrease was 10 percent to 25 percent, although some firms lost as much as 90 percent. Of the survey respondents, 34 percent reported that their workload was down, 24 percent said it was up, and 42 percent felt that it had stabilized. A similar survey by *Engineering News-Record* showed a 20 percent decrease in design work backlogs from early 1991 levels, indicating that work was becoming more difficult to secure.

Firms were taking a variety of steps to improve internal operations and increase competitiveness. Most firms were increasing their workload-to-staff ratio to save money, and decreasing fees to attract more business. This was often accomplished by relying on part-time help from trained architects that were called on only when they were absolutely necessary. A popular trend was "hoteling," whereby employees would check into offices for short stints on special projects until their services were no longer needed, or several employees would use the same office but at different times of the day.

One of the most important internal changes for many companies was the increased use of technology to lower labor costs. In fact, 12 percent of respondents in the *Architectural Record* survey indicated that despite an increase in billings they had elected to diminish the size of their staff. Computer automated design (CAD) systems were a major factor in this increased productivity for some firms. "I've eliminated my whole office staff with a computer," said Philadelphia Architect David Steele in "Architectural Record," March 1993. Many companies were also eliminating clerical help with the aid of new office technology. For instance computers, answering machines, and cellular phones were replacing receptionists in some offices.

In addition to increasing the productivity of their internal operations, many firms in 1993 were expanding their service offerings. Some companies were going into project management, using their design expertise to streamline the construction process and save money for contractors and owners. Other architecture firms were expanding into interior design, facilities management, and environmental planning and engineering to increase revenues. Conversely, some firms were reducing their offerings, choosing instead to specialize in tiny niche markets where they held a competitive edge. Niche growth areas in the commercial market for architectural

services included designs for privatized prisons, arenas, hospitals and other health care facilities, long-term care facilities, warehouses, and recreational structures around river boat gambling casinos.

Entering new markets was another way that architecture firms were trying to maintain profitability. As design work for commercial construction continued to decline through 1993, public works projects were allowing many firms to increase revenues. For instance, while the amount of new hotel space plummeted 40 percent in just one year between 1991 and 1992, the value of new public works projects steadily increased from almost \$91 billion in 1989 to over \$102 billion by 1992. Water supply facilities and miscellaneous public buildings, which grew in 1991 and 1992 at a rate of 5 percent and 7 percent, respectively, offered the greatest potential for architecture firms competing for public works commissions. Design projects related to utility construction and conservation also offered increased opportunities.

After the recession of the early 1990s, the industry began to grow again, bringing in over \$14.6 billion in 1994. Revenue was up 8.7 percent from 1993, and up by almost 20 percent from 1991, and industry strategists predicted the growth would continue well into the twenty-first century. According to the American Institute of Architects (AIA), building activity would increase by an average of 1 percent each year from the levels of the first half of the 1990s.

Commercial development of suburban office space contributed to the life of the industry in the early 1990s, as commuters fled the cities and downtown office vacancy rates soared. Even when urban office vacancy rates stabilized by 1996, suburban office occupancy increased, and vacancy rates in the suburbs dropped by 9 percent annually, as growing numbers of businesses abandoned their outmoded urban operations in favor of modern new quarters in the suburbs.

Social and Political Factors. Until the late 1990s, one of the most stable areas of growth for the industry had been retail construction sales, which increased a steady rate of 2.5 percent every year from 1980 to 1996. But several factors were pushing that figure down. Home shopping through network clubs and the Internet was taking away the need for retail centers. Also, as the baby-boomers aged, services became more of a concern than goods, lessening the need for retail centers even more. Some projected decline was offset by the effects of the Americans with Disabilities Act of 1990. Compliance with the act required that many newer buildings be made handicap-accessible; this was expected to provide millions of dollars in architectural design contracts, along with rehabilitation and maintenance design work, especially for aging infrastructure.

Computerized Design. Two important advances in the architectural services field in the early 1990s were computer-aided design (CAD) software programs and 3-D modeling. As late as 1993, architects in many offices were still designing with ink or pencil on vellum or Mylar surfaces. Designers sat at a drafting board and used triangles and compasses to produce precise technical drawings. With the introduction of CAD, however, an increasing number of professionals moved away from the drawing board and onto the computer to develop their designs. Although both methods were extremely labor intensive, CAD offered the advantages of allowing architects to save their work, to duplicate and move parts of a design, and to make changes more easily. Additionally, many tasks that were cumbersome on the drawing board were easily accomplished via CAD. Calculations of surface areas and volumes for earthwork projects were among the functions made easy by the CAD software.

Critics of CAD argued that it was too costly for smaller firms to implement, that it stifled the design process and limited flexibility, and that it displaced architects. Others maintained, in contrast, that the implementation of CAD systems increased productivity for designers and reduced staffing requirements. For instance, J. F. Borelli, a New York architect, increased billings at his firm by 125 percent in two years by 1992 when he expanded his CAD implementation. He maintained his staffing level at 65 employees and discovered that clients increasingly requested that projects be developed with the CAD software.

Even more sophisticated than CAD software were new 3-D modeling systems that allowed architects to design projects in three dimensions on computer. Three-dimensional modeling enabled architects to create “virtual walk-through” presentations of their projects, in order for clients and builders to ascertain a better sense of the reality of a structure. Through the implementation of three-dimensional animation, clients and builders might conveniently view the successive stages of a project, or they might view structures from different angles. By 1993, several larger firms used 3-D modeling regularly. The technology remained expensive, but the subsequent savings in construction time and improved communications between designer and client often justified the implementation of 3-D software and accelerated the recovery of equipment costs.

Turn-of-the Century Design Trends. As architects of the late twentieth century turned increasingly to new digital technologies for purposes of productivity, they experimented with 3-D technology to develop “e-topia” structures in modern communities, according to William J. Mitchell in *Architectural Record*. In pursuit of e-topia, an expansion of the kiosk concept, designers undertook the design of virtual malls for on-line commerce, as well

as virtual amusement parks and other conceptual structures that were previously limited to the physical realm. Through virtual reality technology, architects became further empowered in the arena of restorative construction. Modern designers ushered the art of structure restoration to a new level of evolution at the threshold of the twenty-first century by tapping the potential of 3-D systems and virtual reality to redefine the parameters of architectural restoration. Through the process of virtual reconstruction, historical structures became available for simulated viewing in their original state. Even ancient structures that ceased to exist altogether at some time in the past might be recreated in simulation form, through intensive application of the technique.

Increasingly, as the twentieth century drew to a close, what was once old became new again, including the architectural theories of feng shui, which experienced a revival in the United States during the 1990s. Progressive architectural firms, encouraged in part by academics at the University of Buffalo, subscribed to the ethereal concepts of the ancient Chinese art, the substance of which involves strategic placement of space and energy. Proper implementation of feng shui begins prior to construction of a building, with the selection of a site. During the design phase, the orientation of the structure must allow for consideration of the forces of wind and water, as implied in the words “feng shui.” Despite the ancient mystic and religious connotations of feng shui, adherence to the practice resulted in building designs not unlike those of mid-twentieth century architects.

In stark contrast to feng shui, designer Gideon S. Golany in a 1997 publication discussed the use of geo-space (building underground) to squeeze more space for structures from cluttered landscapes in highly populated areas. Building groundward presents a number of advantages, according to Golany, for better protection from the elements and lower energy consumption. The practice is most advantageous as a means of conservation, and despite the speculative nature of underground construction for human occupation, geo-space designers implemented designs in Montreal, Paris, and Japan by the end of the 1990s. Geo-space designs were particularly well-disposed to the growing trend among architectural designers to become involved in community development from the initial inception, in order to create a customized and cohesive functionality of design, in coordination with existing regional demographics.

CURRENT CONDITIONS

At the turn of the twenty-first century, conditions worsened for the commercial building industry as the economy weakened and businesses began to reign in spending. At the same time, businesses found it much more difficult to secure funding for expansion efforts.

Large projects, including office towers, suffered most severely as a result of the return to conservative lending policies, which brought an end to what some observers called speculative lending. Projections through 2006 indicate the likelihood of suppressed demand for office space.

Despite the slump in commercial construction in the early 2000s, the residential housing market—approximately 15 percent of total billings—held strong. Interest rates neared historic lows in 2001 and 2002, fueling new home construction. New housing starts, the number of new homes—both single- and multi-family—under construction, rose from 1.58 million in 2000 to 1.60 in 2001.

In order to encourage a continued source of work contracts, engineering and construction companies devised “one-stop shop” (design-and-build) services. Often, these firms offered architectural services at very low or negligible costs, so as to help the company secure large construction and project management contracts. Gaining prominence at the turn of the twenty-first century, the design-build industry saw sales for the top 100 design-build companies grow 22.3 percent to \$39.89 billion in 2000. Consequently, U.S. nonresidential construction market share for the top 100 design-build firms grew to 35 percent in 2000, compared to 25 percent in the mid-1990s. As stated in *Engineering News Record*, “The trend is clearly away from project-by-project management and toward management of larger construction programs for clients.” The Design-Build Institute of America predicts that design-build companies will increase their share of the U.S. nonresidential construction market to 45 percent by 2005.

INDUSTRY LEADERS

Of the E/A firms that were not primarily engaged in the architectural services industry, companies such as Day & Zimmerman, ABB Lummus Crest, Incorporated, and Sverdrup Corporation, which operated as a subsidiary of Jacobs Engineering Group Inc., each held a significant share of the market in the early 2000s. Largest among them was Day & Zimmerman of Philadelphia, Pennsylvania, with total revenues estimated at \$1.3 billion in 2002. Other E/A leaders included Austin Company of Cleveland, Ohio, with \$820 million in billings in 2002.

Extremely large among the architecture/engineer firms in 1998, Hellmuth, Obata & Kassabaum, Incorporated of St. Louis, Missouri, had estimated billings of \$233 million in 2001. The company originated as a purely architectural firm in 1955, and by 2001 it had developed into an international firm with 1,500 employees. One of the largest purely architectural design firms, California-based Gensler & Associates/Architects,

posted \$305 million in billings in 2002. Unlike Gensler, which employed 2,000 individuals in 2001, the majority of firms offering purely architectural services had four or less employees, as the more lucrative contracts habitually go to the engineering/architecture firms.

Among the most notable architectural projects of the 1990s was the largest building in Europe, designed by American architect Cesar Pelli. The 800-foot building was part of London's massive Canary Wharf development, an office and retail project comprising over 6.45 million square feet of space. Illustrative of many commercial projects completed at that time, however, the project was a financial flop and contributed to the financial collapse of its developer.

WORKFORCE

Most architects complete a five-year accredited college program. They must then work for at least three years before becoming eligible for certification after a series of exams. The National Council of Architectural Registration Boards, which administers the licensing exams, recognized over 30,000 registered architects in 1999. Of all licensed architects in the late-1990s, 82 percent worked in an architecture firm. That percentage was made up of about one-third solo practitioners, another third in firms with fewer than four people, and the last third in firms with more than four employees. Those that did not work in an architecture firm were employed in the commercial/industrial sector (5 percent), design firms (3 percent), government jobs (3 percent), universities or schools (2 percent), contractor firms (2 percent), and engineering firms (1 percent). Jobs for licensed architects were expected to grow about as fast as those in most other U.S. industries, with most job openings expected to result from professionals transferring to other occupations or leaving the work force.

With modern technologies affecting the industry, new jobs openings emerged for technical staff. In 1999 AIA reported 57,000 members nationwide, including students, interns, and other non-licensed professionals. As architecture firms hired drafters with CAD skills and other technical specialties, only 7 percent of industry workers in the mid-1990s were architects, although that number was projected to increase by 27.9 percent by the year 2006. The largest segment of the workforce in this industry was drafters, who comprised 12 percent of the total. Additionally, 9 percent of the workers were civil engineers, and an additional 8.2 percent were electrical engineers and electronics experts. By 2006 the number of electronics and computer specialists was anticipated to increase by a factor of 94.4 percent according to projections based on the U.S. Bureau of Labor Statistics. The clerical workforce combined, among the smallest segments of the industry except for computer programmers, comprised 5.5 percent of the

total employment, with typists (including word processing personnel) projected to decline by 15.8 percent by 2006. Other occupations within the architectural services industry included surveyors, drafters, CAD operators, and specification writers.

AMERICA AND THE WORLD

Overall, surpluses on both cross-border and affiliate trade reflected the United States' strength in major market development and extensive experience in multiple foreign markets. Particularly the United States' widely acknowledged expertise in oil and gas construction and engineering made countries like Venezuela, which was expanding its petroleum sector, and Saudi Arabia, already a powerful oil producer, even more in need of U.S. design expertise. Demand for services notwithstanding, cross-border trade remains subject to certain service barriers in many foreign countries. American architects and engineers who work in some countries are subject to the country's internal licensing requirements for those professions. In Venezuela and other countries, foreign engineers and architects must successfully complete the national professional examination process, including completion of a validation process through a Venezuelan university.

RESEARCH AND TECHNOLOGY

Climate Control. Peter Segalla, in *Buildings*, cited the issue of climate control as a critical concern for designers at the turn of the century. In apartment buildings, office space, and private residence, the notion of individual preferences for what is "too cold" and "too hot" contribute to the basic comfort, livability, and usability of a design. Segalla further encouraged the refinement and use of underfloor air distribution technology based in modular, insulated floor space that affords individualized climate control within the flooring. Segalla operates Peter Segalla Design in New York City; he implemented the technology in his design of a 93,000-square-foot building in Salt Lake City.

In 1999 the National Renewable Energy Lab (NREL) announced a promising new software tool called Energy-10. Energy-10 very quickly determines the most efficient energy and air flows within structures, to simplify the implementation of energy-saving designs for both climate control and lighting. NREL estimated that 40-70 percent energy savings might be realized with the use of Energy-10. The product can be applied toward the design of any type of structure, from a small residence to a large urban complex. Based on input regarding the size of a structure, in terms of floor space and number of stories, type of climate control system, and geographic location, Energy-10 assesses the potential rewards of designing solar heating, insulation, daylight and shading, and other features into a planned structure.

SURVEYING SERVICES

This industry is comprised of establishments primarily engaged in providing professional surveying services and photogrammetric engineering. Types of surveys produced include land, water, and aerial surveys.

NAICS CODE(S)

541360 (Geophysical Surveying and Mapping Services)

541370 (Surveying and Mapping (Except Geophysical Services))

INDUSTRY SNAPSHOT

All physical characteristics and points on the earth's surface exist in positional relationship to other character-

istics and points. Surveying is the process whereby these land relationships are measured and described. It uses the mathematical principles of geometry and trigonometry to identify horizontal and vertical placement and elevation. Surveys are primarily used in establishing property boundaries and in map making.

There are two major types of surveying: plane surveying and geodetic surveying. Plane surveying does not account for the curvature of the earth's surface. It is used primarily for smaller areas where this curvature produces insignificant deviations between the survey results and reality. According to information provided by *Public Works*, surveys of areas measuring "no more than 12 miles or so in any one direction" can be handled as if they were taken on a flat surface or plane. Geodetic surveying is used for larger areas in which it is necessary to make mathematical computations to account for the earth's curvature.

According to the U.S. Department of Commerce's *1992 Census of Service Industries*, there were 8,418 establishments in the United States offering surveying services, down from the 8,436 establishments in 1987. Their combined receipts were just under \$3 billion in 1994, up 5.2 percent from the 1993 figure of \$2.7 billion.

BACKGROUND AND DEVELOPMENT

Surveying techniques developed in the ancient world, when people began to describe the dimensions and shape of the earth. Homer (in approximately the ninth century B.C.) envisioned the earth as a flat disk surrounded by oceans. Pythagoras, a Greek philosopher of the sixth century B.C., imagined a spherical world. Gauging the circumference of the earth was first accomplished in 240 B.C. by the Greek astronomer Eratosthenes, who measured the angle of the sun from two points on earth separated by 500 miles. His calculations gave him an answer of 25,000 miles, remarkably close to the earth's actual circumference (24,901.55 miles around the equator and 24,859.82 miles through the poles).

Before men knew the earth's overall dimensions, however, they developed techniques for measuring and locating parts. As early as 3800 B.C., the Babylonians conducted land surveys for taxation purposes. In approximately 2900 B.C., the Egyptians used surveying techniques to site, level, and erect the pyramids. By 1400 B.C., they were able to survey the land along the Nile River and reestablish field boundaries when floods erased previously established markers. Ancient Greeks were also acquainted with surveying methods. Their knowledge was passed on to the Romans, who refined and further developed surveying techniques used in building roads, bridges, buildings, and monuments.

Early surveying instruments were designed to help technicians accurately measure the angles necessary to

calculate precise distances. One instrument, developed by the Romans, was called a groma. The groma was a cross-shaped instrument used to make a right angle. It had plumb lines suspended from each of its four ends to aid in leveling.

Another early surveying tool, the astrolabe, was used to measure angular heights. Through the centuries innovators improved upon the astrolabe's basic design. Glass lenses were added to make sighting sharper and more accurate. Larger astrolabes were developed for astronomical use, and smaller ones were fashioned for mariners. Plumb bobs were added to help determine a true vertical line.

Some instruments that were originally developed to aid navigators were also used by surveyors and map makers. An instrument called a cross-staff, or sighting stick, was developed to identify latitude. It had a sliding crosspiece and three sight holes that could be lined up on the horizon and sun to measure the angle. Users of early cross-staffs had to mark this angle and perform complex mathematical calculations to determine their latitude. Later cross-staffs were marked for direct readings.

Both the astrolabe and cross-staff required their users to make direct sightings on the sun. Because of the visual problems associated with this task, results were not entirely accurate. In 1607, a device called a back staff was first described. The back staff was designed so that the sun, when placed directly behind the instrument, cast a thin shadow on its staff.

The first precise theodolite was built for the British Royal Society by Jesse Ramsden during the late 1700s. A theodolite was an instrument consisting of a transit (a device used to measure angles) and a level. Surveyors used the theodolite to measure land areas by determining horizontal and vertical angles and applying trigonometric principles in a process known as triangulation.

Surveying played an important role in the development of the United States. During the colonial period, land was often received by private citizens as a result of a grant from a governmental unit for specified purposes or as payment for services. Recipients would have the tract surveyed and defined for the purpose of establishing the boundaries of their legal ownership. This type of survey was called a "metes and bounds" survey. The word "metes" referred to the boundary lines or limits of the property. The word "bounds" also referred to the demarcation of property limits. Metes and bounds surveys were conducted by beginning at a specified point and describing the perimeter of the land by referencing natural or artificial markers, called monuments, then describing the geometric lines connecting these physical objects. Metes and bounds surveys sometimes resulted in disputes when subsequent and adjacent property owners defined overlapping tracts.

To help make the definition of property lines more uniform, a national grid survey pattern was established during the late eighteenth century, and was subsequently used to describe and define property limits in more than 70 percent of the continental United States. Under the Land Ordinance of 1785, townships were defined as square areas, six miles on each side, oriented to the compass points. Each township was subdivided into 36 sections, each containing 640 acres (one square mile). Sections were further subdivided to yield tracts of land that were sold to individuals.

During the 1930s, the United States began implementing state grid systems under which states would maintain State Plane Coordinate (SPC) systems. These would provide permanent point identification and would ultimately fall under the control of a national network. Two types of SPC systems were adopted. One, called the Lambert projection, was used by states with a greater East-West shape. The second, the Mercator projection, was used by states with a greater North-South shape.

Surveying distances in the United States were measured using foot and decimal parts. Angles were measured in degrees, minutes, and seconds. Positions were specified by identifying latitude and longitude or by referencing coordinates from an identified reference point. Elevation was measured from an established "bench mark," which was a permanent marker (either artificial or natural) with a known elevation above or below a specified surface (such as sea level).

Surveyors were required to take meticulous notes concurrently with the process of conducting the survey. These notes were recorded in field notebooks, which were then permanently kept under carefully controlled conditions. In the United States, field notebooks were considered legal documents.

The precision of a survey and its cost were related. "First Order" surveys were the most precise and the most costly. Other orders of surveys, termed second, third, and fourth, descended in precision and expense. Specific types of surveys were used for different purposes. Topographic surveys described the shape of the ground; hydrographic surveys mapped the bottoms of water bodies; construction surveys marked areas for specific projects such as buildings, bridges, and highways; underground surveys were conducted for pipelines, tunnels, and mining operations.

INDUSTRY LEADERS

Most architectural and engineering firms offer surveying services, and do a majority of surveying work themselves. The pure surveying firms characteristically are small and have only a fraction of industry billings. The top pure surveying company in 1996 was BSC Group, Inc. with \$10 million. Other leaders include Flood

Data Services, Inc. (\$9 million); Tobin Surveys, Inc. (\$6 million); Towill, Inc. (\$5 million); McIntosh and McIntosh PC (\$5 million); and Toplis and Harding, Inc. (\$5 million).

One of the largest surveying establishments in the United States was MSE Corporation. MSE, a privately held organization owned by Sol C. Miller, was first organized as a partnership in Indianapolis, Indiana in 1960 and incorporated in 1962. In 1996, MSE expanded to 350 employees and completed its 300th project assignment.

WORKFORCE

Surveyors and mapping scientists held about 101,000 jobs in 1996. Engineering and architectural services firms employed about three-fifths of these workers. Federal, State, and local governmental agencies employed an additional quarter. Major Federal Governmental employers are the U.S. Geological Survey, the Bureau of Land Management, the Army Corps of Engineers, the Forest Service, the National Oceanic and Atmospheric Administration, and the National Imagery and Mapping Agency (NIMA), formerly the Defense Mapping Agency. Most surveyors in State and local government work for highway departments and urban planning and redevelopment agencies. Construction firms, mining and oil and gas extraction companies, and public utilities also employ surveyors and mapping scientists. About 8,000 were self-employed in 1996.

This is one of the few professional occupations in which employment is expected to decline. Employment of surveyors and mapping scientists is expected to decline slightly through the year 2006, as the widespread availability and use of advanced technologies, such as the Global Positioning System, Geographic Information Systems, and remote sensing, are increasing both the accuracy and productivity of survey and mapping work. Job openings, however, will continue to result from the need to replace workers who transfer to other occupations or leave the labor force altogether.

As technologies become more complex, opportunities will be best for surveyors and mapping scientists who have at least a bachelor's degree and strong technical skills. Increasing demand for geographic data, as opposed to traditional surveying services, will mean better opportunities for mapping scientists involved in the development and use of geographic and land information systems; however, upgraded licensing requirements will continue to limit opportunities for those with less education.

Even as demand is increasing in nontraditional areas such as urban planning and natural resource exploration and mapping, opportunities for surveyors and mapping scientists should remain concentrated in engineering, ar-

chitectural, and surveying services firms. According to the *Occupational Outlook Handbook* published by the Bureau of Labor Statistics, growth in construction through the year 2006 should require surveyors to lay out streets, shopping centers, housing developments, factories, office buildings, and recreation areas. However, employment may fluctuate from year to year along with construction activity. In addition, employment of mapping scientists and surveyors by private firms and the federal government will continue to be affected by budget cutbacks and technological efficiency.

The median weekly earnings for surveyors and mapping scientists were about \$694 a week in 1996. The middle 50 percent earned between \$547 and \$849 a week; 10 percent earned less than \$446 a week; 10 percent earned more than \$1,000 a week.

The median weekly earnings for survey technicians were about \$461 a week in 1996. The middle 50 percent earned between \$378 and \$725 a week; 10 percent earned less than \$294 a week; 10 percent earned more than \$942 a week.

In 1997, the federal government hired high school graduates with little or no training or experience at salaries of about \$14,240 annually for entry level jobs on survey crews. Those with one year of related post-secondary training earned about \$15,540 a year. Those with an associate degree that included coursework in surveying generally started as instrument assistants with an annual salary of about \$17,450. In 1997, entry level land surveyors or cartographers with the federal government earned about \$19,520, \$24,180 or \$29,580 a year, depending on their qualifications. The average annual salary for federal land surveyors in early 1997 was about \$47,850; for cartographers, about \$52,500; and for geodesists, about \$62,760. The average annual salary for federal surveying technicians was about \$28,600; for cartographic technicians, about \$34,840; and for geodetic technicians, about \$45,050.

RESEARCH AND TECHNOLOGY

Towards the end of the twentieth century, new technology has been changing the nature of the work of surveyors and survey technicians. For larger projects, surveyors are increasingly using the Global Positioning System (GPS), a satellite system that precisely locates points on the earth using radio signals transmitted by satellites. To use this system, a surveyor places a satellite signal receiver (a small instrument mounted on a tripod) on a desired point. The receiver simultaneously collects information from several satellites to locate a precise position. The receiver can also be placed in a vehicle for uses such as tracing out road systems. Since receivers now come in different sizes and shapes and the cost of the

receivers has fallen, much more surveying work is being done by GPS.

Some surveyors perform specialized functions, which are closer to those of a mapping scientist than a traditional surveyor. For example, geodetic surveyors use high-accuracy techniques, including satellite observations, to measure large areas of the earth's surface. Geophysical prospecting surveyors mark sites for subsurface exploration, usually petroleum related. Marine surveyors survey harbors, rivers, and other bodies of water to determine shorelines, topography of the bottom, water depth, and other features. The work of surveyors and mapping scientists is changing due to advancements in technology. These advancements include not only the GPS, but also new earth resources data satellites, improved aerial photography, and geographic information systems (GIS), which are computerized data banks of spatial data. From the older specialties of photogrammetrist and cartographer, a new type of mapping scientist is emerging. The *geographic information specialist* combines the functions of mapping science and surveying into a broader field concerned with the collection and analysis of geographic information.

According to an estimate reported in *ENR* magazine, about 80 percent of future surveying would be accomplished using GPS. The remaining 20 percent of surveying tasks would be done by conventional methods only in areas in which GPS was not able to be used. These included underground locations, such as tunnels, and heavily congested urban regions.

SIC 8721

ACCOUNTING, AUDITING, AND BOOKKEEPING SERVICES

This category covers establishments primarily engaged in furnishing accounting, bookkeeping, and related auditing services. It includes those businesses that use

data processing and tabulating in connection with these services, but those whose primary aim is to provide such data processing and tabulating are classified in **SIC 7374: Computer Processing and Data Preparation and Processing Services**. Establishments providing tax preparation services without also providing accounting, auditing, or bookkeeping services are covered in **SIC 7291: Tax Return Preparation Services**.

NAICS CODE(S)

541211 (Offices of Certified Public Accountants)

541214 (Payroll Services)

541219 (Other Accounting Services)

INDUSTRY SNAPSHOT

Accounting, auditing, and bookkeeping services serve key functions in America's (and the world's) economic engine. In such publications as *The Bottom Line*, the global significance of the accounting profession has long been confirmed: "The world's capital markets rely on financial statements certified by independent auditors. If the integrity of those statements could not be trusted, investment would come to a halt and economic growth would be paralyzed." The close relationship between the accounting industry and the economy as a whole became increasingly apparent in the early 2000s as a wave of corporate scandals not only rocked the U.S. accounting industry but also undermined an already weakened economy. The Enron bankruptcy, that resulted in the demise of Big Five accounting firm Arthur Andersen in 2002 was followed by admissions of fraudulent accounting by WorldCom Inc., the criminal indictment of Tyco International Ltd.'s CEO and CFO, and various other accounting impropriety charges levied against firms like Kmart Corp., Adelphia Communications Corp., and Merrill Lynch & Co. As scandals mounted, investor confidence waned, pushing the already beleaguered stock market down further.

In response to the growing number of high profile corporate fraud cases, the Bush administration passed the Sarbanes-Oxley Act in 2002 as part of an effort to crack down on fraudulent accounting practices and to bolster investor confidence. The United States Congress also stripped the American Institute of Certified Public Accountants of its regulatory duties, granting auditing oversight responsibilities to a new federal board.

ORGANIZATION AND STRUCTURE

Different fields in the accounting profession represent different degrees of affiliation with the world of commerce. Public accountants run their own businesses or are employed by accounting firms to meet the particular accounting needs of their clients. Accountants employed by companies to record and summarize financial data are known variously as management, industrial, cor-

porate, or private accountants. Internal auditors are employed by companies to check records for signs of inefficiency, mismanagement, or fraud. Accountants and auditors employed in government not only produce and check the financial records pertaining to the institution for which they work, they also audit persons or businesses regulated and taxed by government. Each of these broadly defined fields is further subdivided by choices of specialization, yielding a wide variety of niches for accountants to fill.

Associations. Numerous organizations within the accounting profession cater to the specialized needs of different groups of accountants, ranging from the Association of Black CPA Firms to the American Women's Society of Certified Public Accountants to the National Association of Accountants. By far the largest and most important of the organizations within the profession, however, has been the American Institute of Certified Public Accountants (AICPA), which not only represented more than 330,000 CPAs at the beginning of 2000, but also served as the voice of the profession as a whole through its activities, recognized by the Securities and Exchange Commission (SEC) as a self-regulating body and setter of standards until 2002, when the federal government took over those responsibilities. The AICPA's three special member divisions neither monitor competency nor provide accreditation, but serve as outlets for volunteer members with particular interests; they are the Federal Tax Division (dating from 1983), and two divisions created in 1986—Personal Financial Planning, and Management Advisory Services.

In addition to the standards established by the AICPA's Auditing Standards Board (ASB) and by other standards boards, the standards that have governed the accounting profession are those known by the acronym GAAP—Generally Accepted Accounting Principles. According to *Principles of Accounting*, “The general acceptance of accounting principles is not determined by a formal vote or survey of practicing accountants. An accounting principle must have substantial authoritative support to qualify as generally accepted. References to a particular accounting principle in authoritative accounting literature constitute substantive evidence of its general acceptance.”

BACKGROUND AND DEVELOPMENT

Through the earliest financial record-keeping dates back to the very origins of international trade—modern accounting methods developed with the introduction of the double entry technique, whereby debits are assigned to the left side of a ledger and credits to the right. The value of this fundamental method seems to have been grasped first in the commercial republics of Italy at some point before the fourteenth century.

More sophisticated accounting techniques were not needed until Great Britain's industrial revolution and ascent to global pre-eminence created business conditions of hitherto unprecedented scope and complexity. As noted in *Modern Accounting Theory*, “from about the beginning of the nineteenth century the rise of manufacturing, trading, shipping, and all the various subsidiary services (such as the provision of the many kinds of insurance), the vast ramifications of the London money market, and the opening of world markets (such as the Liverpool Cotton Exchange) made accurate financial accounting and reporting a prime necessity for the maintenance of Great Britain's commercial empire.” With the exception of the field of consolidated accounting, where, “practice in the United States developed before it did in Great Britain and was to provide the leadership for the latter,” the early history of American accounting was therefore defined by the adaptation of British innovations and precedents to the novel conditions of business development in the United States.

In due course, as the United States increasingly assumed Great Britain's mantle as the world leader in economic affairs, still further developments took place in accounting methods. Many of the most important accounting principles were not introduced until the early decades of the twentieth century. These changes took place in response to the emergence of huge industrial firms, large stockholders' groups, government regulation, and continued economic growth. According to *Principles of Accounting*, all of these factors combined to help “create the large groups of interested parties who require a constant stream of reliable financial information concerning the economic entities they own, manage, or regulate,” a type of information “meaningful only when prepared according to some agreed-on standards and procedures.”

A further stimulus to the American accounting industry took place early in the twentieth century with the introduction of the national income tax in 1913. The American Bar Association took the position that income tax law fell entirely within the province of lawyers, and the resultant turf war between that association and the AICPA was not resolved until the mid-1950s, after a number of lawsuits, at which point the preparation of tax returns became solidly established as a key business area for American accountants.

The stock market crash of 1929 prompted the Federal Securities Act of 1933 and the Federal Securities Act of 1934. These pieces of legislation required that audits of the financial statements of public companies be made by independent certified public accountants, further bolstering the accounting profession. In addition to generating business for such accountants, these acts had the effect of raising the prestige of the accountancy profes-

sion, because the government neither insisted on providing auditors of its own nor set auditing standards, but rather accepted the integrity of the profession and the standards that it developed by means of self-regulation.

However, such self-regulation did not satisfy some critics, who took the view that government should play a more active part in such a highly critical area of the economy. Nor did it spell an end to controversy within the profession. At the end of the 1960s, especially, there was “a period of unprecedented stress for the individual members and institutions of the accounting profession,” in the words of the March 1972 *Report of the Study on Establishment of Accounting Principles*, which cited the dramatic growth of accounting firms, new accounting issues and business practices, and corporate mergers as particular factors. According to *The Bottom Line*, that 1972 report proposed the establishment of an independent standard-setting body, the Financial Accounting Standards Board (FASB), whose scope was defined as follows by one of its former chairpersons: “FASB standards are binding on most companies and independent auditors, with stiff penalties for departures. The ethics rules of the American Institute of CPAs, the CPA licensing requirements of the 50 states, and the regulations of the Securities and Exchange Commission all mandate conformity with the Board’s pronouncements.”

But the establishment of the FASB in 1973 did not put an end to controversy, as it was a body perceived as having a bias in favor of business and the private sector. Therefore, the Governmental Accounting Standards Board (GASB) was instituted in 1984 for standard-setting in relation to state and local government, confining the FASB’s jurisdiction to solely nongovernmental entities. Some analysts saw defects in this new arrangement, however, pointing out that institutions within the private sector and within the public sector were not always so different from each other as to justify the maintenance of different sets of standards for each, and that the entire idea of having different standards for the two sectors was by no means automatically a good thing—especially as still other sets of standards governed auditing procedures in federal government.

In recent years a number of the industry’s largest companies have endured harsh criticism from some quarters. The savings and loan crisis of the 1980s, in which many of those institutions were felled by bankruptcy, tarnished the reputation of the industry-leading “Big Six” accounting firms, which were responsible for auditing most of the failed thrifts.

In the early 1990s, the accounting, auditing, and bookkeeping industry supported firms of vastly different economic status, from the giant accounting firms that comprised the Big Six to one-person operations. The difference in scale between the larger and smaller ac-

counting businesses was so pronounced and led to such a difference in the type of services offered by each size of business that accountancy in the United States sometimes was viewed as “two separate and distinct professions,” according to *The Bottom Line*, which noted that “major national firms were known for their audits of major publicly held companies and for the breadth of their management advisory services. The smallest firms, for the most part, emphasized personal attention to small businesses and individual taxpayers. The mid-size firms typically carved out a market niche in which they performed a variety of services.”

In theory, such a division of labor should have guaranteed the peaceful coexistence of accountancy firms of varying sizes. However, tension between firms had long been a characteristic of the modern accountancy profession in the United States, and reflected a variety of factors. For instance, there was a suspicion among the smaller firms that the larger ones were exploiting to their own advantage their ability to offer financial services at a loss-leading discount, thereby attracting potentially lucrative new clients in a way impossible for businesses with fewer resources to match. Moreover, the intermediate position occupied by mid-sized firms was an inherently unstable one: with smaller firms becoming more specialized, and larger ones having a matchless range and depth, mid-sized firms risked being left with no niche at all, and often ended up merging with larger outfits.

In addition, mergers among clients had a profound impact on the relative fortunes of larger and smaller accounting firms, especially as such mergers, already a cause for concern in some quarters during the 1970s, became a far more prominent feature of the business scene during the next decade. According to a study undertaken by the Senate Subcommittee on Reports, Accounting and Management of the Committee on Government Operations (1976), “As a by-product of the corporate merger movement that has concentrated control over the Nation’s economic resources among fewer and fewer institutions and individuals, small and medium-sized CPA firms have been displaced as independent auditors by large accounting firms.”

Moreover, as this same study reported, such displacement also tended to occur when companies decided to sell shares to the public: “Underwriters and bankers often inform companies that a nationally known firm must be retained as independent auditor in order to sell securities to the public at the highest possible price, or obtain a necessary loan.”

Industry receipts grew by roughly 30 percent from 1992 to 1996, when they surpassed the \$50 billion milestone. Annual growth in the 1990s was slower, however, than the double-digit percentage increases of the late 1980s. In the mid-1990s accounting firms moved toward

confronting the ethical and legal problems of their clients, including such issues as corporate governance and accountability, according to *Oregon Business*.

Large international firms branched out into management consulting services. However, according to *The CPA Journal*, the attractive consulting fees may have led many firms to ignore potential conflicts of interest in serving as an auditor and as a management consultant to the same client. The profession's standards also were said to be jeopardized by the entrance of non-CPA partners and owners into influential accounting firms. Many companies facing these problems, like Arthur Andersen, split their accounting and management consulting operations into separate divisions or companies to avoid accusations of impropriety.

During the mid to late 1990s, accounting firms evolved by restructuring their services and offering new services such as attestation and other assurance services, according to *The CPA Journal*. The growing internationalization of business was another important factor in changing the way the industry functioned. According to *Oregon Business*, international bookkeeping operations grew at a faster pace than domestic operations. The restructuring proved to be favorable for the continuation of mergers among accounting firms. By 1998, the Big Six had been reduced to the Big Five, with the merger of Price Waterhouse and Coopers & Lybrand.

Aside from the trend toward mergers among large national accounting firms, there was a movement during the late 1990s for other businesses, such as financial institutions, to acquire CPA firms, according to an article in the July 1999 issue of the *CPA Journal*. This had the potential to allow services traditionally offered exclusively by CPAs to be offered by non-CPAs. In the late 1990s, many issues concerning regulation, licensing, state laws, and peer reviews remained unresolved. The AICPA continued working to clarify and develop guidelines for some of these issues.

CURRENT CONDITIONS

The U.S. accounting industry was rocked by scandal in the early 2000s. Arthur Andersen, one of the Big Five accounting firms, was convicted of obstruction of justice in 2002; the charges related to its work for Enron, which had stunned Wall Street a year earlier with an unexpected bankruptcy. Also in 2002, WorldCom revealed that it had improperly accounted for \$4 billion in expenses; Tyco International CEO Dennis Kozlowski and CFO Mark Swartz were indicted on charges of embezzling a total of \$170 million and engaging in illegal sales of Tyco stock; and Merrill Lynch was investigated for auditing conflicts of interest.

In an effort to protect investors and to increase the accountability of the accounting industry, the U.S. fed-

eral government signed the Sarbanes-Oxley Act into law in July of 2002. The act called for the formation of a federal board to oversee corporate auditing activity, a task formerly handled by the American Institute of Certified Public Accountants. It also increased the fines and changes levied against businesses and individuals convicted of corporate fraud.

When Arthur Andersen shut its doors in 2002, the remaining Big Four players scrambled to secure the business of Andersen's largest clients. According to a March 2003 *Business Wire*, this was likely to have specific ramifications for accounting firms serving smaller clients. "The expectation is that the large international and national firms will be looking at the clients at the bottom of their client lists and deciding which ones might be a better fit for a local or regional firm. These large firms need to keep their most profitable clients happy and to do that they need to manage their resources appropriately." This trend was expected to provide an unprecedented opportunity for smaller firms to secure new business. However, the regulations put in place by Sarbanes-Oxley were also expected to make it more difficult and costly for small companies to perform SEC audits. As a result, many industry analysts predicted that small and medium-sized firms would begin to consolidate in 2003 and beyond.

INDUSTRY LEADERS

After Arthur Andersen began phasing out operations in the wake of a criminal indictment related to the Enron scandal, the Big Five accounting firms became known as the Big Four—KPMG International, Ernst & Young, Deloitte Touche Tohmatsu, and Pricewaterhouse-Coopers. While these firms were the most well-known in the profession, the American economy also supported regional and local firms, as well as thousands of accountants who maintained their own small businesses. Other industry leaders of the early 2000s included American Express, H&R Block, Merrill Lynch, and Oppenheimer.

WORKFORCE

Because every state established its own licensing requirements, there were some differences in the type of education and experience required of a person seeking to become a CPA. Essentially, the requirements consisted of a four-year college degree, one or two years of on-the-job experience, and a passing grade on the CPA examination.

The shortage of teachers with doctoral degrees in accounting—largely attributable to the higher pay available to talented accountants in public and industrial accounting—presented a major hurdle to those who advocated the desirability of requiring a fifth year of education for CPAs, and prompted the AICPA to institute a

financial aid program for doctoral candidates, in hopes of boosting the number of faculty in accounting.

Any student capable of meeting the existing educational requirements faced good prospects because of the anticipated healthy state of the American accounting profession in the twenty-first century. Through the year 2005, job growth in accounting was predicted to be higher than the average for all occupations tracked by the U.S. Department of Labor—and this in a context where the numbers of students graduating with degrees in accounting had remained essentially stable.

Though CPAs were expected to have a better choice among a greater range of employment activities, other accountants and accountants without college degrees could be expected to find niches in a growing market. Moreover, accountants of all levels of training and experience could take confidence from the fact that downturns in the national economy seldom had an adverse impact on their chosen profession, because even a poorly performing economy still generated data that had to be analyzed and interpreted.

Of the roughly 2 million clerks engaged in various forms of bookkeeping, about a third worked in wholesale and retail; about a quarter worked in social, educational, health, or business services; and about a quarter worked part-time. Their employment prospects were seen as vulnerable to increasing computerization of office functions.

At the beginning of the 1990s, the average starting salary for junior accountants in the federal government was \$17,000 annually. By the close of the century, a college graduate who began working in public accounting could expect to earn \$26,000 to \$36,750; salaries offered in corporate accounting began at \$27,000 and capped at \$33,750. College graduates with a master's degree could expect to add 10 percent to their starting salary.

Unsurprisingly, members of the accounting profession who had greater experience earned significantly more during this same period. Managers and directors in accounting firms commanded an annual average salary of \$56,250 in small accounting firms and could earn up to \$92,000 in large firms (usually after a period of five to eight years). In 8 to 12 years, once an individual reached partner status in an accounting firm, average first-year salaries were reported to be \$175,000 (*1999 Robert Half and Accountemps Salary Guide*).

Demand for qualified accounting professionals continued to grow during the early 2000s. The target accounting firms for most fresh graduates were the Big Four. Accounting firms were in constant search of qualified personnel. Consequently, they were offering flexible working hours and a more democratic promotion system, according to *The Practical Accountant*.

In her article on the changing roles of CPAs, Tami Kegley discussed the need for CPAs of the future to have knowledge of “the international market, technological applications and strategic knowledge management.” Another area expected to grow is the consulting assurance area, according to Leigh Knopf of the AICPA. Other factors affecting the future of CPAs are increased competition with non-CPAs and the globalization of the accounting industry.

AMERICA AND THE WORLD

The largest of the accountancy firms in the United States possessed the resources to conduct extensive business overseas. Some of the smaller firms worked in conjunction with similar outfits overseas by associating with them in cooperative networks. With the increasing trend toward a global economy that was apparent at the end of the twentieth century, the importance of such international transactions was sure to increase, stressing the desirability of essentially uniform worldwide accounting standards in making cross-border financial data as accurate and useful as possible.

Because the American way of doing business exerted a powerful influence on the rest of the world throughout the twentieth century, and because American accounting standards, building on British precedent and developed over the course of that century, had established a level of sophistication and authority recognized around the world, international accounting standards greatly conform to an American model.

SIC 8731

COMMERCIAL PHYSICAL AND BIOLOGICAL RESEARCH

This industry classification covers establishments primarily engaged in commercial physical and biological research and development on a contract or fee basis. Noncommercial research establishments funded by endowments, grants, or contributions are classified in **SIC 8733: Noncommercial Research Organizations**. Separate establishments of aircraft, guided missile, or spacecraft manufacturers primarily engaged in research and development on these products are classified in several SICs concerned with transportation equipment manufacturing.

NAICS CODE(S)

541710 (Research and Development in the Physical Sciences and Engineering Sciences)

541720 (Research and Development in the Life Sciences)

Commercial physical and biological research organizations are supported by commercial firms and organizations that invest a portion of their annual budget in research and development (R&D). These industries apply the knowledge acquired through R&D toward developing products for domestic and international markets. Commercial physical and biological research is routinely undertaken in a vast array of subject categories, including agricultural, biological, chemical, engineering, physical, and industrial research. Studies in these arenas serve to improve already existing products, and to develop new ones. Nearly every firm in every major industry has a division or subsidiary devoted to commercial

physical research. Many products that arise out of these research efforts appear solely in the retail consumer market; others contribute to improving industrial processes.

Commercial, physical, and biological research surfaced among the fastest growing segments of the U.S. economy beginning in the early 1990s and continuing into the early 2000s. Research and development companies experienced explosive growth with associated high volatility. According to the U.S. Commerce Department the total annual U.S. expenditures for research and development grew by 9.3 percent in the year 2000 to \$162.7 billion; this was the largest increase since 1995. The two fastest-growing segments of the industry—information and electronics manufacturing and medicines and medical devices—accounted for more than two-thirds of all research and development spending in the United States, compared to slightly more than half in the mid-1990s.

While other industries cut back during recession periods, commercial research and development divisions often enjoyed increased budgets. For instance, a fiercely competitive business environment in the early 1990s led companies to place a substantial premium on first-to-market technology, thus accentuating the importance of research and development for maintaining and expanding market share. Drug companies increased their R&D expenditures by 13 percent to about \$11 billion or 16 percent of sales, in response to public concerns over physical and biological phenomena such as the spread of AIDS. In the latter years of the decade innovative new concepts—such as controversial experimentation with cloning—further fueled the R&D economy. Despite the downturn in the technology industry in the early 2000s, R&D budgets in the technology sector continued to grow. In March of 2001, the Semiconductor Industry Association announced its intent to grow its research efforts twofold. Industries experiencing decreased R&D spending in the early 2000s included aerospace, chemical manufacturing, and basic industries and materials.

At the turn of the twenty-first century, the roster of R&D industry firms fluctuated drastically. One major player, Science Applications International Corporation (SAIC) was a private, employee-owned company headquartered in San Diego, California. SAIC reported annual sales of \$6.09 billion in 2002, for a 3.4 percent annual sales growth. SAIC employed 40,400 workers in 2002 and ranked at number 288 among the *Fortune* 500. The firm contracts an estimated 50 percent of its workload with government entities.

Also prominent is Quintiles Transnational Corporation, the largest research provider to pharmaceuticals manufacturers, which maintained operations in 30 countries worldwide. An S&P 500 company, Quintiles is headquartered in Durham, North Carolina. In 2002, the firm employed over 15,500 workers and posted \$1.99

billion in sales, a 23 percent growth. Quintiles' PharmaBio Development subsidiary offers R&D services to healthcare companies in exchange for new product royalties. In 2002, a management-led buyout team was in the process of taking Quintiles private. Additionally, Chiron Corporation, devoted to pharmaceutical research, reported \$972.9 billion in sales for 2002. Chiron, a public company headquartered in Emeryville, California, is largely owned (42 percent) by Novartis.

SIC 8732

COMMERCIAL ECONOMIC, SOCIOLOGICAL, AND EDUCATIONAL RESEARCH

This classification includes establishments primarily engaged in performing commercial business, marketing, and other economic, sociological, and educational research on a contract or fee basis. Noncommercial economic, sociological, and educational research establishments funded from endowments, grants, or contributions are classified in **SIC 8733 Noncommercial Research Organizations**.

NAICS CODE(S)

541730 (Research and Development in the Social Sciences and Humanities)

541910 (Marketing Research and Public Opinion Polling)

Members of this classification gather and interpret data in the areas of business and economic research, educational research, market research, public opinion, and sociological research. Utilized to track such varied phenomena as product launches, television viewing habits, and political popularity, this industry has become an increasingly integral part of the sociological landscape of the United States. Demographic surveys and poll results

are used to determine everything from a publication's advertising focus to the popularity of legislative initiatives under consideration. Indeed, the plethora of polls and surveys in the 1990s came under increased criticism from observers who charged that such polls, particularly with regard to politics, were in themselves forces that influenced public opinion.

Market research, routinely utilized by companies involved in myriad industries nationwide, grew and changed rapidly between the 1930s and the 1990s. The philosophical underpinnings of this growth were based on a consumer, market-driven orientation. Thus the emphasis was on discovering the needs and wants of the consumer and creating a product that fulfilled those needs and wants, as opposed to a product-driven philosophy centered on creating a product and trying to sell it without first consulting the marketplace to determine the appetite for the product.

In order to systematically gather such information and analyze it, larger corporations support marketing departments. Through a variety of means—mostly surveys—these departments evaluate a product's acceptance in the marketplace and track its sales. Many other corporations, large and small, contract with commercial research companies that specialize in such demographic studies.

Though some critics claim that the "scientific method" cannot be applied to inexact sciences such as anthropology, economics, geography, political science, psychology, and sociology, sociologists continue to use advanced mathematical statistics and other quantitative methods, as well as computer technology, to evaluate and interpret data. Much of their information is derived from a variety of sources such as census reports, government studies, and questionnaires from large samples of people. Commercial nonphysical research firms also employ qualitative methods such as direct observation and historical research.

As surveys and polls have become widely used tools for gathering demographic and other pertinent information, some of the best known firms in this industry — AC Nielsen, Gallup, and Harris — have become familiar names to the average consumer. By the end of the 1990s, in fact, Nielsen had become the unquestioned leader. According to *Ward's Business Directory of U.S. Private and Public Companies*, other industry leaders included IMS International Inc., Gartner Group Inc., and Moody's Investors Service.

In 1998, there were an estimated 5,595 establishments in this industry, billing \$9 billion, a 2 percent increase from the previous year. In 1999, 149,500 workers were employed, working just over 30 hours per week for average wages of \$14.78 per hour.

SIC 8733

NONCOMMERCIAL RESEARCH ORGANIZATIONS

This category includes establishments primarily engaged in performing noncommercial research into and dissemination of information for public health, education, or general welfare. Establishments included here operate primarily on funds from endowments, contributions, and grants. The research is frequently contracted out and funded by these establishments. Establishments primarily engaged in commercial physical and biological research are classified in **SIC 8731: Commercial Physical and Biological Research**, and those engaged in commercial economic, sociological, and educational research are classified in **SIC 8732: Commercial Economic, Sociological, and Educational Research**.

NAICS CODE(S)

541710 (Research and Development in the Physical Sciences and Engineering Sciences)

541720 (Research and Development in the Life Sciences)

541730 (Research and Development in the Social Sciences and Humanities)

Colleges and universities are leaders in noncommercial research, with Stanford University, the University of Texas at Austin, Harvard University, the University of Arizona, Ohio State University, and the University of Chicago topping the list. These universities provide research on a variety of subjects, and the knowledge they gain benefits the whole of society. They specialize in technical research, such as engineering, physics, biochemistry, and biology. Academic aspects of universities are discussed in greater detail under **SIC 8221: Colleges, Universities, and Professional Schools**. Academic research in the United States is funded largely through taxpayer dollars in the form of government grants and

occurs at the individual level rather than at the organizational level. Although federal funds are dispensed largely to individual researchers, educational institutions classified under the "Research I" category receive tens of millions of dollars annually in federal support. Additionally, "Research II" institutions receive between \$15 million and \$40 million every year.

Government Funding Sources. The National Institutes of Health (NIH) dispenses billions of research dollars each year in the form of grants. Twenty-two organizations, including the National Library of Medicine and the John F. Fogarty International Center, fall under the budgetary control of the National Institutes of Health. Most prominent among the research institutes are the National Cancer Institute, the National Heart, Lung, and Blood Institute, and the National Institute of Diabetes and Digestive and Kidney Research. According to U.S. budget estimates for the year 2001, NIH funds for research purposes total \$18.172 billion, from a projected NIH budget of \$20.068 billion. Of the total research funds, the top three research institutes will receive \$3.25 billion, \$2.070 billion, and \$1.21 billion, respectively.

The U.S. National Science Foundation (NSF) controls an additional \$3.641 billion in research funds. NSF research dollars go largely to the National Research Center. Research projects funded by NSF extend to biological sciences (\$511 million), computer sciences (\$529 million), polar programs (\$223 million), geoscience (\$583 million), and engineering, math, and physical sciences (\$1.338 billion). In addition to NIH and NSF, the U.S. government provides funding to research efforts under the auspices of other departments including the Department of Energy, the Department of Agriculture, and the National Aeronautics and Space Administration.

One of the leading non-profit research organizations in the United States, the Smithsonian Institution receives approximately \$200 million in U.S. taxpayer dollars annually for research and collections management purposes. Overall, the research budget of the Smithsonian comprises approximately one-third of the total budget of the Institute.

Private Sector Non-commercial Research. Silicon Valley in California is well known for its economic development in the high-tech industry. The community began as a collaborative effort between educational institutions and small businesses, in response to mutual concerns for technological innovation. State-of-the art technologies developed in the Valley afford nonprofit research researchers with online access to news and developments through the Internet. The American Association for the Advancement of Science's EurekAlert! is a World Wide Web site that provides research news from all over the world. This site was created with the intention

of providing a bulletin for universities, nonprofit organizations, and corporations to post new discoveries and advancements in science. Researchers, journalists, and the public at large access information disseminated through this and other Internet-based sites.

The Better Business Bureau (BBB) is a nonprofit organization that provides reports and information that safeguard consumers against unscrupulous businesses. Another consumer information provider is the Consumers Union, established in 1936 "to provide consumers with information and advice on goods, services, health and personal finance."

calibration and certification testing; dosimetry (measurement of radiation); film badge service (radiation detection); food testing; forensic services; hydrostatic testing services; product testing; metallurgical testing; pollution testing; radiographing welded joints on pipes and fittings; seed testing; veterinary testing; and industrial X-ray inspection.

As people in the twentieth century became increasingly aware of environmental and other physical hazards, they wanted to know about the quality of two very broad categories: substances that entered their bodies, and objects they came into contact with on a daily basis. In some cases, the constitution and/or reliability of substances and objects can be perceived easily, but the effects of radiation or toxic chemicals often are less immediately apparent or noticeable. For this reason, a broad range of testing laboratories developed in the twentieth century, especially where legislation mandated certain safety standards. The Food and Drug Administration (FDA), the Environmental Protection Agency (EPA), and the Food Safety and Inspection Service of the U.S. Department of Agriculture are the three best-known government agencies with which the testing laboratory industry is involved.

Because of the myriad federal regulations regarding food, drugs, equipment, and general products, testing for all kinds of substances and hazards has spawned its own industry. Food testing laboratories are among the most common testing laboratories. A number of laws directly relate to food: the Food, Drug, and Cosmetic Act; the Fair Packaging Act; Pure Food and Drug Laws; Consumer Product Safety Act; the Occupational Safety and Health Act; the Water Pollution Control Act; the Rodenticide Act; and the Clean Water Act. Companies that produce, package, and market food must be sure their products comply with all of the federal laws governing their products.

Devices that are used in hospitals and doctors' offices for diagnostic purposes, such as X-rays or mammography machines, must also be subjected to a wide range of tests on a regular basis to be sure they are functioning according to specifications and are calibrated properly. Some instruments used for detecting radiation intensity are the well-known Geiger-Muller counter, the Cutie Pie survey meter, and the scintillation counter. Some functions and calibrations must be tested on an annual basis, while others are tested on daily, weekly, or monthly schedules. Hospitals and other medical facilities contract with independent laboratories that provide trained professionals and physicists to perform such on-site inspections and to make repairs when necessary. They also train operators to complete the necessary daily tests that are mandated for peak performance and the optimum safety of both the operator and the patient.

SIC 8734

TESTING LABORATORIES

This classification covers establishments primarily engaged in providing testing services. Establishments primarily engaged in performing clinical laboratory testing for the medical profession are classified in **SIC 8071: Medical Laboratories**.

NAICS CODE(S)

541940 (Veterinary Services)

541380 (Testing Laboratories)

Testing laboratories exist in both corporate in-house and independent settings and include varied services such as assaying; automobile proving and testing grounds;

Other laboratories work with the government, medical community, and other industries to provide a wide range of services in nearly every field from automobile testing to forensics and metallurgy. Many facilities feature mobile laboratories out of necessity and offer technicians cross-certified in accordance with the latest American Society for Nondestructive Testing (ASNT), American National Standards Institute (ANSI), and military requirements, enabling them to serve in technician, auditor, and inspector capacities.

The history of testing laboratories is a relatively short one. By the beginning of the twentieth century, members of the food manufacturing industry had begun adding untested chemicals to their products. Growing concern about such untested products prompted Congress to pass the Pure Food and Drug Act in 1906. This act established the Food and Drug Administration with jurisdiction over the safety of food additives and drugs that were already proven harmful. In 1938, the Cosmetic Act expanded that authority to drugs, which must undergo vigorous testing before reaching the marketplace. Subsequent legislation in 1957, 1958, and 1962 required additional testing and compliance with regulations regarding food, drugs, and cosmetics.

After 1945 and the dawning of the Atomic Age, people realized the dangers of radiation. They also realized that the use of radiation was not confined to warfare; the medical community was establishing a whole new use for the technology. X-rays, although no longer new, were in widespread use, as were the new radioisotopes (for diagnostic purposes), and radiation treatment for cancer therapy. Euphoria over the new treatments was soon tempered by concern, and public demand led to new legislation to set acceptable standards for exposure. Because of all the regulations regarding food, drugs, cosmetics, radiation, and related products, commercial testing laboratories materialized all over the country.

The development of varieties of lab tests seems to change historically along with society's concerns: first it was food, then radiation, and in the 1990s, the environment that raised concern. Thus, previously established labs have expanded their services to include environmental testing, and new, specialized labs have come into being specifically for environmental testing.

American Society for Testing and Material. In 1993, the American Society for Testing and Materials (ASTM) inaugurated a proficiency testing program. The program offers services to testing laboratories within all industries in an endeavor to coordinate testing standards worldwide. ASTM is a section of the International Association for Testing Materials and was founded in 1898 to encourage the development of materials standards for the railroad construction industry. Throughout the twentieth century

ASTM expanded the scope of its programs and commitments from steel and construction materials in 1898, to war-essential materials in the 1940s. ASTM branched into environmental and consumer product standards in the 1970s and established the Institute for Standards Research (ISR) in 1988. In the year 2000, ASTM published its *International Directory of Testing Laboratories*, listing more than 4,000 testing facilities. These included firms involved in acoustic and vibration testing, biological testing, chemical testing, chromatography, electrical and electronic testing, geotechnical testing, mechanical testing, metrology, nondestructive evaluation, optics and photometry, radiation and ionizing, surface analysis and microscopy, sensory evaluation, spectroscopy, thermal analysis, and thermal and fire testing. Facilities engaged in chemical testing were most populous, while radiation and ionizing testing labs were least prevalent. An overwhelming majority of laboratories were located in the United States and Canada.

INDUSTRY LEADERS

LabOne Inc. of Lenexa, Kansas, earned \$102 million in 1998, nearly doubling its 1997 revenues. Also in 1998, the company experienced an overall sales growth of 29.5 percent, and increased its employee count by 34.6 percent. Other industry leaders in the late 1990s were Applied Bioscience International Inc., a public company based in Arlington, Virginia, which reported \$183 million in sales for 1997; and Farmingdale, New York's Tyree Organization Inc., with \$118 million. Market share was widespread, and some 36 companies claimed annual sales of \$10 million or more.

MANAGEMENT SERVICES

This category covers establishments primarily engaged in furnishing general or specialized management services on a day-to-day basis and on a contract or fee

basis. Establishments in this industry do not provide operating staff. Management and operation of a business, where operating staff as well as management is provided, is classified according to the activity of the establishment managed.

NAICS CODE(S)

561110 (Office Administrative Services)

INDUSTRY SNAPSHOT

The management services industry is highly fragmented and unstructured. It consists of a conglomeration of different services for almost every sector of the economy. As a result, this entry presents examples of companies that are representative of different segments of the industry, and describes how the proliferation of management services is affecting the American economy and work force. Construction management services, which make up the largest single division of the industry, are highlighted.

The U.S. Bureau of the Census estimated that the management services industry generated revenues of about \$13 billion and employed about 300,000 workers in the late 1980s. In the early 1990s, however, the industry continued to expand at a rapid pace, with some major segments growing by more than 30 percent per year. Plodding growth in the 1980s and early 1990s was a general shift in the dynamics of the American economy. Going into the mid 1990s, companies in all economic sectors were increasingly seeking the expertise and flexibility offered by professional management firms. By 1997, the U.S. Bureau of Census estimated that total receipt had reached \$30.3 billion.

ORGANIZATION AND STRUCTURE

Management service firms benefit their customers by providing expertise in certain areas of the company's operations. In addition to expertise, companies may also benefit from increased flexibility. By contracting a service firm to manage a short-term project or administrative task, for instance, a company avoids the expensive and time-consuming chore of hiring, managing, and later eliminating workers.

Many service companies specialize in managing, or outsourcing, one niche of an organization's operations. Some companies, for instance, manage an establishment's mail room, or handle all electronic communications in an organization, such as voice and electronic mail. Other companies oversee various marketing and selling activities, or manage high-tech product development projects.

A construction supply manufacturer, for example, might consider its core competency to be the development and production of paving tiles and concrete forms.

However, the company must also engage in several activities at which it may not be particularly adept, such as managing internal data and information systems, motivating its sales force, and handling administrative paperwork. By hiring service companies that specialize in managing each of these subordinate functions, the manufacturer is able to focus its resources on its competitive strengths, thereby increasing its overall productivity.

Within the service division, most of the projected job growth is in just two industry groups: business services, with a job gain of 3.6 million, and health services, with an increase of 3.2 million. Together, these industry groups account for 59 percent of the job growth in the services division and 38 percent of the increase in total non-farm wage and salary employment. The industry groups with the third and fourth largest projected job gains within the services division are social services, with a 1.1 million increase, and engineering, management, and related services, with an increase of 1 million jobs. Together, these four industry groups account for 78 percent of job growth in the services division and 50 percent of the total increase in non-farm wage and salary employment.

During 1988, approximately 508,000 jobs were reported in the management services industry. By 1998, a scant 10 years later, the number of jobs in this service sector doubled to over 1,034,000 jobs. Management services firms were primarily engaged in offering management services to almost every industrial, commercial, and nonprofit sector of the U.S. economy. In addition, many companies classified in other industries offered management services to their clients. Typical services included management of health care facilities, hotels and motels, all types of business offices, factories, research and charity organizations, theaters, restaurants, commercial and residential properties, and other operations.

Construction Management. The largest single division of the management services industry was construction management. Firms practicing this discipline were hired to organize, staff, direct, plan, and control a development project. They also offered in-house design or construction services. By hiring a professional manager, developers usually hoped to speed up construction, lower development costs, and increase overall project quality. To achieve these goals, many management companies specialized in one type of development, such as power generation facilities, transportation infrastructure, office buildings, health care facilities, land reclamation, or renovations.

In the late 1980s, construction managers were generating about \$4 billion in revenue per year—roughly equivalent to 25 percent of total annual U.S. management service contracts. Engineering and construction firms accounted for 75 percent of all construction management

services. Design firms captured about 10 percent of the market, general contractors held a 5 percent share, and pure construction management companies accounted for 10 percent of this segment's billings.

Industry Associations and Accreditation. There is no central licensing agency for management consultants. In fact, no guidelines or regulations exist in the industry at all as standards for operating practices. The only available form of acknowledgement of consulting expertise is the Certified Management Consultant designation which is granted by the trade association, the Institute of Management Consultants.

Another primary industry association is ACME (formerly Association of Consulting Management Engineers). Both ACME and the Institute of Management Consultants operate as divisions of the Council of Consulting Organizations (CCO). Other industry associations include the Society of Professional Management Consultants, the Association of Management Consulting Firms, the Association of Management Consultants, and the Association of Internal Management Consultants.

BACKGROUND AND DEVELOPMENT

Companies have offered management services in various forms for decades, such as construction firms that developed company facilities early in the Industrial Revolution. It was not until the 1970s and 1980s, however, that an identifiable management services industry gained stature in the United States.

Several developments led to the proliferation of management services. Significantly, as the rapid economic growth characteristic of the post-World War II boom years began to fade in the 1970s, large corporations began to seek ways to increase the efficiency of their operations and gain a competitive edge. While corporations had traditionally handled almost all of their administrative and office management activities with in-house staff, some firms began seeking the expertise and efficiency that management contractors offered. Particularly during the 1980s, as corporations restructured their organizations, reduced layers of management, and cut administrative overhead, the demand for specialized management services burgeoned. Likewise, as the economic representation of small businesses mushroomed during the 1980s, management services became important partners for many small companies that outsourced administrative tasks.

Also influencing industry growth was the proliferation of government regulations. New employment rules, safety and environmental regulations, financial reporting laws, and other constraints forced many firms to seek the assistance of outside professionals to handle administrative paperwork and to avoid litigation. Concurrent ad-

vances in computer, information, and communications technologies provided the tools many management services needed to serve their markets.

By 1992, U.S. management service firms were garnering nearly \$23 billion per year and paying \$9.7 billion in wages to just over 215,000 employees. Remarkably, annual receipts almost doubled (from \$13 billion in 1988). More, the industry's reported 1988 payroll was nearly \$7 billion and employment was to over 280,000. Fewer employees generated greater profits, perhaps due to the double-edged sword of an economic downturn in the late 1980s and early 1990s while, concurrently, increased global competition in all industries induced continued expansion of the management services industry.

INDUSTRY LEADERS

Indicative of a growing trend in the management services industry, ARAMARK Corp. provided management services in three divergent lines of business: food and support services, uniforms, and childcare. 1999 sales topped \$6.7 million and their employee payroll included 152,000 workers. Two-thirds of company revenues derived from food, building maintenance, and housekeeping services provided to businesses, prisons, and colleges. ARAMARK also managed concessions at sports and other recreational facilities, operated before- and after-school programs, and provided employee on-site childcare via Children's World Learning Centers.

ServiceMaster L.P. of Downers Grove, Illinois, was characteristic of many management service firms in that it offered a broad range of related services. ServiceMaster was comprised of seven major divisions that were established to respond to the entire facility development process: strategic facility planning, architecture/engineering, interior design, equipment planning, construction services, project management and development, and computer-aided facility management. Formerly Maricia Capps & Associates, ServiceMaster's 51,740 employees earned their firm net income of \$4.7 million during 1998.

Evidence of general industry growth in the late 1980s and early 1990s was Amerihost Properties, Inc., of Illinois—one of the fastest growing hotel and motel management firms in the United States. After beginning operations in 1987, Amerihost grew to manage 90 hotels. Although its operations were national, a majority of their hotels were in the Midwest and the South. Focusing on small communities, Amerihost sought out a market niche in mid-priced hotel rooms. While operated under the AmeriHost Inn name, it also managed hotels under franchise agreements with Days Inn, Holiday Inn, Ramada Inn, and Hampton Inn. Franchised management services proved successful for AmeriHost: with a scant 1,820 employees, total revenues were \$68.6 million in 1998. Capitalizing on this trend, the company planned to ex-

pand into the twenty-first century through a new franchising program under its signature operations.

WORKFORCE

About 25 percent of the work force was employed in secretarial, bookkeeping, and clerical jobs. Management and executive jobs represented about 15 percent of total employment, and management support, financial management, and administrative services jobs accounted for an additional 10 percent. Other occupations relate to computer programming and information systems management, engineering, marketing, and public relations.

Because the industry will likely realize strong growth, the U.S. Bureau of Labor Statistics estimated that most occupations in the industry will thrive between 1998 and 2008. In fact, almost every position in the industry will increase employment by more than 45 percent. Jobs for managers and administrators, for instance, should grow in addition to a marked increase in management support jobs. Positions for marketing and public relations professionals were also expected to take a dramatic increase by 2008. Total employment in this industry section was estimated at just over 1 billion jobs in 1998. By 2008, almost another half million jobs were expected to be created.

RESEARCH AND TECHNOLOGY

New management techniques and advanced communications technologies will continue to propel the expansion of management services into the new millennium. The trend toward corporate reductions in middle management, renewed emphasis on core competencies, and expanded government regulations will encourage companies to increasingly employ and form partnerships with specialized services.

Wireless communication devices, electronic and voice mail, portable computers and digital devices, and advanced information management systems will allow companies to make greater use of outside consulting and management services. Construction management firms will especially benefit from portable electronic devices that can be used on-site. Scheduling, estimating, and field engineering activities will become more precise with the development of new software and communications technology.

Eventually, the division between management consulting services and the companies that hire them will become less distinct for several reasons. For instance, firms will retain a greater number of their employees as independent contractors and home-based workers. In addition, companies will form more partnerships with their competitors, or with firms in noncompeting industries, that resemble management service arrangements. Eventually, a large portion of U.S. companies will begin to

view themselves as providers of specialized management services.

With the proliferation of Internet access throughout the 1990s, management services began to embrace a new paradigm, virtual service and outsource firms. No longer limited by geography, such enterprises could advertise, interact, communicate, and service clients from any place in the world. Coupled with an increased reliance by an ever-growing interglobal business culture, "virtual firms" could also engage in robust service support to international clients with subject-matter experts of international reputation. By expanding customer base and tapping into a worldwide labor force, the service management industry promised to revolutionize through the use of advanced wireless and communications technologies.

SIC 8742

MANAGEMENT CONSULTING SERVICES

This industry consists of establishments primarily engaged in furnishing operating counsel and assistance to management of private, nonprofit, and public organizations. These establishments generally perform a variety of activities, such as strategic and organizational planning; financial planning and budgeting; marketing objectives and policies; information systems planning, evaluation, and selection; human resource policies and

practices planning; and production scheduling and control planning.

NAICS CODE(S)

541611 (Administrative Management and General Management Consulting Services)

541612 (Human Resources and Executive Search Consulting Services)

541613 (Marketing Consulting Services)

541614 (Process, Physical, Distribution, and Logistics Counseling)

INDUSTRY SNAPSHOT

In the early 2000s, management consulting was an \$80 billion enterprise within the United States and a \$100 billion industry worldwide. Nothing has funneled more money into the business world than information technology consulting, which boomed in the 1990s as companies groped for ways to harness the benefits of office automation, network computing, and e-commerce. Other important consulting specialties include general strategy, marketing and branding, leadership, logistics, human resources, and industry-specific practices. All told, one standard reference on the industry lists 118 distinct types of consulting services offered and 98 industries served.

In many ways the industry has been propelled by what could be described as business fads—philosophies, events, and practices that ignite intense interest for a few years but gradually fade. One such example was the rise of reengineering, a form of organizational change dictated by management strategy, of the early and mid-1990s. Later in the decade, however, corporate leaders set their gaze on challenges like e-commerce and employee satisfaction, which was especially worrisome in the United States in the late 1990s while labor was in short supply.

By the turn of the twenty-first century, the majority of management consultancies were offering Internet-related services to the hordes of businesses launching online ventures. Those who had resisted delving into the e-commerce arena were scrambling to make up for lost time. When the technology industry in North America crashed, fueling a more widespread economic malaise, management consultancies began to see their revenues slow. As a result, the industry was characterized by both fee reductions and layoffs in the early 2000s.

ORGANIZATION AND STRUCTURE

Individual Firms. The most common organizational structure for a management consulting firm is that of a corporation. A typical consulting firm might employ research associates at the lower level, with consultants and senior consultants at the next level. Managing consultants are next in the hierarchy. At this level, individuals typi-

cally have greater degrees of client interaction, as well as responsibility for the success of consulting projects. Finally, at the top of a typical firm's hierarchy are partners. In addition to running the operations of the organization, partners are generally responsible for bringing new business into the firm.

Management consulting firms usually operate in project teams. Depending upon the firm and assignment, consultants on project teams often spend more time at the site of the client's offices than they do at their own. There, they gather data and interact extensively with personnel from the client organization, make recommendations, and often work on implementing solutions. Often, client personnel will work as part of the consulting team for the duration of the project to ensure that the organization has input into the process. Client participation increases the likelihood that the solutions will be implemented effectively.

Management consulting firms generally operate on a project fee or hourly fee basis. Fees in the consulting industry tend to run very high, due to the significance of the problems that consultants help their clients to overcome.

Industry Structure. Management consulting firms range in size from sole practitioners to large businesses. As far as areas of expertise, some firms are devoted to specific practice areas while others offer a broad range of services to varied clientele. For example, a consulting firm might specialize in providing clients with compensation and benefits packages, to the exclusion of all other services. Yet other firms might provide a broad range of advisory services—combining such varied forms of advice as consulting the chief executive officer on general business strategy and consulting a management information systems (MIS) executive on a new computer network. A major segment of the consulting market is occupied by consulting organizations that are part of Certified Public Accountant (CPA) firms. Such firms attempt to serve their tax and audit clients with management consulting services as well. Another type of consulting function is one that exists within a non-consulting organization. Such internal consultants provide specialized services for their corporations. An example is an internal human resources consulting department within a *Fortune* 500 corporation that serves the varied divisions of the organization as if they were external clients.

In addition to providing expertise or advice, many management consultants perform in the role of process consultant. This approach recognizes that the client firm already possesses knowledge of its own industry and internal corporate environment that exceeds the knowledge available to the consultant. Therefore, the role of the management consultant is one of facilitating the process of

pulling solutions out from within the client organization and providing insight with an objective point of view.

Because the management consulting industry is unregulated, any individual or company that offers advice in exchange for compensation may be classified as a consultant. For this reason, the definition of a management consulting firm often varies, depending upon the source of information. Nonetheless, an understanding of the industry can be ascertained by separating consulting firms into distinct categories and contrasting the categories.

The following breakdown describes the most common and most widely recognized types of consulting organizations, first by organizational structure, and then by consulting specialty (also known as “practice area” within the industry).

Large Consulting Firms. This classification represents the largest players in the management consulting industry whose primary service is providing expertise and consultation to management. The broad heading of large consulting firms encompasses the larger of the generalist consulting firms and strategy consulting firms.

Big Five Accounting/Consulting Firms. A handful of large public accounting and consulting firms lead the industry on an international scale. These include the so-called Big Five: Andersen Worldwide, PricewaterhouseCoopers, Ernst & Young, Deloitte & Touche, and KPMG Peat Marwick. Consulting divisions of the Big Five are especially strong in information technology (IT) and management information systems (MIS) consulting. These firms typically offer strategic or generalist management consulting services as well. As of the late 1990s, though, the marriage of public accounting, particularly auditing services, and consulting was a troubled one; most of the top firms attempted to wall off their accounting and consulting practices to avoid appearing to have conflicts of interest.

Small Firms/Boutiques. Small firms or boutiques often provide specialized services or offer expertise that focuses on one industry or a single business practice area. These firms tend to be small, lesser-known niche players that do not regularly compete directly with the larger consulting organizations. Many of these firms operate in a single, geographic region. Some small or boutique firms service only one client.

Sole Practitioners. Perhaps the most difficult segment to define in the management consulting industry is that of the sole practitioner. This group encompasses many outplaced or retired executives and part-time consultants who offer expertise in areas where they have a great deal of experience. Sole practitioners are often engaged by smaller firms and even their previous employers. This classification of the consulting industry also includes

university professors who provide consulting in their areas of teaching expertise.

Internal Consulting Organizations. Large corporations may have recurring project work for which the expertise of external management consultants would be required on an ongoing basis. Many such firms have developed internal consulting staffs in order to deal with this demand in a more cost-effective manner. Such internal organizations may be generalists or may specialize in corporate strategy, human resources issues, information technology, or other areas that are critical to the company’s operation.

IT/MIS. The information technology segment is the largest segment of the consulting industry. The Big Five all provide expertise in this area and draw substantial revenue from it as well. Firms that specialize in information technology tackle business problems by applying technology to provide solutions. For example, a firm specializing in information technology might help a corporation to become more efficient in their order fulfillment operation by installing computers and equipment that automates the process. One of the firms that is best known in IT/MIS consulting is Andersen Consulting.

Compensation/Benefits Consulting. Compensation/benefits consulting firms represent the second largest independent segment of the industry in the United States. Firms that specialize in compensation/benefits consulting offer services related to human resource management with specific expertise in practices such as developing corporate grading and compensation schemes, titling plans, and benefits packages. Examples of firms that practice primarily in the compensation/benefits consulting practice area include the Hay Group and Hewitt Associates.

Generalist Consulting. Generalist management consulting firms typically provide advice on strategy to their clients but may also have internal expertise in specific industries, such as banking or health care, or in particular practice areas, such as new product development or operations. Generalist consulting firms often provide consulting in IT/MIS and compensation/benefits as well. Examples of generalist firms include McKinsey & Company, Inc.; Booz, Allen & Hamilton, Inc.; and Arthur D. Little, Inc.

Strategy Consulting. Strategy consulting firms specialize in providing advice on corporate strategy to senior executives—answering such questions as, “How can our firm improve profitability?” Strategy firms compete with generalist firms for strategic engagements but do not provide the nonstrategy services of the broader, generalist firms. However, the larger strategy firms, as they have expanded their lines of business, have become more difficult to distinguish from the generalist firms. Exam-

ples of firms that have traditionally been regarded as strategy firms include the Boston Consulting Group and Bain & Company.

Specialty Consulting Practice Areas. This segment is by far the most difficult to define, for it encompasses so many different possible practice areas. Specialty consulting firms are often boutiques or small to medium size organizations that service a niche in the consulting market.

Marketing Consulting Firms. These firms provide marketing research, product test markets, target market selection, and other services directly related to the marketing of client products or services. Perhaps the best known marketing consulting firm is Yankelovich, Skelly and White/Clancy Shulman Inc.

Business Re-engineering/Organizational Effectiveness. This specialty in management consulting refers to the radical redesigning and rebuilding of the processes and functions of a business to recreate the company as a highly effective, cohesive whole that performs optimally. The concept of “Business Re-engineering” was originated by the Index Group (Now CSC/Index, Inc.). Increasingly, other consulting firms are also developing this line of business—most notably, Andersen Consulting.

Environmental Consulting Firms. With increased public attention on the environment, and increased governmental concern over hazardous waste, environmental consulting firms have seen increased demand for their services in recent years.

Health Care Consulting. There are two primary specialties that fall under the heading of health care consulting. The first practice area is providing general advisory services such as strategy consultation or cost-containment studies for health service agencies (e.g., Health Maintenance Organizations) and hospitals. The second practice area is in helping corporations to select employee health benefit plans that minimize costs and provide the best health care coverage for the organization.

As health care costs continue to rise in the United States and concern for health coverage increases, this consulting specialty has been experiencing growth as well. In addition to specialty firms that provide health care consulting, many of the larger consulting organizations also service this industry.

Changes in the economy can affect firms in different ways. For instance, if the economy slows and businesses become more concerned with the bottom line, they may put off decisions such as automating. This negatively impacts the information technology segment of management consulting. At the same time, however, executives of corporations in hard times might be more prone to call upon a consulting firm that can help them to find ways to

increase their revenues, contain their costs, or reduce their head count.

For consulting firms, approximately 20 percent of their costs are consumed in new business development. Costs for marketing activities include the production and distribution of promotional materials, salaries of partners who are responsible for client development and new business, and association memberships. The area in which firms may expend the greatest amount of resources, however, is in the competitive bidding process, also known in the industry as the “bake-off.”

A bake-off occurs when a client with a problem approaches several consulting firms. These firms each spend time and money becoming acquainted with the client’s organization, attempting to develop internal champions for their firm. The bake-off often involves several personnel from each consulting firm, all dedicating their time, without pay, at the site of the potential client in order to gather a better understanding of the problem. At the end of the competitive bidding process, the client chooses one of the firms, or none, and the remainder have invested resources without remuneration.

Because of the expense involved in acquiring new clients, consulting firms try to become the “house consultants” for their existing clients. In doing so, the firm may become so trusted by the client that it can bypass the competitive bake-off and be engaged directly by client management. This is an enviable position for a consulting firm to be in, as it can minimize business development costs and ensure a more steady flow of income.

Industry Associations and Accreditation. There is no central licensing agency for management consultants. Nor are there any industry guidelines or regulations as standards for operating practices. The only form of acknowledgement for consulting expertise is the Certified Management Consultant designation that is granted by the trade association, the Institute of Management Consultants.

Another primary industry association is ACME (formerly Association of Consulting Management Engineers). Both ACME and the Institute of Management Consultants operate as divisions of the Council of Consulting Organizations (CCO). Other industry associations include the Society of Professional Management Consultants, the Association of Management Consulting Firms, the Association of Management Consultants, and the Association of Internal Management Consultants.

BACKGROUND AND DEVELOPMENT

The practice of consulting began in the late 1880s. At that time, Frank Gilbreth was conducting time-and-motion studies to improve bricklaying techniques. At about the same time, Frank W. Taylor was applying time studies to improve the steel industry. In 1886, Arthur D.

Little founded the consultancy that bears his name and is now one of the largest consulting firms in the world. Little began working in 1881 to bring scientific ideas to management practices. The next industry event was the introduction of a quality aspect to time and motion. In the 1920s, Charles Bedaux enabled his clients to make tremendous leaps in productivity by improving quality.

In the 1950s and 1960s, small firms began to proliferate as former sole practitioners expanded their business. Then, in 1963, the Boston Consulting Group was founded on the notion of giving strategic advice to clients. Management consultancy recognized this event as critical in changing the role that management consultants played. During the 1960s, CPA firms entered the fold and made the formal transition from offering advice related to their accounting activities to charging clients for business advice in a traditional consulting manner.

Consulting revenues in the United States grew steadily throughout the 1970s and 1980s and more rapidly in the 1990s, rising from \$28.9 billion in 1990 to \$70.7 billion in 1998, according to estimates by the Census Bureau. Separate calculations by the Kennedy Information Research Group, which publishes newsletters, periodicals, and research reports on the industry, placed the global value of consulting services at \$100 billion as of 1999. Information technology services, reported Kennedy Information, represented fully 60 percent of the industry's revenue. Based on estimates of 1998 consulting revenues, the top ten firms alone had more than \$33 billion in consulting receipts.

E-commerce consulting was perhaps the most important trend of the late 1990s and early 2000s. A natural fit with the industry's well-developed IT consulting practices, e-commerce advice and implementation typically involved steering conventional businesses toward a successful Internet strategy. There was, of course, also a market for consultants within pure-play Internet firms that were trying to break into the business. Leading consulting firms like Andersen and Deloitte found e-commerce such a potent consulting formula that they raced to set up separate e-commerce units to cater to this market.

Consolidation had a major impact on management consulting in the late 1990s, particularly among top-tier firms. Whereas observers used to speak of the Big Six or even the Big Eight, by the late 1990s consolidation had brought the top echelon down to five members. One of the most prominent mergers was between two members of the then-Big Six: Price Waterhouse and Coopers & Lybrand, which merged in 1998 to form PricewaterhouseCoopers. And in 2000, one of the remaining five, Ernst & Young, sold its consulting business to France-based Cap Gemini Group, effectively removing the Ernst & Young accounting practice from the consulting business.

CURRENT CONDITIONS

The U.S. management consulting industry was marked by an unprecedented level of cutbacks and layoffs early in the twenty-first century. The rise of Internet startup consultancies such as Scient and Viant in the late 1990s had presented a new form of competition to traditional consultancies, which were forced to compete both for new clients seeking to incorporate Internet technology into their business practices and for a rapidly shrinking pool of qualified employees. As a result, many firms began boosting their compensation packages to retain existing employees, as well as to attract new help. When the Internet market began to falter in 2000, weakening the U.S. economy, many consultancies were left overloaded with highly paid help. As stated in the July 2001 issue of *The Economist*, "consultants are finding that their rate of attrition—the rate at which people leave voluntarily—has shrunk dramatically as rival jobs (such as joining an Internet start-up or venture-capital operation) have become less attractive." When revenues began to wane in the early 2000s, many firms reduced headcount in an effort to bolster earnings.

Attrition at two of the industry's leading firms, Accenture and McKinsey, fell from 20 percent in 2000 to 12 percent in 2001. Accenture laid off 4 percent of its workforce and asked hundreds of employees to take a leave of absence that year. Pricewaterhouse Coopers also lightened its workforce and reduced pay to all U.S. consulting employees by 7 percent. Similarly, Cap Gemini Ernst & Young cut 4 percent of its global workforce, and KPMG Consulting laid off 7 percent of its staff. Consequently, between October of 2000 and October of 2001 the worldwide consulting industry saw its ranks fall by nearly 5 percent from a total of 600,000 employees to 572,000 employees.

Along with reducing their ranks, many consultancies trimmed their fees in an effort to remain competitive. According to *Consultants News*, fee increases will likely remain under 5 percent in the early 2000s, compared to 12 percent in 1998. The difficult market conditions also left some consultancies with no choice but to shutter operations. Cambridge, Massachusetts-based A.D. Little, hit particularly hard by the management and technology consulting industry downturn, declared bankruptcy in early 2002.

The industry continued to face an absence of mandatory certification requirements and lack of enforceable industry standards at the turn of the twenty-first century. One potential conflict-of-interest involves the growing number of alliances between management consultancies and information technology suppliers, which some analysts believe could influence a consultant's recommendations about information technology products. Also of concern is the conflict inherent in an accounting firm that

conducts auditing activities, as well as management consulting activities. In the late 1990s the U.S. Securities and Exchange Commission (SEC) began investigating Big Five auditors to ensure their independence from their consulting clients. Eventually, the SEC accused KPMG of violating federal securities law by auditing a company managed by a KPMG Consulting employee. This litigation prompted PricewaterhouseCoopers to put its information technology consulting operations up for sale. It also fostered Cap Gemini's \$11 billion acquisition of the consulting arm of Ernst & Young in 2000 and KPMG's decision to spin off its consulting operations into a publicly traded company in 2001. In a similar move, Accenture (Andersen Consulting) also separated from its accounting business, although this had more to do with the desire of Andersen consultants to separate from the firm's slow growth accounting operations.

INDUSTRY LEADERS

Accenture Ltd., formerly known as Andersen Consulting, is one of the world's largest management consulting firms, with more than \$13.3 billion in revenues and 75,000 employees in 2001. Under its parent company Andersen Worldwide, Andersen Consulting had been an offshoot of one of the Big Five accounting firms and had offered some form of consulting services since at least the 1920s. The two Andersen segments epitomized the struggle between the older accounting side of the business and the new consulting side. The original Arthur Andersen & Co. accounting firm dates to 1918. The consulting wing had grown to match the accounting business in terms of revenues in the late 1990s, with big banks and communications companies as some of its largest clients.

In 1998, Andersen Consulting voted to split completely from Andersen Worldwide, which, in addition to its accounting and auditing work, was a competitor in the management consulting industry. Wanting to separate itself from what it viewed as the less lucrative auditing industry, the consultancy earned full autonomy from Andersen Worldwide in 2000; it was then that Anderson Consulting completed its name change to Accenture. The firm conducted its initial public offering in 2001.

A. T. Kearney, Inc. was founded in 1926 as a production and engineering consulting firm that served manufacturing clients. Over the years, A. T. Kearney has grown into a full service, generalist consulting firm employing more than 5000 professionals, half of whom operate as consultants. In 1995 the firm was bought by Electronic Data Systems Corp., a large systems integration and technology service provider. Sales in 2000 totaled \$1.3 billion, and operations spanned 43 countries.

Booz, Allen & Hamilton, Inc. is another generalist consulting firm that was founded in 1914. Booz-Allen employed 11,000 consultants in more than 100 offices

worldwide in 2001. The firm is organized around industry groups such as advanced technology, applied sciences, energy and chemicals, financial services, information and strategic systems, and marketing-intensive industries. It is split into two operating segments, the Worldwide Commercial Business unit and the Worldwide Technology Business unit. Global revenue in 2001 was \$2 billion.

Cap Gemini Ernst & Young Group, Paris, France, is a global management consulting firm with fully integrated capabilities in strategy, operations, people, and information management. In 2000 Cap Gemini catapulted to the consulting industry's top five with its \$11 billion purchase of Ernst & Young's consulting business. Based on 1998 results, Ernst had been the third-largest consultancy and Cap Gemini was eighth-largest. The combined company had an estimated 60,000 employees and a major presence throughout Western Europe and the United States. Sales in 2001 totaled \$7.4 billion.

McKinsey and Company, Inc., a generalist consulting firm, is perhaps the best known of the generalist management consulting organizations. Founded in 1926, McKinsey experienced tremendous growth in the 1980s and 1990s, expanding to more than 11,000 professionals and a total of 84 offices by 2001. Most of this growth for McKinsey came from international expansion. In the United States, McKinsey reported approximate sales of \$3.4 billion in 2001. McKinsey provides consulting services that address top management issues for large organizations. The majority of its work is in the area of strategy and organization. The remainder is conducted in specialized practice areas such as marketing, manufacturing, and technology.

The largest accountancy in the world, PricewaterhouseCoopers was created by the high-profile 1998 merger of Big Six rivals Price Waterhouse and Coopers & Lybrand. Founded in London in the late 19th century, Price Waterhouse was one of the world's oldest and most prestigious accounting firms, and by the 1990s was a massive international management services purveyor. Coopers & Lybrand was a prominent accounting firm in its own right, dating to a 1957 merger of two multinational accounting concerns. Like Andersen and others, PricewaterhouseCoopers has suffered from internal tension between its accounting and consulting arms; the company was considering splitting into two separate entities. In 2001 the firm brought in an estimated \$20 billion in sales, and operations spanned over 150 countries.

WORKFORCE

For the most part, large management consulting firms hire people with MBAs from top business schools as entry level consultants. For higher level positions, specialists may be recruited directly from the competition or from the industry. The latter is particularly true if an

individual can offer industry expertise that would assist the consulting firm in expanding or serving its existing client base. Depending upon the industry and the needs of the particular firm, individuals with more advanced degrees or degrees in technical specialties (such as economics or computer science) may be selected as well. Some consulting firms will take academically strong candidates from top undergraduate schools as lower entry level consultants or analysts/researchers.

Overall, consultants in medium-to-large generalist or strategy firms are analytically oriented, well-educated individuals. In the past, management consultants in the United States were typically white males. Like other industries, consulting firms have been diversifying, especially as these firms increase their exposure in foreign markets.

The industry also comprises small firms, boutiques, and sole proprietorships that are composed of technical specialists such as information technologists or marketing consultants. These individuals may be displaced corporate professionals or individuals who have left larger consulting firms to start their own practices. It is also common for sole practitioners to perform consulting work on the side, in addition to their full-time positions with other companies.

Another segment of the consulting industry is that of university professors who consult to complement their full-time positions in teaching. These professors typically hold advanced degrees and are specialists in a particular field of research. This segment of the consulting population is self-regulating via the Academy of Management, Division of Managerial Consultation, which provides a code of ethics for its 800 members. The fastest growing segment of this market is systems analysis and administrative services managers; the areas seeing the least amount of growth by the year 2005 will be typists, word processors, secretaries, and bookkeeping/accounting clerks.

RESEARCH AND TECHNOLOGY

The application of technology is a significant tool of the consulting industry. Many of the largest firms in the industry generate their revenue by applying technology solutions to business problems. An example of this is redesigning a distribution operation and inventory tracking system to automate the entire process with robotics, computers, scanners, and advanced software to control the system. Still other firms specialize in training corporate personnel to use technology.

SIC 8743

PUBLIC RELATIONS SERVICES

This category covers establishments primarily engaged in the preparation of materials, written or spoken, that are designed to influence the general public or other groups in promoting the interests of their clients.

NAICS CODE(S)

541820 (Public Relations Services)

INDUSTRY SNAPSHOT

The primary focus of the public relations industry is to project a favorable impression of a person, product, company, or organization and to win public confidence and approval. As a result, public relations involves communication with a variety of individuals and organizations, as well as the general public. Independent professionals, specialized companies, or in-house public relations departments carry out public relations services.

The 1990s proved to be a lucrative decade for the public relations industry, which experienced a notable 250 percent in revenues growth between 1990 and 2000. In the year 2000 alone, sales grew 32.9 percent, an industry record for annual growth, in the United States. This surge was fueled in large part by the rise of the technology sector, which grew to account for 41.0 per-

cent of industry revenues in 2000. The U.S. public relations industry was valued at \$4.2 billion in 2000.

When the technology industry crashed in 2001, and the U.S. economy weakened, businesses in nearly every sector began to tighten public relations budgets. As a result, industry revenues fell 2.65 percent in 2001. To offset the impact of this downturn, many public relations firms began to lay off employees. Eager to find new sources of revenue, some larger firms began to compete for smaller accounts. In addition, some companies reduced their rates, which increased competitiveness, but also undercut profitability.

ORGANIZATION AND STRUCTURE

About 98 percent of public relations firms were set up as taxed-based entities, with the remainder organized under the not-for-profit distinction. Giant advertising agencies, which have incorporated public relations functions into their consumer services, owned many of the larger public relations (PR) firms. In order to achieve an international presence, these multiple firms formed a network of independent companies, creating a trend within the public relations industry.

The majority of public relations firms made their headquarters in or around major metropolitan areas. International operations expanded more rapidly than domestic, with new markets in Eastern Europe and the Commonwealth of Independent States (former Soviet Union) proving to be very promising.

Certain basic activities common to all public relations efforts included the development of sound policies in the public interest, the implementation of a public relations campaign recognizing the importance of public goodwill, and the establishment and maintenance of the organization's integrity.

With the current trends toward global marketing and frequent changes in communication technology, the accreditation of public relations experts took on greater importance. Universities offering post-graduate degrees in public relations provided courses on topics including the nature of human communication and the role of the media in public relations. Programs like those offered through Boston University and the University of Miami also provided areas of specialization in the fields of corporate, government, and non-profit sectors.

BACKGROUND AND DEVELOPMENT

The public relations industry was once synonymous with publicity, and for many years that was its chief mission. Many analysts claimed that the profession grew directly out of the boom-and-bust periods of the 1920s and 1930s. Indeed, during the Great Depression the public began to regard private industry as a failure and turned to big government for salvation. Due to these pressures,

major business interests turned to public communication. The first public relations people were top newspaper journalists, practiced in the art of reporting and writing.

Due to the increased government regulation of business during the New Deal, the public relations industry grew following World War II. Additional factors affecting its growth included the growth of organized labor, the generally higher level of public education, and the recognition by all institutions of their dependence upon public approval. Until the 1950s, public relations was a business of generalists. The range of problems handled generally related to publicity, crisis management, financial public relations, speech writing, and community relations.

The Washington-based Public Affairs Council, established in 1954, focused its original mission to stimulate and train business executives to become active and effective in politics. At roughly the same time, companies such as Ford, General Electric, and Johnson and Johnson established political education and good citizen programs to get their own executives involved. The Public Affairs Council eventually became the professional association for corporate public officers.

By the end of the 1950s, a handful of companies had established public affairs departments. Their major priorities were to formalize the firms' federal government relations and to encourage executives to participate in political activities. The 1960s were experimental years of growth for public affairs. The Public Affairs Council estimated that during that decade, upwards of 500,000 business managers and executives attended formalized political education courses.

Toward the end of the 1960s, an outbreak of riots in some large cities triggered the development of urban affairs and social responsibility units in many firms. A concerned business community undertook new philanthropic and community initiatives organized under the directive of the corporate public affairs department. By the 1970s, these programs expanded to include job training for the disadvantaged, housing, transportation, law and order, health, education, and economic development initiatives. The Public Affairs Council doubled its membership during this time, and it was estimated that between 800 and 1,000 national companies had organized public relations departments.

Some critics regarded business responses to these social ills as cosmetic. For example, a large number of programs were undertaken to educate the public about how the economic system worked and its contribution to social well-being. Some companies undertook expensive advocacy-advertising programs to carry the business story to the public. Still others hoped that sponsorship of high-quality television programs, increased charitable contributions, and similar good works could replenish

goodwill. Many of these efforts continue to the present day, but they are not regarded as a quick fix for perceptions of the citizens or the elected officials.

The growth of public affairs departments reflected business' recognition that managing business-society relations was a permanent task. Companies recognized that public relations strategy had to go beyond image building, political action, or social responsibility to be effective. A new term, "issues management," grew out of these needs and began to describe the public relations efforts of corporate entities in the late 1970s.

The election of Ronald Reagan in 1980 molded public relations programs for the next decade. Aspects of the political environment under Reagan included a reduced role of government in public life, substantial cutbacks in federal funding of social programs at the local level, and reform and relaxation of business regulation. Cutbacks in spending and reduced regulatory activity at the federal level required companies to pay more attention to state government relations activities. Even more challenging to companies was the growing pressure for business to assume the financial burden for the cost of social programs once paid for by the federal government.

By the early 1990s, workers in public relations specialized in many different areas, such as labor relations, financial relations, health care, and product publicity. Although the scope of its function broadened, the field of public relations became more specialized to accommodate the complex issues involved in an effective public relations campaign. The profession evolved from a "fire fighting" to a "fire prevention" role in the conduct of everyday corporate business.

The Internet. The public relations industry sustained a dramatic impact with the introduction of the Internet. In 1993, ProfNet, a collaboration of public information officers providing journalists with access to expert sources, was launched. Its members included colleges, corporations, nonprofit organizations, and law firms. ProfNet also included an online catalog of 2,000 leading experts across all disciplines.

As the use of the Internet continued to grow, the transition to interactive communications required a change in thinking and created new opportunities for building relationships between organizations and their public. The Internet could deliver messages combining various methods of communication: text, audio, graphics, still pictures, animation, and full-motion video. The challenge for the public relations professional was to use this tool to the organization's advantage, allowing for more one-to-one communication while maintaining the credibility and trust essential for the organization's well-being.

The Internet also drove the increasing globalization of the marketplace. In 1999, the United States held an over-

whelming lead in Internet users, with more than 110 million, which was nearly 43 percent of the total 259 million worldwide Internet users. By 2002, the United States was projected to have one-third of worldwide Internet users, declining to 27 percent by the end of 2005. The most notable impact on the public relations industry by the growth of the Internet was in the re-evaluating of the traditional marketplace. Conventional boundaries defining not only economic but geographic roles were being redefined with the increasingly expanding global market.

Public relations programs could constantly monitor the Internet in order to identify ways to communicate with targeted audiences through this new medium. Companies using the Internet could take advantage of the one-to-one marketing opportunities presented by the Internet to reach opinion leaders in industry. Extending the organizations' presence to the World Wide Web and commercial online services transcended traditional public relations. These communications efforts could combine the best of traditional PR—strategic consulting, marketing support, media relations, public affairs, crisis management, investor relations, even special events—with the vast reach of the Internet.

The recession of the early 1990s had a negative effect on public relations firms and corporate communication professionals. The industry experienced a 26 percent jump in employment between 1980 and 1990, but this subsequently declined. For example, Hill and Knowlton Inc., one of the larger public relations firms, cut its work force by 25 percent in 1991, based on an 11.8 percent decline in billings.

In the 1980s, public relations agencies averaged 20 employees per \$1 million in business, but that figure fell to 12 employees per million in the 1990s. The downsizing that occurred in the public relations industry required firms to outsource many tasks to independent public relations professionals. Firms realized savings on overhead, payroll taxes, and benefits under this arrangement.

A survey conducted by the Public Relations Society of America showed no growth in jobs in 1991 for the public relations industry as a whole, but many professionals in the field expected future industry growth. Specifically, 39 percent of public relations professionals surveyed expected their firms to expand in the next several years, while 45 percent predicted no change in employment, and only 5 percent anticipated additional downsizing. These numbers looked even better for the nonprofit sector, where expectations for staff expansion were 17 percent, compared to expectations of downsizing of 12 percent. Corporate public relations departments expected to experience downsizing as the reengineering process continued for American corporations. Sectors such as legal, health care, and environmental public relations were expected to achieve strong growth during the late 1990s.

By 1998, with the recession a distant memory and the economy booming, public relations services thrived. All of the top 10 agencies experienced growth.

CURRENT CONDITIONS

After experiencing record revenue growth of 32.9 percent in 2000, the \$4.2 billion public relations industry saw its revenues decline 2.7 percent in 2001. The reason for such an abrupt decline was multifaceted. The industry's significant growth in the later half of the 1990s had been fueled in large part by the technology industry's meteoric rise. In fact, by 2000, more than 40 percent of the industry's revenues were attributable to the technology industry; as result, when the technology industry crashed, the public relations industry was particularly vulnerable to the downturn. At the same time, the general economic weakness in the United States was also prompting firms in other industries to tighten their belts, a process that quite often involved reducing their public relations budgets. According to Impulse Research, PR budgets dropped an average of 21 percent in 2001, from \$4.8 million to \$3.8 million.

According to an April 2002 article by the Council of Public Relations Firms, the economic downturn had a profound effect on public relations firms. "The biggest firms are laying off employees, slashing their prices for the first time in five years and chasing small accounts that they wouldn't have bothered with in the late 1990s boom." One industry giant, Burson-Marsteller, laid off 15 percent of its workforce in 2001. Another large public relations firm, Edelman, trimmed its ranks by 10 percent after sales dropped 5 percent that year. Porter/Novelli saw its revenues dip 13 percent and initiated its first staff reduction program in nearly a decade.

INDUSTRY LEADERS

Burson-Marsteller, Hill and Knowlton, and Porter/Novelli were the big three in the public relations industry as of 2002. Burson-Marsteller, a company founded in 1953, employed 1,600 professionals in over 30 countries. Sales for 2002 were \$175 million. Clients included multinational corporations, business organizations and professional associations, as well as governmental bodies and not-for-profit agencies. These have included Sun, Apple, TRW, Scott Paper, Sunbeam, BellSouth, Ford Motor Co., Westinghouse, and the U.S. Olympic Committee.

Hill and Knowlton was a member of the WPP Group integrated communications services family and operated globally with 65 offices in 35 countries. Having gained a reputation for exceptional service, Hill and Knowlton continued to enjoy continued growth, as sales increased 7.4 percent to \$325 million in 2001. The company employed 1,117 professionals around the world. The company had a strong European presence with a London office overseeing

all administrative aspects for the firm. European income contributed 40 percent of worldwide business.

Porter/Novelli, which operated roughly 100 offices in 55 countries around the world, saw tremendous growth in the mid-1990s, partly due to acquisitions of such firms as Brodeur & Partners and Copithorne & Bellows. However, total sales for the company dropped 13 percent in 2001. The firm specializes in two growing marketplaces: health care and technology. Clients have included BASF Corporation, National Broiler Council, and the Kids ThinkLink.

Other industry leaders include Shandwick International and Edelman. Peter Gummer founded Shandwick International in London, England, in 1974. In 1985 the company was listed on the London Stock Exchange and began expanding worldwide, mostly by acquiring other geographically dispersed public relations firms that complemented Shandwick in terms of culture, services offered, and location. In the late 1990s, Shandwick International boasted over 100 offices worldwide while employing over 1,700 public relations professionals. Shandwick International was itself acquired by The Interpublic Group of Companies Inc. (IPG) in October 1998.

Founded in 1952, Edelman is a New York-based, privately held corporation with 32 offices in 20 countries. In 2001, the company was the largest independent public relations firm in the United States, with \$223 million in annual fees and more than 2,000 staff members. About 65 percent of the firm's worldwide billings came from its U.S. operations, with 25 percent coming from Europe and 10 percent from elsewhere. Of the firm's 38 offices, 9 were located in the United States. Recognized as a technology leader, Edelman was the first of the major agencies to have its own home page.

WORKFORCE

The majority of occupations in the public relations field fall into the support category. General managers and top executives account for less than 10.0 percent, followed by secretaries at 6.8 percent, related workers not elsewhere classified at 4.5 percent, and general office clerks at 3.1 percent. The average entry-level salary in public relations for a person with a baccalaureate degree is approximately \$18,000-\$22,000, while those with additional education or experience, as well as graduating members of the Public Relations Student Society of America, can qualify for higher salaries.

An account executive of a consulting firm can earn upwards of \$35,000, as can a person with a comparable responsibility in a company's public relations department. A public relations director for a small- to medium-sized organization might earn \$35,000-\$40,000, while the range for the large corporation is approximately \$40,000-\$60,000. A salary survey performed by the Pub-

lic Relations Society of America placed the median annual figure for public relations professionals at \$46,204.

AMERICA AND THE WORLD

Public relations services took on a global perspective in the late 1990s, and many corporations included public relations as part of their international marketing communications mix. This resulted in many larger firms establishing branch offices and affiliates in foreign countries. Independent firms formed exchanges with other firms in locations around the world, and countries took a fresh look at public relations in positioning themselves for future economic growth. Care was also taken to provide news distribution service and media relations in a format that was readily usable by using the native languages of the region.

SIC 8744

FACILITIES SUPPORT MANAGEMENT SERVICES

This group covers establishments primarily engaged in furnishing personnel to perform a range of services in support of the operations of other establishments or in

providing a number of different continuing services, on a contract or fee basis, within another establishment. Included in the industry are establishments primarily engaged in the private operation of jails and adult correctional facilities, whether or not providing both management and supporting staff.

NAICS CODE(S)

561210 (Facilities Support Services)

INDUSTRY SNAPSHOT

The facilities support services industry encompasses firms that provide facilities management services on a contract or fee basis. New government regulations enacted throughout the 1980s combined with efficiency efforts bolstered industry revenues past \$5.3 billion annually in 1990 and \$6.4 billion in 1995. Growth continued throughout the 1990s. By 1997, there were 2,490 establishments in this industry employing 112,137 employees. Annual receipts were nearly \$7.6 billion.

ORGANIZATION AND STRUCTURE

Facilities support management service companies are involved in operating and managing sports complexes, jails, office buildings, stadiums, museums, hospitals, hotels, retail establishments, and almost any other type of facility. Contract facility managers are expected to reduce costs or improve the profitability and efficiency of the establishments or operations they oversee. Indeed, it is because of their expertise that they are expected to operate a facility more efficiently and safely than could a staff employed and managed by the facility owner. Many believe that the impartial opinion of the contract facility manager makes them more efficient.

The role of facility management firms has traditionally been associated with janitorial services, mailrooms, and security. Industry participants, however, in the 1990s, may also be responsible for facility design and construction, management of computer and communications systems, property acquisition, environmental oversight, and other factors related to the quality and functionality of a facility. A company hired to manage a firm's data processing systems, for example, may bring technical know-how that its employer would have great difficulty cultivating in-house. The ever-changing world of high technology and computers make it difficult for a company to keep staff continually educated. Soaring educational costs are often a detriment. Additionally, a company hired to operate a sports complex may bring a mix of knowledge related to grounds keeping, accounting and reporting, and sports marketing, among other functions.

Besides expertise and efficiency, establishments that employ facility managers receive other important bene-

fits. A chief advantage of outsourcing facility management duties is that an entity is able to reduce liabilities related to personnel. A corporation that contracts a firm to manage one of its factories, for instance, is able to substantially reduce headaches related to staffing, training, workers compensation expenses and litigation, employee benefits, worker grievances, and general management and payroll responsibilities. Rather than tracking hours and writing checks for an entire staff, it simply pays the management company. In addition, an establishment can quickly reduce or increase its staff on an as-needed basis without worrying about hiring or severance legalities. In other words, a large portion of the benefit provided by contract managers is not directly related to facilities management.

BACKGROUND AND DEVELOPMENT

Owners have employed managers to operate their facilities for centuries, and contract management services have been used throughout most of the twentieth century to handle grounds maintenance, janitorial responsibilities, food preparation, and other individual tasks. Only during the latter half of the 1900s, and particularly during the 1980s, has the use of large-scale management services that oversee entire facilities and complexes become widespread. Two dominant factors that have driven this trend are the proliferation of government regulation and the quest for corporate and institutional efficiency.

As government oversight at the federal, state, and local level mushroomed during the period from the 1960s to the early 1990s, many establishments became overwhelmed with complex rules and restrictions. Almost every industry was barraged with a separate set of regulations aimed at their niche. Hospitals, for example, were forced to comply with thousands of complex mandates related to waste disposal, malpractice liability and protection, and safety. But even general regulations that apply to all facilities have ballooned. Churches, schools, and factories alike must comply with stringent laws regarding staffing, employee and civil rights, patron and employee safety and comfort, recycling and energy conservation, and pension and health benefits. Adding to those are a profusion of environmental laws related to factors such as indoor air quality, grounds maintenance, and hazardous emissions.

The emphasis on efficiency, the second influence driving the use of contract facilities managers, emerged during the 1980s. An increasingly competitive global business environment, combined with slower domestic market growth and greater competition at home, forced U.S. companies in all industries to cut costs. Likewise, public pressure to reduce spending convinced many government entities, particularly at the local level, to farm out facilities management duties to more efficient firms in

the private sector. Many entities found they could reduce personnel expenses through workforce cutbacks and at the same time boost efficiency by outsourcing tasks to specialized managers. "Outsourcing is a result of downsizing," said William L. Gregory, vice president of the International Facilities Management Association (IFMA).

CURRENT CONDITIONS

Facilities support service industry revenue shot up from about \$2.25 billion per year in 1982 to \$6.4 billion by 1995. The trend toward outsourcing continued during the 1990s as corporate cost-cutting and downsizing persisted and government regulatory activity accelerated. Between 1995 and 1997, the industry had grown and increased revenue by almost 16 percent. Indeed, a growing number of companies were viewing the act of employing and managing workers as a hefty liability. The shift in focus toward more employee benefits put a hold on aggressive hiring practices and put a greater demand on contract workers. Rather than risk exposure to lawsuits and workers compensation claims, many establishments were letting more adept facilities managers bear the risk of employing workers so they could concentrate on their core specialties.

Besides employee regulations, sweeping new mandates during the early 1990s that intensified the emphasis on facilities managers included the Americans with Disabilities Act (ADA) and Clean Air Act (CAA). The ADA decreed a long list of requirements related to disabled employee and patron access with which most facilities must comply. The CAA created new standards for indoor air quality and hazardous emissions. In addition to legislation, court rulings were forcing employers to respond to health risks, such as carpal tunnel syndrome and eye strain provoked by working with computers.

In addition to efficiency and regulatory factors, security issues were increasing the need for contract facilities managers in the mid 1990s. One of the fastest growing industry segments was corporate security services. Contractors were being called in to manage advanced electronic security and surveillance systems that controlled employee access to electronic information, reduced the possibility of work place violence, and discouraged theft and vandalism by employees and patrons. An abundance of outside security firms were enlisted by the retail industry to control theft problems such as shrinkage, an industry term used to describe shop lifting by both patrons and employees.

INDUSTRY LEADERS

An example of a fast growing facilities support services firm in the mid 1990s was Wackenhut Corrections Corp., of Florida, a subsidiary of Wackenhut Corp. Es-

established in 1984, Wackenhut Corrections Corp. emerged as a dominant international provider of prison design, construction, and management services. The company designs buildings; staffs prisons with guards, social workers, doctors, and cooks; and manages inmate education programs, among other tasks. By mid 1997, Wackenhut managed 28 prisons in the United States, 3 in Australia, 2 in England, 1 in Canada and 1 in Puerto Rico. Company revenue topped \$312.8 million in 1998 and employees numbered approximately 8,000. "It is raining prison deals," said President George C. Zoley, in the February 18, 1994 issue of *South Florida Business Journal*. ". . . the business is growing exponentially."

Another successful facilities support company in the mid 1990s was Axiom Real Estate Management Inc., of Connecticut. Formed in 1992, Axiom was a joint venture between International Business Machines and Grub & Ellis Co., a national real estate company. Later, in September of 1997, Axiom became a wholly-owned subsidiary of Grub & Ellis; the venture was renamed to Grubb & Ellis Management Services, Inc. Although property management firms are excluded from this industry classification, Axiom provided a range of support services ranging from computer systems management to complete facilities oversight. The joint venture was established to take advantage of the corporate downsizing trend. Among other services, Axiom performs a full array of engineering, administrative, and financial duties.

About 800 companies competed in the facilities support services industry throughout the 1990s. Most of these companies were relatively large — the average industry participant had 80 workers, compared to an average of 13 for all U.S. service firms. The largest competitor by far was Ogden Corporation, a global provider of support services to energy and environmental agencies, airports and airlines, sports and entertainment facilities, industrial plants, office buildings, and government agencies. Ogden increased its net income 15 percent in 1993 to \$17.5 million, but by 1998 its 21,970 employees helped bring in revenue of almost \$1.7 billion.

During the 1990s, other large companies in the industry were Serv-Air Inc. of Texas, Canisco Resources, Inc. of Delaware, Nuclear Support Services of Pennsylvania; Bionetics Corp., of Virginia, and Antarctic Support Associates of Colorado. The median annual revenue of the top ten competitors during the 1990s typically ranged from \$50 to \$100 million.

Employment prospects for the industry are positive, since facilities management outsourcing is expected to proliferate. Jobs for secretaries and other clerical workers, which account for a large share of this industry's workforce, should increase more than 50 percent between 1990 and 2005, according to the U.S. Bureau of Labor Statistics. Most labor and management opportunities

should increase similarly. Employment of computer programmers and systems analysts will leap by more than 100 percent by 2005, as will openings for management and financial analysts and marketing professionals. Furthermore, workers in this industry are well compensated. The average payroll per employee in the mid 1990s was about \$33,000—35 percent higher than the average for all other U.S. service industries.

SIC 8748

BUSINESS CONSULTING SERVICES, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in furnishing business consulting services, not elsewhere classified, on a contract or fee basis, including such specialties as agriculture, city planning, radio consulting, test development, and traffic consulting.

An important part of this classification's title and definition, "not elsewhere classified," needs some clarification so that the classification may be properly understood. This classification is one of a group of five industries called Management and Public Relations Services. The largest service industry in this group is **SIC 8742: Management Consulting Services**, which is somewhat similar in function to this industry, but is several times larger in terms of its revenues and work force.

NAICS CODE(S)

611710 (Educational Support Services)

541618 (Other Management Consulting Services)

541690 (Other Scientific and Technical Consulting Services)

ORGANIZATION AND STRUCTURE

Business consulting services, not elsewhere classified, includes businesses involved in supplying counsel and assistance to companies in the following areas: agricultural consulting; city planners, except professional engineering; economic consulting; educational consulting, except management; industrial development planning service; radio consultants; systems engineering consulting, except professional engineering or computer related; testing and test development and evaluation service, educational or personnel; and traffic consultants.

Hundreds of companies have reported activities in this industrial classification, including those involved in the testing of aptitude and skill for suitability in academic and vocational endeavors, and environmental consulting with or without testing. Other companies have offered business consulting as adjuncts to their main functions, as in the fields of insurance or guard services.

Business consulting services, not elsewhere classified, provide a wide range of specialized technical assistance to businesses, nonprofit organizations, and government establishments. Some of these service firms are small, some are quite large, and others are small parts of large organizations whose major activities are in other fields.

Reasons for Using Consultants. As with all consulting, the specialties that have been successful are those where the client organizations require temporary expertise in areas where they have not found it feasible to employ a professional staff, or where a knowledgeable advisor may be wanted to give an authoritative independent opinion on an important matter. Profitable consultants usually have areas in which they are considered especially authoritative or skilled.

Industry Size. According to the most recent data available from the U.S. Census Bureau, total receipts for firms in the industry were approximately \$15.2 billion in 1998, a 5 percent increase over the previous year. The number of employees in this service industry was estimated at 94,100 in 1998.

Industry Associations and Accreditation. There is no central licensing agency for management consultants. In fact, no guidelines or regulations exist in the industry at all as standards for operating practices. The only available form of acknowledgment of consulting expertise is the Certified Management Consultant designation, which is granted by the trade association, the Institute of Management Consultants.

Another primary industry association is ACME (formerly Association of Consulting Management Engineers). Both ACME and the Institute of Management Consultants operate as divisions of the Council of Con-

sulting Organizations (CCO). Other industry associations include the Society of Professional Management Consultants, the Association of Management Consulting Firms, the Association of Management Consultants, and the Association of Internal Management Consultants.

BACKGROUND AND DEVELOPMENT

Consulting grew slowly in the years before 1950, when there were less than 100 firms in the industry. The number of firms expanded rapidly after 1950, however, and by 1990 well over 1,000 firms were established. According to Service Industries USA, in 1998 there were an estimated 22,000 firms, representing an enormous increase during the 1990s.

Pre-World War II. The consulting field had its beginnings in the late 1880s. The Arthur D. Little Company, founded in Cambridge, Massachusetts in 1886 was among the first prominent consulting firms and was still an industry leader in the early 1990s. The company provides both business and management consulting and specializes in engineering-related research for its clients.

A new impetus in consulting came around World War I with the concepts of scientific management pioneered by Frederick W. Taylor and Frank and Lillian Gilbreth. Their studies of worker productivity in factories led to the widespread use of time studies. In 1929, a small group of firms joined together to form a trade association known as the Association of Consulting Management Engineers (ACME). In the 1930s and 1940s, such new consulting firms as McKinsey & Co. and Booz-Allen & Hamilton established themselves by broadening their scope of services to cover finance, organization, and policy issues. These firms, which have become among the most successful in the industry, also helped bolster troubled companies during and after the Depression.

Post-World War II. The consulting field grew rapidly in size, scope, and diversity from World War II to the mid 1990s. Many small firms were established and larger companies grew and branched out to meet ever-changing business needs. Many firms, for example, were hired to provide training and assistance for computer technology and methods. Public accounting firms initially offered consulting assistance as a sideline, but it has since come to represent a significant portion of revenues and profits.

In 1968, groups of consultants and consulting firms organized the Institute of Management Consultants (IMC), an individual membership organization that acts to further its members' interests as well as to certify and assure the ethics and capabilities of its members. In 1989, ACME and IMC established an overseeing umbrella organization, the Council of Consulting Organizations (CCO).

Growth and Change. This industry grew rapidly in the late 1980s and through the 1990s. Overall, the industry grew at an annual rate of nearly 20 percent between 1987 and 1991. In 1993, the industry grew 11 percent from the previous year, then 22 percent in 1994, 16 percent in 1995, 3 percent in 1996, and 5 percent in 1997.

Several conditions have led to this growth. For example, an increasing number of firms were solicited to provide testing and analysis assistance on environmental issues. Additionally, psychological testing was in greater demand in the early 1990s as more academic and vocational organizations came to rely on such test results. In these areas, many companies found it more expedient and cost effective to use an outside service for a fee, rather than to hire a staff with the requisite skills. Companies also benefited from the further advantage of receiving an objective judgment from an independent outside service.

According to the *U.S. Industry and Trade Outlook*, demand for professional services is expected to continue to increase into the new millennium, but at a slower rate than during the latter half of the past decade. A major force behind this growth will be the increased use of computers, the Internet, integrated systems, and other high-technology equipment. The challenge for this industry will be to train and retain qualified consultants.

The leading firms discussed below reflect the diversity in the specialties of professionals in the business consulting services field. Many of the smallest firms in the industry, not covered here, have very narrow specialties in which they have special expertise, or serve small geographical areas in which they have become well known.

INDUSTRY LEADERS

According to *Ward's Business Directory of U. S. Private and Public Companies*, the industry leader in 1998 was Prudential Resources Management of Valhalla, New York; second was National Shopping Service of Los Angeles, California; third was Post Buckley Schuss and Jeering Inc., of Miami, Florida; and fourth was Den Corp/Information and Engineering Technology of Fairfax, Virginia.

WORKFORCE

Diversity of Skills. Because this industry is a field with many different types of functions, the work force is made up of individuals of many different specialties. For instance, environmental consulting requires engineers, psychological testing requires psychologists, economics consulting requires economists or MBAs, and city planning consulting requires architects, civil engineers, and landscape architects. The city planning consulting segment of the industry has 100 firms ranging in size from

solo practitioners to businesses with over 5,000 employees.

SIC 8811

PRIVATE HOUSEHOLDS

This industry consists of private households that employ workers on or about the premises who serve in occupations usually considered as domestic service. This classification includes baby-sitting; domestic service; private estates; noncommercial farmhouses; private households employing cooks, maids, chauffeurs, and gardeners; personal affairs management; and noncommercial residential farms.

NAICS CODE(S)

814110 (Private Households)

INDUSTRY SNAPSHOT

This industry, unlike most others, is comprised of individuals, not companies. More than half a million households paid employers' taxes on private household workers and more than 802,000 household workers were employed in the United States in 1996. General house workers accounted for about 63 percent of available jobs; 34 percent of this workforce were engaged in child care. Historically, demand for help in this industry has been greater than the supply of workers. The need for household workers increased during the latter part of the twentieth century as more women with children entered the workforce and as an aging population often required private attendants or companions. As the baby boomer generation ages, employment opportunities for personal attendants will continue to rise. In 1995, 40 percent of all persons employed in private households were involved in childcare and 4 percent were housekeepers, or butlers.

ORGANIZATION AND STRUCTURE

Generally, the organization of this industry can be defined by a simple employer and employee relationship, with one or more employers per household worker. In large households with sizable staff, a butler or head

housekeeper manages the other workers. Some private household employees contract with placement agencies that act as a partial employer, often by offering benefits to the workers and acting as an intermediary between employer and employee.

Traditionally most U.S. domestics have been “general house workers” responsible for duties such as dusting; sweeping and vacuuming; and cleaning fixtures, ovens, and bathrooms. Some general house workers also take on such duties as cooking and childcare, although these are usually considered specialty areas. Another category of household workers includes those specifically involved in childcare. Workers employed on an hourly and casual basis are usually referred to as baby-sitters; those employed on a regular, ongoing basis who are in charge of infants are usually considered nannies; and workers in charge of older children are tutors or governesses. Household workers who assist the elderly or disabled are referred to as companions or personal attendants. Such employees generally prepare meals and do light housework, but, depending on the person’s needs, may also help in bathing and dressing. Most household employees are also involved in the personal aspects of the employer’s life. This is mainly true with nannies and personal attendants. Oftentimes, it is the household employee who is the stable figure in the lives of those being taken care of.

Large households employing workers may include a housekeeper, butler, cook, caretaker, and/or a launderer. Housekeepers and butlers are responsible for hiring and supervising household staff, and they normally do light housework. Butlers also answer phones, deliver messages, serve food and drinks, and act as personal attendants. Cooks are responsible for preparing and serving meals, ordering food supplies, and keeping the kitchen clean. Caretakers carry out heavy housework and maintenance, including light carpentry and plumbing.

BACKGROUND AND DEVELOPMENT

Domestic workers have existed for centuries; early on, however, service often took the form of slavery or indentured servitude. In 1870, there were approximately 960,000 private household workers in the United States. Between 1870 and 1910, demand for such work increased rapidly because industrialization sparked a proliferation of middle- and upper-class families in urban areas. At this time, demand was easily met by the vast number of immigrants in the country. Yet, with this advance in industrialization, the status of household work declined. The gap between factory and domestic workers was widened by the emergence of benefits and legislation to protect factory workers.

For a short period, roughly between 1910 and 1920, the number of domestic workers in the United States

declined. This drop was mainly due to the advent of compulsory education of children and the introduction of child labor laws. Between 1920 and 1940, the number of domestics working in the United States jumped from 1.36 million to a peak of 2.28 million. Domestic help was changing from a mostly live-in, full-time profession to one in which servants lived on their own and even worked on a part-time basis. This was spurred on, in part, because families living in small homes or apartments still hired household help. After World War I, this occupation drew immigrants with minimal language skills and African-Americans moving north, for whom domestic service was one of the few occupations available. Since 1940, the number of private household workers in the United States has decreased. Despite having long dominated the industry, women began to leave these jobs when outside opportunities increased and they were able to work in better occupations.

In the early 1990s, the treatment of household help, particularly nannies, was publicized as a result of lawsuits against employers involving sexual harassment and physical violence. An article in the *Wall Street Journal* claimed that “nannies are among the most exploited workers in the country.” Stories of unfair wage practices, long hours, and physical abuse emerged in the media. However, nannies and other household workers have had few legal rights in fighting harsh working conditions. In 1993, most states did not place a limit on the number of consecutive hours or days a household worker could work. Moreover, sexual harassment of household workers has not been illegal in most states. In New York, human rights laws have prohibited sexual harassment and discrimination of employees, but has specifically excluded domestic workers.

In 1993, employers’ tax obligations were highlighted when it was discovered that one of President Clinton’s nominations for attorney general had hired an illegal alien and had not fully complied in paying social security taxes for an employee. As a result, President Clinton proposed simplifying the tax laws for employers to make it clearer if they are required to pay social security tax on wages. Unless a private household worker is an independent contractor—which is rarely the case—employers are required to pay social security tax on any employee earning more than \$50 per quarter to the federal government and any additional taxes required by their states.

CURRENT CONDITIONS

Upon entering the 1990s, this industry continued to have a short supply of workers due primarily to the working conditions, low status, and lack of health and fringe benefits (although some placement agencies offered benefits). Also in the early 1990s, changes in immigration laws made work permits more difficult to obtain.

The trend in the 1990s has been away from private household help for childcare and toward the use of nurseries, which are often sponsored by employers. Other trends for childcare have included more use of day care facilities, which are operated by private companies and individuals working out of their homes.

While the actual number of workers declined by 6,000 workers from 1992 to 1998, opportunities for employment in this industry sector was expected to remain robust through 2006. In essence, more lucrative employment was available due to a robust economy in which employers competed for a scarce labor pool. With an increasing number of women joining the workforce, demand for household help, child care, and (with an increasing population of senior citizens), elder care. In lieu of private household employers, the trend at the end of the 1990s was towards increasing dependence on domestic cleaning firms, child care establishments, and temporary help firms.

WORKFORCE

In the latter half of the 1990s, there were roughly 802,000 private household workers employed in the United States. More than half were general house workers, about 40 percent were child care workers, and about 4 percent were housekeepers, butlers, cooks, and laundresses. Nearly two-thirds of household employees worked part-time (35 hours or less per week).

Experienced and highly recommended workers employed by wealthy families in major metropolitan areas may earn \$800 to \$1,200 a week. Private household workers who live with their employers may be given room and board, medical benefits, a car, vacation days, and education benefits. However, most private household workers receive very limited or no benefits.

Earnings of private household workers varied depending on household, staff size, geographic location, and experience. Generally, full-time live-in housekeepers, cooks, butlers, nannies, and governesses earned the highest remuneration. Experienced, well-referenced domestic workers serving wealthy families in large metropolitan areas were the highest paid household workers. For the most part, however, private household workers were employed part time and did not receive any benefits. Some workers lived with their employers and received room, board, and a package of benefits competitive with U.S. industry, but, in some states employers could deduct a minimal amount for room and board, making the salaries of some household workers lower than the minimum wage. The Bureau of Labor reported that, in 1996, median annual earnings for full-time private household workers were \$11,600 for cleaners and servants, \$11,100 for cooks, child care workers received \$10,500, and

\$7,500 was the average wage for housekeepers and butlers.

AMERICA AND THE WORLD

In 1999, the Bureau of Labor Statistics indicated that a majority of household workers were women (62 percent). African-Americans composed 13 percent of all industry workers, while 9 percent were Latino.

According to the Center for Migration Studies, at least 10 percent of the United States' 3 million illegal immigrants worked in childcare in 1993, with roughly another 10 percent working in other private household occupations. Legally, over 10,000 Western Europeans work in the United States through cultural exchange programs.

Great Britain, like the United States, has reported shortages of child care help. In a 1990 study, 48 percent of British women who were unemployed said they had to stay at home to raise their children because they were unable to find help. Because of this shortage, salaries for nannies in Great Britain have increased significantly. In other European countries, childcare help is largely covered by the state, reducing the need for such workers. A study by the European Economic Commission showed that Denmark, France, Belgium, and Italy offered the most generous state assistance for childcare. In the Scandinavian countries, childcare is typically provided by employers.

SIC 8999

SERVICES, NOT ELSEWHERE CLASSIFIED

This group covers businesses that primarily provide services, not elsewhere classified (NEC), such as authors, lecturers, radio commentators, song writers, weather forecasters, writers, and artists working on their own account.

NAICS CODE(S)

- 711510 (Independent Artists, Writers, and Performers)
- 512210 (Record Production)
- 541690 (Other Scientific and Technical Consulting Services)
- 512230 (Music Publishers)
- 541612 (Human Resources and Executive Search Consulting Services)
- 514199 (All Other Information Services)
- 541620 (Environmental Consulting Services)

The services, NEC, group included many specialties ranging from inventors and lecturers to stained glass artists and cloud seeders. According to government statistics, 14,587 firms employed 81,136 people in this category in 1992. A majority of firms in this category had annual sales under \$100,000, with 6,848 having sales below \$49,000, and 8,607 with sales between \$50,000 and \$99,000. The size of such firms also favored the smaller firm, with 19,826 having less than 5 employees.

The largest industry sector was actuarial firms, with ten percent of the industry workforce in the 1990s. Actuaries use mathematical models and statistical techniques to analyze risk. They develop and price insurance products and financial instruments, analyze financial institutions, and help manage pension and employee benefit plans. Actuaries also perform other jobs requiring advanced statistical analysis and mathematical modeling, such as investment management.

Although their profession is considered rewarding and lucrative, actuaries typically must pass exams that may require several years of study during their employment. But experienced actuaries typically earn over \$50,000 annually, and often make as much as \$100,000 or more. Demand for actuaries was expected to rise more than 50 percent between 1990 and 2005, according to the Bureau of Labor Statistics.

Except for clerical workers, geology and geophysical services were the second largest industry category, accounting for about 6 percent of the workforce. Geologists study the earth's composition and structure. Geo-

physicists study matter and energy and how they interact. Members of both professions may consult on construction projects, such as dams and roadways; locating raw materials for extraction by mining and drilling companies; and predicting natural disasters. Salaries for experienced professionals in these fields were about \$40,000 per year in 1992. Jobs for geologists and geophysicists could rise 70 percent by 2005, fed by more environmental research and the hunt for new mineral reserves.

Writers, editors, and technical writers made up 5 percent of the miscellaneous services workers in the mid 1990s. Often working as contractors or freelancers, writers and editors were hired by publishers, television and radio stations, and other media groups. They also worked for companies and individuals, writing speeches, marketing materials, manuals, and other compositions. Editors usually managed and reviewed the work of writers, and were often involved with the publishing process. While yearly salaries varied, experienced writers commonly earned \$25,000 to \$35,000 and editors generally drew \$30,000 to \$45,000.

While salary and employment prospects vary by occupation, the overall job outlook was positive for miscellaneous services workers through the 1990s. Demand for most occupations should rise more than 50 percent between 1990 and 2005. Computer programming services, which accounted for roughly two percent of the workforce, should rise nearly 100 percent. Job growth may also be strong for commercial artists, meteorologists, interior designers, and science and math technicians and managers.

PUBLIC ADMINISTRATION

SIC 9111

EXECUTIVE OFFICES

This category covers offices of chief executives and their advisory and interdepartmental committees and commissions.

Executive offices are those held and directly controlled by mayors, governors, city managers, county supervisors, and the president of the United States. They encompass heads of local, state, and national governments. They formulate and project policy, prepare budgets, handle major emergencies, appoint and nominate leaders and judges, and work to improve the lot of constituents, among other activities.

NAICS CODE(S)

921110 (Executive Offices)

ORGANIZATION AND STRUCTURE

According to a 2003 report released by the United States Conference of Mayors and Global Insight, local metropolitan areas drive the nation's economy. They accounted for 85 percent of national output and 87 percent of the nation's economic growth from 1992 to 2002. In 2002, there were 87,900 identified units of government operating in the United States, comprising 87,849 local governments, 50 state governments, and the federal government. Local governments were further subclassified as 3,043 county governments; 19,431 municipal governments; 16,506 town/township governments; 13,522 school districts; and 35,356 special districts. State and local governments took in approximately \$1.3 trillion dollars in revenues in 2001 and employed 307,000 persons (full-time equivalents) for government administration alone.

Local. The three basic types of municipal government structures in the United States are mayor-council, commission, and council-manager. Although they typically oversee relatively small geographical units, local governments may exercise great control over the daily lives of their constituents. They are charged, for example, with providing fire and police protection, waste disposal, and other services.

In the mayor-council government, the mayor is elected as the executive and usually controls the council, which is also elected. The council formulates ordinances that the mayor enforces. Some systems use a weak-mayor system, in which the mayor is subordinate to the council. Examples of large cities with mayor-council organizations are Boston, New York, Chicago, and Seattle.

In contrast, a commission government consists of several commissioners elected to serve as heads of city departments. The presiding commissioner usually acts as the mayor. Cities with commissioners include Tulsa and Salt Lake City.

A council-manager government has an elected council. The council hires a city manager to run various city departments. The city manager is the chief executive of the city and is ultimately responsible for running the government and advising the council. The council also elects a mayor to chair the council and officiate at major functions and events. Des Moines and Cincinnati have council-manager governments.

The United States Conference of Mayors was organized to improve municipal government through cooperation with the federal government. It is comprised of about 1,183 mayors from cities with a population of more than 30,000. According to the *Statistical Abstract of the United States: 2002*, the largest cities by population were New York, Los Angeles, Chicago, Houston, Philadelphia, and San Diego.

State. The 50 state governments are structured similarly to the government of the United States. Each state has an executive, legislative, and judicial branch, as well as its own constitution. The executive branch is headed by a governor whom the voters elect. Below the governor is the lieutenant governor. Among the primary duties of the governor's office are the preparation of a state budget and the guidance of new legislation. In addition, a governor acts as the commander-in-chief of the state militia (national guard) during times of peace.

In accomplishing his or her responsibilities, the governor enjoys the power to summon special sessions of the legislature, veto legislation, and issue pardons and commute sentences for most crimes. Although the executive powers afforded most governors may seem extensive, their authority is often diminished by the existence of independent agencies over which they have little control.

Most governors are elected to four-year terms, but several states have a limit of two years. Other states set no limit on the number of terms a governor may serve. They may be forcibly removed from office, however, through impeachment or recall.

National. The United States has a presidential government, which is distinguished by the fact that it is practically independent of the federal legislative branch. This contrasts with cabinet governments, utilized in many European nations, in which the executive body is drawn from and responsible to the legislative arm. As a result, the president is solely responsible to the voters and theoretically is free from congressional control.

The president has expansive powers granted by the Constitution. Paramount are his duties as commander-in-chief of the armed forces, the authority to declare war and to make treaties, the ability to veto legislation, and his role as ceremonial head of state. In addition to the formal powers provided by the Constitution, the office of the president has evolved into a much more powerful government entity than was conceived by the founding fathers. The president is responsible for conducting foreign affairs, appointing judges and other officials, and initiating and developing legislation. Furthermore, he has effectively become a guardian of the economy and is held largely responsible for factors such as the employment rate and standard of living.

The president is chosen through an electoral college. Voters choose electors on the state level who have been nominated by political parties and have pledged to vote for that party's candidate. Each state is allowed a number of electors equal to the combined total of its representatives and senators. The candidate who receives the majority of electoral votes receives the presidency. In the elections of 1800 and 1824, no candidate won a majority, so the House of Representatives selected the president.

The president serves a term of four years and is limited to two elected terms and a total of 10 years in office. To be eligible for the office, he or she must be a natural-born citizen of at least 35 years of age, have resided in the United States for 14 or more years, and not have a felony conviction.

The office of the president has more than 17 offices. Among them are the office of the vice president; the White House office, which encompasses counselors, staff, and assistants; the National Security Council, which advises on military policy; the Office of Homeland Security; the Council of Economic Advisers; and the Office of Management and Budget (OMB). The OMB is one of the most consequential executive offices. It evaluates, formulates, and coordinates management procedures and program objectives within federal departments and agencies. It also advises the president on relative legislation and proposals.

Although not clearly defined in the Constitution, the cabinet is described in the Twenty-Fifth Amendment as "the principal officers of the executive departments." An institution of tradition and custom dating back to George Washington, the cabinet is composed primarily of the heads of the 14 executive departments. It also may include the vice president and heads of other federal departments and agencies, as well as other individuals selected by the president. Cabinet appointments are subject to confirmation by the Senate. The Cabinet's sole function is to advise the president.

WORKFORCE

Although very few executive positions are available at the state or federal level, numerous opportunities to serve in executive positions exist within local governments. Many officials on the local level, such as mayors, do not hold full-time, year-round positions. They often have jobs, are retired, or have household responsibilities. Executives on the local, state, and federal level reach their positions in a number of ways. Many are attorneys, though public figures from all walks of life may be able to secure enough votes to capture an office.

City and county managers who are appointed by councils or commissions typically have a more definite career path than elected officials. Although they come from a variety of backgrounds, many have a master's degree in public administration or business. Managers of larger jurisdictions are expected to exhibit expertise in financial, administrative, and personnel matters associated with public management. Because they often are appointed by revolving administrations, city and county managers also need keen political and interpersonal skills that will help to keep them employed. Job growth opportunities are very limited. Many existing local and municipal offices are expected to try to reduce expenses and

personnel. Opportunities are greatest in regions with growing populations, particularly in the Southwest. In addition, some communities have been hiring city managers for the first time in an effort to boost the efficiency of their government.

According to the U.S. Bureau of Labor Statistics, there were 54,000 top executives at the legislative level in 2000. Median salaries for legislators ranged from \$12,530 to \$34,720 that year. However, some earned as little as \$11,560 and others made as much as \$62,860. Salaries for county managers averaged \$107,500 in 2000, whereas city manager salaries averaged \$92,338. According to the Bureau, the Council of State Government's *Book of the States, 2000-2001* reported that gubernatorial salaries ranged from \$65,000 to \$179,000 (plus a vehicle and an official residence).

the authority to levy taxes, regulate commerce, borrow money, and exercise a number of additional powers.

Although it has been amended to alter the function of the legislature, the U.S. Constitution that became effective in 1789 defines the federal legislative branch. The Tenth Amendment to the Constitution expressly reserves to the states all powers not specifically granted to the federal government in the Constitution. State legislative bodies have been likewise organized under state constitutions. The conceptual structure of most U.S. legislative bodies largely reflects European initiatives, such as the Magna Carta (1215) and the English Bill of Rights (1689).

The authoritative purview of U.S. legislative bodies is often challenged in legal efforts to clarify the scope, limits, and respective balancing of federal versus state power. This helps to maintain the vitality and viability of the Constitution when applied to contemporary issues and crises. Accordingly, the U.S. legislative system has remained a healthy model for democracies around the globe.

ORGANIZATION AND STRUCTURE

All U.S. governing bodies at the national and state levels—and most local governments—are distinguished by the fact that their executive, legislative, and judicial branches are practically independent of one another. This portentous difference contrasts with cabinet governments, utilized in many European nations, in which the executive body is drawn from and responsible to the legislative arm. As a result, the president is solely responsible to the voters and is theoretically free from direct legislative control. Likewise, legislative bodies are relatively unfettered by the executive branch. This separation of powers, combined with a system of checks and balances, serves to reduce the potential power of the government to domineer U.S. citizens. For example, chief executives can veto legislative initiatives, but legislators can override their vetoes.

State legislators initiate, draft, and vote on proposed state laws. Each state has two legislative bodies, an upper house (Senate) and a lower house. Nebraska, which has only one house, is the exception. The lower house is usually called the House of Representatives, or in some states the Assembly or the House of Delegates. The size of legislatures varies. For example, during the early 2000s Georgia had 236 legislators, whereas Nevada had only 63. However, within each state, all representatives are elected from districts with an almost equal number of citizens. About half of the legislators meet annually to vote on laws, and the other half meet twice each year. Upper house members are customarily elected for a term of four years and lower house members for a term of two years.

Most community legislative bodies exist under one of three types of government. Under mayor and council systems—the most common type of local governing body in the United States—an elected council acts as the

SIC 9121

LEGISLATIVE BODIES

This category covers legislative bodies and their advisory and interdepartmental committees and commissions at the local, state, and national level.

NAICS CODE(S)

921120 (Legislative Bodies)

INDUSTRY SNAPSHOT

Legislative bodies (from the Latin *lex*, "law," and *latio*, "a bringing") include the U.S. Congress, state legislative assemblies, and local commissions and boards. These entities are responsible for proposing, selecting, and amending the laws that govern all Americans. They have

legislative body. Its ordinances are typically subject to confirmation by the mayor, who is the head of the executive branch. Conversely, in the commission form of government, the elected commission essentially serves as both the legislative and executive body. The third type of system, council-manager government, operates similarly to the commission arrangement, the primary difference being that the council appoints a manager to oversee governmental departments rather than running the departments itself. Also at the local level are a variety of county legislators, who also receive their lawmaking authority from the state.

Congress. Congress constitutes the legislative branch of the federal government. It is the responsibility of Congress to develop, draft, amend, and vote on laws and proposed legislation that applies to the entire nation. In addition to their legislative duties, members of Congress also spend much of their time representing constituents in grievances against the federal bureaucracy. Congress convenes once each year, beginning on January 3, for a few months. It also holds special hearings on important public issues. In addition, the president may call special sessions of Congress.

Under the original U.S. Constitution, Congress is vested with the "Power to lay and collect Taxes, Duties, Imposts and Excises, to pay the Debts and provide for the Common Defense and general Welfare of the United States." Some of the powers specifically outlined in Section 8, Powers of Congress, include the authority to: borrow money, regulate cross-border and interstate commerce, coin money, establish post offices and roads, grant creative (patent) rights, declare war, and "make all Laws which shall be necessary and proper for carrying into Execution the foregoing Powers."

Congress is comprised of the Senate (upper house) and the House of Representatives (lower house). Both houses can introduce and amend bills. However, many of the laws on which Congress votes are written or proposed by the executive branch. To become law, bills must receive a majority vote from both houses and be signed by the president. If the president refuses to sign a bill, Congress can override the veto with a two-thirds majority vote from both houses.

The Senate was originally formed to represent the states and the upper class of society. Although its role has changed, it still retains some privileges, such as the power to approve or reject some presidential appointments, to try officials impeached by the House of Representatives, and to ratify or reject treaties. The Constitution allows each state two Senators. Senators are directly elected by the people of the state they represent and serve a term of six years. Senate elections are staggered so that no more than one-third of all Senate seats are up for election during any

year. Although the vice president serves as the Senate president, the strongest Senate leaders are the majority floor leader and the minority floor leader, who are elected by caucuses of their respective political parties.

The House of Representatives was originally designed to represent the people. The proxies in this legislative body are elected from districts of approximately equal size in states throughout the United States. Each state gets at least one representative, and the total number of U.S. districts is limited to 435. "Apportionment" of House seats among the states is predicated on U.S. Census results. Alaska, Montana, North Dakota, South Dakota, Vermont, Wyoming, and Delaware each had only one representative in 2003, whereas California, for example, had 53 House members. The House is led by the speaker, who is selected by the majority party. Among other duties, the speaker presides over debates and appoints some committee members.

Bills introduced by either Senate or House members are sent to standing—or permanent—committees. Committees meet in private to amend, hasten, delay, or kill the bills. There were 19 standing committees in the House and 16 in the Senate in 2003, each of which was concerned with a special subject, such as public works and transportation, foreign affairs, or agriculture. Committee chairpersons, who often possess significant power, are usually members of the majority party that have served the longest on their committee. In addition to standing committees, there are several special and select committees. In 2003, the Senate had four select committees: aging, ethics, intelligence, and Indian affairs. The House had two: intelligence and homeland security. Finally, joint committees unite members from both houses to draft compromises of conflicting bills that each house has passed. In 2003, there were four joint committees: economic, library, printing, and taxation.

After a bill is passed by a committee, the house votes on it. In the House of Representatives, the bill must also pass through the Rules Committee before it is put to a vote. If the bill passes, it is sent to the other house where it is again subjected to a committee. If changes are made, a joint committee develops a compromise bill that each house must accept. The final bill is sent to the president. If he does not sign or veto the bill within 10 days, it becomes a law. On the other hand, if Congress adjourns before the 10-day period expires, the bill is effectively vetoed, or "pocket vetoed."

BACKGROUND AND DEVELOPMENT

The first Continental Congress was convened in Philadelphia in 1774. Representatives of all states except Georgia attended. The group passed intercolonial resolutions calling for a boycott of British trade. The Constitution of the United States of America was created between

May and September of 1787, in Philadelphia, by a group of delegates from 12 of the original 13 states. That document, which became effective in 1789, outlined the structure of the legislative as well as the executive and judicial branches of the federal government.

The Constitution reflected a blend of British law, a general distrust of government, Pilgrim political heritage, and European political philosophy from authors like John Locke and Montesquieu. Manifest in the Constitution was the concept of legislative supremacy by a representative body, particularly in matters of economics. Legislative dominance related to taxes and other laws was tempered by the separation of powers and an innovative system of checks and balances. In addition, the framers of the Constitution were careful to retain independence of state and local legislative bodies.

The Constitution was also unique in that it established a system whereby lawmakers could amend the document. Amendments could be passed by a consensus of two-thirds of both houses, or by a state-supported national convention. By 1999, the Constitution had 27 additional amendments (the last in 1992). In addition, as the role of the United States in world politics expanded, particularly following World War II, the function of Congress changed. While the powers of the federal executive branch increased, legislative dominance diminished in some areas, including fiscal control. However, Congress remains the primary force in U.S. government.

As the federal legislative branch changed during the 20th century, so did the role of state and local legislative bodies. Early in the nation's history, federal and state powers were succinctly delineated. The Constitution assigned exclusive powers to both state and federal legislatures and provided for concurrent powers to be exercised by both levels of government. Federal courts, independent of Congress, mediated disputes and helped to determine spheres of state and federal influence. States, meanwhile, delegated legislative authority to local governments.

But the autonomy of state legislatures declined during the mid-1900s as the federal government ballooned in massive proportions, particularly after World War II. After giving itself the power to tax the income of U.S. citizens in 1913 (the 16th amendment to the Constitution), Congress swelled its income tax revenues from \$5.4 billion in 1920 to \$360 billion by 1980, and then an estimated \$1.9 trillion (individual and corporate income taxes, along with excise taxes, and social insurance and retirement receipts) by 2002. As a result states became increasingly dependent on federal government resources, and state and federal legislative bodies formed closer relationships.

Although they have evolved to meet the demands of a changing world, U.S. legislative bodies have remained relatively intact, from a Constitutional perspective. Be-

sides a greater concentration of power at the federal level, several trends have characterized the legislative process. One of the most dominant is an emphasis on legislative oversight. This entails the responsibility of state and national legislators to continually review, investigate, and evaluate how well the policies and programs of the government are being executed. The purpose of legislative oversight is to reduce excessive and inefficient laws and bureaucracy.

A primary oversight tool developed during the latter decades of the century was "sunset legislation," which established a means of automatically terminating agencies, boards, and committees that are not specifically reauthorized by the legislature. Sunset laws had been adopted in 36 states by the mid-1980s. By the 1990s, however, several states had ceased using the sunset laws because of various logistical and political hindrances. The focus shifted to term limits and balanced-budget laws.

Congress entered the millennium with a balanced budget for the first time in decades. Several major pieces of legislation of global import were on the verge of final vote. The issues reflected the times: Year 2000 ("Y2K") computer glitches, gun control, and interest rates. One of the most sensitive and politically charged issues for legislators was allocating funds for military efforts overseas, such as in peacekeeping missions, or in assisting new democracies rising from volatile beginnings.

CURRENT CONDITIONS

By the early 2000s, security issues—both at home and abroad—were of great concern to members of Congress. In response to increased terrorist threats, which included attacks against the United States on September 11, 2001, as well as mail tainted with anthrax, the U.S. Department of Homeland Security was formed. The Senate approved the new agency in November 2002 as the 107th Congress came to a close. The Associated Press dubbed the approval as "the largest government reorganization since World War II." A month earlier, Congress also passed a resolution that gave President George W. Bush the power to use military force against Saddam Hussein, who had been ordered to dispose of weapons of mass destruction by the United Nations. The Senate voted 77-23 in favor of this issue, and the House voted 296 to 133. In spring of 2003, Bush used the powers granted by Congress, as the United States invaded Iraq in an effort to destroy the Hussein's regime.

Another major initiative affecting Congress was the Bipartisan Campaign Reform Act of 2002 (BCRA). Effective on November 6, 2002, this legislation resulted in significant changes to federal campaign finance law. BCRA also is known as the McCain-Feingold Bill, because U.S. Senator John McCain (R-Arizona) and U.S. Senator Russell Feingold (D-Wisconsin) were instrumen-

tal in its development. Although many Democrats and Republicans favored the law, many were also opposed to it. These opponents filed lawsuits at the federal level calling the law unconstitutional on First Amendment grounds. These lawsuits eventually were combined into one court case, *McConnell v. FEC*, which was appealed to the U.S. Supreme Court in May of 2003.

WORKFORCE

In 2003, there were 535 congresspersons, about 7,500 state legislators, and thousands of local legislative bodies. The numbers were not expected to increase before 2006, although some local governments may expand as a result of increased regulation and growth forecasting. In a recent year, of the 535 U.S. Congressional members, 470 were male and 65 female. Caucasian members totaled 474, with 61 minorities. Ten members were over the age of 75, and nine members were under the age of 35. By far, the majority of members fell within the 40- to 60-year age group.

On a daily basis, legislators work with their voters, meet with lobbyists and special interest groups, read reports, write legislation, and meet with fellow legislators and other government workers. They may also appoint department heads and commission members, approve budgets, do research, and perform various ceremonial duties. National legislators, particularly, also spend time working to secure reelection. Local legislators often work part-time—they hold another full-time job, are retired, or run a household. State legislators usually work full-time for a few months each year and then only part-time. Congresspersons work long hours most of the year.

Eligibility requirements for local and state legislators vary, though residency is a common prerequisite. Likewise, Senators and House members in Congress must be residents of the state from which they are chosen. House members are typically residents of their districts, though that is not required by the Constitution. Senators must be 30 years old and have been U.S. residents for nine years or more, whereas House members must be 25 years of age and at least seven-year residents. Although there are many routes to becoming a legislator, it is common for state and national representatives to have law degrees, a history of public service, and/or a military background. But public figures from all walks of life, including astronauts, entertainers, and businessmen, are commonly elected to serve.
