VOLUME 1

INTRODUCTION	xxiii	SIC 2041: Flour and Other Grain Mill Products	46
FOREWORD	xxv	SIC 2043: Cereal Breakfast Foods	50
FOOD & KINDRED PRODUCTS		SIC 2044: Rice Milling	54
SIC 2011: Meat Packing Plants	1	SIC 2045: Prepared Flour Mixes and Doughs	55
SIC 2013: Sausages and Other Prepared Meat Products	6	SIC 2046: Wet Corn Milling	56
SIC 2015: Poultry Slaughtering and Processing	10	SIC 2047: Dog and Cat Food	57
SIC 2021: Creamery Butter	14	SIC 2048: Prepared Feeds and Feed Ingredients for Animals and Fowls, Except Dogs and Cats	60
SIC 2022: Natural, Processed and Imitation Cheese	15	SIC 2051: Bread, Cake, and Related Products	62
SIC 2023: Dry, Condensed, and Evaporated Dairy Products	18	SIC 2052: Cookies and Crackers	68
SIC 2024: Ice Cream and Frozen Desserts	21	SIC 2053: Frozen Bakery Products, Except Bread	72
SIC 2026: Fluid Milk	25	SIC 2061: Cane Sugar, Except Refining	73
SIC 2032: Canned Specialties	32	SIC 2062: Cane Sugar Refining	77
SIC 2033: Canned Fruits, Vegetables, Preserves, Jams, and Jellies	34	SIC 2063: Beet Sugar	78
SIC 2034: Dried and Dehydrated Fruits, Vegetables, and Soup Mixes	39	SIC 2064: Candy And Other Confectionery Products	79
SIC 2035: Pickled Fruits and Vegetables, Vegetable Sauces and Seasonings, and Salad Dressings	40	SIC 2066: Chocolate and Cocoa Products	83
SIC 2037: Frozen Fruits, Fruit Juices, Vegetables	41	SIC 2067: Chewing Gum	85
SIC 2038: Frozen Specialties Not Elsewhere Classified	44	SIC 2068: Salted and Roasted Nuts and Seeds	88
		SIC 2074: Cottonseed Oil Mills	90
		SIC 2075: Soybean Oil Mills	91
		SIC 2076: Vegetable Oil Mills, Except Corn, Cottonseed, and Soybean	92
		SIC 2077: Animal and Marine Fats and Oils	93
		SIC 2079: Shortening, Table Oils, Margarine, and Other Edible Fats and Oils, Not Elsewhere Classified	94
		SIC 2082: Malt Beverages	95

SIC 2083: Malt	100
SIC 2084: Wines, Brandy, and Brandy Spirits	101
SIC 2085: Distilled and Blended Liquors	109
SIC 2086: Bottled and Canned Soft Drinks and Carbonated Waters	115
SIC 2087: Flavoring Extracts and Flavoring Syrups, Not Elsewhere Classified	122
SIC 2091: Canned and Cured Fish and Seafoods	124
SIC 2092: Prepared Fresh or Frozen Fish and Seafoods	127
SIC 2095: Roasted Coffee	130
SIC 2096: Potato Chips, Corn Chips, and Similar Snacks	134
SIC 2097: Manufactured Ice	140
SIC 2098: Macaroni, Spaghetti, Vermicelli, and Noodles	141
SIC 2099: Food Preparations, Not Elsewhere Classified	145

TOBACCO PRODUCTS

SIC 2111: Cigarettes	150
SIC 2121: Cigars	157
SIC 2131: Chewing and Smoking Tobacco and Snuff	158
SIC 2141: Tobacco Stemming and Redrying	159

TEXTILE MILL PRODUCTS

SIC 2211: Broadwoven Fabric Mills, Cotton	163
SIC 2221: Broadwoven Fabric Mills, Manmade Fiber and Silk	166
SIC 2231: Broadwoven Fabric Mills, Wool (Including Dyeing and Finishing)	171
SIC 2241: Narrow Fabric and Other Smallwares Mills: Cotton, Wool, Silk and Manmade Fiber	173
SIC 2251: Women's Full-Length and Knee-Length Hosiery, Except Socks	174
SIC 2252: Hosiery, Not Elsewhere Classified	176
SIC 2253: Knit Outerwear Mills	177
SIC 2254: Knit Underwear and Nightwear Mills	179
SIC 2257: Weft Knit Fabric Mills	180
SIC 2258: Lace and Warp Knit Fabric Mills	181
SIC 2259: Knitting Mills, Not Elsewhere Classified	182
SIC 2261: Finishers of Broadwoven Fabrics of Cotton	183

SIC 2262: Finishers of Broadwoven Fabrics of Manmade Fiber and Silk	186
SIC 2269: Finishers of Textiles, Not Elsewhere Classified	189
SIC 2273: Carpets and Rugs	190
SIC 2281: Yarn Spinning Mills	194
SIC 2282: Yarn Texturizing, Throwing, Twisting, and Winding Mills	196
SIC 2284: Thread Mills	198
SIC 2295: Coated Fabrics, Not Rubberized	199
SIC 2296: Tire Cord and Fabrics	200
SIC 2297: Nonwoven Fabrics	201
SIC 2298: Cordage and Twine	203
SIC 2299: Textile Goods, Not Elsewhere Classified	203

APPAREL & OTHER FINISHED PRODUCTS MADE FROM FABRICS & SIMILAR MATERIALS

SIC 2311: Men's and Boys' Suits, Coats, and Overcoats	205
SIC 2321: Men's and Boys' Shirts	208
SIC 2322: Men's and Boys' Underwear and Nightwear	214
SIC 2323: Men's and Boys' Neckwear	217
SIC 2325: Men's and Boys' Separate Trousers and Slacks	220
SIC 2326: Men's and Boys' Work Clothing	224
SIC 2329: Men's and Boys' Clothing, Not Elsewhere Classified	227
SIC 2331: Women's, Misses', and Juniors' Blouses and Shirts	229
SIC 2335: Women's, Juniors', and Misses' Dresses	233
SIC 2337: Women's, Misses', and Juniors' Suits, Skirts, and Coats	238
SIC 2339: Women's, Misses', and Juniors' Outerwear Not Elsewhere Classified	243
SIC 2341: Women's, Misses', Children's, and Infants' Underwear and Nightwear	244
SIC 2342: Brassieres, Girdles, and Allied Garments	248
SIC 2353: Hats, Caps, and Millinery	252
SIC 2361: Girls', Children's, and Infants' Dresses, Blouses, and Shirts	255
SIC 2369: Girls', Children's, and Infants' Outerwear, Not Elsewhere Classified	258
SIC 2371: Fur Goods	261

SIC 2381: Dress and Work Gloves, Except Knit and All-Leather	262
SIC 2384: Robes and Dressing Gowns	263
SIC 2385: Waterproof Outerwear	264
SIC 2386: Leather and Sheep-Lined Clothing	265
SIC 2387: Apparel Belts	266
SIC 2389: Apparel and Accessories, Not Elsewhere Classified	267
SIC 2391: Curtains and Draperies	269
SIC 2392: Housefurnishings, Except Curtains and Draperies.	270
SIC 2393: Textile Bags	271
SIC 2394: Canvas and Related Products	272
SIC 2395: Pleating, Decorative and Novelty Stitching, and Tucking for the Trade	273
SIC 2396: Automotive Trimmings, Apparel Findings, and Related Products	274
SIC 2397: Schiffli Machine Embroideries	275
SIC 2399: Fabricated Textile Products, Not Elsewhere Classified	276

**LUMBER & WOOD PRODUCTS,
EXCEPT FURNITURE**

SIC 2411: Logging	278
SIC 2421: Sawmills and Planing Mills, General.	283
SIC 2426: Hardwood Dimension and Flooring Mills	286
SIC 2429: Special Product Sawmills, Not Elsewhere Classified	288
SIC 2431: Millwork	289
SIC 2434: Wood Kitchen Cabinets	293
SIC 2435: Hardwood Veneer and Plywood	293
SIC 2436: Softwood Veneer and Plywood	296
SIC 2439: Structural Members, Not Elsewhere Classified	298
SIC 2441: Nailed and Lock Corner Wood Boxes and Shook	300
SIC 2448: Wood Pallets and Skids	301
SIC 2449: Wood Containers, Not Elsewhere Classified	302
SIC 2451: Mobile Homes.	303
SIC 2452: Prefabricated Wood Buildings and Components.	309
SIC 2491: Wood Preserving	313
SIC 2493: Reconstituted Wood Products	314
SIC 2499: Wood Products, Not Elsewhere Classified	315

FURNITURE AND FIXTURES

SIC 2511: Wood Household Furniture	317
SIC 2512: Wood Household Furniture, Upholstered	318
SIC 2514: Metal Household Furniture	319
SIC 2515: Mattresses, Foundations, and Convertible Beds	321
SIC 2517: Wood Television, Radio, Phonograph, and Sewing Machine Cabinets	323
SIC 2519: Household Furniture, Not Elsewhere Classified	324
SIC 2521: Wood Office Furniture	325
SIC 2522: Office Furniture, Except Wood	330
SIC 2531: Public Building and Related Furniture	334
SIC 2541: Wood Office and Store Fixtures, Partitions, Shelving, and Lockers.	337
SIC 2542: Office and Store Fixtures, Partitions, Shelving, and Lockers, Except Wood.	339
SIC 2591: Drapery Hardware and Window Blinds and Shades	341
SIC 2599: Furniture and Fixtures, Not Elsewhere Classified	344

PAPER & ALLIED PRODUCTS

SIC 2611: Pulp Mills	346
SIC 2621: Paper Mills	353
SIC 2631: Paperboard Mills	361
SIC 2652: Setup Paperboard Boxes	366
SIC 2653: Corrugated and Solid Fiber Boxes	367
SIC 2655: Fiber Cans, Tubes, Drums and Similar Products.	370
SIC 2656: Sanitary Food Containers, Except Folding	372
SIC 2657: Folding Paperboard Boxes, Including Sanitary.	373
SIC 2671: Coated and Laminated Packaging Paper and Plastics Film	375
SIC 2672: Coated and Laminated Paper, Not Elsewhere Classified	377
SIC 2673: Plastics, Foil and Coated Paper Bags.	380
SIC 2674: Uncoated Paper and Multiwall Bags.	381
SIC 2675: Die-Cut Paper and Paperboard and Cardboard	385
SIC 2676: Sanitary Paper Products	386

SIC 2677: Envelopes	392
SIC 2678: Stationery, Tablets, and Related Products	395
SIC 2679: Converted Paper and Paperboard Products, Not Elsewhere Classified	396

PRINTING, PUBLISHING & ALLIED INDUSTRIES

SIC 2711: Newspapers: Publishing, or Publishing and Printing	399
SIC 2721: Periodicals: Publishing, or Publishing and Printing	404
SIC 2731: Book Publishing	409
SIC 2732: Book Printing	416
SIC 2741: Miscellaneous Publishing	421
SIC 2752: Commercial Printing, Lithographic	428
SIC 2754: Commercial Printing, Gravure	432
SIC 2759: Commercial Printing, Not Elsewhere Classified	436
SIC 2761: Manifold Business Forms	439
SIC 2771: Greeting Cards	440
SIC 2782: Blankbooks, Looseleaf Binders and Devices	445
SIC 2789: Bookbinding and Related Work	446
SIC 2791: Typesetting	448
SIC 2796: Platemaking and Related Services	450

CHEMICALS & ALLIED PRODUCTS

SIC 2812: Alkalies and Chlorine	453
SIC 2813: Industrial Gases	459
SIC 2816: Inorganic Pigments	462
SIC 2819: Industrial Inorganic Chemicals, Not Elsewhere Classified	465
SIC 2821: Plastic Materials and Resins	472
SIC 2822: Synthetic Rubber (Vulcanizable Elastomers)	477
SIC 2823: Cellulosic Manmade Fibers	484
SIC 2824: Organic Fibers—Noncellulosic	486
SIC 2833: Medicinal Chemicals and Botanical Products	492
SIC 2834: Pharmaceutical Preparations	497
SIC 2835: In Vitro and In Vivo Diagnostic Substances	506
SIC 2836: Biological Products, Except Diagnostic Substances	507

SIC 2841: Soap and Other Detergents, Except Specialty Cleaners	511
SIC 2842: Specialty Cleaning, Polishing, and Sanitation Preparations	518
SIC 2843: Surface Active Agents, Finishing Agents, Sulfonated Oils, and Assistants	521
SIC 2844: Perfumes, Cosmetics, and Other Toilet Preparations	522
SIC 2851: Paints, Varnishes, Lacquers, Enamels, and Allied Products	528
SIC 2861: Gum and Wood Chemicals	536
SIC 2865: Cyclic Organic Crudes and Intermediates and Organic Dyes and Pigments	537
SIC 2869: Industrial Organic Chemicals, Not Elsewhere Classified	542
SIC 2873: Nitrogenous Fertilizers	548
SIC 2874: Phosphatic Fertilizers	549
SIC 2875: Fertilizers, Mixing Only	551
SIC 2879: Pesticides and Agricultural Chemicals, Not Elsewhere Classified	552
SIC 2891: Adhesives and Sealants	556
SIC 2892: Explosives	559
SIC 2893: Printing Ink	560
SIC 2895: Carbon Black	562
SIC 2899: Chemicals and Chemical Preparations, Not Elsewhere Classified	564

PETROLEUM REFINING & RELATED INDUSTRIES

SIC 2911: Petroleum Refining	566
SIC 2951: Asphalt Paving Mixtures and Blocks	573
SIC 2952: Asphalt Felts and Coatings	575
SIC 2992: Lubricating Oils and Greases	576
SIC 2999: Products of Petroleum and Coal, Not Elsewhere Classified	578

RUBBER & MISCELLANEOUS PLASTICS PRODUCTS

SIC 3011: Tires and Inner Tubes	580
SIC 3021: Rubber and Plastics Footwear	586
SIC 3052: Rubber and Plastics Hose and Belting	587
SIC 3053: Gaskets, Packing, and Sealing Devices	591
SIC 3061: Molded, Extruded, and Lathe-Cut Mechanical Rubber Goods	594

SIC 3069: Fabricated Rubber Products, Not Elsewhere Classified	597	SIC 3259: Structural Clay Products, Not Elsewhere Classified	670
SIC 3081: Unsupported Plastics Film and Sheet	600	SIC 3261: Vitreous China Plumbing Fixtures and China and Earthenware Fittings and Bathroom Accessories	671
SIC 3082: Unsupported Plastics Profile Shapes	602	SIC 3262: Vitreous China Table and Kitchen Articles	674
SIC 3083: Laminated Plastics Plate, Sheet, and Profile Shapes	603	SIC 3263: Fine Earthenware (Whiteware) Table and Kitchen Articles	675
SIC 3084: Plastics Pipe	606	SIC 3264: Porcelain Electrical Supplies	676
SIC 3085: Plastics Bottles	608	SIC 3269: Pottery Products, Not Elsewhere Classified	677
SIC 3086: Plastics Foam Products	611	SIC 3271: Concrete Block and Brick	681
SIC 3087: Custom Compounding of Purchased Plastics Resins.	613	SIC 3272: Concrete Products, Except Block and Brick	682
SIC 3088: Plastics Plumbing Fixtures	615	SIC 3273: Ready-Mixed Concrete	684
SIC 3089: Plastics Products, Not Elsewhere Classified	618	SIC 3274: Lime	688
LEATHER & LEATHER PRODUCTS		SIC 3275: Gypsum Products.	689
SIC 3111: Leather Tanning and Finishing.	622	SIC 3281: Cut Stone and Stone Products	691
SIC 3131: Boot and Shoe Cut Stock and Findings	625	SIC 3291: Abrasive Products	693
SIC 3142: House Slippers	626	SIC 3292: Asbestos Products	696
SIC 3143: Men's Footwear, Except Athletic	627	SIC 3295: Minerals and Earths, Ground or Otherwise Treated.	698
SIC 3144: Women's Footwear, Except Athletic.	630	SIC 3296: Mineral Wool	699
SIC 3149: Footwear, Except Rubber, Not Elsewhere Classified	634	SIC 3297: Nonclay Refractories	700
SIC 3151: Leather Gloves and Mittens.	640	SIC 3299: Nonmetallic Mineral Products, Not Elsewhere Classified	701
SIC 3161: Luggage.	641	PRIMARY METALS INDUSTRIES	
SIC 3171: Women's Handbags and Purses	643	SIC 3312: Steel Works, Blast Furnaces (Including Coke Ovens), and Rolling Mills	703
SIC 3172: Personal Leather Goods, Except Women's Handbags and Purses.	646	SIC 3313: Electrometallurgical Products, Except Steel.	711
SIC 3199: Leather Goods, Not Elsewhere Classified	647	SIC 3315: Steel Wiredrawing and Steel Nails and Spikes.	713
STONE, CLAY, GLASS & CONCRETE PRODUCTS		SIC 3316: Cold Finishing of Steel Shapes.	715
SIC 3211: Flat Glass.	649	SIC 3317: Steel Pipe and Tubes	718
SIC 3221: Glass Containers	654	SIC 3321: Gray and Ductile Iron Foundries	719
SIC 3229: Pressed and Blown Glass and Glassware, Not Elsewhere Classified	659	SIC 3322: Malleable Iron Foundries	722
SIC 3231: Glass Products, Made of Purchased Glass	661	SIC 3324: Steel Investment Foundries	725
SIC 3241: Cement, Hydraulic.	663	SIC 3325: Steel Foundries, Not Elsewhere Classified	727
SIC 3251: Brick and Structural Clay Tile	664	SIC 3331: Primary Smelting and Refining of Copper	728
SIC 3253: Ceramic Wall and Floor Tile	666	SIC 3334: Primary Production of Aluminum.	732
SIC 3255: Clay Refractories.	668		

SIC 3339: Primary Smelting and Refining of Nonferrous Metals, Except Copper and Aluminum	739	SIC 3444: Sheet Metal Work	807
SIC 3341: Secondary Smelting and Refining of Nonferrous Metals	740	SIC 3446: Architectural and Ornamental Metal Work	809
SIC 3351: Rolling, Drawing, and Extruding of Copper	746	SIC 3448: Prefabricated Metal Buildings and Components.	810
SIC 3353: Aluminum Sheet, Plate, and Foil	749	SIC 3449: Miscellaneous Structural Metal Work	812
SIC 3354: Aluminum Extruded Products	754	SIC 3451: Screw Machine Products	813
SIC 3355: Aluminum Rolling and Drawing, Not Elsewhere Classified	757	SIC 3452: Bolts, Nuts, Screws, Rivets, and Washers	816
SIC 3356: Rolling, Drawing, and Extruding of Nonferrous Metals, Except Copper and Aluminum	758	SIC 3462: Iron and Steel Forgings.	820
SIC 3357: Drawing and Insulating of Nonferrous Wire.	761	SIC 3463: Nonferrous Forgings.	822
SIC 3363: Aluminum Die-Castings	764	SIC 3465: Automotive Stampings	824
SIC 3364: Nonferrous Die-Castings Except Aluminum	765	SIC 3466: Crowns and Closures	827
SIC 3365: Aluminum Foundries	766	SIC 3469: Metal Stampings, Not Elsewhere Classified	829
SIC 3366: Copper Foundries	769	SIC 3471: Electroplating, Plating, Polishing, Anodizing and Coloring.	830
SIC 3369: Nonferrous Foundries, Except Aluminum and Copper	771	SIC 3479: Coating, Engraving, and Allied Services, Not Elsewhere Classified	833
SIC 3398: Metal Heat Treating	773	SIC 3482: Small Arms Ammunition	836
SIC 3399: Primary Metal Products, Not Elsewhere Classified	774	SIC 3483: Ammunition, Except for Small Arms	841
FABRICATED METAL PRODUCTS, EXCEPT MACHINERY/ TRANSPORTATION EQUIPMENT		SIC 3484: Small Arms	842
SIC 3411: Metal Cans	776	SIC 3489: Ordnance and Accessories, Not Elsewhere Classified	849
SIC 3412: Metal Shipping Barrels, Drums, Kegs, and Pails	779	SIC 3491: Industrial Valves	850
SIC 3421: Cutlery.	780	SIC 3492: Fluid Power Valves and Hose Fittings	852
SIC 3423: Hand and Edge Tools, Except Machine Tools and Handsaws.	784	SIC 3493: Steel Springs, Except Wire	855
SIC 3425: Saw Blades and Handsaws	785	SIC 3494: Valves and Pipe Fittings, Not Elsewhere Classified	856
SIC 3429: Hardware, Not Elsewhere Classified	786	SIC 3495: Wire Springs.	857
SIC 3431: Enameled Iron and Metal Sanitary Ware	787	SIC 3496: Miscellaneous Fabricated Wire Products	861
SIC 3432: Plumbing Fixtures and Fittings.	789	SIC 3497: Metal Foil and Leaf	862
SIC 3433: Heating Equipment, Except Electric and Warm Air Furnaces.	794	SIC 3498: Fabricated Pipe and Pipe Fittings	864
SIC 3441: Fabricated Structural Metal	797	SIC 3499: Fabricated Metal Products, Not Elsewhere Classified	866
SIC 3442: Metal Doors, Sash, Frames, Molding, and Trim	799	INDUSTRIAL & COMMERCIAL MACHINERY & COMPUTER EQUIPMENT	
SIC 3443: Fabricated Plate Work—Boiler Shops.	801	SIC 3511: Steam, Gas, and Hydraulic Turbines, and Turbine Generator Set Units	868

SIC 3519: Internal Combustion Engines, Not Elsewhere Classified	871	SIC 3567: Industrial Process Furnaces and Ovens	954
SIC 3523: Farm Machinery and Equipment.	872	SIC 3568: Mechanical Power Transmission Equipment, Not Elsewhere Classified.	956
SIC 3524: Lawn and Garden Tractors and Home Lawn and Garden Equipment	877	SIC 3569: General Industrial Machinery and Equipment, Not Elsewhere Classified.	957
SIC 3531: Construction Machinery and Equipment.	879	SIC 3571: Electronic Computers	958
SIC 3532: Mining Machinery	881	SIC 3572: Computer Storage Devices	966
SIC 3533: Oil Field Machinery	885	SIC 3575: Computer Terminals.	972
SIC 3534: Elevators and Moving Stairways	889	SIC 3577: Computer Peripheral Equipment, Not Elsewhere Classified	974
SIC 3535: Conveyors and Conveying Equipment.	892	SIC 3578: Calculating and Accounting Machines, Except Electronic Computers	979
SIC 3536: Overhead Traveling Cranes, Hoists, and Monorail Systems	896	SIC 3579: Office Machines, Not Elsewhere Classified	980
SIC 3537: Industrial Trucks, Tractors, Trailers, and Stackers	899	SIC 3581: Automatic Vending Machines	984
SIC 3541: Machine Tools, Metal Cutting Types	904	SIC 3582: Commercial Laundry Equipment	987
SIC 3542: Machine Tools, Metal Forming Types	907	SIC 3585: Refrigeration and Heating Equipment.	988
SIC 3543: Industrial Patterns	909	SIC 3586: Measuring and Dispensing Pumps	996
SIC 3544: Special Dies and Tools, Die Sets, Jigs and Fixtures, and Industrial Molds	910	SIC 3589: Service Industry Machinery, Not Elsewhere Classified	997
SIC 3545: Cutting Tools, Machine Tool Accessories, and Machinist's Precision Measuring Devices	912	SIC 3592: Carburetors, Pistons, Rings, and Valves	998
SIC 3546: Handtools.	915	SIC 3593: Fluid Power Cylinders and Actuators	1000
SIC 3547: Rolling Mill Machinery	918	SIC 3594: Fluid Power Pumps and Motors	1001
SIC 3548: Electric and Gas Welding and Soldering Equipment.	919	SIC 3596: Scales and Balances, Except Laboratory	1003
SIC 3549: Metalworking Machinery, Not Elsewhere Classified	920	SIC 3599: Industrial and Commercial Machinery and Equipment, Not Elsewhere Classified.	1004
SIC 3552: Textile Machinery	921		
SIC 3553: Woodworking Machinery	924	ELECTRONIC & OTHER ELECTRICAL EQUIPMENT & COMPONENTS, EXCEPT COMPUTER EQUIPMENT	
SIC 3554: Paper Industries Machinery	926	SIC 3612: Power, Distribution, and Specialty Transformers	1006
SIC 3555: Printing Trades Machinery and Equipment.	927	SIC 3613: Switchgear and Switchboard Apparatus	1008
SIC 3556: Food Products Machinery	931	SIC 3621: Motors and Generators	1010
SIC 3559: Special Industry Machinery, Not Elsewhere Classified	932	SIC 3624: Carbon and Graphite Products	1016
SIC 3561: Pumps and Pumping Equipment.	937	SIC 3625: Relays and Industrial Controls	1018
SIC 3562: Ball and Roller Bearings.	940	SIC 3629: Electrical Industrial Apparatus, Not Elsewhere Classified	1020
SIC 3563: Air and Gas Compressors	945	SIC 3631: Household Cooking Equipment	1021
SIC 3564: Industrial and Commercial Fans and Blowers and Air Purification Equipment.	949	SIC 3632: Household Refrigerators and Home and Farm Freezers.	1025
SIC 3565: Packaging Machinery	951		
SIC 3566: Speed Changers, Industrial High-Speed Drives, and Gears	953		

SIC 3633: Household Laundry Equipment	1030	SIC 3713: Truck and Bus Bodies	1137
SIC 3634: Electric Housewares and Fans	1034	SIC 3714: Motor Vehicle Parts and Accessories	1144
SIC 3635: Household Vacuum Cleaners	1037	SIC 3715: Truck Trailers	1149

INTRODUCTION

The *Encyclopedia of American Industries (EAI)* is a major business reference tool that provides detailed, comprehensive information on a wide range of industries in every realm of American business. Volume one provides separate coverage of 459 manufacturing industries. Volume two presents 545 essays covering the vast array of service and other non-manufacturing industries in the United States. Combined, these two volumes provide individual essays on every industry recognized by the U.S. Standard Industrial Classification (SIC) system. Both volumes of *EAI* are arranged numerically by SIC code for easy use. Additionally, each entry in the fourth edition includes the corresponding North American Industry Classification System (NAICS) code(s).

CONTENT AND ARRANGEMENT

Industry Essays. The *Encyclopedia's* business coverage includes information on historical events of consequence, as well as relevant trends and statistics entering the twenty-first century. Sections of coverage in an essay may include the following:

- **Industry Snapshot:** Provides an overview of the industry and identifies key trends, issues, and statistics.
- **Organization and Structure:** Discusses the configuration and functional aspects of the industry, including government regulation, sub-industry divisions, and interaction with other industries.
- **Background and Development:** Relates the industry's genesis and historical development, including major technological advances, scandals, pioneering companies, major products, important legislation, and other factors that shaped the industry.
- **Current Conditions:** Provides information on the status of the industry in the late 1990s to early 2000s, with an eye to industry challenges on the horizon.

- **Industry Leaders:** Profiles major companies within the industry and includes discussion of financial performance.
- **Workforce:** Contains information on the size, diversity, and characteristics of the industry's workforce.
- **America and the World:** Discusses the global marketplace for the U.S. industry, as well as international participation in U.S. markets.
- **Research and Technology:** Furnishes information on major technological advances, areas of research, and their potential impact on the industry.
- **Further Reading:** Provides users with suggested further reading on the industry. These sources, many of which were also used to compile the essays, are publicly accessible materials such as magazines, general and academic periodicals, books, annual reports, and government sources, as well as material supplied by industry associations. This edition also includes references to numerous Internet sources. When available, the URL address and updated or visited date of these resources is included, although such addresses are apt to change frequently.

Graphs. The *Encyclopedia of American Industries* includes almost 350 informative, easy-to-read graphs detailing a wide range of key economic and business information. Graphs without source information have been compiled from the research material used to write the essay or from original research.

Conversion Tables. Two industry classification tables allow cross-referencing of SIC categories with the NAICS industry codes. (Please see below for additional information.)

Indexes. The *Encyclopedia of American Industries'* index contains alphabetic references from both volumes to

companies, trade associations, significant business trends, government agencies, historical figures, and key legislation. It also includes cross-references for acronyms and variant names.

ABOUT INDUSTRY CLASSIFICATION

Encyclopedia of American Industries offers tools to analyze industries using two industry classification systems. The primary system, the Standard Industrial Classification (SIC) system, was established by the U.S. government to provide a uniform means for collecting, presenting, and analyzing economic data. SIC codes are still widely used by federal, state, and local government agencies; trade associations; private research organizations; and business professionals to promote comparability in the presentation of statistical data. In addition, *EAI* includes reference tables for the 1997 North American Industry Classification System (NAICS), which has been adopted by the U.S. government as its new standard for economic data. Each essay includes the corresponding NAICS code(s) as well.

1987 Standard Industrial Classification (SIC). Each SIC code classifies business and nonprofit establishments by the types of activities in which they are engaged; in other words, it is “industry-oriented.” An establishment is an economic unit where a service is performed or a product is manufactured or sold (generally at a single physical location). To be recognized as a separate industry within the SIC system, a set of establishments must be statistically significant according to criteria such as the number of persons employed and the volume of business conducted. Each establishment is placed in an SIC category according to its primary activity, which is determined by the industry from which it derives the most revenue. Many large companies, however, operate multiple establishments and may participate in several industries, thus it is possible for a company to be a leading force in SIC categories outside of its primary industry.

The SIC system comprises four levels of classification, as described below:

- Divisions: The broadest SIC categories are divisions that define an activity in very general terms: Agriculture, Forestry, and Fishing; Mining; Construction; Manufacturing; Transportation, Communications, Electric, Gas, and Sanitary Services; Wholesale Trade; Retail Trade; Finance, Insurance, and Real Estate; and Public Administration, for example.
- Major Groups: Within these broad categories are major groups. Each begins with a unique two-digit code that makes up the first two numbers of the complete four-digit SIC code. In the case of Manufacturing, the major group codes range between 20 and 39. Examples of two-digit groups in Manufacturing are:

Food & Kindred Products (20); Tobacco Products (21); Furniture & Fixtures (25); Printing, Publishing, & Allied Industries (27); and Industrial & Commercial Machinery & Computer Equipment (35).

- Industry Groups: Major groups are further subdivided into three-digit industry groups. Each is assigned a three-digit code based on the two-digit code for its major group. For example, Printing, Publishing & Allied Industries is broken down into 271 for Newspapers, 272 for Periodicals, and 273 for Books.
- Industries: Industry Groups are divided still further into specific classifications that are assigned complete, four-digit codes based on the Industry Group. These four-digit classifications are the basis for the industries detailed in *EAI*.

1997 North American Industry Classification System (NAICS). Although NAICS has officially replaced the SIC system, industry information is still maintained in SIC categories for this edition. The *Encyclopedia of American Industries* provides conversion tables to compare SIC data with NAICS data, which the governments of Canada, Mexico, and the United States jointly adopted. It includes broad classifications that are common among the three nations as well as unique national-level classifications. Industries are specified within NAICS by up to six digits, however in some cases the most specific category is only five digits. The conversion tables provided in this book reflect the U.S. version of NAICS, which contains six digits.

NAICS is similar in principle to the SIC system but differs in industry specificity and grouping; NAICS is “production-oriented,” or dependent on the activity of the industry. Also, although the U.S. Census Bureau calls NAICS a hierarchical numbering system, it does not have broad terms broken down into narrower terms, broken down into sub-classifications, then sub-sub-classifications—as with the SIC system.

Unfortunately, total reliance on NAICS data means the loss of historical information for some industries. To help combat this, in 2001 the Census Bureau is slated to release its information in both SIC and NAICS formats.

FOREWORD

EXPANSION SUSTAINED: A MACRO VIEW OF U.S. ECONOMIC ACTIVITY AND INDUSTRY TRENDS

A multitude of events, most perhaps coincidental, converged to produce the thriving U.S. economy of the 1990s and early 2000s. By most measures, the period of expansion has been the longest in U.S. history, as well as one marked by a particularly elusive mix of favorable conditions. Vigorous macroeconomic growth, low price inflation, high labor participation rates, rising personal incomes and wealth, and a sharply rising stock market are only some of the auspicious hallmarks of the vibrant, world-leading economy.

To keep everything in perspective, though, it's useful to consider the unlikely convergence of events that intensified and prolonged the expansion. To take only a few examples, such diverse influences as very inexpensive oil prices (until late 1998); economic troubles in Asia, Russia, and Latin America; and the commercialization of a communications network known as the Internet all worked to the U.S. economic benefit. Cheap oil, for instance, helped keep price inflation down and, in doing so, probably helped forestall the Federal Reserve's raising of interest rates. Meanwhile, currency slumps and economic problems elsewhere in the world helped funnel capital into U.S. markets, fueling price growth in the stock markets and, at least temporarily, providing capital to U.S. businesses. And for its part, the Internet's mainstream emergence triggered a deluge of spending on computer hardware, software, and services extending to nearly every sector of the economy. Had the timing been different, and had there not been such a convergence, the economy might have pattered out years earlier.

But far from pattering out, the U.S. economy barreled forward, breaking records with surprising ease and causing some economists to rethink their theories about sustainable growth. In 1999 the U.S. gross domestic product approached \$9.26 trillion in current dollars, marking a robust 4.2 percent gain after inflation is factored out.

That came on the heels of two previous years of 4-plus percent growth in real terms. All the while, inflation remained largely at bay, and the U.S. unemployment rate hovered at 30-year lows.

Both companies and individuals benefited from the 1990s expansion. Corporate earnings at U.S. firms advanced decisively throughout the decade, with before-tax profits more than doubling between 1990 and 1999. In the meantime, real disposable personal income grew by about 26 percent in total over the period, or by about 15 percent on a per capita basis.

INTERNET AND E-COMMERCE INCREASINGLY PERVERSIVE

Moving on to events that have contributed to economic growth, an obvious question is, what is the impact of the Internet on traditional industries and the economy as a whole? Clearly, any attempt at a comprehensive answer could fill an entire book, and on just one industry at that. With that in mind, there are several broad implications to consider.

Online Marketplaces. Whereas in the mid- and late 1990s most Internet activity was confined to individual companies and trade organizations establishing a presence, since the late 1990s a new crop of sites has been recreating industries and vertical supply chains online. A few examples of these electronic marketplaces:

- The metals industries have multiple sites devoted to trading metals online.
- Three top paper companies in 2000 announced a global online marketplace that allows businesses to buy and sell forest products in a multi-vendor environment and do so seamlessly by integrating their purchasing and logistics systems with the site.

CHANGES ON THE HORIZON

The following industries are expected to experience the greatest change in net output—positive or negative—through 2008

Biggest Gainers	Annual growth
1. Computer and office equipment	14.5%
2. Electronic components	10.9%
3. Computer and data services	10.3%
4. Car rental services	9.3%
5. Communications equipment	8.1%

Biggest Decliners	Annual decline
1. Watch and clock manufacturing	-11.7%
2. Luggage/handbag manufacturing	-2.2%
3. Bowling centers	-2.2%
4. Bookbinding	-1.9%
5. Newspapers	-1.4%

Source: *Monthly Labor Review*, Bureau of Labor Statistics, November 1999

- A large truck-parts manufacturer has launched a site to enable online purchases of parts and trucking-related services from a variety of providers.

These sites and a multitude of others aim to offer a competitive, usually neutral exchange that lets companies and consumers quickly determine a range of prices and options available and complete a transaction on the spot. The emphasis in the future, moreover, will be on providing value-added information and services via the online marketplace beyond simply quoting prices and entering transactions.

The trend toward industry marketplaces online, most pronounced in the lucrative business-to-business e-commerce category, is likely to get much bigger. Forrester Research, a market research firm, predicted that by 2003 the business-to-business online market would be worth \$2.7 trillion—and more than half of those sales would be conducted through online marketplaces. In perhaps a less rigorous survey of business-to-business conference attendees, Forrester found that fully 71 percent of corporate leaders expected their companies to participate in such marketplaces by 2001.

Competitive Impact. Aside from shifting business and consumer transactions to an electronic medium, e-commerce promises to upset the competitive status quo in some industries. One reason is rising cost transparency associated with the Internet. As buyers gain access to fuller information about how much competing products cost and how much components of those products sell for, they'll enjoy a stronger negotiating position with suppliers. This means many suppliers will increasingly com-

pete on price—potentially cutting into profits—and find it necessary to justify their mark-ups if they're not the low-cost producer.

Ultimately, as well, winners and losers will emerge in the e-commerce field. Developing and maintaining sophisticated e-commerce sites requires considerable skill and resources, and for some companies the investment will exceed the revenue potential. This is already apparent in several of the online retail categories, where competition for consumer mind share and market share is intense and even the leaders have had a tough time turning a profit, let alone the lower-tier players. This dynamic is widely expected to result in retail consolidation as the less able competitors are bought out, refocused, or simply go out of business, all this while online sales continue to grow in the aggregate at phenomenal rates. Observers see this weeding out as a necessary stage in the evolution of e-commerce.

ROBUST CAPITAL FLOWS AND INVESTMENT

Investment is a means of generating new growth opportunities by funding promising economic endeavors. By most measures, the U.S. economic investment climate was markedly robust in the 1990s. This includes not only the celebrated gains in the stock markets, which were awash with capital from both domestic and international sources, but also strong advances in corporate fixed investment and research and development (R&D). Expansion in these areas is usually seen as a platform for future economic growth.

Overall, Federal Reserve statistics pinpointed growth in gross private domestic investment at nearly 47 percent between 1995 and 1999. Private investment in equipment and software, a major component of corporate fixed investment, grew in the late 1990s at a torrid 8 to 12 percent a year, two to three times the rate of growth in the broader U.S. economy. Spending on information technology hardware and software contributed heavily to the increase.

Meanwhile, R&D spending trailed somewhat because of cutbacks in federal grants for research. R&D is responsible for, among other things, breakthrough technologies that can greatly impact entire industries and, potentially, the economy as a whole. Spending in this area grew at a more modest average of 6.6 percent annually from 1995 to 1999, according to a report compiled by the National Science Foundation (NSF), yet that rate still outpaced GDP growth. While federal support has diminished since the early 1990s, corporate R&D funding has more than picked up the slack, and now accounts for almost three-quarters of R&D spending in the United States. The NSF estimated total R&D outlays in 1999 at \$247 billion.

Venture Capital. Venture capital has also become a key source of financing for new, innovative companies. The use of venture capital, privately placed equity (and sometimes debt) funding for start-up companies, burgeoned in the 1990s with the influx of new Internet-related companies, and more importantly, the boom in Internet stocks. Venture capital firms take massive stakes in risky albeit promising companies in hopes of cashing out handsomely months or years later when the companies go public. In 1999 venture capital in the United States soared to \$36.5 billion, almost three times the 1998 level and a sixfold increase from 1995.

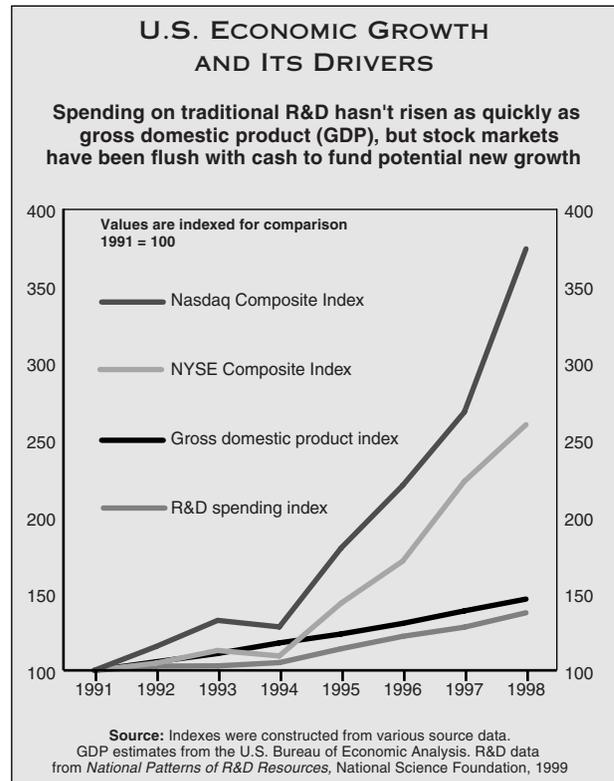

Despite its dramatic rise, venture capital directly impacts only a narrow portion of the economy—primarily Internet and health-care technology concerns. In the late 1990s between 1,000 and 2,000 companies a year, only a fraction all new start-ups, received venture backing. Total funding through venture capital also pales in comparison to other modes of investment, which measure in the hundreds of billions of dollars and even trillions.

Soaring Stocks. The buoyant stock markets represent a different kind of investment—that of capital—and often a more speculative kind. Nonetheless, they have been an increasingly important source of operations funding for start-ups and acquisitive companies. Increasing reliance on market equity has fed into so-called New Economy theories, which hold that, among other things, new technology companies—especially Internet firms—aren't as burdened by higher interest rates as traditional companies because they hold less debt. However, this assertion has been hotly contested and the evidence for it is spotty.

Still, the price growth of technology shares, in particular, has been staggering. From mid-1990 to mid-2000, the NASDAQ Composite Index, a broadly based stock gauge with heavy technology weighting, skyrocketed 600 percent. And that's even after a precipitous decline in early 2000, when the index peaked above the 5,000 mark, but soon tumbled back to the 3,500 range. A handful of computer and Internet firm shares grew by even greater multiples, although there was also no shortage of also-rans that failed to deliver exponential investment growth.

Other leading indexes such as the New York Stock Exchange Composite Index and the Standard & Poor's 500 also recorded sharp gains in the 1990s, although not nearly as big as the NASDAQ's. All told, the NYSE Composite, a broad measure of established, large-capitalization stocks, rose 220 percent from mid-1990 to mid-2000, while the narrower S&P 500, another large-cap metric, climbed 282 percent.

Reasons Behind the Rally. A few trends have contributed to the prolonged stock rally. For one, an ongo-

ing trend toward self-managed 401(k) retirement plans has funneled vast sums of cash into the market, particularly into mutual funds. U.S. assets held in mutual funds more than doubled from \$1.9 trillion in 1995 to more than \$4.5 trillion by the end of 1999, based on statistics published by the Federal Reserve. Estimates by industry groups placed the 1999 value at closer to a whopping \$6 trillion. While either figure includes asset appreciation in the general stock market and other sources, to give an indication of how much new money has been flowing into funds, one estimate valued new inflows into mutual funds at \$165 billion in 1999 alone.

Another event that helped ignite the U.S. stock markets was, oddly enough, economic crisis elsewhere in the world. In the wake of the Asian currency crisis of the late 1990s, when fiscal vagaries in up-and-coming Southeast Asian countries triggered a debilitating withdrawal of international capital from several of the region's emerging markets. Global investors effected a so-called flight to quality by pumping their money into U.S.-based assets. A similar story unfolded in Russia in 1998, when the country's currency collapsed amid foreign investors' jitters over ineffective reforms and political corruption in that beleaguered country.

Back at home, continued low interest rates helped stimulate demand for stocks over bonds and other more rate-sensitive investment vehicles in the United States.

Indeed, the Federal Reserve in 1998 lowered interest rates as a direct result of fears over international economic strife. With safer instruments like bonds and bank certificates of deposit offering underwhelming returns—and some U.S. Treasury securities in shorter supply thanks to the balanced federal budget—many investors chose to test their luck in the stock markets instead. As well, low interest rates tend to keep capital flowing more freely generally in the economy, fueling economic activity in myriad ways.

INTERNATIONAL TRADE PATTERNS

Trade liberalization, the lowering or elimination of tariffs and other trade restrictions, has been the keystone of many free-market advocates' economic and political programs. Momentum toward so-called free trade grew in the 1990s with the conclusion of major multilateral trade agreements such as the General Agreement on Tariffs and Trade (GATT), the North American Free Trade Agreement (NAFTA), and a series of accords that brought about greater integration between the 15 nations of the European Union (EU). While the implementation of these agreements hasn't always lived up to the theory, overall they've been the main policy thrust behind what's known to many as globalization, or the expansion of corporate enterprises and their supply chains across international boundaries.

According to World Trade Organization (WTO) figures, in 1999 countries exported a collective \$5.6 trillion in merchandise (including some double counting from re-exports) and \$1.3 trillion in commercial services. Western Europe, including both EU and non-EU countries, is the world's largest exporting region, supplying about 42 percent of global exports in 1999. Asia and North America followed, with 27 percent and 17 percent, respectively. The regional rank order was the same for imports, although North America occupied a larger share.

U.S. Trade Performance. Despite perennial worries about the trade deficit, the United States remains the world's largest single-nation exporter of merchandise, shipping nearly \$700 billion worth in 1999. It leads the next-largest exporter, Germany, by a comfortable margin, and for the most part, U.S. exports have been growing faster than either Germany's or those of Japan, the third-largest exporter. Top U.S. export sectors in terms of dollar value include aerospace, electronic and mechanical components (especially semiconductors), motor vehicle parts, computer equipment, and telecommunications equipment. Those five industry groups accounted for 20 to 25 percent of all U.S. exports in the late 1990s. Canada, Mexico, and Japan were the largest destination countries, and the EU ranked number two (behind Canada) when treated as a single market.

Meanwhile, the sectors most dependent on foreign-made goods include some of the same: motor vehicles, computer equipment, oil, electronic and mechanical components, and parts and accessories for office equipment. Altogether, the United States imported \$1.059 trillion worth of products in 1999, leaving a yawning merchandise trade gap of \$364 billion. In descending order, the largest suppliers of imports into the United States include Canada, Japan, Mexico, China, and Germany. Thus, the United States maintains trade deficits with most of its biggest trading partners, but it does have country-level surpluses with a number of smaller partners, including the Netherlands, Australia, Belgium, Egypt, Argentina, and Hong Kong.

Trade in services remains a bright spot for observers who lament the merchandise trade deficit, although there are some indications that the services trade has been losing a bit of its luster. In 1999 the United States exported \$252 billion worth of services, including foreign tourism, royalties, and professional services rendered abroad. That compares with \$182 billion in imports. However, the trade surplus in services has been narrowing since its 1997 peak at \$82 billion; it fell to \$74 billion in 1998 and to just below \$70 billion in 1999. Economic softness in parts of Asia and Latin America contributed to the declines. But some economists believe services are an inherently shallow base on which to build an export program, and thus weren't swayed even when the surplus was mounting.

Interpreting the Trade Deficit. The U.S. trade deficit widened significantly throughout the 1990s in the face of a strong U.S. dollar, substantial wealth creation domestically, and economic troubles in some parts of the world. These and other circumstances conspired to create heightened demand for foreign-made goods, and only moderate demand for U.S. goods abroad. The problem isn't that U.S. exports haven't been growing, but that imports have climbed consistently at a faster pace.

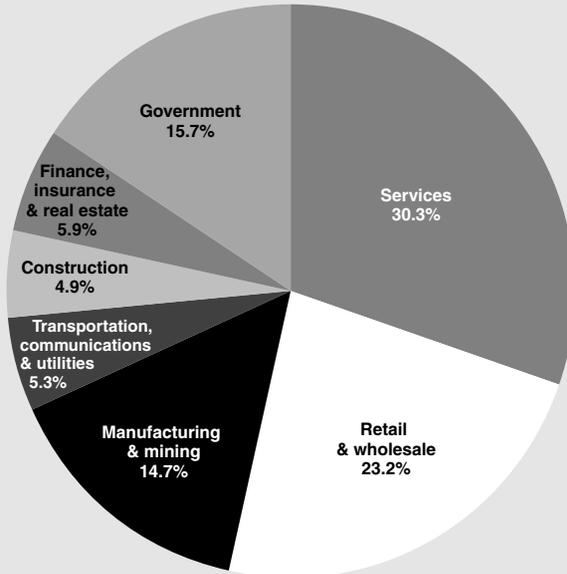

All of this feeds into the continuing debate over whether a massive trade deficit is really a problem when most of the other economic ducks are in a row, so to speak. Mainstream economic theory holds that trade deficits are harmful over the long term because they usually lead to current account deficits for a country, where the current account is an economic concept encompassing the net national income from international transactions. The current account deficit, in turn, demonstrates that foreign entities are getting an increasing share of U.S. dollars and assets.

And here's where the damage might be done: as emerging economies regain their steam after the late-1990s setbacks, foreign holders of U.S. currency could begin to rid themselves of dollars and dollar-denominated assets in favor of assets based elsewhere. The resulting

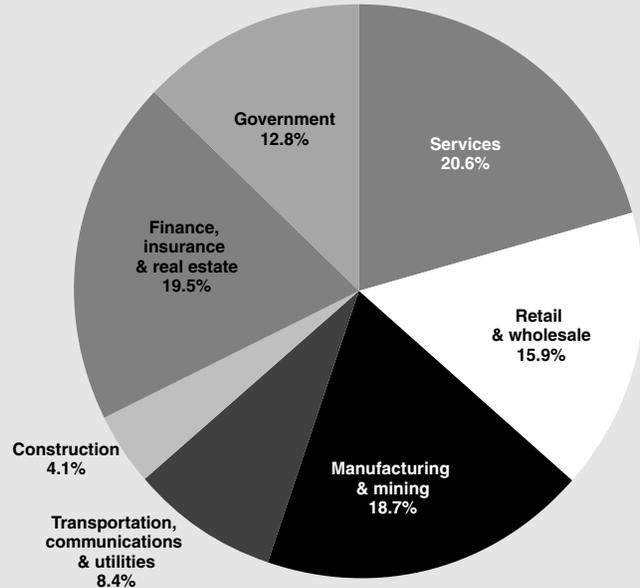

TWO VIEWS OF U.S. INDUSTRY SECTORS

In the nonfarm economy, services and retail prove labor intensive, occupying a bigger share of the work force than what they contribute to gross product. The finance sector gives the best return for the number employed. Not shown is agriculture, which makes up less than 2% of gross product.

By Share of Labor Force (1999)

By Gross Product (1997)

influx of dollars in the foreign exchange markets would likely drive the dollar's value down, particularly if the transition is sudden. A weak dollar would, over time, tend to improve the trade balance by making imports into the United States less attractive on price and exports out of the United States more attractive on price. But correcting the balance that way, according to many economists, would probably be an unpleasant process to say the least. A declining dollar would tend to cause price inflation, and as a result, interest rates would creep upward. Further into the vicious cycle, tighter control on capital flows would tend to slow purchases, and ultimately, economic growth. The dismal outcomes could include rising unemployment, stagnant or bearish financial markets, and in the worst case, recession.

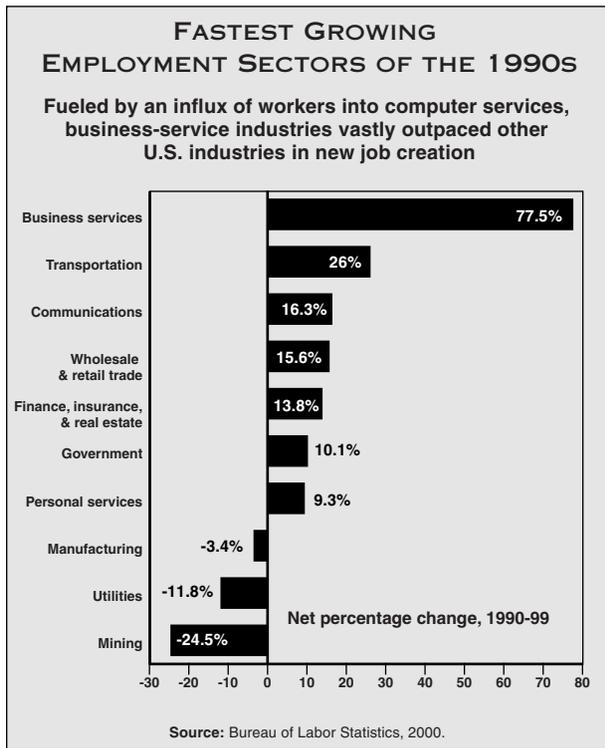

Each step in the pernicious cycle has been observed in recent times. Indeed, the late-1990s Asian financial crisis stemmed in large part from capital flight and currency sell-offs in otherwise economically dynamic countries. However, the question is, at what point is a current account shortfall bad enough to cause such an adverse chain of events? Clearly that threshold is harder to reach with an economy as large and as stable as that of the United States. Even clearer is the plain fact that the United States has been running current account deficits

for the better of two decades, through bad economic times and good.

SECTOR TRENDS

Macroeconomic forces aside, a host of industry- and sector-specific trends add texture to the U.S. economic mosaic. The most important of these trends are already rooted firmly in the economy:

- Widespread investment in information technology and communications infrastructure continues to stimulate brisk demand for products and services in those areas.
- Electronic transactions increasingly alter and supplant physical transactions in sectors as diverse as entertainment, consumer retailing, wholesaling, and banking, to name a few.
- Manufacturers cope with declining profitability on sales of physical products by bundling them with value-adding services.
- Commoditized, low-value-added manufactures and services are being sought more and more from foreign providers with lower overhead costs.
- Seemingly contradictory binges of outsourcing and mergers/acquisitions continue at large corporations as they try to optimize their economies of scope and scale.

All of those patterns are expected to persist for the foreseeable future. A more detailed discussion of specific sectors follows.

Manufacturing. It's well documented that manufacturing industries as a whole are in the midst of a long-term decline as a proportion of the U.S. economy. A few manufacturing industries have suffered real setbacks because of changing technology and market forces, foreign competition, and other factors, but in general the decline is the result of simply a slower rate of growth than other sectors of the economy, notably service industries.

U.S. employment in manufacturing has diminished slightly since the 1980s, and a forecast by the Bureau of Labor Statistics anticipates a very minor further decrease in the early 2000s. Manufacturers of nondurable goods like apparel, food, and chemicals are expected to deliver the weakest performance within the sector, both in terms of employment declines and the value of industry sales.

By contrast, makers of durable goods such as industrial machinery, computers and communications devices, semiconductors and electronic components, and medical goods are predicted to fare better. Some will actually boost their employment levels modestly, and overall they're likely to continue increasing productivity and output at vibrant rates throughout the first decade of the twenty-first century.

Business and Transportation Services. Services of all sorts are expected to occupy a growing share of U.S. eco-

nomical output. Business and transportation services, subsectors of the broader service economy, contain a very diverse mix of industries, but most of them are experiencing robust growth. Business services include the computer and data service industries, which have been enjoying exceptional growth and are expected to continue to do so over the long term. Indeed, the Bureau of Labor Statistics forecast computer services to post the third-fastest growth rate in gross output of all industry groups. Business services also contain such specialties as personnel and recruiting firms and equipment leasing companies. All combined, business services in the 1990s added more new employees to their ranks than any other industry sector, and while the rate is expected to slow, the sector's growth is apt to continue outpacing that of the broader economy well into the 2000s.

Transportation services range from passenger transit to cargo delivery services via air, land, and sea. Growth in these areas hasn't been as swift as in general business services, but they have turned in solid results amid steadily rising demand as the broader economy grows. More of the same is in the offing. Although net employment growth in transportation services will probably be minuscule in the 2000s, consolidation and greater efficiency are expected to keep output rising at a healthy clip. Worth special mention is the car-rental business, which has recorded strong annual gains over the past decade and is projected to continue that trend in coming years.

Communications Services. The communications sector is one of the pillars of the information economy, and indeed, the world economy. The sector's prominence has risen considerably as its infrastructure has grown ever more vital to modern lifestyles and economic activities. Whether it's traditional wireline phone service, wireless communications, high-speed data networks, or entertainment and rich-content electronic media, demand for communications services has swelled in recent years as technological change and deregulation have helped usher in new forms of service at increasingly affordable rates.

The communications industries are undergoing tremendous consolidation, as witnessed by an array of once unthinkable mergers in the late 1990s and early 2000s among local-service carriers, long-distance providers, wireless services, Internet access providers, cable TV system operators, and content providers. Many expect the momentum toward consolidation to continue. As a result, job growth in most communications businesses will be subdued. But industry revenues on the whole will remain on a steady upward track, even as service prices continue to drop.

Retail and Wholesale Trade. With a few exceptions, the retail and wholesale sectors aren't known for dramatic

growth. Rather, they tend to eke out a modest existence by sheer volume of transactions, benefiting from the fact most personal consumption spending is channeled through retail firms. In essence, retailers are logistics and marketing specialists who take a vast, disorganized universe of products and render them accessible and possibly more attractive to potential buyers. Meanwhile, wholesalers work behind the scenes, supplying retailers and other businesses with a preordained assortment of goods.

Thus, because their main function is in aggregating merchandise for sale, retailing and wholesaling face more than most sectors a potentially drastic paradigm shift with the onset of electronic commerce. Some prognosticators have gone so far as to say the customary wholesale business could be eliminated entirely by a combination of e-commerce and powerful chain retailers that can negotiate directly with manufacturers. Retailers, too, must contend with unfavorable economics versus virtual storefronts—the infrastructure of a retail chain is costly and inefficient compared to a high-tech inventory and outsourced logistics system. It's precisely with such a sys-

tem that some electronic challengers hope to wrest market share from traditional retailers.

Still, retailers have several things going for them. In some cases, such as with food purchases, many observers believe that consumers will be reluctant to give up the tactile and visual experiences of shopping in a store, and they'll hesitate to give up the spontaneity of deciding what to buy just minutes before they consume it. Retailers' existing physical infrastructure and market share also provide a powerful platform from which to launch integrated e-commerce/traditional retail ventures. As for conventional wholesalers, they have some infrastructure and market advantages as well, but are probably more vulnerable in the long run.

Whatever the impact of e-commerce, traditional wholesalers and retailers aren't likely to be extinct anytime soon. But their tepid growth rates are expected to slow further in the early 2000s, including both the rate of new job creation and the rate of sales growth. Restaurants, especially, are predicted to lag. Retail and wholesale saw substantial consolidation during the 1990s, and more of the same is anticipated in the 2000s.

AGRICULTURE, FORESTRY, & FISHING

SIC 0111

WHEAT

This industry consists of establishments primarily engaged in the production of wheat or whose sales of wheat account for more than 50 percent of total value of sales for their agricultural production.

NAICS CODE(S)

111140 (Wheat Farming)

INDUSTRY SNAPSHOT

Wheat farms in the United States produced an estimated 2.9 billion bushels of grain in the 2001-02 season, harvesting approximately 53 million acres with an average yield of 42 bushels per acre. Wheat is the third largest crop in the United States in terms of acres harvested, with Kansas, North Dakota, Montana, Washington, and Oklahoma harvesting the most. Season average farm prices (SAFP) for American wheat were projected to be between \$2.75 to \$2.85 per bushel and depended on an enormous range of environmental, political, economic, and technological factors. Although some wheat is used as livestock feed, it is largely used to make flour. The United States is the world's top exporter of wheat. In the early 2000s roughly 50 percent of total harvested crops were accounted for in exports.

Due to the importance of U.S. wheat in international trade and the integral role the U.S. Department of Agriculture (USDA) played in every sector of the agricultural economy, wheat farmers were in many ways more affected by shifts in the political climate than by actual weather conditions.

The U.S. wheat industry was also a world leader in research and development, a point underscored by the unparalleled variety of wheat grown by American farmers. While the Hard Red Winter (HRW) Wheat crop is much larger than other wheat crops (accounting for about 40 percent of the total wheat supply), there were five other commercial classes of U.S. wheat: Hard Red Spring (HRS), Soft Red Winter (SRW), White, Durum, and Red Durum.

Distribution, Production Conditions, and Use. Although wheat is grown in virtually every state, the focal point of the industry is in the central and southern Great Plains Region where Hard Red Winter Wheat is produced. There, in states like Kansas, Oklahoma, Nebraska, Texas, and Colorado, the winters are cold and dry, while the summers are hot. Precipitation, which varies over the region (between 13 and 30 inches annually), can fluctuate drastically, and droughts periodically afflict wide areas for a succession of years. Farms are generally large and employ extensive, as opposed to intensive, methods of crop production. Wheat farmers employ various systems of crop rotation depending on field soil moisture. Most often, farmers alternate a year of wheat with a year of fallow to conserve soil moisture, and HRW wheat is sown in late autumn and harvested in the spring. Wheat production is highly mechanized in the region. A farm worker can typically sow 100 acres or combine-harvest 50 acres in a workday. When milled, HRW wheat produces strong baking and high-quality bread-making flours.

The main region for Hard Red Spring wheat is the northern Great Plains region, where winters are too harsh for HRW wheat production. The soils are deep, rich, black or brown grassland soils. HRS wheat is usually sown in late April and harvested in August. On average, 80 percent of the annual 15 to 25 inches of rainfall comes during this short growing season. A great variety of crops

are used in rotation with wheat, and summer fallowing is becoming rare except in the driest areas. The climatic and soil conditions give HRS wheat a high protein content, strong gluten, and high baking strength. Its flour is excellent for breadmaking and can support weaker flours when combined with them in breads.

The Pacific Northwest is the third significant American wheat-producing region. There, on the Columbia Plateau in the valley of the Columbia River, large areas of rolling farmland are protected by mountains, and the climate is moderated by the Japanese Current. Most of the wheat grown in this region is white-grained, or "White wheat." It is produced in semi-arid zones (10-20 inches of rainfall/year), sown in autumn, and harvested in the spring. Because of the varying altitudes, however, almost all other kinds of wheat (including various wheats falling under the "White" designation) are also cultivated. The region's wheat production, crop rotation, and mechanization methods are similar to those used by farmers in the Great Plains. Because of the different topography of the Columbia Plateau, however, combines are often specially designed with self-leveling mechanisms to operate on hillsides. Most White wheat flour is suited only for pastry and crackers.

The Eastern part of the country produces wheat on a much smaller scale than the rest of the country and also generally produces inferior wheats of a softer texture and lower protein content. The majority of the wheat in this region, including Soft Red Winter in the central and southeastern states and White in New York and Michigan, is grown as part of a complex crop rotation system on farms that specialize in other agricultural products. However, the farming methods used on these smaller farms have often resulted in higher wheat yields than those recorded in the major wheat regions.

ORGANIZATION AND STRUCTURE

Wheat farmers are part of a large and increasingly complex agribusiness commodity system. The multileveled structure of the wheat industry as a whole includes farm suppliers, storage operators, processors, wholesalers, and retailers, as well as government institutions, futures markets, and trade associations. Despite the continuing movement toward expansion and consolidation, however, the wheat farmer is still, by and large, an independent operator. Farmers generally till and harvest their own land and sell goods to the highest bidder at the next level of the wheat system, usually a grain elevator operator or a miller-agent.

Certain support and control structures are necessary to ensure an adequate wheat supply for the consumer market while controlling production levels to secure price levels. With one harvest a year for each class of wheat, combined with year-round consumption, imbalances be-

tween supply and demand are sometimes immense. Moreover, forecasting supplies can be difficult, since such forecasts must rely on weather conditions, which affect both the quality and quantity of wheat from year to year. In addition, technological advances have resulted in higher yields, which makes projections even more indeterminate. Consequently, without price supports, wheat farmers can fall prey to severe price, and thus, income, swings. The economic, social, and political repercussions of such fluctuations demand that the government assume some control of the wheat-growing industry.

Government Programs. The USDA submits a new wheat program every year as an amendment to a larger legislative act (like the Food, Agriculture, Conservation, and Trade Act), under which all agricultural activity is regulated. In these programs, the USDA makes adjustments to various price and income support strategies. First, the wheat program (like any other commodity program) bases support payments on a certain fixed "eligible production," which is defined as a farm's wheat acreage multiplied by its yield (both averaged over five years). Exceeding the set acreage makes a farmer ineligible for payments, while exceeding the yield means that only the excess production is excluded from program benefits. To give wheat farmers some flexibility in planting decisions, there are "flex acreage" provisions that allow farmers to set aside some program acreage to lie fallow or to plant with other crops. Other provisions affecting a farmer's acreage are called Acreage Reduction Programs (ARPs), which are designed to control production, raise market prices, and lower government outlays. The USDA usually requires program participants to idle some percentage of their base acreage, a number that is set annually by the Secretary of Agriculture.

Perhaps the most important annual figures released in wheat programs are the target prices for each class of wheat. For each bushel of eligible production, the wheat farmer is assured of receiving the target price, and he also receives deficiency payments equal to the difference between the target price and either the current market price or the loan rate, whichever is highest. If the target price is \$4 per bushel and farmers can only get \$3.50 for a bushel (either as a loan or as an actual price), then they receive a deficiency payment of \$.50 per bushel. Additionally, loan rates are set by the government and also act as price supports, because they are nonrecourse loans in which the government's right to recovery is limited to the crop used as collateral. If the market price is close to, or below, the loan rate, then the wheat farmer simply defaults on it and transfers title of his crop to the government. Excess units of production, while not eligible for deficiency payments, are included in the loan program; consequently, loan rates are important to consider when making planting decisions.

Although these price and income support provisions directly influence wheat farmers, there are many other programs under existing agricultural legislation that also profoundly affect a farmer's business. Other types of government assistance include wheat stock control mechanisms, credit programs, and crop insurance and disaster payment provisions.

In order to give the farmer some control over the point at which his wheat enters the market, the government established the Farmer-Owned Reserve (FOR). Under the direction of the Secretary of Agriculture, the FOR makes multiyear loans to wheat producers to maintain reserve stocks. Whenever less than 300 million bushels of wheat are maintained in the FOR and the market price is less than 140 percent of the nonrecourse loan rate, participation in the FOR is encouraged through incentives like raising storage payments. By the same token, if participation exceeds 30 percent of the estimated use of wheat, the Secretary of Agriculture closes the reserve. Once the market price exceeds the target price or 140 percent of the loan rate for the year in which the crop is harvested, a farmer enrolled in the FOR no longer receives storage payments and can market his wheat.

The other stock control mechanism is the Commodity Credit Corporation (CCC), which acquires surplus wheat through loan forfeitures and direct purchases; it then releases its stocks only under certain domestic and foreign programs. In early 1999, the USDA's CCC purchased more than 1 million metric tons of HRW wheat. Valued at approximately \$133.5 million at the time, it was the largest purchase of wheat on a single day by the CCC.

Programs that provide either direct credit or credit guarantees are essential to wheat producers. The Farmer Credit System (FCS), not formally a government agency even though it is sponsored by the USDA, provides credit and related services to wheat farmers. However, since 1987, the FCS has operated in conjunction with a new entity, the Federal Agricultural Mortgage Corporation ("Farmer Mac"), which establishes underwriting standards for agricultural mortgages, and, to a degree, covers defaults. Finally, the Farmer's Home Administration (FmHA) is a guarantor of loans made by agricultural lenders and also acts as a lender of last resort for family farmers who are unable to obtain credit under reasonable terms.

A variety of crop insurances are available to farmers to insure some portion of their established yields, with premiums subsidized by the government. Historically, farmers have not purchased insurance, which cannot cover all of their losses. Disaster payment legislation has, thus, regularly been passed to cover major droughts or flooding.

The last two major areas of government intervention in the wheat-growing industry—trade and environmental conservation—serve to illustrate the larger context in which the industry operates. Primarily as a way of protecting American farmland from erosion (but also to control soil salinity and off-farm environmental threats), the USDA solicits bids from year to year for enrollment in its Conservation Reserve Program (CRP). If a farmer's bid is accepted, the farmer enters into a 10-to-15-year contract with the government, under which he/she agrees not to plant on a certain acreage without the Secretary of Agriculture's approval; in return, the farmer receives an annual payment.

Associations and Commissions. The government plays a significant role in the wheat-growing industry largely because farmers asked for assistance, and there are several organizations through which farmers can voice their concerns. The National Wheat Council (NWC) was formed in 1965 to coordinate the activities and interests of the wheat complex as a whole. The National Association of Wheat Growers (NAWG) was organized 15 years prior to the NWC as a nonprofit organization designed to promote the specific interests of wheat farmers. It acts primarily as a lobbying organization, focusing on legislative matters. The group also funds research on improving the quality and yields of American wheat and works in coordination with other wheat industry associations in market promotion. In addition to this national institution, there are many wheat associations and commissions at the state level as well. State associations are involved in state policy, while commissions are nonpolitical bodies that are supported by a fee automatically charged against each bushel of wheat sold in a state—the county elevator operator usually acts as a collection agency. Commissions also administer research, education, and promotion programs. Because of the success of wheat-price support programs, the National Farmers Organization (NFO)—which is a prominent bargainer for other commodities—has not become a major player in the wheat-growing industry.

Farmer Cooperatives. Although the majority of farms are nonintegrated, and the need for farmer cooperatives has diminished with the steady support of the government, such joint venture groups still make up a substantial portion of American wheat farming. In this type of common-ownership organization, farmer members pool their crops and store them in their own cooperative-owned elevators. Farmer-cooperative commission agents then sell the wheat, in many cases, to farmer-cooperative terminal elevators. The attempts by farmer cooperatives' to control the marketing and processing channels have also brought about a few farmer-cooperative exporters and flour millers.

BACKGROUND AND DEVELOPMENT

Wheat was introduced to North America by explorers, traders, settlers, and soldiers in the sixteenth and

seventeenth centuries. Spanish wheats were cultivated in the southeast, and British and French wheats were produced in the northeast. The first permanent American wheat cultures were developed at the Jamestown colony in Virginia and at Plymouth, Massachusetts, in the early 1600s. New York was the largest wheat-producing state until the late nineteenth century. The center of the wheat industry shifted to new territories as progress was made in railway construction and farming mechanization. In the midwestern wheat belt, the wheat economy developed into its present form, with railroad and commissions agents and, eventually, farmer cooperatives, overseeing it from production to consumption.

In the first part of the twentieth century the technological revolution affected every phase of wheat operations, and economies of scale and specialization strategies began to develop. Together with increases in domestic and foreign demand, the industry developed rapidly. It was not until after World War II, however, that the government began to intervene and established itself as an important “market” for wheat.

The American wheat-farming industry has followed the general agricultural movement of consolidation and reduction. In recent decades, both the number and size of U.S. wheat farms has been decreasing. Most importantly, the proportion of tenant operators has been increasing, and that of owner-operators has been decreasing. Still, even with yields rising almost annually, production leveled off, and supplies have generally been down.

There has been a trend toward less government involvement in the agricultural sector as a whole, and wheat farmers generally viewed this optimistically. The year 1996 ushered in a new era of market-dependent farming after Congress passed the “Freedom to Farm” bill, which curtailed government involvement by gradually reducing farm subsidies over a seven-year period set to end in 2002. This bill allowed farmers to sow as many acres as the market dictated, without having to rely on government planting stipulations. Still, the government planned to maintain some control to avoid surplus or shortage crises. Wheat growers were encouraged by the increasing domestic demand for wheat since 1970. In 1993, the per capita level of consumption increased to its record high of 143 pounds. Furthermore, 1995-96 period brought the industry some of its highest prices ever, averaging \$4.55 per bushel from almost 70 million acres with a yield of 35.9 bushels per acre.

High wheat production in the United States and globally since 1995, along with a weak demand, drove down prices in the late 1990s. As a result of the high yields in 1998, wheat prices failed to break \$3.00 per bushel for the first time since 1990. At this time U.S. wheat supplies were at their highest level since 1987. In the fall of 1998, the USDA announced wheat donation

programs to needy countries in an effort to curb the excess stock.

The estimated cash value of wheat supplies in 1998 was \$6.9 billion, down from \$8.6 billion in 1997. The lower value of wheat was primarily due to the Federal Agriculture Improvement and Reform Act of 1996 (commonly called the Farm Bill). Since the bill allowed greater flexibility for farmers to respond to market price and demand changes, the USDA estimated that farmers planted the lowest wheat acreage in more than 10 years in 1998. Wheat farmers’ stocks from previous crops were high, thus demanding a lower planting. Despite a lower value, wheat was still the third largest cash crop in the United States during the late 1990s.

Lower acreage and yields were projected by the USDA to reduce the U.S. wheat output in 1999 to the lowest level since 1973. Producers were encouraged to switch to other crops or leave more land fallow, due to lower returns on their crops. Globally, wheat production was expected to be down, as major wheat exporters’ supplies were large.

CURRENT CONDITIONS

Amid slack demand, U.S. supplies of wheat were dropping in the early 2000s. According to USDA projections, production levels fell from approximately 2.2 billion bushels in the 2000-01 season to 2.0 billion bushels in 2001-02 season. Over the same time period total wheat supplies (which include stocks of wheat already on-hand and imports) fell from 3.4 billion bushels to 2.9 billion bushels, respectively. Bad weather reduced overall wheat yields in 2001-02 period. After record yields in the 1998-99 season (43.2 bushels per acre), yields decreased to 42.0 bushels from 1999 to 2000, and 40.2 from 2001 to 2002. As supply levels decreased, the season-average farm price for wheat was projected to rise from \$2.62 per bushel in the 2000-01 season to between \$2.75 and \$2.85 in the 2001-02 season.

USDA projections reveal that the majority of U.S. wheat consumption occurred in the category of domestic use (1.3 billion bushels). The second largest category was food, accounting for some 945 million bushels. Feed and residual uses ranked third, at 225 million bushels.

A major agricultural industry development took place when the Farm Security and Rural Investment Act of 2002 was signed into effect. Also known as the 2002 Farm Bill, this legislation gave wheat farmers access to marketing loans, as well as both direct and counter-cyclical payments, according to the USDA. Signed on May 13, 2002, this legislation is effective for a period of six years. It replaces 1996 legislation that intended to decrease farmers’ dependence on government assistance.

Consumers' Research Magazine criticized the 2002 legislation for its potential negative impact on international trade, explaining that "The new United States farm bill not only will be bad for taxpayers and consumers, but also will seriously undermine the United States' position in future trade negotiations. Despite the United States' commitment to reduce agricultural subsidies during the last multilateral trade round, the new farm bill will increase support for the agricultural sector by about 80 percent over the last farm bill, amounting to an additional \$82 billion over the next 10 years."

WORKFORCE

A noteworthy development in the American wheat-farm workforce was the growing numbers of tenant operators, farmers who cultivated their wheat on rented land. Approximately 15 percent of all wheat was produced through tenancies, while only 35 percent was produced by full ownership farmers. Another significant development is the aging of the wheat-industry's workforce. The largest numbers of wheat producers are between the ages of 55 and 64. Moreover, while the number of farmers over age 64 is increasing, the number under 35 is decreasing. As the industry has grown more and more mechanized, young people in wheat-farming communities have had to find other types of employment.

AMERICA AND THE WORLD

U.S. wheat growers produce much more wheat than the domestic market can consume; consequently, they market their wheat aggressively to other countries in order to sustain themselves. Although the United States is still the number one exporter of wheat, its market share has been reduced dramatically since the 1970s. Both China and the former Soviet Union, for example, were expected to reduce their purchases of U.S. wheat by between 25 percent and 40 percent in the 1990s. This development has forced the United States to seek out other major markets.

In 2001 and 2002, Nigeria and the European Union were importing higher levels of wheat from the United States, according to the USDA. However, at that time the nation's leading international markets included Mexico, Egypt, Japan, and the Philippines. In that same period, the USDA projected that exports of U.S. wheat would reach their lowest levels since the mid-1980s, falling about 8 percent from the previous year. This decline was attributed in part to competition from other nations, including Syria, the former Soviet Union, Australia, and Eastern Europe. Decreased domestic output also factored into this situation.

Two major developments in U.S. wheat exportation occurred at the end of the twentieth century. In late 1998, Brazil agreed to re-open its market to U.S. wheat. Closed

to U.S. wheat importation since 1996, Brazil lifted the embargo after a series of negotiations with the USDA. In mid-1999, President Clinton lifted U.S. sanctions on food and medicine for Libya, Sudan, and Iran. As a result, Libya bought 16,000 tons of wheat in late 1999.

Trade Expanding Provisions. An important program geared toward international trade in wheat was the Export Enhancement Program (EEP), under which the government offered subsidies to domestic exporters. Although these subsidies were available (under certain guidelines) to exporters of any commodity, they have been used primarily to counteract European Community (EC) competition in wheat and wheat flour. The United States also offered loan guarantees to foreign purchasers of U.S. wheat and under Public Law 480 (or the 1954 Food for Peace Program) provided some surplus wheat to low- and middle-income countries through subsidized sales or as donations. In return, the revenue the country generated went toward specific developmental projects. Public Law 480 funds were also regularly used to support wheat farmers' associations and commissions. There was a smaller Food for Progress program (Section 416 of the Agricultural Act of 1949) geared toward the implementation of market-oriented agricultural reform in less wealthy countries as well. These programs were all under constant scrutiny of American wheat farmers to ensure that they continued to generate business for them.

RESEARCH AND TECHNOLOGY

Land grant universities like Texas A&M and Kansas State University perform a great deal of research that has been very successful in developing stronger strains of wheat and more effective chemical fertilizers. Yields are expected to continue to rise as a result of this work. Increasingly, however, concerns for the environment are pushing researchers away from sheer yield growth projects. Instead, researchers have been working to develop ways to maintain farmers' profitable yields while lessening their dependence on chemicals. In addition, droughts and sun-scorched farms have led to international nonprofit research efforts for enhancing the productivity, profitability, and sustainability of wheat and corn and for developing a wheat hybrid that is more heat resistant. Theoretically, such a wheat hybrid would alleviate some of the capriciousness involved in growing wheat.

sent some 90 percent of rice production and consumption, while the United States produces less than 2 percent of total output.

BACKGROUND AND DEVELOPMENT

Although rice is not considered a major American crop, the American rice industry is more than 300 years old. Rice was introduced in America around 1685, when a British sea captain, John Thurber, brought a load of the grain to the colonies from Madagascar. Rice first appeared as a commercial crop in the Carolinas in the seventeenth century. After peaking in the mid-nineteenth century, rice production in South Carolina and Georgia began to decline as a result of the Civil War, bad weather, and increasing competition from Louisiana. The industry began to shift toward plantations along the Mississippi River where steam-powered river pumps provided a more efficient irrigation system than the Carolina tidal gates. Soon thereafter, the industry developed in the milling and shipping center of New Orleans and grew rapidly and independently amid the explosive transformations of the American industrial economy in the early twentieth century.

Depending largely on government acreage allotment, conservation, marketing, and loan and deficiency payment programs, which adjust incentives annually to control production, between 2.5 and 3.5 million acres of U.S. farmland have been used for rice cultivation annually. Most of this land was in the Mississippi River Delta in Louisiana, Arkansas, Mississippi, and Missouri. Texas and California provided the two other major rice-farming centers, with Florida adding marginally to the total.

Because of its capital intensive nature and its extensive use of irrigation and canal systems, the rice industry naturally aligned itself to the technological progress of the industrial revolution and modernized much faster than the cotton and sugar industries. In addition, the industry’s development of a coordinated network among its various milling interests, distributors, and broker/agents, was a useful organizational model for other southern agricultural industries. The modern rice industry has concentrated far more on distribution and marketing channels than on production.

With a growing year spanning from August to July, modern rice production has been aided by the use of land plans that till and level the soil, creating fields that slope slightly for uniform flooding and controlled draining. Rice farmers also have relied on lasers to determine where to place water control levees. Sowing has been facilitated by the use of seed drills and airplanes in the early spring. During the growing season, rice must be kept constantly in a water depth of two to three inches. Rice producers also apply fertilizer from airplanes to yield consistent and healthy crops. After the rice matures,

NAICS CODE(S)

111160 (Rice Farming)

INDUSTRY SNAPSHOT

Rice farms in the United States grew to almost 9,300 in the 1990s. With more than three million acres harvested annually, rice production remains stable. However, prices were falling during the early 2000s in the wake of record crop production and supply levels. For the 2002-03 season an estimated 3.2 million acres of rice were planted in the United States, yielding a projected record 6,611 pounds per acre. Rice production is measured by the hundredweight (cwt). One cwt equals 100 pounds. Production in the 2002-03 season was projected to reach 212 million cwt. Based on a projected season-average farm price (SAFP) of \$3.70-\$4.00 per cwt, the value of rice production was expected to reach at least \$784 million. The United States is a relatively small player in the world market for rice. According to the U.S. Department of Agriculture (USDA), Asian nations repre-

the fields are drained. At harvest time, farmers use combines to cut rice, separate the grain from the stalk, and convey the grain into trucks. The trucks then transport the grain to dryers where warm air removes moisture until the product is ready for shipment to rice mills.

Domestic consumption of rice subsumes three primary uses: direct food use, processed food use, and beer production use. Direct food use has constituted the largest segment of rice consumption at 58 percent of overall use. Growing over the years, processed food use has accounted for 25 percent of total domestic rice consumption. In this market, use in cereal has long been the highest, making up 44 percent of the processed food division. Other noteworthy processed foods containing rice include candy bars, soups, and crackers. Finally, beer production constitutes 17 percent of total domestic consumption.

In the mid- to late 1990s, U.S. rice production accounted for approximately two percent of the world total with annual sales consistently over \$1 billion. The United States has ranked tenth as a producer of rice and second, behind Thailand, as an exporter of rice, averaging around 20 percent of the annual world export market share for many years, until India's emergence as a major rice exporter in 1995. After India's foray into the export market, the United States became the third leading exporter. With a small but expanding domestic consumption base, the industry has, from its inception, relied heavily on foreign markets in selling its high quality rice varieties. During the 1980s, Latin America became the largest customer for American rice; however, lower prices and proximity began to favor Thailand and other exporting countries in the competitive European, North African, and Asian markets. As Americans became increasingly health conscious in the 1980s, domestic consumption of rice began to rise. Use of rice in processed foods such as cereals and candy also contributed to the increased consumption of rice. Breweries have also used rice consistently as a cereal adjunct for making beer. By 1991, domestic use had actually overtaken exports as a proportion of total annual rice production. In 1995, domestic per capita rice consumption climbed to its all time high: nearly 25 pounds per capita—up almost 10 pounds from its 1985 level. With stiff competition worldwide from less expensive rices, American rice producers have begun concentrating increasingly on national demand as domestic prices often exceed international prices, forcing competitors to characterize the United States as a residual rice exporter.

As rice related legislation became increasingly crucial, the USA Rice Federation formed in 1994 to represent the industry and to lead policy making, research, education, and efficiency initiatives and endeavors to benefit all segments of the industry. In 1996 President

Clinton signed the long-anticipated landmark Federal Agriculture Improvement and Reform Act, the so-called "freedom to farm" bill, which called for the incremental reduction of farm subsidies over a seven-year period, after which government income support would cease altogether. Before, the government had issued subsidies to producers who agreed not to plant an overabundance of rice and other grains. With this piece of legislation, the government paid subsidies to farmers whether or not they planted anything for the seven-year transition period.

Rice producers confronted the intended transition from government income support to becoming independent by devoting increased attention and effort to advancing rice production technology and efficiency, i.e., to developing methods for yielding larger crops with less effort, using less acreage. These moves, rice producers hoped, would stabilize the volatility of the coming farming age and counteract losses incurred from the loss and diminution of farm subsidies.

During the late 1990s, rice production efficiency continued to increase. The 1998 growing year, although not as productive as 1997, yielded almost 5,900 pounds per acre. With surplus supplies of rice and low domestic prices, U.S. rice exports increased to 85.2 million hundredweight (cwt) in 1998.

CURRENT CONDITIONS

The trend of market dependence that began in the early 1990s shifted directions in the early 2000s with the passage of the Farm Security and Rural Investment Act of 2002. Prior to this legislation, government assistance to rice farmers had gradually decreased in an effort to wean rice farmers from government subsidies and safety nets and to make them more market dependent. However, the 2002 legislation delayed many of the reforms associated with the "freedom to farm" bill and greatly expanded the level of government support to farmers.

Consumers' Research Magazine criticized the new legislation for its potential negative impact on international trade, explaining that "The new United States farm bill not only will be bad for taxpayers and consumers, but also will seriously undermine the United States' position in future trade negotiations. Despite the United States' commitment to reduce agricultural subsidies during the last multilateral trade round, the new farm bill will increase support for the agricultural sector by about 80 percent over the last farm bill, amounting to an additional \$82 billion over the next 10 years."

According to the USDA, 3.04 million acres of rice were harvested in the 2000-01 season, with a yield of 6,281 pounds per acre. In comparison, 3.26 acres were harvested in the 1998-99 season, yielding 5,663 pounds per acre. For the 2002-03 season an estimated 3.2 million acres of rice were planted in the United States, yielding a

projected record 6,611 pounds per acre. That season, projected rice exports also reached record levels, at 100 million cwt. This gain represented an annual increase of 6 percent.

CORN

This entry includes establishments primarily engaged in the production of field corn for grain or seed. Establishments primarily engaged in the production of sweet corn are classified under **SIC 0161: Vegetables and Melons**, and those producing popcorn are classified under **SIC 0119: Cash Crops Not Elsewhere Classified**.

NAICS CODE(S)

111150 (Corn Farming)

INDUSTRY SNAPSHOT

The United States is the world's leading producer and exporter of corn, growing about 40 percent of the global supply. Argentina, the next largest exporter, is a distant second. Although corn is grown in all 50 states, more than 80 percent of it comes from the section of the Midwest known as the Corn Belt, which consists of parts of Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri, Nebraska, Ohio, South Dakota, and Wisconsin. The leading corn-producing states are Iowa, Illinois, and Nebraska. In 2001 the U.S. corn crop was estimated at 9.5 billion bushels.

Throughout the 1990s corn was the number one U.S. crop in terms of acreage, with more than 70 million acres

devoted to it. Throughout the decade, planted acreage of corn accounted for approximately 24.0 percent of all major field crops, the highest in the United States. By 2001 this percentage remained relatively unchanged. At that time, corn represented almost 25 percent of all crops harvested in the United States, accounting for some 75 million acres. Corn has been the leading U.S. feed grain. Bushel usage rose steadily during the late 1990s and leveled off in 2000 and 2001 near 6.0 million bushels. Corn was a major source of livestock feed in the 1990s and early 2000s, with approximately 50 percent of the annual harvest being fed to chickens, hogs, and cattle.

By the early 2000s corn had a large variety of industrial and food applications. Although sweet corn was classified elsewhere (as a vegetable rather than a grain), field corn was an ingredient in many processed foods including breakfast cereals, salad dressings, margarine, syrup, soft drinks, and snack items. Corn had also been adapted for use in the manufacturing of ceramics, construction materials, disposable diapers, paper goods, textiles, and health and medical products such as penicillin, antibiotics, and vitamins. It had also been converted into fuel (ethanol) and biodegradable plastic.

ORGANIZATION AND STRUCTURE

Harvesting. In terms of harvesting, corn is the largest U.S. crop. Corn is planted in the spring and harvested in the summer and fall. The marketing season for the crop runs from September 1 to August 31.

Most corn is harvested with a combine, which picks the corn from the stalk, removes the husks, and shells and cleans the corn. The shelled corn is dried for storage. Corn can also be harvested with a machine that picks the corn and strips the husk but leaves the kernels on the ear. The ears are then stored in bins that allowed the corn to dry.

Harvesting of corn for grain begins when the moisture content is about 28 percent, and harvesting for silage corn begins when the moisture is about 50 percent. A forage harvester chops the corn stalks close to ground level and grinds it into small pieces. The silage is blown into a wagon following behind and is then stored in a silo where fermentation preserves it.

Federal Price Supports. Government price supports for corn began with the Agricultural Adjustment Act of 1933. The legislation granted federal payments to farmers who reduced production of surplus crops. In 1938 Congress enacted a law to set up nonrecourse loans that gave farmers money for their crop so they could hold onto it and sell it when prices went up. The loans also guaranteed the farmers a minimum price for their corn. If the farmers could not sell their crop at a higher price than the government had lent them against the crop, they could

simply forfeit the crop to the government. However, the 1996 “Freedom to Farm” legislation promised to end this method of agricultural support. The law called for the gradual reduction of loans over a seven-year period, ending with the termination of government subsidies altogether after 2002. This move, the government hoped, would make farmers more dependent on the market and less on the government. However, in 2002 the federal government enacted new legislation—the Farm Security and Rural Investment Act of 2002—that ensured support to farmers for another six years.

Acreage Reduction Programs (ARP) paid farmers to set aside an amount of land on which they would not grow corn; the amount of land set aside depended upon the corn reserves already available. However, the optimal amount of set-aside land depended upon one’s perspective. For example, the agriculture secretary announced a five percent set-aside for 1992, ordering all farmers who received government corn subsidies to set aside five percent of their corn acreage. Farmers wanted to see higher set-asides to limit production and keep prices up. Grain companies, however, wanted to see no land set aside in order to increase production and lower prices to make corn more competitive on the world market.

A government program for conservation reserves paid farmers not to plant corn or other crops on highly erodible cropland for ten years. They instead were required to plant grass or another ground cover and could not use that land for hay or grazing their livestock. According to James Bovard, a policy analyst and author of *The Farm Fiasco*, the conservation program was idling land that was equivalent to the entire state of Ohio and would cost the United States more than \$20 billion by the time it expired in 1999. Bovard claimed that this program paid three times the going price for renting land.

Corn and other feed-grain supports raised costs for livestock producers, and those expenses were passed on to consumers. However, farmers and others who supported the government agricultural programs claimed that U.S. consumers had stable food supplies and prices because of the programs.

Critics contended that these programs, which were initially adopted in 1933 to confront an emergency situation, had become a burden to U.S. consumers and taxpayers and were hurting the United States in world trade. While U.S. farmers were being paid not to plant, thus reducing the amount of grain available for export, farmers in some nations were planting as much as they could to take over world markets, the critics said. Among the critics were grain dealers who urged that the United States and other countries end price supports and exercise free trade policies instead.

BACKGROUND AND DEVELOPMENT

Corn has figured prominently in the history of people in America. Native Americans cultivated it long before the Europeans arrived. Corn became a staple in the diet of the Europeans, and each wave of settlers moving farther and farther west across the continent carried corn to plant.

In 1837 John Deere introduced a steel plow, which made turning the heavy midwestern soil easier because soil did not stick to it as it did to wood or cast-iron plows. Mechanical corn planters were also developed during the 1800s, and mechanical corn pickers became common in the 1930s and 1940s.

During the 1920s corn pushed wheat aside as the country’s main grain crop. This change reflected in part the changing eating habits of Americans, who began eating more poultry, red meat, and dairy—and less bread and other wheat products. Poultry, cattle, and dairy livestock thrived on corn, which was cheap and abundant.

Since 1920 the total number of farms has declined from 6.5 million to fewer than 2.2 million. During that same time, the average farm size has grown from less than 150 acres to 450 acres. Much of this consolidation was due to technology, as improvements in seeds, fertilizer, and machinery allowed fewer people to farm more acreage.

During the 1970s easy credit prompted many farmers to purchase expensive machinery and more land. The value of farmland tripled and, in some cases, quadrupled. In the early 1980s, however, the value of farmland in the Corn Belt dropped 52 percent, according to Hugh Ulrich in *Losing Ground*. Interest rates shot up and grain exports dropped, resulting in low prices and a surplus of grains. Farmers were unable to repay their loans; in order to maintain their income, they bought and planted more acreage and went deeper into debt. Droughts in 1986 and 1988 decreased production, and farmers needed federal aid. The mid-1980s saw thousands of family-owned farms fail. However, in the 1990s corn became a precious commodity domestically and internationally with its multifarious food and industrial applications.

The North American Free Trade Agreement (NAFTA) of 1993 has brought the U.S. corn industry increased access to the Mexican market. Corn exports to Mexico have risen, because the trade accord has reduced support for Mexican corn growers, forcing the country to rely on imported corn. In its first year of implementation, Mexico imported 2.5 million metric tons (98.5 bushels) of corn. Another emerging key importer of U.S. corn was the Pacific Rim in Asia.

During the 1990s, environmental concerns came to the forefront of the industry. For starters, increased crop yields were taking a toll on the nation’s water supplies. Pesticides and fertilizers contaminated ground water in

major agricultural areas and invaded the drinking water of people who depended on wells for their water. The nation's fertile topsoil continued to erode and, as farms expanded, erosion became more of a problem because larger fields were more vulnerable to topsoil erosion. Use of heavier equipment also contributed to the problem. As the United States and other nations began to deal with environmental issues more intensely, erosion and pollution caused by farming received more attention, especially from farmers growing corn.

By the 1990s, the development of better hybrids and improved production methods, farmers could grow more grain even though they were planting less acreage. In 1932 almost 2.9 billion bushels of corn were grown on almost 110.5 million acres, resulting in an average production of about 28.4 bushels per acre. Twenty years later, three billion bushels were grown on only 81.8 million acres, for an average of 37.6 bushels per acre. Although weather, soil, disease, and pests played a big part in the size of the crop each year, production and production efficiency continued to increase, culminating in a record 1994 harvest of 10 billion bushels, with a yield of 138.6 bushels per acre. After hovering around 72.6 million harvested acres in 1996, 1997, and 1998, acreage fell slightly to 70.5 million in 1999 and then rose to 72.4 million in 2000. However, overall average yields increased over the same time period, climbing from 127.1 bushels per acre in 1996 to 136.9 bushels per acre in 2000.

CURRENT CONDITIONS

Consistent with past trends, in the early 2000s farmers continued to benefit from better hybrids and improved production methods, resulting in better yields on less acreage. In 2001, although average harvested acres were at their lowest levels since 1995 (68.8 million), average yield reached a near-record level of 138.2 bushels per acre.

As of the early 2000s, a large portion of the corn grown in the United States was still used by the farmers who grew it or by their neighbors. About 60 percent of the crop was consumed by livestock on the farm on which the corn was grown or by animals on nearby farms.

Corn that went on the market for export, industrial use, or trade passed through the hands of agribusinesses, such as Cargill Inc. or ContiGroup Companies Inc. (CGC). These privately-held grain trading companies bought corn, stored it in their huge grain elevators, processed it into cornstarch or corn syrup, or sold the corn and milled corn products in the United States and around the world.

The rest of the crop was exported or sold for processing to other companies. Wet millers prepared the crop for use, with starch being the leading product. Corn oil is produced by pressing the germs of the corn and is used in

making margarine, mayonnaise, and other foods. Further processing turns cornstarch into corn syrup or high fructose corn syrup. High fructose corn syrup has emerged as the leading sweetener in the United States, with more consumed per capita than cane sugar and beet sugar combined. It is produced by converting some of the glucose in cornstarch into fructose and is now used in place of other sugars in soft drinks and processed foods. It became popular with food and beverage processors because it was cheaper than cane and beet sugar, which were supported by federal price levels and quotas on foreign sugar. By the late 1990s industrial demand for corn as high fructose corn syrup began to increase, and in 2001 a record 548 million bushels were used for its production.

Legislation. One important development in the agricultural industry during the early 2000s was the Farm Security and Rural Investment Act of 2002, also known as the 2002 Farm Act. According to the U.S. Department of Agriculture (USDA), the legislation "provides direct government income support to eligible feed grain producers mainly through three programs: direct payments, counter-cyclical payments, and the marketing loan program." Signed on May 13, 2002, and made effective for a period of six years, the bill replaced legislation enacted in 1996 that attempted to make farmers more dependent on the market, as opposed to government assistance. Citing information from the Congressional Budget Office, the National Corn Growers Association (NCGA) reported that the new bill was "projected to increase spending by \$46 billion on a wide range of titles dealing with farm commodity programs, conservation, trade, research, nutrition, rural development, credit, forestry and energy."

In order to help minimize their profession's inherent risks, farmers also continued to rely on other forms of insurance and subsidies in the early 2000s. In particular, corn growers were benefiting from clean air regulations and related subsidies connected to the production of ethanol.

RESEARCH AND TECHNOLOGY

Improved Seeds and Techniques. Farmers have always tried to find the best ways to increase crop yield and quality. They knew that the size of their crop depended on the seed they used, so they saved the best and largest ears of corn for seed. They carefully observed the results of their seed selection and learned to develop strains adapted for their locations and conditions. Farmers could increase the quality of their crop and the bushels per acreage yield by selecting the right seed. Scientists and farmers began to apply knowledge of hybrid corn-seed breeding, which involved fertilizing one strain of corn with another to produce corn with particular characteristics.

With the realization that biotechnologists would be able to genetically engineer seeds to produce corn with specific traits—such as modified proteins, oils, or starches and resistance to disease and insects—the NCGA has supported the creation of a comprehensive gene map of corn in order to realize the industry's goals of creating corn hybrids for different environments, thus reducing the reliance on pesticides and fertilizers. In its report *The World of Corn 2002*, the NCGA emphasized its support of this initiative: "Mapping the corn genome has the same importance to the corn industry as mapping the human genome has to human health."

The NCGA indicated that the majority of corn crops (75 percent) in 2001 were non-biotech in nature. Some 18 percent of planted acreage was insect-resistant, while 7 percent was herbicide-tolerant. The USDA revealed that these totals had increased by 2002, reaching 24 percent and 10 percent, respectively. The agency expected planting of insect-resistant corn to increase because of rising infestation levels attributed to the European Corn Borer (ECB). In addition, it indicated that biotech corn was seeing the highest adoption rates on larger farms.

Corn-Based Products. In 1975 a team of USDA scientists developed a starch substance that could absorb 2,000 times its weight in moisture. This discovery was widely applied by manufacturers of disposable diapers.

Ethanol, a corn-based fuel, increased corn demand on an even larger scale. Sales of ethanol have skyrocketed. Only a few million gallons of the fuel were produced in the early 1980s. By the late 1980s, more than 850 million gallons were produced, and 86 percent of it was distilled from corn. Although some analysts predicted that ethanol use would rise steadily in the 1990s and early 2000s, ethanol use increased only slightly: about 7 percent of the U.S. corn crop or 690 million bushels of corn generally have been used for ethanol production.

When the Environmental Protection Agency (EPA) mandated that lead be removed from gasoline, ethanol became an octane booster, for ethanol added to gasoline created an oxygenated fuel that cut carbon monoxide exhaust emissions. Sixty major metropolitan areas in the United States failed to meet EPA carbon monoxide levels and were mandated to oxygenate gasoline during the winter months. The ethanol industry grew rapidly from 1980 to 1986, but when crude oil prices dropped, the ethanol market dried up. Moreover, ethanol, also known as gasohol, was an expensive product.

Corn was also becoming an environmentally-friendly product in the plastics industry. New technology was able to process starch into methylglucoside, a biodegradable plastic. This corn plastic breaks down after being buried in landfills for only seven months, while oil-based plastic never breaks down completely. By 2003 the

NCGA was working with the U.S. Department of Energy and other experts within the agricultural industry to develop a number of plant-based alternatives to petroleum-based products. These initiatives had the potential to benefit corn producers in numerous ways. Corn also has been used to create calcium magnesium acetate (CMA), a deicing substitute for rock salt. Since CMA contains neither sodium nor chloride, this deicer was safe for watersheds and agricultural areas, and it would not damage roads, bridges, and automobiles.

SIC 0116

SOYBEANS

This industry consists of establishments primarily engaged in the production of soybeans.

NAICS CODE(S)

111110 (Soybean Farming)

INDUSTRY SNAPSHOT

Soybeans are the second largest cultivated crop in the United States, behind corn, with more than 70 million acres harvested annually. In 2001 the United States produced more soybeans than any other country, producing about 42 percent of the world's total. According to American Soybean Association (ASA), soybeans provided 83 percent of the edible consumption of fats and oils in the United States in 2001.

Soybeans, which possess high quantities of protein, and soybean products are used in a wide range of food

and industrial products. Soy products have three major divisions: soy oil products, whole bean products, and soy protein products. Food products include baby food, cereal, diet foods, imitation meats, processed meats, soy sauce, tofu and miso, salad dressings and margarine, cooking oil, candy, and baked goods. Soybeans are used in pet foods and as the leading source of protein meal for U.S. livestock. Industrial uses for soybeans include wall-board and plywood, medicines, soaps and disinfectants, pesticides, fertilizers, candles, linoleum, varnish, fire extinguisher fluid, and paint.

ORGANIZATION AND STRUCTURE

Federal policies have affected the output and price of U.S. soybeans. The government has supported soybean prices by setting the bottom price for both soybeans and other competing crops. Under the U.S. Department of Agriculture's (USDA) Commodity Credit Corporation, farmers could borrow money against their crops when they harvested them, with the harvest serving as collateral, and could sell their harvest at any time. At the end of nine months, the farmer had to repay the loan or forfeit the harvest to the government. This program has allowed farmers to sell when prices were high and thus more easily pay back the loan, and it has guaranteed them a minimum price set by the USDA even if market prices dipped below the loan rate. For the most part, soybean prices have been at or above the government loan rate since 1950.

Although there were no restrictions or production quotas for soybeans, programs controlling the production of other crops, such as wheat, feed grains, cotton, and rice, have often cut down on the number of acres available for soybean cultivation, since supply control programs for other commodities prohibited the planting of other crops on that acreage. Reduction of potential soybean acreage, however, has reduced supply and maintains higher soybean prices.

BACKGROUND AND DEVELOPMENT

Soybeans, legumes related to clover and peas, were cultivated in Eastern Asia 5,000 years ago, but they were not grown in the United States until the beginning of the nineteenth century, when they were grown experimentally for use as livestock feed. When soybeans were processed into oil and meal, the primary use was for fertilizers. Their use as fodder grew also, but the events of World War II created an increased demand for soybeans for human and animal consumption, causing its industrial applications to expand as well. Because soybeans were an inexpensive protein source, their use has been credited with aiding in the expansion of the poultry industry in the 1970s and 1980s.

Controversy and drops in exports ensued in 1996 when U.S. producers tried to sell a mixture of regular and

genetically engineered soybeans to the European market. Though U.S. policy did not require labeling of genetically engineered products, European customers demanded to receive only soybeans that were not tampered with genetically. This controversy cost producers \$150 million, almost 10 percent of their European exports.

Although soybean producers have viewed with consternation agricultural bills such as the 1990 five-year act that preserved price controls for soybeans and other crops, they were pleased with the Federal Agriculture Improvement and Reform Act of 1996, which alleviated the fears generated by the preceding agricultural legislation. The American Soybean Association (ASA) welcomed the bill, with its more equitable rate of marketing loans that allows soybean growers similar funds as other major cash-grain growers are eligible to receive. Indeed, soybean production was expected to benefit dramatically from the FAIR legislation because of high domestic and international demand for soybeans. The increasing success of soybeans began in the 1994-95 season, when soybean oil consumption, for example, increased to 13 billion pounds. Moreover, soybean yields, which started to increase prior to the bill, have continued this trend. In 1994 the soybean industry recorded a yield at 41.4 bushels per acre, up substantially from 1993's 32.6 bushels per acre yield, with the total soybean yield a record 2.5 billion bushels. Since 1994, soybean yields have consistently been high as a result of the FAIR Act's provision to allow farmers the flexibility to plant more acres of soybeans. This trend continued through the late 1990s. For example, according to the ASA, soybeans were planted on a record 72.4 million acres in 1998, producing a record soybean crop. However, prices paid to farmers per bushel were the lowest average since 1985, making the 1998 crop value of \$13.9 billion lower than previous years.

CURRENT CONDITIONS

In the early 2000s, soybean yields continued to increase and prices continued to fall. ASA data revealed that in 2001 soybeans were planted on 74.1 million acres, producing a record crop of approximately 2.9 billion bushels. However, average prices paid to farmers fell sharply, dropping 42 percent from 1996 levels and lower than 1972's average price. Consistent with past trends, at \$12.3 billion the 2001 crop value was much lower than in past years.

Soybeans are grown in more than 30 states, making soybeans the second largest crop in cash sales in the United States, and the largest value crop export. Soybeans and products are now promoted by the ASA in more than 100 countries.

The United States has continued to dominate the export market, in part because of production efficiency,

which has created an abundance of soybeans and soy products for exportation, giving U.S. producers the advantage of offering their product at a lower price than producers from competing countries. According to the ASA, U.S. soybean and soybean products exports totaled \$7.1 billion in 2001. That year, the European Union (21.5 percent), China (18.7 percent), Mexico (13.9 percent), and Japan (13.4 percent) were the leading U.S. export markets.

The Farm Security and Rural Investment Act of 2002, also known as the 2002 Farm Bill, provided increased levels of support for U.S. Farmers, reducing the intent of past legislation to make farmers more dependent upon the market, as opposed to government support. For soybean farmers, the 2002 Farm Bill provided benefits in numerous areas. In addition to marketing loans and other forms of financial support, it ramped up funding for conservation and bio-energy programs and provided increased support on the trade front by strengthening funds for initiatives like the Food for Progress program.

SIC 0119

CASH GRAINS, NOT ELSEWHERE CLASSIFIED

This industry includes establishments primarily engaged in the production of cash grains, not elsewhere classified. Primary cash grains in this classification include dry field and seed peas and beans, safflowers, sunflowers, and popcorn. The industry also includes farms growing barley, buckwheat, lentils, oats, sorghum, rye, mustard seeds, cowpea and flaxseed.

NAICS CODE(S)

111130 (Dry Pea and Bean Farming)

111120 (Oilseed (except Soybean) Farming)

111150 (Corn Farming)

111191 (Oilseed and Grain Combination Farming)

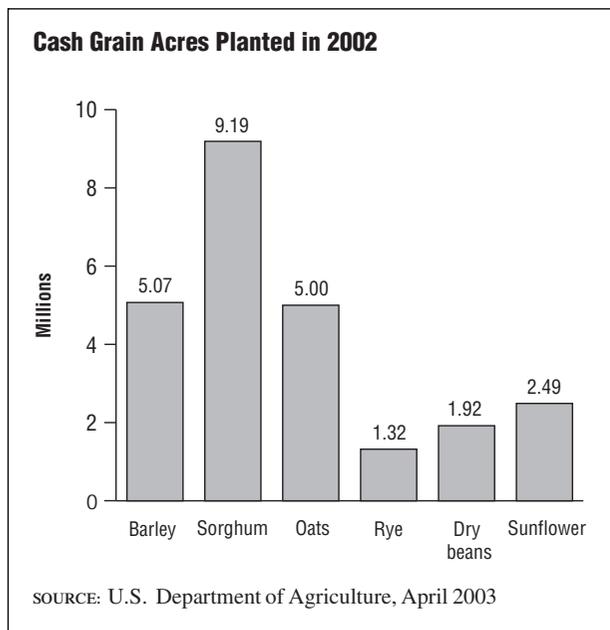

111199 (All Other Grain Farming)

Major members of this industry, such as barley, oats, sorghum, and dry beans combined for more than \$2.2 billion in production in 2002, according to the U.S. Department of Agriculture (USDA). This group of cash grains accounted for more than 21 million acres of farmland in the early 2000s, which yielded more than 715 million bushels per year. Cash grains, like most U.S. crops, had depended on government price supports since the Great Depression up until 1996, when Congress passed the Federal Agriculture Improvement and Reform Act, or "freedom to farm" legislation. This act gradually decreased subsidies over a seven-year period, with a goal of eliminating them by 2002 and ushering in a new era of market-dependent farming. However, the passage of the 2002 Farm Bill, signed by President Bush in May of that year, extended price subsidies for cash grains and other crops for an additional six years.

Barley. About 60 percent of the barley grown in the United States is used for livestock feed, especially dairy and beef cattle. Another third of the crop is used for malt by the food and brewing industries. Barley has been affected by acreage reduction programs through which the U.S. government has paid farmers to suspend the planting of barley on portions of their land. In 2001, barley acres planted reached a record low of 4,967, compared to the nearly 9,000 bushels planted in 1991. Between 1998 and 2003 annual U.S. barley production fell from 352 million bushels to 227 million bushels. Over the same time period, yield per acre harvested dropped from 60 bushels to 54.9 bushels. North Dakota, Idaho, Montana, Washington, and Minnesota are among the top barley producing states.

Genetic research may enhance barley's future by developing breeds of barley that can yield leavening flour for breads—conventional barley flour alone cannot yield raised loaves of bread—and that are resistant to disease. If biotechnology produces such a barley hybrid, then the demand for barley would likely increase because of its growing efficiency: barley yields about 35 more bushels per acre than wheat.

Sorghum. Valued at \$883 million in 2002, sorghum (cereal grasses, also called milo) is used primarily for livestock feed. Close to two-thirds of the sorghum grown in the United States is used as livestock feed. About one-third of the U.S. sorghum production is exported, primarily to Japan and Mexico. Between 2000 and 2001, U.S. sorghum exports grew 26 percent. Applications of sorghum in food, seed, and industrial processing account for about two percent of the U.S. crop. The use of sorghum in liquors has been its most common food appli-

cation. Sorghum is also processed into starch, oil, and dextrose. Production has suffered a modest decline since the early 1990s. Sorghum, which has competed with corn as a primary livestock feed, yielded only 50.7 bushels per acre in 2002, compared to 72.6 bushels per acre in 1992. Growers planted 9.5 million acres in 2002, compared to the 13,177 acres planted a decade earlier.

Oats. Oats, the smallest agricultural contracts traded on the Chicago Board of Trade, is used as a cash grain as well as for on-farm uses as straw, pasture, forage, or as a companion crop to help establish an alfalfa crop or other legume crop. Leading states in oat production include Iowa, Minnesota, South Dakota, and Wisconsin. Although the value of oat production grew from \$175 million in 1999 to \$212 million in 2002, oat production dropped to its lowest level on record in 2001, with only 117 million bushels harvested. These trends reflect the view that U.S. oat crops are viewed as inferior to foreign oats. While oat consumption in general gained ground as food in the early 2000s due to growing evidence that eating oats helped to reduce cholesterol, an increasing proportion of this consumption was of foreign oats.

Rye. A minor crop in the United States, rye is used primarily as livestock feed and is often mixed with other grains. Rye, especially rye flour, is also used for food. Less than two million acres were planted annually during the 1990s and early 2000s. Approximately one-third of this acreage was harvested, and the rest was grown for grazing, ground cover in the winter, or was plowed under to enrich the soil. Leading rye-producing states are South Dakota, Georgia, North Dakota, and Minnesota. In 2002, 286,000 acres of rye were harvested, valued at \$23.7 million.

Dry Beans. The United States has consistently been a major dry bean exporter, ranking second behind China in exports and fifth in the world in production. Leading states producing dry beans include North Dakota, Michigan, and Nebraska. Dry edible beans, including pintos, garbanzos, navy beans, limas, black, and black eye, have constituted this industry's third largest segment with annual sales of \$519 million in 2002. With mild fluctuations, dry bean production has risen and has been predicted to continue this trend, regularly yielding more than 20 million hundredweight (cwt.). In 2002, the average yield of dry beans was 1,736 hundredweight (cwt) per acre from 1.9 million total acres. The largest dry bean crops were pinto, navy, black, and great northern beans. Pinto bean crops totaled more than 40 percent of total dry bean production.

Sunflower/Safflower. Sunflower and safflower seeds produced nearly 4.2 billion pounds from just over 3.1 million acres of farmland at the turn of the twenty-first century. Sunflower production has maintained this level of production with 2.65 million harvested acres in 2002. These seeds are primarily used in cooking oil, as the oil content of sunflower seeds is typically 40 percent or higher. Safflower oil had a peripheral industrial application, because it resembles linseed oil, and safflower cakes were used as high-protein livestock supplement. As sunflower seeds have become more acceptable in international markets, demand is expected to increase.

Popcorn. Popcorn is native to the Americas and has been cultivated and eaten by Native Americans for centuries. The United States grows nearly all the popcorn used in the world. Nebraska, Indiana, and other Corn Belt states have consistently been the leading popcorn producers in the United States.

SIC 0131

COTTON

This industry classification includes establishments primarily engaged in the production of cotton and cottonseed.

NAICS CODE(S)

111920 (Cotton Farming)

INDUSTRY SNAPSHOT

Farmers harvest approximately 17 million bales of cotton every year from an average of more than 12 million acres planted annually. Cotton's many uses make it a major U.S. textile export, increasing in 2001 to 11 million bale equivalents shipped, a 75-year high. Often overlooked as significant, the cottonseed produces more than 9 billion pounds of feed for livestock on average and more than 154 million gallons of cottonseed oil (used for a variety of food products ranging from margarine to salad dressing) annually. According to the National Cotton Council, cotton stimulates an estimated \$120 billion in business revenue on the nation's economy.

BACKGROUND AND DEVELOPMENT

Earliest records of domesticated cotton or *Gossypium* date back to 5000 B.C. and traces of cotton processed into cloth have been found in Peru with the estimated date of 2500 B.C. Since the eighteenth century, the United States has been a leading producer of cotton, usually the second largest. Virginian colonists grew and exported small amounts of cotton since the founding of the colony in 1607 using imported seed from the West Indies, but it was the invention of Eli Whitney's cotton gin in 1793 that allowed cotton to become a major component of the American economy. According to Harold Woodman, author of *King Cotton and His Retainers*, exports of cotton increased from 500,000 pounds in 1793 to more than 90 million pounds in 1810. In the three decades preceding the American Civil War, cotton production accounted for more than half of the nation's exports. Spurred by continuing worldwide demand, U.S. cotton production and acres planted grew steadily until reaching its peak in 1925, when 45 million acres of American soil were planted with cotton. By the early 1990s, U.S. mills annually consumed some four billion pounds of cotton.

The mechanization of cultivation and harvesting led to dramatic changes in the U.S. cotton industry. In the early 1950s, only 18 percent of U.S. cotton was harvested mechanically; by 1967 that figure had jumped to 95 percent, and productivity increased with mechanization. As a result, total acreage devoted to cotton production dropped 75 percent between the 1920s and the 1990s, while annual production stabilized at approximately 16 million bales. U.S. cotton growers produced close to 20 percent of the world's cotton supply throughout the 1980s, and approximately half of their annual production during that time was exported.

Because cotton requires warm conditions for germination and growth, it has always been grown in the

southern regions of America, from Virginia to California. For three centuries, U.S. cotton production was centered in the area stretching from the Atlantic coast westward to central Texas. However, the increasing availability of irrigation facilities has allowed western growers to produce cotton that is more consistent in color and weight. By 1995, the largest producers of cotton were Texas and California, with annual harvests of about 4.5 million and 2.5 million bales, respectively. Although California growers plant approximately one-quarter the number of acres as Texas growers, their yield per acre has often been triple that of Texas growers.

Two kinds of cotton are grown in the United States: American upland cotton, which accounts for 95 to 98 percent of production, and Amer-Pima, which accounts for two to five percent of production. Cottonseed is planted mechanically between February and June and is harvested in the fall, usually before the first frost. The cotton plant grows three to six feet tall, has broad bushy leaves and a stalk that measures up to an inch in diameter. After flowering, the cotton plant produces a boll, which contains the seeds and fiber that are eventually harvested. Cotton bolls are harvested mechanically after the plants have been defoliated, either by frost or by application of chemicals. The harvested bolls are cleaned, ginned (a process that strips the fibers from the seeds), packed into bales weighing approximately 500 pounds, classified according to staple (fiber) length, grade, and character, and then brought to market. The longest cotton fibers are processed into yarns for making fabrics, the shorter fibers, called linters, are used as a source of cellulose for industrial applications. The seeds are processed into cottonseed oil, while the seed husks are used as a feed for livestock.

The emergence of the man-made fiber market in the mid-1970s represented the greatest challenge to cotton's dominance of the world fiber market. With the introduction of fibers such as polyester, cotton's share of the clothing market fell from 50 percent in 1970 to 34 percent in 1975, according to *The Economist*. The cotton industry responded to this challenge by forming Cotton Incorporated, a promotional organization funded by voluntary levies paid by cotton growers. During the 1980s and 1990s, cotton began to reclaim the fiber and lint market; it recaptured 50 percent of the U.S. retail clothing market, indicative of its success worldwide.

Though the cotton industry had been stabilized by U.S. government subsidies and price supports that eased the pressures of a volatile world cotton market since 1933, Congress passed the 1996 Freedom to Farm Bill in an attempt to bring about a new era of market-dependent farming. The bill called for the freezing and incremental reduction of farm subsidies over a seven-year period ending altogether in 2002. However, the

Farm Security and Rural Investment Act of 2002, also known as the 2002 Farm Bill, reversed conditions by returning to higher levels of government support for farmers.

Along with other agricultural products, cotton producers faced pressure to implement more environmentally-friendly production techniques. Retailers and manufacturers, such as Esprit, O Wear, Eco Sport, and GAP, called for an increased supply of organic cotton and began to market organic cotton products. In the 1980s, the United States accounted for only 3 percent of the world's farmland but almost 25 percent of the world's pesticide use.

Because organic cotton cost up to three times as much to produce as traditional cotton, customers buying the clothes manufactured with pure organic cotton were not pleased with the prices. After spiking to more than 25,000 acres in 1995, organic cotton farming dropped to 10,000 acres in 1996. Following the rise and fall, retailers and manufacturers introduced new blended cotton clothing, which allowed customers the benefit of organic cotton while keeping the prices down. According to the Organic Trade Association's 1997-98 survey, more than 4 million pounds of organic cotton were grown in Arizona, California, Missouri, New Mexico, and Texas. Additionally, in 1997 Ecomall.com revealed that more than 1 million pounds of organic cotton were purchased by Levi's, the world's largest apparel user of cotton.

CURRENT CONDITIONS

Cotton is produced on more than 31,400 farms in the United States, with 98 percent grown in fourteen states. Texas is the largest grower, producing an estimated 5.0 million bales of cotton in 2002, while Mississippi, the second largest, produced only 1.9 million bales.

In the early 2000s, the cotton industry was benefiting from increased demand. According to the U.S. Department of Agriculture (USDA), in 2002 demand for domestic cotton increased more than 3 million bales, reaching 18.7 million bales. This increase was fueled by explosive growth in exports, which grew 60 percent from 2001 to 11 million bales. Such export levels had not been seen for 75 years. While exports skyrocketed, consumption at domestic textile mills fell 13 percent from 2001, settling at 7.7 million bales. Levels this low had not been seen since the 1987-88 season. The USDA attributed this situation to reduced mill capacity and output amid weak economic conditions. In addition to lower levels of consumer spending, a strong U.S. dollar that favored imports also contributed to the downturn in domestic consumption.

A major agricultural sector development occurred on May 13, 2002, when the Farm Security and Rural Invest-

ment Act of 2002 was signed. Impacting the industry for a period of six years, the 2002 Farm Bill provides higher levels of support for farmers. As the USDA explains, the legislation "Alters the farm payment program and introduces counter-cyclical farm income support; expands conservation land retirement programs and emphasizes on-farm environmental practices; relaxes rules to make more borrowers eligible for Federal farm credit assistance; restores food stamp eligibility for legal immigrants; adds various commodities to those requiring country-of-origin labeling; and introduces provisions on animal welfare." *Consumers' Research Magazine* criticized the bill for its potentially negative impact on international trade. However, many sectors within the agricultural industry stood to benefit from higher levels of support for export programs, provided as a direct result of the new farm bill.

SIC 0132**TOBACCO**

This classification covers establishments primarily engaged in the production of tobacco.

NAICS CODE(S)

111910 (Tobacco Farming)

INDUSTRY SNAPSHOT

This industry is composed of small U.S. farms that grow and sell tobacco to cigarette companies and other tobacco product retailers. In 2001, the farm value of U.S. tobacco crops reached \$1.9 billion, according to the U.S. Department of Agriculture (USDA). The links between tobacco and several serious diseases, such as cancer and emphysema, first suggested in the 1960s and confirmed in the 1990s, have posed serious threats to the industry. Into the early 2000s, criminal and civil lawsuits against cigarette manufacturers focused public attention on the role of the tobacco industry in promoting health-threatening products and contributed to diminishing demand for tobacco. Increased exports of foreign-grown tobacco also affected American growers. However, changes in federal regulations and in harvesting and processing techniques have somewhat mitigated the uncertain future of tobacco farming.

ORGANIZATION AND STRUCTURE

Small farms, particularly in the southeastern regions of the United States, grow most of the nation's tobacco. The total number of farms producing tobacco in the United States dropped from 512,000 in the mid-1950s to roughly 89,700 in the late 1990s, at which time the number classified as tobacco farms—organizations deriving at least 50 percent of sales from tobacco—dropped to about 65,800. Though tobacco farms have increased in size since the 1950s, their average size remains relatively small in comparison to other types of farms.

The major tobacco growing states are North Carolina, Kentucky, and Tennessee. With South Carolina, Virginia, and Georgia, they produce more than 90 percent of the tobacco grown in the United States. In all, 17 states grow appreciable acreage of tobacco. Establishments from North Carolina and other states compete with each other at tobacco auctions, where major tobacco companies purchase their crops.

Flue-cured tobacco is produced in the southeastern Coastal Plain and the Piedmont region from Virginia to Florida. This variety of tobacco is by far the greatest component (about 95 percent) used in American cigarettes. Flue-cured is also the kind of tobacco most used in exported products. Fire-cured, or Class 2, tobacco is pro-

duced in central and western Virginia, Tennessee, and Kentucky. This tobacco has broad, dark green leaves, which are heavily drooping and gummy to the touch. After curing they are light to dark brown and strong in flavor. Class 2 tobacco is principally used in snuff in the United States, but it is also used for cigar manufacture and chewing tobacco in other countries. All other American tobacco is air-cured and is principally used in cigars, except for the light air-cured and Maryland types. Burley is currently grown in Kentucky and Tennessee and to a lesser extent in Ohio, Indiana, Virginia, West Virginia, and North Carolina. Major cigar tobacco districts include New England, Pennsylvania, Ohio, Wisconsin, Georgia, and Florida.

Priming and stalk cutting are the two methods of harvesting used in tobacco production. Three methods of curing—flue-curing, fire-curing, and air-curing—are used. Curing barns are typically 18 to 20 feet tall. Ventilators permit the flow of ambient air around suspended stalks of stalk-cut tobacco or around suspended leaves of flue-cured and cigar wrapper tobacco. Supplemental heat is used on air-cured tobacco during inclement weather. Before tobacco is suitable for consumption, it must be fermented and aged, which brings the tobacco leaves to their peak color and aroma and eliminates harsh or bitter taste. Finally, most tobacco products in the United States have various amounts of sweeteners, flavorings, or humectants added to increase or modify their natural flavor and aroma.

BACKGROUND AND DEVELOPMENT

As one of the first native crops to be commercially grown and marketed, tobacco has long been a key crop in the American South. Historical records indicate that commercial cultivation of the crop began as early as 1612. In the eighteenth century, tobacco became such a coveted item that it was being used as legal tender for payment of wages, taxes, and debts. In fact, it had become the greatest single source of wealth in Virginia, Maryland, and North Carolina at that time. Until cotton became king in 1803, tobacco was rated as the nation's most valuable export commodity.

A large part of this wealth was generated by the huge international market that quickly developed. In 1614, there were 7,000 tobacco shops in London alone. In 1617, Virginia was shipping 20,000 pounds of the product to England; by 1628, this number increased to 500,000 pounds and, in 1638, 1.4 million pounds. By 1771, England and Scotland were, collectively, importing about 102 million pounds of tobacco from the Chesapeake colonies in the New World. This is a remarkable amount of export considering that the product was being shipped by wooden, wind-driven ships that had to overcome severe transportation obstacles to complete delivery. More

than 150 years later, 590 million pounds of tobacco were being shipped overseas from the United States, half of this still passing through the Virginia ports.

In the early part of the nineteenth century, tobacco began to lose its place as the premier export to the Old World. More of it began to be consumed at home. Farmers and other consumers took to the pipe along with their chewing habits. As snuff became more and more associated with British dandyism, pipe smoking took first place as the desired mode of tobacco consumption.

The quality of most tobacco during antebellum years was poor compared to today's standards. In New England, a harsh, narrow leaf called "shoe-string" was produced. The South grew a dark, heavy "shipping leaf" that was quite different from the light, sweet Bright tobacco raised today. This all changed in 1864 with White Burley, a strain of tobacco that was remarkable for its capacity to absorb sugar and flavoring, which was first produced at this time. Burley was first grown prodigiously in Ohio; today it is predominantly a product of Kentucky and Tennessee. The effect of Burley on the industry cannot be overestimated. It revolutionized smoking and the chewing industry after the Civil War and had an equally strong impact on the cigarette industry during World War I.

A significant part of the industry's history has to do with the search for superior tobacco products abroad. This search was primarily focused on Cuba and Mexico. A large part of this focus was due to the popularity of Cuban cigars in America. Cigar imports from the Antilles reached the 4 million mark by 1811. A booming cigar industry sprang up in Havana during this time and has not abated since.

Cigars achieved their prominence as a symbol of aristocracy during the "Brown Decades," after the Civil War. Also during this era, modern cigarettes began to appear on the scene. All cigarettes were initially "roll-your-own." It was not until 1866 that tailored cigarettes were produced in America and England. These also were hand-rolled, since the modern machine-produced methodology for cigarette manufacture had not yet been invented. These cigarettes were also larger than the cigarettes common at the beginning of the twenty-first century and were often made from Turkish tobacco grown in Greece, Bulgaria, and Turkey. New York, with its preponderance of immigrants and large pool of inexpensive labor, served as a central site of cigarette production and mass consumption.

Though tobacco has historically been a labor-intensive crop, averaging as much as 300 hours of labor per acre, new techniques for producing, harvesting, and curing have reduced labor and permitted increased acreage per farm. Flue-cured tobacco, once tied by hand, is

now marketed as loose leaf. The introduction of mechanical harvesters also reduced labor, as did the shift from sheets to bales. Successful growth of tobacco also requires a good supply of well-developed seedlings for transplanting. On American farms, these are usually produced in a cold frame covered with cheesecloth, plastic, or glass. The tobacco seeds are sprinkled on top of the soil and then tamped firmly into the ground. A high state of fertility and adequate soil moisture must be maintained throughout the growing season to ensure vigorous production. Tobacco crops are also regularly attacked by fungi, bacteria, viruses, and a number of other harmful parasites that must be combated by raising disease-resistant crops. Without such varieties of tobacco, the industry would not be viable in certain areas of the United States.

Despite these difficulties, tobacco remains relatively lucrative for small farmers. It is the most profitable crop in the southeastern region of the United States, generating relatively high prices per acre. In Kentucky, for example, tobacco comprised only 1 percent of farmland in 1992 but generated 40 percent of net farm returns and, in 1994, each acre of tobacco grown in the United States for domestic use generated more than \$43,000 in state and Federal excise taxes at the retail level. Estimates suggest that, for farmers, one acre of tobacco can net between \$1,200 and \$1,500 compared to about \$75 per acre for corn or soybeans. For this reason, many tobacco farmers continue to resist pressure to shift from tobacco to other crops, though demand for tobacco has declined significantly and continued price supports are far from certain. From 1981 to 1997, U.S. tobacco production declined about 20 percent, and cigarette consumption fell about 24 percent. During the past two decades, America's share of the world tobacco market has also declined. Because of a Clinton administration tariff proclamation in 1995, imports into the country increased about 27 percent. The import of less-expensive cigarettes composed of foreign-grown tobacco also had a negative impact on domestic industry sales.

By the late 1990s, changing attitudes toward smoking forced the cigarette industry to change the way it sold cigarettes. Though the link between the inhalation of tobacco smoke and such diseases as heart disease, cancer, and emphysema was first publicized in 1964 in a report to the U.S. surgeon general, tobacco companies successfully evaded for decades any legal responsibility for producing and marketing a dangerous product. But this avoidance ended in 1998 when the leading U.S. tobacco companies agreed to pay \$206 billion to 46 states to settle a plethora of suits filed to recover Medicaid money states spent to treat smoking-related diseases. Individual and class action suits also resulted in massive damage payments, and, in October 1999, the nation's largest cigarette

maker, Philip Morris, admitted that scientific evidence shows that smoking causes lung cancer.

The impact of this admission and judgments of liability in smoking-related deaths weakened tobacco companies' financial performance and contributed to reduced demand for American tobacco. In 1998, U.S. cigarette consumption dropped seven percent from the previous year, and production declined six percent during the same period. Exports also fell, declining seven percent in 1999. Though cigar consumption rose by a staggering 50 percent from 1993 to 1997, price increases on cigarettes and tax hikes served to further reduce demand for tobacco.

Quotas for 1999 were reduced by 29 percent for Burley tobacco and 17 percent for flue-cured, with the effective quote for 1999 nearly 20 percent lower than the previous year. Tobacco farmers expected to harvest about 650,000 acres of tobacco in 1999—about 11 percent less than in 1998.

In 1999, tobacco farmers pushed for receipt of \$328 million from a proposed \$7.4 billion farm aid package. Though legislators from tobacco states argued that tobacco growers had a right to be compensated, like other farmers, for lost income, others argued that the government should not be involved in helping tobacco farmers produce a crop associated with major health risks.

Government Legislation. The U.S. government became involved in the tobacco industry in the 1930s, when its main purpose was to stabilize tobacco prices. Designating tobacco as a basic, storable commodity, the Agricultural Adjustment Act of 1933 resulted in cash payments to tobacco farmers who restricted production. Although the legislation was found unconstitutional several years later, substitute legislation authorized payments to farmers who followed soil conservation guidelines. Because of the need of buyers and producers for uniform standards on which to base marketing decisions, Congress enacted the Tobacco Inspection Act of 1935, thereby setting the framework for the development of tobacco grade standards. The Act also enabled the daily distribution of daily price reports for each grade and authorized the Secretary of Agriculture to designate tobacco auction markets, where growers would receive mandatory inspection of their tobacco. The Agricultural Act of 1938 called for marketing quotas for specific types of tobacco.

Legislation had become extremely tight in the late 1990s. When plans were made in 1996 to authorize the Food and Drug Administration (FDA) to classify nicotine as a drug, leading tobacco-growing states argued that ensuing new regulations would severely impact Virginia's \$5 billion tobacco industry (of which \$175 million went to farmers), and result in a loss of jobs, loss of

tax base, reduced ability to finance schools and other government services, as well as jeopardizing sporting and cultural events sponsored by brand name tobacco products. On the other hand, studies by anti-smoking groups predicted exactly the opposite, suggesting that lost jobs and revenues would be more than compensated for by new jobs and industry. The FDA, for one, argued that its restrictions would have a relatively minor effect on U.S. tobacco sales and cost just 2,500 agricultural jobs. Though tobacco companies first resisted FDA regulation of tobacco, in 1998 they agreed to cooperate with the Clinton administration's efforts and accept FDA regulation. Later that year, however, a federal court ruled that the FDA did not have the legal authority to regulate tobacco, reserving this power for Congress.

Tobacco growers and legislators have disagreed on how to respond to declining demand for U.S. tobacco. While a provision of the 1998 legal settlement requires cigarette makers to pay \$5.1 billion to compensate growers for decreased demand, farmers in many states complain that this amount is only a fraction of what they need. During the late 1990s Senator Wendell Ford of Kentucky introduced a bill to compensate tobacco farmers \$4 a year for every pound of quota lost, while keeping the present quota and price support system intact. Senate Agriculture Committee Chair Richard Lugar, in contrast, argued that federal regulation makes tobacco growing less competitive. His proposal, costing about \$15 billion, sought to buy out existing quotas and phase out federal price supports. The Lugar bill also proposed to provide tobacco-producing regions with \$300 million in aid.

CURRENT CONDITIONS

By 2003 the tobacco industry continued to face a number of significant challenges, including a weak economic climate and falling demand. According to the U.S. Department of Agriculture (USDA), the lion's share of U.S. tobacco is produced for cigarettes. The domestic consumption of cigarettes fell more than 1 percent in 2002, following similar decreases in 2001 and 2000. At the same time, Bureau of Labor Statistics data revealed that cigarette prices were increasing. Prices climbed eight percent in 2001 and were expected to increase by this same percentage in 2002.

USDA estimates indicate that 886.0 million pounds of tobacco were produced in 2002, down approximately 105 million pounds from 2001. The total number of tobacco acres planted decreased four percent in 2002, reaching 434,310 acres. Due in part to disease and poor weather, yields also decreased in 2002, falling from 2,293 pounds per acre in 2001 to 2,040 pounds per acre in 2002. That year, about 94 percent of tobacco was produced for the manufacture of cigarettes. The next largest market for U.S. tobacco was cigars, accounting for some two percent

of crops. The remainder of crops included fire- and air-cured tobacco used for other purposes.

In the early 2000s legislation continued to play an important role in the tobacco industry. Senator Max Cleland of Georgia introduced the Aid to Tobacco-Dependent Communities Act of 2002. In the U.S. House of Representatives, Congressman Ernie Fletcher of Kentucky introduced the Tobacco Equity Elimination Act of 2002 in conjunction with a number of other U.S. representatives from Georgia, Kentucky, North Carolina, and Tennessee. According to an article by Wayne Harr in *FarmProgress*, both bills proposed to “buy out tobacco quota while maintaining a restructured tobacco program.” In addition, each piece of legislation was “gathering support from tobacco and non-tobacco groups over bills introduced earlier, which called for a buyout of quota and FDA regulations but did not retain any type of tobacco program.” In addition to these two bills, the Farm Security and Rural Investment Act of 2002—which provided higher levels of government support for farmers in general—also had implications for tobacco farmers.

AMERICA AND THE WORLD

Despite increased competition from other nations, the United States remained a fixture in the international tobacco trade during the early 2000s, leading in the categories of cigarette exports and tobacco leaf imports. In the first nine months of 2002, tobacco imports surged 23 percent, reaching 458 million pounds. However, high U.S. prices hindered tobacco exports. Exports were expected to fall 15 percent in 2002, dropping from 411 million pounds in 2001 to 360 million pounds.

Although global tobacco leaf production increased in the mid-1990s, reaching 14 billion pounds and accounting for 40 percent of the tobacco used in the United States, the effects of new legislation and decreasing demand have been felt by tobacco growers world wide. Reacting to lower market prices and predictions of increased stocks, other nations have reduced plantings.

In recent years, international tobacco advertising regulations greatly affected the major countries around the world, as well as in the United States. Canada, for example, banned cigarette vending machines and tobacco brands’ sponsoring of sporting events. In Norway, an existing law banning tobacco advertisements became stricter by including indirect advertisements. Tobacco advertising in Poland was banned on private and state radio and television media, and the European Union dealt a severe blow to the European tobacco industry when it banned advertising and sponsorship, to begin in 2002. The World Health Organization (WHO) and the World Bank have also instituted tobacco control initiatives. Tobacco growers, representing about 33 million workers

worldwide, are making plans to develop a global alliance to advocate for their interests.

SIC 0133

SUGARCANE AND SUGAR BEETS

This industry classification includes establishments primarily engaged in the production of sugarcane and sugar beets.

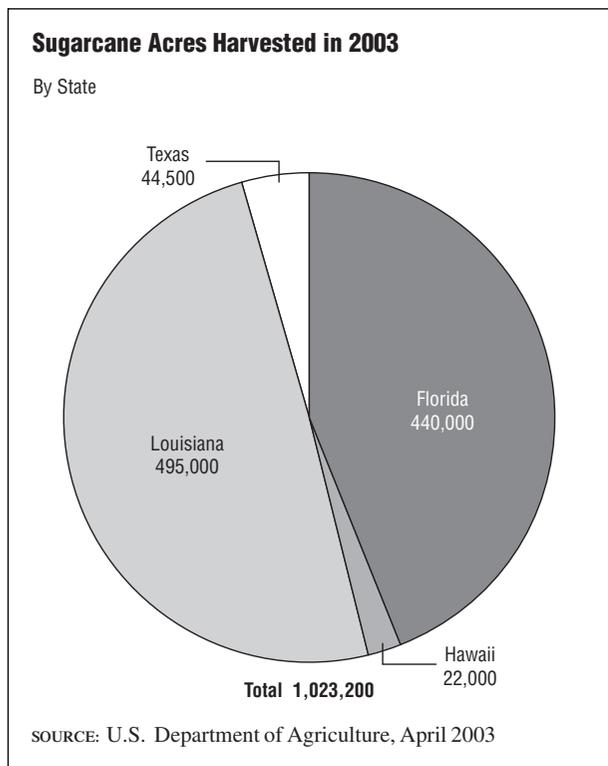

NAICS CODE(S)

111991 (Sugar Beet Farming)

111930 (Sugarcane Farming)

BACKGROUND AND DEVELOPMENT

The story of the sugar industry in the United States is in fact the story of two industries: one devoted to producing sugarcane and the other to producing sugar beets. Before the twentieth century, sugarcane accounted for 95 percent of world consumption of sugar. However, mod-

ern planting and refining techniques helped make sugar beet production profitable. By the 1980s, sugar beets and sugarcane shared equally in the U.S. sugar market. Sugarcane was introduced to the United States from the Caribbean region by Jesuit priests traveling to Louisiana in 1751, and the first U.S. sugar refinery was built in the same state in 1795. Sugarcane is produced only in Florida, Hawaii, Louisiana, and Texas. Western pioneers desiring their own source of sugar began sugar beet production in the United States around 1870, but their efforts proved unprofitable until the development of irrigation systems in the 1890s. Beet production provided 25 percent of the nation’s sugar needs by 1920. The Red River Valley area of Minnesota and eastern North Dakota are the largest U.S. beet producing regions.

Sugarcane and sugar beets are grown mainly to produce table sugar and sucrose. Sugarcane is also produced to manufacture alcohol as fuel for vehicles. Although refining processes for sugar sources are similar, cultivation and harvesting techniques are quite different. Sugarcane is planted using stalk cuttings, and matures between eight and sixteen months, depending on the region. A crop of sugarcane may produce acceptable yields for two to three years before being replanted and, in the case of Hawaii, where there is no danger of frost, can be harvested year round. Sugarcane is most often harvested mechanically, with specially designed harvesters that cut the stalk at the bottom, strip the unneeded leaves and top, and transfer the cane to a wagon. Prior to mechanical

harvesting, sugarcane production required vast numbers of laborers who, in many cases, worked under conditions of slavery or near-slavery.

Grown primarily in twelve states, sugar beets, on the other hand, are harvested annually, and have benefited greatly from the attention of agricultural specialists who devised seed types and planting methods that encourage maximum yields. Still, great care must be taken to ensure adequate distance between plants, weed control, planting depth, and proper fertilization. One study showed that 50 percent of sugar beet production costs were expended in cultivation. However, mechanical cultivation and harvesting equipment makes labor costs in sugar beet production negligible. Both sugar industries have attained yields that are among the highest in the world: the average yield for sugarcane was roughly 35 tons per acre in the early 2000s; yield hovered at 20 tons per acre for sugar beets.

Sugar farmers, especially in Florida, faced environmental concerns throughout the 1990s. In 1991, the state was sued by the federal government to clean up the discharge from sugar farms as parts of Florida’s Everglades were choked with cattails, a weed that grows from run-off from sugar fields. In 1999, the federal government revealed the Restudy, a major plan to clean up the Everglades.

CURRENT CONDITIONS

The U.S. sugar industry has long been bolstered by government programs designed to elevate the prices that sugar producers receive for their product. Prices for sugar have traditionally gone through dramatic swings, and this trend has continued into the early 2000s as the price per bushel of sugarcane jumped from \$26.10 in 2000 to \$29 in 2001.

In 1996, the U.S. government sought to alleviate farm subsidies and loans altogether. The 1996 Farm Bill called for the freezing and gradual reduction of agricultural loans and subsidies over a six-year period, resulting in termination of the program in 2002. Government assistance had been especially important to sugar producers because of the market’s volatility. Though the bill met stiff resistance from sugar producers and lobbyists, it eventually passed, leading to some closures. In 2002, however, President Bush signed into law the 2002 Farm Bill, which extended farm subsidies for an additional six years.

The sugar industry has undergone a number of changes since the 1970s. Per capita consumption of sugar (both beet and cane) plummeted from 1970, when it stood at roughly 102 pounds, to 1980, when it stood at about 60 pounds. By 2002 it had fallen to 45 pounds. The corn sweetener market has claimed much of sugar’s old market share. This steady drop in consumption led to a

reduction in cane sugar refineries, from 22 in 1981 to just 12 at the turn of the twenty-first century.

Falling domestic consumption cost the U.S. sugar industry approximately \$250 billion in 2001 alone. Between 1999 and 2003, domestic sugar sales fell from 10.11 million short tons in 1999 to 9.67 million short tons. As a result, production began to wane as well. Sugar beet acres planted fell from 1.42 million in 2001 to 1.36 million in 2002; acres harvested declined from 1.36 million to 1.33 million over the same time period. Similarly, sugarcane acres harvested fell from 1.02 million in 2001 to 995,000 in 2002. Minnesota, Idaho, North Dakota, California, and Michigan led in sugar beet production in 2003, while Florida and Louisiana led in sugarcane production.

INDUSTRY LEADERS

In the early 2000s, the leading sugar farmers included A and B Hawaii Inc. at over \$200 million in sales and 1,500 employees, as well as its subsidiary Hawaiian Commercial and Sugar Co. Also at the top of the industry heap was Sterling Sugars Inc. with \$40 million in sales and 200 employees in 2003. U.S. Sugar and Flo-Sun are leaders in Florida; each controls 40 percent of the state's sugar industry. While the 1996 Farm Bill forced these companies to diversify to survive, the passage of the 2002 Farm Bill has eased the pressure to do so.

AMERICA AND THE WORLD

Low world sugar prices threatened U.S. import protections at the turn of the twenty-first century and was predicted to increase Mexico's access to the U.S. sugar market. According to the USDA, imports from Mexico reached 260,000 tons in 2000, compared to 155,000 tons the previous year. Thanks to NAFTA, Mexico may import roughly 280,000 tons of sugar, duty-free, to the United States as of 2001.

SIC 0134

IRISH POTATOES

This industry classification includes establishments primarily engaged in the production of potatoes, except sweet potatoes, which are part of **SIC 0139: Field Crops Except Cash Grains, Not Elsewhere Classified**.

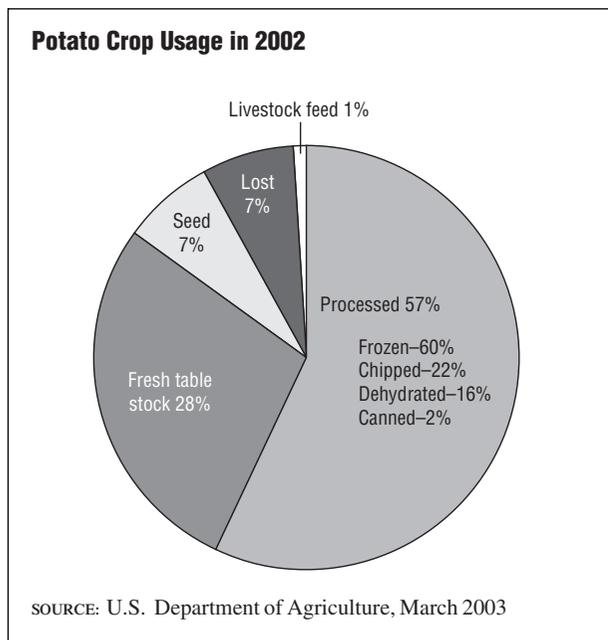

NAICS CODE(S)

111211 (Potato Farming)

The potato, a member of the nightshade family that produces thick, fleshy tubers from underground stems, was introduced into the United States around 1719, but it was not mentioned in crop production data until the 1840 census, which listed 160.4 million pounds of potatoes grown. American per capita potato consumption peaked in the early twentieth century at 198 pounds, dropped to about 103 pounds by 1956, and rose again to its 2002 level of 140 pounds per person as people consumed more processed potatoes. Of the total U.S. potato crop in 2002, 28 percent was distributed fresh to consumers, while 69 percent was processed, either frozen as chips or shoestrings, dehydrated, or canned. In addition, a portion of each year's 438 million hundredweight crop (hundredweight is a unit of measure equaling 100 pounds, abbreviated cwt.) is used for seed and for feeding livestock. Although there are more than 80 varieties of potatoes planted in the United States, six varieties dominate production: Russet Burbank, Russet Norkotah, Atlantic, Ranger Russet, Frito-Lay, and Shepody.

American potato farmers plant relatively few acres, just 1.3 million in 2002, yet the high yield of Irish potatoes allows them to supply domestic potato production of almost 500 million cwt. of potatoes per year, according to U.S. Department of Agriculture (USDA) statistics. In fact, the Irish potato yields more food per unit area of land planted than any other major crop. Potatoes are grown commercially in 35 American states, from Alaska to Maine to Florida, but more than 50 percent of the 2002 potato crop was produced by just three states: Idaho, Oregon, and Washington. Western states account for 65 percent of total U.S. potato production, while Central states produce another 25 percent, and Eastern states make up the remaining 10 percent. Altogether, U.S. growers tend to produce about seven percent of the world's potatoes.

Mechanization revitalized potato farming by reducing the amount of manual labor involved. Seed potatoes

(precut sections of potato) are planted using an automatic planter pulled behind a tractor. Such planters can plant four or more rows at a time and require only a tractor driver and a tender. Potatoes are harvested mechanically as well, with machines that dig out the entire potato plant, shake free excess dirt and rocks, and deposit the potatoes in an adjacent truck. In the southern United States, potato farmers are able to reap four harvests per year, while in the northwestern states, where most of the U.S. crop is grown, potatoes are harvested primarily in the fall. After they are harvested, potatoes are placed in cool (45-60 degrees Fahrenheit), humid storage areas to allow for healing of surface damage, a process called curing. Because potatoes are distributed throughout the year, roughly 63 percent of each year's potato crop is placed in storage, where the potatoes are maintained in carefully controlled conditions to prevent rot, dehydration, and a wide range of diseases.

In recent years researchers have attempted to counter various diseases that can affect potato crops. One promising experiment undertaken by Purdue University researchers was to take a gene from tobacco plants and insert it into potato plants. "This gene codes for a protein, called osmotin, that brings death to the fungi by chemically drilling holes in their cell membranes," noted *Business Week* in 1994. "For humans, the protein is probably safe . . . since it's produced by many food plants." Testing continues on the potato, as well as other crops such as soybeans, corn, and tomatoes.

The potato crop's value hovered between \$2 and \$3 billion in the early 2000s. Major potato producers include Sunny Farms and Anthony Farms, Inc., which averaged about \$8 million and \$7 million in sales from potatoes per

year, respectively. The 2002 growing season brought U.S. farmers a crop of 438 million cwt. from some 1.3 million acres. A slight decrease in domestic french fry consumption growth was offset in the early 2000s due to increased exports. U.S. potato farmers exported more than 1 billion pounds of frozen french fries, more than half of which went to Japan.

In recent years, as research reveals more about the potato both as a source of nutrition and vitamins and its chemistry—how it is metabolized and synthesized by the human body—scientists and researchers are coming to some interesting conclusions. Studies indicate that potatoes rank with other glycemic foods: potatoes raise a person's blood sugar as much as sugar does. Because the starches in white bread and potatoes are quickly metabolized as sugars by the body, diabetics are potentially at risk; some nutritionists and scientists recommend that the potato be reclassified as a complex carbohydrate, along with rice and pasta, rather than as a vegetable. In 2002, potatoes accounted for 15 percent of U.S. vegetable cash receipts.

SIC 0139

FIELD CROPS EXCEPT CASH GRAINS, NOT ELSEWHERE CLASSIFIED

This entry includes establishments primarily engaged in the production of field crops, except cash grains, not classified elsewhere. This category includes a range of crops for human or livestock consumption, encompassing farms that produce alfalfa, broomcorn, clover, grass seed, hay, hops, mint, peanuts, sweet potatoes, timothy, and yams. This category also includes establishments deriving 50 percent or more of their total value of sales of agricultural products from field crops, except cash grains, but less than 50 percent from products of any single industry.

NAICS CODE(S)

- 111940 (Hay Farming)
- 111992 (Peanut Farming)
- 111219 (Other Vegetable (except Potato) and Melon Farming)
- 111998 (All Other Miscellaneous Crop Farming)

Sweet Potatoes and Yams. Yams grown in the United States are actually a variety of sweet potato, but with a moister, golden red flesh. Sweet potatoes are light yellow or pale orange in color. Yams, grown primarily in North Carolina, account for about half of all sweet potato consumption in the United States, and are consumed mainly in the northeast and mid-Atlantic states. North Carolina is the leading producer of sweet potatoes, with Louisiana, Mississippi, and California following as major producers. With increasing production and sales of sweet potatoes, 2003 brought the total number of acres harvested to 91,000, compared to 83,500 acres harvested in 2002, despite a drop in acres planted from 97,200 to 94,000 over the same time period.

Hay. Grass, alfalfa, clover, and timothy are all used for livestock fodder. Farmers grow hay for their own livestock or for commercial sale. Some dairy farmers buy grain and use their fields for quality forage crops since well-managed alfalfa, for example, can provide more net income per acre than grain crops such as corn or soybeans, according to farmers and researchers in the trade journal *Implement & Tractor*. In 2003, harvested hay

continued the trend of decreased production with 64.3 million acres harvested, compared to 64.5 million acres harvested in 2002. Leading hay producers in 2003 included Texas, Missouri, North and South Dakota, and Kansas. South Dakota was the leading alfalfa producer.

According to *Implement & Tractor*, Wisconsin researchers have found that the nutritional value of alfalfa and other hays depends on when it is cut and have noted that milk production of dairy cattle rose dramatically when cows were fed alfalfa that was harvested at first flower. In some areas, hay marketing cooperatives hold regular hay auctions with hay-testing services, since demand is up for high quality hay for dairy cattle.

Peanuts. Peanuts have ranked as the eighth leading field crop with an annual value of about \$1.2 billion, and the United States is one of the third largest producers of peanuts in the world. The United States harvested about 1.22 million acres of peanuts in 2003. Georgia is the leading producer, averaging about 50 percent of the country's total peanut crop per year. Other leading producers include Texas, Alabama, Florida, North Carolina, Oklahoma, and Virginia.

The peanut industry has been regulated by government price support and quota programs since the 1930s. Though support prices guarantee peanut farmers a minimum price for their crops, the Federal Agriculture Improvement and Reform Act of 1996, or Farm Bill, reduced and froze the loan rate at 10 percent. The government also imposes production quotas on regions and even on individual farms within the regions, according to the unit's historical share of production; the nation's total production quota is based on expected food and seed use for the coming year. However, the 1996 Farm Bill called for the elimination of the floor quota, because, in recent years, production had fallen below the 1.35 million tons stipulated in the 1990 bill. The legislation allows for the annual determination of the year's quota to avoid the previous situation of being manacled to a quota from years before. The government has set up a two-tiered pricing system which distinguishes between "quota peanuts" and "additional peanuts." Quota peanuts are used for domestic food products or for seed and receive higher price supports than additional peanuts. Additional peanuts can be sold only for export or for processing into peanut oil or peanut meal. Farmers may produce both quota and additional peanuts. The 2002 Farm Bill, signed by President Bush in May of that year, amended the Farm Bill by extending price supports to peanut farmers for the next six years.

Mint. Oregon is the leading producer of peppermint, followed by Washington and Idaho. Production costs can be high for growers. Spearmint is primarily grown in Washington, Wisconsin, and Indiana. Mint varieties, as

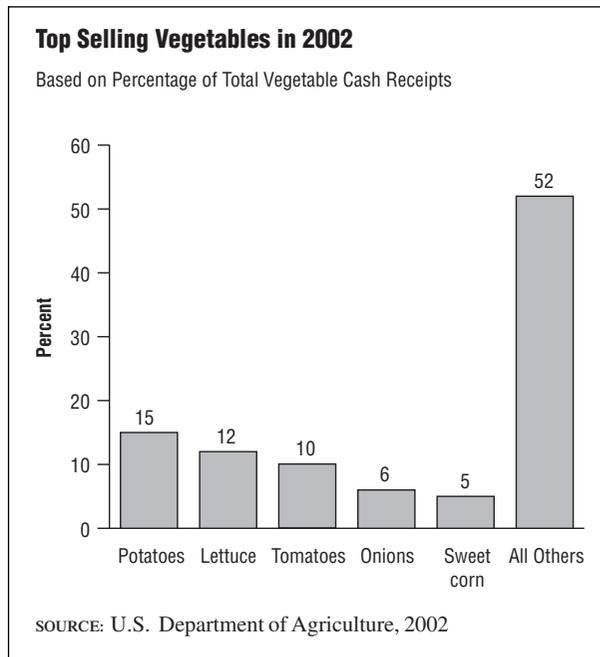

herbs and oils, have a host of applications, including being a spice, a cosmetic agent, an ingredient in tea, and a flavoring for toothpaste. Although the total number of peppermint acres harvested in the United States declined by nearly 1,000 in 2002 to reach 5,200 acres, yield per acre grew from 50 pounds to 60 pounds over the course of that year. Spearmint harvested in 2002 also fell by 1,000 acres, settling at 2,200 acres, as yield declined 24 percent.

SIC 0161

VEGETABLES AND MELONS

This entry includes establishments primarily engaged in the production of vegetables and melons in the open, including asparagus, beans, broccoli, cabbage, cantaloupe, cauliflower, celery, sweet corn, cucumber, green peas, lettuce, onions, peppers, squash, and tomatoes.

NAICS CODE(S)

111219 (Other Vegetable (except Potato) and Melon Farming)

Of the produce included in this category, tomatoes, onions, and iceberg lettuce led per capita consumption, as well as vegetable cash receipts, in the late 1990s and early 2000s. Vegetables and fruits (truck farm products) are the second largest food group in the United States by volume and consumption, behind milk and dairy products. California, Florida, Texas, Arizona, and New York are the largest truck farming states. Produce is sold directly to processors, wholesalers, retailers, or consumers by truck farmers. Large truck farms usually specialize in one or two crops for shipment to the rest of the country, while smaller farms may grow a large variety for sale at local farmers' markets, stands, and stores. Smaller farms may also market their produce together through a cooperative in order to negotiate better prices.

Truck farms developed as people moved to cities and could no longer grow their own produce. With the building of railroads and highways, and the development of

refrigerated transportation, truck farmers were able to ship their produce farther. Trucks and trains could carry out-of-season produce to the north from truck farms in the south.

Truck farmers in the United States have had to contend with periodic scares regarding the safety of fruits and vegetables. Various consumer and environmental groups claimed that too many pesticides, fungicides, and other chemicals were used on crops. Government agencies and industry groups, however, have insisted the food supply is safe and any chemical residue is well within government limits. Domestic growers have also defended their produce from fears about contaminated imports. Because produce is integrated into stores, usually without differentiation between foreign and domestic products, domestic growers have been concerned their produce would be affected by any suspicion about the quality of the imported goods.

In 1992 the Environmental Protection Agency (EPA) issued new rules requiring employers to protect farm workers from pesticide poisoning, although these national rules were still not as strict as those in place in California. The new rules barred employees from going back into freshly sprayed fields, with the quarantine periods ranging from 12 hours to three days, depending upon the chemical used. After pesticide concern continued to escalate, President Clinton signed a bill in 1996 that required the EPA to establish safe levels of tolerance for pesticide residue on both fresh and processed fruits and vegetables. The bill also mandates that the EPA register all new and old pesticides. Chemicals that cause "unreasonable adverse effects" will not be registered,

according to this piece of legislation. The bill also covers imported produce, calling for the rejection of any imports with unregistered pesticide residue or tolerance-excessive residue of any sort.

Tomatoes. Florida tomato growers compete with Mexico for winter tomato sales. In 1992, Mexican farmers were able to deliver tomatoes to the U.S. border at about half the \$9 production cost of a Florida-grown 25-pound box of tomatoes. However, in 1996, after receiving petitions from concerned growers, the United States and Mexico reached an agreement that would place a lower limit on the cost of a 25-pound box. The pact does not restrict the amount of tomatoes the United States imports; instead it ensures price equity. The tomato processing business had been very profitable and the industry expanded quickly, resulting in over production and excess capacity. Even though processing tomato farmers reduced acreage by 25 percent in 1992, the California yield was about 7.4 million tons of processing tomatoes.

California, Mexico, and Florida also produced the first genetically-altered tomato. After five years of testing, the United States Food and Drug Administration (USDA) approved for public consumption the first genetically altered food in 1994. Tomatoes grown by Calgene Inc. were cleared for distribution to the public under the Flav'r-Savr brand name. The tomatoes, which are more expensive than tomatoes grown through more traditional means, were created when scientists isolated the gene that causes tomatoes to soften. They then manipulated its genetic make-up to slow down the softening process, allowing more time on the vine for it to ripen. Public interest groups, however, allege that the altered tomatoes carry a gene that causes the plant to become resistant to antibiotics and charge that the presence of the gene may cause humans to build up the same resistance. Supporters of the process however, argue that health concerns are unfounded and point to the superior taste that results from the procedure. The controversy over the safety of genetically modified food extended into the early 2000s.

Tomatoes have also received some positive media attention as a Harvard medical researcher, Edward Giovannucci, MD, announced a preliminary link between tomato consumption and the reduced risk of developing prostate cancer. Tomatoes contain lycopene, a red carotenoid related to beta-carotene, to which Giovannucci has attributed this salubrious effect. Research on the effects of lycopene continues.

CURRENT CONDITIONS

Per capita vegetable and melon consumption dropped two pounds in 2002 to 439 pounds. An increase in canned and frozen vegetable consumption was offset by a decline in fresh vegetables, due in part to higher

prices and recessionary economic conditions. Top vegetable and melon growers in the early 2000s included R.D. Offut Company, Grimmway Farms, Tanimura and Antle, and Dole Fresh Vegetables.

The United States remains one of the largest producers and exporters of canned vegetables, although it has also increased its imports of fruits and vegetables, especially from the Caribbean and Latin America. The value of U.S. vegetable and melon imports in 2002 grew 6 percent to reach \$4.8 billion, while the value of exports rose 2 percent to \$3.3 billion.

The United States increased its tomato imports by 37 percent in 2002; as a result, imports accounted for roughly 8 percent of total U.S. tomato consumption. Per capita consumption of fresh tomatoes reached a record high of 18.3 pounds that year, despite the decline in consumption of other fresh vegetables. Florida and California harvested the majority of U.S. tomato crops.

The 1996 Farm Bill introduced a new era of market-oriented production that had ramifications on all agricultural sectors. Analysts received the bill favorably because the legislation offered farmers more flexibility and yet protected specialty crop growers from market fluctuations by stabilizing the commodity market. The bill was also expected to promote more sound business practices through the alleviation of surplus production, making U.S. producers more competitive in the twenty-first century. Additional legislation designed to increase the competitiveness of U.S. producers was signed by President Bush in May of 2002. Among other things, the 2002 Farm Bill mandates that vegetables and melons be labeled with their country of origin as of September 2004. Many industry analysts believe this will give U.S. vegetable and melon producers increased brand identity.

SIC 0171

BERRY CROPS

This industry covers establishments primarily engaged in the production of cranberries, strawberries, and bush berries. Agricultural products in this last category include blackberries, blueberries, currants, dewberries, loganberries, boysenberries, and raspberries.

NAICS CODE(S)

- 111333 (Strawberry Farming)
- 111334 (Berry (except Strawberry) Farming)

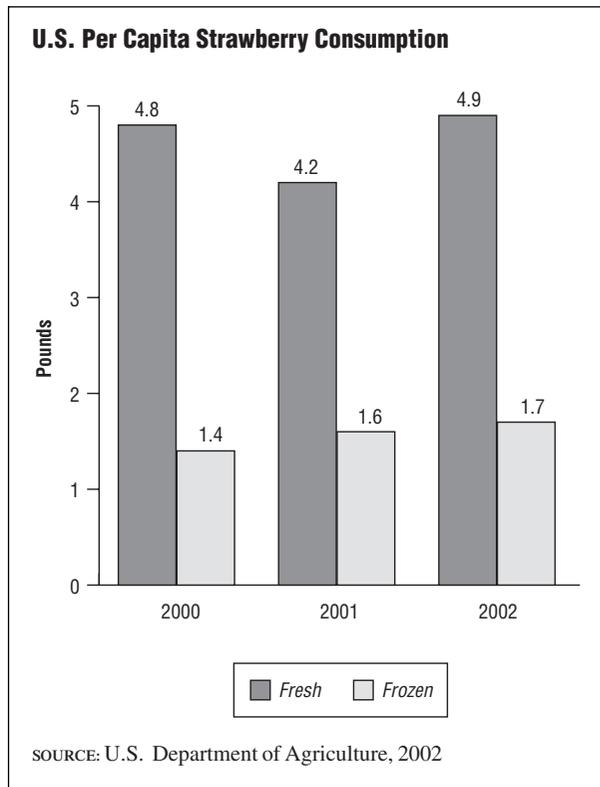

INDUSTRY SNAPSHOT

The berry industry in the United States has a history as old as the continent. Native American peoples relied heavily on certain berries as a staple in their diet and passed on their knowledge of the fruit to the first European colonists. The production of cranberries, strawberries, blueberries, and raspberries is a profitable agricultural enterprise that began in the early nineteenth century. In more recent decades, the industry has been dominated by large commercial farms, particularly in states like California, Oregon, and Washington. Research and development factors have become an influential element in the industry, as increasingly larger berry-growing companies employ scientists who work to genetically improve the fruit. Researchers also strive to combat the possible side effects of one uncontrollable factor—the weather. A late spring frost can seriously damage a farm’s entire harvest.

Fluctuations in consumer preferences also play a significant role in the industry. For instance, cranberries—fruit indigenous to North America—enjoyed a surge in popularity throughout the 1990s and into the early 2000s. Wisconsin is the leader in cranberry production, followed by Massachusetts, New Jersey, Oregon, and Washington. In 2002, farmers harvested 36,400 acres, which yielded 5.68 million barrels. The average yield per acre was 155 barrels. Cranberry production in 2003 was forecasted to reach 5.83 billion barrels.

Production of strawberries, the largest segment of this classification, is led by the state of California, which produces nearly 80 percent of the nation’s entire berry crop and nearly 10 percent of the world’s annual supply. An estimated 1.6 billion pounds, worth roughly \$1.08 billion, went to market in 2001. Per capita consumption of strawberries reached a record 6.6 pounds in 2002.

Production of blueberries, cultivated blackberries, boysenberries, loganberries, and raspberries all declined between 2002 and 2003. However, the value of produc-

tion of cultivated blackberries rose from \$21.8 million to \$31.4 million. The value of production of blueberries grew from \$20.0 million to \$21.8 million. New Jersey, Michigan, and North Carolina have been the leading producers of blueberries, while small commercial farms operating in California, Indiana, Maine, and Massachusetts also account for a percentage of the total blueberry output.

ORGANIZATION AND STRUCTURE

The berry industry in the United States is increasingly dominated by large agricultural enterprises. These farms employ a staff of horticulturists to develop and perfect new varieties of berries. Production and processing work on both commercial and smaller farms is carried out by large numbers of seasonal workers at harvest time. The berries are shipped out to a distribution center, where each farm receives the market price for its crop. Fresh berries destined for supermarkets are then shipped as quickly as possible, while the rest of the fruit is sent to processing centers to be frozen or used in other products such as juices. Larger commercial enterprises may have an in-house marketing staff that works with grocers to place their product in large eye-catching displays. However, much of the advertising end of the berry business is taken care of by umbrella groups. For instance, Ocean Spray Cranberries, Inc., a Lakeville, Massachusetts-based cooperative of growers, has launched national print, television, and radio advertising campaigns to in-

crease consumer awareness of the fruit. In the strawberry industry, growers belong to the California Strawberry Advisory Board, a collective organization responsible for marketing the fruit at both the height of strawberry season as well as in leaner months. The last type of group relies heavily on cooperative advertising efforts with grocery chains and produce retail outlets, but this is sometimes a difficult task. The campaign must be coordinated based on predictions of the likely date of the crop's ripeness, coupled with incorporation of other factors such as weather conditions and shipping problems.

CURRENT CONDITIONS

The production and sale of all types of berries have benefited from increased consumer health consciousness. Beginning in the 1980s, people began to incorporate more fresh fruits and vegetables into their diets as a way to reduce fat and increase vitamin and nutrient intake. Research in the 1990s revealed that berries are high in vitamin C and fiber, are low in calories, and contain high levels of antioxidants. The demand for berries of all types has dramatically increased over the years and in some cases has even doubled. In the early 2000s, the Agricultural Research Service discovered that blueberries, cranberries, and huckleberries contained resveratrol, a compound believed to help prevent cancer.

Cranberry harvests have also enjoyed a boom in recent years. In 1977 total output was 2.1 million barrels, valued at \$38.1 million. By 2003 production had nearly tripled to over 5.7 million barrels. The forecast for the 2003 crop was estimated to reach nearly 6 million barrels. Of all the major cranberry producing states, only Wisconsin expected a decrease. Production in Massachusetts was estimated to grow 17 percent to 1.7 million barrels in 2003, after jumping 20 percent in 2002. The New Jersey crop was expected to produce 470,000 million barrels, reflecting an increase of 9 percent from the previous year. Washington was forecasting production of 170,000 barrels, up 5 percent from 2002. Factors contributing to these increases were the lack of marketing restrictions in 2002 and 2003. Whereas growers were once allowed to sell only 65 percent of their average sales to processors, the lifting of these restrictions in 2002 allowed them to increase acreage significantly.

The increases in these harvests are also due to improvements in crop management that allow growers to harvest more berries per acre and at the same time better control some effects of inclement weather. Sales of fresh cranberries are tied to a short season in the fall, when they are harvested. This segment accounts for only 5 percent of the fruit's sales, but the product's use in traditional holiday dishes generates a strong demand during those few weeks. Dried cranberries or "craisins," on the other hand, have helped expand the cranberry market

beyond seasonal demand due to their use in cereals and fruit mixes.

Strawberry production is the most viable of all sub-industries classified in the category. In recent years both its production and value has escalated substantially. In 1977 the value of U.S. strawberry crops totaled \$219 million. By 2002, the value of these crops had grown nearly fivefold to \$1.08 billion. The majority of the strawberry proceeds, \$972.6 million, came from fresh-market sales, while about \$112.8 million came from processing sales. The U.S. Department of Agriculture (USDA) reported that the per capita consumption in the United States reached 6.6 pounds of fresh strawberries and 4.9 pounds of frozen strawberries.

RESEARCH AND TECHNOLOGY

Combating insect population and the ravages of horticultural diseases is a major preoccupation of berry growers across the United States. In states where a certain fruit is a vital component of the area's agricultural economy, government-financed research stations exist to study growing methods and problems. In the Massachusetts Cranberry Experiment Station, for instance, horticulturists and entomologists discovered in 1929 that the blunt-nosed leafhopper was responsible for the scourge of the "false-blossom" disease, which had devastated cranberry harvests for decades. They researched ways to eradicate it through pesticides and fertilizers. Cranberry producers have also experimented with increasing the yield from each crop in processing the berry. Since 1955, they have managed to triple the amount of product from each acre.

In the strawberry industry, research has played a vital role in the development of the business since World War II. Working with the California Department of Agriculture, growers were able to create new varieties of the fruit that could better withstand insects and the vagaries of rain and wind. Research into improved growing and harvesting methods, in conjunction with university agricultural labs, also made a great impact on the state's strawberry industry. By the early 1990s, one acre of land could produce twenty-five tons of the fruit, a tenfold increase over a decade. Other research has looked at increasing the amount of nutrients in fruits. In the 1980s government researchers detected traces of ellagic acid in strawberries, a compound thought to have cancer-inhibiting qualities. Since then, experiments have been conducted to increase the amount of the acid in the fruit as well as in other berries. Research reports made public in 1993 asserted that raspberries and strawberries were found to have their own natural mold-inhibiting compounds. Termed 2-nonanone, this compound occurs naturally in the fruit; when used to chemically treat the berry, it further prolongs the shelf life of the fruit with no adverse effects.

Research has also played a role in creating new product segments in this industry. The boysenberry is a recent type of fruit developed from loganberry, blackberry, and raspberry strains, yielding a seedless berry ideal for jams.

In 1998, five new cultivars of blackberries, blueberries, and strawberries were developed and released that had the advantage of ripening before or after the typical growing season, which made the berries available longer throughout the summer. The new berry cultivars were also developed to produce much larger fruit than existing commercial counterparts. One of the cultivars, the Black Butte berry, is almost twice the size of most fresh blackberries. The Siskiyou cultivar, which ripens a couple weeks ahead of the main berry season, has already developed a niche market. The Chandler cultivar, a highbush blueberry, is a large midseason berry that provides ripe fruit for four to five weeks. Most blueberries only ripen over a three-week period. Two new strawberry cultivars, named Firecracker and Independence, will produce berries longer, thus extending the strawberry season up to 3 weeks. The development of new cultivars continued well into the early 2000s.

SIC 0172

GRAPES

Establishments in this industry are primarily engaged in the production of grapes.

NAICS CODE(S)

111332 (Grape Vineyards)

INDUSTRY SNAPSHOT

Grape production has consistently constituted one of the largest U.S. non-citrus fruit crops, usually competing with apples for the greatest amount of total fruit produced. In the general fruit category, however, grapes have always trailed oranges. The farm value of the grape crop has totaled approximately \$1.5 billion to \$2 billion

each year since the mid-1980s. The two types of establishments engaged in the production of grapes in the United States are grape farms and vineyards. Grapes are grown for table use, processed into wine or juice, canned or frozen, and dried for raisins. California, Washington, and New York lead the country in grape production, although California alone produces about 90 percent of the country's grapes. California also leads in wine consumption. California had more than 100 wine grape farms in 2003.

While European grape varieties account for 90 percent of cultivated grapes in the world, early attempts to grow them in the United States were unsuccessful because of native pests and diseases. As a result, U.S. grape growers began domesticating native species. The Concord grape, an American variety, is a favorite of eastern growers and accounts for 80 percent of the eastern crop. Most eastern grapes are processed into grape juice and wine, while California is the major table grape growing region of the country.

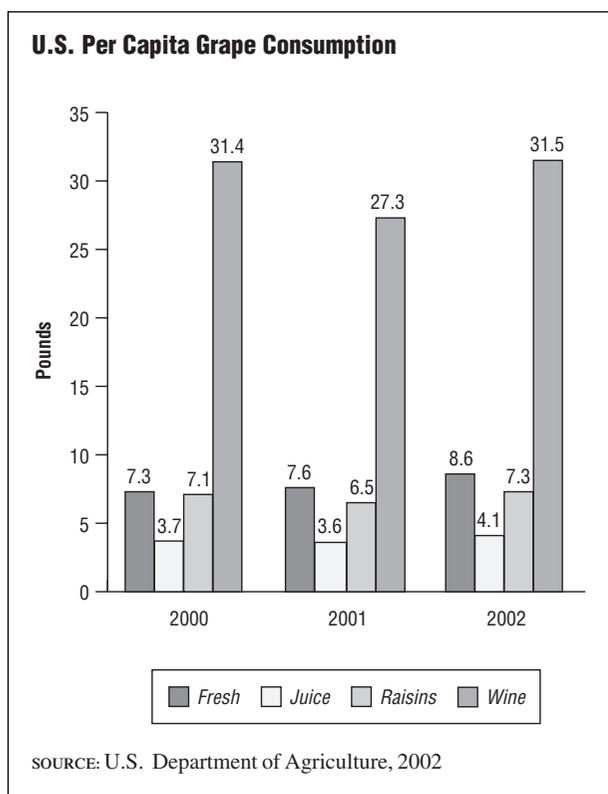

Grape growing is labor intensive. The vines are trained to grow on a system of stakes and wire and are pruned to develop the desired shape for maximum production and quality. Hand pruning continues throughout the year. Other practices used by growers to increase production or quality include thinning of the berries, and clusters and girdling.

The many diseases and pests that attack grape vines are a continuing threat to the industry. Throughout the late 1980s and early 1990s, the Napa Valley of California was infested with a new strain of root pest. Industry losses as a result of the infestation were estimated to be \$600 million.

Harvesting is also an arduous task, especially for table grapes, because they require special care to avoid bruising. Because of the higher cost for field labor, mechanical picking is used for grapes intended for wine or raisins.

The California Table Grape Commission has identified several important trends that benefit the grape industry. First, the large number of two-income households in the United States has increased the demand for convenience food items, and health-conscious consumers find that grapes meet all the criteria in convenience and nutrition. Second, children are playing a growing role in the marketplace with grapes being their number one snack food choice.

Exports of California table grapes to other countries have increased at record levels each year since 1985 and by the early 1990s represented 14 percent of the total crop. A saturated domestic market, a willingness of American farmers to grow varieties favored by foreign buyers, adoption of international packaging, and im-

provements in handling and shipping are credited with the dramatic rise in exports. California also hosts a thriving vineyard economy, producing many world-famous red and white wines. About 680 wineries in California produce over 90 percent of the country's wine. For red wine, the grape varieties zinfandel, cabernet sauvignon, and merlot made up 59 percent of California's red wine variety grape acreage in 1995 and 30 percent of the state's total wine variety grape acreage. For white wine, the grape varieties chardonnay, colombar, and chenin blanc made up 80 percent of the state's white variety grape acreage and 40 percent of California's total wine variety grape acreage.

CURRENT CONDITIONS

Research and innovation, coupled with encouragement from state governments, have transformed grape growing in the United States. Laws encourage research and promotional activities; new pest controls have reduced the amount of chemical control; and new cultivation techniques have increased quality. One of the most dreaded grape enemies is phylloxera, an aphid-like insect that attacks susceptible grape rootstock. Private industry and universities have developed varieties of grapes that offer greater diversity and that have superior pest tolerance and extended growing seasons.

In 2002, among the major fresh fruits consumed by Americans were bananas, apples, oranges, and grapes.

Combined, they accounted for nearly two-thirds of fruit eaten. Due to increased grape production and imports, per capita consumption of fresh grapes alone grew from 7.6 pounds in 2001 to 8.6 pounds in 2002. Raisin consumption increased slightly to 7.3 pounds in 2002, after several years of fluctuation. Grape juice consumption increased from 3.6 pounds in 2001 to 4.1 pounds in 2002, although it still remained below 1999 levels of 4.8 pounds. Despite recessionary economic conditions, consumption of grapes used to make wine increased from 27.3 pounds to 31.5 pounds. Prices for fresh-market grapes ranged between 27 cents per pound and 37 cents per pound in both 2002 and 2003.

In the early 2000s California's grape crop continued to grow despite a slowdown in the state's wine industry, which was valued at \$33 billion in 2002. Overproduction pushed prices down, which impacted growers throughout the state. Despite efforts by California grape growers to limit production, total U.S. wine grape harvests in 2003 were expected to grow 8 percent to reach 3.3 million tons, while raisin grape harvests were forecasted grow 7.2 percent to reach 400,000 tons.

Overcapacity was also exacerbated by a 28.4 percent increase in U.S. grape imports, which grew to 320.4 million pounds during the 2002-03 marketing season. Leading importers included Chile, Mexico, and South Africa. Wine imports also grew 10.7 percent to 150 million gallons. During this season, while wine exports increased 27.3 percent to 82.3 million gallons, overall grape exports decreased by 7 percent to 530 million pounds, and raisin exports dipped 2.7 percent to 96.2 million pounds.

Hit particularly hard by increased imports was California's San Joaquin Valley, which produced roughly 40 percent of worldwide raisin crops as of 2002. Lower labor costs, as well as reduced import tariffs, allowed Australia, Chile, Greece, Iran, South Africa, and Turkey to compete against California raisin growers. At the same time, higher export tariffs made it difficult for U.S. producers to compete internationally. As a result, the raisin industry began to curb production by paying farmers to pull vines or to allow raisins to die on the vines in 2002. Industry advocates began to call for additional intervention by the U.S. government.

INDUSTRY LEADERS

Some of the leading grape producers are the National Grape Cooperative Association Inc. of Westfield, New York, with annual sales of \$579 million in 2003; Guimarra Vineyards Corp. of Bakersfield, California, with estimated sales of \$100 million; and privately owned Delicato Vineyards with estimated sales of \$79 million.

SIC 0173

TREE NUTS

This classification covers establishments primarily engaged in the production of tree nuts, including almonds, filberts, macadamia nuts, pecans, pistachios, and walnuts.

NAICS CODE(S)

111335 (Tree Nut Farming)

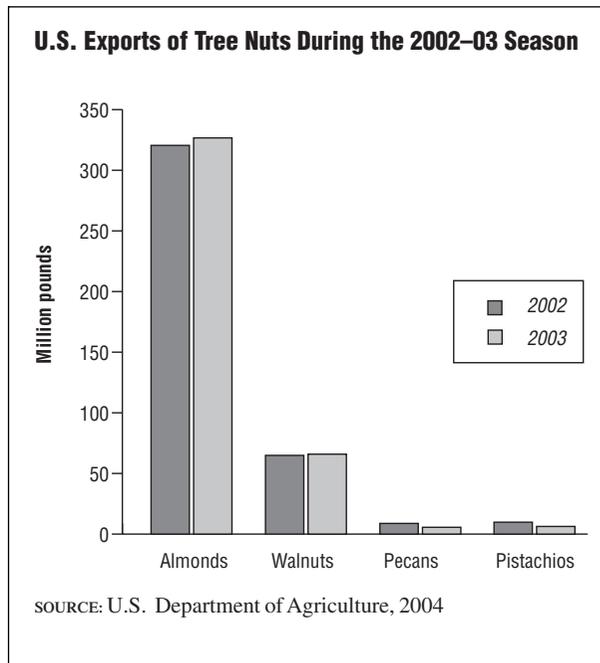

INDUSTRY SNAPSHOT

Nuts are high in unsaturated fat and low in saturated fat, and they are considered to be a high-energy food containing dietary fiber and essential vitamins and minerals. Most varieties are used throughout the year as nutritious snacks. Products containing nuts include ice cream, candy, assorted baked goods, and even, in the case of almonds, cosmetics.

The United States is a dominant world player in the commercial production of tree nuts with 875 companies claiming tree nut production as their primary operation. The total crop value of tree nuts produced in the United States was reported by the U.S. Department of Agriculture (USDA) to be approximately \$1.5 billion in 2001. By contrast, the value of the 1971 crop was only \$194 million. In addition, the per capita consumption rate was 2.5 pounds in 2001.

California alone grows 83 percent of U.S. nut crops. In fact, nearly all almonds, pistachios, and walnuts are produced in California. Almonds generate roughly \$1 billion in sales annually, making them California’s number-one export. Almond exports grew from 320 million pound to 326 million pounds during the 2002-03 growing season. California is also the second largest producer of pistachios in the world, behind Iran.

U.S. production of pistachios reached a record 243 million pounds in 2001, compared to just 1.8 million pounds in 1977. Filberts or hazelnuts are grown in Ore-

gon and Washington State, and production has more than tripled in 20 years, according to the USDA. Macadamia nuts are native to Australia but have become an important crop in Hawaii over the past 50 years. The outlook for macadamia nut producers is especially bright, as demand continues to exceed the available supplies.

The pecan, the black walnut, and the butternut (white walnut) are native to the United States. Pecans grow in the central and southern United States. Georgia is the leading pecan producer and also accounts for 5 percent of total U.S. tree nut production. New Mexico and Texas also produce pecans. Native walnuts grow throughout the central Mississippi Valley and the Appalachian regions. Only the imported English or Persian walnut, grown in northern and central California and Oregon, is considered to be of commercial importance. At the turn of the twenty-first century, per capita consumption of almonds, pecans, and pistachios was on the rise, while consumption of walnuts declined.

Almonds, the sixth largest U.S. food export, and the largest horticultural export, are shipped to more than 90 foreign countries. Europe and Japan are the largest markets for almonds, while Canada and Germany are the largest markets for U.S. tree nuts in general. Because per capita consumption of almonds remained at less than one pound as of 2003, U.S. almond growers tended to export roughly 75 percent of production. Exports to Europe received a boost with the passage of the General Agreement on Tariffs and Trade (GATT). Before its passage, almond shipments over 100,000 pounds incurred a 7 percent tax. A 2 percent tariff was imposed on shipments under 100,000 pounds. GATT doubled the allowable tonnage under the 2 percent limit and provided for a gradual

decrease of the 7 percent tariff to 5.5 percent. U.S. producers continue to seek new market opportunities.

Tree Nut Production in America. These nuts are grown in orchards using modern cultivation methods that include supplemental irrigation, fertilizers, and insect and disease control for maximum productivity. Harvesting is mechanized, with the exception of macadamia nut gathering, in which the nuts are shaken from the trees and transported to processing factories. Here the hulls or shells are mechanically removed, and then they are electronically sorted and graded.

BACKGROUND AND DEVELOPMENT

Government agencies have been instrumental in establishing the importance of tree nuts in the United States. Several important pieces of legislation have been implemented over the years, such as the almond marketing order that established the Almond Board of California in 1950 to stabilize the volatile almond market, and the creation of the California Pistachio Commission in 1981 to aid the development of the industry. In addition, the USDA has been instrumental in developing more productive varieties of pecans that have expanded the industry.

Though the consumption level dropped to a mere .5 pounds per capita, the 1995 almond crop still brought in a USDA-estimated \$1 billion. That same year California yielded 148 million pounds of pistachios from about 60,000 acres, a crop valued at about \$141.6 million.

Although well below 1993's record crop of 365 million pounds, 1995's 268-million-pound crop was much stronger than the previous year's 199-million pound yield. The USDA estimated that the 1995 crop had a value of almost \$250 million. The 1994 walnut crop weighed in at more than 235,000 tons with a value by the USDA at nearly \$239 million. In 1995, the United States exported 38,396 metric tons of shelled walnuts.

CURRENT CONDITIONS

After jumping to an all-time high of \$2 billion in 1997, the production value of tree nuts dropped back to \$1.4 billion the following year. By the early 2000s, this had increased to \$1.5 billion. Tree nut production in the early 2000s exceeded 2 billion pounds as both U.S. and international demand increased. Per capita consumption of tree nuts in the U.S. grew from 1.7 pounds in the late 1970s to 2.5 pounds in the early 2000s.

Due to increased production of pistachios, which reached a record 243 million pounds in 2000, the U.S. had become the second largest grower of pistachios in the world by the early 2000s. Accounting for 20 percent of total pistachio production worldwide, the United States was second only to Iran, which accounted for 51 percent of total pistachio production. U.S. pistachio growers ex-

port roughly 44 percent of their crops each year. Leading export markets include Hong Kong, Belgium, Italy, and Germany. Although pistachio exports declined 35.3 percent to 6.3 million pounds in the 2002-03 growing season, U.S. per capita consumption, which grew to a record high of one-quarter pound in 2001, continued to increase.

Increased demand for higher quality pecans in the early 2000s fueled an increase in U.S. pecan imports. During the 2002-03 growing season imports increased 31.2 percent, growing from 27.7 million pounds to 36.4 million pounds. Mexico is the leading supplier of pecans to the United States. Georgia typically produces roughly 33 percent of all U.S. pecans; however, difficult weather conditions in 2002 pushed that figure down to 25 percent. Exports of pecans during the 2002-03 growing season declined 35.3 percent, falling from 9.8 million to 6.3 million. Per capita consumption of pecans has averaged nearly one-half pound throughout the early 2000s.

INDUSTRY LEADERS

Founded in 1910 as the California Almond Growers Exchange, Sacramento-based Blue Diamond Growers is the largest almond grower-owned cooperative with 4,000 members. Blue Diamond's members produce one-third of California's almond crop. Sales in 2003 totaled \$433 million.

Diamond Walnut Growers, Inc., of Stockton, California, produces 50 percent of the country's walnut crop. Based in Hawaii, the privately owned Mauna Loa Macadamia Nut Corp. posted a net income of \$1 million on sales of \$17 million in 2001.

SIC 0174

CITRUS FRUITS

This industry consists of establishments primarily engaged in the production of citrus fruits.

NAICS CODE(S)

111310 (Orange Groves)

111320 (Citrus (except Orange) Groves)

INDUSTRY SNAPSHOT

Citrus fruits include oranges, tangelos, temples, tangerines, lemons, limes, and grapefruits. Oranges make up about 65 percent of total worldwide citrus production; tangelos, temples, and tangerines make up 15 percent; lemons and limes 10 percent; and grapefruits, 10 percent. Oranges and grapefruit account for approximately 90 percent of U.S. citrus production.

With more than 20,000 U.S. producers of all sizes, no one grower is dominant in the production phase. The industry governs its own marketing orders. Growers heed marketing factors as they specify grade and standard of crop leaving the region. They control the amount of product leaving the region during marketing season, and designate periods when no new product can be shipped. Growers also provide market support such as research and price information, and provide market development programs. Throughout the late 1990s and early 2000s, the number of citrus fruit acres planted has steadily declined. Acres planted in 2002 totaled 1.05 million, compared to 1.15 million in 1997.

ORGANIZATION AND STRUCTURE

Florida, California, Texas, and Arizona, all subtropical regions, produce the bulk of citrus fruits in the United States. Tropical cultivation is not as productive since seasonal changes are necessary for proper fruit growth. Citrus trees can withstand short periods of light frost, but hard frosts of long duration can be devastating.

The modern citrus industry depends on regular and frequent irrigation, fungicides, herbicides, pesticides, and other fertilizers. Harvesting is still often accomplished through manual means, although mechanical techniques are increasingly being used.

In the fresh fruit market, there is a great deal of competition, especially considering that, since around 1970, the per capita consumption of fresh oranges has declined, and since 1976, the consumption of fresh grapefruit has also decreased. With some fluctuations in between, per capita consumption of oranges has dropped from 16.2 pounds in 1970 to 12.1 pounds in 2002, while grapefruit consumption tapered off from 8.2 pounds in 1970 to 4.8 pounds in 2002. Of the total orange harvest in 2002, only 14 percent was consumed as fresh fruit, while 40 percent of grapefruits were consumed fresh. In the United States, almost all fresh citrus was garnered from domestic sources.

Processed fruit takes two forms: ready-to-serve juice (also known as single-strength equivalent, or SSE) and

concentrate. Both forms have become very popular among consumers, mostly for their convenience. The variety of canned, frozen, and ready-to-serve juices in supermarkets is clear evidence of how the public responds to the processed product.

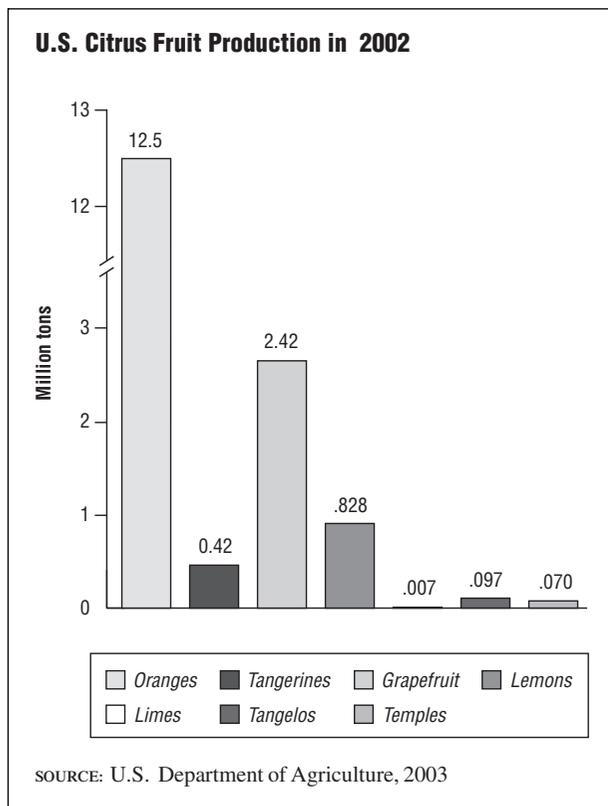

Citrus growers in the United States generally operate under one of three production philosophies. The first of these is to physically hand the fruit over to a packinghouse, processor, or middleman. A second option involves contracting with the packinghouse, processor, or middleman before the fruit is ready for harvest. In both cases, the seller and buyer agree to a satisfactory price before the fruit goes to market. The third option is an arrangement wherein the grower places his fruit along with a number of individual growers into a "pool" for sale on the open market. Profit is then determined by the selling price of the pooled fruit.

Citrus processing is a lucrative business. In addition to the primary products of frozen concentrate, chilled juice, and canned juice, processing also yields a number of by-products such as food additives, pectin, marmalades, cattle feeds (from the peel), cosmetics, essential oils, chemicals, and medicines. The processor can sell all these products to the appropriate industry for a profit.

BACKGROUND AND DEVELOPMENT

Until the 1950s, citrus fruits were cultivated and traded on a local basis almost exclusively. Speed and care in shipping the perishable fruits were of great concern. However, the development of citrus concentrate in the late 1940s had a lasting impact on the citrus industry worldwide. Concentrating the fruit permitted the storage, transportation, and transformation of product far from the groves. In contrast to fresh fruit consumption, processed citrus consumption has remained fairly stable since 1972. According to the Florida Department of Citrus, Economic and Marketing Research Department, per capita orange consumption in processed form (frozen concentrated juice, chilled juice, and canned single-strength) has fluctuated little since the early 1970s. Since the 1970-71 growing season, retail prices have risen steadily, in large part because of the healthy market for frozen concentrated orange juice.

By the 1995-96 growing year, Florida processed about 85 percent of the oranges and grapefruits grown in the United States, including 64 percent of its own orange production and 57 percent of its grapefruit crop. This process effort yielded 94 percent of the nation's frozen concentrated orange and canned orange juice, as well as 76 percent of canned grapefruit juice. In 1996, the USDA projected that U.S. orange juice production would rise to its record level of 1.3 billion SSE gallons. However, not all of the fruit processed was domestically grown. Nearly half of all processed juices available in America come

from imported juice concentrate. Under the North American Free Trade Agreement (NAFTA), for example, the United States must import 44.1 million (SSE) gallons.

In recent years, cooperatives have been created in all four citrus producing states; in Florida they account for 22 percent of that state's processing volume. Conglomerate integration—firms that are subsidiaries of national food conglomerates—is also a significant presence in the industry, processing 35 to 45 percent of all the citrus that Florida processes.

CURRENT CONDITIONS

According to the U.S. Department of Agriculture (USDA), the citrus industry, which is based primarily in Arizona, California, Florida, and Texas, produced 16.3 million tons of citrus fruit during the 2002 growing season, as opposed to the record-high 17.8 million tons produced in 1996. The drop in production is attributed to fewer acres planted, the result of reduced demand. Oranges constitute the country's largest fruit crop with nearly 12.5 million tons produced in 2002.

Total orange-bearing acreage in the United States reached its peak during the early 1970s. After receding for a period following the 1979-80 season, the total acreage devoted to citrus production began to rise in 1996-97, but has fallen off slightly since then. According to the National Agricultural Statistics Service (NASS), a division of the USDA, in the 2002 growing season, approximately 1.05

million acres were devoted to citrus production, compared to 1.15 million acres in 1997. Among the four major producing states, orange-bearing acreage was as follows: Florida had 70 percent; California had 28 percent; and Texas and Arizona together claimed approximately 5 percent of total orange-bearing acreage. Florida, as the major supplier of grapefruit, held around two-thirds of the acreage of the crop. Texas and California together accounted for nearly 23 percent of grapefruit acreage.

After peaking at 13.6 million tons in 1998, orange production in the United States plunged to 9.8 million tons before rebounding to 12.2 million tons in 2001. Production climbed further to 12.5 million tons in 2002. Grapefruit production has seen a more gradual, consistent decline with production falling from 2.6 million pounds in 1998 to 2.42 million pounds in 2002. Tangerine production climbed from 373,000 tons in 2001 to 420,000 tons in 2002, while lemon production dropped from 996,000 tons to 828,000 tons and lime production fell from 11,000 tons to 7,000 tons over the same time period.

The citrus industry has also been enmeshed in controversy in recent years. Citrus growers have long enjoyed the benefits of Depression-era laws that established quotas governing citrus sales. Deepening concern about reputed abuse of the quotas by Sunkist and a number of its leading cooperative members prompted the government to eliminate 1993 marketing orders for navel oranges. With the quotas effectively blunted, wholesale prices plunged. Sunkist has been particularly wounded, both by the allegations that the firm used these quotas to increase retail prices and the financial difficulties brought on by the removal of the quotas. Despite their ongoing tribulations, however, Sunkist, with sales of \$964 million in 2002, remains the world citrus industry's wholesale giant.

INDUSTRY LEADERS

Leading establishments in the citrus fruit production industry are located in Florida and California. Companies such as Duda and Sons Inc., Lykes Bros., Inc., Orange-Co Inc., and Ben Hill Griffin Inc. are among the leaders in Florida, while leading companies in California include Royal Citrus Co., Limoneira Co., ET Wall Co., and Pandol Brothers.

The best known distributor of citrus fruits in the United States is Sunkist Growers, Inc. For the past 104 years it has been the dominant force for citrus growers in California and Arizona, and is a formidable presence in Florida as well. It operates a cooperative of some 6,000 members and accounts for 65 percent of the growers in the states of California and Arizona.

AMERICA AND THE WORLD

The largest citrus producing countries, accounting for more than 70 percent of the world's supply, include

the United States, Brazil, Japan, Spain, Italy, Egypt, South Africa, and Morocco, with Brazil leading the world in citrus production. With oranges and grapefruit accounting for approximately 90 percent of all U.S. citrus production, Florida has become a world player; it, along with Brazil, produces most of the world's concentrate.

While the U.S. fresh and processed orange industry is domestically oriented, imports are expected to grow largely due to two factors: the heightened demand for chilled orange juice and improved port facilities. At the same time, these improved facilities allow for more exports, a facet of the industry that growers are trying to enhance. The United States exports orange concentrate to both Canada and Mexico. These exports account for less than 10 percent of the total American domestic supply. Demographically and in price structure, the Canadian market differs little from the United States, and before 1986, Canada was the major purchaser of U.S. exports of orange concentrate. Since January 1994 when the NAFTA guidelines were implemented, frozen concentrated orange juice (FCOJ) exported to Mexico has quintupled, whereas the importing of SSE orange juice has gradually decreased about 20 percent of what it was in 1990. Also on account of NAFTA, which gives products from the United States preferential treatment, all citrus juices made from only one fruit must come only from NAFTA-grown fruit.

In contrast, the European market is very different demographically from the United States. European imports from other suppliers, such as Spain, are priced substantially lower than the American product. To alleviate the disparity, the industry has proposed a two-price system, in order to maintain the price of concentrate sold domestically (already higher relative to the rest of the world), and export the concentrate at a lower price to successfully compete.

To further interest in concentrate produced in the United States, which has been steadily declining in popularity for ten to fifteen years, growers have advanced programs in quality control, packaging innovations, and cross-merchandising, where, for example, FCOJ is paired and successfully marketed with another breakfast food such as waffles. The Duty Drawback Program is another program designed to encourage processors to develop foreign markets. It states that if, within a three-year period, a processor or importer exports a specific quantity of concentrate, duties paid on imports of "like concentrate" will be refunded, or "drawn back."

The export of fresh grapefruit is also of concern to U.S. growers, especially when dealing with Japan. Trade restrictions, import quotas, embargoes, and tariffs have resulted in substantially higher prices for American grapefruit in the Japanese market, yet, even with home-grown

grapefruit available, the demand in Japan for fresh grapefruit allows U.S. growers to capitalize on the market.

Citrus exports to Korea grew 41 percent in the 2001 growing season due to lower duty fees there. As part of the Uruguay Round Agreement, Korea had established a quota of 15,000 tons for citrus fruit in 1995. As stipulated by the agreement, this quota increased by 5,000 tons in both 1996 and 1997. Thereafter, it increased by 12.5 percent annually through 2004. U.S. exports to Korea that meet the quota requirements are charged significantly less duty than non-quota imports.

SIC 0175

DECIDUOUS TREE FRUITS

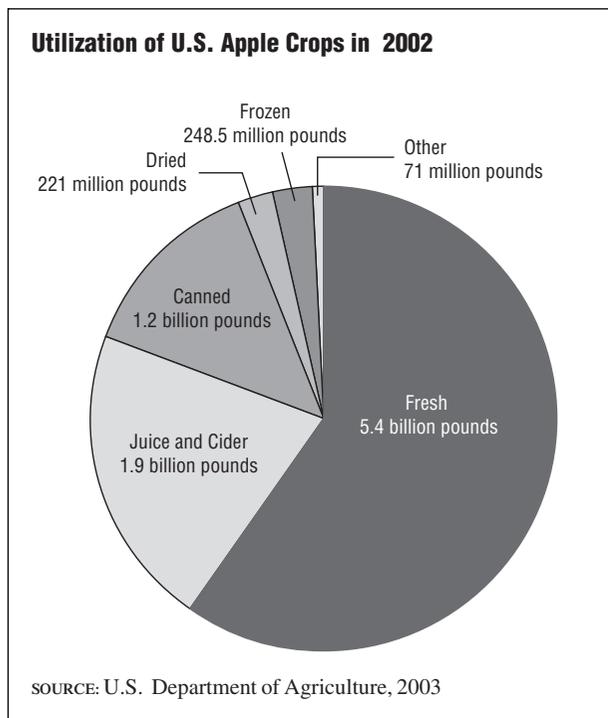

This classification includes establishments primarily engaged in the production of deciduous tree fruits. Establishments primarily growing citrus fruits are classified in **SIC 0174: Citrus Fruits** and those growing tropical fruits are classified in **SIC 0179: Fruits and Tree Nuts, Not Elsewhere Classified**.

NAICS CODE(S)

111331 (Apple Orchards)

111339 (Other Noncitrus Fruit Farming)

The deciduous fruit industry consists of farms and orchards that maintain and harvest a variety of fruits, specifically apples, apricots, cherries, nectarines, peaches, pears, persimmons, plums, pomegranates, prunes, and quinces. According to the U.S. Department of Agriculture, apples led 2002 crop production with 4.2 million tons, followed by 1.2 million tons of peaches, 912,000 tons of pears, and 690,000 tons of prunes and plums. The value of the apple crop alone in 2002 was in excess of \$1.6 billion. The apple crop also constitutes the country's third largest fruit crop, trailing grapes and oranges.

In 2002, more than 1.8 million acres of farmland were devoted to the growth of major deciduous fruits in the United States. This is indicative of the steady market for deciduous fruits, as the acreage devoted to deciduous fruits 15 years earlier was about 1.7 million acres and harvesting techniques have allowed growers to glean more fruit from fewer trees.

Deciduous fruits are divided into two groups according to climate requirements: warm-temperate fruits and cool-temperate fruits. Warm-temperate fruits include apricots, peaches, and plums. Cool-temperate fruits include apples, pears, and cherries. Both categories need a certain, short-period of low temperatures during winter dormancy, called a chilling period, in order to flower and produce fruit.

Chilling periods vary greatly not only among disparate fruits, but among different varieties of the same fruit as well. For example, some varieties of peaches require 250 hours of chilling while others demand as many as 1,000 hours. Apples and cherries generally need more than that. An inadequate chilling period can result in a number of problems. Flower buds may die or blossoms may drop before they open. Those flowers that do develop may not set fruit, or the fruit may be undersized. Growers consider the chilling period of primary importance in the success or failure of their crops. These temperature conditions therefore preclude commercial production of deciduous fruits in colder or warmer climates.

Top deciduous fruit producers by revenue are CM Holtzinger Fruit Company and Wells and Wade Fruit Company, both located in Washington. Top apple and

pear companies by acreage are Stemilt Management and Naumes. Top stone fruit companies are Gerawan Farming and Lane Packing.

Apples. More land is devoted to the growing of apples than any other fruit in this category. Leading apple-producing states are Washington, New York, Michigan, and California. Out of nearly 8.6 billion pounds of apples produced in 2002, Washington accounted for 5.3 billion pounds; New York, 650 million pounds; Michigan, 500 million pounds; and California, 420 million pounds. U.S. producers faced consistent worldwide demand for apples, though competition from France and New Zealand remained strong. In the 2001-02 marketing year, Taiwan, Canada, and Mexico were the major importers of U.S. apples, accounting for more than 50 percent of all U.S. apple exports, according to the USDA. Canada, Chile and New Zealand were the largest exporters of apples to the United States.

Apricots. Apricot production in the United States has been fickle in the last decade. Although production climbed to 153,200 tons in 1994, it plummeted to a mere 60,500 tons in 1995. In 1998 production was back up to 118,000 tons, but by 2001 this had dropped back down to 82,460 tons. Production in 2002 rebounded to 90,140 tons. California, Washington, and Utah are the leading apricot producing states, with California producing the lion's share of the crop. The domestic usage distribution for 2002 was as follows: 18,090 tons were fresh market, 30,500 tons were canned, 8,000 tons were dried, and 10,500 tons were frozen.

Cherries. Cherries, classified as two types, (sweet and tart), have experienced waning demand in the late 1990s and early 2000s. Whereas production yielded more than 384,000 tons, by 2002 this had fallen to 180,200 tons. The value of the 2002 crop was estimated at about \$301 million. Sweet cherries accounted for more than half of the total cherry production. Leading sweet cherry producing states include Washington, Oregon, Michigan, and California. Leading tart cherry producing states included Michigan, Utah, and Wisconsin. In 2002, roughly 5,780 tons of sweet cherries were canned or otherwise processed, while 126,455 tons were fresh and 24,340 tons were brined. Nearly 29 million pounds of tart cherries were frozen, more than 17 million pounds were canned or otherwise processed, and approximately 800,000 pounds were fresh.

Peaches. After declining from 1.31 million tons in 1997 to 1.21 million tons in 2001, peach production increased to 1.28 million tons in 2002. Throughout the early 2000s, per capita consumption of peaches declined steadily, falling 9.3 pounds in 2002. Of this total, 5.3 pounds were fresh, 3.4 pounds were canned and one-half pound were frozen. California, South Carolina, Georgia, and New Jersey rank as the leading producers of peaches in the

United States, Canada, Japan, and Latin American countries have been major importers of U.S. canned peaches. U.S. peach exports declined from 271 million pounds to 269 million pounds during the 2002-03 growing season, while imports during this season jumped 20.2 percent to 124 million pounds.

Pears. The United States is the third leading producer of pears, growing roughly 5 percent of worldwide pear output, compared to the 52 percent grown by China and the 6 percent grown by Italy. Consequently the United States exports nearly 35 percent of its pear crop. Throughout the 1990s and into the early 2000s, acreage devoted to pears steadily declined, falling to 63,150 in 2003. Pear production between 2000 and 2002 totaled 1.9 billion pounds, roughly 58 percent of which was sold fresh. Washington, California, and Oregon consistently lead the country in pear production. The Pacific Bartlett variety accounts for more than 50 percent of the U.S. pear crop, according to the USDA.

Plums and Prunes. Throughout the late 1990s and early 2000s, plum and prune production fluctuated. Whereas producers yielded 926,000 tons in 1997, only about 559,000 tons were produced in 1998 and 735,000 tons in 1999. Production jumped to 902,000 tons in 2000, only to fall again to 690,000 tons in 2002. Oregon and Idaho are the leading producers of plums and prunes. Washington has cut production in half since 1986.

ments deriving 50 percent or more of their total value of sales of agricultural products from fruits and tree nuts (Industry Group 017) but less than 50 percent from products of any single industry.

NAICS CODE(S)

111336 (Fruit and Tree Nut Combination Farming)

111339 (Other Noncitrus Fruit Farming)

This relatively small American industry produces fruits that are normally grown in more tropical regions of the hemisphere. Members of this category are avocado orchards, banana farms, coconut groves, coffee farms, date and fig orchards, kiwi fruit farms, olive groves, and pineapple and plantain farms. Avocado, olive, and date production comprises the bulk of crops in this category. Most producers are small commercial enterprises situated in warmer states such as Hawaii, California, and Florida. The number of such farms engaged in producing fruits and tree nuts in this industry has been in steady decline since the 1980s. The production value for tree nuts was \$1.5 billion in the early 2000s, while the value of U.S. fruit production was roughly \$10.5 billion. The value of fruits, tree nuts, and berries is forecast to increase by about \$4.9 billion between 2003 and 2012.

As of 2004 the two top companies were Dole Food Company of Westlake Village, California, a privately owned company with over \$4.3 billion in revenue, and Chiquita Brands International, of Cincinnati, Ohio, which emerged from Chapter 11 bankruptcy in 2002 to post sales of roughly \$1.4 billion.

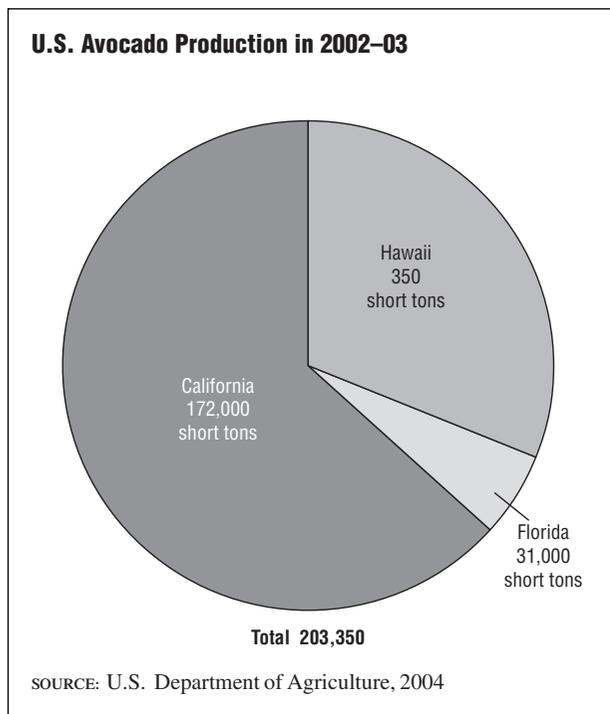

Looking at the individual components of this industry classification is necessary due to great fluctuations in various crop yields from year to year. The apparent lack of any one statistical pattern over a span of a decade may be due to the fragile nature of such perishables as avocados and olives. These smaller, exotic crops are extremely dependent on favorable weather conditions for the success of the year's harvest. The import market also plays some role in the fluctuation within the industry.

California avocados continue to yield steady profits for growers, who produce about 90 percent of the American avocado crop; Florida produces almost all of the rest. Despite wildfire damage in California during 2003, the state still managed to increase production 15 percent to 198,000 short tons in the 2003-04 growing season. Florida avocado production increased from 23,000 short tons in 2001-02 to 31,000 short tons in 2002-03. Many U.S.-grown avocados are exported to Canada, Japan, the Netherlands, and France. Imports account for roughly 33 percent of U.S. avocado consumption, compared to 17 percent in the early 1990s. As of 2003, Chile remained the leading supplier of avocados to the United States, accounting for 65 percent of total imports.

SIC 0179

FRUITS AND TREE NUTS, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in the production of fruits and nuts, not elsewhere classified. This classification also includes establish-

California is also the center of olive production in the United States. Black olives are the most commonly grown variety. The output from the state's olive groves varies greatly from year to year; production dropped from 134,000 tons in 2001 to 99,000 tons in 2002. In this sector approximately 2 to 5 percent of the year's crop is crushed for oil. Much of the rest is canned or used in other products.

Date production in the United States is centered primarily in Coachella Valley, an arid region about 130 miles east of Los Angeles. In the early years of the twentieth century, ranchers received date plantings from the USDA as an incentive to settle the region. The industry did not begin to thrive until 1913, when a collective organization was formed to purchase imported date plants from North Africa. In 2002 production was roughly 20,000 tons.

The center of the U.S. fig-growing industry is likewise located in California. Per capita consumption in the United States, however, has declined steadily since the 1960s. Though they are grown year-round, fig harvest is at its heaviest during the fall months. In 1993 production reached the highest levels since 1966—59,000 tons—but sank to 40,000 in 2001. Imported figs from Turkey and Spain provide the greatest competition to American fig growers.

Hawaii is the center of the coffee-growing industry in the United States; it is also the locus of American banana production. This state's annual banana yield has seen steady increases since the 1980s—with some declines

from year to year. In 2001, 28,000 tons were produced, although this figure dropped to 19,000 tons in 2002. And while U.S. banana consumption rose to 30.7 pounds in 1999, by 2002 this had waned to 26.7 pounds. The largest American grower—Cincinnati-headquartered Chiquita Brands International—performed poorly as a result of a corporate takeover; in 1995 the value of one of its shares rose only one cent. Chiquita's main rival, the Dole Food Company, assumed Chiquita's former number-one spot in the market. Eventually Chiquita filed for Chapter 11 bankruptcy protection, from which it emerged in 2002.

In this industry, growers of fruits and tree nuts face stiff competition from foreign competitors. This sector of agriculture in the United States is relatively small compared to its status in other countries. For instance, countries in North Africa produce a sizable portion of figs and dates for export abroad, while olive tree acreage figures for areas in the Middle East, Greece, and Italy are staggering. In such countries these industries have been vital components of the local economy for literally thousands of years. Coffee growers in the United States face heavy competition from foreign countries—most notably Brazil, Mexico, and Ecuador. However, American growers are finding some success in the cultivation of exotic fruits such as mangoes and passion fruit.

SIC 0181

ORNAMENTAL FLORICULTURE AND NURSERY PRODUCTS

This category includes establishments primarily engaged in the production of ornamental plants and other nursery products, such as bedding plants, bulbs, florists' greens, flowers, shrubbery, potted plants, flower and veg-

etable seeds and plants, and sod. These products may be grown outdoors, or under cover of a greenhouse, frame, cloth house, or lath house.

NAICS CODE(S)

- 111422 (Floriculture Production)
- 111421 (Nursery and Tree Production)

The floriculture market increased by 2 percent in 2002, after having slowly but steadily climbed throughout the decade from \$2.5 billion in 1990 to \$3.9 billion in 1998. The wholesale value of floriculture crops was estimated at \$4.88 billion in 2002. The leading floriculture crop producer, California, accounted for \$962 million of this total, while Florida accounted for \$877 million. Combined, the two states produce 38 percent of U.S. floriculture. The total number of growers declined 8 percent in 2002 to 10,216.

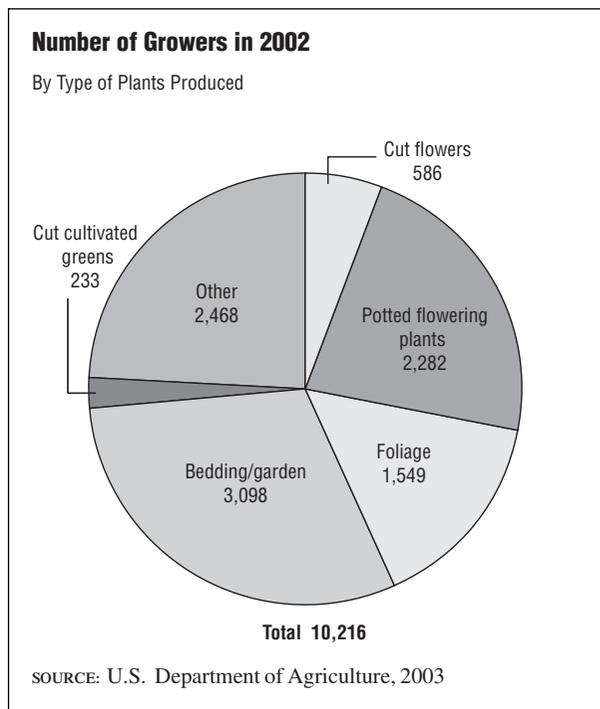

With a wholesale value of \$2.28 billion, bedding and garden plants account for 49 percent of floriculture crops. Between 2001 and 2002, the value of bedding and garden plants rose 5 percent, accounting for the majority of industry growth. The wholesale value of foliage plant crops grew 2 percent to \$663 million in 2002, while the value of cut flower crops dropped 2 percent to \$410 million, reaching its lowest point since 1986. This segment of the industry suffered in part due to increased foreign competition. The value of potted flowering plants remained steady at \$822 million.

California, Florida, Texas, Michigan, and Ohio were the top producers of bedding plants. They accounted for 42 percent of the 2002 value of floriculture crops. Bedding plants included impatiens, petunias, geraniums (the 2002 top-seller), marigolds, pansies, and more. Begonias, zinnias, salvia, gerbera, dusty miller, snapdragons, alyssum, and coleus also had a healthy share of the market.

Also in 2002, according to the USDA, the amount of covered area in floriculture crop production was 911 million square feet, down from 1.07 billion square feet in 1997. Greenhouse space was 531 million square feet of this covered area, while film plastic structures were 368 million square feet. Shade and temporary cover accounted for 380 million square feet of covered area, the remaining area being rigid plastic or glass greenhouse area.

Operations increased the use of hired workers in 2002. Overall, 79 percent used hired workers in 2002, compared with 78 percent in 2001. On average growers used 15.3 hired workers per operation in 2002.

The cut-flower industry continued to suffer from foreign competition, particularly from warmer climates where growers do not need to heat greenhouses and labor is less expensive. After declining steadily in the late 1990s, the cut-flower industry was down another 2 per-

cent in 2002. The number of cut flower growers fell 6 percent to 586 in 2002. California produces roughly 68 percent of all U.S. cut flowers. Imports account for approximately 60 percent of cut flowers sold in the United States, with the top import countries being Colombia, Ecuador, and the Netherlands.

The month of May, which includes Mother’s Day, accounts for approximately 11 percent of florists’ annual sales. According to industry statistics, the personal consumer breakdown of floriculture was as follows: outdoor bedding/garden plants, 49 percent; cut flowers, 28 percent; flowering/green houseplants, 23 percent.

Industry leaders include Hines Horticulture, Inc., with 2002 sales of \$336 million; The Scotts Company, with 2003 sales of \$1.9 billion; and privately owned Color Spot Nurseries. The mega-company Monsanto, with 2003 sales topping \$3.3 billion was also a major player, as well as being in a variety of other related feed and seed agricultural businesses. Other industry leaders included Ohio-based Yoder Brothers Inc., Idaho-based Rogers Seed Company, and California-based Monrovia Nursery Company.

SIC 0182

FOOD CROPS GROWN UNDER COVER

This industry consists of establishments primarily engaged in the production of mushrooms or fruits and/or vegetables grown under cover.

NAICS CODE(S)

111411 (Mushroom Production)

111419 (Other Food Crops Grown Under Cover)

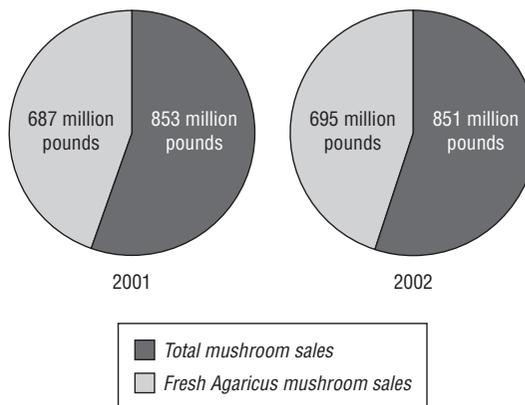

Mushrooms are by far the largest segment of crops grown under cover. According to the U.S. Department of Agriculture (USDA), mushrooms were the fourth-largest vegetable crop in 2001, after potatoes, tomatoes, and lettuce. That year, U.S. growers sold 853 million pounds of mushrooms—a value of nearly \$863 million. Although production tapered off slightly in 2002, falling to 851 million pounds, the value of total mushroom production increased 5 percent to \$912 million.

Specialty mushrooms, including the *Agaricus* variety, account for 18 percent of total mushroom sales in the United States. *Agaricus* mushrooms combined with shiitake, oyster, and other specialty mushrooms to generate \$156 million in sales for 2001. Nearly half the *Agaricus* mushrooms grown in the United States come from Pennsylvania. California ranks second in *Agaricus* mushrooms production. Brown *Agaricus* mushrooms—which include Portabella and Crimini varieties—are the fastest growing sector of the mushroom industry. Between 1999 and 2002, Brown *Agaricus* mushroom sales grew more than twofold to 50 million pounds.

The top two companies in the industry at the turn of the twenty-first century were Monterey Mushrooms, Inc. of Santa Cruz, California, with \$160 million in sales; and Vlastic Farms, Inc. of Blandon, Pennsylvania, with \$150 million in sales.

In the late 1990s and early 2000s, sales of processed mushrooms declined as imports increased and as consumers increasingly preferred fresh mushrooms. In 2001, sales of processed mushrooms declined 18 percent, reaching their lowest level in 30 years. In contrast, fresh mushroom sales, particularly of *Agaricus* mushrooms, continued to climb. Fresh *Agaricus* mushroom sales totaled 695 million pounds in 2002. Due to an increased supply of fresh mushrooms, the trend in the mushroom industry has moved toward lower prices. Production effi-

U.S. Mushroom Sales in 2001 and 2002

SOURCE: U.S. Department of Agriculture, 2003

ciency allows growers to harvest about 5.75 pounds per square foot.

Early in 1993, the National Mushroom Research and Promotion Act was passed. Under the act, producers and importers of fresh mushrooms with sales of at least 500,000 pounds can be assessed up to one cent per pound by the Mushroom Council to be used in generic promotion and research.

SIC 0191

GENERAL FARMS, PRIMARILY CROP

This industry classification is comprised of establishments deriving at least half the value of their total agricultural sales from crops, but less than 50 percent of the sales are from the products of any single, three-digit industry group. Crop farms deriving 50 percent or more of their total agricultural sales from products classified within a

single three-digit grouping are classified according to that grouping.

Specified three-digit classifications are: 011 cash grains (wheat, rice, corn, and soybeans); 013 field crops (cotton, tobacco, sugarcane, sugar beets, and potatoes); 016 vegetables and melons; 017 fruits and tree nuts (berries, grapes, citrus and tree fruits such as apples, cherries, peaches, and pears); and 018 horticultural specialties (ornamental and nursery products and food crops grown under cover, such as mushrooms and bean sprouts).

NAICS CODE(S)

111998 (All Other Miscellaneous Crop Farming)

INDUSTRY SNAPSHOT

Farming has long been one of the staple industries in the U.S. economy, and at the beginning of the twenty-first century, the United States was the world leader in crop harvesting. Like many industries, crop farming underwent rapid consolidation in the late 1990s, in which large agribusiness firms increasingly took the place of smaller family farms, resulting in reduced employment levels, as farms tried to boost efficiency to remain competitive.

According to the U.S. Department of Agriculture, in 2001 there were 2.16 million farms in operation in the United States, up just a fraction from 2000. This increase of approximately 0.1 percent occurred primarily in small farm operations of \$1,000 to \$9,999 in sales. The total cash receipts for agricultural crops sold in 2001 fell to \$88.5 billion, down from \$106 billion in 1997. Nearly three-quarters of total sales was derived from various grains, of which the largest portion came from corn for grain, which brought sales of \$19.2 billion. Other major sources of revenue in 2001 included hay (\$12.6 billion); soybeans (\$12.4 billion); fruits, nuts, and berries (\$11.6 billion); vegetables (\$10.4 billion); wheat (\$5.6 billion); cotton (\$3.4 billion); and tobacco (\$1.9 billion). In 2000 net income for the U.S. farm industry was \$46.4 billion, down from a decade-high \$54.8 in 1996, but up from a decade-low \$36.9 in 1995.

In addition to battling chronically low agricultural-commodity prices in the late 1990s and early 2000s, farmers faced a host of challenges relating to environmental and health concerns. As consumers and regulators placed heightened emphasis on water and land conservation and the minimization of pollutants, many farmers have rapidly attempted to reorganize their production to become more environmentally sound. Moreover, concern was on the rise over the presence of chemicals in foods, forcing farmers to rethink their pest- and quality-control practices. Finally, the practice of genetically modifying seeds and foods has generated national and international

controversy relating to environmental, economic, health, and ethical concerns.

ORGANIZATION AND STRUCTURE

In 1997, 86 percent of farms classified in the industry were owned by sole proprietors. Nine percent were organized as partnerships, two percent were family corporations, and about two percent were held by non-family corporations. The remainder were operated by other entities, such as cooperatives, institutions, and estates. These statistics were comparable to the ownership structure for all U.S. farms.

Farm operators were classified by their ownership interest in the land. Full owners owned the land they operated; part owners operated part of their own land and rented the remaining land; tenants rented the land they worked. Sixty percent of all general crop farms were predominantly operated by full owners, while partners operated 30 percent and tenants 10 percent.

BACKGROUND AND DEVELOPMENT

European colonists learned about cultivating plants indigenous to the United States, developed an agricultural industry, and modified it to suit their own needs. European settlers brought horses and oxen to the continent and put them to work as draft animals. They imported seeds and introduced wheat, rice, barley, oats, rye, and buckwheat. In areas with rich soil, abundant production soon surpassed local demand, and, during the seventeenth century, exports were used to finance imports of manufactured goods. Crop production varied by area; in New York, Pennsylvania, New Jersey, and Delaware, farmers were primarily grain producers. In addition to grains, farmers in Maryland, Virginia, and North Carolina grew tobacco and vegetables. Rice and indigo were the main crops in South Carolina and Georgia. Commercial production of indigo, which had prospered under British rule because of preferential trade treatment, ceased following the Revolutionary War. Cotton was not fully developed as a commercial crop until later.

Colonies were generally forbidden to trade with countries other than their "mother" country. English colonies traded only with England; Dutch colonies traded only with Holland; Spanish colonies traded only with Spain; and French colonies traded only with France. This type of trade restriction was one of the contributing factors leading to the Revolutionary War.

Events surrounding the war's conclusion set the stage for the development of farming practices within the United States. Under the terms of the peace treaty signed in 1783, England surrendered its claim to the colonies and its claim to an additional 237 million acres located west of the Ohio River. The original 13 states agreed that the western territory would be held in public domain by

the federal government for the purpose of distributing it equitably to settlers.

The process of selling units of western land to farmers began in 1785, two years before the Constitution was adopted. Under the terms of the Land Survey Ordinance, lands were portioned off into townships containing 36 sections of 640 acres (one square mile per section). These were further subdivided into 16 units. Farmers could purchase up to four units, equaling one-quarter section (a total of 160 acres), at one dollar per acre. Within 10 years of the end of the Revolutionary War, an estimated 100,000 settlers had begun farming in the Ohio River valley and the Cumberland River valley.

Farmers who moved west often left depleted soils in the east. Overproduction of single crops, such as cotton or tobacco, drained the land of the nutrients needed to maintain soil fertility. Thomas Jefferson was a leader against the practice of single-crop agriculture. He believed that farms should be diversified and self-sufficient. His experiments with crop rotation and botanical research made significant contributions to the nation's agricultural industry. Jefferson also developed an improved "moldboard" to improve plowing efficiency. (A moldboard was the part of a plow that turned the soil.) To help farmers share agricultural knowledge, agricultural societies were formed.

A major innovation occurred at the end of the eighteenth century, when Eli Whitney invented the cotton gin, a mechanical device able to separate cotton fibers from cotton seeds. The combination of the cotton gin and slave labor made cotton a profitable crop for plantation-style agriculture. Another crop grown on plantations was tobacco. As the South increased its reliance on single-crop, nonfood agriculture, it became dependent on imports from other regions for food.

The nineteenth century opened with new opportunities for farming in America. The United States purchased the Louisiana Territory in 1803, opening up possibilities for new settlers from the Mississippi Delta to the Dakotas. The century also brought a mechanical revolution to farming. John Lane introduced the all-steel plow. Cyrus McCormick invented the horse-drawn reaper, a device able to harvest more than 10 acres per day—a four-fold increase over what a skilled worker could harvest. McCormick's reaper was first built in 1831 and patented in 1834. Other nineteenth-century farm machinery developments included two-row corn planters, combines, threshing machines, and hay balers.

As the nation's infrastructure developed, the ability to transport western farm products to eastern markets improved. The number of settlers moving west increased, and demand for western land intensified. The Preemption Act of 1841 allowed squatters the right to purchase up to

160 acres at \$1.25 per acre. The Swampland Act of 1849 was designed to create more cultivatable land by draining swamps.

Cotton and tobacco continued to make major contributions to the country's economy. In 1850 almost half of all U.S. exports were cotton shipments headed for English textile mills. In 1859 U.S. tobacco growers harvested 430 million pounds, a 106 percent increase over a 10-year period. In 1860 approximately 60 percent of the nation's working population was involved in the farming industry. Their efforts brought a steady increase of U.S. agricultural products to the world marketplace.

The Civil War disrupted farming, particularly in the South, where plantations were devastated, and the region's economy ground to a halt. According to J. J. McCoy in *To Feed a Nation*, the cash value of southern plantations fell by 48 percent between 1860 and 1870. The post-Civil War years in the South saw an increase in the numbers of tenant farmers and an increase in the number of diversified farms, as the region made an attempt to improve its production of food.

During the Civil War, several major agricultural initiatives were undertaken. On May 15, 1862, President Abraham Lincoln signed legislation creating the U.S. Department of Agriculture (USDA). Also in 1862, the Homestead Act was implemented. Under its provisions, heads of households could receive up to 160 acres of publicly held property, for a filing fee of \$10, if they farmed it for five years.

In 1877 the Desert Land Act provided another means by which settlers could receive land. The act required that lands received be irrigated. It also recognized that arid land was less productive than other types of land and, as a result, permitted people to acquire up to 640 acres. In 1887 the Hatch Experiment Station Act was passed to fund agriculture experiments and investigations in all states and territories. In 1889 the USDA was promoted to the level of a cabinet office and began publishing its *Yearbook of Agriculture*. In 1898 the USDA established an office for the systematic introduction of foreign plants. The long-standing governmental policy of converting publicly held lands to private hands was challenged in the 1890s by a Conservation Movement. Under the influence of conservationists, the government started setting aside public lands to preserve forests and watersheds.

During the first decades of the twentieth century, U.S. farmers prepared for war in Europe. Government pronouncements encouraged the production of excess food in anticipation of heavy export possibilities. Farmers expanded operations and put more land under cultivation. When the United States entered the war, labor shortages intensified the development of costly labor-saving machinery. High commodity prices during

the war years led to high profits for farmers. Following the war, however, European nations had no money with which to buy American products. The export market failed to meet expectations, and U.S. farmers were forced to sell surplus crops at low prices.

During the 1920s, the U.S. farming industry endured a time of crisis. In 1922, for an average farmer, the estimated cost of growing a bushel of oats was more than the sale price. Between 1922 and 1927, an estimated 1 million people left farms in search of other work. Small farmers could not afford to purchase the labor-saving machinery necessary to reduce their costs or buy expensive improved seeds to improve per acre yields. In addition, share croppers and tenant farmers, unable to make use of modern farming methods, relied on traditional methods, which caused damage to the soil and further reduced crop yields. As a result, poor farmers became poorer, and soil depletion problems worsened, particularly in the South and the Southwest. Soil erosion led to dust storms that were exacerbated by drought conditions. In Kansas, Missouri, and Oklahoma, the topsoil blew away, resulting in the Great Dust Bowl. Throughout the 1930s, federal efforts were aimed at improving the farmers' economic plight and preserving the nation's soil.

With war again brewing in Europe, farmers once more were encouraged to expand production in anticipation of increased demand for U.S. products abroad. In a series of events paralleling those of the World War I era, heavy demand existed during the war years, and exports plummeted following the war. Farm surpluses once more led to declining crop prices and difficult economic conditions for farmers. In 1948 Congress passed the Agricultural Adjustment Act, which included price supports for farm products.

Despite the economic turmoil, technological advances for the farming industry continued. The 1950s and 1960s brought expanded reliance on machinery. By 1955 sprinkler irrigation systems were being used on 2 million acres. A mechanical tomato harvester was developed in 1959. Tractor sales increased, and the development of a tractor-mounted electric generator enabled farmers to use electricity in remote areas.

Traditional plowing methods were blamed for fostering soil erosion. During the late 1980s, researchers estimated that 4 billion tons of soil were lost every year to erosion. Although crop management practices aimed at reducing soil losses by reducing or eliminating plowing had been under investigation since the 1930s, they did not become feasible until the development of chemical weed control methods during the 1960s. During the fuel crises of the 1970s, farmers began to look more favorably on the possibility of eliminating plowing.

The advent of giant machinery transformed the farming industry. Large machines required large areas to operate efficiently. In addition, they needed uniform conditions. As a result, small and mid-sized diversified commercial farms became less profitable. Owners found it necessary to supplement their incomes with nonfarm work. Some sold family farms to larger entities. According to a USDA estimate, 5 to 8 percent of all farmers left farming in 1985. By 1997 the farm population totaled 5.02 million, representing only 1.9 percent of the total U.S. population.

As the number of farms in the United States fell, the average number of acres per farm increased. Between 1970 and 1980, average farm size grew from 374 acres to 426 acres. By 1997 it stood at 487 acres. Total acreage in farms overall, however, decreased. In 1970 the nation's farms totaled 1.1 billion acres; in 1980, only 1 billion acres were classified as farmland and, in 1990, the total had dropped further to 960 million acres. By 1997 U.S. farmland totaled 931.79 million acres.

The farming industry in the late 1990s was plagued by the lowest commodity prices in decades. This trend was especially harmful to small farmers, who require a greater percentage of their budget to move products to market. By 1999, however, the entire industry was growing desperate. Corn output that year totaled 1.47 billion bushels, marking the third-largest single-year drop (about 3 percent) in U.S. history. The drought that hit the American Northeast that summer exacerbated the problem. Meanwhile, profits continued their decade-long decline. According to USDA reports, only 23 cents of every dollar spent on food represented farm value. The largest component cost of food was labor (38 cents), a figure that rose 4 cents during the 1990s. Other costs included packaging (8.5 cents), transportation, machinery, depreciation, advertising, fuels, taxes, and interest.

One reason for low farm profits was the existence of a surplus for many farm commodities. The Federal Agriculture Improvement and Reform Act of 1996 (FAIR), also known as the Freedom to Farm Act, was designed to help alleviate surpluses in traditional crops—such as corn and soybeans—by encouraging farmers to diversify into new crops. Congress drafted the bill to encourage U.S. producers to become more market-oriented in operations and not rely as heavily on government supports, subsidies, and planning. This new legislation marked the beginning of the gradual departure of government from farming and planting decisions. FAIR called for the elimination of price supports after 2002, with price support payments decreasing over the years leading up to 2002.

While this law was always a thorn in the side of small farmers and populist farming organizations for reducing government programs to aid farmers, generally to the advantage of large agribusiness firms, the Freedom to

Farm Act has met with increasing calls for reexamination from the latter groups, as the slumping commodities prices began to eat into profit margins. The American Farm Bureau Federation in 1999 voted to reexamine Freedom to Farm, seeking greater crop and revenue insurance and assistance programs. Despite Freedom to Farm, the U.S. farming industry still relies heavily on governmental subsidies. In 1999 the U.S. government made \$22.9 billion in subsidy payments to crop farmers. Intense lobbying also brought \$7.4 billion in relief aid in the fall to help farmers recover from the drought.

In addition to facing economic challenges, the agricultural industry found itself under increasing criticism regarding environmental concerns. One issue regarded water conservation, as environmentalists spearheaded efforts to reduce consumption levels. A total of 279,442 farms, covering 55.06 million acres, utilized irrigated land in 1997. This represented 15 percent of all farmland. More than 50 million acres of this total was on harvested cropland. The average crop farm irrigated 197 acres in 1997, up from 159 acres a decade earlier. Although innovations in irrigation systems helped lessen water requirements, some people claimed that irrigating crops was depleting the nation's fresh water supply. Greater emphasis on efficiency led to positive developments, however; between 1982 and 1997, the rate of erosion by water on U.S. croplands was reduced by 24 percent.

Farms were also blamed for polluting water supplies. Contamination resulted from discharges of chemicals used in pesticides and fertilizers and sediment from soil erosion. Some critics estimated that as much as 80 percent of the nitrogen and phosphorous in the nation's fresh water supplies came from agricultural run-off. An estimated 55 percent of impaired river miles and 58 percent of impaired lake acres were attributed to agricultural run-off. In addition to surface water, ground water supplies were impacted. One study estimated that half of the nation's drinking water wells contained detectable levels of nitrate. Nitrate levels higher than those recommended by the Environmental Protection Agency (EPA) were found in 2.4 percent of rural private domestic wells and 1.2 percent of community water systems.

In an effort to alleviate the problem, some farms installed grass waterways to catch sediments and to filter phosphorous and pesticides out of run-off. Catch basins were sometimes used to help control the flow of water from irrigation systems. Researchers also investigated ways to reduce nitrate contamination of ground water supplies by improving plants' ability to use nitrogen. Fertilizer application methods were also under review. In addition to FAIR, President Clinton also signed the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and the Federal Food, Drug, and Cosmetic Act (FFDCA) into law in 1996. These acts require the EPA to set

tolerance levels for pesticide residue on fresh and processed foods. The former act regulates the manufacturing, sale, and use of pesticides, while the latter governs pesticide residues. The EPA must also register all new farm chemicals and reregister all old pesticides, denying the registration of some of the more noxious pesticides that have unreasonable effects.

In addition to the possible health consequences of nitrogen and phosphorous (both fertilizer nutrients), the chemicals were blamed for causing excessive algae growth in lakes and streams. Excessive algae growth was one cause of premature lake aging, a process called eutrophication. Sediment deposit from soil erosion was another contributing factor.

To mitigate these growing problems, many farmers began to incorporate conservation tillage. Conservation tillage differed from conventional tillage by the amount of soil surface covered with crop residue. While conventional tillage methods used plows to turn the soil and cover crop residue, conservation tillage practices left crop residue in place, so that it could protect the soil from excessive wind and water erosion. Crop residue also helped retain moisture and reduce the need for irrigation. Although conservation tillage methods were effective in helping reduce soil erosion, they typically required specialized equipment and relied on chemical herbicides to control weeds. The principal methods of conservation tillage used during the early 1990s were called no-till, ridge-till, strip-till, and mulch-till (also called reduced-till). No-till leaves the soil undisturbed from harvest to planting, with the exception of periodic nutrient injections; weed control is accomplished primarily with herbicides. Ridge-till conservation tillage likewise leaves the soil undisturbed save for nutrient injections, while weed control is handled either by herbicides or cultivation; ridges are rebuilt during conservation. Finally, mulch-till disturbs the soil just prior to planting. No-till practices left the most plant residue on the soil and reduced soil losses by more than 75 percent. Other conservation tillage methods varied in effectiveness but generally reduced soil losses by 50 to 75 percent. Some type of conservation tillage was utilized on 109.8 million acres in 1997, while an additional 40 million acres were farmed in narrow strips to help prevent erosion.

Another area of conflict between farmers and environmentalists concerned the use of wetlands. During the early years of the twentieth century, the USDA promoted a policy of transferring wetlands to private ownership. USDA-endorsed programs were aimed at draining swamps and "reclaiming" land for cultivation purposes. During the mid-1970s, the USDA revised its policies concerning wetlands. In 1985 the Food Security Act defined wetlands based on soil and vegetation types and stopped price support payments to farmers who contin-

ued converting wetlands to crop lands. The American Farm Bureau Federation, lobbying on behalf of its member farmers, successfully opposed more restrictive federal wetlands regulations in 1989. By 1997, some 255,410 farms totaling 29.49 million acres were protected under Conservation Reserve or Wetland Reserve Programs.

Not all farmers, however, were opposed to the efforts of the environmental movement. Some favored alternative agricultural methods relying on crop rotations to disrupt the reproductive cycles of weeds, insects, and crop diseases. Alternative agriculture, also called organic or natural, was a labor-intensive practice, and such crops were typically more expensive than those produced on farms employing traditional forms of cultivation.

Many general crop farmers have been successful in finding their niche in the growing organic-foods industry. Targeting customers concerned with the health and environmental risks associated with chemicals, pesticides, and genetically modified foods, the organics sector has emerged from specialty health stores and a fringe customer base to assume a significant position in the mainstream consumer market. Organic agricultural products constituted the fastest-growing sector of the farming industry during the 1990s, with annual sales of \$5 billion in the United States by 1999. Organic farmers eschew the synthetic chemicals and gene-tampering technologies many farmers use to boost yields and create more productive livestock. To qualify as organic, crops must be completely free of such chemicals, a fact that demands organic farmers to plan carefully far in advance to ensure appropriate planting patterns. Organic crops must be maintained on land that is free from any chemical infiltration, including soil and water supplies. Because of the greater risk and investment required, organic farming is a more costly undertaking than nonorganic farming, and thus organic commodities fetch a higher price at the market.

One of the hottest issues relating to agriculture in the late 1990s was the use of biotechnology to genetically alter seeds in order to boost yields or enhance food quality. More than 40 genetically engineered crops were developed between 1995 and 1999, while the amount of farmland devoted to such crops increased tenfold, reaching 76 million acres. About 37 percent of corn and nearly half of all soybeans incorporated biotech engineering. For many years, such crops were used primarily in livestock feeds, though that was changing by the end of the 1990s, when such products were increasingly being sold directly to consumers.

One reason for the turn toward biotechnology in crop production is the realities of demographics and geography. While the world population is expected to surpass the 10 billion mark by 2030, analysts project that farmers

could face a severe shortage of adequate farmland. As a result, the ability to boost yields and limit pest infestation has increasingly become a priority. However, biotech alteration is also emblematic of the trend toward consolidation within the farming industry, as bigger farms attempt to produce more for less input in order to remain competitive.

While proponents of genetically modified food technology contend that its use will lead to benefits for producers and consumers alike in the form of greater yield, lower costs, and higher-quality products, criticism has been widespread, emanating from environmental activists decrying the polluting effects of soil and water; health monitors concerned about the safety to humans of genetically modified food consumption; and consumer advocates and small farmers worried about the potential monopoly power wielded by large agribusiness concerns working with biotechnology firms.

Environmentalists and industry analysts further warn that the continued use of such powerful pest-control mechanisms will effectively result in the breeding of more powerful, and more resistant, "super pests." These fears were acknowledged by the technology's leading industry proponents, who insisted that, for that reason, the technology must be more rapidly developed and implemented in order to stay a few steps ahead of the pest evolution.

Small farmers were most particularly concerned with the rising use of technology designed to manufacture seeds that are sterile. Farmers have always saved seeds at the end of the year's crop harvest for use in the following year's planting. By introducing destructive toxins that render the seeds sterile, companies' genetically modified seeds are often engineered to be usable only once, thus forcing farmers to repurchase seeds from the manufacturers every year. In addition to the potential health hazards posed by these toxins, the degree of control this practice could afford seed suppliers has many farmers concerned. Moreover, biotechnology firms increasingly insist on legal agreements with farmers that those seeds that are fertile be used only once, a move that has hardly been popular among farmers.

Concerns about genetically modified food were for many years far more widespread in Europe and Japan than in the United States. By the end of the 1990s, that was still true, but the margin was diminishing rapidly. Many large U.S. firms have noticed this trend and fear the potential economic damage they could sustain by overinvesting in a product line that consumers come to avoid. As a result, some farmers have announced that they were placing restrictions on the genetic modification of crops, while they wait to see how negative public opinions eat into the market for such foods.

By 1999 farmers were beginning to take advantage of electronic commerce on the World Wide Web to market their products. Web sites acting as bulletin boards, as well as online auction sites, took off in the late 1990s, affording farmers a relatively cost-effective way to take their products to market and purchase necessities such as agricultural chemicals. By the end of 1999, however, Internet access was mainly concentrated among the largest farm operations; only 29 percent of all U.S. farms were online, but more than half of that figure was derived from farms with annual sales of more than \$250,000. At any rate, the Internet was viewed by analysts as an indispensable aspect of farming's future, likely to spur an increased trend toward specialty niche crops with significant value-added properties.

CURRENT CONDITIONS

U.S. beginning grain stocks totaled 77.8 million metric tons in 2001. Domestic production for the year totaled 324.8 million metric tons, the lowest production amount in five years, but just slightly off the 10-year average production level of 326.8 million metric tons. With the addition of 5.7 million metric tons, the overall production year total of available grain and feed was 408.3 million metric tons. Of that total, 256.2 million metric tons were used domestically, and 88.7 million metric tons were exported, leaving a year-end stock of 63.5 million metric tons.

In 2001 corn for grain production totaled 9,507 million bushels, with an average bushel price of \$2.00, reflecting a slight rebound in prices from \$1.82 and \$1.85 per bushel in 1999 and 2000, respectively. Annual production value totaled \$1.92 billion. Including 1.9 billion bushels in reserve, 2001 corn on-hand totaled 11.42 billion bushels. Of that, 7.9 billion bushels were used domestically, and 1.98 billion bushels were exported, leaving year-end reserves of 1.55 billion bushels.

In 2001, 1.96 billion bushels of wheat were produced domestically, reflecting an ongoing decrease in acres dedicated to wheat. The average price of \$2.80 per bushel (up from \$2.48 and \$2.62 in 1999 and 2000, respectively) resulted in a total production value of \$5.55 billion. This compares negatively to the 10-year price high of \$4.55 per bushel reached in 1995 that resulted in an annual production value of \$9.79 billion. Approximately one-half of wheat production was used domestically, primarily for food, with smaller amounts dedicated to feed and seed. Exports accounted for 1 billion bushels.

Although rice production reached a high of 231 million cwt. in 2001, price deterioration resulted in an overall decline in production value to \$895 million, compared to \$1.76 billion in 1997. Market price averaged \$9.43 per cwt. for the years 1995-1998, before falling significantly in 1999 and remaining low. Approx-

imately 58 percent of U.S. rice was used domestically, with the balance exported. Sorghum for grain totaled 515 million bushels (with a much smaller amount used for silage), for a production value of \$998 million. Just under half of sorghum was used domestically, with approximately 52 percent marked for export. Oats production continued to steadily decline, with just under 117 million bushels in 2001, compared to over 294 million bushels produced in 1992. The per-bushel price of \$1.50 was up slightly after a three-year decline. Nearly all oats are used domestically.

At \$94.1 billion, cash receipts for U.S. farm crop production in 2000 were up slightly from 1999 (\$92.6 billion), but down overall from \$111.1 billion and \$101.7 billion in 1997 and 1998, respectively. Over a three-year period, food grain cash receipts fell 37 percent; feed crops fell 27 percent; cotton fell 35 percent; and oil crops fell 16 percent. Vegetables, fruits and nuts, and other crops showed marked improvements in cash receipts, with an overall increase of over 15 percent between 1997 and 2000.

INDUSTRY LEADERS

One of California's largest agricultural companies, Sun World International, a division of the water and agricultural resources firm Cadiz, Inc., was one of the leading general crop farm operations in the late 1990s. Established in 1976 and headquartered in Coachella, California, the firm quickly became one of the leading producers of a range of commodities, including carrots, green onions, cantaloupes, and seedless watermelons. Sun World was an innovator in growing and marketing unique crop varieties, relying on selective breeding programs to develop branded produce; by the late 1990s, the company operated the world's largest fruit-breeding programs. Sun World farmed about 14,000 acres of agricultural crops.

Sun World provided 75 different products to markets in all 50 states and more than 30 countries. It was noted for its many alliances with academic and research organizations aimed at the enhancement and modification of its breeding programs.

WORKFORCE

Employment in the U.S. farming industry has been declining rapidly for many years. About 2.2 million people worked in farming in 1997, down from 2.8 million in 1994. Over the longer term, the drop is even more dramatic; in 1950 the farming industry employed 9.9 million. Moreover, increasing numbers of farm operators supplement their income with other employment. In 1997 only 50.3 percent of all farmers claimed farming as their principle occupation; more than 60 percent of farm operators supplemented their income with other employment.

Career opportunities included jobs in production, processing, and marketing. Wages varied widely according to the size and structure of the farm, the nature of the job held, and the education level of the employee.

The most common job in the farming industry was hired farm labor, the majority of whom were field laborers. There were 884,000 hired workers on U.S. farms in January 2003, down 1 percent from the previous year. In January 2003 hired workers were paid, on average, \$9.32 per hour, up 35 cents from the same period of the previous year. Field workers earned an average of \$8.29 an hour, and livestock workers earned an average of \$8.91 an hour. The majority of hired workers are employed by large farming operations that take in revenues greater than \$250,000 a year.

AMERICA AND THE WORLD

Although the United States contains less than 7 percent of the land in the world, the country produced 13 percent of the world's farm commodities. The U.S. Department of Agriculture estimated that the United States controls 47 percent of the world market for soybeans, 19 percent of the world's cotton, 12 percent of all wheat, and 36 percent of the world's corn.

The leading crop exports for U.S. farmers include coarse grains, with exports of \$9.3 billion in 1997; soybeans, with \$6.3 billion; wheat, with \$6.9 billion; and cotton, with \$3 billion in exports. Significant trading partners included Japan (\$11.7 billion), Canada (\$6.1 billion), and Mexico (\$5.4 billion). The North American Free Trade Agreement (NAFTA) has been responsible for increasing trade among the United States, Canada, and Mexico. Other major export markets were in western Europe (\$8.2 billion), Asia (\$14.8 billion), and Latin America (\$10.5 billion).

The United States also imported about \$2.6 billion in grain and feeds, while other leading import commodities included those that were not grown or could not be grown domestically, such as fruits and nuts, coffee, cocoa, vegetables, and grain.

In addition to regular sales of agricultural production, the U.S. government funded exports of food under its Food for Peace program. The Food for Peace program began in 1959 and provided food items from U.S. surplus production to developing nations.

According to some industry forecasters, the demand for U.S. products on the global market would decline as other nations developed their own farming industries. Low labor costs in some countries were expected to enable them to produce crops more cheaply than could be accomplished in the United States. In addition, improved technology, such as the availability of advanced irrigation systems, was improving the ability of some countries

to grow crops. For example, Saudi Arabia achieved self-sufficiency in wheat production using a center-pivot irrigation system. Thus, U.S. producers expected to face increased competition, as more countries entered the trade market and improved their agricultural conditions at home. However, as consolidation of farming grows, highly leveraged agribusiness firms are likely to wield greater influence on the world market. Moreover, as land availability diminishes and genetically modified crops take on heightened priority, the globalization of farming will likely help major U.S. players. One of the central tasks of U.S. officials is the strengthening of accords relating to intellectual property rights to be enforced by the World Trade Organization. Such provisions would grant patent control to developers and owners of genetically modified (GM) technology, thereby allowing them to charge other businesses for the use of such technology.

RESEARCH AND TECHNOLOGY

Historically, technological advances in the agricultural industry focused on increasing land productivity and reducing labor costs. The mechanical revolution in farming, which began during the nineteenth century, accelerated through the middle of the twentieth century. For example, to produce one acre of corn in 1850, it took approximately 30-35 hours using draft animals, a walking plow, and hand planting procedures. In 1930 it took approximately 6-8 hours using horses and early tractors. In 1995 the same task took 2.5 hours using a tractor, a 5-bottom plow, a 25-foot tandem disk, a planter, an herbicide applicator, and a combine. Increasing crop yields also reduced the amount of land necessary to meet the nation's per capita food and fiber needs from about four acres in 1900 to less than two by 1995.

During the latter part of the twentieth century, however, the focus of agricultural research shifted to environmental issues. Pesticides (such as DDT) and herbicides (such as 2,4,5-T) were criticized for their potential negative human health consequences. Researchers intensified their efforts to produce less toxic alternatives.

Computer technology was also being used to bring about agricultural advancements. Geographic information systems (GIS), computer modeling and simulation, and fertilizer- and irrigation-monitoring systems were among the many computer-based systems that were popular with farmers in the late 1990s. One of the primary functions of such technology was to help increase farm profitability through the reduction of resource use. GIS, which combines farm-positioning sensors, aerial photography, and farm-equipment sensors, was particularly poised as a primary tool by which farmers can analyze the myriad factors and data necessary for farmers to most efficiently utilize their land, boost yields, and cut down on resource consumption. The accumulated information

affords farmers the ability to analyze specific factors, such as soil nutrients, in particular plots of land on their farms, thus enabling them to make effective decisions about water allocation, fertilizer application, crop selection, pest control, and so on. Moreover, computer-based precision irrigation systems monitor crops to ensure that they receive the appropriate amount of water, which can be applied automatically when the system deems it necessary.

The 1996 Freedom to Farm Act put an end to the long-standing farm subsidy through which the farming industry benefited from the government-developed satellite mapping systems. Farmers used these systems to aid in the selection of farmland for qualities such as richness of soil and the availability of resources such as water. Because farmers, under Freedom to Farm, are no longer required to report acreage and planting patterns to the Department of Agriculture, the government's aerial photo-mapping system was rendered obsolete. The larger agribusiness farms were expected to take over this role, providing this much-needed service to the farming industry for a fee.

SIC 0211

BEEF CATTLE FEEDLOTS

This classification covers establishments primarily engaged in the fattening of beef cattle in a confined area for a period of at least 30 days, on their own account or on a contract or fee basis. Feedlot operations that are an integral part of the breeding, raising, or grazing of beef cattle are classified in **SIC 0212: Beef Cattle, Except Feedlots**. Establishments that feed beef cattle for less than 30 days, generally in connection with their transport, are classified in **SIC 4789: Transportation Services, Not Elsewhere Classified**.

NAICS CODE(S)

112112 (Cattle Feedlots)

INDUSTRY SNAPSHOT

According to the U.S. Department of Agriculture, at the beginning of April 2003, cattle and calves for slaughter on feedlots with a capacity of 1,000 or more head totaled 10.7 million. This represents an 8 percent and 7 percent decrease from the same time period in 2002 and 2001, respectively. Of the total feedlot inventory, steer and steer calves accounted for 63 percent, or 6.72 million. Heifers and heifer calves totaled 3.92 million. Three states dominated cattle feedlot production: Texas had 2.7 million beef cattle on feedlots; Kansas, 2.3 million; and Nebraska, 2.2 million. Combined, these three states accounted for two-thirds of all beef cattle feedlot production.

The total number of beef cows in the United States in April 2003 was 33 million. One-third of the nation's beef cattle (10.7 million) is produced on large feedlots. The remainder are either grazed or raised on smaller feedlots with capacity under 1,000 head. The average price per 100 pounds in 2000 was \$69.52 for steers (heifer prices vary slightly). The price per hundred weight in March 2003 averaged \$72.70. Prices during the 1990s ranged from a decade high of \$76.23 in 1993 to a decade low of \$70.06 in 1998.

The early 2000s continued the trend toward larger feedlot operations. However, the industry exists under a

cloud of environmental suspicion regarding the damage caused by waste runoff, as well as the effect of growth hormones injected into cattle to promote quick weight gain.

ORGANIZATION AND STRUCTURE

The feeding of grain to cattle is unique to the United States. Americans and an increasing number of international consumers have developed a taste for American grain-fed beef, as opposed to beef cattle fattened on grass only. The cattle that are fed in U.S. feedlots are young steers and heifers that have been weaned from their mothers, perhaps run on grass for another season or two, and then placed in the feedlot for further finishing. Typically this finishing period lasts between 110 and 150 days, during which the cattle may grow from 800 pounds to 1,250 pounds by eating a ration containing grain, by-products, and hay that gives American beef its unique taste known throughout the world.

Prior to the 1970s, farmer feeders would send their "fat" cattle to an auction or terminal market, and packers would have representatives there to buy them. But by 1993 less than 7.6 percent of fed cattle were purchased by packers through public auctions. Instead, packers staffed their own buyers, who visited the huge feedlots and perused the "show lists," which are pens containing cattle being sold that week. After settling on a price for particular cattle, buyers then purchased the cattle directly from the feeder.

Because ranchers have been increasing their investment in genetic technology, a growing number of them have been retaining ownership of their cattle from the time they are born until the time they are processed by packers. Owning cattle through the finishing stage allows ranchers to be rewarded directly when their cattle are sold to satisfy packer and consumer demands. Ranchers, however, are more vulnerable than other farmers during market drops. Under retained ownership agreements ranchers can buy feed outright and pay only a yardage charge, pay a set price per pound gain, or pay only for the amount of feed used.

Cattle are pen-lotted in a feedlot after being vaccinated. They are lotted by owner, and pen riders check the cattle daily and pull any sick or nonperforming cattle. Some feeders keep feed in front of the cattle at all times, while others feed them twice a day with huge feed trucks that place the feed in bunkers. The feed is mixed either in a large mill or by trucks that mix it while carrying it to the cattle. The ration contains grain, hay, and by-products, such as cottonseed and almond hulls. Computers keep track of the amount of grain consumed, the cost of grain, the cattle's daily weight, and the number of days on feed. When the cattle are eventually processed, the owner receives a computer report with all of this information.

Cattle are fed by investors, ranchers, or packers, who want to guarantee a steady supply of cattle for their packing plants. Such cattle are referred to as "captive supply." The captive supply generally represents about 20 percent of the cattle on feed at any one time, and the government watches this number as an indicator of packer concentration. When cattle are considered good enough to be graded "choice," they can be sold in a variety of ways. They might be sold by the pound while the cattle are still alive, or they might be sold "in the meat," based on what they weigh when hanging on a packer's rail. The cattle business is currently attempting to achieve "value-based marketing," whereby cattle are priced according to the quality and amount of meat in the carcass rather than by their weight alone. Thus, there is a growing trend toward selling cattle on "grade and yield." This strategy helps prevent packers from buying overly fat animals.

BACKGROUND AND DEVELOPMENT

The grain-growing region of the Midwest dominated the U.S. cattle feeding industry in the 1970s. Huge American grain surpluses caused by government price supports provided cheap food for livestock and made cattle feeding a standard practice in the nation's beef industry. Iowa was the nation's leading cattle feeder during this period, feeding over 4 million head per year, or approximately 20 percent of the nation's cattle. Nebraska and Illinois were the other top cattle feeding states in the Midwest. These three states combined with California to account for 62 percent of all fed cattle in the United States.

Across the country a majority of American cattle were fed by small, farmer-owned operations. These farmers used cattle to market their grain. If grain was drawing a satisfactory price, farmers would sell it outright. But if farmers were unsatisfied with the price of corn, barley, or oats, they might market their grain indirectly by feeding it to cattle or hogs. Midwestern feed farmers typically acquired their cattle by attending livestock auctions themselves or by having commission buyers purchase steers or heifers that had been raised and bred by ranchers. The cattle would then be placed in pen lots on the feeders' farms. Small mills on the farms processed the grain used to feed the cattle. For decades this was how the majority of U.S. cattle were "finished." (The "finishing" period was once referred to as "fattening." But as Americans began to limit their fat intake, feeders decided to refer to this stage of the cattle's growth as finishing.)

The geographic center of the cattle feeding industry began to shift from the Midwest to the southern plains states in 1972. By the 1980s the biggest cattle feeders were located primarily in Texas, Nebraska, Kansas, and Colorado. During the 1990s these four states accounted for over 60 percent of the total beef production annually. Iowa had

fallen to fifth place among cattle feeding states by 1999, marketing only about 1 million finished cattle a year, or about 5 percent of the nation's total. This represented a drop for the Iowa cattle feeding business of more than 3 million head since 1970. California and Montana also experienced severe declines in their cattle feeding business, both down more than 25 percent since the 1970s.

Several reasons explain why the nation's cattle feeders moved. First, the southern plains states provided tax incentives for cattle feeders to leave the Midwest. Second, it was much cheaper to feed and slaughter beef in modern facilities that were located far from large population centers, where wages and land values were high, and environmental restrictions were often prohibitive. Third, low transportation costs made shipping boxed beef across the country cheaper than shipping grain to feedlots. Fourth, many cattle feeders in the plains states transformed the grazing land surrounding their feedlots into farmland that grew grain to feed the cattle, increasing the efficiency of their operations and decreasing the need to buy grain from the Midwest. Fifth, several Midwest cattle feeders began focusing their operations on growing corn and soybeans to capitalize on the grain market boom of the 1970s.

Cattle feeding operations also grew larger, as they migrated to the plains states. In 1980 small farm feedlots with fewer than 1,000 head accounted for 25 percent of fed cattle sold in the country. By 1997 these feedlots made up only 15 percent of the fed cattle sold. At the same time, the share of cattle in medium (capacity for 16,000 to 31,999 head) and large (capacity for at least 32,000 head) commercial feedlots increased from 43 percent in 1980 to nearly 60 percent in 1997. Large commercial feedlots experienced the largest increase in share, accounting for 35 percent of cattle on feed in 1999 as compared with only 22 percent in 1980. In Kansas the percentage of cattle fed in large feedlots rose to 87 percent in the 1990s, while in Texas it rose to 97 percent. In these and other large cattle feeding states it was not uncommon to see feedlots capable of holding over 100,000 head of cattle at any one time.

The Corn Belt states have suffered the largest loss of market share. Just as many industrialists left the Rust Belt for the Sun Belt, cattle feeders in the 1990s fled the Corn Belt for Texas and the plains states, and have been thriving there since. More than half of all beef slaughtered in this country is processed in plants west of the Mississippi River. Most cattle feeding takes place between the western bank of the Mississippi and the eastern slope of the Rocky Mountains in large feedlots that commonly contain more than 50,000 head of cattle.

According to industry analyst Topper Thorpe, beef production continued to concentrate within a 400-mile radius of Grand Island, Nebraska. Where Iowa, Minne-

sota, and Missouri once fed 17 percent of America's cattle, they accounted for barely 10 percent in the 1990s. The eastern Corn Belt also suffered in the 1990s, as states in that region accounted for just 7 percent of total U.S. fed cattle. Lack of financing hurt farmers throughout the Corn Belt, causing many to go out of business or shift their resources to other endeavors. The Corn Belt also became less environmentally suited to feedlots, as population density increased. Additionally, increased federal regulation made the feedlot business more costly and burdensome. Regulations governing water quality, runoff, erosion, and drainage forced many small operators out of business.

Changes in the meat packing industry also helped transform the feedlot business. More than 405 packing plants shut their doors since the mid-1980s. In the 1990s three large corporations controlled nearly 80 percent of U.S. boxed beef production. To be competitive a packing house should process over 500,000 head per year, and most of these superplants relocated to the plains states. If the location of American feedlots were plotted on a map and then dovetailed with an overlay of a map identifying the packing houses, they would form a heart shape covering the nation's midsection. Nebraska, Kansas, Texas, and Colorado have the largest number of processing facilities. They are also the four largest packer states.

The business aspect of the feedlot industry has become increasingly sophisticated. Most feedlot managers have computers on their desks to check current prices, futures, and the amount of grain consumed on their farms. Advanced communication devices allow managers to track the performance of individual animals from ranch to feedlot to packing plant. Tracking individual animals once involved a blizzard of paper and a bevy of manpower. Today the job is made easier by computers, electronic identification tags, high-speed data transmission networks, and specialized software. Computers sort the data. Electronic tags track the animals. Software makes the system work. But it is communications devices and data transmission networks that tie the system together by allowing managers to easily access, collect, and share data. Ranchers use the beef quality data from packers to improve herd genetics, while feedlots use the data to decide which ranches best suit their needs.

Cattle feeders hope that this technology increases their profit margins. The feedlot industry returned to profitability in the late 1990s after sagging earlier in the decade. Cheap feed prices in 1999 made it more profitable to fatten cattle than to slaughter them. In August 1999 cattle prices rose 3.4 percent, while the cost of corn, the main ingredient in livestock feed, rose only 2.2 percent. Feedlots had faced negative margins since late 1997, with losses accelerating in February 1998 due to the sharp break in fed cattle prices, as the domestic

market adjusted to larger supplies of higher quality beef than normally would have entered the export market.

Downsizing. Nearly all segments of the beef cattle industry were in a downsizing mode during the 1990s. The consolidation was especially pronounced in the feedlot sector. In the mid-1960s there were 200,000 feedlots scattered around the country. In 1997 that figure had fallen to 110,000 lots. But the largest 2 percent were marketing 95 percent of the nation's fed cattle. Those numbers were not expected to change much in the first few years of the twenty-first century.

The feedlot industry requires individual farmers to invest a great deal of capital in their cattle. A typical steer going on feed costs a cattle feeder over \$600, and at least another \$200 in costs are incurred during the feeding phase. Consequently, many small cattle feeders teetered on insolvency or went out of business in the 1990s. As the packing industry became concentrated, packers started looking to build fiscally sound strategic alliances with their suppliers. Packers were not inclined to build such alliances with financially unstable smaller feeders. Marketing alternatives for smaller feeders dwindled, as fewer fed cattle were marketed at auction. Large feeders were better able to hedge their cattle using futures contracts. The practice of hedging saved many feeders from the wild price swings common to the cattle business. Large diversified companies were also more resilient during lean years than their unvariegated smaller competitors.

Mad Cow Disease. Bovine spongiform encephalopathy (BSE), commonly called "Mad Cow Disease," shocked the beef-eating world in 1986 and culminated in a frenzy in 1995, as producers in the United Kingdom found escalating numbers of afflicted cattle throughout the country. BSE is a fatal disease that affects the central nervous system of cattle. The U.S. Department of Agriculture promptly attempted to allay consumers' concerns by releasing studies showing that no cases of BSE existed in the United States. As a precautionary measure, the United States does not import cattle from countries with reported cases of BSE. Moreover, many scientists contend that the disease is not transmissible through an infected cow's meat or through physical contact.

Nonetheless, Texas cattle ranchers sued talk-show host Oprah Winfrey for defamation in 1996, after one of her guests told a national television audience that the cattle industry had potentially exposed Americans to Mad Cow Disease by feeding cows the remains of live animals. The cattle ranchers blamed Winfrey for sagging beef prices and requested money damages totaling \$11 million. Winfrey argued that the dip in cattle prices was caused by high feed costs, oversupply, and low prices of competing meats. In 1998 a federal jury in Amarillo, Texas, sided with the talk-show host.

CURRENT CONDITIONS

Beef cattle feedlot operations continue to be financially dominated by large corporations with diversified interests that have refined the process of raising calves to slaughter-ready weight. Calves are typically housed on a feedlot for six months and fed grain, along with antibiotics, synthetic growth hormones, and protein supplements to push the animals' weight up as quickly as possible. The result is readily available beef products at relatively low prices. However, according to Kenneth Eng in *Feedstuffs*, "The classic image of the 'family farm' has been replaced by the negative image of a 'corporate factory farm,' resulting in increased danger that perception may replace reality."

Along with the perception that large corporate farming operations have squelched the beloved national image of the family farmer, large feedlot operations have provoked a stir of controversy centered around the environmental damage caused by waste runoff and air pollution. According to the Natural Resources Defense Council and the Clean Water Network, as reported by *Mother Earth News*, feedlot waste can be found in the watershed up to 300 miles away. Subject to the Clean Water Act, feedlot operations must follow regulations to ensure that the quality of the area water is not harmed. However, runoff remains a serious environmental concern.

Also subject to the Clean Air Act, feedlot operations are having a much harder time controlling the levels of nitrogen and ammonia that are given off by mass concentrations of cattle. According to the Environmental Protection Agency (EPA), cattle are responsible for over 43 percent of nitrogen released into the atmosphere. In 2002 the EPA introduced a new farm animal pollution curb, which is expected to reduce the presence of the main pollutants produced by cattle waste and urine by 25 percent. The noxious odors caused by the feedlots are leading to a growing number of lawsuits from area residents. According to Elizabeth Becker, "Residents contend that feedlots destroy the quality of pastoral life with their odor and threaten the environment and public health with noxious air pollution and seepage of polluted water into drinking and surface water."

Despite the environmental concerns, corporate feedlot operations provide the country with a growing proportion of its red meat. As a result, the presence of large feedlots will remain an important part of the U.S. cattle industry. Although feedlot operators deal with uncontrolled fluctuations in the marketplace, environmental and ecological concerns have the most potential to introduce havoc to the industry.

INDUSTRY LEADERS

Cactus Feeders of Amarillo, Texas, ranked first among U.S. cattle feeders, owning feedlots with a capac-

ity for 480,000 head of cattle. Cactus Feeders reported revenues of \$625 million during fiscal year 2001, ending in October. In an industry dominated by large corporations, the largest at the beginning of the twenty-first century was ContiGroup (formerly known as Continental Grain). Its home office was located in Chicago, Illinois, but the company owned feedlots in six different states. Capable of feeding 405,000 cattle at one time, and marketing nearly 1 million fed cattle during the course of a year, its division ContiBeef runs the second largest cattle feedlot operation in the nation.

ConAgra Cattle Feeding of Greeley, Colorado, ranked third, owning four lots with a capacity for feeding 320,000 head. National Farms Inc., of Kansas City, Missouri, ranked fourth, owning seven lots with a capacity for 274,000 head. Caprock Industries (a division of Cargill) of Amarillo, Texas, ranked fifth nationally among cattle feeding businesses, owning four lots with a capacity for feeding 263,000 head of cattle.

J. R. Simplot of Idaho, who had been included on *Forbes* list of the 400 richest men in America, was another leader in the cattle feeding industry. Simplot gained his fortune through potato farming and became one of the largest cattle feeders in the United States. He developed a system of feeding the potato waste from his French fry plants to cattle in his feedlots. Simplot was also one of the largest ranchers in the country.

Some industry leaders such as ConAgra ran both meat packing and feedlot operations. ConAgra fed its cattle in Colorado and Idaho, and was also a major meat packer. ConAgra entered the cattle feeding business to assure a ready supply of cattle for its processing plants. The company's biggest acquisition was the purchase of Monfort of Greeley, Colorado, which had once been among the largest cattle feeders in the country. Monfort was also one of the country's largest lamb packers.

As the feedlot business entered a new millennium, industry experts warned that even some of the leading cattle feeders might be forced to downsize or go out of business. According to industry analyst Topper Thorpe, efficiency would separate the successful cattle feeding operations from those that fell by the wayside. Several recent studies have been released concerning efficiency in the beef industry. In 1997 Idaho researchers released two studies showing that rainbow trout that had been given the cattle hormone bovine somatotropin (BST) grew nearly 70 percent faster and 50 percent more efficiently than untreated fish. Prior to these studies BST had been used to boost milk production in dairy cattle. But the growth hormone is now being studied for its stimulation in beef cattle. In 1998 scientists at the Agricultural Research Service Grazinglands Research Laboratory in El Reno, Oklahoma, released a three-year study showing that beef cattle finish as efficiently on grass

pastures with a low grain supplement as they would on a mostly grain diet.

The beef industry as a whole opened the twenty-first century on a mixed note. Annual per capita beef consumption declined to about 66 pounds in 1999, after peaking at 87 pounds in 1976. Public perceptions that red meat is less healthy than chicken, turkey, or pork were largely to blame for the fall. Beef has lost much of its market share to pork and poultry, going from 59 percent in 1980 to about 46 percent in 1999. Industry reports predict that by 2004, beef's market share will further drop to 26 percent, pork will advance to 26 percent, and poultry will rise to 47 percent. But beef is still America's favorite source of protein. The United States produced a record amount of beef in 1999. At the same time, consumers were spending \$5 per capita more on beef in 1999 than the year before. The beef industry also began a \$25 million marketing campaign in 1999. Advertisements reprised the catchy "Beef: It's what's for dinner" tag line, and beef companies introduced a host of new products.

SIC 0212

BEEF CATTLE EXCEPT FEEDLOTS

This classification covers establishments primarily engaged in the production or feeding of beef cattle, except feedlots. Establishments primarily engaged in raising dairy cattle are classified in **SIC 0241: Dairy Farms**.

NAICS CODE(S)

112111 (Beef Cattle Ranching and Farming)

INDUSTRY SNAPSHOT

In 2002 there were over 96.7 million head of cattle in the United States, down from 103.5 million in 1998. Total value of all herds for 2002 was \$72.2 billion. There were 1.05 million independently owned farms and ranches producing beef cattle for breeding and for feeding in the United States at the beginning of 2002. Although dairy farmers produce 20 percent of the beef in this country, that beef is largely a by-product of the milk business and is not included in this industry classification. This category includes all activities of ranchers or beef farmers up to the time their cattle are sent to the feedlot. Issues regarding the operation and management of feedlots are discussed in **SIC 0211: Beef Cattle Feedlots**.

Texas had the largest number of cattle in 2002, with 13.6 million head. Kansas and Nebraska followed with 6.7 million and 6.6 million head, respectively. Of the total number of beef cows, 11.7 million were housed in confined feedlots with over 1,000-head capacity.

The sale of cattle and calves is the largest segment of the American agricultural economy, which in turn comprises 16 percent of the gross national product. Moreover, sales of cattle and calves account for almost one-fifth of the country's farm and ranch cash receipts. Beef cattle are one of the few agricultural commodities produced in all 50 states, and the industry comprises more than 1 million businesses.

Beef has been central to America's dining habits for a long time. Recently, however, poultry has made great strides in eroding that primacy. Much of poultry's popularity has been attributed to lower prices and low fat content. The beef industry has worked hard to produce and promote a leaner product, and cites that one-third of all Americans have eaten some type of ground beef in the past 24 hours. Despite the many advances of the poultry industry, beef surpasses its competitors in both production and sales.

The United States is the largest producer of beef products in the world, although it ranks fourth in total number of beef animals. This high production rate is made possible by the high efficiency of U.S. producers. The United States is the third largest exporter of beef in the world. It is also the largest importer of beef, particularly of ground beef in frozen form. Despite a recent drop in annual beef consumption, U.S. per capita beef consumption ranks third in the world.

ORGANIZATION AND STRUCTURE

Because a vast amount of acreage is needed to support beef cows, cattlemen own or manage more land than any other single industry. In the meadows of Montana or

the irrigated pastures of California, one acre of land supports a cow and her calf for an entire year. In the deserts of the Southwest, however, an entire section of land, or 640 acres, can support only a handful of cows.

More than 1.2 billion acres of this country are considered agricultural lands by the USDA; this comprises approximately 50 percent of the United States and two-thirds of the contiguous states. Though two-thirds of this land is considered to be grazing land, 90 percent of it is unsuitable for growing commercial crops because of limited rainfall, steep slopes, rocky terrain, or poor soil. Thus, the land can only be used for pasturing beef cattle, sheep, goats, bison, horses, and wild animals.

These grazing lands are ideal for cattle, because the cattle can convert grass and other forages into high-protein food sources. The typical beef cow does not spend a single day in a cattle fattening feedlot, but instead lives on grass and hay her entire life, being retained for breeding and nursing. Her offspring may be fattened in a feedlot for 20 percent of their lives, or her female offspring may be kept as replacement females. A typical range cow loses her productivity between the ages of 8 and 10 and must be replaced.

The cow is like a factory for the beef industry: she generates more cattle. Beef cows have a nine-month gestation period and usually give birth to a single calf either in the fall or the spring. These calves are called "commercial" cattle as opposed to "purebreds," which are born from both a sire and dame of purebred ancestry. The majority of calves in this country are born in the spring and sold in the fall. The average calf weighs between 80 and 85 pounds at birth and lives on a diet of grass and its mother's milk. The calves run beside their mothers until they are weaned, which usually occurs when the calves are between six and eight months old. At this age, the calves usually weigh between 500 and 550 pounds, though there are significant variations due to management and feed conditions.

While they are still running alongside their mothers, the calves are gathered or rounded up much like they were in the early days of ranching. The calves are then branded by their owners and vaccinated for a variety of diseases. Bull calves are altered or castrated, at which time they are called steers. Steering a bull prevents fighting, accidental breeding with cows and heifer calves, and allows for easier management.

Before the calves are weaned, bulls are turned in with the cows to breed them. Normally, between 80 and 90 percent of the cowherd will be bred successfully. Those cows that don't conceive are referred to as "open" and are sold for beef. The bulls that are used are usually purebred cattle in which multigeneration pedigrees have been maintained by a breed association. These bulls are

produced by purebred breeders, whose sole intent is to provide seedstock for the commercial beef cattle producer. These purebred producers test their cattle for weight gain and meat quality, and keep extensive records on their pedigreed livestock. When commercial producers subsequently purchase bulls in the spring or fall of the year, they are aided by a pedigree and by computerized records that indicate how a particular sire's offspring might perform. The price of these commercial bulls usually ranges from \$1,500 to \$4,000, while the purebred sire that was used to produce them might cost upwards of \$20,000. It is not uncommon for a particularly good purebred bull to be syndicated for several hundred thousand dollars or to be purchased by a bull stud. The use of artificial insemination and embryo transfer has become commonplace in the beef cattle industry and has made it possible to use genetics from the best cows to produce several offspring per year instead of a single calf.

When the calves are ready for weaning, they can be sold through an auction market or over a satellite video hookup known as a satellite auction. They may also be traded in-country by an order buyer, or the cattlemen may prefer to retain ownership. The calves are then run as "stockers." Stockers go back to feeding on grass, until the time they weigh approximately 800 pounds. Other weaned calves may go straight into the feedlot for the final finishing stage and skip the stocker stage completely. As cattlemen continue to improve the genetics in their herds, many calves are weaning in excess of 650 pounds and reaching a finished weight of 1,250 pounds in the feedlot, when they're just over one year old.

Many ranchers consider themselves nothing more than grass farmers. Their job is to convert grass to beef as efficiently as possible. Cattle spend between 80 and 100 percent of their lives on grazing lands and have played a role in sustainable agricultural systems for centuries. Their manure and urine naturally fertilize the grasslands, and their hoofing action breaks up the crust of the soil. When they are run in the proper manner without overgrazing, cattle play a key role in maintaining soil productivity and keeping forages in a healthy condition. These forages in turn protect soil from wind and water erosion, and leguminous forages, such as alfalfa, add nitrogen to the soil.

While per capita consumption decreased during the 1980s and 1990s, and beef lost market share to poultry, the industry experienced one of the most prolonged profitable periods in its history. This is probably due to the fact that hundreds of thousands of beef producers left the industry during the last downturn in the cattle market. Several factors have been responsible for the decline in beef consumption since 1986.

Competing Meats. Per capita annual boneless beef consumption in the United States stood at 64.7 pounds in

1998. This was down considerably from 1975, when per capita consumption peaked at 95 pounds, yet per capita consumption stabilized in the 1990s. With ebbs and flows, consumption levels have remained at 62 to 65 pounds, signaling that major declines may be over.

A combination of factors contributed to beef's decline in the late 1980s. Competition from competing meats got the attention of beef producers, as poultry challenged beef's position as "The King of Meats." In the early 1990s, the poultry industry proudly announced that more chicken was consumed per person in this country than beef. This was the first time in the industry's history that beef was displaced as the most consumed meat in the country, in terms of poundage. Cattlemen like to point out, however, that beef at the retail level is a 94 percent boneless product, while chicken is only 69 percent boneless. On an edible meat basis, therefore, Americans still eat more beef—64.7 pounds versus 49.2 pounds of chicken in 1998. On a dollar basis the difference is more dramatic. Americans spent \$187.91 per person on beef in 1998 compared with \$125.16 on pork and \$112.50 on chicken. As the largest dollar volume item sold in grocery stores, beef represents more than 6 percent of all grocery store sales. It is estimated that in 1999, Americans consumed 36.5 pounds of beef cuts compared to 27.7 pounds of ground beef.

However, beef producers were still concerned about beef's declining market share. In the late 1980s, for example, cattlemen began to voluntarily assess themselves one dollar per head every time a beef animal was sold and pooled these proceeds toward advertising, research, and education. Much of that money was spent on finding better ways to compete with poultry and seafood.

The War on Fat. After experiencing decades of adulation from the public, the beef industry faced a host of new problems and new adversaries beginning in the early 1980s. The cattle industry was unaccustomed and unprepared for this avalanche of negative publicity. First there was the "war on fat." A Gallup poll in the early 1990s determined that the top dietary concern among consumers was the amount of fat in their food. This caught the beef cattle industry off guard.

American cattle differ from most beef animals produced in the world because they are grain fed. This grain finishing period, which usually lasts around 100 days, is unique to this country. It makes for a better tasting piece of beef, but it also increases the amount of fat in the beef carcass. In surveys of American beef consumers, taste remains the number one reason why they select beef over competing meats. This taste is achieved by intermuscular marbling, the tiny flecks of fat visible to the eye in steaks and roasts. This marbling is what gives beef its flavor and is one of the main criteria used in determining the grade and the price of beef.

Because of the manner in which beef animals distribute fat, intermuscular marbling is the last place where fat is deposited. Before the fat is distributed as intermuscular marbling, it is first deposited on the outside of the animal, visible to the consumer as the outer rind of fat on a piece of steak. Studies sponsored by the Meat Board estimated that the beef industry was producing 2,825 truckloads of fat at 40,000 pounds per load annually. This inefficient production of fat was costing all segments of the industry \$4 billion annually. This figure, however, still does not represent the loss of per capita consumption that may have been attributable to fatty beef.

Faced with this dilemma, the beef industry declared its own war on fat. Due largely to a program sponsored by commercial beef producers, retailers have reduced the amount of external fat on meat cuts by 27 percent. The fat rind on most cuts is trimmed to one-quarter and even one-eighth of an inch. In some cuts, the fat trim is completely removed.

Commercial cattle producers have also responded by using new genetic enhancements on their cattle. Throughout its history, the U.S. beef industry has relied largely on three breeds of cattle—Angus, Hereford, and Shorthorn. These breeds were of English descent and were introduced to this country when pioneer cattlemen wanted to improve the degree of muscling found in Longhorn cattle.

In their quest to find faster growing and leaner breeds, cattlemen looked to Europe for new genetics, and since the 1960s there has been a constant parade of new breeds of beef cattle into the United States. Beginning with the Charolais from France, it is estimated that there have been over 76 different breeds of beef cattle introduced into the United States. Some of these breeds, such as the Charolais, Simmental, and Limousin have made major contributions to the beef industry, while many others were quickly discarded. These breeds from Europe became known as the “Continental Breeds” or “Exotics.” Although they have not displaced Angus and Hereford as the most popular beef breeds, they are quite commonplace in crossbreeding programs.

It has become the norm in the beef industry to blend the genetics from two or three breeds for maximum heterosis or hybrid vigor. This results in faster growth, increased disease tolerance, and leaner beef. A cattleman, for example, might breed a Hereford bull with an Angus cow and then cross the resulting crossbred female with an exotic breed. Such crosses have become extremely popular and have helped reduce fat.

As fat content has decreased, some critics argue that the flavor of beef has suffered. Consequently, beef producers are faced with the challenge of producing animals whose meat has the taste Americans prefer without the fat.

Value Added Products. Beef is still largely sold as a generic product in retail grocery stores, whereas chicken and pork are often sold as “branded” products with fancy packaging and attractive labels. The beef industry has struggled with the concept, launching many private label brands with little success. However, the meat packing industry is concentrated in the hands of three major packers who have shown a reluctance to enter the branded meat business. This factor has also contributed to the decrease in the per capita consumption of beef.

Several breed associations have attempted to market a branded product with their breed name on the package. In many cases they have backed up the labels with extensive advertising programs. Many exotic breeds attempted to market “lite” beef with fewer calories and less fat. Other companies have introduced organic and “natural” beef products. Of the more than 200 companies that have tried to discover and exploit such niche markets, less than a dozen remained in business in the 1990s. The industry continues to search for ways to successfully brand beef, seeing it as a way to increase sales.

The most successful branded product has been Certified Angus Beef. This brand features highly marbled Angus beef. A great deal of effort goes into selling Angus beef carcasses to restaurants and high-end retail stores.

Beef Safety. Throughout the 1990s beef producers faced a challenge from outbreaks of a strain of E. coli. Ground beef is the product most affected by the bacteria, as E. coli do not penetrate the inner muscling of steaks and roasts, and are easily destroyed when the outside meat is heated, seared, or barbecued. The safety hazard occurs when the E. coli are ground up with the hamburger, and the meat is not cooked at temperatures high enough to destroy the bacteria. The E. coli incidents were thought to be a problem with culled beef and dairy cows that are ground for hamburger. These outbreaks caused new labeling laws on meat products that urged consumers to follow proper cooking instructions and not to eat rare hamburger. New studies on irradiation and acid rinses of beef carcasses were also implemented. The USDA insists that despite the E. coli incidents beef remains a very safe food. In 1996 President Clinton announced a new, expanded meat inspection program that required the participation of the private sector as well as the USDA. The USDA implemented the Hazard Analysis and Critical Control Points (HACCP) system to replace the look-touch-smell system that began in 1907. The new system also requires companies to use antimicrobial chemical sprays and irradiation to combat meat contamination hazards; to determine where in the production process contamination takes place and prevent it from occurring; and to submit samples to the USDA.

Concern for bovine spongiform encephalopathy (BSE), popularized as “Mad Cow Disease,” came to a

head in the 1990s, as producers in the United Kingdom continuously found escalating numbers of afflicted cattle throughout the country. BSE is a fatal disease that affects the central nervous system of cattle. The USDA estimated that 171,000 head of cattle were diagnosed with BSE in Great Britain between 1986 to 1998. Several other European countries reported indigenous cases of BSE. During the past 10 years, the USDA BSE Working Group has taken aggressive measures to prevent BSE from entering the United States. Additionally, the U.S. government and the USDA have conducted studies showing that no cases of BSE exist in the United States. As a precautionary measure, the United States does not import cattle from countries with reported cases of BSE. Moreover, many scientists contend that the disease is not transmissible through an infected cow's meat or through physical contact.

The industry has long been haunted by critics, consumers as well as researchers, who object to the use of hormones in modern day beef production. Although the hormones occur naturally and are administered in small doses, the critics say that they pose health risks. The debate will likely intensify as new biotech products, such as BST, are introduced. These hormones produce meat and milk more efficiently and with less fat. Companies that have attempted to market such hormone-free products have not fared well economically.

Challenges to the Industry. Beef cattle producers have been facing an increasing number of challenges from environmentalists. Although cattle ranchers consider themselves "the original environmentalists," they are facing increasing federal environmental regulations involving endangered species and wetlands protection. As the largest private landowners in the country, ranchers are most affected by laws that restrict the rights of private property owners. Such issues have begun to overshadow diet and health concerns. Because the cattle business provides the primary livelihood for thousands of small communities, the resolution of such environmental issues as endangered species and wetlands protection is of vital importance.

Some environmental groups have questioned the amount of grazing land devoted to the cattle industry. Buffalo grazing developed our nation's grasslands. Beef cattle replaced the buffalo, and in the early years of the industry some abuses existed, when rangeland was free for the taking and there were no fences. Cattle barons ran as many cattle as they could, and during years with inadequate rainfall some rangelands deteriorated. However, according to the U.S. Bureau of Land Management, the overall condition of the national rangelands, both public and private, has improved during the past 50 years. Eighty-seven percent of this land is considered "stable or improving." However, the National Resources Conser-

vation Service of the USDA considers only 39 percent of rangelands to have no serious resource problems. They hoped to increase this to 45 percent by the year 2002.

Although there is no government price support program for beef cattle, the government does operate a Conservation Reserve Program (CRP), whereby cattle producers and farmers are paid to keep previously farmed or marginal lands out of production for 10 years. Since 1980, 45 percent of cattle producers have participated in some form of government conservation program. During the same period, 64 percent have participated in private conservation programs, such as rotational grazing and range management systems. Range science concepts are relatively new and have only been put into practice since the 1960s. New ideas are emerging almost daily as to how beef cattle can best be integrated into an environment that also accommodates wildlife and growing numbers of people.

The beef cattle industry faced many other challenges during the 1990s. Although vegetarianism has remained relatively stable at about 3 percent of the population, an increasing number of people are occasionally eating vegetarian dinners. Although beef is a nutrient-dense food with a caloric content similar to that of chicken, it is generally not perceived as such by a large part of the general population. Health care and nutritional experts recognize, however, that beef can be part of a well-balanced diet because it is a good source of iron, zinc, and vitamin B-12.

Exports. Although there were difficulties in marketing beef during the 1980s and 1990s, there have also been some stunning success stories. The most economically significant success for the industry has been the increased demand for American beef internationally. The United States produced 24.9 percent of the world's beef supply in the 1990s, with exports representing 9 percent of the value of all U.S. beef production. From 1981 to 1998, export values increased from \$1.9 billion to \$4.4 billion. It is estimated that between 10 and 12 percent of the value of every steer produced domestically comes from the added demand created by the export market. Consequently, the National Cattlemen's Association was very much in favor of the North American Free Trade Agreement (NAFTA), because Mexico is a growing market for American beef. Exports to Mexico increased nearly 47 percent during 1994, the first year of NAFTA. This was followed by a brief downturn with the devaluation of the Mexican Peso, but rebounded by the end of the decade. NAFTA has been criticized for contributing to lower domestic cattle prices in the face of foreign imports, in spite of the fact that NAFTA did not change the regulations on cattle imports. Beef exports also suffered somewhat due to the slowdown in the Asian economy, and are down from a high of \$5.3 billion in 1995. In 1999, 82.7

percent of exports went to Japan, Mexico, Canada, and the Republic of South Korea. European markets are less receptive to U.S. beef, which has been treated with hormones. Despite these slowdowns, exports significantly exceed imports, and there continues to be a strong export market for U.S. beef and by-products.

CURRENT CONDITIONS

All fresh retail beef prices averaged 304.0 cents per pounds at the beginning of 2002. Average retail price during 2001 was 299.7 cents per pounds. In 2002 Americans consumed 231.3 pounds of meat per capita. Of that total, beef accounted for 67.7 pounds, or 29.3 percent of American meat intake. This represents the fourth consecutive year of decline in the consumer's choice of beef. Red meat accounted for 42 percent, 36 percent, and 30 percent during the 1970s, 1980s, and 1990s, respectively.

The average beef cattle price per 100 pounds in 2000 was \$69.52 for steers (heifer prices vary slightly). Prices during the 1990s ranged from a decade high of \$76.23 in 1993 to a decade low of \$70.06 in 1998. Prices climbed into the mid-\$70s during 2002, but demand was reduced, so overall sales were flat. Traditionally, beef prices increase in the spring and early summer months, as retailers prepare to stock up for the "grilling-out" season.

Beef cattle weights have increased substantially in the recent past, so that the amount of beef processed has grown, even though the number of cattle slaughtered has declined slightly. According to Rich Pottorff of *Agri Marketing*, "Cattle weights have been increasing for years, but the increases have been especially large in the last couple of years. Through the first half of this year, cattle dressed weights are almost 30 pounds heavier than in 2001. This results in a 4 percent increase in beef production with essentially no increase in slaughter."

The beef cattle industry experienced a downturn after the terrorist attacks of September 11, 2001, primarily because consumers cut down on eating out. The erosion of the beef market continued into 2002. The industry was also negatively affected by the discovery of mad cow disease in Japan, which is the largest importer of U.S. beef. Year-on-year cattle prices were down 10 percent between 2001 and 2002. Significant drought in the West left pasture land in poor shape, suggesting that it would be some time before ranchers would restock their herds.

WORKFORCE

The largest cattle ranch in the United States is the family-owned King Ranch in Texas. While much of the West was settled by large ranchers with investor money from England, today the American cattle industry is largely made up of small, family producers. In 1996, 79.8 percent of U.S. beef operations had less than 50 head of

cattle. The King Ranch's herd of 60,000 reveals the extremes in the modern day beef industry.

Approximately 98 percent of all American cattle producers are considered small or midsize (less than 500 cattle) by the National Cattlemen's Association. These ranchers raise the majority of the nation's beef cattle, accounting for 86 percent in 1996. While the cattle feeding and meat packing industries continue to become more concentrated in the hands of fewer and larger corporations, the beef cow herds remain in the hands of small or midsize producers. Cattle are also raised as a sideline, a hobby, or in conjunction with a farming operation. In addition, they are often used to consume what is left after crops have been harvested.

The work on a typical ranch varies with the season. In winter, when grass is dormant or covered with snow, the cattle must be fed hay. Ranchers usually grow and store this hay in the summer, but some ranchers purchase their hay. In the spring and summer, cattle are branded and worked; this requires hiring more hands. Several ranches share cowboys during these roundups. One of the more difficult chores comes at calving time, when cowboys routinely check the cows and heifers. Heifers are females that have not yet had a calf and usually have much more difficulty calving than an aged cow. A cowboy must often assist heifers in the birthing process.

In Nevada, male and female ranch workers are referred to as buckaroos, in Texas they may be called cowpunchers, and in Montana they are cowboys. Though they are referred to by a variety of names, these workers generally perform the same duties and receive a fairly low wage for their work. Typically they are given a house, a ration of beef per year, a pickup truck, and a monthly salary that ranges from \$650 to \$2,000. The National Cattlemen's Association estimates that the industry produces about 186,000 full-time jobs.

The beef cattle industry is steeped in tradition. For example, 42 percent of U.S. beef cattle operations with more than 100 head of cattle have been in the same family for over 50 years, and 21 percent have been in the same family for 75 years. Many of these firms are known by the brand they give their cattle, such as the Pitchfork or the Four Sixes. The latter brand is simply 6666, which is said to be the poker hand the founder of the ranch was holding when he won the ranch.

While being a cowboy used to be a romantic notion, far fewer young men and women had aspirations of becoming cowboys in the 1990s. It is projected that the need for cowboys will continue to decline through 2006. The production of beef remains high, but this is due more to the increased weight of animals than to larger herds.

There are several barriers to entry into this industry. It is difficult to find a ranch in America today that will be

profitable. Ranches are often priced according to cow/calf unit, which is the amount of land necessary to run a cow and her calf for one year. This calculation is used to figure the carrying capacity of the land. Typically a ranch today sells for \$1,500 to as high as \$3,000 per cow/calf unit.

Many ranches were up for sale in the 1990s, and a lot of them had federal land-grazing permits. Most eastern cattle ranches are composed entirely of “deeded land.” In the West, however, the government owns sizable amounts of land in each state. For example, the federal government owns 86 percent of Nevada, 52 percent of Oregon, 49 percent of California, 64 percent of Idaho, 67 percent of Utah, 49 percent of Wyoming, and 41 percent of Arizona. This land has traditionally been rented to public lands ranchers who run their cattle part of the year on these marginal lands. These ranchers own small deeded ranches and use much of the farming land for hay production. The deeded acreage is usually surrounded by large blocks of federal land. Ranchers often lease this ground from the federal government as a means of supplying cattle with water. The rancher is responsible for maintaining fences and overseeing the property. These lands are governed under a multiple-use concept, which means that other citizens can use the lands as well. However, Congress has attempted to increase the land rent and put constraints on the public lands ranchers.

RESEARCH AND TECHNOLOGY

There were about 100 million cattle in the United States during the 1990s, and the industry was producing as much beef as it did in the 1970s, when its cattle inventory numbered 120 million. Such efficiency has been made possible by the use of technology—new breeds, computerization, and increased mechanization. Output per man hour in agriculture has increased twice as fast as that in manufacturing industries. American beef cattle producers are producing nearly 25 percent of the world’s beef supply with just 10 percent of the world’s cattle population. Other countries have been unable to match U.S. efficiency standards. For example, prior to the breakup of the Soviet Union, they had nearly 20 percent more cattle than the United States but produced 20 percent less beef.

The use of production testing and artificial insemination has made it possible to use the best genetics the industry has to offer. Fertilized eggs from superior producing cows are being flushed and then implanted in lower quality recipient cows, so that their offspring will have highly predictable traits for growth and meat quality. In effect, the recipient cow acts as a surrogate mother for a calf that carries none of her genes.

Breed associations keep extensive computer records, and the use of “Expected Progeny Differences” has

made it possible for a rancher to select his cattle using statistical analysis.

Money from ranchers’ voluntary dollar per head assessment is being pooled and used to map the genes of beef cattle. It is expected that such research will allow future ranchers to implant genes for tenderness, marbling, or any number of economically important beef cattle traits.

Quality control became the watchword of the industry in the 1990s. The beef cattle industry initiated its own Beef Quality Assurance program to assure consumers that beef is a wholesome food. Beef Quality Assurance programs have been sponsored by 41 states, which account for 98 percent of all cattle marketed. Additionally, the Pathogen Reduction Act of 1996 required the industry to update its inspection methods, which had changed little in the previous 50 years. During 1996 to 1999 the new inspection methods were put into effect. As of January 20, 2000, all raw meat and poultry products were being inspected using methods capable of detecting invisible pathogens.

Microchips and scanners are being tested as a means to maintain cattle identification. For instance, a calf could be implanted with an identification chip at birth, and when that animal’s carcass is hung on the rail, the chip could be scanned, and the individual could be traced back to its original owner. The chip could also reveal vaccination records, pedigree information, and feedlot data. Such information would allow the industry to identify superior producing animals and weed out those of poorer quality.

SIC 0213

HOGS

This category covers establishments primarily engaged in the production or feeding of hogs on their own account or on a contract or fee basis. A general trend toward vertical integration in the industry has resulted in larger, more integrated hog operations that often play diverse roles—including breeding, raising, feeding, feed production, butchering and processing, distribution and marketing—in the process of getting hogs from the weaning pen to the market place.

NAICS CODE(S)

112210 (Hog and Pig Farming)

INDUSTRY SNAPSHOT

The U.S. Department of Agriculture estimates that American producers maintained about 97 million hogs on farms and feedlots in 2003, compared to 61 million in 1997. Processed pork totaled 97 million pounds in 2003. Throughout the late 1990s and early 2000s, consumer demand for pork continued to grow, fueling roughly \$38 billion in annual sales by 2003, as well as \$72 billion in economic activity. U.S. hog production is only about 10 percent of the world total, but the United States is the second-largest exporter of pork in the world.

ORGANIZATION AND STRUCTURE

Besides meat, pork products provide a broad range of needs, serving as a source for over 40 drug and pharmaceutical products as well as varied industrial and consumer products, from chemicals to leather goods. Such widespread demand fueled increasingly fierce competition, with a general trend toward larger farms and vertically integrated operations that controlled every step of the production process, from birth to grocery store sales. With escalating competition, industry leaders in the 1990s and 2000s strove to increase pork's market share by appealing to consumers. Lower prices resulting from supply surfeits of the early 1990s were a start. But the pork industry was faced with the task of reversing years of market decline largely brought on by consumers' growing health concerns, which had resulted in a general shift in consumption from pork, beef, and red meats to less fatty fish and poultry. In 1986 the National Pork Producers Council (NPPC) launched its "Pork—the Other White Meat" promotional campaign to emphasize a new health-awareness in the industry and to lend fresh pork a brand name type identity. In 1996, NPPC began a new phase of its campaign, emphasizing the versatility of pork, epitomized by its "Taste What's Next" slogan.

In December 1991 the University of Wisconsin, working with the U.S. Department of Agriculture and the hog-raising industry, published findings that indicated that pork examined in 1990 contained 31 percent less fat, 17 percent fewer calories, and 10 percent less cholesterol than its equivalent in the *1983 USDA Nutrient Handbook*. The NPPC estimated that in contrast to the hog of the 1950s, the hog of the 1990s contains 50 percent less fat. Whereas before the average hog had 2.86 inches of backfat, now the average hog only has 1.1 inches.

In the early 2000s, roughly 80 percent of the nation's hogs came from farms that produced over 5,000 hogs a year. Furthermore, a survey by Brock Associates of Milwaukee and Elanco Animal Health division of Eli Lilly & Co., suggested that the country could have as few as 100 producers by the year 2050. The majority of survey participants—250 leading hog producers, veterinarians, meatpackers, and scientists—believed that the pork in-

dustry would move along the same lines that the poultry industry had in previous years, with a massive shake-down in the number of small or independent producers. Industry observers noted that hog production was rapidly becoming less labor-intensive and more capital-intensive, a condition that had not been problematic for corporate outfits able to bring significant resources to bear. Independent farmers, however, have to compensate for their lack of capital through extra work and by securing the latest technology through public universities, cooperative deals, and other sources.

Competition for such resources to acquire the necessary funding for the buildings, equipment, and technology needed to produce the most competitive hogs has grown increasingly fierce. Producers have to seek increasingly tight financing through combinations of credit institutions, investor groups, insurance companies, and allied industries such as feed producers and packers. Financing is contingent on overall efficiency, management ability, complete and accurate records, and a sound business plan. In order to best meet such demands, producers have to rely increasingly on genetics, nutrition, and advanced record-keeping systems.

The Typical Hog Farm. Whether corporate or independent, typical hog farms have operated along roughly similar lines, consisting of designated buildings or areas for breeding, farrowing, nursing, growing, and finishing the animals. Depending on various factors—available capital, amount and type of labor, future plans, existing facilities, and management style—a producer could provide a comfortable and efficient environment in many ways. To conserve land for harvesting purposes and to better control animal environments, producers increasingly turned to enclosed buildings for the different stages of production. In the past, fully controlled environments were almost exclusively reserved for nurseries, where baby pigs had to be carefully protected against weather, insects, and disease.

From Gestation to Market. The gestation period for a sow or gilt (young female that has not yet had its first litter) lasts 114 days, during which a careful diet is provided to ensure a healthy litter. Farrowings averaged 8.8 pigs per litter in feeder pig production and 8.52 pigs saved in farrow-to-finish operations, with average pigs weaned increasing to 8.4 in 1995 up from 7.1 in 1980. Facilities for farrowing (giving birth to baby pigs) ranged from pasture systems with A-frames or other types of shelter to confined quarters that could be totally or partially confined. Though significantly more expensive, total confinement facilitated handling of hogs, disease control, feeding control, and reduced labor expenditure for the farmer.

After three to five weeks, pigs are weaned (removed from their mother) and moved to a nursery—dry, warm,

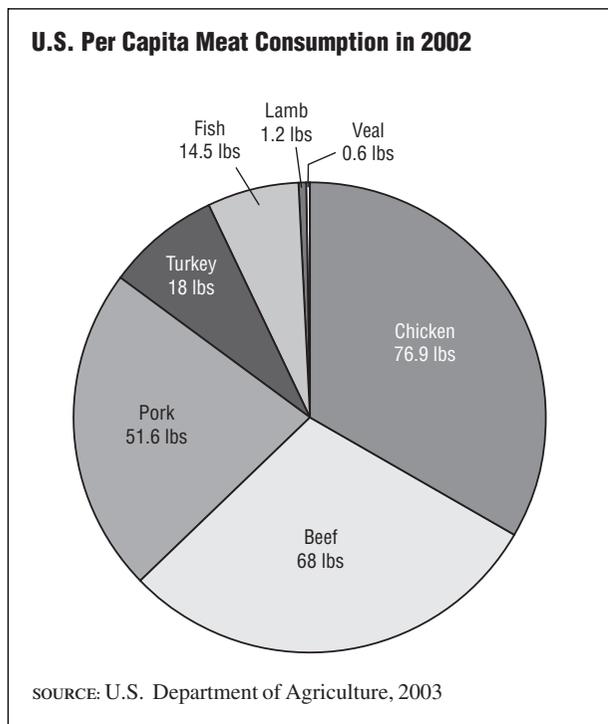

and draft-free facility that generally features slotted floors to keep the young animals free of their own waste. After reaching an age of eight or nine weeks, by which time the pigs weigh an average of 50 pounds, the pigs are moved to another area for growing until they reach roughly 120 pounds; finally, they are finished (fattened or fed in preparation for slaughter) until they've reached the marketable weight of 220 to 250 pounds.

Feed and Supplements. From farrow to finish, food intake is carefully monitored to assure proper growth and development and, above all, marketable fat-to-muscle ratio. They are usually fed a ration of 20 percent protein in the nursing stage, changed in an incremental fashion to 13 to 15 percent for finishing. U.S. producers tended to prefer corn as the staple diet, supplemented by high-protein soybean meal and other feeder concentrates usually acquired from specialized feed producers.

Breeding. Generally, eight major breeds remained prominent in the United States throughout the 2000s: Yorkshire, Landrace, Chester White, Berkshire, Hampshire, Duroc, Poland China, and Spot. Purebred hogs are generally raised to be sold to commercial producers as seed stock for crossbreeding purposes. The objective of crossbreeding programs is to combine the most desirable traits of select breeds in order to arrive at the desired characteristics of leanness, meatiness, feed efficiency, growth rate, and durability. In the 1990s and early 2000s, farmers have increasingly depended on the research and expertise of independent breeders to provide them with stock designed to yield a more competitive hog herd. In addition, a growing proportion of breeding stock consists of hybrid (crossbred) hogs. Hybrid hogs have become a significant part of breeding stock replaced annually in the U.S. herd.

Whether a producer secures breeding stock from a breeder or from the resident herd, choice of breeders can make or break a herd. Considerations in boar selection include such traits as temperament, birth rate, feed efficiency, carcass merit, feet and leg soundness, and past performance records with litter mates. Sow herd replacements are often gilts from large litters that exhibited fast growth and leanness.

Three basic breeding systems have been commonly employed: the simplest lets one boar run with a group of sows and gilts. Although such a method requires little labor, it complicates the detailed record keeping of breeding dates. Another option is a hand breeding system that puts one boar with one female at a time; this puts less stress on the boar and is easier for record keeping. A third breeding method involves artificial insemination. This route requires the greatest level of management for the producer, but minimizes the spread of disease organisms or uncontrolled genetic material.

The Market. Once a hog has reached an average of 230 pounds and 4.5 to 6.5 months of age, it is considered ready to market. The producer has several options at this juncture, including livestock exchanges, cooperative marketing agreements, terminal markets, auctions, and direct sales to packers. Terminal markets are typically located near major metropolitan areas, where commission firms represent the producer before the product is brought to nearby slaughtering plants. Auctions, on the other hand, were developed to provide a point of sale for small lots of livestock in rural communities. Direct sales to packers became increasingly popular with advances in animal transportation vehicles, which facilitated both delivery of livestock to packers and shipment of dressed carcasses to consumption centers.

Playing off the ever-shifting forces of supply and demand, producers can also sell their product at livestock exchanges, hedging their hogs on futures markets like the Chicago Mercantile Exchange (CME). Market prices for hogs and pork products can be extremely volatile, influenced by a wide range of factors, including seasonal and cyclical supply fluctuations; shifting consumer demand patterns due to seasonal influences like holidays and temperature patterns; the impact of the fortunes of competing products like beef and poultry; and the price of grains, such as corn and soybeans, that serve as hog feed.

Industry Cooperation. In order to best address changes in production, marketing, technology, and consumer preferences, pork producers have organized at local, state, and national levels. In addition to countless cooper-

atives and local clubs and councils, the pork industry was represented by four main organizations in the 2000s: the National Pork Bureau (NPB), the National Pork Producers Council (NPPC), the Pork Industry Group (PIG) of the National Live Stock & Meat Board, and the U.S. Meat Export Federation (MEF).

The National Pork Bureau was established by Congress under provisions of the Pork Promotion Research and Consumer Information Act of 1985. Its purpose was to organize and manage funds raised by a legislative check-off on all hogs and pork products sold domestically and imported, at the rate of 35 cents per \$100 of value. The NPB contracted different organizations to coordinate specific checkoff-funded programs. The NPPC, for example, coordinated national product promotion and marketing efforts. That group was also responsible for a wide range of programs in producer research and education. The MEF assisted NPPC in cultivating foreign markets of U.S. pork. PIG coordinated informational programs aimed at health care professionals and schools, including nutrition and product research related to pork.

Meat Inspection Policy. In 1996 President Clinton announced a new, expanded meat inspection program that would require the participation of the private sector as well as the USDA. The USDA implemented the Hazard Analysis and Critical Control Points (HACCP) system to replace the look-touch-smell system that began in 1907. The new system requires companies to use new technology, anti-microbial chemical sprays, and irradiation, to combat meat contamination hazards, to determine where in the production process contamination takes place and prevent it from occurring, and to submit samples to the USDA. Besides these measures, the NPPC has taken steps to ensure pork does not become contaminated. Calling for participation at the producer level as well as at the processing level, the NPPC strove to reassure consumers of pork’s safety.

BACKGROUND AND DEVELOPMENT

Dating back 40 million years according to fossil records, hogs were domesticated in China by 4900 B.C. and in Europe by 1500 B.C.. The animal was reputedly brought to the New World from Europe by Columbus and then, more notably, by Hernando de Soto, who was dubbed “the Father of the American Pork Industry” for landing hogs at Tampa Bay, Florida, in 1539. By the time of de Soto’s death in 1542, his herd of 13 had grown to 700 strong. Pork colonization continued with other explorers: Hernando Cortez introduced hogs to New Mexico in 1600 and Sir Walter Raleigh brought them to the Jamestown Colony in 1607.

Hog population grew alongside, and sometimes in conflict with, humans—a long solid wall was constructed on the northern edge of Manhattan Island to control

roaming hogs, eventually becoming the Wall Street area of the country's largest city. By the end of the seventeenth century, the typical farmer owned between four and five hogs, which were raised largely on Indian corn. Pioneers carried a growing hog population westward in the nineteenth century.

By the mid-1800s, pork was being commercially slaughtered in Cincinnati, which acquired the moniker Porkopolis as a result. During this period, 40,000 to 70,000 hogs per year were driven along trails to eastern markets. The development of railroad lines and eventually the refrigerated railroad car ushered in the modern era of the hog industry. The midwestern states led the nation in hog production after 1920.

CURRENT CONDITIONS

About 97 million hogs were slaughtered in 2003, generating 19 billion pounds of processed pork and retail pork sales of roughly \$38 billion. Compared to 3 million in the 1950s, the number of U.S. pork producers in 2003 totaled only 85,760. Consolidation has contributed significantly to this decline as farms producing 5,000 or more hogs per year accounted for 80 percent of total U.S. hog production in 2003. This situation for the small farmer continued a trend that saw the industry concentrating itself into corporate-based finishing and marketing operations. More than 50 percent of the inventory share of U.S. hog marketings come from the large contract hog operations. In this contractual situation, the contractor agrees to provide the hogs, feed, medication and supplies. The contractee supplies the housing, utilities and labor.

Animal Rights. The pork industry's efforts to produce an efficient, lean pig, as well as the consumption of its product have aroused animal rights groups. Common ground between these two groups is perhaps impossible to achieve, since the industry's livelihood is predicated on continued consumption of pork and other hog byproducts. But numerous, if not effective, measures had been taken over the years. As early as 1873 legislation—the Humane Treatment of Livestock Act—was enacted to prevent cruelty to livestock while in transit on railroads. It was repealed and replaced in 1906 by the 28-hour law controlling feed and water availability and handling procedures of livestock. The Humane Slaughter Act of 1958 also contained humanitarian guidelines, though no non-compliance penalties were enforced. These and numerous other rules continued to spark controversy over such issues as animal confinement, feed supplements, and slaughtering methods. Groups such as the People for the Ethical Treatment of Animals (PETA), a Washington, D.C.-based nonprofit animal protection organization, continue their opposition to the pork and beef industries.

Drugs and Pork. Concerns were also voiced by consumers, veterinarians, hog buyers, and the NPPC over the

use of drugs by hog farmers. Efforts have been mounted in recent years to develop better methods of detecting drug residues in table-ready pork in an effort to alert producers and curtail the practice. Industry interest also revolved around the possible uses and abuses of porcine somatotropin (PST), a growth hormone that would greatly reduce fat while increasing lean meat and diminishing the amount of feed needed for a pound of weight.

INDUSTRY LEADERS

In 2003 the leading pork producers in the United States were Smithfield Foods, of Smithfield, Virginia, followed by PSF Group Holdings, of Kansas City, Missouri; Seaboard Corporation, of Shawnee Mission, Kansas; Prestage Farms, of Clinton, North Carolina; and Cargill, Incorporated, of Minneapolis, Minnesota. Sales at Smithfield Foods grew 7.5 percent to nearly \$8 billion in 2003, although net income declined 87 percent to \$26.3 million. Revenue for PSF Group declined 10 percent to \$608 million in 2003. According to the U.S. Department of Agriculture, the leading hog-producing states include Iowa, North Carolina, Minnesota, Illinois, Indiana, and Nebraska. Other leading states included Missouri, Ohio, South Dakota, and Kansas. During the early 2000s, pork production expanded outside the corn-belt states to Colorado, North Carolina, and Texas.

AMERICA AND THE WORLD

The United States imported and exported substantial quantities of hog products in the early 2000s and is among the world's largest pork exporters in the world, accounting for roughly 10 percent of global production. The world's leading exporter of pork in 2003 was Canada, and the United States and Denmark tied for second place. The top customers for U.S. pork exports in the early 2000s were Japan, Russia, Canada and Mexico. In 1996 U.S. exports of pork had reached the \$1 billion mark, a milestone which the NPPC attributed in part to the implementation of the General Tariffs and Trade Agreement (GATT) and to the North American Free Trade Agreement (NAFTA). U.S. pork exports were expected to grow 7 percent to 1.3 billion pounds in 2004.

RESEARCH AND TECHNOLOGY

Checkoff-funded programs organized by the pork industry forged ahead in research and development toward efficient and safe pork production that would better attract domestic consumers and compete in world markets. Of the many advances sure to affect the hog industry of the future, several could be especially notable, including the use of repartitioning agents as feed additives to encourage less fat, leaner meat, and faster growth; and biotechnology that would advance gene mapping to a point where growth, fat-to-lean ratio, and prolificacy could be better controlled from the laboratory. In fact, by

2003, technological advances in genetics had allowed North Carolina to increase efficiency to the extent that it ranked as the second-largest pork producing state as of 2003.

SIC 0214

SHEEP AND GOATS

This classification covers establishments primarily engaged in the production of sheep, lambs, goats, goats' milk, wool, and mohair, including the operation of lamb feedlots, on their own account or on a contract or fee basis.

NAICS CODE(S)

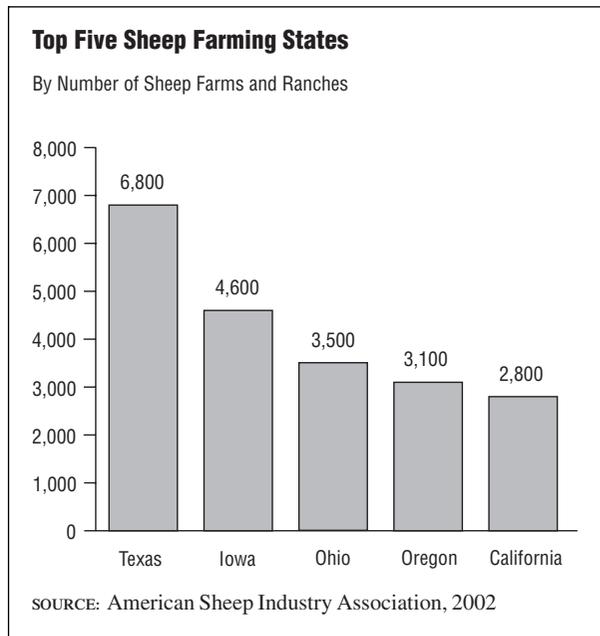

112410 (Sheep Farming)

112420 (Goat Farming)

In 2002 there were 64,170 sheep operators in the United States, compared to 68,810 in 1998. The number of operations has continued to drop each year since 1992 when the U.S. Department of Agriculture (USDA) reported about 100,000 sheep operations. Although sheep and goats are produced in every state, western states produce 80 percent of the total U.S. flock. Sheep and goats are among the most versatile animals in the world. They can live in many climates from the desert Southwest to the colder climates of Wyoming, and they can efficiently turn barely edible browse into food and fiber. Many farmers use sheep to clean up crop residues. In the West, sheep are often run on alfalfa fields under temporary fence. Goats, however, are even more hearty than sheep, and, therefore, can make do on land that even sheep cannot.

Along with the decline of operations is the decline in gross sheep and lamb production. According to *USDA-NASS Agricultural Statistics*, in 2003 the total number of sheep and lambs was 7.8 million, down 4 percent from 2002. Breeding sheep numbered 4.6 million in 2003, while market sheep and lambs numbered 3.2 million, both reflecting a 4 percent decline from 2002.

Sheep. In eastern states the farm flocks are generally small, while in the West the flocks are much larger, often

numbering in the thousands. The top five sheep-producing states as of 2002 were Texas, California, Wyoming, South Dakota, and Colorado. Texas alone accounted for 1.05 million of the 6.4 million sheep raised by farmers and ranchers in 2003. California boasted a sheep population of 790,000; Wyoming, 460,000; South Dakota, 380,000; and Colorado, 370,000.

Sheep production in the United States is unique among all sheep-producing countries, because the U.S. market emphasis is on meat, rather than wool production. Three-fourths of the American sheep producer's income is derived from the sale of meat, whereas, in the rest of the world, wool is the primary commodity. Sheep that are processed before the joints in their legs ossify produce meat referred to as "lamb," while older sheep produce mutton. There is a very distinct difference between the two types of meat, and lamb is priced significantly higher.

The female sheep is called a ewe and she may give birth to one or more lambs. The national average is 1.1 lambs per ewe per year. Sheep producers are weaning 20 percent more lambs per ewe in this country than 10 years ago. The lambs are raised in the spring and are processed for meat when they reach approximately 125 pounds at 5 to 6 months old. Most lambs go straight to processing right off grass, but some lighter lambs may spend the final finishing stage in a feedlot eating a high-concentrate grain ration. Many sheep flocks are still herded by Basque shepherds and their well-trained dogs.

Consumer demand for the taste of fresh American lamb is growing, especially at restaurants, where usage is up dramatically. Consumers are eating 16 percent more lamb than ever before and retailers are allocating 38 percent more shelf space to selling American lamb.

Lamb prices commanded by producers, however, have fallen in recent years, while the retail price of lamb has risen.

The sheep industry has experienced some wild price swings. In just one year the price of lamb per head fell from \$100 to \$45. Prices rose in 1996 to \$86.50 per head, yet they have fluctuated greatly in the past decade. Wool prices grew 25 percent in 2003 to an average of \$0.72 per pound, or a total value of \$27.4 million, from \$21.9 million in 2002.

Historically, American lamb producers have blamed the lamb packing industry, which has become concentrated into a few hands, and imports from Australia and New Zealand for their losses. To differentiate their fresh product from frozen imported products, the American Lamb Council launched a program in 1990 to label and market selected fresh American lamb that is leaner than the imported product. The program has been successful and that product now accounts for 22 percent of the American lambs being marketed.

Beginning in the late 1990s, increased imports of lamb meat from Australia and New Zealand began to endanger the survival of U.S. sheep producers, according to the American Sheep Industry Association. In September 1998, the American Sheep Industry Association and industry supporters filed a Section 201 trade action petition with the U.S. International Trade Commission. The Trade Commission investigated the effects of increased lamb imports on the U.S. sheep industry and reported recommendations to the White House. On July 7, 1999, President Clinton imposed a three-year tariff-rate quota program and \$100 million in assistance to the sheep industry. The program began in July 1999, and imposed a tariff on all lamb imported from Australia and New Zealand through July 2002.

Although the United States is not a major player in the world wool market, U.S. wool is known for its bright color and strength. Domestic wool production fell to 38.1 million pounds in 2003, compared to 41.2 million pounds in 2002; 53.8 million pounds in 1997; and 89.2 million pounds in 1989. The number of sheep and lambs shorn declined 8 percent to 5.06 million head in 2003. Wool exports fell from \$108.5 million in 2001 to \$91.6 million in 2002. Because of fluctuation in payments, U.S. farmers have typically shied away from wool production. Also, world output of wool is 6 percent higher than demand, and it could take 10 years just to eliminate the wool stockpiled in Australian warehouses. However, the sheep industry remains a vital contributor to the U.S. economy. Sheep contribute \$7 billion to the gross national product when domestic lamb and wool production is sold at the retail level. The production of lamb and wool in this country accounts for 350,000 jobs.

Sheep killed by animal predators is a serious issue for livestock operators. At the turn of the twenty-first century, predators accounted for approximately 36 percent of sheep and lamb losses, resulting in lost income of an estimated \$35 million, according to the American Sheep Industry Association. Coyotes are the major predator of sheep and lambs.

Goats. The American goat industry is made up of milk goats that are run in small farm flocks and backyard operations as well as large mohair operations primarily in the dry and arid southwestern states. Mohair, like wool, creates a versatile fabric for warm and cold weather and can be found in apparel and furniture. Goat meat has increased in popularity in the United States, as well.

Texas is the leading mohair producing state, while New Mexico and Arizona produce nearly all of the rest of the country's mohair. The three-state total for goats clipped in 2002 was 248,000 head, down considerably from 936,000 head in 1997, according to *USDA-NASS Reports*. In 2002, each goat averaged a clip of 7.6 pounds, up slightly from 7.3 pounds in 1997. The goat producer received approximately \$2.48 a pound for the mohair in 1998, up from \$2.25 per pound in 1997. The USDA estimated that the value of the 2002 yield was \$3.1 million, reflecting a decline of 9 percent from 2001.

According to the United States Department of Agriculture, during World War II and the Korean conflict, the United States imported half the wool required for military uniforms and blankets. The National Wool Act of 1954 was enacted to reduce dependency on foreign wool imports and increase domestic production by providing a subsidy for wool and mohair producers in the United States. The subsidy provided direct payment to farmers based on their production: the more wool they produced the more federal funding they received. A portion of the import tax levied on wool provided the money for the subsidy program. In 1955 the amount of wool sheared was 283 million pounds compared to 89 million pounds in 1988. The price of mohair dropped from \$5.10 per pound in 1979 to just \$0.95 per pound in 1990. In 1993, Congress voted to eliminate the subsidy at the end of the 1995 fiscal year, saying the program had failed to increase domestic wool production, disproportionately benefited the few largest producers, and wool was no longer a strategic material. The Federal Agriculture Improvement and Reform Act of 1996 upheld the earlier elimination of wool and mohair subsidies, in an effort for the government to reduce spending. However, the 1999 Omnibus Appropriations bill and the 2000 Agriculture Appropriations bill made interest free loans available to mohair producers once again. In the early 2000s, the U.S. government put into place Wool and Mohair Assistance Loans and Loan Deficiency Payments covering the 2002-07 crop years.

SIC 0219

GENERAL LIVESTOCK, EXCEPT DAIRY AND POULTRY

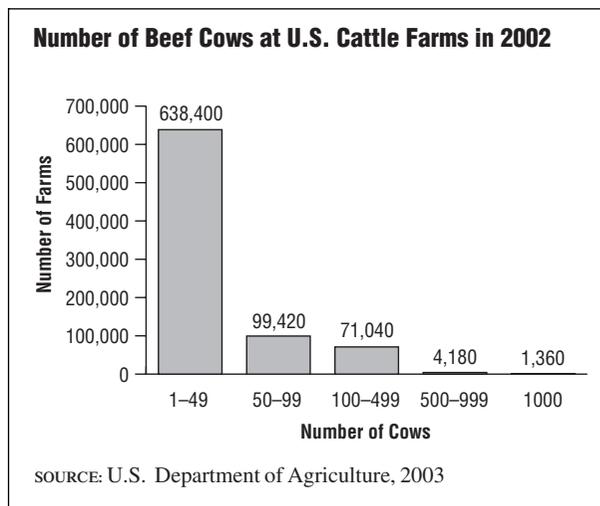

This classification covers establishments deriving 50 percent or more of their total value of sales or agricultural products from livestock such as cattle, hogs, sheep, and goats, but with less than 50 percent deriving from any single one of those livestock categories.

NAICS CODE(S)

112990 (All Other Animal Production)

The multi-faceted, diversified livestock farm had faded from the American landscape by the early 2000s because of industry emphasis on specialization. Large farms focused on raising a single animal were poised to all but replace diversified farms and ranches by the end of the twentieth century. Cattle production, for example, grew into an enormous industry. In the early 2000s, the industry was valued at \$70 billion. Additionally, although only 1,360 of the 814,400 U.S. cattle farms had more than 1,000 cows in 2002, these farms accounted for roughly one-third of the country's cattle production and an even larger percentage of cattle value. Cattle farms with less than 100 head of cattle continued to decline in both number of farms and in dollar value production. Overall, the number of beef cattle farms dipped by 2 percent in 2002.

Farmers grazed herds on harvested crop land, which made cattle raising a lucrative side-business. Many

smaller farms were able to support small- to moderate-sized herds this way.

Like the cattle industry, many hog producers became increasingly larger operations as well. In this \$11 billion industry, liberal production laws in states such as North Carolina have attacked large corporate hog farms, but the trend in hog production favors the growth of large-scale organizations. The number of farms that sold more than 5,000 hogs and pigs accounted for roughly 80 percent of total hog output by 2003. This does not mean that ranchers and farmers have given up on diversifying their operations. The species of livestock and the character of the business have changed, though, over the years, and those establishments that fit in this classification are apt to be small family-run outfits. The number of these small operations continued to decline throughout the early 2000s.

Nevertheless, several of the larger beef cattle operations have made some moves toward diversification. Some are also involved in the raising of horses. With the growing popularity of team penning, cutting, roping, and other equine recreational sports, the sale of working ranch horses has become an important source of income for a number of smaller ranches.

Historically, cattle and sheep bred in America did not graze the same land; indeed, cattlemen and sheepherders often viewed each other as rivals. This has changed, however, as studies have indicated that running cattle and sheep together helps keep predators at bay. Shepherders now believe that coyotes are intimidated when cattle are present, thus drastically cutting sheep losses. Running the two species together is also becoming popular for another reason. Overgrazing of plant species is decreased because the cattle eat the grasses while the sheep eat broad-leafed weeds, forbes, and shrubs. Running the two species together is thus a growing phenomenon in parts of the country to both protect the livestock and the land.

SIC 0241

DAIRY FARMS

This classification includes establishments primarily engaged in the production of cows' milk and other dairy products and in raising dairy heifer replacements. Such farms may process and bottle milk on the farm and sell at wholesale or retail. However, the processing and/or distribution of milk from a separate establishment not on the farm is classified in manufacturing or trade. Establishments primarily producing goats' milk are classified in **SIC 0214: Sheep and Goats.**

NAICS CODE(S)

112111 (Beef Cattle Ranching and Farming)

112120 (Dairy Cattle and Milk Production)

INDUSTRY SNAPSHOT

Dairy farming is one of the leading agricultural activities in the United States, with dairy cash receipts totaling \$20.5 billion in 2002. Because of scientific advances increasing milk production, the total number of dairy cows in the United States has been declining steadily since 1970, whereas the total output per cow has increased significantly. The overall number of dairy farms was 97,560 in 2001, down from 123,700 in 1997. Despite the 21 percent decline in milk cow operations, milk production increased 6 percent, from 156,001 million pounds in 1997 to 165,336 million pounds in 2001.

The dairy farm industry has been undergoing some significant changes during the early twenty-first century, caused by changing government regulations regarding milk subsidies and environmental management, geographical shifts in dairy farm populations, increased herd size, and increased milk production per cow. Despite setbacks during the 1990s caused by foot-and-mouth disease and mad cow disease that shook the entire cattle industry, milk products have become an increasing part of the American diet. In 2000 dairy products accounted for 9.08 percent of food dollars, up from 6.65 percent in 1995.

ORGANIZATION AND STRUCTURE

Number and Size of Farms. Every state in the country has dairy farms; however, warmer climates are not generally suited to efficient year-round milk production. Basically, about 88 percent of milk produced in the United States is produced in the 22 states considered to be the nation's Dairy Belt. The Dairy Belt is in the northern region, extending from New York to Minnesota, though California is the largest milk-producing state in the country. Wisconsin, a Dairy Belt state, is the second largest dairy-producing state. Wisconsin led in dairy production for many years, earning the state the title "The Dairy State," but California surpassed it in total dairy production in 1994 and has held the lead ever since. For 1997 and 1998, California produced 7.1 billion pounds of milk during the April-June quarter (the season of highest milk production), while Wisconsin produced 5.8 billion. Other leading dairy states are New York, Pennsylvania, and Minnesota.

Since the 1950s, the number of farms has decreased 50 percent, and the number of farms with dairy cows has decreased almost 90 percent. This is due to the shift toward larger scale, industrial dairy farms. A farm with 100 milking cows was considered big in 1950, while farms with 5,000 milking cows were becoming the norm toward the end of the twentieth century.

As recently as 1987, more than 70 percent of the American dairy farms had fewer than 72 cows, but this large segment of the dairy farmer population produced only about 37 percent of milk sold. However, in the mid-to late 1990s the U.S. Department of Agriculture (USDA) reported that larger farms of 100 or more head accounted for 68.4 percent of the country's total dairy herd. In the South and the West, dairy farms of 500 head or more are increasing. Dairy farming in the nation's Dairy Belt in the north is also headed toward larger, mass-production enterprises, although at present smaller herds still predominate this area. Yet larger dairy farms are able to take advantage of the advances in technology, including fully automated milking parlors, computerized feeding systems, and genetically engineered drugs and hormones, allowing these farms to produce even more milk per head and weakening the ability of small- and medium-sized farms to compete. Many small- and medium-sized farms sell their milk to member-owned dairy cooperatives that process and distribute the milk and other dairy products.

Marketing Orders. For purposes of administration of the government milk subsidy program, dairy farmers in much of the country are part of marketing orders, which are geographic zones set up by the government during the Depression to regulate milk pricing. Farmers voted to form these orders, and the government set the minimum prices for each order that bottlers and other milk processors had to pay. Not all areas chose to be part of this

system, but as of 1994, 38 orders regulated about 70 percent of U.S. milk production.

Dairy Farming Regulations. State and local laws regulate conditions under which milk is produced, collected, and processed because it is so easily contaminated. Most milk is sold as Grade A, when dairy farms meet strict sanitation standards. Milking machine equipment must be washed and sanitized, and the milk house and milking parlor floors must be kept clean. Farmers must also test their cattle for disease periodically, vaccinate all calves against the disease brucellosis, which affects humans, and remove sick cows from the herd. On the other hand, milk that fails to meet these standards is sold as Grade B.

BACKGROUND AND DEVELOPMENT

Dairy cows have been an important part of life in America since the first English settlers arrived in Jamestown in the early 1600s. Cattle continued to move west with the settlers. Each family kept two or more cows with their “dry” times staggered, so that they would have milk year round.

As towns grew, farmers kept more animals and sold any surplus milk they had. Because milk was highly perishable, farmers could not live very far away from consumers. In the mid-1800s, as the big cities expanded, farms became further removed from consumers, and transportation of milk before it spoiled became a problem. But as more and more railroad lines were built, milk could be transported by train as far as 50 miles. Sanitation and refrigeration were a problem though, and it wasn't until they were dealt with that dairy farming could become a major industry.

Pasteurization, developed by Louis Pasteur in France in the 1860s, kept milk safe longer and enabled milk to be shipped farther. However, this process was not widely used in the United States until the early 1900s. Further development of refrigerated transportation and methods to retard spoilage also contributed to the growth of dairy farming.

The five most important dairy breeds in the United States in the late 1990s were Holstein, Jersey, Ayrshire, Brown Swiss, and Milking Shorthorn. Each breed has a different strength, either in quantity of production, composition of its milk, or suitability to a region's conditions. Eighty-five percent of dairy cattle in the United States are Holsteins, which produce large quantities of milk. Jerseys produce the milk richest in butterfat and protein, and they also tolerate heat better than other breeds.

During the period of 1996-1998, U.S. dairy farmers had an annual production rate of almost 72 million metric tons of milk. Throughout the 1990s the U.S. milk cow inventory steadily shrank, but milk production per cow

increased. The number of dairy cows in 1998 was estimated to be 9.2 million head. In 1997 the number was about 9.3 million. In the period between 1993 and 1997, the average was about 9.5 million. Dairy products that come from milk include butter, cheese, ice cream, sherbet, frozen yogurt, and dry milk.

The United States was the largest producer of milk in 1999, with 72.6 million metric tons. India, with 36 million metric tons was a distant second, yet it produced its volume with more cows than the United States. This disparity in milk per cow stems from the ability of U.S. cows to yield 7.3 kilograms of milk per cow, while India's cows only averaged 1.9 kilograms per cow. Industry analysts predicted that the trend of larger dairy farms with fewer cows would persist, followed by a concentration of dairy processing as well.

The 1996 Federal Agriculture Reform and Improvement Act (FAIR) addressed a lot of concerns that had been brewing over the decades about milk price regulation, price supports, and market orders. For years, critics had demanded changes in these dairy-management policies. FAIR called for the elimination of the milk price support program that took effect in 2000. The price support amount was scheduled to decrease from \$10.35 to \$9.90 over the period leading up to 2000. After that, the subsidy will become a recourse loan—an inventory loan from the government—for processors who have butter or cheese in storage. The government hoped this move would get rid of the floor on dairy products.

The 1996 Farm Act also nixed the fee assessed for maintaining the price-support program. Dairy farmers welcomed this change because, under the 1990 Farm Bill, they had to pay \$.11 per hundredweight. Though not fully articulated within FAIR, the milk marketing order system has undergone modification as well. FAIR mandated the reduction of the current 33 orders to just 10 to 14. In addition, the Agricultural Marketing Service (AMS) and the USDA have three years to develop and put into action a reformed milk marketing order system, which among other things, will include a replacement formula for the old Minnesota-Wisconsin Price Series, where the standard for milk prices was based on the cost for producing Grade B milk in these two states. With the elimination of the price support program, analysts believe exports could rise, because the support program kept U.S. prices well above competitors' prices. Furthermore, the 1996 Farm Act allowed The National Dairy Promotion and Research Board to use check-off revenue for international marketing. FAIR also strengthened The Dairy Export Incentive Program (DEIP) and called for the establishment of a dairy export trading company. Making the United States a more viable contender in the world dairy market, legislators hope, will lubricate the transition from price support to market dependence.

However, the government continued to set minimum prices for milk, based on the farm's distance from Eau Claire, Wisconsin, which is in the heart of dairy country. Theoretically, the price was based on how much shipping milk from Eau Claire would cost if supplies were not available locally. Milk for drinking was worth between one and two cents more per gallon for every 100 miles from Eau Claire. Under this policy, farmers in Texas were paid more for milk than Wisconsin dairy farmers. And processors had to pay at minimum a regional price set by government guidelines. Milk has been the only commodity for which the agriculture secretary can dictate the minimum price to be paid a farmer.

The complicated system, which requires 500 Department of Agriculture employees to administer and takes up three volumes of the *Code of Federal Regulations*, was instituted in the 1930s, before refrigerated transportation was widely available. The South had often faced milk shortages because milk was perishable in the heat, and raising cows in that climate was very expensive. Southern farmers were paid a bonus as an incentive to expand. However, technology today reduces the cost of shipping milk from surplus states, such as Wisconsin, to distant destinations. Technology has also developed new options for shipping milk. For example, in the 1970s scientists devised a way to remove water from milk to make it less expensive to ship. But the federal rules made reconstituted milk more expensive than local milk, so this technology has not been pursued.

The Eau Claire rule led to an increase of dairy farming in warm regions, even though they were not efficient places to run dairy farms. While many Midwestern farmers claim they are hurt by the regulations, farmers from many other regions support the Eau Claire rule, since they fear that revocation of that rule would result in the shipment of Wisconsin milk across the country, driving thousands of dairy farmers out of business. Southern farmers especially oppose deregulation, claiming they could not afford to remain in business without price supports.

CURRENT CONDITIONS

Dairy farms, as well as dairy cow milk production, continue to increase in size. In 2001, 35 percent of total milk cow inventory was on operations of more than 500 head, which produced 39 percent of all milk. In 1997 just 24 percent of milk cow inventory was on 500-plus head farms, which produced 29 percent of all milk. Dairy farms smaller than 500 head accounted for 65 percent of milk cows and 61 percent of milk in 2001, down from 76 percent of milk cow inventory and 65 percent of all milk in 1997. During the period from 1997 to 2001, operations of over 500 head grew by 20 percent, from 2,336 to 2,795 operations. On the other hand, dairy farms of under 500

head have decreased by 22 percent, from 121,364 to 94,765 operations. The biggest dairy operations—those with over 2,000 head—totaled just 325 farms, but produced 21 billion pounds of milk annually, compared to approximately 10 billion pounds produced by all 27,000 dairy farms of under 50 head.

The shift to larger operations has also increased the average milk production per cow, as large farms tend to be more efficient, thus producing a greater percentage of milk. In 2001 the yearly average milk production per cow on operations of more than 500 head was 20,446 pounds, compared to 16,919 pounds per cow annually on operations of less than 500 head.

Geographically, milk farm operations continue to grow in the western region of the United States and shrink in the southeastern and Midwestern regions. From 1997 to 2001, California, Idaho, and New Mexico showed the greatest increases, and Texas, Missouri, and Minnesota showed the greatest declines. California and Wisconsin remain the leading producers of milk. In 2001 California had an inventory of 1.59 million milk cows and cash receipts of \$4.6 billion, and Wisconsin had an inventory of 1.29 million milk cows and cash receipts of \$3.2 billion.

In April 2003 milk prices were at a 25-year low, caused by an oversupply of milk in the marketplace and a reduction in government subsidies. The National Milk Producers Federation outlined a voluntary plan to reduce milk marketing and decrease herd sizes to tighten milk supplies. Although the milk industry is expected to remain relatively flat during the early 2000s, dairy farmers are more concerned about the impact of new Environmental Protection Agency (EPA) regulations regarding dairy waste management systems. New requirements for managing waste must be met by 2006, and the cost of implementation has been estimated to be between \$5 billion and \$10 billion by the deadline.

INDUSTRY LEADERS

In 1998 Progressive Dairies, located in Bakersfield, California, was the nation's largest single dairying business, with a herd of 18,500 located in California, Texas, and Georgia. Horizon Organic Dairy is the nation's top seller of organic milk.

WORKFORCE

Dairy farmers and workers put in long hours with few days off, since the cows must be milked twice a day every day. Farmers must also keep the barns and pens cleared out, clean milking equipment, and keep track of each cow's food consumption and milk production. Most dairy farmers also plant crops to provide feed for their cattle in the winter. Many smaller dairy farms have been in the same family for a few generations, but very few

new family farms have been started in recent years because the costs of land, equipment, and a dairy herd are prohibitive. But the increase in larger dairies is changing the landscape of dairy-related employment. On a large dairy farm in Oklahoma, Braum's Dairy Farm, employees earn \$8 to \$9 per hour, working in six-day intervals punctuated by two days off. The dairy also provides benefits and a savings plan. However, such wages and amenities are not feasible for smaller farms.

Because of their increasing size, the larger dairy farms don't depend as heavily on human labor as they once did. A large portion of the tasks associated with dairy farming are automated, even the milking of cows.

RESEARCH AND TECHNOLOGY

Computers. Many farms have joined the computer age, enabling farmers to keep track of food consumption and milk production to better manage their herds and their finances. Computerized systems also allowed farmers to design better feeding programs for their herds. Computer controlled trolley systems allowed some dairy farmers to deliver just the right food mix to each individual cow, based on the cow's current milk production, age, weight, overall health and its stage in the lactation cycle. A personal computer in the farmer's home is linked with a programmable controller in the barn. Boards in the controller correspond with the various mechanical hardware in the barn. The correct amount of feed, with the correct ratios of forage (corn and hay), grain, soybean meal, and minerals, is measured out for each cow. This computerized system can make the daily adjustments necessary, as a cow's needs change daily based on its milk-producing cycle. The system then delivers the custom-mixed feed to the appropriate cow. Before this system was developed, farmers had no easy way to custom-design a diet for each cow and deliver that diet as much as three times a day. Computers also allow farmers to keep track of milk production as well.

Artificial Hormones. While America had more milk than it needed, the budding biotechnology industry was producing a hormone that could increase milk production as much as 25 percent, which drove down dairy prices. Bovine somatotropin (BST), a natural protein found in cattle, has been artificially produced in pharmaceutical labs. Farmers remained skeptical about its use: would it drive down prices by producing a glut of milk? Would consumers believe milk was tainted if it had artificial BST? Companies producing the artificial protein said BST was present in all milk, and milk from cows treated with laboratory BST did not have any higher BST content than milk from untreated cows.

Dairy farmers were in a difficult position: they had already learned to increase milk production through better feed and breeding methods, but BST promised to

further increase milk production with even smaller herds. Farmers feared that use of the hormone would produce a vast surplus of milk that would bring prices down. Still, the USDA had predicted that 60 percent of dairy cows would be given the hormone by the year 2000. Farmers were not as enthusiastic about the hormone as the pharmaceutical companies, but farmers who wanted to stay competitive would have to give BST to their herds.

BROILER, FRYER, AND ROASTER CHICKENS

This category includes establishments primarily engaged in the production of chickens for slaughter, including those grown under contract.

NAICS CODE(S)

112320 (Broilers and Other Meat-Type Chicken Production)

INDUSTRY SNAPSHOT

Although the number of poultry farms decreased by half over the last 50 years, output rose dramatically, from about 1.5 billion birds in 1959 to almost 8.0 billion at the turn of the twenty-first century. By 2002 poultry production had exceeded 38 billion pounds, reflecting a 3.2 percent increase from the previous year. Domestic poultry consumption grew 5.7 percent in 2002 to nearly 76 pounds.

The industry survived the late twentieth century recession reasonably unscathed. In the early 1990s, it had benefited from unprecedented consumer demand for poultry. In 1992 sales of chicken had outstripped those of red meat for the first time. By 2002, chicken accounted for a 41.7 percent share of the meat market.

Chicken was also being marketed more widely, particularly in fast food restaurants. Between 1970 and 1990, about 25,000 outlets introduced chicken in the form of sandwiches or nuggets, and these numbers continued to grow into the twenty-first century. There was also steady growth in the number of specialist fast food chicken chains, such as KFC and Church's Fried Chicken. The broiler, fryer, and roaster industry and the fast food industry have worked closely together to develop products especially for these markets.

ORGANIZATION AND STRUCTURE

In the early 2000s, 7 to 10 companies controlled about 50 to 60 percent of the chicken market. These were vertically integrated concerns—companies with control over every stage of poultry growth and production from egg production to broiler slaughter.

By the start of the twenty-first century, independent farmers under contract to large poultry companies grew 89 percent of the chickens, a 10 percent decrease from the mid-1990s. The remainder were farmed directly by the companies themselves. Under the contract system, the company provided the chicks, feed, medication, and transportation to market. The farmer furnished the housing, equipment, labor, and miscellaneous supplies, and agreed to raise the birds until slaughter. Farmers were generally paid according to how much feed was needed for the birds to achieve market weight. The less they needed, the cheaper the chickens were to produce and the more farmers earned.

BACKGROUND AND DEVELOPMENT

Broiler production increased from 34 million in 1934 to approximately 6 billion in 1990. Output has increased in all but five of the last 50 years. Better breeding, feeding, and disease control—combined with more sophisticated

housing—reduced broiler production time by two weeks between 1980 and 1990. In 1935, it took a farmer 16 weeks to produce a 2.9-pound broiler, with 4.5 pounds of feed needed per live weight. By 1988, a farmer could produce a four pounder in just six weeks, on less than two pounds of feed per live weight. This increase was realized by the use of intensive farming methods; new systems of temperature, feed, and water control; careful breeding; and the use of antibiotics to speed the birds' growth.

Increased national and international demand for chicken and chicken products fueled steady industry growth, about 5 percent per year since the early 1960s. In 1995, chicken producers raised about 7.33 billion birds with sales of over \$11.4 billion. Total broiler production continued to increase, surpassing 1995's approximately 34 billion pound level of production. About 50 percent of chickens were sold directly to consumers, another 40 percent were sold to restaurants, and 10 percent went for export or pet food.

Despite a sustained drop in the price of chickens in 1994 and 1995, in 1996 wholesale prices for broilers climbed to about 60 cents per pound, while broiler parts held at roughly \$1.92 per pound for boneless breasts and about 96 cents for breasts with ribs on. Retail prices ranged from 98 cents per pound for fresh whole broilers to about \$2.05 for bone-in breasts.

In 1996, per capita consumption of chicken stood at 72.9 pounds. The type of chicken consumed changed in the latter part of the twentieth century. Chicken was marketed as "whole," "cut-up and parts," or "further processed." Sales in the latter two categories rose steadily, partly due to the fact that consumers considered them time-saving. The market share of cut-up and parts grew from 15 percent in 1962 to 56 percent in 1990. Sales of further processed chicken also increased, from 2 percent market share in 1962 to 26 percent in 1990, of which boneless chicken comprised 80 percent. Also included in this category were value-added products such as nuggets, which became very popular in the 1990s; chicken strips; patties; and versions of buffalo wings.

However, sales of whole chickens plummeted to about 20 percent of all chicken sales in 1994. This trend continued throughout the 1990s and was predicted to continue into the next century. On the other hand, the popularity of rotisserie chicken, as marketed by restaurants such as Boston Market, somewhat stabilized whole chicken sales.

In 1996, the U.S. Department of Agriculture (USDA) revamped its meat inspection system to ensure a high standard of safety. Under the new system, scientific tests and modern technology supplanted the former system, which relied on the inspectors' abilities to perceive contamination themselves. The new method, the Hazard

Analysis and Critical Control Points (HACCP), required poultry companies and the USDA to participate in an effort to reduce and prevent contamination.

CURRENT CONDITIONS

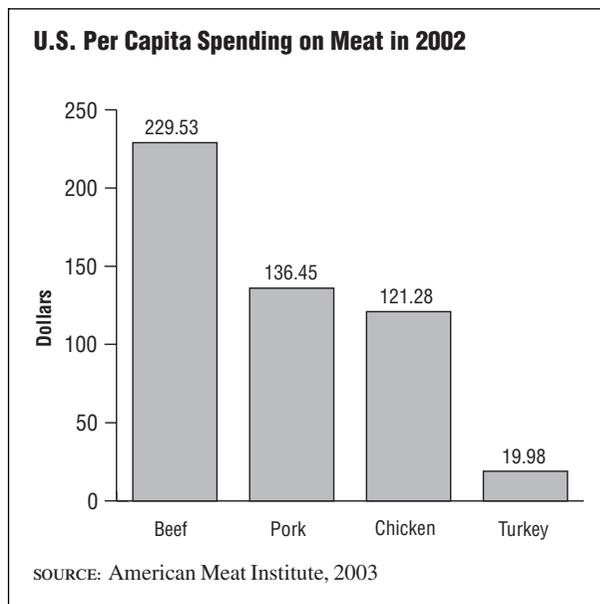

By the start of the twenty-first century, there were 175 poultry-processing plants in the United States. The industry employed approximately 240,000 workers. Poultry production grew 3.2 percent to 38.1 billion pounds in 2002. That year per capita consumption was 75.6 pounds, which amounted to \$229.53 in poultry expenditures annually. Boneless chicken breasts continued to be the most popular cut.

Controlling the spread of disease and ensuring worker safety will most likely continue to be two of the major challenges facing the poultry industry throughout the twenty-first century. In 2002, Pilgrim’s Pride instituted the largest meat recall in U.S. corporate history when it removed 27 million pounds of poultry from shelves due to suspected contamination with listeria.

Another example has to do with the impact of chicken processing on the environment. Chicken feed contains large amounts of the strengthening nutrient phosphorus, which is difficult for chickens to digest. Therefore, the chickens’ waste material, much of which is used as manure, also contains high levels of phosphorus. If manure runs off into ponds and streams, human water supplies can be endangered. Industry researchers and scientists from the University of Delaware have worked to develop a corn hybrid with a more easily digestible phosphorus. However, processors still face public perception of the negative effects of genetically altered foodstuffs, and it may be some years before such products see widespread use.

In the early 2000s, consumer concern regarding antibiotic use at poultry plants began to rival concerns regarding disease. As a result, industry leaders Tyson Foods, Perdue Farms, and Foster Farms began to remove antibiotics from feed for healthy chickens.

Worker safety was also a concern, since increased product demand and faster machinery had significantly increased the USDA-maximum production line speed from 70 birds per minute in 1979 to up to 180 birds per minute by the early 2000s. The rate of worker injuries had also increased so that cumulative-trauma disorders, such as carpal tunnel syndrome and tendonitis, were 16 times the national average among poultry workers. The National Institute for Occupational Safety and Health determined that 49 percent of the workers in one plant’s deboning line sustained injuries to their upper bodies. Additionally, the U.S. Department of Labor estimates that one in every six workers will suffer some sort of on-the-job injury, compared to a rate of one in twelve for the manufacturing industry in general.

INDUSTRY LEADERS

The industry was dominated by Tyson Foods, Inc. in the early 2000s producing over 25 million head of chicken. In 2003, Pilgrim’s Pride Corp. bought the chicken processing assets of ConAgra Inc., becoming the second largest poultry processor in the United States. Other industry leaders included Gold Kist and Perdue Farms.

Tyson Foods, Inc., based in Springdale, Arkansas, was the world’s largest producer, processor, and marketer of poultry-based foodstuffs. The bulk of its business was concerned with value-enhanced poultry products, such as chicken patties, precooked and prepackaged chicken, and Rock Cornish hens. Tyson controlled all aspects of its poultry production, from genetic research and breeding, to hatching, rearing, and feed milling. It was also concerned with veterinary and technical services, transportation, and delivery. With 120,000 employees, Tyson posted sales of \$24.5 billion in 2003.

John Tyson, the grandfather of the current chairman, entered the poultry business in the 1930s, although it was not until 1947 that the company was incorporated under the Tyson name. After starting out as a dealer in chicken, John Tyson began raising them. During the 1950s, the company significantly expanded, and in 1958 it opened its first processing plant in Springdale, Arkansas. In 1960, Don Tyson became manager. Three years later, he renamed the company Tyson’s Foods, Inc. and introduced Tyson Country Fresh Chicken, packaged birds that have become the company’s mainstay. In 1971, the name was changed yet again to Tyson Foods, Inc.

Although the company has grown steadily over the years, a veritable explosion in its trade occurred in the

1980s, as health conscious consumers switched from red meat to chicken. By 1985, it had achieved \$1 billion in annual sales. Between 1984 and 1989, Tyson's profits more than quadrupled, while its revenues tripled. Tyson Foods had consolidated its dominance of the market by purchasing key poultry operations, including Prospect Farms, Consolidated Food's (now Sara Lee) Ocoma Foods Division, Heritage Valley, Lane Processing, and the Tasty Bird division of Valmac. In 1989, it beat out rival ConAgra, Inc. for control of Holly Farms, the nation's leading brand name broiler producer. Tyson was also involved in the Mexican food business, produced by-products for pet food, and acquired a stake in a fishery.

Headquartered in Springdale, Arkansas, the chicken capital of the nation, Tyson Foods also had processing plants in 13 states. As of 2004, it was run by chairman and CEO John H. Tyson. In addition to being number one in the U.S. market, Tyson exported to Canada, Mexico, Central America, the Caribbean, the Commonwealth of Independent States, the Middle East, the Far East, Sweden, and the United Kingdom. Japan had also become an important customer of Tyson chicken: Tyson supplied Japan with over 50 percent of all its U.S. chicken imports.

Tyson Foods' chief competitor was Pilgrim's Pride Corp., a diversified food company that became number two in the U.S. poultry business in 2003 when it acquired the chicken processing arm of ConAgra, Inc. The company as a whole earned \$2.6 billion in fiscal 2003 for all of its divisions and employed a total of 24,800 people. Based in Pittsburg, Texas, Pilgrim's Pride markets its products in Asia and Europe, as well as in the United States. It is headed by chairman Lonnie Pilgrim.

ConAgra had been involved in the broiler industry since 1982 when it bought Country Pride, a leading producer of broilers. It continued to market chickens under this label and also under its Country Skillet and Frozen Banquet brands. ConAgra came into existence in 1919 as the Nebraska Consolidated Mills Company. Its founder, Alva Kinney, concentrated on the grain milling business, and it was not until the late 1940s that the company entered the prepared foods industry. The company continued to diversify through the 1960s, when it first gained an interest in the chicken market, developing poultry growing and processing sites in Georgia, Louisiana, and Alabama. In 1965, it expanded into the European market, eventually forming a partnership with BioterBiona, SA, a Spanish breeder of chickens, other livestock, and animal feed. In 1971, the company changed its name to ConAgra, meaning "in partnership with the land." It was first listed on the New York Stock Exchange in 1973.

During the early 1970s, the company languished as many of its acquisitions failed to thrive. In 1975, former Pillsbury executive Charles Harper was brought in as president to turn ConAgra around. He purchased Banquet

Foods Corporation in 1980 as a way to increase ConAgra's share of the chicken market. In 1982, ConAgra moved into first place in the chicken industry when it formed Country Poultry, Inc. By the following year, the division was the nation's biggest poultry producer, with more than a billion pounds of brand-name broilers. In 1987, it tightened its grip on the broiler industry when it bought Longmont Foods, another poultry producer. It was eventually pushed into the number two spot by Tyson Foods. Competition between the two companies intensified in 1999 when Tyson filed suit against ConAgra, charging ConAgra with luring away four top-ranking Tyson employees and stealing company secrets. Tyson eventually won the legal skirmish.

Atlanta-based Gold Kist Poultry Group, a farmers' cooperative formed in 1933, reported sales of \$1.85 billion in 2003 and employed 17,000 people. Perdue Chickens, a privately-run company headed by James Perdue and based in Salisbury, Maryland, reported sales of \$2.7 billion in 2003 and employed 20,000 people. Leading chicken-producing states included Arkansas, Georgia, Alabama, North Carolina, and Mississippi.

WORKFORCE

U.S. chicken processors employ a total of about 240,000 workers. Approximately 73 percent of chicken farms employed fewer than four workers in the early 2000s, and over 9 percent employed between five and nine workers. About 4.5 percent of operations employed over 100 people, while 2 percent employed between 10 and 14, and 3 percent, between 20 and 49. Approximately 1 percent employed between 15 and 19 and 1 percent between 50 and 99 workers.

Although most poultry farmers worked as independent contractors for the large poultry companies, their relationship was usually one of dependence. Fewer poultry producers meant that farmers often had no choice but to take what they could get. Although they may have depended on a company for their livelihood, they did not enjoy the benefits of employment, such as workers' compensation, health insurance, or paid vacation time. In order to be eligible for a contract, growers had to invest heavily in plants and equipment, thus tying themselves up with debt for long periods of time. Their contracts with poultry companies did not last the length of their mortgages, but were automatically renewable unless either party wished to cancel. In practice, this meant that farmers were guaranteed no more than the next flock of chickens.

Although there was some talk of setting up a growers' organization to lobby for legislative change in the industry, growers were fearful of being boycotted or blacklisted by the producers if they tried to organize. The poultry industry's political clout was legendary. Its political action committee contributed hundreds of thousands

of dollars to politicians, particularly those from the South. John Tyson, head of the largest poultry company, was a personal friend of former-president Bill Clinton and contributed generously to his election campaign. The poultry companies defended the contract system by pointing out that they provided employment, and that they offered farmers a steady income.

Some steps to protect the growers have been taken, although growers said they did not go far enough. They wanted to see laws that would require poultry companies to: pay them within a specified time; provide for mediation in the case of disputes; allow growers to recoup their investment if the contractor backed out of the deal; adjust prices for growers whose income was affected by weight; and prevent unfair trade practices.

AMERICA AND THE WORLD

Most of the market leaders had a stake in the poultry market abroad. For example, Tyson Foods, Inc. had important markets in western Europe, the Caribbean, Mexico, and the Pacific Rim. The latter alone accounted for almost 50 percent of all exports in this category. Demand for U.S. chicken had also increased in Russia and former Soviet Union countries. According to the USDA, exports reached a record 5.5 billion pounds in 2001, accounting for 18 percent of U.S. broiler production. Russia and China, including Hong Kong, accounted for nearly 60 percent of all U.S. exports. South Africa, Mexico, Canada, and Japan were also significant importers of U.S. poultry.

The future of poultry exports faced uncertainty in the early 2000s, due to various quota and bans put in place by other countries. For example, Russia established a quota of 553,500 metric tons for U.S. chicken imports on May 1, 2003. Due to concerns over the use of antibiotics during production, the Ukraine banned U.S. chicken imports on January 1, 2002. At various times throughout the early 2000s, Japan banned U.S. poultry imports due to the presence of Avian Influenza discovered in U.S. chickens. Exports in 2002 declined 13.6 percent, although USDA forecasts called for this number to rebound as the U.S. poultry producers began to resolve trade disputes with other countries.

SIC 0252

CHICKEN EGGS

This category includes establishments primarily engaged in the production of chicken eggs, including table eggs and hatching eggs, and in the sale of cull hens.

NAICS CODE(S)

112310 (Chicken Egg Production)

INDUSTRY SNAPSHOT

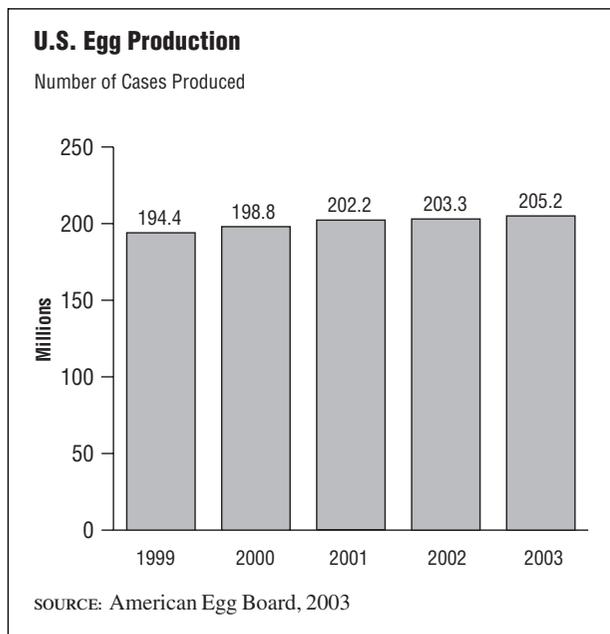

According to the U.S. Department of Agriculture, between 1986 and 2002 the number of U.S. egg producers declined from 2,500 to 700. Throughout the 1990s and early 2000s, the largest egg producers had tended to grow in size by acquiring smaller companies. In 2002 a total of 10 egg making companies boasted flocks of more than 5 million; 61 companies had flocks of more than 1 million; and 295 companies housed 75,000 or more hens. As a result, overall production was heavily consolidated by a few companies who ran massive operations; upwards of one million birds was not uncommon at these farms.

BACKGROUND AND DEVELOPMENT

The chicken egg farm industry has been strong since the beginning of the 1990s, although it is subject to fluctuations. The size of the nation's laying flock has varied in the past few decades, with a noticeable effect on price. Although the national laying flock has steadily decreased from 317 million in 1967 to 290 million in 1983 to 258 million in 1998, the production level has increased over the years from 170.5 billion cases in 1984 to an estimated 192.5 billion in 1999.

In 1993, large eggs sold for 76 cents per dozen, but in 1996, prices increased dramatically to a record average high around 90 cents per dozen. By 1998, the price was back down to 78 cents. Egg farmers tried to affect future pricing by slowing the rate of increase of the broiler hatching egg flock, thus reducing production. The flock grew by only a fraction of a percent in 1995 and only 1 percent in 1996, compared with a 6 percent growth rate in 1991. Therefore, prices rose in late 1995 and remained strong throughout 1996.

The production rate on some egg farms is impressive in comparison with other livestock farms. Some farms have 1.5 to 2 million laying hens, producing about 400

million eggs a year. The number of farms with 1 million or more hens, or layers, has increased in the 1990s. "Large complexes of a million or more layers are one result of increases in layer productivity and feed conversion rates, and developments in egg handling and processing technology," according to the U.S. Department of Agriculture (USDA). Sources in the business claim that the number of large egg farms (more than 75,000 layers) has grown by 20 percent since 1980, whereas the overall number of farms has declined. This move toward larger facilities, to take advantage of economies of scale, is expected to continue.

However, the factory-style facilities designed to accommodate large flocks frequently attract criticism for the manner in which the birds are treated. Space is at a minimum, and the layers are often literally "hen-pecked" by frustrated fellow birds; they also are given antibiotics to reduce the diseases that spread easily in this environment. It is this type of farming, though, that allows for high levels of production and low prices. The alternative is "free-range" eggs produced by hens that are allowed to roam freely and are not confined to a cage. However, because production is limited, "free-range" eggs are more expensive than factory-produced ones.

In larger "corporate" chicken farms, eggs are collected via machinery and conveyor belts that transport the eggs directly from the layers to cleaning stations where they are washed, ridding them of bacteria, dirt, and blood spots. Even though the USDA has not established a storage time limit, eggs are generally stored for one to seven days prior to being shipped to stores. Throughout the storage and transportation period (pre-market), eggs are refrigerated to ensure freshness and safety. Due to the grand scale

of production, modern egg farms require extensive capital investments in the form of environmentally-controlled shelters, computerized egg flow controllers, and packaging machinery.

CURRENT CONDITIONS

Although annual per capita egg consumption fell substantially throughout the 1980s and early 1990s (from 275 in 1980 to 225 in 1992), it rose to 245 eggs in 1998 and to 254.6 million by 2002. Analysts have attributed egg consumption growth to the fact that more people are using more egg products due to positive news regarding egg health and cholesterol. Broken shell egg production and consumption also has continued to increase. For example, 63 million cases of eggs were used in the manufacture of liquid, frozen, or dried egg products in 2003, compared to 53 million cases in 1997.

Egg products are regarded as more versatile and safer than shell eggs since they are pasteurized to eliminate bacteria. According to the USDA, "Eggs are increasingly being broken and used in liquid, dried, and frozen form by food manufacturers, as well as by hotels and restaurants. Part of this increase reflects restaurants buying liquid pasteurized eggs instead of shell eggs. It also reflects growth in supermarket sales of convenient, value-added products in forms other than shell eggs." Increased demand for egg products has led many egg farmers to build egg breaking and processing plants on their properties. Several farmers have also introduced a production process dedicated to egg products, where eggs are automatically transported by conveyor belt from the hens to breaking and processing stations.

Since the mid-1990s egg production in the United States has grown steadily. Of the 205 million cases of eggs produced in 2003, more than half were sold at the retail level, roughly one-third were processed, and the remainder were either sold to food service operations or exported. Leading export markets include Canada and Hong Kong.

Throughout the early 2000s, the five top egg-producing states represented one-half of all U.S. layers. Iowa was the nation's top egg-producing state, followed by Ohio, Pennsylvania, California, and Indiana.

Prevention of salmonella poisoning from eggs was a major concern of the industry. Of the 67 billion eggs consumed by Americans each year, the Federal Drug Administration (FDA) estimates that one in 20,000 carries salmonella bacteria. Date-stamping on egg cartons and better consumer education were two recommendations from the government. In August 1999, Rose Acre Farms became the first producer to print "laid on" dates directly on their eggs. In 2003, Sauder's Eggs began listing "sell by" and "use by" dates as well.

INDUSTRY LEADERS

Like most aspects of the poultry business, the egg farm industry is dominated by a few major players. In recent years, the tendency toward huge egg factories has become even more pronounced. By 2002, 61 egg-producing companies had more than one million layers; 10 of those had more than five million layers.

Pilgrim's Pride Corporation, based in Pittsburg, Texas, was an industry leader throughout the 1990s and early 2000s. Founded in 1963 by CEO Lonnie A. (Bo) Pilgrim, the vertically-integrated company is totally involved in the poultry business, with the production of chicken eggs being just one of its concerns. The company's chief markets are the western United States and Mexico; it also exports to Eastern Europe and the Pacific Rim. In 2003, the company reported total revenues of \$2.6 billion and employed 24,800 people.

Although an industry leader, Pilgrim's Pride has had financial problems. Until the mid-1980s, the company's sales grew by about 20 percent annually. However, this growth was financed by massive debt, equivalent to four times the value of the company's equity. In the mid-1980s, the company started reducing its debt, but suffered badly from falling prices for its products. To protect itself, Pilgrim's Pride entered the prepared chicken market in 1986.

After reaching an all-time financial low in 1988, the company rebounded in 1989. Its decision to surrender the ailing retail market and concentrate on the food service industry had proven savvy. It also benefited from entry into the Mexican market. As a result, its net sales increased by 30 percent to give the company a profit-to-sales ratio of more than 3 percent. Sales continued to rise through 1991 due to Pilgrim's Pride's expansion within the Mexican market, increased export sales, and steady demand for its further processed and prepared chicken products. Pilgrim's Pride's profits, however, did not keep pace, but instead fell by 21 percent.

In 1992 Bo Pilgrim sold off 18 percent of his stock to the Archer-Daniels-Midland (ADM) Co. as part of a deal that enabled Pilgrim's Pride to extend its loan maturities. Pilgrim controlled approximately 65 percent of the company. As part of the agreement, Pilgrim's Pride agreed to indemnify ADM against losses for an unspecified period of time. The deal also stipulated that ADM cannot control more than 20 percent of the firm.

In addition to rescheduling loans in 1992, Pilgrim's Pride attempted to deal with its financial woes by appointing a new president, Monty Henderson, to replace William Voss. Henderson sought to postpone the company's loan repayments, consolidate its indebtedness, and improve Pilgrim's Pride's operating and financial flexibility.

Another major chicken egg producer in the 1990s was Cal-Maine Foods Inc., based in Jackson, Mississippi. Its primary classification is as a producer of chicken eggs. It is also involved in raising hogs and beef cattle. The company employed 1,534 people and earned about \$12.2 million on sales of \$387.5 million in 2003. Finally, Hillandale Farms of Florida Inc. has been a key egg producer. In 2003, the company reported revenues of \$87.5 million and employed 250 people.

AMERICA AND THE WORLD

The United States has been one of the world's largest egg-producing countries. Only China, with an annual production of 284 billion eggs, ranks higher. U.S. egg exports in 2003 equaled 1.6 million cases.

The most important markets for U.S. eggs are Canada, Belgium, Hong Kong, Japan and Mexico; combined, these markets accounted for roughly 75 percent of exported eggs in the early 2000s. Many other countries also rely on the United States for their eggs. Increased demand in the European Union has created a new market for U.S. eggs. Analysts predict egg exports will continue increasing through the end of the decade due to escalating production and lower domestic prices.

SIC 0253

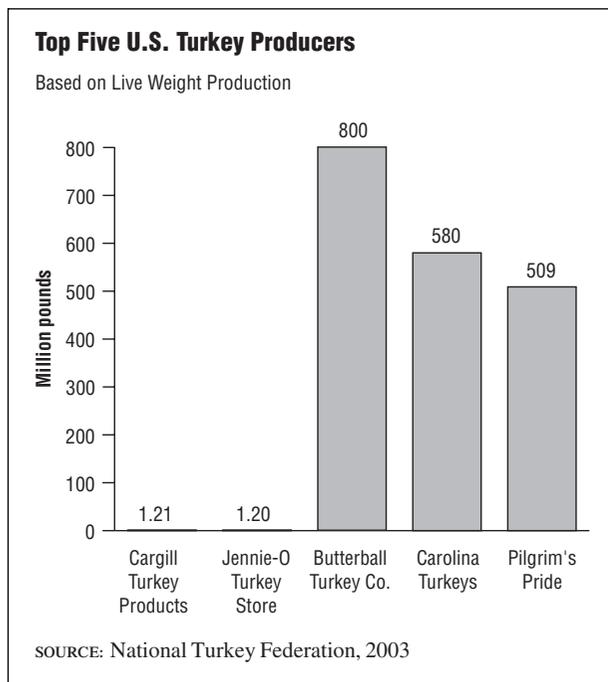

TURKEYS AND TURKEY EGGS

This category includes establishments primarily engaged in the production of turkeys and turkey eggs.

NAICS CODE(S)

112330 (Turkey Production)

Turkey production in the United States was on the decline in the late 1990s and early 2000s, after peaking with a record 310 million birds produced in 1996, according to the U.S. Department of Agriculture (USDA). Al-

though U.S. turkey production climbed 1 percent to 274 million birds in 2003, this number was well below the 301 million birds produced in 1997. In 2004, U.S. turkey growers decided to implement a 4 percent decrease in the number of birds raised.

Through 2002 North Carolina remained the turkey capital, producing 45.5 million birds that year, down from 50 million birds in 1998. In 2003, however, Minnesota, usurped North Carolina as the top turkey producer in the United States with 45 million birds, compared to 44.5 million turkeys produced in North Carolina. Arkansas and Missouri tied for a distant third, producing 26.5 million turkeys each in 2003, while fourth-ranked Virginia produced 23 million. During 2003, these states accounted for 71 percent of all turkeys produced in the United States.

Turkey production in 2002 grew from 7.15 billion pounds live weight to 7.40 billion pounds live weight, due to an increase in the number of birds slaughtered, as well as heavier bird weights. Producers received an average wholesale price of 64.5 cents per pound in 2002, down nearly 3 percent from 2001. Retail prices declined by roughly 4 percent over the same time period.

Turkey exports dropped 10 percent to 439 pounds in 2002. The decline was due in large part to decreased demand in Mexico, the largest export market for U.S. turkey producers, accounting for roughly 45 percent of U.S. turkey exports. Also impacting export numbers was the ban on U.S. turkey imports implemented by Russian officials during a portion of 2002. Turkey exports grew by nearly 20 percent in 2003, however, due to a recovery

in the Mexican economy. Analysts expected additional growth in exports in 2004.

In the late 1990s and early 2000s, the turkey industry grappled with many problems, including flattened consumption, weak selling prices, increasing problems with turkey disease, high feed costs, excess inventories, and low selling prices. Technology also hurt the industry. Genetic engineering has produced turkeys with larger breasts, leading to excess inventories. Also, a growing number of processors are using less meat and supplementing with fillers—like basting solutions—in place of meat. This has led to a glut of turkey. To offset this trend, turkey growers throughout the U.S. planned to decrease production in 2004. Minnesota planned to reduce the number of turkeys raised by 4 percent; North Carolina, by 11 percent; Arkansas, by 2 percent; Missouri, by 4 percent; Virginia, by 4 percent; and California, by 7 percent.

While the number of turkeys produced has declined, so has the number of establishments engaged in the industry, as well as income for those establishments. Between 2000 and 2002 turkey farm income declined from \$2.82 billion to \$2.70 billion. According to the National Turkey Federation, the industry is led by Cargill Turkey Products, which produced about 1.21 billion pounds live weight in 2003. A close second, the Jennie-O Turkey Store produced 1.20 billion pounds live weight that year. Butterball Turkey Co. is the third-leading producer, with 800 million pounds, followed by Carolina Turkeys at 580 million pounds and Pilgrim's Pride at 509 million pounds.

SIC 0254

POULTRY HATCHERIES

This category includes establishments primarily engaged in operating poultry hatcheries on their own account or on a contract or fee basis.

NAICS CODE(S)

112340 (Poultry Hatcheries)

This is a small industry, with less than 800 businesses operating primarily as poultry hatcheries in the United States, according to the U.S. Department of Agriculture. This number has been falling in the late 1990s and early 2000s due in part to massive vertically integrated operations that produce chickens in great quantities and raise them from hatchery to slaughterhouse.

As this industry is highly automated, most operations have a small staff. Roughly half of all poultry hatcheries employ fewer than five workers. The remainder of the establishments maintain staffs of various sizes.

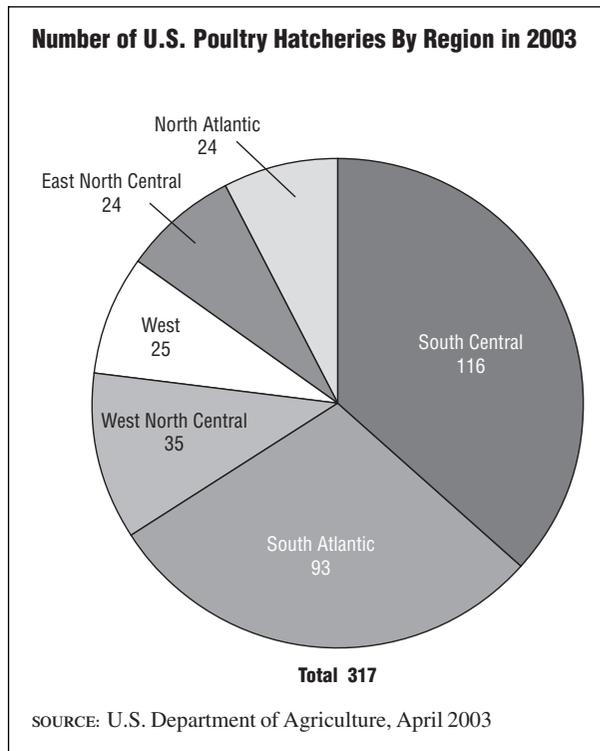

A few companies controlled the majority of the hatchery market in the early 2000s. These were mainly giant, vertically integrated operations that had multiple interests in the poultry business. The remaining hatcheries were mostly family-run operations, with a majority making between \$100,000 to \$250,000 in annual revenues. Many of these smaller businesses produced chicks on a contract basis for the large poultry companies. In 2003, the number of chicken hatcheries declined from 322 to 317, while the number of turkey hatcheries fell from 59 to 58. Chicken egg capacity declined from 874 million to 861 million, while turkey egg capacity dropped from 45.7 million to 45.5 million.

In 2002, U.S. hatcheries produced 9.08 billion broiler-type chicks, up 1 percent from 2001. However, egg-type chicks hatched during this period decreased to 421 million, down 7 percent from 2001. Georgia, Arkansas, and Alabama, respectively, produced the most broiler-type chicks in 2002; Indiana, Iowa, and Pennsylvania led with the most egg-type chicks hatched.

The United States produced 38.1 billion pounds of poultry in 2002, up 3.2 percent from 2001. Domestic poultry consumption grew 5.7 percent in 2002 to nearly 76 pounds. Revenues at hatcheries may be on the rise because poultry production is expected to continue increasing in the early 2000s due to low feed costs and an increasing domestic demand for poultry—up 5 to 7 percent annually.

The nation's number one chicken producer, Tyson Foods Incorporated, is a vertically integrated operation with \$24.5 billion in sales in 2003. Tyson, based in Springdale, Arkansas, employs more than 120,000 people across the United States and Mexico and operates 54 hatcheries. Although it is the industry leader, it is primarily classified as a poultry slaughterer and processor.

Another industry leader is Purdue Inc., based in Showell, Maryland, with \$2.7 billion in sales and 20,000 employees. Atlanta-based Gold Kist Poultry Group, a farmers' cooperative formed in 1933, reported sales of

\$1.85 billion in 2003 and employed 17,000 people. Wampler-Longacre Chicken Inc., acquired by Pilgrim's Pride Corp. in August of 2000, earns an estimated \$370 million and employs 4,000 people.

SIC 0259

POULTRY AND EGGS, NOT ELSEWHERE CLASSIFIED

This category includes establishments primarily engaged in the production of poultry and eggs, not else-

where classified. This industry also includes establishments deriving 50 percent or more of their total value of sales of agricultural products from poultry and eggs (Industry Group 025), but less than 50 percent from products of any single industry.

NAICS CODE(S)

112390 (Other Poultry Production)

Included in this industry are businesses engaged in operating duck farms, geese farms, pheasant and pigeon farms, quail and squab farms, and poultry egg farms, except chicken and turkey eggs. Although accounting for only a small percentage of overall poultry and poultry egg sales, the geese, pheasant, pigeon, and other birds farmed in this industry benefited from brisk sales throughout the mid-1990s, as consumers' taste shifted from red to white meat. Consumption, however, flattened toward the end of the decade and remain stagnant throughout the early 2000s.

According to the U.S. Department of Agriculture (USDA), Americans consumed roughly one-third a pound of duck in 2003, compared to nearly half a pound in 1986. Goose consumption was even less. Between 2002 and 2003, the number of ducks slaughtered under federal inspection increased from 23.9 million birds to 24.3 million birds; however, this number remained lower than the 2001 figure of 26.2 million birds. In terms of live weight, between 2002 and 2003 the amount of ducks slaughtered grew from 160.3 million pounds to 160.8 million pounds, a figure that accounted for less than one percent of poultry

industry activity in 2003 and remained lower than the 173 million pounds of duck slaughtered in 2001. Between 2002 and 2003, the live weight of other poultry slaughtered fell from 12.6 million pounds to 9.9 million pounds.

In the early 2000s, the majority of poultry farms in this category were small-scale operations employing less than five people and earning less than \$250,000 per annum. More than 75 percent of the businesses in this group employed zero to four workers.

SIC 0271

FUR-BEARING ANIMALS AND RABBITS

This classification covers establishments primarily engaged in the production of fur and fur-bearing animals and rabbits. These include chinchilla farms, fox farms, fur farms, mink farms, and rabbit farms.

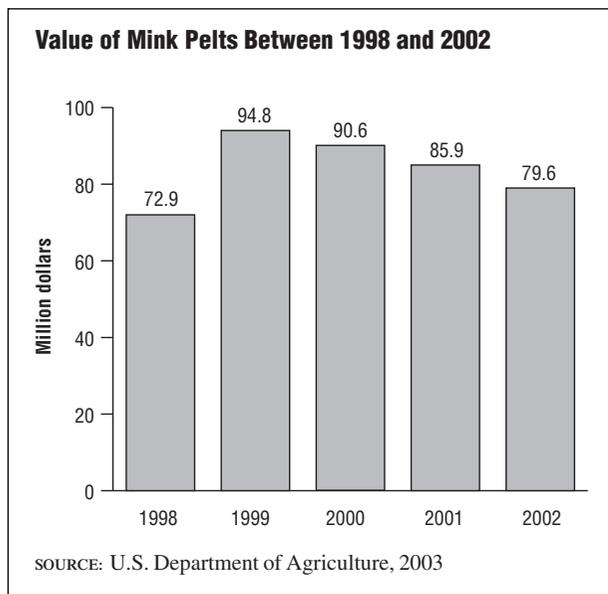

NAICS CODE(S)

112930 (Fur-Bearing Animal and Rabbit Production)

In 2003 a total of 318 establishments raised mink for pelts, down from 439 in 1998. Utah had the largest number of farms, with 80, followed by Wisconsin, with 69, and Minnesota, with 33. Of these, 20 establishments also raised fox. Value of the 2.60 million pelts produced that year was \$79.6 million.

The majority of fur-bearing animal farms are small-scale operations that earn less than \$250,000. In fact, no operation reports revenues of over \$5 million. Most of the establishments in this industry employ fewer than five people.

In recent years, the fur-bearing animal raising industry has suffered the ill effects of fur's increasingly negative image. Many stores have closed down their fur departments under pressure from animal rights activists and in response to decreasing sales. As a result, sales of fur-bearing animals to the retail fur industry have steadily declined over the past few years. Although sales increased during the boom years of the 1980s, they plunged again as resistance became more pronounced. High-profile protest groups such as People for the Ethical Treatment of Animals (PETA) have proven adept at cast-

ing the industry in an unflattering light. PETA has launched many rescue missions where members target fur farms and release the animals. In the 1990s the industry made a comeback, as fur came to be regarded as a versatile fabric, and the American economy improved. However, when the economy weakened in the early 2000s, fur sales once again dipped.

Mink has generally accounted for 50 to 60 percent of all fur production and sales. Only 601,000 females were bred in 2003, compared to 733,000 in 1998. Most pelts produced that year were of the standard color class, followed by mahogany, gunmetal, demibuff, and ranch wild. Despite increased production and sales, the fur industry faces an uncertain future.

SIC 0272

HORSES AND OTHER EQUINES

This classification covers establishments primarily engaged in the production of horses and other equines such as burros, donkeys, and mules.

NAICS CODE(S)

112920 (Horse and Other Equine Production)

INDUSTRY SNAPSHOT

In 1908, when Henry Ford rolled out his first car, there were more than 21 million horses in the United States. That number eventually shrank to 3 million, as horses were no longer needed to pull military cannons, plow fields, or haul freight. The horse raising industry has been a resilient one, however. By 1996 the number of horses in the United States had risen back to 7 million head; however, the number had declined to 5.32 million by 1999, and it continued to fall in the early 2000s. The U.S. equine industry was valued at \$112.1 billion in 2002.

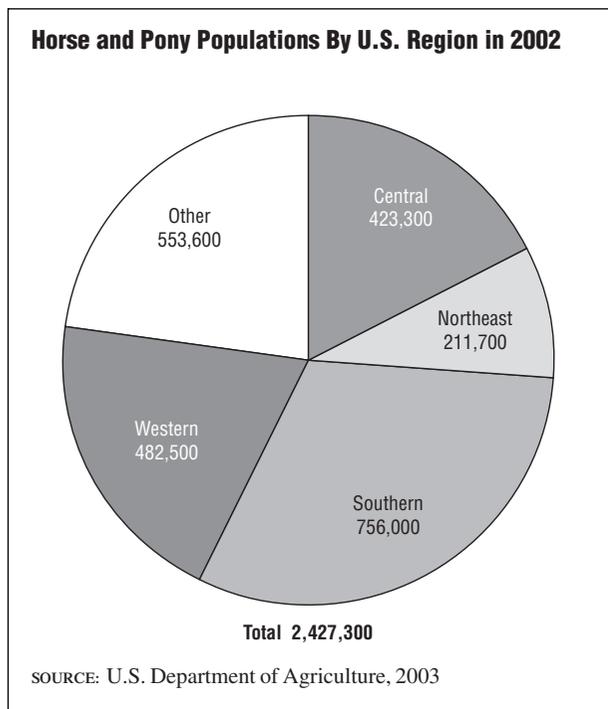

Horses have long done America's hard work. Horses are still used on ranches and feedlots. Occasionally helicopters or motorcycles are used to gather and check cattle, but the horse is still the preferred method of transportation for the modern-day cowboy. Horses and mules are also still used as pack animals and carriage animals. Primarily, however, most horses in the United States in the early 2000s were used for pleasure. While rodeo, recreational riding, and horse shows increased in popularity, horse racing was in decline—although exports of horses used for racing did increase during the economic boom years at the turn of the twenty-first century. As a result, although yearling thoroughbred sales took by far the most money, the most growth was seen in other breeds, including unfamiliar breeds such as miniature horses.

ORGANIZATION AND STRUCTURE

Horse breeding establishments usually specialize in one breed of horse for a particular usage. For example, a quarter horse breeder may produce horses to be used solely for herding, cutting cattle, or quarter horse racing, whereas a paint breeder may raise horses to show at halter in a show ring, or vice versa. Whatever the purpose, the breeder depends on the reproductive capacity of the stallion and the brood mare band.

Successfully breeding domesticated horses is one of the more difficult tasks in raising livestock. A stallion that is capable of achieving a conception rate of 75 percent is regarded as acceptable, compared with a conception rate of 90 percent for a stallion in the wild, who would run with 30 to 40 mares.

Well-grown fillies (young female horses) can be bred when they are two years old so they will first foal when they are three years of age. Many breeders think it best to wait until the filly is three before breeding her for the first time. If she is properly cared for, a mare will reproduce up to 15 years of age, and even longer in many cases. Mares can be pasture bred, hand bred (a method where the stallion is brought to the mare), or artificially inseminated, a growing practice. Some breed associations, though, do not allow a foal to be registered if it was

conceived through the use of artificial insemination. The Jockey Club, the main registrar of thoroughbred horses, is one of the last breed organizations that will not allow this method.

Stud farm establishments provide standing exceptional stallions, enabling horse owners to bring their mares to get bred to an animal they could not otherwise afford. The owner of an exceptional stud horse may own his/her own band of mares or only breed outside mares belonging to other people for a stud fee. Most horse farms and ranches have a combination of the two.

Foals that have just been weaned from their mother's milk in auction sales or through what is called "private treaty" can be sold as weanlings or retained on the farm and broken (the practice of training a horse to accept a saddle, a bit, and a rider) for riding. This training usually begins when the foal is about 18 months old.

Horses that show promise can be campaigned at horse shows, endurance races, ropings, rodeos, polo matches, or numerous other activities. A firm that is in the business of breeding horses may sell the offspring once a year at a production sale or consign them to an auction. There are literally hundreds of auctions around the country where such animals are consigned and sold to prospective buyers. These auctions usually feature one breed of horse.

BACKGROUND AND DEVELOPMENT

The horse, humankind's primary method of transportation until relatively recent times, was of vital importance to America's development. Horses pulled the heavy

Conestoga wagons between the Ohio and Mississippi Rivers and were the main tools of working farmers. In eighteenth- and nineteenth-century America, the horse was held in such high esteem that theft of such an animal was commonly held to be a hanging offense. In addition to its important role in commerce and transportation, the horse was an important military supply.

When horses became unnecessary as central vehicles for transportation, their numbers dwindled. Dozens of breed associations, however, launched attempts to preserve many breeds of horses and the traits for which those horses were best known. These breed registries maintained studbooks, kept track of pedigrees, published their own magazines, and sponsored shows for their breed. In the early 2000s more than 150 breed organizations operated in the United States, generating nearly one-quarter of total industry revenues. However, the revenue generated by the horse industry does not lie in breeding alone. Horse shows, rodeos, and racetrack wagering also generate sales.

Even the federal government is in the horse business. On vast acreage owned by the Bureau of Land Management (BLM), wild horses and burros still run free. Due to the overpopulation of such equines, the government regularly gathers up the horses and maintains them in a horse feedlot, or offers them for adoption to the general public for a small fee. Between 1981 and 1984, more than 11,000 of these animals were rounded up and removed from the Naval Air Weapons Station, which works with the BLM in managing these wild herds.

Tax law changes in 1986 dealt a devastating blow to the horse industry. Prior to that time horses could be depreciated rapidly and their owners received a 10 percent investment tax credit just for the pleasure of owning a horse. The sudden excess of horses triggered a dramatic increase in the number of animals slaughtered for human consumption abroad. Despite half-hearted attempts to market horse meat in the United States, consuming the flesh of an equine is still considered taboo in this country, even though it is legal.

Residents of France, Belgium, Japan and many other parts of the world include horse meat in their diet. The United States is the largest producer and exporter of horse meat, with 15 horse slaughter plants. As of the 1990s, roughly 90 percent of processed horse meat was exported to other countries, with the remaining ten percent going into fertilizer and dog food. Nearly 75 percent of U.S. overseas horse meat sales went to France, Belgium, and the Netherlands. Mexico and Canada are the second- and third-largest U.S. took 11 percent, and Japan buys 3 percent; some of the horse meat also finds its way to Southeast Asia and South America. A growing contingent of animal rights groups have targeted the practice, hoping to see it outlawed entirely or regulated out of business.

Types of Horses Bred. The American quarter horse is the most popular and the largest equine breed registry membership, with more than 288,000 horse breeding members in 77 countries around the world. The quarter horse was developed in this country and derives its name from the fact that it is the fastest horse in the world in running the quarter mile.

The Thoroughbred is the most popular horse used for racing in this country and is quite commonly bred to horses of other breeds to add speed and versatility. The number of Thoroughbred breeding operations is the highest in Kentucky, with Florida second and California third.

A rapidly growing breed is the American paint horse. These are beautifully colored horses with much the same athletic ability as the quarter horse. Pinto horses are colored like the paints but have their own breed registry.

Arabian horses have been the breed of choice for entertainers and celebrities seeking tax write-offs. Historically, the Arabian is the oldest major pure breed of horse. They are unexcelled in endurance races and because of their beauty are popular with people who show horses at halter. Their popularity has grown rapidly among amateur competitors in all fields and Arabian interest by young competitors has grown by 88 percent since 1988, due partly to the fact that in 1992 there was more than \$300,000 in prize money awarded in Arabian horse shows.

The popularity of Arabian horses led to problems with determining the purity or integrity of a horse's breeding, particularly with South American breeders. In 1997, the Arabian Horse Registry of America was expelled from the World Arabian Horse Organization for refusing to register horses it considered impure. In 1998, Arabian Horse America was founded to support the industry of Arabian horse breeding in America, another sign of the breed's growing popularity. Arabian racing was also a growing sport: between 1996 and 1997, the number of horses racing went up nearly 8 percent, with purses totaling \$4.5 million.

One of the most distinctly marked breeds of horse is the Appaloosa, the breed with spots on its rump. The Appaloosa Horse Club is responsible for maintaining the purity of this breed, which first achieved fame as the horse ridden by the Nez Perce Indians of Idaho. As the history of the Wild West continues to be of interest in Europe, so too has the popularity of the Appaloosa grown abroad. International registrations recently surged 65 percent in just one year, and in 1992 there were 526,000 registered Appaloosas in existence throughout the world. Very few of these horses, however, were actually purebred Appaloosas—less than 3,000.

The purity of Appaloosas also became an issue as the breed became more popular in the 1990s. In 1997, a

movement was started to find and breed "Foundation Appaloosas" in order to help the pure breed survive.

The American Morgan was the first and the oldest recognized American breed, and was developed entirely in this country. In the 200 years of its existence in America, 125,000 purebred Morgans have been registered.

There are dozens of other breeds of horses, including the Missouri fox trotter, Peruvian Paso, American Indian horse, Palomino, American mustang, Paso Fino, Icelandic, the Standardbred, Tennessee Walking Horse, and several breeds of draft horses, including Percheron, Belgian, and Clydesdale. The sport of draft horse pulling experienced significant growth in the early 1990s, with contests and demonstrations held at numerous county and state fairs.

According to a 1998 article in *The Economist*, rapid industry growth in the late 1990s reflected a fad for the horse as a status symbol: "What the new owners will do with their purchases varies, but not many will work them or even ride them. The horse trade has become a metaphor for what is happening to the West. Horses, like the ranch land from which they spring, are being bought for their looks, not their usefulness." A 1998 study from the U.S. Department of Agriculture also suggested that most horses were maintained for personal use. Over two thirds of horse owners kept them primarily for pleasure; only 15 percent used them primarily for farm or ranch work. In the states surveyed, more than 45 percent of horse owners owned only one or two horses.

For many horse owners, the animals were also considered an investment. This has long been true with thoroughbred racehorses, but a less obvious choice that became more common in the late 1990s was miniature horses. Linda Brown, a Texas breeder of miniature horses, told the *Dallas Business Journal* in 1999 that "A miniature horse has a possibility of making your initial investment back for you almost every year." In 1999, a high quality miniature horse could sell for as high as \$42,000, and even more for a show champion—over \$100,000. More commonly, the horses sell for \$1,500 to \$10,000. While the most common way for breeders to profit was through selling offspring, some owners of miniature horses made money by using the ponies for children's parties, school programs, and private lessons. Of the nearly 78,000 miniature horses registered worldwide, more than 13 percent were in Texas. Over half of these horses sold were exported.

The use of horses for logging also increased in the late 1990s. According to the North American Horse and Mule Loggers Association, membership went up by a sizeable 440 percent between 1991 and 1997. Horse logging, using breeds including Percherons and Belgians, has the advantage of being much kinder to the environment, although it is also more expensive than mechanized alternatives. The

method is best suited to thinning existing stands of trees or clearing small lots or home sites, making large-scale growth for horse sales in this market unlikely.

In the racehorse market, as thoroughbred prices edged higher in the late 1990s, other groups of horses became popular with less wealthy consumers. A quarter horse yearling cost up to \$10,000 less than a thoroughbred, and because it could begin racing sooner, an owner could begin making money from the horse more quickly. Quarter horses made up 39.5 percent of horses by breed. Sales of two-year-old horses also increased as more horses from that age group began to win big-money races. Some industry observers suggest that an excess of top-quality yearlings helped to create the market, which was popular with buyers looking to start racing sooner than they could with yearlings. The growth of this market created new opportunities for investors, who purchased yearlings and trained them for resale, sometimes reaping returns of more than 2000 percent from their initial investment.

CURRENT CONDITIONS

The market for horses had increased steadily throughout the late 1990s. Estimates in the late 1990s maintained a count of more than 7 million horses in America, representing a growth rate of 20 percent over the past decade. However, by 2003 this number had fallen to 5.2 million. The decline was due in large part to the recessionary economic conditions experienced in the United States in the early 2000s. The thoroughbred yearling and broodmare markets, which had experienced significant growth in the economic boom of the late 1990s, were particularly hard hit by the recession. Public auction horse sales declined 22 percent in 2001, from \$1.07 billion to \$835 million. The September 11 terrorist attacks further depressed the U.S. economy, which impacted sales in 2002 as well.

Another common standard for measuring the growth of the industry is the thoroughbred foal count, which had increased sizably every decade since 1910, until beginning to fall in the late 1980s. The different standards for growth reflect the decreasing popularity of horse racing in America and increasing interest in horses for other purposes. By this standard, the industry was still in a slump at the beginning of the twenty-first century, despite modest gains in the late 1990s. After reaching a low of 31,874 in 1995, compared to 51,296 in 1986, the U.S. foal count rebounded to 32,800 in 1998, to 33,265 in 1999, and to 33,360 in 2000. However, by 2002 this number had declined to 32,927.

The number of equine sold in the early 2000s totaled roughly 560,000 annually; these were valued at \$1.8 billion. Throughout the 1990s and early 2000s, the U.S. equine breeding industry became increasingly concentrated in a handful of states. As of 2002, the state of

Kentucky accounted for five percent of total equine sold and 37 percent of the total value of these sales. It also housed nearly 30 percent all registered foals in the United States. Florida was home to another 12.6 percent of registered foals, while California produced 10.9 percent.

Arabian horse breeding continued to grow in popularity in the early 2000s. Compared to 82,000 in the early 1990s, the number of purebred Arabian horses registered in the United States, Canada, and Mexico in the early 2000s totaled 237,000. The number of Arabian horse owners in North America grew from 28,019 to more than 100,000 over the same time period. The state of Florida saw significant growth Arabian horse breeding in the early 2000s as two leading Florida-based breeders, Lasma Corp. and Rohara Arabians, expanded operations. By 2003, Florida had become the eleventh-largest U.S. breeder of Arabian horses, and Lasma had become the largest Arabian breeding operation in the United States with roughly 450 horses. In terms of registered purebred Arabians, California was the top state with 42,404, while Texas came in second with 12,856.

In 1999, horse sellers had started taking advantage of a new tool for boosting sales: the Internet. Industry leader Keeneland held auctions using live audio and video, and the results were unprecedented. *Computerworld* reported record-breaking sales: "A one-day record was set on November 8 when sales totaled \$99.3 million. The 1999 September yearling sale was the largest in Keeneland's history. It sold nearly 3,500 horses—about 10 percent of the 1998 U.S. foal crop. It ended the 11-day auction with gross sales of \$233 million, a 38 percent increase from last year." Keeneland's January 2004 sale of 1,258 horses during its Horses of All Ages auction garnered \$49.3 million, the fourth-largest amount in the auction's history. Along with the extended reach afforded by the Internet, this increase in sales was due to a recovering U.S. economy.

INDUSTRY LEADERS

Most operations in this industry are small and privately owned. Of the largest organizations with the highest revenues, most are breeders and sellers of thoroughbred racehorses. By revenue, the largest operation is Keeneland Association of Lexington, Kentucky, with operating revenues of roughly \$20 million. Others include Lasma Corp., based in Ocala, Florida, as well as Jonabell Farm Inc. and Calumet Farm Inc., both of Lexington, Kentucky.

AMERICA AND THE WORLD

Exports in horses increased steadily from the mid-1980s. Main importers of U.S. horses in the early 2000s included Japan, the United Kingdom, Canada, Ireland, and France. Popular breeds for export included American Quarter Horses, thoroughbreds used for racing,

and Tennessee Walking Horses, which are used for English riding.

RESEARCH AND TECHNOLOGY

The main threat against horse breeders in this country were various diseases that can affect the breeding stock, as well as the general horse population. Vaccinations are the main prevention against disease, as well as cleanliness in the breeding facility, however, outbreaks occasionally occur, and for some diseases there are no vaccines yet available. Equine viral arteritis has been prevalent throughout the world and in many different breeds, and causes abortion and respiratory disease. There is no vaccine for this virus and it is especially dangerous to breeding stock because infected stallions may show no clinical signs of the disease, therefore passing it to other mares. Leptospirosis is another cause of abortion and stillbirth. This disease can be carried by wildlife, in their feces. Other dangerous diseases include the equine herpes virus, equine influenza, and rotavirus, which can cause death in foals. Many universities with veterinary medical programs are studying these diseases in hopes of eliminating them altogether.

The highly publicized West Nile Virus, spread mainly by mosquitoes, had been on the rise in the United States since 1999. In fact, by 2002, more than 15,257 cases of the virus had been recorded in 43 states. A vaccine for West Nile, made commercially available in August of 2001, was licensed by the U.S. Department of Agriculture in February of 2003. The vaccine was considered 95 percent effective for horses.

SIC 0273

ANIMAL AQUACULTURE

This industry classification includes establishments engaged in the production of finfish and shellfish within a confined space and under controlled growing and harvesting procedures. It includes farmed aquatic animals intended as human food (catfish, trout, and oysters), bait (minnows), and pets (goldfish and tropical aquarium fish). Establishments primarily engaged in hatching fish and in operating fishing preserves are classified in **SIC 0921: Fish Hatcheries and Preserves**.

NAICS CODE(S)

112511 (Finfish Farming and Fish Hatcheries)

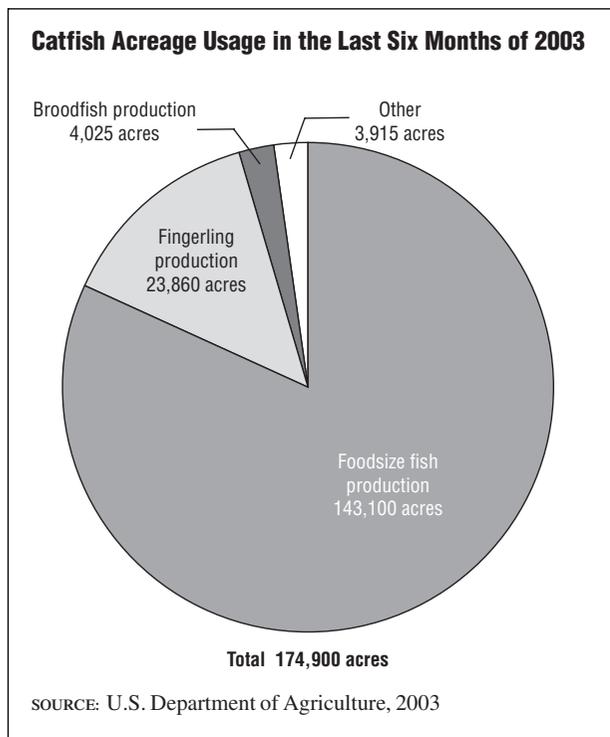

112512 (Shellfish Farming)

112519 (Other Animal Aquaculture)

The aquaculture industry entered the 2000s with significant economic promise. Production was small but growing. Aquaculture crops had doubled between 1975 and 1983, and although the U.S. aquaculture industry met with relatively flat growth in the per capita consumption of seafood throughout the 1990s, both domestic production and imports were expected to increase in the early 2000s, due in part to increasing good news about the health benefits of seafood. Of total seafood consumed, shrimp, salmon, tuna, and catfish accounted for the largest segment of the aquaculture industry in 2003, according to the U.S. Department of Agriculture (USDA). The USDA predicts that competition from the growing pork and poultry industries will pose greater challenges throughout the twenty-first century.

Despite somewhat slow growth, consumption of farm-raised seafood was on the rise. According to the United Nations's Food and Agriculture Organization, aquaculture production had more than doubled between 1990 and 2000, producing aquatic animals and plants worth more than \$42 billion. Sales of catfish from growers to processors were predicted to reach between \$470 and \$480 million in 2003. These figures represent substantial growth over 1985 statistics, when aquaculture posted U.S. farm receipts valued at only \$205 million. Seafood industry analysts expect aquaculture to play an ever-increasing role in providing fisheries products to the marketplace.

The aquaculture industry is not, however, limited to seafood production. Ornamental fish exports increased in the early 2000s, particularly to Asia, despite recessions and financial crises. During the first half of 2003, U.S. ornamental fish exports rose to \$4.4 million. The largest export market for ornamental fish is Hong Kong. The value of ornamental fish imports remained steady at \$43 million in 2003.

Although aquaculture is a relative newcomer to U.S. economic importance, the industry itself is not new and has applications in many parts of the world. The Japanese have raised oysters for centuries; the ancient Romans also raised oysters. Many Pacific island nations have turned swampy seaside areas into simple fish farms.

During the 1860s, the United States developed techniques for raising salmon and trout in captivity. By 1990, nearly all catfish, rainbow trout, and hybrid striped bass consumed in U.S. restaurants were harvested from fish farms.

Catfish. Sales of catfish remained strong in the early 2000s, with 2003 sales from growers to processors reaching 650 million pounds. This marked a 3 percent increase over 2002 sales. Production remained strong due to stable prices and lower feed costs. The leading catfish producing states include Alabama, Arkansas, Mississippi, and Louisiana, which together account for more than 90 percent of total catfish production. Due to low prices, catfish growers began to reduce their acres of ponds in use in 2003. Catfish farmers used 174,900 acres of ponds in the last half of 2003, compared to 173,900 acres during the same period in the previous year. Of these acres, 143,100 acres were devoted to foodsize catfish production, while 23,860 were used for fingerlings (feeding), and 4,025 for broodfish (breeding) production.

Shrimp. Shrimp is one of the most highly regarded crops. It is the most popular seafood product in the United States and boasts the highest consumption.

Shrimp are especially suitable for farming because of their high market value, rapid growth, and low position on the food chain. Successful shrimp culturing operations are already underway in Ecuador, Thailand, and China, and aquaculturists predict their growth in the United States. However, the U.S. continued to rely heavily on shrimp imports, when grew 41 percent between 1998 and 2003. In fact, in 2003, shrimp imports, which exceeded 1 billion pounds, were worth an estimated \$3.3 billion. Thailand is the largest shrimp importer to the United States, accounting for \$393 million in shipments during the first half of 2003 alone.

Tilapia. Production of tilapia in the United States continued to increase in the late 1990s and 2000s, with the north central region dominating tilapia production. Production is expected to expand in the north central and southern regions as well. If live product continues to generate greater demand than processed product, long-term prospects are not exceedingly optimistic for domestic growers. The U.S. Department of Agriculture, however, expects the larger long-term market demand to be for processed products. Between 1998 and 2003, tilapia imports soared 230 percent to 100 million pounds.

Mussels, Clams, and Oysters. Exports of clams and oysters declined slightly in the late 1990s but rebounded in the early 2000s, despite slower than expected economic recovery in Asian economies. In the first half of 2003, exports of mussels, clams, and oysters jumped 19 percent to 5 million pounds. Oysters saw the most significant growth, accounting for nearly half of total exports. According to the USDA, increasing mollusk prices coupled with continued weakness in Asian economies will curb demand for mollusk exports in 2004 and 2005. Imports of clams grew 27 percent to 4.4 million pounds in the first six months of 2003, while imports of oysters grew 31 percent to 9.6 million pounds. Mussel imports, however, declined 16 percent to 24.2 million pounds during this time period.

SIC 0279

ANIMAL SPECIALTIES, NOT ELSEWHERE CLASSIFIED

This category includes establishments primarily engaged in the production of animal specialties, not elsewhere classified, such as pets, bees, worms, and labora-

tory animals. This industry also includes establishments deriving 50 percent or more of their total value of sales of agricultural products from animal specialties, but less than 50 percent from products of any single industry. Establishments included in this group are alligator farms, apiaries, aviaries, cat farms, dog farms, frog farms, honey production farms, kennels that breed and raise their own stock, laboratory animal farms (rats, mice, guinea pigs), rattlesnake farms, and silk and silkworm farms.

NAICS CODE(S)

112910 (Apiculture)

112990 (All Other Animal Production)

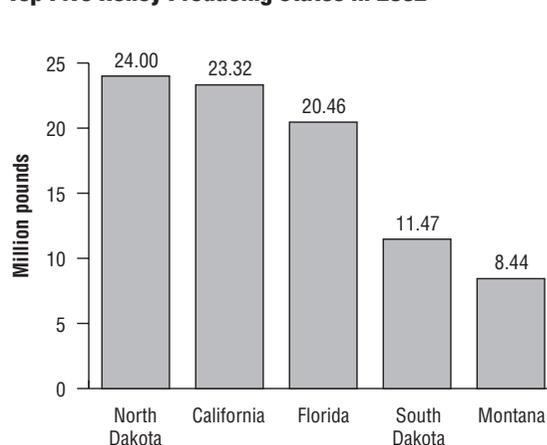

Developments in this industry in the late 1990s and early 2000s included rising sales of exotic birds, which pet owners increasingly preferred over cats and dogs, as well as the expansion of the market for reptiles and their prey, crickets. Informed consumers who saw the poor breeding conditions of exotic birds began to demand better breeding practices. The growth of the exotic bird market spurred growth in the entire pet industry. Fluker Farms Inc. of Baton Rouge, Louisiana, which led the industry in breeding and supplying reptiles and crickets, sought to strengthen its market by expanding into iguana breeding; they also added novelties to its feed supplies like chocolate-covered crickets, which it sold in the United States as well as in Japan.

Industry leader Charles River Laboratories of Wilmington, Massachusetts, with sales of \$554 million in 2002, had been sold by parent company Bausch and Lomb Inc. to Global Health Care Partners in July 1999. Charles River dominated the industry by supplying laboratory animals to research facilities. Though renounced conspicuously by animal rights groups and activists, laboratory animal production was a successful facet of this industry, due to the constant demand for medical research. The industry's second leading company was Denver-based Covance Research Products Inc., which operated five facilities throughout the United States. The remainder of the list of industry leaders is dominated by overseas operations.

Honey. Honey production in the United States has fluctuated since 1986, when beekeepers garnered about 16.9 million gallons of honey. In 1989 production fell to only 14.9 million gallons, then rose in 1992 to 19.4 million gallons. In 1994 production dropped slightly to 18.3 million gallons.

The number of colonies producing honey in 2002 totaled 2.52 million, 1 percent higher than in 2001. The yield per colony declined 8 percent between 2001 and 2002, falling from 74 pounds to 67.8 pounds. Honey production over this time period declined from 185.4 million pounds to 171.1 million pounds. The leading

Top Five Honey Producing States in 2002

SOURCE: U.S. Department of Agriculture, 2003

honey producing states in 2002 were North Dakota, California, Florida, South Dakota, and Montana.

Llamas. As competition in many show animal industries has escalated, many farmers have turned to llama production. In 2004 the International Llama Registry reported 27,870 llama owners in the United States. Producers—both professional and amateur—gravitated towards llamas because of their relatively low cost and their low-maintenance dispositions. Llamas do not require expensive feed; they can thrive on hay. The average llama sells for \$750, although high quality show animals cost upwards to \$15,000.

SIC 0291

GENERAL FARMS, PRIMARILY LIVESTOCK AND ANIMAL SPECIALTIES

This classification includes establishments deriving 50 percent or more of their total value of sales of agricultural products from livestock and animal specialties and their products, but less than 50 percent from products of any single three-digit industry group.

NAICS CODE(S)

112990 (All Other Animal Production)

INDUSTRY SNAPSHOT

According to the U.S. Department of Agriculture, a total of 2.12 million farms were in operation in 2002. General livestock farms account for only a very limited number of livestock and poultry farms, as most sales in this category come from farms specializing in a specific animal. General livestock farms tend to be small, with fewer than 50 employees and modest sales, though some, such as Euribrid BV, a subsidiary of Nutreco Holding N.V., and Nevada Nile Ranch Inc. registered multimillion-dollar sales volumes. Farmers in this category mostly maintained traditional livestock, such as sheep, cattle, hogs, turkeys, and chickens, though many diversified into more specialty animals, such as elk, bison, and llamas. In addition, most general livestock farmers harvested traditional crops as well, either for feed or for retail.

The roots of general farming in the United States go back many years. A period of specialization occurred in the nineteenth century; general farming, however, remained ubiquitous but was concentrated particularly in the Appalachians. Farm wisdom advises against “putting all your eggs in one basket,” and there are many beneficial combinations of different types of livestock and crops.

CURRENT CONDITIONS

Perhaps the most severe challenge facing general livestock farmers at the beginning of the twenty-first century was the severe lull in agricultural-commodity prices, due in large part to the massive production levels generated by large-scale factory farming; factory farms, generating an increasing share of national agricultural output, are further able to produce their goods at lower costs, further exacerbating the pricing crisis. The net result has been to squeeze small and mid-sized farmers, which constitute the bulk of the general livestock farms in the United States, out of the market place if they are unable to find an appropriate niche allowing them to create economies of scale. The average size of farms between 1997 and 2002 grew from 431 acres to 441 acres, and the number of farms with 2,000 acres or more grew from 74,426 to 78,037.

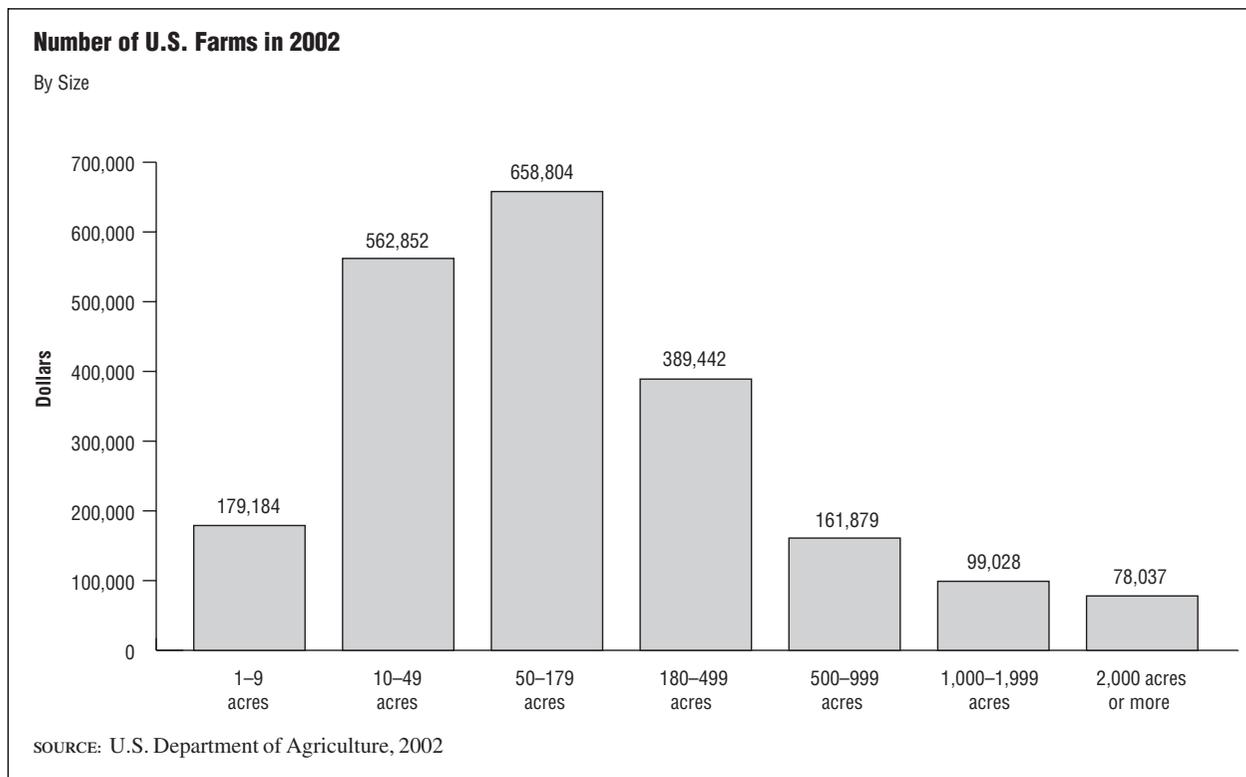

Many livestock farmers have been successful in finding their niche in the growing organic-foods industry. Targeting customers concerned with the health and environmental risks associated with chemicals, pesticides, and genetically modified foods, the organic sector has emerged from specialty health stores and a fringe customer base to assume a significant position in the mainstream consumer market. Organic agricultural products

constituted the fastest-growing sector of the farming industry during the 1990s, with sales of \$5 billion in the United States by the early 2000s. A typical use of livestock in conjunction with raising organic crops involved grazing cattle through rotations of oat and soybean fields, thereby improving soil conditions and helping to control weeds.

Organic farmers eschew the synthetic chemicals and gene-tampering technologies many farmers use to boost yields and create more productive livestock. Both the animals themselves and all the feed they consume must be completely free of such chemicals in order to be labeled organic, a fact that demands organic farmers plan carefully far in advance to ensure appropriate feed supplies and access. Organic livestock must be maintained on land that is free from any chemical infiltration, including soil and water supplies. Moreover, animals themselves must be carefully monitored for illnesses, to which they are more susceptible than their non-organic cousins since organic animals cannot be administered antibiotics used to stave off disease; thus, an animal discovered with a communicable disease must immediately be removed from the herd lest it affect the remaining supply. Because of the greater risk and investment required, organic farming is a more costly undertaking than non-organic farming, and its consequent products fetch a higher price at the market.

The health and safety concerns related to livestock farming have assumed increasing prominence on the national scene. The Environmental Protection Agency (EPA), in conjunction with the National Pork Producers Council, addressed environmentalists' protests over on-farm odors and waste disposal, particularly on pork farms, with the development in 1997 of the On-Farm Odor/Environmental Assistance Program (OFO/EAP), whereby risk factors are identified and assessed. This environmental-management program was designed to reduce odors and prevent contamination of surface or ground water. It calls for periodic governmental inspection (with the cooperation of farmers) of farming sites, buildings, manure-handling systems, deceased-animal disposal methods, and land application. The OFO/EAP's checklist includes questions about seepage in the building's foundation, cleanliness of animal-storage facilities, pipe conditions, and drainage facilities and equipment. As a cooperative program rather than a mandate, farmers are encouraged to consider the financial benefits afforded by implementing sanitary environmentally sound waste-management systems.

Chickens, longtime barnyard fixtures, have been used as scavengers, feeding on spilled feed and insects around barns and rabbitries, resulting in savings in feed costs and improved sanitation of the animals' living areas. However, the type of environment has had to be

carefully matched with the right type of chicken. For example, only non-flying chickens typically are used near rabbit cages; otherwise, they fly on top of the cages and contaminate them with their droppings. Other types of scavengers have filled similar roles. Earthworms, for example, have been kept under rabbit cages with success, for they can process the rabbit droppings and can themselves be sold as bait.

Other symbiotic relationships have been successfully fostered in livestock farming. Hogs have been kept with cattle to feed on waste grain. Goats have a rather hardy digestive system, but they are usually kept alone due to their differences from cattle in size and temperament. Horses seem to act as catalysts to tetanus in goats; these two species, therefore, are not usually kept together, or tetanus shots are used as a precaution. Goats, meanwhile, are not usually stored with sheep, due to the high susceptibility of both to parasites. Cattle, sheep, and goats, though, have grazed open pastures together successfully, because each feeds on different levels of vegetation.

Food-borne illnesses, such as E. coli, salmonella, listeria, and others, garnered a great deal of attention in the late 1990s and early 2000s. In California, 1.5 million pounds of low-heat processed milk was withheld from the market in 1999 when it was learned that 140 cows on a California ranch had died from exposure to botulism; this was only thirteen months after some 400 cows had met a similar fate at another California dairy farm. The

disease was tracked to large bales of hay, suggesting that the attempts by some farmers to cut costs by packaging hay in larger bales was creating compromised feed allotments. In 2002, Pilgrim’s Pride instituted the largest meat recall in U.S. corporate history when it removed 27 million pounds of poultry from shelves due to suspected contamination with listeria.

U.S. Department of Agriculture USDA regulations prohibit fowl from dairy barns, due to the birds’ susceptibility to tuberculosis. Waterfowl tend to be more resistant to tuberculosis than chicken and pheasants. Unlike most emerging focus on food-borne illness in the farming industry, concern over tuberculosis infection is targeted more at small farms and “homesteads” than at factory farms, since the former’s birds tend to be free-ranging and are kept longer than. Chickens more than two years old are more likely to spread the disease, which can be transmitted to humans either directly from the birds or through cattle or swine. Soil contamination is also a threat that can persist even after the affected birds are destroyed.

A late 1990s study conducted by the University of California Agricultural Issues Center concluded that an outbreak of bovine spongiform encephalopathy (BSE), also known as “mad cow” disease, like those that have plagued the United Kingdom’s beef industry since the mid-1980s, could cost the U.S. agriculture industry more than \$14 billion—\$8 billion from farm income if the disease ever made its way onto U.S. soil. BSE causes a

fatal, degenerate brain disease in cattle. It has been caused by sheep material, infected with transmissible spongiform encephalopathies (TSEs), used in cattle feed. In December of 2003, an animal infected with mad cow was discovered at the Sunny Dene Ranch in Mabton, Washington. As a result, the U.S. government slaughtered hundreds of cattle with possible ties to the infected cow and also recalled about 10,400 pounds of raw beef. Shortly thereafter, roughly 30 countries, including Japan and Mexico, banned all imports of U.S. beef. Japan, which accounts for 32 percent of total U.S. beef exports, formally requested that all U.S. beef be tested for mad cow. As of February 2004, however, U.S. officials had determined such testing to be unnecessary.

To accommodate public outcry against these increasing tendencies, the federal government has sprung into action. The Food and Drug Administration (FDA) has placed limits on the amount of aflatoxin, which results from mold growth on livestock feed, that can appear in human or livestock items for consumption. Meanwhile, the EPA has taken regulatory steps aimed at imposing pollution-discharge permits on the nation's larger farms by 2005, affecting everything from feed supplies to equipment. These and similar developments are expected to increase costs to farmers in the form of testing and prevention systems and other expenses relating to staving off food-borne illnesses and livestock contamination.

More broadly, however, factory farms themselves have come under fire, even from the Department of Agriculture, for the perception that they inherently lend themselves to pollution and food contamination. While the trend in all agricultural sectors has been toward larger, more centralized farming, such farms have been found to be fertile ground for manure spills that contaminate water and kill fish, as well as for high levels of nitrogen- and phosphorous-based water contamination. This has focused attention on the comparative benefits of small-scale farming, which has been gradually displaced by factory farms. After years of protests from small farmers and environmentalists, the prominence of food-borne illnesses and contamination have led the Department of Agriculture to investigate the possibilities of reversing the long shift toward factory farming. While most industries have experienced a tightening concentration of ownership and production, the immediate negative consequences of this pattern in the agricultural industry have forced regulatory bodies to reconsider traditional policies. Federal tax programs, for instance, have long been tilted in favor of large agribusiness, offering incentives for capital-intensive expansion of operations, as well as exemptions from federal labor laws for large farms dependent on hired labor. For general livestock farmers, the majority of whom are relatively small, these developments could be a welcome form of relief.

SIC 0711

SOIL PREPARATION SERVICES

This category covers establishments primarily engaged in land breaking, plowing, application of fertilizer, seed bed preparation, and other services for improving the soil for crop planting. Establishments primarily engaged in land clearing and earth moving for terracing and pond and irrigation construction are classified in **SIC 1629: Heavy Construction, Not Elsewhere Classified**.

NAICS CODE(S)

115112 (Soil Preparation, Planting and Cultivating)

The soil and topography of the land, along with the climate of an area, determines the type of farming that can be done. For example, wheat, corn, and other grains are most efficiently grown on level land where large, complex machinery can be used. These crops are commonly grown on the prairies and plains of Iowa, Illinois, Indiana, Nebraska, Ohio, Kansas, and southern Minnesota and Wisconsin. Cotton, tobacco, and peanuts—all crops that require longer growing seasons—are primarily grown in the South. Most of the country’s fruits and vegetables are grown in California, Texas, and Florida.

To promote growth and germination, soil must provide water, heat, oxygen, and essential nutrients. The soil must also be compressible enough to allow root penetration and plant growth. Among the most important operations in the crop preparation industry are tilling, liming, and fertilizing soils in preparation for crop planting.

Tilling is commonly done for several reasons: to eradicate crop residuals from previous plantings, such as corn stalks or wheat stubble; to destroy weeds; and to modify the structure of the soil to accommodate planting. Traditional tilling, which typically involves plowing, leaves less than 15 percent of plant residue on the soil surface. It temporarily aerates the soil and controls weeds, but over the long term, decomposing plants and

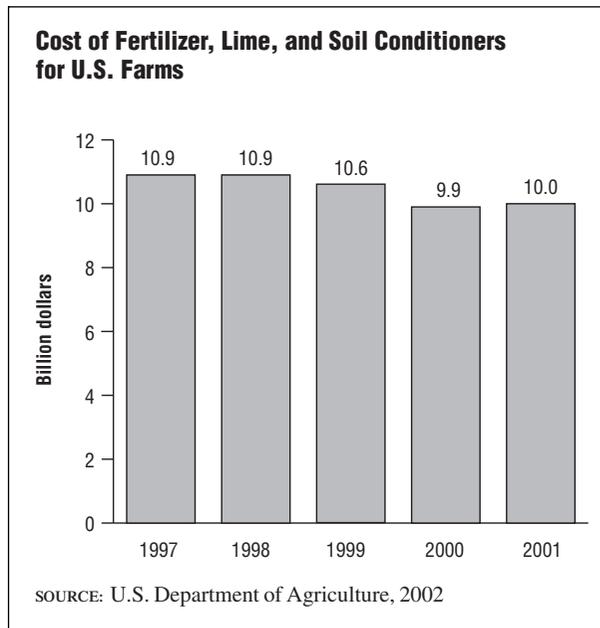

compaction destroy the structure of the soil and actually reduces aeration.

To combat the problems resulting from conventional tilling, soil preparers increasingly turned to conservation tillage in the late 1990s and early 2000s. Conservation tillage systems leave at least 30 percent crop residue after planting and minimize water runoff and soil. The practices can stave soil erosion by as much as 90 percent. The most common types of conservation tillage are no-till, ridge-till, and mulch-till. The no-till system involves leaving the soil undisturbed from harvest to planting except for nutrient injection and controlling weeds primarily with herbicides. The ridge-till system also leaves the soil undisturbed from harvest to planting except for nutrient injection, but weeds may be controlled with herbicides and/or cultivation and the ridges are rebuilt during cultivation. The mulch-till system disturbs the soil prior to planting and accomplishes weed control with herbicides and/or cultivation. Many U.S. farmers also utilized reduced tillage methods, which leave 15 to 30 percent crop residue after planting. According to the Conservation Technology Information Center, no-till crops encompassed more than 55 million acres by the early 2000s. Conservation tillage not only saves farmers nearly 310 million gallons of fuel per year, it also reduces water- and wind-based soil erosion by nearly 1 billion tons annually. A new method of conservation tillage, non-inversion deep tillage, was found to boost cotton yields by more than 20 percent, according to a study released by the Agricultural Research Service in 2003.

Liming involves spreading agricultural lime, containing calcium carbonate and magnesium carbonate, to soils with undesirably high levels of acidity, thereby increasing their pH levels. Optimal lime requirements depend on both the condition of the soil and the crop to be planted.

A fertilizer is any natural or synthetic origin that is spread in soils to supply one or more essential nutrients. Fertilizer carriers or materials that are mixed together and processed to produce fertilizer are mixed fertilizers. Fertilizers come in several forms: solid, liquid, or gas. The most commonly used fertilizers contain various concentrations of nitrogen, potassium, and phosphorus. The National Agricultural Statistics Service (NASS) reported that U.S. farm expenditures on fertilizer, lime, and soil conditioners declined between 1997 and 2001, from \$10.9 billion to \$10.0 billion. These conditioners accounted for 5 percent of total farm production expenditures in the early 2000s, compared to 6 percent of total expenditures in the late 1990s.

Environmental concerns over fertilizer use became increasingly publicized in the 1990s and 2000s, particularly regarding the contamination of ground water from nitrogen supplies. Farmers began turning to crop prepara-

tion services for custom application of fertilizers, as Federal and State laws required licensed applicators for many more chemicals. Domestic farmers also started using different fertilizer management methods, including foliar fertilization application—direct application of fertilizer to plant leaves—and fertilizing several times during the growing season rather than applying fertilizer once. It was thought that several smaller applications of fertilizer lessened the amount of nitrates seeping into the ground. Farmers also began to test and analyze soil and plants to better assess the need for fertilizing. Because of the low cost of nitrogen, however, farmers were hard-pressed to drastically cut their usage.

One important operation for the soil preparation services industry is the decontamination of soils. Volatile organic compounds (VOCs) are among the most problematic soil contaminants. A number of methods for VOC decontamination were tested in the 1990s, and the vapor extraction system was among the most effective of these, with 85 to 100 percent removal rates. The problems involved in accommodating environmental regulations passed in the late 1990s, particularly regarding site remediation and containment, suggest that soil decontamination will remain an important activity for the industry well into the 2000s.

There are few firms whose primary activity is soil preparation services. The largest of these is Waste Stream Technology Inc. of Buffalo, New York. Waste Stream was founded in 1986 and generated sales between \$1 and \$2 million during 2003. The firm is involved in the bioremediation of contaminated soils and provides environmental laboratory services for soil, water, and waste. Waste Stream is a subsidiary of the publicly held

Sevenson Environmental Services of Niagara Falls, New York. Another key player in the industry is Soil Solutions located in Winston-Salem, North Carolina.

SIC 0721

CROP PLANTING, CULTIVATING, AND PROTECTING

This group covers establishments primarily engaged in performing crop planting, cultivating, and protecting services. Establishments engaged in complete maintenance of citrus groves, orchards, and vineyards are classified in **SIC 0762: Farm Management Services**.

NAICS CODE(S)

481219 (Other Nonscheduled Air Transportation)

115112 (Soil Preparation, Planting and Cultivating)

The crop planting, cultivating, and protecting industry encompasses a variety of services, including: aerial dusting and spraying; bracing of orchard trees and vines; citrus grove cultivation; corn detasseling; hoeing; insect control for crops, with or without fertilizing; irrigation system operation; planting crops; pruning orchard trees and vines; weed control; and other miscellaneous activities. The highly fragmented industry is dominated by small, private, local companies. As a result, statistical data on this group is scant.

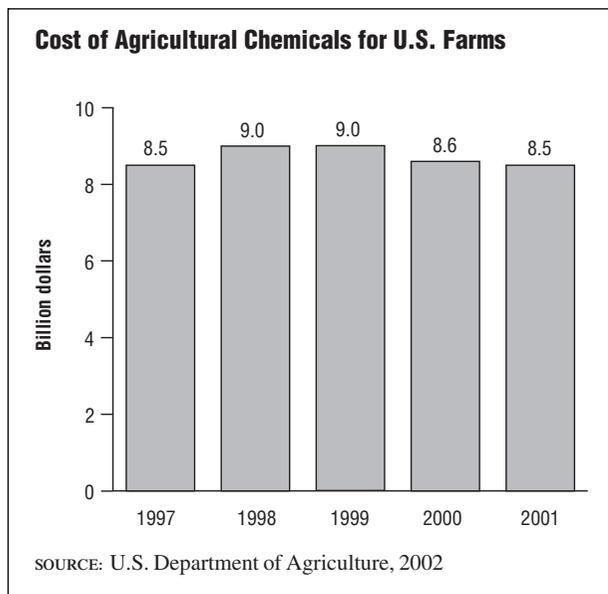

Most industry activities, such as corn detasseling and hoeing, are relatively self-explanatory. One of the larger and more complex services is aerial application, or crop dusting, which usually entails dusting or spraying crops of large acreage with pesticides and weed control chemicals from an airplane. Aerial application is used for more than 65 percent of crop chemical applications in the United States, according to the National Agricultural Aviation Association (NAAA). Besides increasing the speed and efficiency of the dusting process, aerial crop dusting eliminates the need to apply chemicals with wheeled vehicles that could damage crops. The crop dusting industry faced repeated shutdowns in 2001 after the September 11 terrorist attacks raised concerns that crop dusters could be used to spread biological contaminants.

The need for crop services is an indicator of the trend toward advanced, large-scale farming practices that accelerated during the post-World War II U.S. economic expansion. During the 1950s, 1960s, and 1970s, U.S. farms became increasingly mechanized to take advantage of economies of scale. Importantly, the development of advanced pesticides, herbicides, fertilizers, and other chemical treatments resulted in an entire chemical application services industry. Likewise, new machinery significantly increased the amount of cultivated land which a single landowner could efficiently manage. Aerial crop dusting, performed as early as the 1920s using World War I surplus aircraft, for example, gave way to advanced higher-altitude craft by the early 1950s.

Indeed, while farmers during the early 1900s usually performed most crop management activities, many farm owners in the 1990s are more business owners and managers than conventional farmers. Farm owners commonly contract planting and seeding, irrigation, pest control, and other duties to specialized outside service providers.

The trend toward greater farm automation continued into the late 1990s and early 2000s. Aerial crop dusting, for example, became a complex, high-tech endeavor, with advanced crop dusting systems employing global positioning systems (GPS) to indicate precise location and to show which rows of crops need dusting. These modern systems are more efficient than the previously used flagging system, which required flag men on the ground to communicate where spraying or dusting was needed. Modern aerial dusters, which cost anywhere between \$100,000 and \$500,000, also benefit from on-board computers that automatically control spray width and coverage density. Computer systems are also capable of plotting fields and provide information about the best path for dusting a certain area, taking into consideration applicable weather conditions. Crop dusters also use computers to keep track of the types and amounts of chemicals used, as well as when and where they were sprayed.

Environmental safety of crop protection products (chemicals used to control insects, diseases, and/or weeds) became an increasingly important focus in the 1990s and 2000s. According to a report released by the National Center for Food and Agriculture Policy in November of 2000, pesticide sales in the United States increased 93.7 million pounds between 1992 and 1997, the latest year for which specific data is available. Fungicides, herbicides, insecticides, and other pesticides were also on the rise, making this industry, and its impact on the environment, a significant public concern. While the Food Quality Protection Act, signed into law in August 1996, provided some significant changes in food safety and pesticide laws, including major revisions in pesticide

registration and use provisions of chemicals, pesticide use remained a controversial issue in the early 2000s.

In the late 1990s and early 2000s, state representatives continued to promote legislation regulating pesticide use, and despite a 1997 report by the Environmental Protection Agency (EPA) that indicated pesticide usage among U.S. farms had dropped significantly since the all-time high in 1979, activist groups contended that pesticide use was on the rise, and controversy over the safety of pesticides grew stronger. The U.S. Department of Agriculture reported that between 1999 and 2001, total farm expenditures on agricultural chemicals declined from \$9 billion to \$8.5 billion. CropLife America, formerly known as the American Crop Protection Association (ACPA), an organization to which most major pesticide manufacturers and distributors belong, has been instrumental in providing information on regulatory changes as well as promoting the environmentally sound use of crop protection products. The ACPA notes that pesticides used on U.S. farm fields are rigorously tested, and only about one out of 20,000 pesticides is approved for usage on crops. Still, such groups as the Environmental Working Group and Pesticide Action Network North America lobby for more stringent controls on pesticide use and advocate less toxic pest control methods, such as crop rotation, introduction of beneficial insects, mulching, and use of low-toxicity pesticides such as sulfur, soaps, and biopesticides.

SIC 0722

CROP HARVESTING, PRIMARILY BY MACHINE

This industry encompasses establishments primarily engaged in mechanical harvesting, picking and combining of crops, and related activities, using machinery provided by the service firm. Crops undergoing mechanical harvesting include berries, fruit, cotton, grain, nuts, sugar beets, sugarcane, and vegetables. Companies that provide threshing, combining, silo filling, and hay mowing and baling services are also included in this classification. Farm labor contractors providing personnel for manual harvesting are classified in **SIC 0761: Farm Labor Contractors and Crew Leaders**.

NAICS CODE(S)

115113 (Crop Harvesting, Primarily by Machine)

INDUSTRY SNAPSHOT

This industry is comparatively small, and it is dominated by family-owned companies. Crop harvesters, both manual and mechanical, are directly reliant on the economic fortunes of the American farming community, the sole client of the harvesters.

ORGANIZATION AND STRUCTURE

American agribusiness is a huge, diversified industry and encompasses several specialized sectors. Besides the farmer (also called the grower), who manages the land and cultivates the crops, there are industries based around companies that harvest, process, distribute, and transport farm products and farm supplies. There are also industries based around companies that supply materials and services to the farmer. Contract or custom harvesters are part of the former group.

It is increasingly common for farmers to enter into contracts to sell their produce before it has matured. Contract farming is an arrangement with a buyer, such as a food processor or marketer, to sell and ship the produce to the buyer upon harvesting. The custom harvesting company may be an intermediary part of this arrangement. If the company has been contracted to do the harvesting, it may also make the arrangements for selling and shipping the product to the buyer on the grower's behalf.

The farmer agrees to a price at the time of the contract. This arrangement can benefit either the grower or the harvester/buyer, depending upon supply and demand of the particular type of crop at harvest time. If there is a nationwide bumper crop of green beans, and the farmer is selling green beans, the farmer may get a higher price for the crops with a contract than if he or she waited for the harvest and bid with many other farmers waiting to sell their beans. If crop production is low, creating high demand, the buyer comes out ahead because the farmer could have sold for a higher price, had he or she known there would be a smaller supply. The custom harvester, having agreed to buy a crop at a certain price before it has matured, is subject to similar losses or gains.

The custom harvester contracts production with the food processor. The contract will specify the delivery of tons of produce per day, which will fluctuate according to weather conditions or other variables. The custom harvester also contracts with the grower to produce the crop. The harvester begins working with the grower when it is time to plant the crop. The harvester's field representative works with the grower to coordinate various facets of the planting process. For the harvester, this is to set standards for the crop and ensure quality control. The field representative delivers the seed and develops the timing for planting, fertilizing, and harvesting the crop. The grower pays for the seed, because it is held against his or her account when the grower is paid for the harvested crop.

Large harvesters generally have a variety of equipment that enables them to harvest the crop of their choice. They harvest with their own machinery, load the produce onto their own semi-tractor-trailers, and ship it to the processor. Large contract harvesters also have trucking and communications systems in place. These systems are crucial because, in order to fulfill the contract with the processor, the harvesting company may have to send trucks, equipment, and harvesting crews to different states for harvesting jobs. They go wherever they need to fill the packing window. Weather can determine the order in which the harvester chooses the farms. Timing is crucial, because each crop matures at a different rate and must be harvested at its peak. Increasingly, harvesting companies use computers to track the planting dates, varieties, and pesticides (herbicides, fungicides, insecticides) used by different growers. The time frame for a harvesting job can range from a few days to two weeks, depending upon crop, terrain, and size of acreage.

Mechanically-Harvested Crops. In deciding whether to harvest mechanically or manually, farmers must consider what type of crop and plant is being harvested. Grain crops are harvested mechanically. In the case of vegetable crops, however, they may be harvested mechanically if a hardy variety or if not intended for the fresh market. Many fruits and vegetables, especially cit-

rus fruits, are harvested almost exclusively by hand because they must arrive on the fresh market in perfect condition, and mechanical harvesting can scratch or bruise produce. Damage is a major concern of reap harvesting. Damage is usually minimal if the harvesting equipment is kept clean and adjusted correctly for the crop. Even with hand harvesting, however, machinery, such as conveyor belts, will likely be used to transport the fruit from the field, to cool it and perhaps wrap it. Farmers may also choose to harvest by hand if they have secured a high price for their crop and can afford manual labor. They may combine their options within the same crop, picking large, mature vegetables first by hand for the fresh market and then bringing in machinery to harvest smaller vegetables for sale to a processor.

Time is also a major consideration. If farmers need to harvest quickly, they will need to harvest mechanically. In deciding whether to harvest by themselves or to contract with a custom harvester, farmers have another set of factors to consider. If the farmers have a lot of acreage, they may own a combine harvester. Often, they will make arrangements to harvest the crops of their neighbors as well. If the farmers grow grain and do not have enough acreage to justify making the capital investment in a combine harvester (about \$120,000), they will need the services of a contract harvester.

Convenience and assistance may be a factor as well. Farmers may find it easier to have the input of the custom harvester in determining crop planting, timing, harvesting, and sale issues. Even if the farmers do own a combine harvester, they may still contract a custom harvester. One reason is that the window of opportunity for harvesting is small. Farmers may need to get grain out of the field immediately or risk losses because of bad weather, for example. If they don't have the capacity to do the job themselves, they may seek help from a custom harvester.

Equipment. The combine harvester used for grains tends to be different from the one used for vegetables, although the manufacturers strive to make the machines more interchangeable through modifications. Harvesting machinery is generally classified by crop. A harvester must be adjusted to harvest a specific crop and to keep trash out of the load. A grain harvester is called a combine harvester because it cuts, threshes, and cleans grain in one operation. Corn is harvested by mechanical pickers that snap the ears from the stalk so that only the cobs are harvested. Stripper-type cotton harvesters strip the entire plant of both open and unopened bolls. Hay and forage machines include mowers, crushers, windrowers, field choppers, balers, and grinders.

Root crops such as potatoes are harvested with diggers, which often pull up rocks and unwanted vegetation with the potatoes. Some machines can sort this trash

out, while other machines carry people who sort it by hand. Sugar-beet harvesters lift the whole root from the ground, clean it, and deliver it to a bin. Vegetable crops such as broccoli, asparagus, celery, lettuce, and cabbage are still harvested largely by hand.

For the fresh market, some vegetables and nearly all fruits are still harvested by hand. For processing, drying, and occasionally for fresh market, mechanical tree and bush shakers with catching belts, bins, pallets, and electric lifts reduce harvesting and handling labor.

BACKGROUND AND DEVELOPMENT

Some custom harvesters are family-run outfits that started as growers, purchased expensive harvesting equipment, and entered into agreements with other local farmers to harvest their crops. They are likely to grow crops and maintain livestock in addition to their harvesting operations. Others are large and sophisticated operations that coordinate production with the grower from planting to sale and delivery.

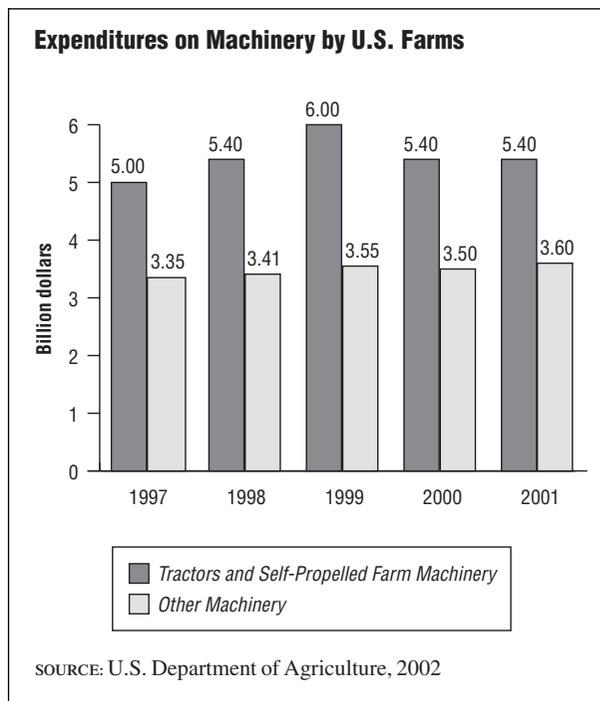

The history of mechanical harvesting itself dates back to Cyrus McCormick’s marketing of the mechanical reaper in the early 1840s. The reaper could harvest grains only; mechanical harvesters for root and vegetable crops weren’t invented until the 1930s. McCormick’s invention was an important part of the agricultural revolution that began in the eighteenth century.

The agricultural revolution dramatically increased a farmer’s ability to produce crops. The technique of crop rotation allowed farm land to be used continually. Machinery allowed ever larger areas to be worked, and farmers increased their acreage. When mechanical harvesters and other devices were created to do formerly manual labor, production increased to a level that surpassed national consumption. The McCormick reaper permitted the cultivation of the vast Midwestern plains states.

The proportion of human labor used in the production of farm goods dropped by measurable degrees as a result of farming advances, while capital spending on feed, machinery, fertilizer, and other farming staples increased dramatically.

Farmers now rely heavily on specialized technology to sustain and increase production. Farmers are also highly dependent on outside sources for their equipment and services, such as custom harvesting. Because of these specialized interrelationships, farmers and the businesses that support them have also necessarily become increasingly sophisticated in their cash management techniques.

In the late 1990s efforts to develop new machines to facilitate the labor-intensive harvesting of crops intensified. In Florida, for example, providers of citrus for the production of juice faced labor shortages, and exploration

of mechanical harvesting options became necessary. The most promising type of mechanical harvesting system appeared to be the “continuous canopy shake and catch,” which resulted in as much as a 75 percent decrease in harvesting costs. These systems were appropriate only for fruit destined for juice production, as fruit for fresh consumption would suffer from too much damage from the machinery.

CURRENT CONDITIONS

Because this industry sustains itself by providing services to farmers, it is affected by many of the same economic, climactic, and industrial conditions that affect farmers. The early 2000s saw a slight improvement in the American farm economy, after three years of decline in the late 1990s. Net farm cash income was more consistent and higher than in previous years. After falling from \$207 billion in 1997 to \$187 billion in 1999, U.S. farm cash receipts climbed to \$193 billion in 2000 and to \$202 billion in 2001. Farmers who stored grain were able to take extra advantage of relatively high commodity prices. After grain reserves had reached historically low levels in 1993-94, producers had expanded their crops to keep up with increased national and international demand.

In 2003 about 10.3 billion bushels of corn were produced, the highest on record and a significant increase over the 2002 crop of 9.01 billion bushels. Wheat production fluctuated dramatically in the early 2000s as well. After falling to 1.9 billion bushels in 2001 and to 1.6 billion bushels in 2002, wheat production rebounded to 2.3 billion bushels in 2003. Soybean production dropped

12 percent in 2003, falling to 2.42 billion bushes, its lowest level since 1993.

In 2001 farmers spent a total of \$25.4 billion on farm services, up from \$23.5 billion in 1996. This figure covered all farm services, not only expenditures for the mechanical harvesting of crops. Also in 2001, according to the U.S. Department of Agriculture, expenditures on tractors and self-propelled farm machinery remained steady at \$5.4 billion, while spending on other farm machinery increased from \$3.5 billion to \$3.6 billion. These figures suggested continued use of mechanical harvesting equipment on U.S. farms.

INDUSTRY LEADERS

Among the leaders in the mechanical harvesting services industry in the early 2000s were Noblesse Oblige Inc. of Seeley, California; Apio of Guadalupe, California; and Fresh Western Marketing of Salinas, California. Other companies engaged in providing mechanical harvesting services were geographically clustered in agricultural regions in such states as Texas, Kansas, Oklahoma, Indiana, Wisconsin, Florida, and California.

SIC 0723

CROP PREPARATION SERVICES FOR MARKET, EXCEPT COTTON GINNING

This classification covers establishments primarily engaged in performing services on crops, subsequent to their harvest, with the intent of preparing them for market or further processing. Establishments primarily engaged in buying farm products for resale to other than the general public for household consumption and which also prepare them for market or further processing are regarded as wholesale trade establishments. Establishments primarily engaged in stemming and redrying tobacco are classified in **SIC 2141: Tobacco Stemming and Redrying**. Establishments engaged in ginning cotton are classified in **SIC 0724: Cotton Ginning**.

Expenditures on Services by U.S. Farms

SOURCE: U.S. Department of Agriculture, 2002

NAICS CODE(S)

115114 (Postharvest Crop Activities (except Cotton Ginning))

The scope of operations included under the crop preparation services for market industry is large. It includes bean, grain, and seed cleaning; corn, peanut, and nut shelling; fruit and vegetable sorting, grading, and cooling; grain, hay, fruit, and vegetable drying; packaging of fresh or farm-dried fruits and vegetables; potato and yam curing; grain fumigation; custom grinding; and tobacco grading. U.S. farms decreased their total expenditures on farm services from \$25.7 billion in 2000 to \$25.4 billion in 2001.

The leading firm in the crop preparation services for market industry is Deli Universal Inc. of Richmond, Virginia, a unit of Universal Corp., which posted 2003 sales of \$2.6 billion and employed 28,000 workers. The second-leading company is Golden Peanut Co. of Alpharetta, Georgia, with more than 1,000 employees working at its eight shelling plants, two specialty products plants, and two hulls processing plants as of 2004. Golden Peanut specializes in peanut flours, which it roasts to achieve the color and flavor of roasted peanuts. Used in peanut butter flavored confections, these flours control fat migration and extend shelf life. Other industry players include Dole Fresh Vegetables of Salinas, California, a subsidiary of privately owned Dole Food Co., and Diamond Walnut Growers Inc. of Stockton, California, which posted sales of \$331 million in 2003.

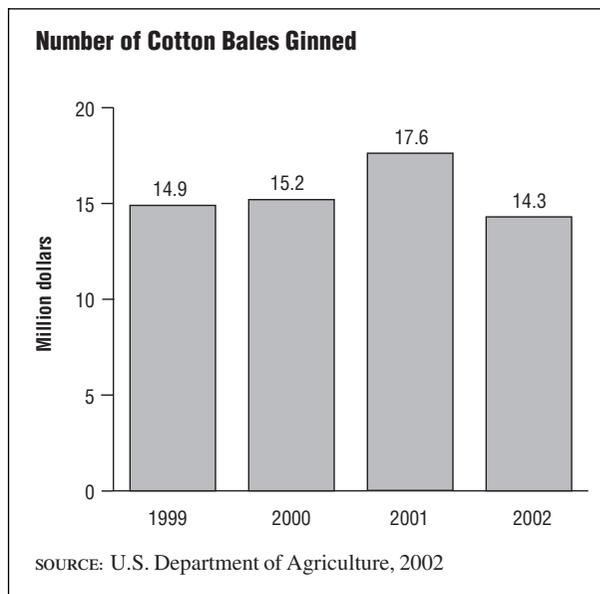

Average wages for the agricultural services industry totaled \$10.95 per hour in the early 2000s. Earnings in crop preparation can vary greatly, depending on the season. Many workers find work only in the growing or harvesting seasons and are unemployed or work in other

jobs during the rest of the year. Most industry workers either manage crop production activities livestock and dairy production. According to the Economic Research Services, jobs in farm-related agricultural services sectors would experience more modest growth than other sectors in the early 2000s due to the increased use of machinery, as well as other practices that have increased efficiency on farms.

SIC 0724

COTTON GINNING

This category includes establishments engaged in cotton ginning.

NAICS CODE(S)

115111 (Cotton Ginning)

Cotton gins are machines used to separate cotton fibers from cotton seeds, a process that must be done before cotton fibers can be used for textiles. High quality cotton is the combined result of the original characteristics of the fiber and the degree of cleaning and drying it receives. The amount of trash and moisture in the cotton helps to determine the efficiency of the overall ginning process.

In 2002, cotton gins in the United States produced approximately 14.4 million bales of cotton, compared to 17.6 million bales in 2001. The decline was due to poor weather conditions and falling prices, as well as an increase in foreign production. Low labor costs in countries like China and Brazil had allowed global cotton producers to flood the U.S. market with inexpensive cotton. U.S. imports of cotton had grown by 5 million bales between 1997 and 2001, while exports to major markets like China had declined due to the impact of the weak yen on the Asian economy.

In the early 2000s, some establishments operated a single gin, while larger companies operated as many as two dozen gins each. Texas and Missouri are the leading cotton-producing states, with 3.76 million bales and 1.84 million bales, respectively; nearly 40 percent of all cotton grown in the United States is ginned in these two states.

California is third in the nation in cotton ginning production, producing 1.62 million bales, or 11.3 percent of total U.S. production, followed by Arkansas with 1.59 million bales, or 11.1 percent. A newcomer to the cotton industry, Kansas built its first cotton gin in 2002.

The two industry leaders as of 2003 were Anderson Clayton Corporation of Fresno, California, which is owned by Australia-based Queensland Cotton Holdings Ltd., and Lyford Gin Association of Lyford, Texas.

Eli Whitney, a schoolteacher from Massachusetts, is generally given credit for inventing the first cotton gin in 1773. Whitney's gin, which he patented in 1774, was actually an improvement on an earlier invention known as the Churka gin. The Churka gin used rollers to loosen the cotton fibers, but it was almost useless on the tight, fuzzy variety of cotton that was grown in the Southern states. Whitney replaced the rollers with revolving wooden spikes that pulled the fibers down narrow slots, through which the seeds could not fall. A brush would then clean the cotton from the spikes. The hand-cranked Whitney gin drastically improved the pace of cotton cleaning and made cotton a profitable crop for Southern farmers.

Hodgen Holmes, a mechanic who had worked for Whitney, further improved the cotton gin by replacing the spikes with saw-toothed metal cylinders, which were more effective in grabbing hold of the cotton fibers. Holmes, who received a patent on his gin in 1776, also opened up the bottom of his gin so cotton could be fed into the top of the machine in a continuous process. Mechanical cleaners were added to the basic cotton gin in the 1840s to remove the leaves and stems left by harvesting. The first drier to reduce the moisture content of the cotton before ginning was patented in 1929.

Although the basic technology developed by Whitney and Holmes has remained in use, modern gins have become much more complex. In the early 1960s, cotton ginners developed an improved version of the Churka roller gin for use on long-fiber Pima cotton grown in the Southwest. These roller gins used two knife blades, one revolving and one stationary, to separate the cotton from the seeds. Pima cotton accounted for about 5 percent of the cotton grown in the United States.

Many giners also sold or processed cottonseed for additional revenue. According to the National Cotton Council of America, more than five billion pounds of cottonseed and cottonseed meal were used annually for feeding livestock. Another 100 million gallons of cottonseed oil were used in food products. In the late 1980s, more giners also began to offer compressing and warehouse services.

Until the 1990s, all ginned cotton received the same treatment, without regard to its trash content or its quality. Cotton ginning is a voluminous and complex procedure, which makes it impossible for humans to visually measure or decipher the amount of trash in the cotton or the quality of it; however, new technological advances have improved this situation.

Computerized advancements, for example, now make it possible to monitor and evaluate the ginning process online, as well as evaluate the response of cotton fiber during the process. These new technological advances accurately measure each component of the ginning process, and allow the ginner to process various types of cotton through the minimum machinery necessary to obtain maximum returns while keeping the fiber quality intact.

In 1929 the Department of Agriculture established the U.S. Cotton Ginning Research Laboratory in Stoneville, Mississippi. The research laboratory has received several public service patents for developments that have improved cotton ginning. In 1938, the National Cotton Ginners Association, located in Memphis, Tennessee, was chartered to provide a national voice for several state and regional associations. In the 1990s, the association conducted a gin safety program, disseminated information on technology, and acted as a liaison between the ginning industry and machinery manufacturers. It also tracked federal legislation that affected the industry, including proposals affecting occupational health and safety, migrant workers, and clean-air regulations.

Since then, the effects of cotton processing on human health have been well documented by the National Cotton Ginners Association and the U.S. Department of Labor. The evidence indicates that the dust from cotton processing may be hazardous to a person's health. Many contaminants have been identified that could cause seri-

ous respiratory diseases. Because of these dangers, employers are required to limit the level of breathable cotton dust in the air and take other safety measures, such as supplying employees with respirators, periodic medical examinations, and training programs. In the early 2000s the U.S. Department of Agriculture began studying new uses for cotton gin waste, such as a mulch product that combined ryegrass seed with cotton waste.

VETERINARY SERVICES FOR LIVESTOCK

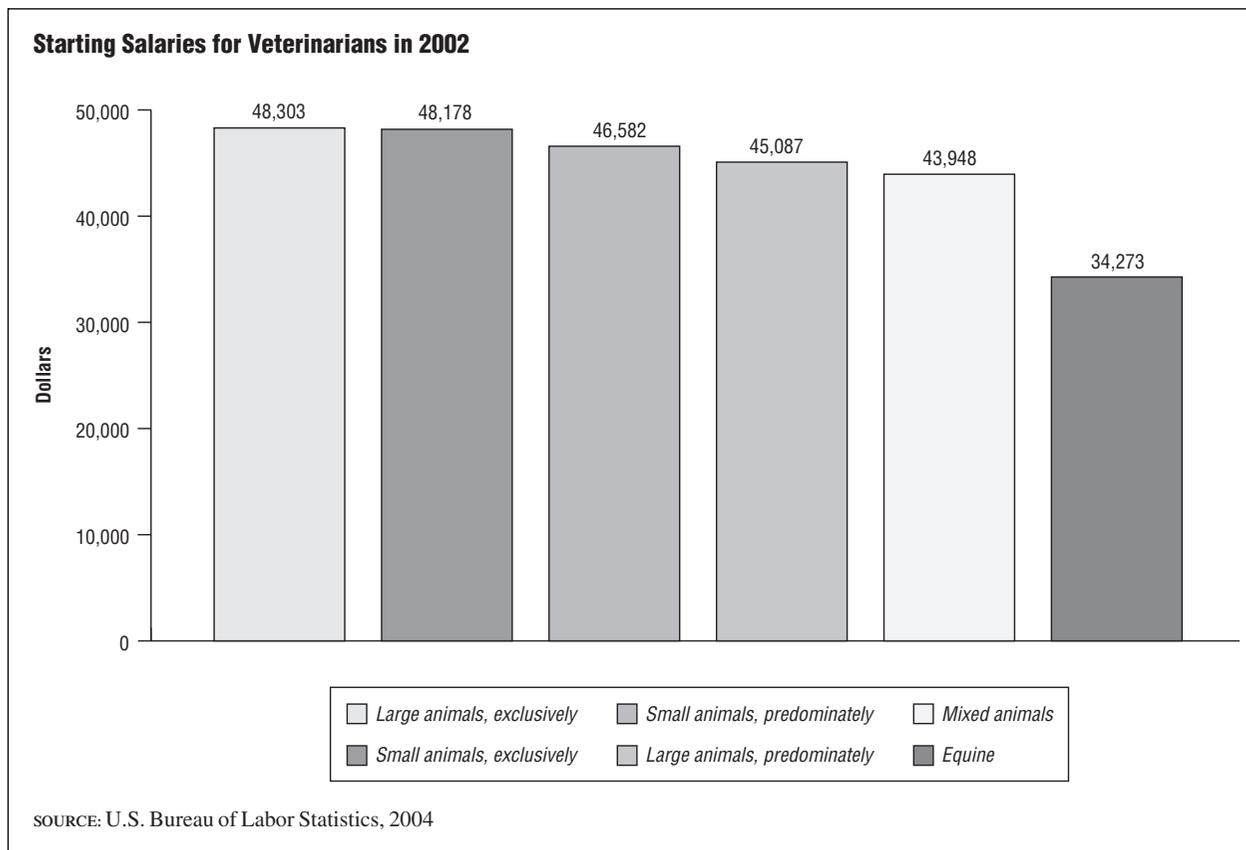

This industry consists of establishments of licensed practitioners primarily engaged in the practice of veterinary medicine, dentistry, or surgery for cattle, hogs, sheep, goats, and poultry. Similar establishments primarily engaged in veterinary medicine for all other animals are classified in **SIC 0742: Veterinary Services for Animal Specialties**.

NAICS CODE(S)

541940 (Veterinary Services)

Roughly half of the food Americans eat is derived from animals (in the form of meat and dairy products). Thus, the focus of this industry is largely aimed at maintaining adequate and safe food supplies for humans through the treatment of injuries and diseases of livestock. Because disease accounts for billions of dollars in lost revenue for the livestock industry—around \$3 billion in the 1990s and 2000s—veterinary establishments specializing in preventive medicine for larger animals (cattle, sheep, and swine) are integral to increasing livestock productivity and profitability.

Approximately 4,000 private veterinary practices were solely "country vet" practices or large animal clinics, providing treatment and preventive services, including the advising of private and commercial ranchers

and farmers on the care and management of livestock and poultry in the 2000s. Although some practitioners specialize in dairy or beef cattle exclusively, most establishments also provide services for sheep, goats, and pigs; a small percentage also treat poultry.

In contrast to the rest of the veterinary industry, where services are most often rendered in a clinic or hospital setting, most veterinary services for livestock are performed on site—that is, in a barn, out in the field, or on a ranch. A beginning livestock practitioner treating predominantly large animals grossed about \$45,087 in 2002 for services rendered, and veterinarians treating large animals exclusively earned about \$48,303. The median salary for all veterinarians totaled \$63,990. On the other hand, federally employed veterinarians of various capacities (nonsupervisory, supervisory, and managerial) averaged about \$72,208 in 2003.

The U.S. Department of Agriculture (USDA) provides veterinary services for researching livestock regulatory medicine. About 2,000 veterinarians were federally employed and engaged in the control and/or elimination of livestock disease and the protection of the public from animal diseases in the 2000s. These services were conducted through the Veterinary Services (VS) division of the Animal and Plant Health Inspection Service, a branch of the USDA. In the early 2000s the VS

group worked to eradicate such diseases as cattle brucellosis, swine brucellosis, bovine tuberculosis, and swine pseudorabies. The division was also responsible for compiling information on the state of animal health in the United States—particularly livestock and poultry—through its National Animal Health Monitoring System, a program established in 1983. The USDA also used recently trained veterinarians as meat inspectors.

The passage of the 2002 Farm Bill, signed by President Bush in May of that year, included a more stringent version of the Animal Health Protection Act (AHPA) designed to control livestock disease. For example, the AHPA boosts maximum civil fines to \$50,000 for individuals caught smuggling animals or animal byproducts into the United States. Those determined to be smuggling such goods for uses other than personal can now be fined up to \$250,000 per violation. As part of the Homeland Security Act passed in response to the terrorist attacks of September 11, 2001, the VS secured additional funding in 2002 to safeguard U.S. animal and food supplies.

Another branch of the USDA, the Livestock and Poultry Sciences Institute, conducted research with the aim of increasing profitability, production efficiency, and the quality and value of livestock products. Among the Institute’s laboratories were the Animal Improvement Programs Laboratory, the Meat Science Research

Laboratory, and the Growth Biology Laboratory, which conducted research pertaining to the improvement of the growth and development of cattle, poultry, and swine.

Although the practice of caring for and treating animals dates back to ancient Egypt, veterinary services in the United States did not develop until the late 1880s, in response to the growth of the livestock industry. During the late nineteenth century and the first half of the twentieth century, almost all veterinary activities in the United States were associated with livestock, especially cattle, hogs, and sheep. A growing concern for public health in relation to the meat supply gave rise to a need for trained individuals capable of curing and preventing livestock diseases.

The first veterinary practitioners for livestock were generally farmers and ranchers who tended their own animals but otherwise had no formal training. In the late 1800s, however, veterinary schools in the United States began cropping up to provide a more specialized education in this field. At about the same time, state agencies became involved in the regulation of livestock health standards and the licensing of veterinary practitioners, moving livestock health care from the local farm or ranch to a more institutional setting.

The increasing population of the United States has created the need for additional food-producing animals. The current emphasis on scientific methods of breeding and raising livestock and poultry is expected to become even more prevalent, requiring additional specialization in the area of veterinary services for these animals. Advances in livestock production have also created a need for veterinary services related to contamination of the food chain by toxic chemicals. Thus, the demand for veterinary services related to the livestock industry is expected to increase, especially in the area of nutrition and disease control, as the continued integration of veterinary services with the livestock industry will be essential in order to address issues of food safety, quality of environment, and animal welfare.

SIC 0742

VETERINARY SERVICES FOR ANIMAL SPECIALTIES

This industry consists of establishments of licensed practitioners primarily engaged in the practice of veterinary medicine, dentistry, or surgery for animal specialties, including horses, bees, fish, fur-bearing animals, rabbits, dogs, cats, and other pets and birds, except poultry. Establishments primarily engaged in the practice of veterinary medicine for cattle, hogs, sheep, goats, and poultry are classified in **SIC 0741: Veterinary Services for Livestock**.

NAICS CODE(S)

541940 (Veterinary Services)

INDUSTRY SNAPSHOT

The veterinary services industry is responsible for the care and treatment of companion animals (pets), sport animals (e.g., racehorses), and some livestock, as well as the protection of the public from exposure to animal diseases such as rabies. These services are generally performed by more than 58,000 licensed veterinarians in the United States, often within the confines of one of the roughly 22,500 animal hospitals and clinics in existence during the early 2000s.

According to the American Animal Hospital Association (AAHA), it is estimated that Americans spend roughly \$20 billion in veterinary services for their pets. Total pet industry expenditures reached \$31 billion in 2003. It is expected that spending on pets, both for veterinary and other products and services, will continue to increase.

ORGANIZATION AND STRUCTURE

The term veterinary clinic is used to describe any veterinary establishment where animals are seen, usually as outpatients needing such services as physical exams, vaccinations, and treatment of minor illnesses and injuries. A veterinary hospital is an establishment that has facilities to treat animals needing to be hospitalized for more than a day. Treatments requiring overnight stays include surgery (most commonly spaying and neutering), tooth extraction, bone repair, and the suturing of wounds.

Because of the substantial investment needed for drugs, instruments, and other start-up costs, most veterinary establishments are group practices, either partnerships or larger facilities that hire individual veterinarians and technicians as employees. Smaller establishments may consist of one to three veterinarians and a technician, who may also serve as receptionist and bookkeeper. Larger establishments may employ several veterinary

specialists, additional technicians, an animal dietician, a dental hygienist, and an office manager.

VCA Antech Inc., based in Los Angeles, California, is the country's largest provider of comprehensive health care services for animals. By 2004, the company owned about 230 animal hospitals in 34 states. VCA's 20 diagnostic laboratories provided services for more than 13,000 animal hospitals throughout America. The company owned 50.5 percent of Vet's Choice pet food and had investments in Veterinary Pet Insurance. Veterinary Centers of America, Inc. reported 2003 sales at \$544 million, a 22.8 percent growth over 2002. VCA had 3,600 employees, 700 of whom were veterinarians, at the end of 2003. Hill's Pet Nutrition, Petco, and PETSMART were its closest competitors in the early 2000s.

About 72 percent of the industry is comprised of veterinarians in private practice. Of these, approximately 50 percent treat small animals, which may be either dogs and cats exclusively, or may include birds, rabbits, hamsters, monkeys, snakes, turtles, and other companion animals. Small-animal services involve pharmacy, surgery, dentistry, ophthalmology, cardiology, orthopedics, oncology, nutrition counseling, obstetrics, radiology, anesthesia, and internal medicine. Mobile and house-call facilities often have established relationships with local veterinary hospitals so that surgical facilities are available when needed.

Geographical region seems to influence the type of veterinary practice. In metropolitan areas, for example, services are generally aimed at treating small companion animals; in rural areas, establishments are more likely to treat livestock and horses.

Large-animal practices comprise less than 15 percent of the industry. Except for horses, these establishments are covered under **SIC 0741: Veterinary Services for Livestock**. Those veterinary services specializing in horses often care for racing horses; such establishments are better compensated financially than most others. Roughly 25 percent of establishments are mixed practices, involving both clinic and house-call facilities. Some of these facilities are affiliated with zoos and primarily provide preventive treatment and health upkeep, including vaccinations, dental care, worming, and grooming.

The cost of routine veterinary services is paid for directly by the individual. However, since the early 1980s, health insurance covering accidents, major injuries, and certain chronic illnesses for dogs and cats has been available in most states. For an annual premium of about \$50 to \$220, with a deductible ranging from \$20 to \$300, animal owners can purchase major medical benefits for their pets that like those available for humans. As a result, there is a growing trend to continue care for many animals that would have previously undergone euthanasia.

All personnel engaged in the private sector of the industry must be licensed. Veterinarians are required to have a Doctor of Veterinary Medicine (D.V.M. or V.M.D) degree from one of the 28 accredited colleges of veterinary medicine, and must pass state board proficiency examinations. Those engaged in specialty services must complete an approved residency program, as well as pass board exams and other board requirements. Some states require licensing of animal health technicians based on minimum educational requirements, an examination, and a fee. In addition, some larger companies, such as VCA, require their vets to have a minimum number of hours of continuing education on a yearly basis. Veterinarians employed by the government need not be licensed.

BACKGROUND AND DEVELOPMENT

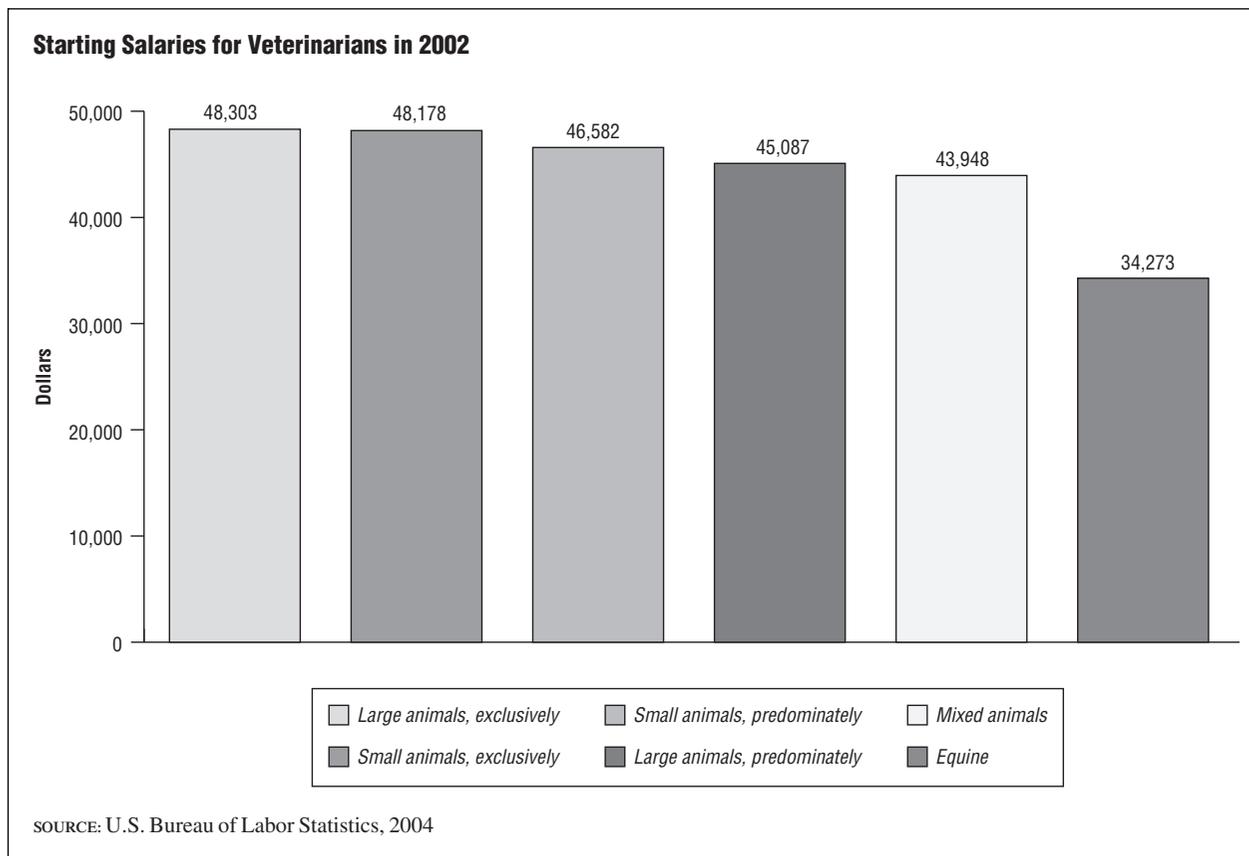

Because most of the procedures and medicines developed for the treatment of human diseases were first tested on animals, the advancement of veterinary medicine, and therefore the development of the veterinary services industry, is closely related to the advancement of human medicine. Although people have kept animals for companionship for thousands of years, the need for practitioners of veterinary medicine did not arise in the United States until 1883, when bans on interstate transportation and exportation of diseased animals to Europe began to hurt this country's growing livestock industry.

The establishment of the Veterinary Division of the U.S. Department of Agriculture (USDA) in 1883 was the first step toward recognition that treatment and preventive care of animals was a necessity. In May 1884 Congress passed an act that established The Bureau of Animal Industry (BAI). Among its aims was "to provide means for the suppression and extirpation of . . . contagious diseases among domestic animals."

With the industrialization of the United States came shorter work hours, more leisure time, earlier retirement, and longer life expectancies. Animals' status as pets began to receive greater attention and a corresponding demand for better veterinary services resulted. According to a 1990 survey, approximately 43 percent of all households had pets, whereas only 38 percent had children. Many of these pet owners treat their animals as family members, which includes ensuring that they receive competent medical care.

CURRENT CONDITIONS

By 2002, 28 percent of all licensed veterinarians were self-employed. The majority of the nation's 58,000 licensed veterinarians catered exclusively to small animals. These veterinarians served the 63.4 million U.S. households owning a cat or dog in the United States as of 2002. Along with being responsible for the care of 60 million dogs and 70 million cats, veterinarians also served other

pets such as birds, which accounted for 2 million veterinarian visits in 2001, as well as rabbits, ferrets, guinea pigs, hamsters, rodents, turtles, and other reptiles.

Veterinary services and specialties exist for nearly all human equivalents, including chemotherapy, CAT scans, ultrasound, prosthetic hip surgery, pacemaker implants, electrocardiograms, kidney transplants, arthroscopic surgery, dental care, and acupuncture. As a result, the industry is expected to become more and more specialized in the coming years. The rising popularity of medical insurance for pets is already allowing more pet owners to afford these technologically-advanced treatments that otherwise would have been too expensive, and some believe that the small, one- to three-person practice will eventually be replaced by large, centralized veterinary hospitals with staffs of 30-50 specialized veterinarians and technicians.

A trend toward more unconventional methods of private practice, such as mobile clinics, low-cost spay clinics, vaccination clinics, and tax-exempt government-subsidized animal welfare groups, has already been noted. Some veterinary facilities also are taking a more holistic approach, considering environmental factors, nutrition, and the psychological needs of animals.

In an effort to increase revenues, veterinary establishments now include the sale of over-the-counter drugs

and pet supplies such as food and parasite-control products. This practice allows for competition with feed stores, pet health centers, and pet supply stores, which also tend to offer free advice on the use of drugs and other animal health products.

The industry is expected to grow faster than the average of all occupations through the year 2012 with a higher demand for specialized facilities in metropolitan areas. An increasing need for additional small-animal clinics is predicted as the pet population increases, although small animal practices might become more competitive because most graduates preferred to live in more populated areas rather than rural ones caring for larger animals. Large, multi-hospital corporations (such as VCA) and clinics that incorporate pet stores and grooming all in one facility may be one way to counteract competition and increase revenues. Advertising, including television, direct mail, newspapers, Yellow Pages advertisements, and advertisements in professional publications, once shunned, will also play a greater role as this industry develops.

WORKFORCE

The veterinary services industry employs approximately 73,000 people, about 58 percent of whom are doctors of veterinary medicine. Veterinary assistants, technicians, and office workers make up the remainder of

the work force. Women account for nearly 40 percent of all practicing veterinarians in the United States.

In 2002, the lowest paid practitioners, typically those first starting out in the industry, earned an average annual salary of about \$38,000. The middle 50 percent of veterinarians averaged between \$49,050-\$85,770, less than half the average gross of a doctor of human medicine and about two-thirds as much as a human dentist with comparable experience. Those earning the highest 10 percent of salaries made roughly \$123,400.

Entry level animal-health technicians, many of whom are trained in laboratory procedures, assisting and monitoring patients, preparation for surgery, administering medication, and feeding, are paid an average of \$16,000 a year. Salaries increase gradually with experience, ranging from about \$23,390-\$28,390 after seven years. The low starting salaries, coupled with the lack of financial growth, has led to a shortage of qualified technicians at a time when the industry itself has become more and more technically-oriented.

AMERICA AND THE WORLD

The World Veterinary Association (WVA) meets every three years to discuss animal welfare throughout the world. One of the association’s objectives in the early 2000s was to develop a policy statement to help set worldwide standards. Another major concern was the potential of diseases being spread across country borders. The organization prides itself on keeping politics out of the discussions and maintaining animal welfare as their priority.

SIC 0751

LIVESTOCK SERVICES, EXCEPT VETERINARY

This classification covers establishments primarily engaged in performing services, except veterinary, for cattle, hogs, sheep, goats, and poultry. Dairy herd improvement associations are also included in this industry. Establishments primarily engaged in the fattening of

cattle are classified in **SIC 0211: Beef Cattle Feedlots**. Establishments engaged in incidental feeding of livestock, often during periods of transportation, as a part of holding them in stockyards for periods of less than 30 days are classified in **SIC 4789: Transportation Services, Not Elsewhere Classified**. Establishments that perform services, except those in the realm of veterinary services, for animals not classified as livestock are classified in **SIC 0752: Animal Specialty Services, Except Veterinary**.

NAICS CODE(S)

- 311611 (Animal (except Poultry) Slaughtering)
- 115210 (Support Activities for Animal Production)

INDUSTRY SNAPSHOT

The raising of cattle, sheep, hogs, goats, and poultry requires several specialized husbandry skills, many of which are performed by members of the livestock service industry. These services range from artificial insemination to pedigree record keeping to sheep dipping and shearing.

Labor use on American farms and ranches has changed dramatically since World War II. In 1950 nearly 10 million workers were employed on farms and ranches, but by 1969 this figure had been reduced to 3.1 million. In subsequent decades, this number continued to drop and held at less than 1 million in the early 2000s. This decrease was the result of the trend toward fewer and larger agricultural enterprises and the increasing use of technological innovation. One result of increasing concentration and the development of very large poultry and livestock feeding enterprises has been the switch from family labor

to the increased use of temporary workers. In the early 2000s, roughly 20 percent of all farms relied on contract labor, a sizable increase from 1980 when only about 2 percent did. Another result has been higher than average unemployment rates among farm laborers. In 2002 roughly 11 percent of the hired farm labor force was unemployed, compared to an average of roughly 6 percent for the U.S. labor force as a whole.

Establishments in this industry provide a range of livestock maintenance services. In 2003 two of the leading livestock service providers in the United States were ABS Global, Inc. and Pig Improvement Company, Inc. A subsidiary of Genus plc, ABS extended its international reach in 2003 with the purchase of RAB Australia Pty. Ltd., the largest private cattle insemination operation in Australia. Also that year, Pig Improvement and Birchwood Genetics, based in Ohio, entered into an agreement designed to boost artificial insemination capacity for both firms.

ORGANIZATION AND STRUCTURE

Breed Associations. These organizations perform many services, including tracking of pedigree information and performance records. Typically, a breeder of purebred livestock registers the offspring of his herd or flock shortly after they are born. To be registered in the national herd book these animals must be of purebred parentage, meaning that both sire and dam were previously recorded with the breed registry. Breed associations keep these records and in so doing maintain the purity of the breed. Most breed associations have a paid field staff whose job it is to assist the purebred breeders in filling out the paper work, designing breeding programs, and even aiding in the selection and procurement of seed stock.

Increasingly, it has fallen to the breed associations to also keep performance data on livestock animals. Breeders send in such data as birth weights, weaning weight information, or—in the case of dairy cows—milk production figures. The breed association then gathers up all the data from the participating breeders and publishes this information in the form of sire summaries and “expected progeny differences.” This computer-generated data aids purebred and commercial breeders in selecting those animals with the highest production traits. The role of the various breed associations is rapidly expanding, primarily because of their large databases of performance information. This data has become increasingly valuable as the animal industries turn to what is known as “value-based marketing.” Purchasers of livestock—feedlots, dairies, piggeries, and processors—demand to know the performance ability and meat quality of the animals before they purchase them.

Examples of breed associations in the beef industry include The American Hereford Association and the American Angus Association. The Holstein Association keeps pedigrees and production information for Breeders of registered Holstein dairy animals. There are more than a dozen sheep registries, including the American Hampshire Sheep Association, the American Suffolk Sheep Society, and the National Suffolk Sheep Association.

Artificial Breeding Services. Another service industry common to most domesticated livestock establishments is the artificial insemination stud and breeding service. Artificial insemination is widely used in dairy cattle and poultry and to a lesser extent with beef cattle and hogs. Those employed in the breeding industry purchase or lease superior animals, house them at their facilities, collect their semen regularly, merchandise the semen, and ship it in frozen nitrogen to their livestock-raising customers. Recent technological innovation is making it possible to sex the semen so that a producer can determine the gender of the resulting offspring.

The concept behind artificial insemination is the same for all species; however, the procedures vary from animal to animal. When superior producing male animals are identified their semen is drawn and extended. Extension is the process whereby 10 cubic centimeters of semen is extended to provide 100 or even 200 doses. For cattle, the semen is frozen and then sold by the straw or ampule to other breeders who in this manner can use the best genetics available. In the case of dairy animals, it might be possible for a superior dairy bull to produce a million offspring through insemination techniques. Without the use of this technology, the bull’s number of offspring and his contribution to the breed would be significantly reduced. But for hogs, the semen must be fresh in order to work. Hence, artificial insemination is more difficult for pigs and has not been as successful. Operations offering this service try to accommodate hog farmers within a 50 mile radius of the operation’s headquarters. Computers and refrigerated trucks play a crucial role in the tracking and expeditious delivery of the hog semen.

In the case of artificial insemination for poultry, the inseminator collects semen from roosters and, using a microscope, records the motility and morphology of the semen. A specified amount is then placed into a syringe-like inseminating gun and the semen is injected into the oviduct of the hen or through a tiny hole in the egg shell. The use of artificial insemination in poultry has expanded such that it accounts for nearly 99 percent of all new birds in the turkey production industry. This production route has resulted in turkeys with much more meat than the average bird of a few years ago. Typical turkeys now have so much meat on their breasts that they are unable to mate in the usual manner.

Technological innovation and research has led to another breakthrough in reproductive physiology—embryo transfer. Just as it is desirable to increase the offspring from a superior male, so too is it advantageous to increase the number of offspring from a superior female. By taking the eggs from an animal's ovary, implanting them in a petri dish with genetically superior semen, and then implanting them back into a recipient female, the breeding potential of superior females is being expanded. The recipient female actually gives birth to an animal that has none of her genes. These tasks are performed by a growing number of businesses located throughout the country.

Central Test Stations. Testing stations are also common to several species of livestock. Sometimes associated with a university, these test stations can also be individually owned. It is the purpose of a test station to feed, weigh, measure, and record the performance of bulls, rams, and boars. The data is used to compare consignments from several breeders and in many cases the animals are then sold at auction to go into other seed stock operations. Through the use of centralized testing stations the universities and land grant colleges have played a vital role in identifying animals with superior genetics.

Fitting Services. The showing of hogs, sheep, goats, and cattle at livestock fairs and expositions is often left to professional fitters. Animals entered in these contests are groomed, fed, and hauled from one fair to another, often by fitting services that perform these services either for a flat fee or a percentage of the prize money. In many instances one fitter's string of show animals might include animals from several different breeders.

Custom Slaughtering. The people who perform these services are few and far between. It is illegal to raise an animal, have it custom slaughtered, and then sell that animal's carcass or meat to another individual without having it inspected by a government inspector. Therefore, most custom slaughtering is done for ranchers or raisers of livestock on animals they have raised for their own family's consumption.

Specialized Species Services. In many instances the services required by one animal species are unique to that animal. Specialized services regarding sheep include sheep herders, sheep shearers (usually contract labor, with payment either by the head or for a flat fee. This is difficult, highly-skilled work), fleece tiers, lambers (individuals hired during birthing season to aid the ewes in delivery), and trappers. The trapper hunts, kills and traps predatory animals that are killing lambs and sheep.

The Animal Damage Control program of the USDA provides direct assistance to private individuals to help protect their animals from injury and damage caused by wild animals. Under the Animal Damage Control Act of

1931 there are state and federal funds available to help pay for the services of a trapper. In the past trappers used to work for a bounty, but most are now independent contractors since most bounties have been discontinued. The trapper's practices and methods are much more regulated and controlled than in the past.

Specialist positions in the poultry service area include caponizers, who castrate cockerels (very young male chickens) to prevent the development of secondary sex characteristics; debeakers; poultry vaccinators; and chick graders and sexers. In the area of dairy cattle, while most work on the modern day dairy is performed by the facility's employees, milk testing is one task that is "farmed" out. The milk tester or sampler can either work for a dairy herd improvement association, a breed association, or an independent service. It is the tester's job to collect milk samples from dairies, processing plants or tank trucks for lab analysis.

SIC 0752

ANIMAL SPECIALTY SERVICES, EXCEPT VETERINARY

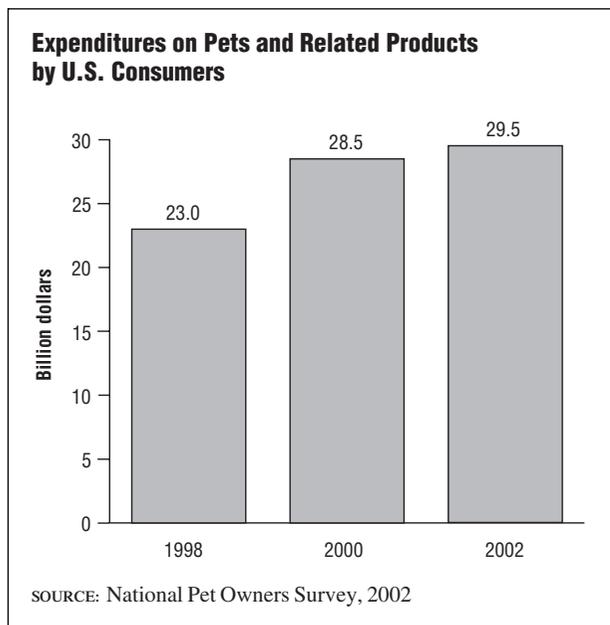

This classification covers establishments primarily engaged in performing services for pets, equines, and other animal specialties. These establishments include kennels, animal shelters, stables, breeders of animals other than livestock, pet registries, and a host of other animal care services. Establishments primarily engaged in performing services other than veterinary for cattle, hogs, sheep, goats, and poultry are classified in **SIC 0751: Livestock Services, Except Veterinary**. Establishments primarily engaged in training racehorses are classified in **SIC 7948: Racing, Including Track Operation**.

NAICS CODE(S)

115210 (Support Activities for Animal Production)
612910 (Pet Care (except Veterinary) Services)

INDUSTRY SNAPSHOT

Roughly 62 percent of all U.S. homes sheltered a pet of some sort in the early 2000s. Total pet industry expenditures neared the \$20 billion mark. Dogs, cats, birds, and

fish were the most popular types, with about 70 million cats and 60 million dogs existing in the United States. Though cats outnumbered dogs, dogs were found in more U.S. households than cats, according to a study conducted by the American Veterinary Medical Association's Center for Information Management. And although the number of households with no pets increased, so did the number of households with more than one pet. Also, pet-related spending by dog owners increased by 38 percent between 1997 and 2002. Because of the nation's affinity for pets, a growing number of animal specialty services have emerged to provide a wide range of general breeding, grooming, care, and training services. The *U.S. Market for Pet Care Products and Pet Supplies* predicts that the pet care and pet supply industry alone will be worth \$8 billion by 2007.

Though dogs and cats were the most popular of companion animals, bird ownership was on the rise in the early 2000s, accounting for 2 million veterinary visits in 2001. Other household pets that enjoyed increased popularity in the late 1990s and early 2000s included rabbits, hamsters, guinea pigs, ferrets, gerbils, snakes, lizards, and turtles.

Animal caretakers held about 151,000 jobs in 2002, according to the Bureau of Labor Statistics. Those outside the farm accounted for roughly 80 percent of this total and earned a median hourly wage of \$8.21. Most of these workers were employed in boarding kennels and veterinary facilities. Other employers included animal shelters; horse stables; and local, state and federal agencies. One out of every four animal caretakers was self-employed in 2002, compared to one out of six in the late 1990s. Due to expected increases in the U.S. pet population, demand for

nonfarm animal caretakers is expected to increase faster than the average throughout the early 2000s.

Pedigree Record Services. The American Kennel Club of New York keeps a list of the number of dogs registered to purebred parents. The Kennel Club's list of the top 50 dog breeds includes such standbys as Labrador Retrievers, which was listed as the most popular breed in the United States for the 13th year in a row in 2002, to breeds growing in popularity such as the Rottweiler did in the late 1990s. In contrast to the widespread interest in purebred dog breeds, only a small percentage of cats are registered with one of the official registering bodies. The largest such body is the Cat Fancier's Association, which sponsors 650 member clubs scattered across the country. As of 2004, the Cat Fancier's Association recognized 37 breeds, including the most recent addition to its list, the Sphynx, added in February 1998. Popular cat breeds included the Persian, the Maine Coon, the Siamese, and the Abyssinian.

Boarding Kennels. Kennels care for small companion animals when their owners cannot. Kennels are used primarily as temporary homes while the pet owner is gone on business or vacation. There is much more to managing a kennel than feeding the animals, cleaning cages, and maintaining dog runs: attendants are often called upon to perform basic acts of first aid, bathe and groom animals, and clean their ears and teeth. At the better kennels, the attendants also play with the animals, provide companionship, and observe behavioral changes that could indicate illness or injury. Often, kennels also sell pet food and supplies, teach obedience classes, help with breeding, and arrange transportation.

Groomers. People who specialize in the maintenance of the appearance of pets are called groomers. Some operate out of kennels while others maintain their own independent businesses. Most groomers learn their trade by working for an established groomer but a few schools do exist that teach the basic skills. The groomer combs, clips, and shapes the animal's coat according to a set of established breed guidelines.

Animal Breeding. The small animal breeder raises animals for a variety of purposes. A breeder of dogs may produce the very best bird dog for hunting or fancy poodles for exhibiting in the show ring. Whatever the animal's purpose, the breeder's task is to produce the animal that is both phenotypically and genotypically demanded by the customer. In the case of dogs, these styles are constantly changing and the breeder must be on a constant look-out for outstanding genetic stock to improve the breed and his profitability. There are numerous pet publications dealing with specific breeds that carry advertising for stud dogs and litters. Numerous shows, trials, and exhibitions allow breeders to display their

excellence in direct competition. Through such endeavors the better dogs become well known and can command impressive fees.

Animal Shelter. More commonly known as “the pound,” the animal shelter provides for the basic maintenance of pets that are lost or abandoned. The shelter screens applicants for adoption, vaccinates newly admitted animals, provides spay and neuter clinics and, as a last resort, euthanizes severely injured or unwanted pets. According to the National Council on Pet Population Study and Policy, the number of dogs and cat entering these shelters continues to rise.

A major problem facing the small animal care industry is the frequency with which euthanasia is used—roughly 5 million dogs and cats are euthanized every year. Overpopulation and unwanted pets are the biggest reasons for these statistics and have prompted shelters to initiate concerted education efforts aimed at lowering those numbers. Recent budget cuts have also forced some shelters to support their populations with food processed from the remains of euthanized animals.

Shelters can be maintained by county, state, and local governments or may be sponsored by charitable institutions and foundations. They are almost always non-profit organizations. One of the most important functions performed by shelters are the vaccination clinics they sponsor on a community-wide basis. They also maintain and operate pet ambulances or trucks in order to respond to emergency calls. It also falls within their jurisdiction to investigate complaints of animal cruelty. Most animal shelters will also aid the urban resident when he is faced with a pest or a livestock rancher who is experiencing losses due to roving packs of wild dogs. In ridding communities of rabid or vicious animals, the shelters work closely with county law enforcement officials.

Large Animal Specialty Services. The use of horses for recreation and competition has increased dramatically in recent years and produced a corresponding increase in demand for training and boarding services. Among these equine services are horse stables, which provide boarding accommodations for horses whose owners do not possess the facilities to house their animals. Fees, which can be tallied on a monthly or daily basis, are broken down for food and board and additional expenses such as veterinary care. Horse training is another key element of this industry. Horses used for pleasure riding, endurance racing, cutting, team penning, showing at halter, or any of the other number of activities must be properly trained.

Some operations also offer horse mating services, which have proven to be quite lucrative. Top breed stud fees continued to rise through the late 1990s and early

2000s, until the economic slowdown in the United States began to weaken sales. According to figures compiled by publishing company The Blood-Horse Inc., the average stud fee for 138 stallions that had two or more crops racing was an estimated \$23,134 in 2000, a 9.1 percent rise from the 1999 average of \$21,207. The most expensive stallions had commanded the highest stud fees and represented the fastest growing portion of the stud fee market in the late 1990s. The average fee for this small group of stallions was \$175,000 for 2000, a 25 percent increase over the 1999 average of \$140,000. By 2002, however, the top price for an incoming stallion had plunged to \$40,000. When the economy began to improve in 2003, this figure rebounded to roughly \$100,000.

SIC 0761

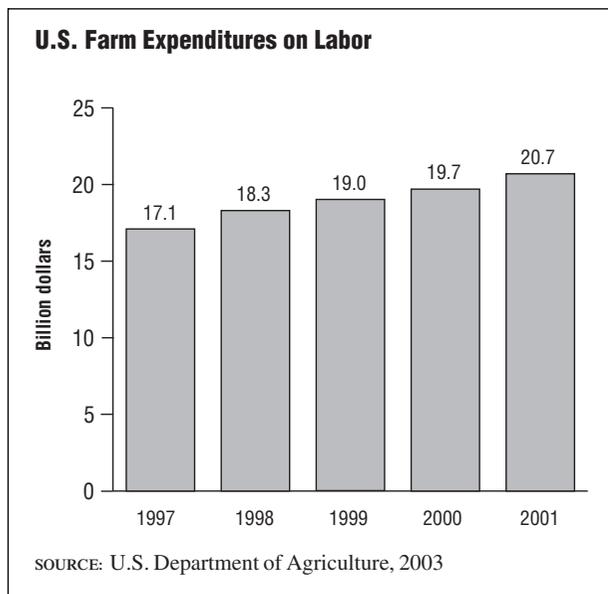

FARM LABOR CONTRACTORS AND CREW LEADERS

This category describes establishments primarily engaged in supplying labor for agriculture production of harvesting. Establishments primarily engaged in machine harvesting are classified in Industry 0722 (see **SIC 0722: Crop Harvesting, Primarily by Machine**).

NAICS CODE(S)

115115 (Farm Labor Contractors and Crew Leaders)

Roughly 500 farm labor contractors were in operation in the United States in the early 2000s. This industry is heavily concentrated in the western United States, particularly in California, where nearly 33 percent of hired agriculture workers were employed by farm labor contractors as of 2003. Farm labor contractors and crew

leaders overcome language barriers and handle paperwork as they recruit, hire, fire, supply, pay, and transport workers for the U.S. agriculture labor market. Contractors are required by law to ensure that all employees performing under their administration are certified in accordance with federal regulations, and are legally responsible for all violations. In general, U.S. farms spent a total of \$20.7 billion on labor in 2001, a figure that includes contract labor expenses, compared to \$17.1 billion in 1997.

Observers have long levied a variety of criticisms at farm labor contractors, most of them stemming from contractors' heavily reliance on migrant labor, including illegal immigrants. The percentage of farm laborers who were migrant workers, a classification that includes all agricultural workers who must travel such a distance as to make it impractical to return to their residence the same day, fluctuates from about 6 percent in the winter months to about 12 percent in the summer.

One of the most frequent criticisms aimed at farm labor contractors (FLCs) and crew leaders is the allegation that they allow growers to sidestep labor laws. Critics say many FLCs short workers on pay, or extract profits from workers for such things as tool rent, transportation, and lodging. Further, critics say, FLCs contribute to worker poverty, income inequality, poor conditions, a regular influx of new undocumented immigrants, and decline of the farm labor movement.

Criticism may be merited. Between July of 2003 and February of 2004, the Department of Business and Professional Regulations conducted 21 inspections of Florida citrus groves, uncovering a total of 257 labor violations in that state alone. Particularly in the FLC-heavy California, the dependence on illegal farm labor, most

notably from previously untapped regions in Mexico, has skyrocketed to an estimated 43 percent of hired farm workers. The increasing use of illegal immigrants has not abated despite a number of federal actions aimed at reducing the number of such immigrants entering the United States. In all, about 90 percent of such workers at the turn of the twenty-first century were from Mexico, 80 percent were men, and 75 percent earned less than \$10,000 per year. To stem the tide of illegal farm labor, state and federal legislatures have made moves to implement "Alien Agriculture Worker Programs," which compel farm labor contractors to become officially sanctioned by their state government to hire "guest" workers for a given period each year.

Contractors insist they've been unfairly criticized. An advocacy group, the National Farm Labor Contractors Association, established in 1967 and based in Fresno, California, lobbies lawmakers on behalf of FLCs, gives legal advice, and provides training, a newsletter, phone numbers, and reference materials. In 2002, several California lawmakers introduced a series of bills, part of the California Agricultural Relations Act, designed to increase the bargaining power of roughly 500,000 field workers. The passage of these bills in the fall of that year prompted the United Farm Workers of America to launch their largest organizing effort in twenty years. Given the size of California's agriculture industry, estimated at \$27 billion, the movement is expected to potentially impact the entire U.S. agriculture industry.

Nationally, labor use on farms and ranches has changed dramatically since World War II. In 1950 nearly 10 million workers were employed on farms and ranches, but by 1969 this figure had been reduced to roughly 3 million. In subsequent decades, this number continued to drop and held at less than 1 million in the early 2000s. This decrease was the result of the trend toward fewer and larger agricultural enterprises and the increasing use of technological innovation. One result of increasing concentration and the development of very large farming enterprises has been the switch from family labor to the increased use of temporary workers. In the early 2000s, roughly 20 percent of all farms relied on contract labor, a sizable increase from 1980, when only about 2 percent did. Another result has been higher than average unemployment rates among farm laborers. In 2002 roughly 11 percent of the hired farm labor force was unemployed, compared to an average of roughly 6 percent for the U.S. labor force as a whole.

California is home to most of the largest FLCs in the nation. The largest was Valley Pride, Inc. of Castroville, California, with \$22 million in annual sales and 400 employees. Also based in California was Tara Packing in Salinas, with \$21 million in annual income and 600 employees. Other major FLCs include Vegpacker, Inc.

of Yuma, Arizona, with sales of \$7 million and 250 employees; Emco Harvesting of Yuma Arizona with \$18 million in revenues; and 5A Harvesting Co. of Labelle, Florida.

SIC 0762

FARM MANAGEMENT SERVICES

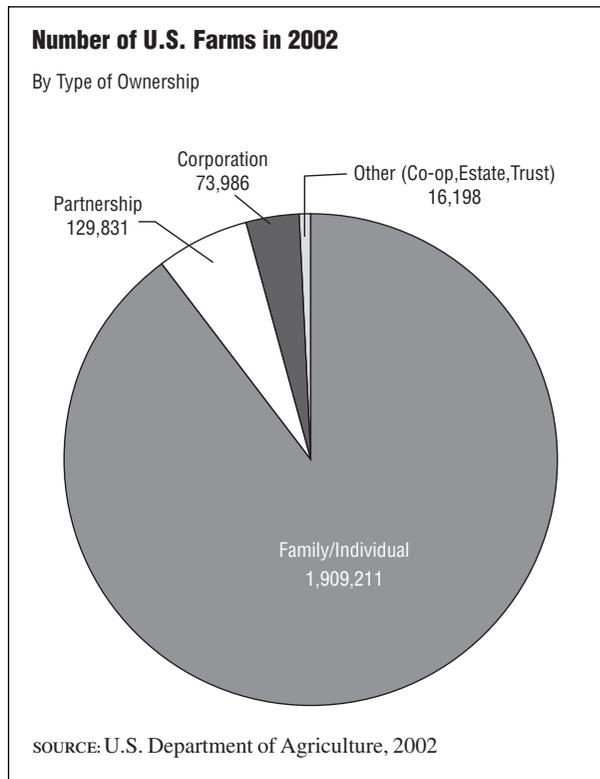

This category describes establishments primarily engaged in providing farm management and maintenance services for farms, citrus groves, orchards, and vineyards. Such activities may include supplying contract labor for agricultural production and harvesting, inspecting crops and fields to estimate yield, determining crop transportation and storage requirements, and hiring and assigning workers to tasks involved in the harvesting and cultivating of crops; but establishments primarily engaged in performing such services without farm management services are classified in the appropriate specific industry within Industry Group 072. Workers with similar functions include agricultural engineers, animal breeders, animal scientists, county agricultural agents, dairy scientists, extension service specialists, feed and farm management advisors, horticulturists, plant breeders, and poultry scientists.

NAICS CODE(S)

115116 (Farm Management Services)

The overall trends in the farming industry portend good news for farm managers. With the increasing consolidation and centralization of farming activities and a more market-oriented approach to the business, farmers are likely to find farm managers ever-more attractive. In the early 2000s, roughly 60 percent of all U.S. farmland was operated by someone other than its owner. According to the *Occupational Outlook Handbook*, farmers, ranchers, and agricultural managers accounted for 1.4 million jobs in 2002. The industry is served by the American Society of Farm Managers and Rural Appraisers.

Professional farm managers have a variety of duties and responsibilities. For instance, the owner of a large

livestock farm may employ a farm manager to supervise a single activity such as feeding the animals. At the other end of the spectrum, a farm manager working for an absentee farm owner may have the responsibility for all functions, from planning the crop to participating in the planting and harvesting activities. Professional farm managers must be able to establish output goals, determine financial constraints, and monitor production and marketing. Farm management firms often handle the financial business of client farms, including the buying and selling of products and even the farmland itself. In addition, a number of firms provide consulting services to farmers and farming companies.

Many types of farming are seasonal. Although farm managers on crop farms tend to work all day during the planting and harvesting seasons, they often work on the farm less than 7 months a year. They spend the rest of the year planning the next season’s crops, marketing their output, and repairing machinery. Farm managers can achieve Accredited Farm Manager (AFM) certification by the American Society of Farm Managers and Rural Appraisers, after sufficient academic training and job experience.

As more people without agricultural backgrounds come to regard farmland as a good investment rather than a vocation, and as family farms give way to corporate farms, farm managers are growing in number and influence. Between 1997 and 2002, the number of family

farms declined from 1.92 million to 1.90 million. However, the number of corporate farms also declined, from 185,607 to 129,831, reflecting an industry trend toward consolidation. As a result, the employment outlook for this industry remained less than favorable in the early 2000s. The average wage for agricultural managers in 2002 was \$43,740.

Among the leading farm management services firms are Orange-co, Inc. of Bartow Florida, with 500 employees; Farmers National Company, with 130 employees and 3,600 clients throughout the Midwest; Indian River Exchange Packers of Vero Beach, Florida, employing 350 workers; and Sun-Ag, Inc. of Fellsmere, Florida, with a payroll of 550 employees.

The early 2000s was a difficult time for many farmers. The industry's vigorous competition, exacerbated by the lowest agricultural commodity prices in decades heightened the demand for shrewd management practices. Proper crop, soil, and feed management systems could make or break a farming enterprise in this environment. Of growing importance was the handling of efficiency measures to cut down on costs and pollution, especially in the socially and economically sensitive areas of water and fertilizer management. Farms were falling under heavy scrutiny by environmentalists, consumers, and the U.S. Department of Agriculture to diminish waste production and eliminate pollution.

One avenue by which farm managers were beginning to recognize financial and efficiency gains was in the trading of emissions between agricultural and industrial operations. Farmers were increasingly called on to overhaul animal-waste-management and fertilizer-application systems and in general gear agricultural processes toward the limiting of greenhouse-gas emissions in accordance with the U.S. standards adopted by President Clinton at the Kyoto Conference in 1997. While the practice of pollution trading has existed for years, it traditionally involved the transfer of pollution credits from one party to another. Greenhouse-gas emissions, on the other hand, involve the actual purchase of the reductions in agriculturally based emissions by industrial firms who can then allocate the emissions allotment in accordance with their industry's regulations. It thus creates a financial incentive for farm managers to streamline farming operations for greater efficiency.

Farm managers need to keep abreast of continuing advances in farming technologies. In the late 1990s and early 2000s, more and more farm managers were using precision agriculture or site-specific farming methods to customize the placement of seed, fertilizer, and chemicals to get more bushels of grain from their land, reduce waste, and prevent pollution of streams. For instance, Ag Technology Inc. estimates that 8,000 yield monitors are in use across the United States. Yield monitors attached

to combines measure the harvest as the combine gathers it. Over one-third of the farm managers using yield monitors also use a global positioning satellite, paired with a receiver that correlates the satellite reading with a fixed point on the ground. Some farm managers are supplementing these technology tools with Geographic Information System, a mapping software.

The passage of the Federal Agriculture Improvement and Reform (FAIR) Act, popularly called Freedom to Farm, was a significant event in this industry in 1996. This new legislation marked the beginning of the gradual departure of government from farming and planting decisions. Once this law was passed, farms began moving toward a market-oriented approach to operations. While this law was always a thorn in the side of small farmers and populist farming organizations for reducing government programs to aid farmers, generally to the advantage of large agribusiness firms, the Freedom to Farm Act has met with increasing calls for reexamination from the latter groups as the slumping commodities prices began to eat into profit margins. It was widely expected that the Freedom to Farm Act would be overhauled before its provisions were to expire in 2002. This prediction came to fruition in May of 2002 when President George W. Bush signed into law the 2002 Farm Act, which increased government subsidies to farmers through 2008.

SIC 0781

LANDSCAPE COUNSELING AND PLANNING

This classification includes establishments engaged in landscape planning and landscape architectural and counseling services.

NAICS CODE(S)

541320 (Landscape Architectural Services)

541690 (Other Scientific and Technical Consulting Services)

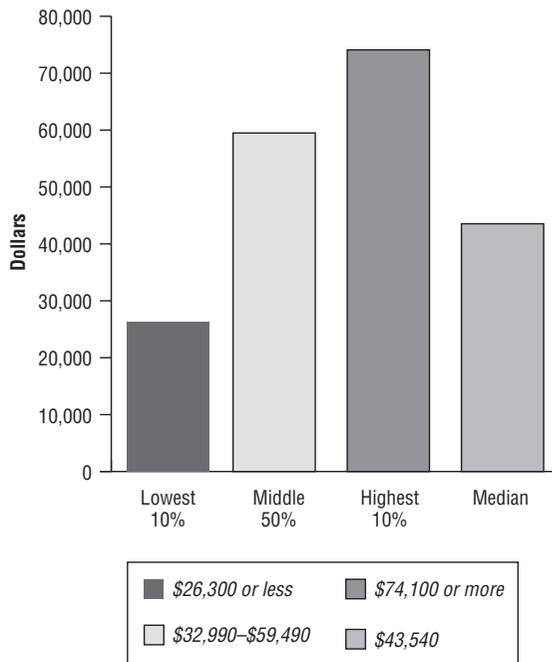

The service industry of landscape counseling and planning is primarily composed of private landscape architecture firms and self-employed landscape architects, although the federal government also hires landscape architects for projects similar to those done by private firms. According to the U.S. Department of Labor, roughly 26 percent of the 22,000 landscape architects in the early 2000s were self-employed, a rate nearly quadruple that of other industries. Major architectural and engineering firms have also started offering in-house landscape architectural services.

Landscape architects working in this industry are responsible for the design and implementation of land use for areas such as parkways, golf courses, parks, shopping malls, and the areas surrounding private homes and businesses. They plan the location of buildings, roads, and walkways; arrange flowers, shrubs, and trees; and design streets to maximize pedestrian access and safety. Landscape architects are hired by a wide variety of groups including real estate developers, municipalities, private citizens, and private businesses.

Often working in conjunction with architects and engineers, landscape architects combine engineering, horticultural, and design skills to create satisfying and efficient environments. They also work to prevent or solve environmental problems due to construction. Once given a particular assignment, a landscape planner conducts detailed analyses of the existing soil composition, vegetation, water drainage, and slope of the land. Next, initial drawings outlining plans for the site are submitted to the client. If the plans are accepted, the landscape architect makes a formal proposal that may include written reports, sketches, models, photographs, land use studies, and cost analyses. Most landscape architecture firms also supervise contractors during the installation of their plan. Commonly, the landscape architecture firm is present at the opening of the site and available for assistance or consultation through the first six months of existence. Landscape design and build services were the second-largest segment of the lawn and garden industry in 2003, accounting for 25.8 percent of industry revenues.

As an art form, landscape architecture can be traced back to the ancient world. The Renaissance enthusiasm for open space, including ornate villas and outdoor piazzas, influenced the chateaux and urban garden movement in seventeenth century France, which produced such masterpieces as Andre le Notre’s gardens at Versailles. In eighteenth century England, landscape planners such as Lancelot “Capability” Brown emphasized naturalistic rather than geometric forms, notably in Brown’s remodeling of the grounds of Blenheim Palace.

Earnings for Landscape Architects in the Early 2000s

SOURCE: U.S. Bureau of Labor Statistics, 2002-03

Sir Humphrey Repton, however, reintroduced formal motifs in such public spaces as Victoria Park in London in 1845 and Birkenhead Park in Liverpool in 1847. These projects greatly influenced the development of landscape planning in the United States and Canada. In the 1850s the title “landscape architect” was first used by Frederick Law Olmsted who worked with Calvert Vaux to design New York’s Central Park, one of the first urban renewal projects in the country. An advocate of public space as a means of making cities more livable, Olmsted also designed the grounds of the U.S. Capitol in the 1879s and was instrumental in developing numerous public parks around the country.

In 1899 the American Society of Landscape Architects (ASLA) was formed by Olmsted’s followers. By the turn of the twenty-first century, the ASLA had approximately 12,000 members. Though the profession grew slowly during the first half of the twentieth century, with landscape architects earning modest salaries, the profession experienced significant growth during the 1980s and 1990s. By 2003, almost 60 universities and colleges in the United States offered a total of 75 accredited baccalaureate and post-graduate programs in landscape architecture, and commissions for landscaping outnumbered the professionals available to execute them.

For many years the design work involved in landscape planning was done by hand at drawing boards but,

in the early 2000s, an increasing number of landscape architects were using computer aided design (CAD) systems to assist them in creating designs. Advances in global positioning systems and computerized Geographic Information Systems (GIS) have benefited landscape architects who work on large-scale projects such as land planning, recreation, campuses, and greenways. Video simulation, a technological tool that helps clients visualize a proposed site plan, is also increasingly used.

The demand for landscape counseling services has a direct correlation to economic conditions relative to private construction rates, building costs, interest rates, growth of business and industry, and government funding of parks and other outdoor facilities. Although only about a quarter of their work is residential, landscape architects have experienced increased opportunities in the residential market due to its robust growth through the early 2000s. Despite a weak U.S. economy during those years, record low interest rates fueled growth in real estate. In fact the 1.085 million homes sold in 2003 set an industry record as interest rates hovered at rates not seen since the 1950s. At the same time, prices for private residential commissions have increased from a high of about a quarter of a million dollars to commissions of \$500,000 or more. Remodeling is also a strong factor in landscape commissions as more homeowners and businesses are becoming aware that landscaping can provide a 100 to 200 percent return, with property value increases between 14 and 25 percent.

A significant opportunity for landscape architects throughout the early 2000s will be in environmental design and public projects. Water quality issues in particular will demand the profession's specialized skills, according to some analysts, as landscape architects will become major players across the nation in compliance with waste disposal procedures, water quality protection, and land preservation. In addition, landscape architects will likely displace engineers as leaders on such projects as planned communities, transportation corridors, and urban planning. Federal initiatives—such as the Environmental Protection Agency's (EPA) Sustainable Development Challenge Grant (SDCG) Program, which provides seed money to encourage local projects that use sustainable development strategies to address serious environmental problems—will also greatly expand opportunities for landscape architects. In addition, passage of TEA-21, which authorizes federal funding for transportation projects, will offer significant possibilities for landscape architects through the early 2000s. Some landscape architects have even started using their skills to improve indoor environments, which further expands the industry's already broad scope.

Industry leaders in this field in 2004 included Calabasas, California-based ValleyCrest Companies, for-

merly known as Environmental Industries, Inc., which acquired TruGreen LandCare in 2001 to broaden its reach in the Northeast and Midwest; SWA Group, headquartered in Sausalito, California; Environmental Earthscapes Inc. of Tucson, Arizona; and Green Thumb Enterprises Inc., based in Chantilly, Virginia. ValleyCrest, which has designed such major projects as the Las Vegas Strip beautification project and the grounds for the Getty Center in Los Angeles, posted 2003 sales of \$620 million, a 2.5 percent increase from the prior year. The company is the nation's largest commercial landscaping business and specializes in landscape construction and maintenance, lawn care, and nursery work in addition to landscape consulting and planning. ValleyCrest's major competitors lagged far behind with sales between \$10 and \$15 million.

Landscape architects must study engineering and graduate from an accredited program in their field. They must then complete a two-year apprenticeship program and pass a rigorous three-day examination to obtain state licensing. A total of 46 states require landscape architects to be either licensed or registered. Apprentice landscape architects can earn between \$45 and \$75 an hour, with licensed principals earning from \$90 to \$200 per hour and annual salaries of between \$50,000 and \$150,000. In the early 2000s, the median salary for landscape architects was \$43,540. Those employed by the federal government earned \$62,824 on average. Landscape designers, who do not have to graduate from any program or pass any licensing tests, perform many of the same tasks as landscape architects, such as the design of hardscaping with walls and walkways, but average about \$50 per hour. Though the majority of landscape architects remain in private firms, an increasing number are migrating to large-scale design firms that offer landscape planning as one of a range of diversified services. The employment outlook for landscape architects is favorable through 2010, according to the 2002-03 *Occupational Outlook Handbook*.

SIC 0782

LAWN AND GARDEN SERVICES

The lawn and garden services industry is comprised of establishments primarily engaged in performing a variety of landscape maintenance services. Companies that install artificial turf are included in **SIC 1799: Special Trade Contractors, Not Elsewhere Classified**.

NAICS CODE(S)

561730 (Landscaping Services)

The industry encompasses an abundance of firms that provide a wide range of services, including sod laying, lawn mowing, and seeding. Firms can also serve niche markets such as lawn mulching, cemetery maintenance, garden planting, fertilizing, lawn spraying and treating, highway center-strip maintenance, and athletic field and golf course turf installation. Lawn maintenance service was the largest segment of the lawn and garden industry in 2003, accounting for 36.8 percent of industry revenues.

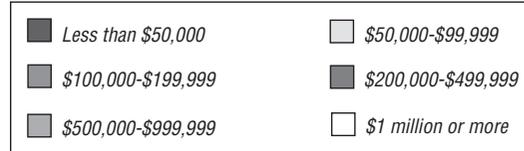

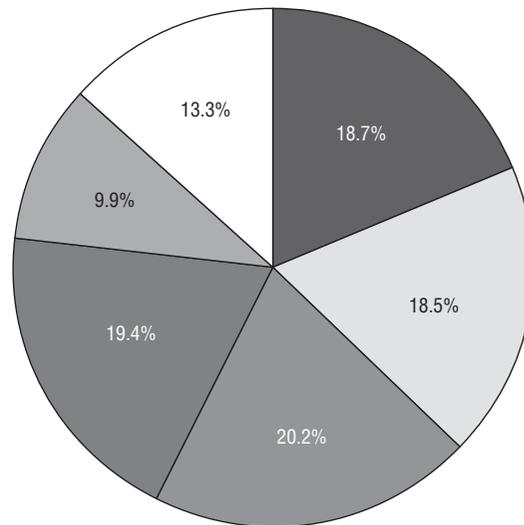

The lawn and garden services industry is mostly comprised of thousands of small, privately owned firms. In fact, firms with sales of less than \$50,000 accounted for 18.7 percent of the industry in 2003. Firms with sales between \$50,000 and \$99,999 accounted for 18.5 percent; while those with sales between \$100,000 and \$199,999 accounted for the highest percentage of industry revenues, 20.2 percent. Firms with sales between \$200,000 and \$499,999 garnered 19.4 percent of industry sales. Businesses with sales between \$500,000 and \$999,999 secured only 9.9 percent of this total; those with sale of \$1 million or more, just 13.3 percent.

Typically, companies in this industry fertilize four to six times and apply herbicides two or three times a year. Some may offer a soil test or a lawn analysis. One kind of lawn management offered by some companies is called Integrated Pest Management, which operates on the idea that all pests cannot be killed, but need to be reduced to acceptable levels through monitoring and total yard management.

The lawn and landscape industry established itself as an important component of the service sector of the economy in the late 1990s. By the early 2000s, retail sales of lawn and garden products and services, including professional landscape, lawn care, and tree care services and related supplies, had reached \$22 billion. Nearly one-quarter of U.S. households utilized professional lawn care services. Industry sales were estimated to reach \$25 billion by 2007, according to the Professional Lawn Care Association of America.

Size of Lawn and Garden Services Firms in 2003

By Annual Sales

SOURCE: *Lawn and Landscape Magazine*, 2003

An identifiable lawn and garden service industry did not emerge until the post-World War II U.S. economic expansion. Housing developments ballooned from just 139,000 in 1944 to 1.9 million per year in 1950, and thousands of tract subdivisions were built on the perimeter of urban America. As an entire suburban culture emerged, replete with private lawns and gardens, the demand for landscape services flourished.

More recently, strong housing starts throughout most of the 1980s, as well as favorable demographic trends, boosted sales in many traditional segments of the landscape services industry. Relatively new services, such as chemical lawn treatments and hydroseeding, also offered growth opportunities. A general trend toward more elaborate landscaping bolstered industry profits as well. Although stalled housing developments and a virtual depression in commercial construction markets soured demand for new landscape installations in the late 1980s and early 1990s, many landscape maintenance firms enjoyed steady growth. Booming new home sales in the late 1990s and early 2000s, fueled by historically low interest rates, also bolstered industry growth.

The continued rise in two-income families throughout the 1990s and early 2000s left homeowners with less available time for lawn care. People also became more aware of the positive environmental effects of lawns such as oxygen production, temperature modification, and pollutant absorbent. At the same time, many firms had started stressing environmentally friendly, "green" landscape installation and maintenance services. New high-tech natural products included slow-growing golf course turf and insect resistant grass seed. Other technological advances that affected the industry included Magic Circle Corporation's new Dixie Chopper, a hydrostatical driven mower. The mower incorporated a turbine-powered military helicopter power unit and boasted a maximum mowing speed of 18 miles-per-hour. Such technological advances and environmental concerns have brought the industry greater expansion and success.

A series of mergers throughout the 1990s resulted in the domination of the industry by one firm. TruGreen merged with ChemLawn in 1992, creating the nation's largest professional lawncare provider, which specialized in chemical landscape treatments. TruGreen Landcare LLC, operating as a unit of ServiceMaster Co., generated sales of \$525.9 million with about 200 employees in 2002. The second largest and fastest-growing company was Barefoot, Inc. of Ohio. Following rapid expansion through mergers and acquisitions, Barefoot had garnered mid-1990s sales of \$95 million and was active in 75 metropolitan markets. But in 1997, TruGreen had purchased Barefoot as well as Orkin Lawn Care, and in March 1999 the company further added LandCare USA, Inc., to its list of acquisitions, thereby solidifying its control of the commercial landscaping market. Purchases in 2000 included Leisure Lawn, based in Dayton, Ohio.

The Professional Lawn Care Association of America (PLCAA), organized in 1979, promotes education, legislation, and public awareness of the environmental and aesthetic benefits of turf. The PLCAA represents more than 1,200 lawn and landscape companies, industry suppliers, and grounds managers in the United States, Canada, and other countries. They have also established a training program for lawn and garden professionals.

SIC 0783

ORNAMENTAL SHRUB AND TREE SERVICES

Companies primarily engaged in performing a variety of shrub and tree services make up the ornamental shrub and tree services industry. Activities common to this industry include ornamental bush and tree planting, pruning, bracing, spraying, removal, and surgery. Tree trimming around utility lines also constitutes a significant share of industry revenues. Companies that perform lawn and garden installation and maintenance are described in **SIC 0782: Lawn and Garden Services**, and companies offering shrub and tree services for farm crops are included in **SIC 0721: Crop Planting, Cultivating, and Protecting**.

NAICS CODE(S)

561730 (Landscaping Services)

INDUSTRY SNAPSHOT

The ornamental shrub and tree industry consists mainly of small, family-owned businesses; most companies offer the service in addition to lawn care and maintenance. Working with shrubs and trees requires more education than merely working on lawns, since there are more plants and pests to know. Roughly a \$40 billion industry, ornamental shrub and tree services attract many firms to the field. The failure rate is high, though, and many companies don't survive the first few years. Tree and ornamental design products and services were the fourth-largest segment of the lawn and garden industry in 2003, accounting for 7.1 percent of industry revenues.

Weather plays a big role in the industry. For example, along the mid-Atlantic area, hurricanes can actually be beneficial for shrub and tree firms, as the destruction opens an opportunity for re-landscaping. Strong housing starts are also advantageous for business.

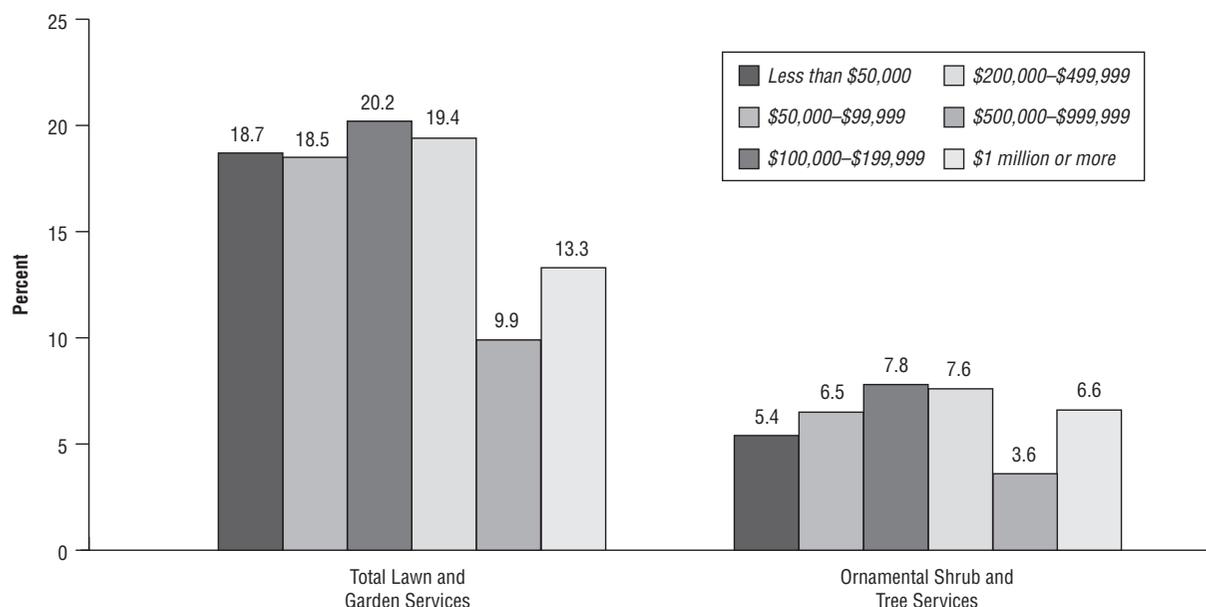

With the booming U.S. economy of the late 1990s, landscaping services of all kinds were in high demand. Labor shortages plagued the industry, with a better-educated younger generation looking for white-collar opportunities. When the economy weakened in the early 2000s, the landscaping industry continued to thrive due to plunging interest rates, which reached their lowest point since the 1950s and bolstered real estate sales.

ORGANIZATION AND STRUCTURE

The biggest difference between lawn care and maintenance and ornamental shrub and tree services is education of employees. A company adding shrub and tree care

Size of Ornamental Shrub and Tree Services Firms in 2003

As a Percentage of Entire Lawn and Garden Services Industry

SOURCE: *Lawn and Landscape Magazine*, 2003

to its business must invest at least six months into education. There are hundreds of shrub and tree types, not to mention pests and pest control. The commitment is costly in terms of time, and companies adding shrub and tree specialists need to be assured their investments will be worth the effort.

BACKGROUND AND DEVELOPMENT

The popularization of the gasoline-powered truck during the early 1900s made it possible for growers to easily transport trees and shrubs, prompting the development of a recognizable industry for ornamental plants. However, it was the rapid proliferation of suburbia during post-World War II economic and population growth that spawned a widespread demand for shrub and tree services. Growth in the number of installation and maintenance contracts for corporate campuses, residences, institutions, and other landscape markets bolstered industry growth throughout the mid-1900s.

Strong housing starts, increased spending on homes by baby boomers, and a general trend toward more elaborate landscapes in both commercial and residential sectors aided many industry participants during the 1980s. When housing developments stalled and commercial construction markets collapsed in the late 1980s and early 1990s, however, many ornamental tree and shrub service companies suffered. Steady utility tree trimming

markets and a revival in housing starts in 1992 and 1993 helped to buoy diminished earnings for some competitors. In addition, a string of natural disasters, including Hurricane Andrew in 1992 and the 1993 floods in the Midwest, hiked demand in some regions.

Housing starts were increasing through the mid-1990s, and by March 1997, the rate of starts was approximately 1.4 million. This increase was encouraging news for the industry.

In the mid-1990s, ornamental shrub and tree service companies tried to take advantage of a trend toward naturalized landscapes. Another growing segment of the industry was the relocation of mature trees from development sites to zoos, housing communities, or commercial properties. Companies also strived to invent advanced strains of shrubs and trees that would deliver improved performance and aesthetics. Utility line tree trimming companies grappled with increased community environmental sensitivity, which forced some companies to adopt low-impact trimming techniques. Many power companies simply suggest carefully planning the planting of trees and shrubs to avoid future problems with power lines—large trees should be at least 30 feet away from utility lines.

From 1995 to 1996, landscaping tree shipments increased—an indication that the industry was doing

well. In 1995, evergreen trees were most popular with 51.8 million units shipped; this increased to 60.2 million in 1996. Shade trees accounted for 37.5 million units in 1995 and increased to 46.6 million in 1996. Flowering trees accounted for approximately 27 million units in 1995, increasing to about 33 million in 1996. About 11 million fruit/nut trees were shipped in 1995; in 1996 about 13 million units were shipped.

As the industry was evolving, more companies, such as Asplundh, were becoming concerned with regulations in order to comply with safety standards. Work crews and customers were often supplied with information on new regulations—including OSHA changes, ANSI standards, and state wage guidelines.

CURRENT CONDITIONS

With the economy booming in the late 1990s, both corporations and private homeowners were spending more on landscaping. The Christmas holiday was a busy time, with malls and office buildings often erecting large, living, Christmas tree displays. Some of these displays could cost up to \$100,000. While the sluggish economy of the early 2000s put a damper on spending in most industries, the landscaping industry was protected by a growing number of housing starts, the result of record low interest rates. In 2003, a record 1.085 million homes were sold. However, the industry did feel the effects of rising healthcare costs, as well as increased fertilizer and fuel prices, all of which undercut profitability.

In 2003 ornamental shrub and tree services accounted for 7.1 percent of the lawn and garden services sales, compared to 5.3 percent in 1998. This extremely fragmented industry is dominated by thousands of small, privately held companies making less than \$1 million in annual revenues. In fact, the ornamental shrub and tree businesses garnering more than \$1 million in sales in 2003 represented only half of the 13.3 percent of all lawn and garden services firms that reached this sales milestone in 2003. The ornamental shrub and tree businesses securing revenues between \$100,000 and \$499,999 made up roughly 15 percent of the 40 percent of lawn and garden service firms that filled this sales bracket. And those posting sales of less than \$100,000 in 2003 accounted for 12 percent of the 37 percent of the lawn and garden service businesses constituting the lowest sales segment of the industry.

The U.S. Department of Agriculture (USDA) defines environmental horticulture as trees, outdoor plants, bulb, turfgrass, and groundcovers, excluding bedding and garden plants. In 2003 the USDA reported that the environmental horticulture industry took in \$13.8 billion—up from \$13.7 billion in 2001. At the retail level, which includes delivery and landscaping services, environmen-

tal horticulture accounted for \$136 per household in 2002, compared to \$120 in 1998.

INDUSTRY LEADERS

Most of the companies in the ornamental tree and shrub industry are small, privately held firms. One leader is Asplundh Tree Expert Co. The company mainly trims trees for public utilities to clear lines. Asplundh reported 2002 sales of \$1.68 billion and employed 27,978 people in the United States, Canada, New Zealand, and Australia.

ValleyCrest Companies, formerly known as Environmental Industries, is a landscaping company that provides shrub and tree services; the company projected sales of \$620 million in fiscal 2003. The company grows more than 2 million trees and has contracts for more than 6,000 gardens—both indoor and outdoor. The company has nearly 40 locations in seven states and 1,500 nursery acres in California.

WORKFORCE

The labor shortage has been felt across the lawn and landscaping industry, even as unemployment began to rise in the United States in the early 2000s. Younger people, who typically fill the labor-intensive positions in the industry, are better educated than ever before and tend to have higher career aspirations. Government restrictions on the hiring of immigrants have hurt the pool of labor also.

RESEARCH AND TECHNOLOGY

The biggest technological advance in the shrub and tree industry is microinjection. Microinjection allows for application of a pesticide in small, concentrated amounts under the bark of a tree. Contractors no longer need to worry about poisoning themselves or other people in the area. The technique saves time because the contractors don't need to notify neighbors, barricade the area, and don special equipment. The only drawback to microinjection is tree wounding, so contractors must take care how they inject the tree.

SIC 0811

TIMBER TRACTS

This category includes establishments primarily engaged in the operations of timber tracts or tree farms for the purpose of selling standing timber. Establishments not holding timber tracts as real property (not for sale of timber) are classified in **SIC 6519: Lessors of Real Property, Not Elsewhere Classified** and logging establishments are classified in **SIC 2411: Logging**.

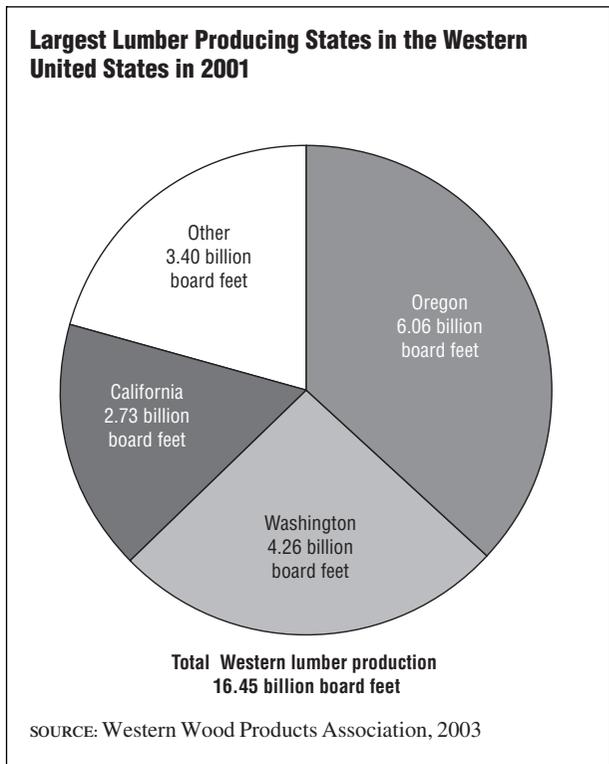

NAICS CODE(S)

111421 (Nursery and Tree Production)

113110 (Timber Tract Operation)

In the United States about one-half of the country is wooded. This amounts to about two-thirds of the nation's presettlement forested land. About 500 million acres of this forested land is classified as timberland, or land capable of growing 20 cubic feet of wood per acre per year. About 130 million acres are owned by the federal government and other state and local governments. The remaining 300 million acres are in relatively small tracts owned by individuals, with 70 million acres being owned by commercial firms. Annually about 4 million seedlings are planted every day. Oregon, Washington, and California are the country's largest timber producing states, accounting for more than three-fourths of Western timber production. Timber is also the South's largest agricultural product.

Live Christmas trees are grown in all 50 states. According to the National Christmas Tree Association, 22.3 million live Christmas trees were sold in 2002, down from 27.8 million in 2001 and from 33 million in 1997. For every Christmas tree cut and sold, the industry plants 2 to 3 seedlings. The industry employs about 100,000 full- and part-time workers and operates approximately 5,000 cut-and-choose farms. Depending on the species, it takes between 7 and 15 years for a tree to grow to an average cuttable height of 6 feet. The retail cost per foot for Christmas trees generally ranges from \$3.10 to \$5.65. The biggest expense for farmers is pruning each tree every year so that they maintain the classic, conical shape demanded by consumers. The leading states for Christmas tree production are Oregon, Michigan, Pennsylvania, California, and North Carolina. The most popular trees are the balsam fir, Douglas fir, Fraser fir, noble fir, Scotch pine, Virginia pine, and white pine. The Scotch pine is usually the largest selling tree, capturing between 30 and 40 percent of the market. According to the U.S. Department of Agriculture, the annual value of the U.S. Christmas tree harvest is around \$440 million, with about 17,000 farms working nearly 137,000 acres.

Tree farms cover a wide range of businesses. After they have cut the original stumpage, giant corporations like Weyerhaeuser plant second- and third-growth on vast timber holdings, which they may keep for their own use or sell. Small tree farmers manage woodlands that range from a few acres to several hundred acres. Some may keep the timber for a small sawmill they own, but most sell the stumpage, either for use in mills or as Christmas trees. Several of the giant timber producers run programs that assist small landowners in exchange for first rights on the timber.

The industry continues to face competition from artificial tree makers, who captured half the market by the early 1990s. Most artificial trees are manufactured in Korea, Taiwan, and Hong Kong. These producers promote their trees as fire-resistant and perfectly designed, with no needles to be swept up. In addition, some argue that artificial trees are more ecologically responsible because they can be used more than once. The tree growers, in turn, say that real trees are a renewable, recyclable resource, while artificial trees contain nonbiodegradable plastics and metals.

According to the Western Wood Products Association, demand for lumber in 2002 reached an all time high of 56.3 billion board feet, beating the previous record set in 1999 at 53.3 billion. It is estimated that 56.7 billion board feet of lumber was sold in 2003, setting another new record. Demand was expected to slip slightly by 2004 but nonetheless remain high. In 2002, 17.4 billion board feet came from the western United States, reflecting a 5.5 percent increase

from 2001. Roughly 18.1 billion board feet were used for repair and remodeling, while 22.3 billion board feet were used for new construction.

The United States imported 21 billion board feet of lumber in 2003, mostly from Canadian lumbering operations. While Canadian imports are expected to decline, European imports are expected to climb, due to increased production there. In the early 2000s, the U.S. International Trade Commission determined that Canadian imports of softwood may be detrimental to the U.S. lumber industry. As a result, when the 1996 Softwood Lumber Agreement expired in 2001, U.S. officials began looking to increase the duty imposed on Canadian softwood imports. Officials from both countries continued to negotiate trade issues into the early 2000s.

Industry leaders and their total 2003 sales are International Paper (\$25.2 billion), which acquired Champion International Corp. for \$7.3 billion in 2000; Weyerhaeuser (\$19.8 billion); Boise-Cascade (\$8.2 billion); and Georgia-Pacific's Timber Co. (\$551 million), which was acquired by Plum Creek Timber Co. in late 2001. Kimberly-Clark (\$14.3 billion) is a major manufacturer of personal paper products, but in 1999 it began divesting itself of its timberland operations. In June of that year, for instance, the company sold 460,000 acres of timberland in Alabama, Mississippi, and Tennessee to Joshua Management LLC for approximately \$400 million. As of 2004, Kimberly-Clark was planning to spin off its paper, pulp, and timber assets as a separate entity.

SIC 0831

FOREST NURSERIES AND GATHERING OF FOREST PRODUCTS

This category covers establishments primarily engaged in growing trees for purposes of reforestation or in gathering forest products. The concentration or distilla-

tion of these products, when carried on in the forest, is included in this industry. Forest products typically gathered are: balsam needles, ginseng, huckleberry greens, maple sap, moss (including Spanish and sphagnum varieties), teaberries, and tree gums and barks. The industry also includes forest nurseries; rubber plantations; gathering, extracting, and selling of tree seeds; lac production; and distillation of gums, turpentine and rosin, if carried on at the gum farm.

NAICS CODE(S)

111998 (All Other Miscellaneous Crop Farming)

113210 (Forest Nurseries and Gathering of Forest Products)

INDUSTRY SNAPSHOT

The U.S. forest products industry (FPI) produces about \$260 billion worth of goods annually according to the American Wood Preservers Institute. The industry employs approximately 1.3 million in the planting, growing, managing, and harvesting of trees and in the production of wood and paper products. The FPI ranks among the top 10 manufacturing employers in 46 of the 50 states, with an annual payroll of around \$46 billion, although between 1997 and 2002, the industry shuttered 72 paper mills and trimmed 32,000 jobs. Oregon, Washington, and California are the largest timber producing states, accounting for roughly three-fourths of Western timber production in the early 2000s. Timber is also the South's largest agricultural product, employing one of every nine southern manufacturing workers.

About one-half of the United States is covered with trees. This represents about two-thirds of the presettlement forested land in the country. Two-thirds of America's forest land, or about 500 million acres, is classified as timberland, or forest capable of growing 20 cubic feet of wood per acre per year. Of this, roughly 30 percent is owned by the federal government and by state and local governments, while about 60 percent is in relatively small tracts owned by individuals, and the remainder is owned by the FPI. About 4 million tree seedlings are planted in the United States daily.

ORGANIZATION AND STRUCTURE

The term "forest products industry" is used to describe all industries dependent upon forest products including the lumber, wood pulp, and paper industries and those activities covered by SIC 0831. However, those activities covered by SIC 0831 are a relatively small part of total FPI activities.

Since the mid-1950s, the forest products industry shifted from a proliferation of companies operating in specialized areas toward a consolidation of operations within large, diversified conglomerates with national and interna-

tional interests. Reflecting these patterns, most forest nurseries and operations involved in the gathering of forest products became affiliated with larger operations in the parent industries of **SIC: 6519 Timber Tract Real Estate** or **SIC 2411: Logging**. Furthermore, in 1986 the standard industrial classification (SIC) system itself was altered to reflect industry trends toward less specific groups. That year, **SIC 0831: Forest Nurseries and Gathering of Forest Products** was created by merging three formerly independent forestry-industry categories: **SIC 0821: Forest Nurseries and Seed Gathering**, **SIC 0842: Extraction of Pine Gum**, and **SIC 0849: Gathering of Forest Products, Not Elsewhere Classified**.

BACKGROUND AND DEVELOPMENT

In 1995, approximately five new trees were planted for every American. Approximately 43 percent of these 1.6 billion seedlings were planted by the FPI. Naturally regenerated trees totaled in the millions. In the 1980s and early 1990s, forest nurseries were affected by increased efforts at global reforestation. Fighting on behalf of cleaner air, endangered species such as the northern spotted owl, and the ecological preservation of old-growth and tropical forests, environmental groups gained tremendous clout. Regarding the spotted owl, only 200 pairs were known in the 1970s, but by early 1992, approximately 3,510 owl pairs were known. In 1995, estimates in California alone were as high as 8,000 pairs. In addition, numerous studies tied the effects of deforestation to depletion of the earth's protective ozone layer and the subsequent warming of atmospheric temperatures. Tree nurseries kept up with increased reforestation efforts. During fiscal 1990, public and private forest owners in the United States regenerated 2.86 million acres by tree planting and artificial seeding. Most forest products companies developed third-generation seedlings to genetically maximize growth, height, shape, and resistance to drought and disease on their tree farms. Such seedlings often yielded increases of 50 to 60 percent per acre of timber. From 1985 to 1995, forest product companies spent more than \$100 million on wildlife and environmental research, employing more than 90 wildlife biologists. During this time, approximately \$400 million of land (about 1 million acres) was donated by the FPI for conservation, recreation, and social causes. In 1994, the industry aligned itself with the U.S. Department of Energy to create Agenda 2020, which is an effort to address environmental and productivity improvements during the next century.

Many of these efforts were aimed at reversing a decline in U.S. forest acreage that began in the early 1970s and continued well into the 1980s. It is estimated that the United States lost nearly 1.5 million acres of forest land each year during this period. However, reforestation efforts began to take hold in the 1990s and U.S. forest depletion dropped to about 500,000 acres annually. Despite these

efforts government sources still predicted a 4 percent decline in U.S. forest land by 2040. Also continuing into the twenty-first century was the ongoing conflict between those forces that want to use public and private forest land for environmentally conscious purposes and those forces that are market driven. Activists were also beginning to rally against genetically modified trees, fearing that wind-borne pollen, which could travel up to 600 kilometers, would trigger unanticipated hazards.

Approximately 95 percent of the bark and wood residues from producing lumber and plywood were used for energy and other products. By some estimates more than 90 million short tons of paper and paperboard were used every year in the United States by the 1990s. By then, Americans recovered about 45 percent of all paper used in the United States, and the paper industry had set a goal to recover more than half of all paper in use by the year 2000. By the late 1990s, Americans were using, on a per capita basis, 749 pounds of paper annually, or the equivalent of a tree 100 feet high and 16 inches in diameter.

The overall paper and forest products industry was on the upswing between spring 1997 and fall 1998. However, this recovery over previous years was set back by the Asian economic crisis. The driving force behind this improvement was largely due to increased activity in paper and packaging. But as this economic sector retreated markedly in late 1998, the wood products sector, which had been slow earlier, began picking up. This revival continued especially through the second quarter of 1999.

Exports have played an increasingly important role in the FPI. In fact, according to Standard & Poor's, 65 percent of the industry's shipment growth between 1988 and 1998 came from export sales. In 1998, exports by U.S. paper manufacturers totaled \$13.7 billion. Although this was down 5.5 percent from 1997, that year tallied the second highest total on record. These exports represented 8 percent of the industry's 1998 shipments. Industry exports of paper, pulp, and various forest products totaled 12 million tons in 1998, down from 13 million tons in 1997.

It is estimated that in 1998 the FPI employed about 20.4 million workers. Many of these workers were classified as forest products technicians and forestry technicians. The former performed supervisory and technical jobs, mostly for private companies that operated lumber mills or manufactured wood products. Salaries for this classification ranged from \$18,000 to a little more than \$21,000. Forestry technicians aided professional foresters in the management of forest resources and work for government agencies as well as private companies. The pay scale for this job classification varied greatly, from \$12,500 to \$28,000 a year, depending on education and experience.

Another job classification in the FPI was that of Forester. Foresters worked for private industry and gov-

ernment agencies and performed a wide variety of tasks. Foresters were required to have a bachelor's degree and many had masters and doctorate degrees. The average starting salary for foresters ranged from \$19,500 to nearly \$43,000 depending on education. In 1997, the average salary for federal foresters, including those in supervisory positions, was \$47,600.

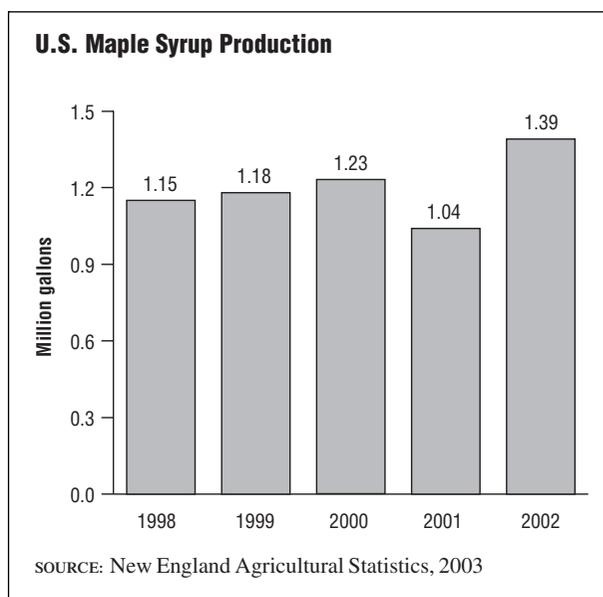

Like many other sectors of the U.S. economy, the FPI went through a process of acquisitions and mergers in the late 1990s. Major transactions included a \$6.5 billion merger between Jefferson Smurfit and Stone Container in 1998. The resultant Smurfit-Stone Container Corp. became the world's leading paper based packaging company. In 1999, International Paper Co. acquired Union Camp in a stock deal valued at \$7.9 billion, and Weyerhaeuser reached an agreement to purchase Canada's MacMillan Bloedel for \$2.45 billion. According to economist Richard Diamond these industry mergers and acquisitions were driven by a number of motives including economic efficiency, diversification, self-defense, and market power.

CURRENT CONDITIONS

In the United States, the largest timber holding companies also are the largest forest nursery and forest product gatherers. In 2003, some of the largest forest product companies were International Paper, which acquired Champion International in 2000 and boasted 2003 sales of \$25.2 billion and 91,000 employees; Weyerhaeuser, with sales of \$19.8 billion; Boise-Cascade, with sales of \$8.2 billion and 24,111 employees; and Smurfit-Stone, with sales of \$7.7 billion and 38,600 employees. Kimberly-Clark, with sales of \$14.3 billion, is a major manufacturer of personal paper products, but in 1999 it began divesting itself of its timberland operations. In June of that year, for instance, the company sold 460,000 acres of timberland in Alabama, Mississippi, and Tennessee to Joshua Management LLC for approximately \$400 million. As of 2004, Kimberly-Clark was planning to spin off its paper, pulp, and timber assets as a separate entity.

Despite the preeminence of these giant companies, many of which are major paper manufacturers, the FPI also is populated with small nurseries, maple syrup producers, owners of small timbered tracts who have them logged for personal income, and even individual ginseng gatherers. Other small companies focus on unique products, such as, sphagnum peat moss, bark nuggets, and mulches. Because of the diverse nature of the SIC 0831 classification and the fact that much of the economic activity represented by it comes from individuals and small cottage industries, comprehensive economic statistics are difficult to come by.

One niche of the FPI that does get reported is maple syrup production. In 2002, U.S. forests produced 1.4 million gallons of maple syrup worth \$38.3 million. Total

production was up from 1.0 million gallons in 2001, but down from 1.5 million gallons in the mid-1990s. New England states produced nearly \$23.1 million worth of maple syrup, with Vermont leading with 500,000 gallons. Between 2001 and 2002, maple syrup exports increased from 4.61 million gallons to 4.67 million gallons, while imports grew from 1.04 million gallons to 1.39 million gallons. Maple syrup prices declined from \$28.61 per gallon to \$27.56 per gallon over the same time period.

Ginseng is a medicinal root that traditionally has been gathered in the wild and exported to China and other Asian countries. Most gathering is done by individuals under permits issued by states. Although wild ginseng commands the highest prices, the herb also is cultivated on farms.

SIC 0851

FORESTRY SERVICES

This industry classification includes establishments primarily engaged in performing, on a contract or fee basis, services related to timber production, wood technology, forestry economics and marketing, and other forestry services, not elsewhere classified, such as cruising timber, fire fighting, and reforestation.

NAICS CODE(S)

115310 (Support Activities for Forestry)

INDUSTRY SNAPSHOT

One-third of the United States is forestland. The challenge for federal government, activists' groups, and private companies is how best to put the resources to work, yet preserve old-growth trees and animal habitats. U.S. forests cover nearly 747 million acres, or one-third of the nation's lands. Of that total, 52 million acres are "set aside" for nontimber use, such as parks and reserves, as proscribed by the federal government. Two-thirds of the forestlands (503.6 million acres) are classified as timberlands, capable of producing 20 cubic feet of commercial wood per year. In 2001 nonindustrial private ownership accounted for 58 percent of timberlands. Twenty-nine percent was owned by the federal government (19 percent, national forest; 10 percent, other public use), and 13 percent was used by the commercial forest industry.

The United States is the world's leading producer and consumer of wood products, supplying 25 percent and consuming 30 percent. According to the American Forest and Paper Association (AFPA), in 2000 Americans consumed an average of 718 pounds of paper products and 18 cubic feet of lumber products. New housing accounts for 40 percent of all lumber use; remodeling and repair, 28 percent; nonresidential and manufacturing, 15 percent; and shipper containers, 9 percent. Paperboard accounts for 45 percent of all paper goods; printing/writing, 31 percent; newsprint, 12 percent; tissue, 7 percent; and packaging and other, 5 percent.

Federal regulations regarding the industry are numerous. They encompass everything from road construction to reforestation mandates. Many in the industry see these regulations as excessively burdensome and a barrier to trade. However, for many years private companies harvested trees on public lands, paying nothing to the public coffers and having little regard to the impact of

wholesale tree clearing. The U.S. Forest Service stepped in, and with the help of public pressure due to awareness to the need for the forests, set up regulations.

ORGANIZATION AND STRUCTURE

During the start of the twentieth century, the economic future of the United States was heavily dependent on the "perpetual supply of timber," as noted in a 1923 editorial in *The Timberman*, a leading forest products journal. The forestry services industry took hold from a philosophy that the nation's forestland was a resource that had to be serviced, protected, and renewed, rather than just harvested and diminished. Protection from wildfires and pest infestation of the nation's forests were essential for survival.

As the timber industry grew and became more competitive, so did related services: timber cruisers hiked through forests to assess logging conditions and estimate the volume of marketable timber; and estimators, log graders, and scalers inspected logs for defects, measured them to determine volume, and estimated marketable content or value for pulpwood and other uses. Timber and related industries grew at a fast pace along with the demand for skilled loggers.

Vast Forest Resources. As the growth of forestland that required servicing increased, so did the growth for the demand of the forestry services industry. In 1996 over 737 million acres—or approximately one-third of the total U.S. land area—was forested. In Oregon, Washington, and California, more than 10 million acres of old-growth forest can be found. Nonfederal public agencies, the forest industry, farmers and ranchers, and other private individuals owned the majority of this forestland.

Fire fighting and prevention, pest control, and forest management plans took hold in the 1980s and 1990s due to the new philosophy of managing the U.S. forests as complex ecosystems, containing interdependent communities of plants, animals, and microbes. This new way of looking at forests was greatly influenced by the declining number of U.S. forestlands during the early 1970s. Reforestation and new forestry management efforts started, in part to prevent the decline of 1.5 million acres each year between 1970 and 1987. The efforts paid off, for by the early 1990s, the rate of U.S. forest depletion had decreased to approximately half a million acres per year. However, government sources still project a decline of 4 percent of forestland to about 703 million acres by the year 2040.

International Forest Servicing. The issues of deforestation, acid deposition, climate change, and endangered species were problems that crossed national boundaries. During the 1980s and 1990s, natural resource issues helped create an international forestry emphasis.

Many U.S. companies and organizations specializing in forestry services increasingly contributed to reforestation efforts in forests from the Amazon to Malaysia. The authorization of the 1990 Farm Bill communicated to the world that the U.S. Forest Service supported forestry services work on an international basis. It coordinated efforts with the U.S. Department of State and other organizations. The Foreign Operations Appropriations Act of 1990 authorized increased funds for international forestry services performed by various agencies, including the U.S. Agency for International Development (AID). By 1991 international operations had gained such clout that the Forest Service elevated the International Forestry Staff to division status. In addition to internationalization at the federal level, private industry leaders were performing forestry services around the world.

Public vs. Private Services. Historically, the forestry services industry has been divided between federal and private control, with the two sectors often overlapping in both cooperative efforts and disputes. With the rise of industrial forestry in the late 1900s, budding forestry products companies developed individual management plans, fire and pest control systems, and business priorities. As early as 1904, the Weyerhaeuser Company reforested 1.3 million acres of timberland in Washington State, and following the 1903 and 1908 fires in the Northeast and the 1902 and 1910 fires in Idaho and the Northwest, private companies drafted the first fire protection organizations.

The scene changed dramatically, however, with the 1905 establishment of the U.S. Forest Service. After the 1920s the Forest Service began a campaign advocating the federal regulation of private timber harvesting. Even though federal forests accounted for less than one-fifth of total U.S. forestland, government regulations influenced private industry in such areas as logging, road construction, reforestation mandates, taxation of private forests, and use of herbicides and pesticides. Entering the 1990s private forest landowners and forest industry leaders took issue with many federal regulations, arguing that forest management plans for public forestlands were incompatible with market-driven interests of private foresters.

BACKGROUND AND DEVELOPMENT

Since its creation, the U.S. Forest Service, the largest bureau in the U.S. Department of Agriculture, served as an innovator and driving force in forestry services. The Forest Service managed the National Forest System (made up of 191 million acres) and worked with state land management organizations to help private landowners apply sound natural resource management practices on their lands. The service's research division strove to develop the means and understanding to enhance and protect productivity of forestlands, with special emphasis

on natural resource issues of national and international scope. Finally, the international forestry arm of the U.S. Forest Service facilitated the exchange of technical expertise and managerial skills with other nations.

At the turn of the twentieth century, public forests had become an immense timber commons with no established property rights and no incentives for responsible harvesting or reforestation. By the 1860s and 1870s, exploitation of vast timber tracts began to stir national attention. A new awareness emerged; in his famous study, "Man and Nature," George Marsh described the central role of forests in overall environmental health, from erosion control to water flow. In addition, the Timber Culture Act of 1873 granted settlers 160-acre tracts, provided they planted and sustained trees on a quarter of the land, and in 1875 the American Forestry Association was founded.

Over the next two decades, a series of measures was taken to control the occupancy and use of forestlands. After legislation to set aside national forest reserves was introduced in 1876, 15 years elapsed until the Reform Act of 1891 finally provided for the creation of forest reserves. By 1892 U.S. President Benjamin Harrison had contained 13 million acres in forest reserves, and by 1893 President Grover Cleveland oversaw an addition of 4.5 million acres.

When the National Academy of Sciences appointed a study commission to consider the future of the forest reserves in 1896, Gifford Pinchot, the future head of the U.S. Forest Service, rose to prominence. His advocacy of forest management aimed at productive use, emphasizing timber harvesting, spurred the 1897 passage of the Forest Reserve Act, which established regulations for the use of forest reserves. Prompted by Pinchot, President Theodore Roosevelt provided the final impetus for the Transfer Act of 1905, whereby forestry management was consolidated in the Bureau of Forestry within the U.S. Department of Agriculture. The Forest Service had been created.

A drive for public regulation of private timber harvest gained considerable impetus with the 1919 meeting of the Society of American Foresters, chaired by Pinchot. The committee forecast that the nation would face a veritable "timber famine" within 50 years if forestry management were not reformed. Under the guidance of Pinchot, the U.S. Forest Service embraced ideals of scientific forestry management, with many critics claiming that it proceeded to employ the gusto of scientific methodology without any of the benefits of scientific problem solving.

With the passage of time came the implementation of numerous programs granting the U.S. Forest Service greater importance and scope in the forestry services industry. The Clarke-McNary Act of 1924 facilitated the

transfer of federal funds and programs to state and local programs. With the New Deal came the 1933 National Plan for American Forestry (also called the Copeland Report), calling for greater federal forestlands and national forest management.

Starting in the late 1950s, the Forest Service forged a general plan of national forestry management that continued to carry substantial influence well into the 1990s. The Multiple-Use Sustained-Yield Act of 1960 mandated that production of timber supplies in national forests be continuous and that a variety of goods and services—including timber, hunting, fishing, and recreation—be produced. The 1974 Forest and Rangeland Renewable Resources Planning Act (RPA) concluded that major shortages of timber were likely to develop and encouraged long-range planning processes. The National Forest Management Act of 1976 provided additional guidance on planning and management of the National Forest System. These acts served as the building blocks for the Forest Service's application of multiple-use forestry management into the 1990s.

American Tree Farm System. In order to foster the sound management of privately owned woodlands, the forest products industry organized the American Tree Farm System, a nationwide conservation program dating back to the 1920s. The program demonstrated that privately owned forestlands could be managed in the public interest without the supervision of the Forest Service.

The Tree Farm program began in 1941, when Weyerhaeuser Timber Co. called on public and local foresters to help protect one of its major tracts in western Washington. The resulting Clemons Tree Farm, named after the pioneer logger Charles H. Clemons, set the precedent for a wide line of similar organizations. Later that year, the West Coast Lumberman's Association and the Pacific Northwest Loggers Association (later the Industrial Forestry Association) established the West Coast Tree Farm Program for the Douglas fir region of western Oregon and Washington. Other tree farms opened throughout the United States, including the Western Pine Association, with a 450,000-acre tract in eastern Oregon and the Arkansas Forestry Commission. Before long, the program went national.

In November of 1941, the American Forest Products Industries (AFPI), then a subsidiary of the National Lumber Manufacturers Association (NLMA), assumed major sponsorship and national promotional role. The organization's dictates were systematically set forth in the *Principles of the American Tree Farm System* of 1954. The AFPI assumed administrative control on a national level, but also divvied out responsibilities to key local forest industry committees around the country. When the AFPI was reorganized as the American Forest Institute (AFI) in

the mid-1960s, the tree farm program lost central support and cohesiveness until the mid-1970s. By 1980, however, the American Tree Farm System registered 38,926 certified tree farms occupying 79.6 million acres of industry-owned and nonindustrial forestland. A green and white diamond-shaped tree farm sign became the symbol for sound private forest management.

Fire Control. The rise of industrial forestry called for a new perspective on fire management. Private timber owners were instrumental in forming the first fire protection agencies. In the early 1900s, fire protection associations emerged in California, the Lake States, Georgia, Kentucky, West Virginia, Pennsylvania, and New Hampshire. One of the most renowned and longest lasting organizations was the Western Forestry and Conservation Association (WFCA), founded in 1909 and boasting members in 11 states and Canada by the early 1980s.

After the General Land Office (GLO) transferred management and fire control of the national forest reserves to the U.S. Forest Service in 1905, the federal role in fire control moved to the foreground. The Forest Service controlled the national forest system, promoted cooperative fire control programs with states and private industry, and led research and planning initiatives toward development of modern forest fire control.

In early 1993 the focus of aerial fire fighting focused on improvements in safety and efficiency for this type of forestry service. NASA-Ames, the Bureau of Land Management, and the USDA-Forest Service signed an agreement to look at air traffic control issues around a fire area to improve communication and safety, work on a standard phraseology for working to extinguish the fire area, and introduce advanced navigation systems with electronic chart displays that reduce disorientation and improve safety and efficiency.

Affiliated government agencies worked separately, but in harmony with the Forest Service. The Forest Service made ties with the National Weather Service in forecasting and monitoring fires. It also chaired the Forest Protection Board from 1927 to 1933, serving as a central hub for cooperative action. Around 1934 the technique known as smoke jumping was introduced, incorporating military paratrooper training strategies to combat fires. During the New Deal, federal involvement assumed the cloak of the Civilian Conservation Corps (CCC). When the Grazing Service and General Land Office reorganized as the Bureau of Land Management (BLM) in 1946, it became the largest federal fire service besides the Forest Service.

Following World War II, CCC ranks had been gravely depleted. Sparked in part by fears of "mass fires" used as offensive weapons by wartime enemies, the Forest Service carried fire-control efforts into the general public. The Cooperative Forest Fire Prevention

Campaign featured Smokey the Bear, a character who spread fire safety messages to a broader audience. By the mid-1950s the Forest Service assumed responsibility for coordinating wildland and rural fire protection for the entire United States, providing material support and planning assistance to state and rural fire agencies. In the 1960s the Forest Service increased its emphasis on the control of wilderness fires. Over the next decades, fire protection services continued to grow and evolve along with changing technology and new forest conditions.

Social Changes. What started in the early 1990s as a small voice of reform in the U.S. Forest Service has turned out to exemplify the debate over the role of the forest industry and the move to protect forests. The Association of Forest Service Employees for Environmental Ethics (AFSEEE) was created for government employees who feared their livelihoods in the U.S. Forest Service could be in jeopardy when environmental assessments might harm the prospects for timber sales. A U.S. Forest Service biologist, Marynell Oechsner, was asked to study how a proposed timber sale would affect wildlife in the Kootenai National Forest in northwestern Montana. She stated it would endanger a species of bear in the forest. The forest was also home to a large number of employed timber workers. She claimed during a Congressional hearing that her U.S. Forest Service supervisor pressured her into deleting the report's findings, which unfavorably affected the bear's habitat, because it would adversely impact the timber companies in the area. Jeff Debonis, a former Forest Service employee who founded AFSEEE, stated, "There's a civil war going on in the Forest Service." Career foresters who believe the agency balances environmental and logging policies are pitted against younger employees who worry that the agency is too beholden to the logging industry. In the mid-1990s, AFSEEE had 8,000 members, 2,000 of whom were U.S. Forest Service employees. Its purpose is to fight for Forest Service employees' rights to express professional opinions without the threat of job termination.

The forest industry, as well as its professionals, has been forced to change due to social, economic, and political pressures in the 1990s that have reduced the number of acres that can be harvested for timber. Many in the industry looked first to public agencies and forest product corporations for employment, but even as the largest single employer, the Forest Service in the U.S. Department of Agriculture, the word "downsizing" is frequently spoken. However, many owners of small forest tracts are hiring forestry consultants to help manage land. The reductions in timber cutting on national forests have caused lumber and timber prices to rise. As profits from timber growing increase, forest product companies, especially the ones with large land holdings, are using more of the services that this industry sector can offer.

Deforestation. Starting in the mid-1980s, world attention veered toward the interrelated problems of global deforestation—especially in tropical forests—and its possible contributions to such environmental problems as global warming. At the 1990 Economic Summit in Houston, Texas, President George Bush proposed a global forest convention to address problems of deforestation, biodiversity, and forest management. At the 1991 Economic Summit in London, these concerns were reiterated in anticipation of the Earth Summit meeting scheduled for June of 1992 in Brazil. Capitalizing on many of the issues raised in these conferences, U.S. President Bill Clinton and his running mate, Al Gore, attracted considerable support of environmentalist groups in the 1993 presidential elections.

By 1993 more than 100 acres of rain forest were being destroyed every hour. The worst victims were the particularly fragile and ecologically rich rain forests in Brazil, Indonesia, and other locations. In the 1990s attention was also focused on the former Soviet Union, where huge tracts of untapped timber were in danger of uncontrolled exploitation. International pressure to curb deforestation in such areas assumed many forms: diplomacy and negotiations around committee tables; export bans and taxes on tropical wood products in Indonesia, Malaysia, and the Philippines; and such creative alternatives as debt-for-nature swaps. Illustrating this last strategy, in 1987 Conservation International acquired \$650,000 of Bolivia's debt in exchange for that government's establishment of a 1.5-million hectares forest reserve to be managed for sustainable development. These and other measures required substantial funding: the World Resources Institute (WRI) estimated a cost of approximately \$8 billion to tackle deforestation between 1985 and 1990 alone.

Public vs. Private. Another condition affecting the forestry services industry was the ongoing battle between the use of public and private forestland for market-driven purposes or for more environmentally conscious purposes, whether or not they made money. At the center of this contentious issue stood the fate of old-growth forests in the Pacific Northwest. Actions to protect diverse ecosystems of the ancient forests raised concern over the impact on small, timber-dependent communities. The northern spotted owl, a regional inhabitant protected under the Endangered Species Act of 1990, became a focal point for the spotty differences between environment and industry, and between public and private forestlands. Many critics of the established system proposed complete privatization of timberlands, arguing that the federally managed system of multiple use and sustained yield also lost tremendous amounts of public money. Additionally, a new challenge to the spotted-owl logging protection arose in March 1997, when a federal appeals

court allowed for new timber industry challenges to Northwest logging reductions that were ordered by President Clinton in 1993. Clinton's Northwest Forest Plan dropped logging levels on national forests in Oregon, Washington, and Northern California to approximately one-fourth the annual averages of the 1980s. The plan intended to protect the old-growth forests that were inhabited by the owl, which was declared an endangered species in 1990. The logging industry alleged the administration violated many procedural requirements that prevented government officials who drafted the plan from obtaining critical information that formulated the logging strategy. The Northwest Forestry Association believed that if the information from the industry was permitted, much more logging would have been made available to timber harvests.

New Forestry Initiatives. Moving into the 1990s, the forestry services industry saw the enactment of numerous forest-related initiatives. For example, 1991 marked the first year of the America the Beautiful program by which the Forest Service worked with state foresters to plant a goal of 970 million trees in rural areas and 30 million trees in urban areas. In March of 1991, the National Tree Trust, a private nonprofit group designed to raise funds for tree planting, opened offices in Washington, D.C. In October of 1993, President Clinton announced the recognition of National Forest Products Week, a period during which Americans were invited to participate in ceremonies and activities calling attention to the need for healthy and productive forests. And following a program calling for "New Perspectives," or "New Forestry," from the 1990s on, the Forest Service tried new ways of incorporating the concept of biodiversity into national forestry management. The course of the forestry services industry was bound for change into the twenty-first century.

In 1995 a new study was underway using a \$1 million, 260-foot construction crane to study the Columbia Gorge forests. Cranes have been in use since 1990 to study the rain forest canopies of Venezuela and Panama, but this is the first time the higher canopies of the temperate forest were studied. The product was a joint effort of the U.S. Forest Service and the University of Washington. Temperate woodlands are estimated to be 40 percent of the world's forests, containing tree species that are the most commercially viable. The study sought to understand the workings of mature forests, so that new ways of harvesting the timber could be found while also preserving its ability to regrow logged sections.

Realizing that the Forest Service needs to work with local citizens and companies, the Camino Real Ranger District of New Mexico's Carson National Forest developed the Northern New Mexico Collaborative Stewardship (NNMCS). The fighting between all groups around the forest had reached a bitter pitch—companies and

workers wanted fewer restrictions on using wood, and environmentalists wanted more. The Forest Service was in the middle and came up with an innovative way to manage all concerns. They literally went door-to-door surveying the surrounding community about concerns for management of the forest.

The NNMCS brings together people, organizations, and/or companies with conflicts and works with them for solutions. The Forest Service feels they are not just responding to one crisis after another, but preventing problems from getting out of control. In one case, the problem of Camino Real's overgrowth was explored, as the practice of control fires has been eliminated. To thin trees by hand was expensive, but the solution brought forth was to raise money to train Native Americans how to thin the forest. Local Hispanic communities used the wood for cooking and building.

Camino Real won an Innovations in Government Award in 1998, along with \$100,000. Recipients of the award have to use 80 percent of the money to set up the prize-winning program in other areas. The toughest challenge is not only convincing local communities to work with the Forest Service; it is convincing government employees to work with the communities.

CURRENT CONDITIONS

The major issues facing the forestry industry in the 2000s continue to be urban sprawl and sustainable development. According to a comprehensive study completed by the U.S. Department of Agriculture's Natural Resources Conservation Service, forestlands in the United States actually increased by nearly 1 percent between 1982 and 1997. However, developed lands grew by 34 percent within the same time period. In other words, the United States gained 3.5 million new acres of forestland, but 25 million acres of new development. The majority of U.S. timberlands are under private ownership. Nearly 10 million nonindustrial private owners control 58 percent of timberlands. Of these, nearly 93 percent are small land owners, with less than 100 acres of timberlands. As long as demand is high for undeveloped lands, timberland owners will likely continue to sell off their forests to developers. Some states are revising tax structures to provide timberland owners with incentives to grow trees rather than sell off lands.

In 2002 the National Commission on Science for Sustainable Forestry undertook a 5-year, \$7.5 million study to develop a scientific basis for improving sustainable forest practices in the United States. Large forest fires that swept through the drought-stricken western regions have some forestry experts arguing that forests have been mismanaged. Too many young trees and too much underbrush, caused both by overlogging and fire suppression, have turned the forests into tinder boxes,

ready to ignite. In 2002 President George W. Bush announced the “Healthy Forest Initiative,” which effectively put aside numerous environmental regulations and appeals processes, allowing timber companies and the U.S. Forest Service to prune forests back to healthy levels.

Bush’s plan was met with the immediate and strong disapproval of environmental groups, who feared that logging companies would take advantage of the freedom from environmental restrictions to overcut mature trees, doing even greater damage to the forests. “When the timber industry and its friends say we have to log the forest to save it, flags go up,” Warren Alford, a regional forestry representative for the Sierra Club in Northern California, told *U.S. News & World Report*. Environmental groups, like the Sierra Club, argue that fires will naturally thin out forests without the intervention of the U.S. Forest Service and commercial loggers. However, with fires becoming hotter and more volatile due to the underbrush, the future for forests will likely involve more hands-on management, rather than less.

INDUSTRY LEADERS

Looming over even the biggest private wood products companies, the U.S. Forest Service remained the largest player in the forestry services industry. In 2001 the organization reported \$8.5 billion in assets and revenues of \$1.4 billion.

Still, the combined ownership of the forest industry, farmers, and other private concerns accounted for roughly 70 percent of timberland in the United States. Much of that land depended on forestry services provided by private companies. After the 1950s, however, the forest products industry saw a consolidation of specialized companies into large and diversified organizations. Forestry services were increasingly performed by subsidiaries or divisions of larger forestry products and related companies. Therefore, the industry leaders in forestry services tended to overlap with leaders in the forest products industry.

International Paper was the leader in forest products in 2002, holding control of 9 million acres of forest in the United States. The company reported a net loss of \$880 million on revenues of \$25 billion in 2002. The second largest paper and building products company is Georgia-Pacific Corporation, which reported a net loss of \$735 million on revenues of \$23.3 billion in 2002. Other leaders are Weyerhaeuser Company, with 8 million acres and \$18.5 billion in 2002 revenues, and Boise Cascade, with 2 million acres and \$7.4 billion in 2002 revenues.

WORKFORCE

The forestry products industry employs 1.5 million people in the United States. In 2001 the U.S. Forest

Service had nearly 30,000 permanent employees and approximately 12,500 contract, summer, and seasonal workers. In 2001 the U.S. Forest Service hired over 3,300 new firefighters.

In the U.S. Forest Service the top positions are chief, deputy chiefs, regional foresters, and stations directors. The positions command a salary of \$90,000 to \$120,000 per year. Many other positions are paid according to market conditions.

There are 17,150 logging tractor operators with a mean annual wage of \$23,810. Log-handling equipment operators make a mean yearly wage of \$24,430, and there are 18,120 employed. There are 11,480 fallers and buckers, and they make a mean yearly wage of \$27,200. Choke setters receive \$27,040 annually and comprise 2,960 workers. There are 20,330 forest and conservation workers receiving a mean yearly wage of \$24,670. Log graders and scalers make up 3,790 of the industry’s employees and have a mean annual wage of \$23,250.

AMERICA AND THE WORLD

By the 1990s the forestry services industry had become international in scope, with most important issues and projects crossing national borders. One example of such internationalism was the decision of the U.S. company Applied Energy Services (AES) to reforest 52 million trees in Guatemala in order to offset carbon dioxide emissions from its coal-fired power plant in Connecticut. AES’s planting project began in June of 1989, with a projected time frame of 10 years and a cost of \$15.7 million.

The Forest Service also stressed international operations. Among them, it worked with over 100 organizations and numerous countries on its Tropical Forestry Program. Latin America, the Caribbean, and South Pacific gained the most attention in that area. The Forest Service also cooperated with foreign countries—including Spain, Israel, and Brazil—in managing fires and forest insect and disease problems. In the early 1990s, the home front, too, was in the process of change. Congressional debates on the North American Free Trade Agreement (NAFTA) bore strongly on the dynamics of the North American wood products industry and, by extension, on the role of forestry services in Mexico, the United States, and Canada.

International concern about deforestation stemmed from links between rates of forest destruction and global warming. Increased carbon dioxide in the earth’s atmosphere was shown to trap the sun’s heat. Since trees replace the carbon dioxide with oxygen, researchers maintained that fewer trees contributed to more carbon dioxide and faster global warming, with potentially devastating consequences to world ecosystems. In 1991 the Global Change Research Program was initiated by the

Forest Service to increase understanding of climate changes.

A project that was born out of the concern for the growing buildup of atmospheric carbon dioxide and the increased threat of global warming uses aircraft for reforestation. A former aeronautical engineer and Israeli immigrant, Moshe Alamaro, was working on a project to drop tree seedlings in open-topped cones from aircraft in order to reach previously inaccessible areas. These "aerial bombs," as they are referred to, bear one-year-old tree seedlings. Areas that are being sought to plant this way are war-torn battlefields, empty deserts, and steep slopes. This wasn't the first time aerial seeding has been tried however. Shortly after World War II, the mountain states in the United States were the site of similar efforts, but rodent predation often got to the edible seeds before they had a chance to grow. Today's technology incorporates the use of rodenticides to increase the tree seed's chances of survival. Honolulu was also a site back in 1925 for aerial seeding after a fire ravaged several acres of forestland.

The forestry industry continued to fight high trade barriers in other countries in the late 1990s. In contrast, other countries face little regulation when exporting forestry products to the United States. During the Uruguay Round of world trade talks, Japan declined to open its wood market to foreign competition, and the European Community decided not to phase out tariffs on paper products for 10 years. As a result, by 1998 the United States had a deficit in this industry of \$9.4 billion, up from \$3.0 billion in 1994.

RESEARCH AND TECHNOLOGY

In the early 1990s, the advent of global positioning systems (GPS) revolutionized the way foresters work. It is comprised of high-tech software, computers, and satellites that can locate a point anywhere in the world. Hand-held GPS receiver systems are now available at affordable prices that give an instantaneous readout of the receiver's longitude, latitude, and elevation. Forestry applications are: improved mapping of roads and walking trails; exact acreages for harvesting, planting, or burn sites; better night walking; increased accuracy in finding archaeological sites or specific wildlife habitats; and exceptional tracking of every vehicle in a forest fleet.

SIC 0912

FINFISH

This industry classification includes establishments primarily engaged in the commercial catching or taking of finfish, including cod, menhaden, pollack, salmon, and tuna.

NAICS CODE(S)

114111 (Finfish Fishing)

INDUSTRY SNAPSHOT

The United States has three major shorelines, situated along the Atlantic Ocean, the Gulf of Mexico, and

the Pacific Ocean. Together these shores, including those of Alaska and Hawaii, span more than 12,000 miles. As do many other nations, the United States holds economic jurisdiction over waters out to a distance of 200 nautical miles. This area is called the nation's exclusive economic zone (EEZ). The U.S. EEZ contains more than 2.2 million square miles. These waters are estimated to contain about 20 percent of the harvestable seafood in the world.

In 2001 the U.S. commercial fishing industry landed 8.2 billion pounds of finfish, up from 7.6 billion pounds in 2000. The finfish landed in 2001 represented 87 percent of all edible and industrial fish products landed and about 46 percent of the value. Finfish made up 84 percent (6.1 billion pounds) of all edible fishery products landed and more than 96 percent (2.1 billion pounds) of all industrial fishery products landed.

Annual per capita consumption of fishery products rose from 12.7 pounds in 1981 to a high of 16.2 pounds in 1987. From 1987 to 2001, consumption fell and stabilized at approximately 15.0 pounds per person per year. Although the National Fisheries Institute set a goal of increasing annual per capita consumption to 20.0 pounds by the year 2000, the actual per capita consumption that year stood at 15.2 pounds. In 2001 per capita consumption of fish and seafood dropped to 14.8 pounds, down slightly from the previous year. Per capita consumption of fresh and frozen products, however, was 10.3 pounds, up .1 pound over 2000. Finfish, fresh and frozen, made up 5.7 of the 14.9 total pounds, with tuna leading the group at 2.9 pounds per capita consumption. The fresh and frozen finfish category includes approximately 1.1 pounds of farm-raised catfish.

Total export value of edible and nonedible fishery products was \$11.8 billion in 2001, up \$1.1 billion from the previous year, whereas import values, at \$18.5 billion in 2001, decreased \$466.3 million over the same period.

ORGANIZATION AND STRUCTURE

Historically, independent fishermen caught fish and sold them to local packers or processors who resold them to retail markets. Although the U.S. fishing fleet still contains independent fishermen, large corporations are becoming increasingly involved in all aspects of seafood distribution.

The U.S. fisheries industry is managed by the National Marine Fisheries Service (NMFS), which is responsible for regulating commercial fishing, finding ways to control overfishing of exploited species, collecting data, and publishing reports about commercial landings. The fishing industry, however, remains a lightly regulated one. Critics of the NMFS have at times accused the agency of concentrating efforts on helping fishermen maximize profits at the expense of protecting fish populations.

The NMFS, however, has instituted a number of measures designed to protect fish population. One way in which the NMFS has regulated fishing is through the use of limited seasons for selected species. Because of intense pressure on selected populations, some seasons are short. Pacific halibut, for example, was once fished during a six-month season. By 1991 the season was limited to two 24-hour periods. In September 1991 approximately 6,000 boats landed 23.7 million pounds of halibut in one day.

The NMFS has also tested the use of quotas and limited entry into established fisheries as a means of regulating stressed fish populations. Such programs have included a moratorium on new entrants into the fishery, quotas based on catch histories of the vessel or fisherman, quotas based on a percentage of the total allowable catch, quotas on specific poundage, quotas based on vessel size or gear, and quotas that can be purchased or traded.

BACKGROUND AND DEVELOPMENT

Commercial fishing is one of America's oldest industries. The bountiful waters off the continent's East Coast attracted fishermen from Scandinavian countries possibly as early as 1,000 years ago. The ocean also provided employment for many European settlers during the seventeenth and eighteenth centuries. Technological innovations and the institution of regulatory agencies during the 1800s prepared the industry for the modern era.

The techniques of netting, harpooning, and pole-and-line fishing used by early fishermen were eventually replaced by more efficient methods of catching fish. Trawling—pulling a funnel-shaped bag to scoop fish from the ocean floor—was introduced in the middle of the nineteenth century. Purse seines, nets that trap fish by closing in a manner similar to a drawstring purse, were introduced early in the twentieth century. Together, purse seines and trawlers catch more fish worldwide than all other types of fishing gear.

Legislation. In addition to technological innovations, the middle of the nineteenth century also saw some fishery resources dwindle. To protect the resources, the government assumed responsibility for fisheries management. In 1871 Congress created the U.S. Commission on Fish and Fisheries and charged it with the responsibility of investigating food-fish populations and making recommendations. In 1956 Congress passed the Fish and Wildlife Act, which established the Bureau of Commercial Fisheries under the auspices of the Fish and Wildlife Service. The National Environmental Policy Act of 1969 included the requirement that an environmental impact statement be prepared for fishery regulations. Both the Endangered Species Act of 1969 and the Marine Mammal Protection Act of 1972 placed restrictions on allow-

able catches of threatened species and species that interact with threatened species.

One significant piece of legislation to affect U.S. commercial fishing was the Magnuson Fishery Conservation and Management Act of 1976 (Magnuson Act). The Magnuson Act extended the U.S. coastal jurisdiction from 12 miles to 200 miles from shore and gave the federal government exclusive authority over domestic and foreign fishing operations within the exclusive economic zone.

Depletion of Fish Populations. The U.S. commercial fisheries industry entered the 1990s with promise and problems. Consumer demand was expected to remain stable, total catches were on an upward trend, and increases in sales were expected to be limited only by the availability of preferred species. The problems centered on charges that fish populations were being seriously depleted because of the combined impacts of overharvesting and environmental degradation. According to some experts, marine fisheries are a very highly threatened resource.

At the beginning of the 1990s, catches of many important species were significantly down from their 1980s levels across the lower 48 states. In addition to habitat impairment, conservationists and environmentalists blamed the drops on overfishing. Critics of the fishing industry claimed that nearly half of the U.S. coastal finfish populations was being depleted because the size of harvests outweighed the ability of the populations to reproduce themselves. Some scientists estimated that as many as 14 species faced commercial extinction, a state wherein too few fish of that species would remain to harvest them economically. The New England, Middle Atlantic, South Atlantic, and Gulf regions all saw total catches drop below their 1980 levels, although rising prices helped stabilize the value of the harvest.

One important species of fish cited as an example was menhaden, an oily, bony fish that is related to herring and harvested in the Atlantic and Gulf of Mexico. Large-scale harvesting of menhaden began in the nineteenth century following the discovery that its oil could be used as a substitute for whale oil. Twentieth-century uses for menhaden included the production of fish oil and fish meal and as a bait fish.

Although the Gulf population remained stable, the Atlantic menhaden population saw wide fluctuations. The largest Atlantic landings took place in the mid-1950s. During the middle of the following decade, the larger, older fish disappeared and the number of landings tumbled. During the 1970s the population appeared to make a tentative comeback, but in 1982 the Atlantic States Marine Fisheries Commission found it necessary to recommend protective regulations. In 1985 U.S. fishermen

landed 2.7 billion pounds of menhaden, but Atlantic takings declined steadily. As a result, the last meal plant in Maine was shut down in September 1988. By 1995 total landings of menhaden had fallen to 2.0 billion pounds. In 1998 menhaden landings stood at 1.7 billion pounds, down from 2.0 billion in 1997. Atlantic takings stood at 608 million pounds.

Bycatch. “Bycatch” was another problem plaguing the fishing industry during the early 1990s. Bycatch refers to unintentionally caught fish, birds, marine mammals, and turtles that are seriously injured or killed. In 1990 Alaskan trawlers fishing primarily for pollack reported throwing away 550 million pounds of other edible groundfish such as cod and halibut. In the late 1990s, 3.5 million fishing boats around the world were catching about 84 million metric tons of fish, plus 27 million tons of bycatch that was discarded. The practice was condemned by critics as wasteful, and fishermen realized that public concern over real or even perceived threats to nontarget species could have negative consequences. Indeed, concern about the number of dolphins killed as a result of bycatching prompted several well-publicized boycotts of leading tuna producers in the 1980s.

In an effort to avoid further legislative involvement, fishermen organized the National Industry Bycatch Coalition in 1992 to discuss possible solutions. The coalition’s goals included the development of new technologies for cleaner fishing; promotion of education in how to use bycatch-reduction gear; support of management style changes to reduce throw-away rates; reduction of bycatch of threatened, endangered, and overfished species to the absolute minimum; reduction of the rate of bycatch mortality; and the development of valuable uses for dead bycatch. The coalition also expressed a determination to work with conservation groups rather than adopt an adversarial stance.

In 1996 Congress passed a bill aimed at fish conservation that required the NMFS, along with eight regional fishing councils from across the nation, to formulate plans to eradicate overfishing, minimize bycatch, and reduce the loss of marine habitats—especially on the sea bottom, which is damaged by trawling. But as the 1990s came to an end, many were questioning the outcome of the law and if steps being taken were enough. Fisheries biologist Joshua Sladek-Nowlis of the Center for Marine Conservation told *Business Week* the reductions were “too little too late.” Fishermen called the tougher regulations on fishing overkill.

Fishermen are often in agreement with conservationists and environmentalists in discussing ominous environmental trends in the areas of breeding-ground pollution, shoreline development, and loss of wetlands. Approximately 75 percent of U.S.-produced seafood

need bays and estuaries for breeding grounds; both types of marine environments have suffered from pollution. Several states have been particularly hard hit in this regard. For example, Louisiana loses about 50 square miles of breeding ground every year. California has lost more than 90 percent of its original coastal wetlands.

According to a 1998 report by the National Academy of Sciences, overexploitation was responsible for a 30 percent decline of fish stocks worldwide. Also, 44 percent were nearing exploitation, the report said. It was also noted that in U.S. waters, 80 percent of commercial fish stocks were disappearing.

CURRENT CONDITIONS

One of the most important issues facing the aquaculture industry in the early 2000s was law reform. In November of 2000, the National Marine Fisheries Service imposed restrictions on finfish and other fish for 20 miles around the shore off Alaska's western Aleutian Islands to protect endangered sea lion populations. Local government officials argued that their \$1 billion annual business of harvesting fish was threatened by such rules. In response, an agreement was made with the federal government that any new fishing restrictions be executed in phases and that allowed some fishing around the sea lion habitat.

In Maine, the future of the fish-farming industry was being scrutinized during an early 2003 Board of Environmental Protection hearing to debate how the state's 27 existing fish farming operations could avoid polluting the Atlantic Ocean. The goal was to draft a permit to legalize all of Maine's commercial fish farming operations under the federal Clean Water Act. The resulting permit would set the precedent for environmental standards for any projected fish farming operations, including how much excess feed, feces, and antibiotics could be discharged into public waters.

Although the federal government continued to create tough new fishing laws that threatened thousands of jobs in the fishing industry, the debate over the science used in creating these laws was flamed by a federal report in December 2002 that reflected a dramatic increase in the fish count, especially cod, haddock, and pollock, off New England's coast. The report came from the National Marine Fisheries Service fall trawl, which also admitted to the fact that its gear was miscalibrated for the previous two years. With the science used to make such estimates about fish populations in question—dividing fisherman, regulators, and environmentalists—a federal judge ruled to postpone stringent new fishing restrictions from August 2003 until May 2004.

In 2000, Alaska led the nation with the most fishing vessels and boats, with 15,606. Louisiana was second with 13,864, and Florida a distant third with 7,816.

INDUSTRY LEADERS

In the early 2000s, leading companies in the industry included Zapata Corporation, through its 60 percent ownership in Omega Protein Corporation. Zapata, of Houston, Texas, had 2001 sales of \$98.8 million, an increase of 17.5 percent from 2000, and employed 992. Omega Protein, with four processing plants in the United States and a fleet of 40 fishing vessels, was the country's leading producer of fish meal and fish oil.

AMERICA AND THE WORLD

Prior to World War II, Japan, which has a long history of relying on sea resources, had the largest fishing operations in the world. By the 1930s the Japanese fleet fished many areas of the Pacific, including Bristol Bay, Alaska. World War II interrupted commercial fishing, but the following years saw an explosion of fishing fleets. In 1948 Japan maintained its position as the world's leading fishing nation in terms of number of pounds caught. The U.S. fishing fleet landed the second largest catch, followed by Norway, the Soviet Union, the United Kingdom, and Canada. Competition increased during the late 1950s and early 1960s as Soviet factory vessels began operating off the eastern coast of the United States and in Alaskan waters. During 1966 the combined Soviet and Japanese fleets took approximately 3 billion pounds of fish from the Bering Sea and the Gulf of Alaska. U.S. harvests, however, entered a state of decline, and by the mid-1960s the United States ranked only sixth in the world. Japan had fallen to second, and Peru, with massive catches of Peruvian anchovies, had assumed the top position.

In 1974 a new international law of the sea was agreed upon, although it was not officially ratified until 1982. Under its terms, many countries declared exclusive economic zones (EEZs) that extended 200 miles from their shores. In a similar move, the United States adopted the Magnuson Act in 1976, legislation that created a 200-mile U.S. EEZ. Under the Magnuson Act the only foreign fishing allowable within the EEZ was that portion of the allowable catch not taken by U.S. vessels. The Magnuson Act, however, did permit joint ventures in which foreign vessels were permitted to receive fish from U.S. vessels. The fish were considered part of the U.S. harvest in such instances.

Overfishing remains a serious problem internationally, with stocks of food fish dropping severely in Southeastern Asian waters, the North Sea, and the Mediterranean Sea. The reduced fish stocks threaten U.S. and European industries and the economies of some developing countries. Part of the problem lies in the fact that western-style management techniques out-compete traditional Third World country industries. Between 1989 and the mid-1990s, fishing catches worldwide increased

from approximately 100 million metric tons to 109 million metric tons. According to a report in *International Agricultural Development*, 7.5 million people in India relied directly on commercial or personal fishing for their livelihoods, whereas in the Philippines 38,000 fishermen were put out of work because of overfishing and competition each year. Exports of fish made up a significant proportion of the gross national product of Thailand. Western countries have taken some steps to address these concerns. The European Union, for example, adopted a strategy that called for a 20 percent cut in its fishing fleet between 1993 and 1996, but most fisheries management experts believed that this might not be enough.

The quality of fish taken by both western and other fleets also declined precipitously in the late twentieth century. Takes of many of the most profitable species—sea shrimp, Atlantic Ocean cod, herring and mackerel, Pacific Ocean perch, tuna, and halibut—were cut in half in the 20 years between 1970 and 1989. Most of the increase since 1989, according to *International Agricultural Development*, was in less lucrative species, especially Alaskan pollack, jack mackerel from Chile, Japanese and South American pilchards, anchoveta, and shark. These species were also considered less nutritious than the more profitable kinds.

Overall, the United States was successful in the finfish industry throughout the 1990s and into the 2000s. In 2001 U.S. imports totaled 5.8 billion pounds, whereas exports totaled 6.6 billion pounds. Imports in 2000 stood at 5.8 billion pounds and exports at 5.2 billion pounds.

RESEARCH AND TECHNOLOGY

The two essential ingredients in the fishing industry are detecting fish (hunting) and catching fish (gathering). Until the modern era, fish detection was done primarily by the eye. The twentieth century introduced new methods of looking for fish. Aircraft scouting, satellite data, echo sounders, and other electronic equipment enabled fishermen to search more efficiently. Innovations were also made in catching fish. Nets made of new materials were rot resistant, less susceptible to abrasion, and more elastic. Larger purse seines became possible when better methods of hauling them were developed. Trawling became more efficient and diverse when faster and lighter trawls were made.

The Redmond, Washington, Marine Conservation Biology Institute estimated that in 1998, there were 89,000 trawling vessels in operation across the globe that fished an area larger than the lower 48 states. Many equate trawling with clearcutting forests. But industry spokesmen declared that the analogy was nothing more than a public relations spiel and said that they were striving to make changes to minimize impact on fish habitats

in order to protect the resources that provided their livelihood.

Research continued during the 1990s on ways to improve on the various aspects of finfish harvesting. Areas under exploration included the introduction of electrical devices to herd fish into nets; the use of acoustical devices to hear noises characteristic of particular species; the development of more sophisticated methods of determining detailed water conditions; and determination of the applicability of luring fish with light, sound, chemicals, and electricity.

In addition to the technical aspects of finding and catching fish, researchers continued looking at ways to ameliorate the social, political, and economic problems of the industry. Promoters researched fish species not previously used commercially and worked on finding processing methods to make underexploited stocks more acceptable to American consumers. New versions of bycatch-reduction gear were developed and tested. Scientists continued their endeavors to understand interspecies relationships in an effort to make fisheries management more successful.

Also, the advent of global positioning systems and depth sounders made it easier for fishermen to find stocks. Likewise, the development of “rockhoppers,” which rolled along the bottom, allowed sea bottoms, including coral reefs, to be fished. At one time this was impossible to do.

Despite modern innovations, commercial fishing at the dawn of the twenty-first century was still basically a hunting and gathering operation. As research efforts continued, modern technological advances aimed at improving the livelihood of fishermen often seemed to run at cross purposes with regulatory efforts to preserve fish stocks.

SIC 0913**SHELLFISH**

This industry classification includes establishments primarily engaged in the commercial taking of shellfish. The shellfish designation includes mollusks (such as clams, mussels, oysters, and squid) and crustaceans (such as crabs, crayfish, lobsters, and shrimp). Establishments primarily engaged in shellfish farming are classified in **SIC 0273: Animal Aquaculture**.

NAICS CODE(S)

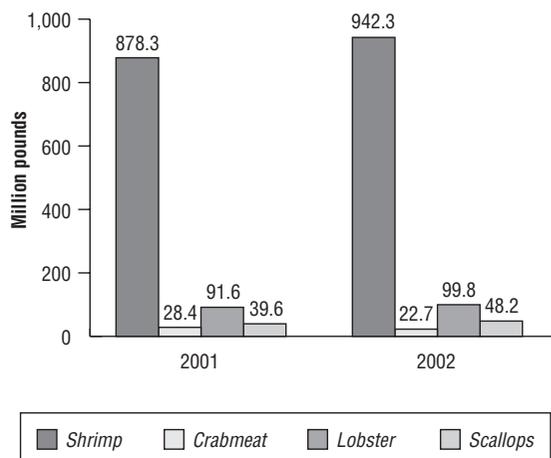

114112 (Shellfish Fishing)

After growing, albeit slowly, in the late 1990s, the market for seafood began to wane in the early 2000s. Total shellfish landings in 2002 were 8.08 billion pounds, down from 8.24 billion pounds in 2001; the value of landings declined from \$1.47 billion to \$1.35 billion over the same time period. Clam landings grew from 122.7 million pounds in 2001 to 130.0 million pounds in 2002, while crab landings increased from 272.2 million pounds to 357.6 million pounds. However, shrimp landings declined from 324.4 million pounds in 2001 to 316.7 million pounds in 2002, and squid landing dipped from 231.6 million pounds to 205.5 million pounds.

Although most shellfish imports decreased during the late 1990s and early 2000s, shrimp imports grew 41 percent between 1998 and 2003. In fact, they jumped 64 million pounds in 2002 alone to 946 million pounds, worth an estimated \$3.4 billion. Despite a weak U.S. economy, shrimp imports throughout the early 2000s had grown significantly due to declining prices. This trend continued in the first half of 2003, with the quantity of imports rising 14 percent while the price declined 1 percent. By the end of 2003, shrimp imports were predicted to exceed 1 billion pounds. Thailand is the largest shrimp importer to the United States, accounting for \$393 million in shipments during the first half of 2003 alone.

Fresh and frozen crabmeat imports declined from 28.4 million pounds to 22.7 million pounds between 2001 and 2002. Over the same time period, fresh and frozen lobster imports increased from 91.6 million pounds to 99.8 million pounds, while fresh and frozen scallop imports increased from 39.6 million pounds to 48.2 million pounds.

Imports of clams grew 27 percent to 4.4 million pounds in the first six months of 2003, while imports of oysters grew 31 percent to 9.6 million pounds. Mussel imports, however, declined 16 percent to 24.2 million pounds during this time period. After declining modestly in the late 1990s, exports of clams and oysters recovered in the early 2000s, despite sluggish economic conditions

Shellfish Imports in 2001 and 2002

SOURCE: U.S. Department of Commerce, 2002

in Asia. During the first six months of 2003, exports of mussels, clams, and oysters rose 19 percent to 5 million pounds. Oysters realized the largest percentage of this growth, accounting for nearly half of mollusk exports. The U.S. Department of Agriculture predicts increasing mollusk prices and continued weakness in Asian economics, the combination of which will likely weaken demand for mollusk exports by 2005.

The U.S. fishery industry produced 950.5 million pounds of canned shellfish products for human consumption in 2002, compared to 858.3 million pounds in 2001. The value of canned shellfish increased from \$1.11 billion to \$1.14 billion between 2001 and 2002.

The largest potential for growth in consumer shellfish demand in the early 2000s and beyond is expected to be shrimp. Industry analysts, however, question whether fishermen can harvest increased amounts of shrimp without damaging the ability of populations to sustain themselves. Other concerns relate to harvesting shrimp without damaging other marine populations, such as sea turtles.

The shellfish industry had entered the 1990s with a myriad of regulatory and management challenges. Many East Coast shell fisheries were recovering from sharp declines during the middle years of the 1980s when algae blooms ravaged fertile scallop grounds and decimated clam populations. Oyster stocks from Long Island to the Chesapeake Bay were threatened by viral oyster diseases. Catches of Alaskan crab, which had dropped from 347 million pounds in 1980 to 129 million pounds in 1985, totaled 281 million pounds in 1990.

As past methods of managing shellfish populations through the use of quotas and limited seasons have not proven entirely successful, government agencies are analyzing new approaches. For example, in the 1990s an innovative management plan for surf clams replaced a policy under which vessels could work a total of only 144 hours annually. The new system, designed to be more flexible, permits the sale and transfer of allocations.

Regulators are also looking for ways to control bycatch problems. "Bycatch" refers to unintentionally caught fish, birds, marine mammals, and turtles that are killed in the harvesting process. Because shrimp are traditionally caught in trawls (net devices pulled behind the boat) they catch significant quantities of other marine animals. Shrimp bycatch was blamed for reductions in red snapper populations and for thousands of turtle deaths. Some reports estimated that as many as 50 to 75 percent of juvenile red snapper were being caught and discarded annually by shrimpers. In addition, a study done by the National Academy of Sciences estimated that trawls killed up to 50,000 turtles per year.

One apparatus used extensively to reduce trawl bycatch by the early 2000s was called a Turtle Excluder Device (TED). TEDs operate by holding the net open so turtles can escape rather than asphyxiate. Florida had started requiring shrimpers within state waters to use TEDs during the middle of 1990.

One major threat endangering shell fishing today is the algal blooms known popularly as "red tides." Shellfish, which are mostly filter feeders, siphon the algae out of the water and feed on it, retaining any toxins in their own bodies. These toxins can then be transferred to people who eat the shellfish, resulting in a syndrome known as paralytic shellfish poison (PSP). Since 1972, "red tides" have increased in frequency worldwide and resulted in the closing of many clamming beds. In the United States, however, PSP poses a very small threat to human life, thanks to efficient monitoring of algal events. The turn of the twenty-first century saw major institutes conducting research into water contaminations.

In the early 2000s, increasing outbreaks of the *Vibrio* bacteria in shellfish, particularly in raw oysters, caused a certain amount of concern over the safety of consuming shellfish. The Interstate Shellfish Sanitation Conference in July of 2001 began lobbying to reduce seafood-borne illnesses by 60 percent by 2007.

SIC 0919

MISCELLANEOUS MARINE PRODUCTS

This industry classification covers establishments primarily engaged in miscellaneous fishing activities, such as catching or taking of miscellaneous marine plants and animals. Plants and animals covered under this code include seaweed, sponges, sea urchins, terrapins, turtles, and frogs. Cultured pearl production also falls under this classification.

NAICS CODE(S)

114119 (Other Marine Fishing)

111998 (All Other Miscellaneous Crop Farming)

The primary marine animal featured under this heading is the turtle. Turtles became popular for meat and soup shortly after Columbus discovered the New World. By 1878 an estimated 15,000 green turtles were shipped annually from the Caribbean to European markets. The market for the turtle began to wane in the 1990s as environmental concerns that the species was nearing extinction mounted.

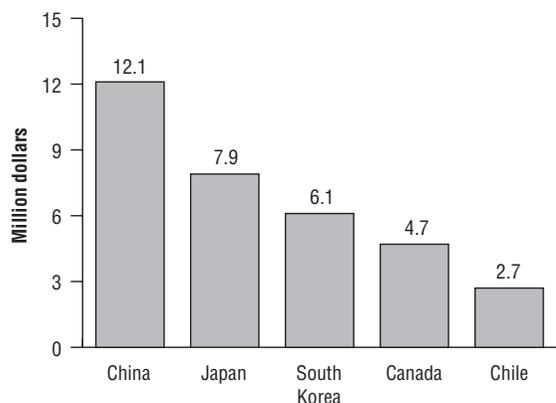

The turtle's popularity as a meal item had created a serious threat to its ability to sustain its population by the turn of the twenty-first century. In addition to risks associated with over-harvesting and habitat loss, thousands of turtles have been injured or drowned as a result of commercial fishing operations.

Many species of sea turtles, such as the hawksbill turtle, Olive ridley, Kemp's ridley, and the green turtle, have been listed as endangered or threatened. In 1973 the Convention on International Trade in Endangered Species of Wild Fauna and Flora drafted a resolution to prohibit the trade of endangered or threatened species including the imperiled sea turtles. The agreement was signed by 95 nations. To further protect the species, the U.S. Department of State began requiring shrimp fisherman to use turtle excluder devices (TEDs) to protect turtles from being killed in shrimp trawls. In 2002, the U.S. government certified the shrimp harvesting practices of 41 countries as turtle-safe.

The diamondback terrapin population has also dwindled, a victim of over-harvesting and diminished habitat. The diamondback terrapin, which lives in

Top Seaweed and Algae Exporters to the United States in 2003

By Value of Exports

SOURCE: International Trade Administration, 2003

estuaries and salt marshes along the eastern seaboard and through the Gulf of Mexico region, is regarded by many culinary experts as the best tasting species of turtle.

In 1920 the population of diamondback terrapins plummeted, spurring the institution of regulatory measures designed to protect it. Governmental agencies undertook breeding efforts to reestablish it in some areas. During the 1960s the diamondback population started to show signs of recovery; however, market demand also increased. In 1989 New York established more stringent regulations defining the size and season for taking turtles. Some environmentalists charge that the rules are inadequate, and they predict another population crash.

Another well-known miscellaneous marine product is seaweed. The two centers of seaweed production in the United States are located in New England and California. Although seaweed is used as a food in Asia, its primary uses in the United States are industrial. Seaweed is used to make agar, which is a jelly-like substance used in laboratories as a culture media and also used as a thickener in food processing; alginates, which are thickeners and stabilizers used in food processing; and algin, a substance used in food processing, pharmaceuticals, the rubber industry, the dairy industry, and the textile industry. A process developed in Scotland in 1950 to make liquid fertilizer from seaweed has also increased its popularity over the years.

Seaweed landings in 2002 reached 103.9 million pounds, compared to 81.9 million pounds in 2001. Seaweeds and algae imports were valued at \$43 million in 2003, compared to \$77 million in 1998. Leading seaweed exporters to the United States were China, which accounted for \$12.1 million of total U.S. imports; Japan,

which accounted for \$7.9 million of imports; and South Korea, which accounted for \$6.1 million of imports.

Another, lesser-known, commercially taken marine product is the sea urchin. In December 1991 urchins from Maine were bringing fishermen about 40 cents per pound. Urchins are typically caught by divers and exported for uses like urchin roe—a traditional food in Japan. Urchins' popularity as an export item, however, has caused concern about the possibility of over-fishing domestic stocks. Because of falling California landings throughout the 1990s, regulators have re-issued seasonal, geographic, and size requirements on red sea urchin catches. Sea urchin landings in 2002 totaled 23.4 million pounds, compared to 27.4 million pounds in 2001. U.S. imports of sea urchins were valued at roughly \$7 million in 2003, compared to \$8 million in 1998. Leading exporters to the United States included Canada and Mexico.

Imports of cultured pearls were valued at over \$204.3 million in 2003, compared to \$280 million in 1998. Japan, China, Hong Kong, and Australia exported the most pearls to the United States. Of the top five importers of cultured pearls—Mikimoto USA, Frank Masteloni & Sons, Imperial Pearl Syndicate, Honora Ltd, and Assael International—only one was not U.S. owned.

SIC 0921

FISH HATCHERIES AND PRESERVES

This category covers establishments primarily engaged in operating fish hatcheries or preserves. Establishments primarily engaged in raising and harvesting aquatic animals are classified in **SIC 0273: Animal Aquaculture**.

NAICS CODE(S)

- 112511 (Finfish Farming and Fish Hatcheries)
- 112512 (Shellfish Farming)

Fish hatcheries were developed during the latter part of the nineteenth century in an effort to supplement dwindling fish stocks. In nature, fish lay thousands of eggs, but most juveniles die in massive numbers because

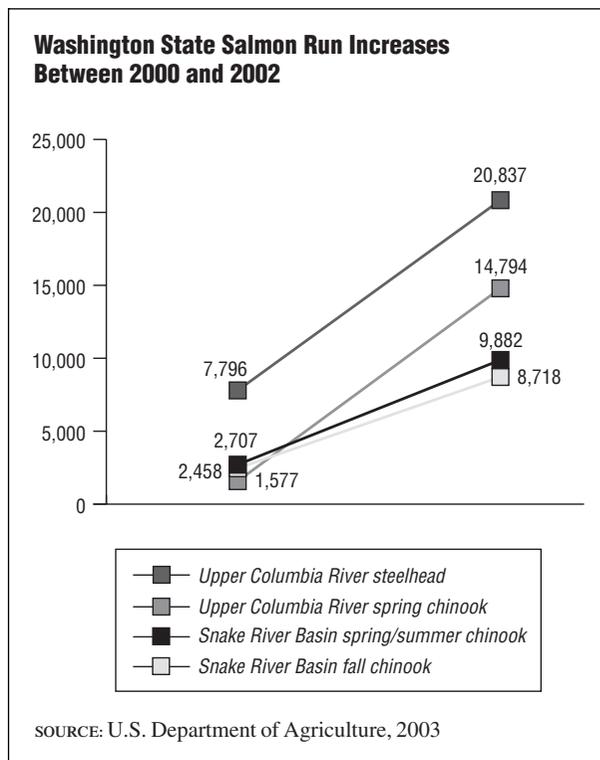

of insufficient food, predators, and diseases. In hatcheries, eggs hatch under controlled conditions and juveniles are able to grow in a protected environment. These conditions result in diminished losses, and young fish can be returned to their natural environment in sufficient quantities to replenish populations.

In 1871, The National Fish Hatchery System (NFHS) was established by Congress through the creation of a U.S. Commissioner of Fish and Fisheries. In 1885, the first hatchery programs were undertaken by the NFHS in an effort to replenish shad and lobster populations. By 1916 the federal government operated more than 100 hatcheries, and many states also had opened their own hatcheries. Fish populations being augmented with hatchery stock included cod, pollack, haddock, flounder, salmon, and lobster.

Hatcheries were also involved in the intentional transplanting of species. Although most programs failed and new stocks did not take hold, there were notable successes. Shad and striped bass (rockfish), two of Atlantic species, were introduced to Pacific waters. Both flourished and briefly sustained commercial fishing. Overfishing, however, led to government action to protect remaining stocks. Although commercial harvesting was prohibited, striped bass and shad continued to be abundant, popular game fish.

Hatchery development began to slow during the 1930s because programs were unable to demonstrate increases in commercial harvests. Hatchery-raised fish were often less able to survive in a natural environment because they were conditioned to being fed, fell prey more readily than wild stock, and were susceptible to stunting, diseases, and parasites as a result of overcrowded conditions in hatchery ponds. Additionally, although millions of fish were released, they represented only a tiny fraction of the ocean's natural population and, as a result, did not make a significant difference.

Because of these problems, fish hatcheries began evolving in different ways. Private, commercial hatcheries redirected themselves toward raising harvestable crops of fish under controlled conditions (see **SIC 0273: Animal Aquaculture**). One remaining type of private, commercial hatchery was the fish preserve. Fish preserves provided a controlled environment for people—usually from urban areas—to visit and experience the thrill of catching a fish. Public hatcheries backed away from commercial species, instead focusing their efforts on replenishing game stock. Even the NFHS shifted its focus and diversified many of its programs to ensure a future for the aquatic ecosystems of the United States. In the late 1990s and early 2000s, U.S. Fish & Wildlife Service hatcheries delivered fish to area bodies of water, while fishermen followed or waited.

As the fish hatchery industry entered the 1990s, most were publicly owned. In 1990 Alaska's fishery enhancement division transferred the last of its commercially oriented hatcheries to private aquaculture associations. Remaining government-owned hatcheries refocused their efforts toward producing fish for sportsmen and enhancing fish populations in rural areas in which they are depended on for subsistence. But the late 1990s and early 2000s saw increased hatchery activity and success. The NFHS integrated the work of fish hatcheries and fisheries management to procure more efficient national restoration programs such as those for Great Lakes lake trout, Atlantic Coast striped bass, Atlantic salmon, and Pacific salmon. In 2004, the NFHS included 70 fish hatcheries, seven fish technology centers, and nine fish health centers. The NFHS focuses their resources on restoring, maintaining, and recovering native and endangered fish populations. For example, Neosho National Fish Hatchery in Missouri began working to restore the pallid sturgeon population in the Missouri and Mississippi rivers in 2002 to offset the impact of dam construction, which had depleted the pallid sturgeon population. The NFHS also maintains the National Broodstock Program (which ensures the availability of disease-free eggs and larvae for various programs), evaluation of hatchery stocking programs and recreational fisheries, and developing and encouraging partnerships between governments and the private sector to provide greater opportunities for conserving and enhancing aquatic ecosystems.

According to a Washington Office Fish Hatchery Species report, roughly 170 million fish are distributed from hatcheries in the United States and more than 140 million eggs produced. Roughly 100 hatcheries operated in the Columbia River basin alone. Most of the fish distributed were cold-water species with Fall Chinook Salmon accounting for nearly half of the total cold-water distribution. A glut of Wild Chinook Salmon prompted the Oregon Department of Fish and Wildlife to halt fishing for hatchery salmon on the lower Columbia River in 2003 after efforts to boost salmon populations in the Columbia River basin had proven particularly effective between 2000 and 2002. Other leading cool-water species include Walleye and Northern Pike. Although warm-water species account for the least number of total fish, the group consists of 30 different species, twice as many as cold- and cool-water species. Leading warm-water species include striped bass, bluegill, largemouth bass, channel catfish, and American shad.

In the early 2000s, 45 states were involved in the distribution of fish and fish eggs from hatcheries. The state of Washington led the nation, responsible for roughly 25 percent of all distributed fish. California and Wisconsin were second and third, respectively. Illinois was the leading fish-egg producing state with Washington and Wisconsin following.

SIC 0971

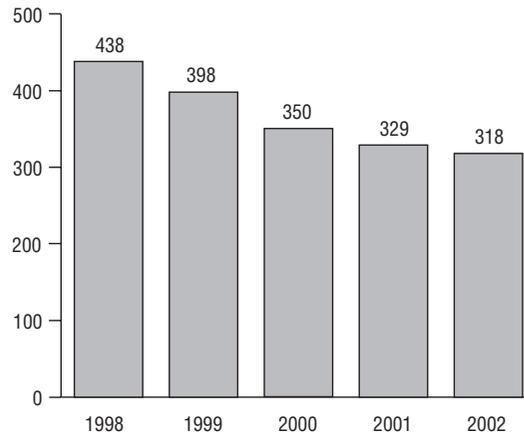

HUNTING AND TRAPPING AND GAME PROPAGATION

This category includes establishments primarily engaged in commercial hunting and trapping, or in the operation of game preserves.

NAICS CODE(S)

114210 (Hunting and Trapping)

Number of Mink Farms Between 1998 and 2002

SOURCE: U.S. Department of Agriculture, 2003

Despite a weak U.S. economy, fur sales in 2002 jumped 13.2 percent to \$1.7 billion due to increased sales in fur and fur-trimmed products made of sheared mink and beaver fur. Roughly 45 percent of fur retailers saw an upswing in store traffic in 2002.

Hunting and trapping are among the oldest industries in the United States. Trading in beaver pelts played a role in the western expansion of the United States. As areas became over exploited, the commercial trade moved further and further west. During the nineteenth century, there were few ordinances governing the taking of fur-bearing animals. As a result some species were threatened. One of the first animal management regulations regarded fur seals. Under the terms of the Alaska Convention of 1911, Japan, Russia, Canada, and the United States agreed to limit catches according to governmental rules. The resulting regulations enabled seal populations to recover and sustain themselves.

The twentieth century brought other regulations to the industry. Seasons for taking animals were open or closed based on the management needs of specific populations. Many jurisdictions instituted laws requiring trappers to check their traps at frequent intervals, usually every 24 hours. The Endangered Species Confiscation Act of 1969 listed animals "threatened with world-wide extinction" and prohibited trading in them.

During the 1960s and 1970s, the United States saw growing antagonism between members of the animal rights movement and trappers and hunters. Animal rights activists aimed their efforts at reducing demand for fur products, which resulted in price declines. Trappers and hunters responded by developing programs in conjunction with governmental regulators to manage populations

of wild animal stocks at sustainable levels and to seek more humane trapping techniques.

There are 23 fur-bearing species in the United States spread among all the states, except Hawaii. Of those 23, eight make up about 92 percent of the annual fur harvest. The species are, in descending order: muskrat, raccoon, opossum, nutria, beaver, coyote, mink, and gray and red fox (gray fox and red fox are often counted together).

Today, the U.S. fur industry is divided into two segments: "wild caught" and "ranch farmed." Wild-caught pelts account for the majority of U.S. fur production, but ranch-farmed pelts are worth much more and account for a larger percentage of annual sales. In 2004 roughly 200,000 trappers were registered in the United States. Mink pelt production in the United States in 2002 totaled 2.6 million pelts, down from the 1998 number of 2.94 million pelts. Wisconsin, the major mink producing state, produced 594,700 pelts in 2001. Total mink pelts produced in 2002 were valued at \$79.6 million, up from \$72.9 million in 1998, but down considerably from \$99.1 million in 1997. Mink farms in the United States totaled 318 in 2002. Utah operated 80 of these farms, while Wisconsin operated 69 and Minnesota operated 33. The two major American fur markets are in New York and Chicago, and there are more than 1,500 retail stores in the United States specializing in fur garments.

Most of the ranch farming in the United States involves mink, but a significant number of fox farms exist as well. A total of 20 mink farms also raised fox. Less than \$100 million in mink, or 95 percent of mink produced in the United States, is exported annually, which accounts for 10 percent of the world's mink supply.

Although hunting and trapping have traditionally involved taking animals for their pelts and skins, the 1990s and 2000s saw increases in other occupations within this classification. Experienced hunters and trappers turned to work as guides for hunting parties. Some trappers focused their efforts on catching animals for research or wildlife management programs. A growing specialty was the practice of capturing wild animals in urban areas so that they could be removed to other environments. Another component of this category is the game preserve, where game populations are controlled to provide a hunting experience for visitors.

MINING INDUSTRIES

SIC 1011

IRON ORES

This classification covers establishments primarily engaged in mining, beneficiating, or otherwise preparing iron ores and manganiferous ores valued chiefly for their iron content. This industry includes production of sinter and other agglomerates except those associated with blast furnace operations. Blast furnaces primarily engaged in producing pig iron from iron ore are classified in **SIC 3312: Steel Works, Blast Furnaces (Including Coke Ovens), and Rolling Mills**.

NAICS CODE(S)

212210 (Iron Ore Mining)

INDUSTRY SNAPSHOT

Virtually all of the iron ore mined in the world is used in steel making. In the United States, the largest producers are concentrated in a few states that account for the country's national output of usable iron ore. According to the U.S. Geological Survey, mines in Minnesota, Michigan, and three other states shipped about \$1.21 billion worth of usable iron ore in 2001, down from the \$1.56 billion shipped in 2000.

The U.S. iron ore industry is dependent on the domestic steel industry, most notably the large integrated steelworks along the Great Lakes. These integrated manufacturers use blast furnaces to turn iron ore, coke, and limestone into pig iron and then into steel.

High labor and fuel costs, declining ore grades, and the inland location of the country's mines make it difficult for the United States to compete in the world iron ore market. U.S. iron ore producers are meeting these de-

mands by making higher-quality fluxed iron ore pellets that can meet the tight chemical and physical specifications that are needed to make higher quality steels.

U.S. iron ore production decreased in the late 1990s in response to the Asian financial crisis that began in 1997, when Thailand devalued its currency and set off a chain reaction of devaluations in the region. Foreign producers, unable to find buyers for their steel products in their depressed regions, supplied low-cost exports to the United States, thereby decreasing the need for domestic iron ore. The situation did not improve during the first years of the 2000s. U.S. mine production of iron ore dropped 26.8 percent to 46.2 million metric tons in 2001, down from 63.1 million metric tons in 2000.

ORGANIZATION AND STRUCTURE

The United States maintained a close relationship with Canada in regard to iron ore trade. Over the course of the 1990s, the United States was a net importer to meet demands for iron ore. Since 1990 about 54 percent of U.S. imports have come from Canada, while 99 percent of U.S. exports went there. The reasons for the tight relationship included ownership and proximity. In 1998 Canadian steel mills owned part of three of the nine iron ore producers that accounted for 99.5 percent of the U.S. ore produced. Likewise, one U.S. iron ore company and one U.S. steelmaker had partial ownership of one of three iron ore producers in Canada. Also, the proximity of the countries and the location of the Great Lakes, which were used for transportation, meant lower shipping costs for each country.

The high-grade direct shipping ore of Michigan and Minnesota has all been mined in the United States. Lower-grade taconite, which requires the more expensive processes of beneficiation and pelletizing, makes up the bulk of U.S. mining today. Many of the pelletizing and

taconite mining facilities are in the interior of the country, forcing higher transportation rail costs to ship to the Mid-Atlantic and Alabama steelworks. Since these mines are far away from saltwater harbors, imported iron ore from Canada, Brazil, and Venezuela makes up a large portion of iron ore consumed on the East Coast.

For the inland steel-making region, those same high rail costs that keep U.S. iron ore from being competitive for use at coastal steelworks also act to keep foreign ores from being used in their region. The St. Lawrence Seaway is an inexpensive transportation route to the Great Lakes, but it can also become a bottleneck for iron ore carriers trying to supply the steelworks in this region. Some oceangoing iron ore carriers cannot enter the Great Lakes because of the short gate-to-gate river locks.

Similarly, U.S. iron ore bound for foreign shores on 1,000-foot ships cannot leave the locks. Ore often has to be off-loaded onto smaller gulf vessels or transferred to railcars at Philadelphia or Baltimore. Sometimes, to reach the many steelworks in the Pennsylvania and Ohio River Valley, iron ore is barged up the Mississippi River through the port of New Orleans.

A handful of states account for the country's national output of usable iron ore. Minnesota and Michigan are by far the largest providers of iron ore in the country. In 2001 Minnesota produced 33.8 million metric tons of ore, out of the 46.2 million metric tons in total U.S. production, while Michigan produced 12.8 million metric tons. Operations from other states accounted for less than 1 million metric ton.

BACKGROUND AND DEVELOPMENT

Making up 5 percent of Earth's crust, iron is the fourth most abundant rock-forming element. Iron ore is the primary source of iron for the world's iron and steel industries and is the cheapest and most widely used metal.

The first known use of iron ore from the United States was when several barrels of ore were shipped from Virginia and Maryland to England for testing in 1608. The ore was found to be of good quality, and an attempt was made to build an ironworks near Falling Creek, Virginia. An Indian raid in 1622 ended that early undertaking.

In 1645 Massachusetts became the first regular production site for iron ore in the colonies with the building of the Hammersmith ironworks just north of Boston. Other furnaces built in Rhode Island, New Jersey, and Connecticut soon followed. During the next 100 years, iron making spread southward and westward, with many new mines opening to meet the surging demand. By the beginning of the Revolutionary War, iron ore was mined

and smelted in 12 of the 13 colonies. Pennsylvania became the center of iron making.

By the 1840s the northeastern furnaces began to close because of a scarcity of charcoal and ore, but smelting in Tennessee, Missouri, Alabama, and Texas easily met the demand. In 1844 the discovery of the reserves contained in the Marquette Range in Michigan supplied new hard ores. Before the completion of the Sault Ste. Marie shipping canal in 1855, development of the industry in this region was slow, but with this new transportation route came further development of the Lake Superior region. By 1885 the Gogebic and Menominee Ranges of Michigan and Wisconsin began producing more than two million metric tons of ore, more than 20 times the volume produced in 1860. Smaller mines in New York, Tennessee, and the Mid-Atlantic states could not compete with the high grades and low water transportation costs of ore coming out of this region. Production from the Vermilion Range in the 1880s and the discovery of the Mesabi ores in the 1890s helped to close most of the Eastern mines in the United States by the turn of the century. Birmingham, Alabama, became a major iron ore center at this time.

Iron ore properties in the Lake Superior district were bought by steel companies, and small mines were consolidated into larger ones by the mergers of large mining companies. The structure of the iron ore industry today is a direct result of the consolidations that took place between 1893 and 1905.

In the 1950s hundreds of U.S. mines closed because of greater imports, the rising costs of underground mining in America, and depleted ores of higher grades. By 1981 some 15 mines accounted for 90 percent of America's iron ore production. Only five years later, increasing steel imports and two severe recessions reduced the number of iron ore mines from 15 to 10. The numbers were slightly up in 1991, when iron ore was produced by 20 companies operating 24 mines (23 open, 1 underground), 16 concentration plants, and 10 pelletizing plants. But by 1998 iron ore was being produced by only 12 complexes with 12 mines (11 open pit, 1 underground), 10 concentration plants, and 10 pelletizing plants. In 1998, 5 companies operating 9 mines produced 99.5 percent of the ore.

Electric arc furnace steel-making in the United States, which accounted for 43 percent of total steel-making in 1993 and does not use iron ore, is the technology most often used by minimills, the chief competition of integrated outfits. Minimills substitute metal and iron scrap for iron ore to melt in their furnaces and made great inroads into integrated steel's market share in the 1980s. The minimills, however, during the 1990s, were faced with 50 percent increases in scrap prices, and as a result they were forced to vertically integrate, sometimes taking on the cost structures of their larger integrated competi-

tors. But minimills remained strong competitors. Their share of the steel market, which stood at 15 percent in 1970, increased to more than 43 percent by 1997.

In the late 1990s, imports of low-priced steel plagued U.S. producers, especially following the Asian financial crisis that began in 1997. While the market picked up early in 1998, which had been looking like a good year with domestic iron ore production and consumption rates into the third quarter exceeding those of 1997, the rates dropped off at year-end because of record imports of low-priced steel. As a result, two of the seven iron ore producers in Minnesota's Mesabi iron range reduced production. Though U.S. steel consumption remained strong that year, a majority of that consumption was met by steel imports. The strength of the U.S. dollar against foreign currencies made imports cheaper. The Asian financial crisis also made imports more enticing. As Asian economies weakened, steel consumption in that region declined, and the area's producers looked to the U.S. market to sell their products. Throughout 1998 the United States imported vast amounts of inexpensive semifinished steel. These falling world export prices also hurt domestic steel producers.

CURRENT CONDITIONS

The U.S. steel industry accounts for 98 percent of iron ore consumption in the United States. Following a relatively strong performance during the 1990s, the iron ore industry stumbled in the early 2000s. In 2001 domestic iron ore mine production dropped from 2000's 63.1 million metric tons to 46.2 million metric tons, or 26.8 percent, of the 1,060 million metric tons produced worldwide. This amount represents the largest decline since 1982. Reported year-to-date total production in October 2002 of 42 million metric tons was slightly ahead of the previous year's October year-to-date total of 39.9 million metric tons.

The reported U.S. consumption of iron ore was 67 million metric tons, down significantly from 76.5 million metric tons consumed in 2000. The consumption of iron ore is directly related to the number of blast furnaces in use. Between 1992 and 2001, the number of active blast furnaces decreased every year but one, falling from 43 in operation in 1992 to 33 in use in 2001.

During 2001 some 13 companies produced iron ore, with 9 companies in Michigan and Minnesota accounting for 99 percent of production. Between 1990 and 2001, domestic suppliers provided 70 percent of U.S. demand. In 2001 domestic production supplied 60 percent of domestic U.S. demand. LTV Steel Mining Company in Minnesota was permanently closed, and Empire Mine in Michigan made a permanent reduction in production. The effect caused an approximately 15 percent decrease in production capabilities or 10 million metric tons per year.

No longer able to compete with low-priced imports, Pea Ridge Iron Ore Company in Missouri, the only active underground iron ore mine in the United States and one of the few in the world, also closed.

Consolidation of mining operations that began in 2000 continued in the following years. In 2001 approximately 50 countries produced iron ore, but the 7 largest producers provided more than 80 percent of the product, with no other country producing more than 5 percent.

Following the economic decline in the United States in early 2001, experts began predicting an upturn for 2002. However, the terrorist attacks of September 11, 2001, stymied all expectations for a quick recovery. At the end of that year, the iron ore industry had taken a major hit. Bankruptcy loomed for several companies, and others stopped production for weeks at a time. During 2002 the iron ore industry was still operating with a net loss of income, as expenses exceeded revenues.

By early 2003 industry leaders were once again looking hopefully to the future, as companies cut costs by employee reductions and scaling back unprofitable business segments. Analysts have also given a nod to an impending improvement in the steel industry that directly affects sales of iron ore. To return to profitability and compete with the increasing competitive international market, iron ore companies will continue to look for ways to cut costs and increase efficiency.

INDUSTRY LEADERS

In 2001 leading companies included Cleveland-Cliffs, with \$387.6 million in sales, and Oglebay Norton, with \$404.2 million, both based in Cleveland, Ohio. Other leaders included Rouge Steel, based in Eveleth, Minnesota, with \$923.5 million in sales; and Northshore Mining, of Silver Bay, Minnesota, with \$387.6 million.

WORKFORCE

In 1996 most iron ore mine workers were union members of the United Steelworkers of America. For decades, up until 1983, union contracts often included generous increases in wages and benefits. But the 1982 recession, subsequent large layoffs, and the need to reduce operating costs brought about new working relationships between the unions and company management. Reductions in real wages, more flexible work rules, and management/labor cooperation were more the norm in the late 1990s.

Mines also began offering incentive bonus plans. In 1997 some 55 metal mines had incentive bonus plans, and in the 1990s, the number of mines offering bonuses rose 37 percent. Bonuses were awarded generally for productivity, safety, profit, attendance, commodity price, and/or meeting sales goals. According to a 1998 study by Western Mine Engineering, the most common bonuses

were fixed bonuses awarded for having a specific period accident-free, according to a report in *American Metal Market*.

Total employment in 2001 was 7,920, down from 11,103 in 1997 and reaching close to the low of approximately 7,000 total employment in the late 1980s. The industry's peak had occurred in 1953 with a total workforce of 40,100. Average hourly wages were \$20.81 in 2001, according to the U.S. Department of Labor's Bureau of Statistics.

AMERICA AND THE WORLD

In 2001 world iron ore production was at 1,060 million metric tons, slightly down from the 1,080 million metric tons produced in 2000, which was a new record for world production. World iron ore production was expected to increase to 1,240 million metric tons by 2006, according to Sydney, Australia-based AME Mineral Economics.

China was the world's largest producer of iron ore with an estimated output of 220 million metric tons in 2001, but China's iron ore is a low-grade product, so the metal content from the ore is substantially lower than other producers. Brazil and Australia rank first and second in production of usable ore, mining 210 million metric tons and 181 million metric tons respectively in 2001.

India also experienced dramatically increased output during the 1990s. In 2001 India produced 79.2 million metric tons, up 10 million metric tons in just four years. Russia and the Ukraine both produced more than the United States in 2001, reporting 86.6 million metric tons and 54.7 million metric tons respectively. The United States ranks seventh in the global production of iron ore.

The United States produced 4 percent of the world's iron ore in 2001, continuing a steady downward trend from its 11.9 percent world market share in 1970. Imports for consumption in 2001 decreased to an estimated 10.7 million metric tons from 1994's level of 17.5, reflecting the lack of demand. Imports of iron ore had reached their peak of 48.8 million metric tons in 1974. Exports for 2001 stood at an estimated 5.6 million metric tons, down from the previous four-year average of 6.1 million metric tons.

World resources were estimated to exceed 800 billion tons of crude ore containing more than 230 billion tons of iron, with U.S. resources estimated at about 110 billion tons of ore containing 27 billion tons of iron. U.S. resources, however, were mainly low-grade taconite-type ores that required beneficiation and agglomeration for commercial use.

RESEARCH AND TECHNOLOGY

Technological advances during the 1990s affected the structure of the iron ore industry in the United States. Many of the integrated steelworks began using fluxed pellets, which were created by adding fluxstone, limestone, and/or dolomite to the iron ore during the balling stage. A more reducible type of iron ore pellet was thus created. In 1990 U.S. production of fluxed pellets made up 39 percent of total iron ore pellet production. In many cases, integrated steelworks were trying to meet the growing fluxed pellet demand.

In the late 1990s, stricter environmental regulations restricting coke oven gas emissions closed some older integrated facilities. But ultimately the closures forced the development of new technologies for those firms providing alternatives to scrap. With the closures, companies became concerned about the availability of low-residue scrap and invested in alternative iron-making technologies. Direct-reduced iron (DRI) is an alternative to scrap. During the 1990s DRI production grew rapidly. Then, responding to the same market conditions as the whole iron ore industry, DRI production dropped dramatically during 2001. Production is expected to return to its growth pattern, when the steel industry regains strength.

SIC 1021**COPPER ORES**

This category includes establishments primarily engaged in mining, milling, or otherwise preparing copper ores. This industry also includes establishments primarily engaged in the recovery of copper concentrates by precipitation and leaching of copper ore.

NAICS CODE(S)

212234 (Copper Ore and Nickel Ore Mining)

INDUSTRY SNAPSHOT

A global commodity business, copper mining and milling is subject to swings in both prices and production levels, depending on world markets and individual companies' operating strategies. World demand for copper has grown steadily since the late 1970s, but in the late 1990s ambitious copper producers, including many located in Chile, the world's largest copper-producing country, ramped up new mining capacity faster than the market could absorb their production. In addition, economic weakness in Asia and Latin America in the late 1990s left global demand growth at a slower pace than some producers anticipated.

As a result, copper supplies ran heavy, and copper prices slumped by as much as 50 percent in the latter half of the 1990s, especially during 1998 and 1999, reaching Great Depression-era levels when adjusted for inflation. Soft prices decimated copper companies' profits and triggered a frantic round of consolidation among major producers. Continuing into the 2000s, soft prices, weak demand, and rising inventories remained problematic for the industry.

The United States is the world's second largest copper producer and a net importer of copper, obtaining a record 37 percent of refined copper from abroad at the turn of the twenty-first century. In 2000 U.S. mines turned out 1.44 million metric tons of recoverable copper valued at \$2.8 billion or approximately 11 percent of world production of 13.2 million metric tons. The U.S. Geological Survey estimated net U.S. consumption of unmanufactured copper materials in 2000 at more than 3 million metric tons along with 1 million metric tons of copper recovered from copper-base scrap.

ORGANIZATION AND STRUCTURE

Stages of Production. Copper extraction and processing involves several stages, which vary with the kind of ore and technology being used. Integrated producers are involved in all stages, including ones that are considered outside the scope of this industry classification. Also, because copper ores are recovered along with a variety of

other useful minerals, most copper-mining companies also have side businesses to handle other metals, such as gold, silver, and molybdenum.

Copper ore, which may be mined underground or, more commonly, at the surface in an open pit, is unearthed with digging equipment or explosive devices. The material is then transported by conveyor or by truck to a mill or plant, often on site, that crushes and grinds the ore into a powder.

In the next step, called concentrating, the powder is mixed with water and chemicals, which cause copper sulfide ores to float to the top, where they may be separated from some of the other minerals. Once the copper is skimmed, the copper mix, or concentrate, may be piped as slurry to another site for additional processing, or it may be dried and transported via truck or ship.

Meanwhile, the leftover liquid, known as tailings, can be processed further for copper oxide ores and other useful minerals. This material can be broken down further by treating with acid, known as leaching, and applying one of several methods to separate the copper from other substances.

Concentrate must be purified and refined before it yields copper that is ready for manufacturing applications. While for classification purposes this advanced processing is the domain of **SIC 3331: Primary Smelting and Refining of Copper**, in practice many of the major copper-mining firms are involved to some degree in these activities. Many mines have smelters or refineries on site.

Copper Sales and Markets. Large copper producers typically sell their products in two ways: by contract and on-the-spot markets. Contracts are usually for one to three years and may involve selling copper ores or concentrates at various points in the production process, depending on the client's needs and capabilities. While many manufacturers require copper in a state that's ready to go directly into their products, and thus purchase it as refined cathode, rod, or wire, others buy concentrate and do their own smelting, refining, shaping, and so forth.

Copper is also sold on the open market. Major world markets, such as the London Metal Exchange, provide a large and efficient medium for financial transactions relating to the copper trade. Transactions may take the form of spot contracts, in which the parties arrange for the physical transfer of copper or futures/options contracts, which are market instruments that enable financial hedging against adverse price movements, but no physical exchange occurs. A variety of copper trading firms and brokerages also act as intermediaries for bringing together buyers and sellers.

Copper Use by Sector. According to the U.S. Geological Survey, building construction uses the largest share of copper in the United States, representing 39 percent of consumption in 2001. Single-family homes in the United States use an average of 422 pounds of copper in their construction. Copper products are used in a variety of building construction materials, and they hold a 92-percent market share of electrical wiring in building (8 percent aluminum). Plumbing and heating components are the second largest building industry use of copper, but this sector faces increasing competition from improved plastic materials.

Electric and electronic products accounted for 28 percent of copper consumption. Copper's electrical conductivity properties enable it to be widely used for telephone and power lines. Other notable sectors that consume copper include transportation equipment, industrial machinery and equipment, and consumer products, each accounting for 11 percent of the market share. Cars, trucks, and vans use copper in their electrical systems and have been increasing their use of copper—about 56 pounds were used per car in 1998, as opposed to 30 pounds in 1981. The popularity of larger models, like sport-utility vehicles, and the growth of electronic features in cars have contributed to copper's success in the transportation sector.

The greatest opportunities for increasing copper sales include new home wiring as well as retrofitting existing homes with up-to-date wiring for digital and cable capacities. Copper, which tends to be more expensive than other materials, boasts excellent energy efficiency, reliability, and strength.

Copper Production. The United States has two major copper-producing regions: the Butte district of Montana and a region composed of Arizona, New Mexico, Utah, and Nevada. In 2000 just 14 U.S. mines supplied more than 99 percent of national copper output. Arizona is the largest copper-producing state, generating 64 percent of the total U.S. output as of 2000.

Copper is a relatively homogeneous product. Copper mined and processed in Arizona is in essence the same as copper mined and processed in Chile. Therefore, success in the copper industry depends on keeping production costs low compared to market prices. Major production costs for U.S. producers include labor costs, environmental regulations, and energy costs. New technical processes have also been central to keeping costs down.

BACKGROUND AND DEVELOPMENT

Copper has been mined since ancient times. The Egyptians, for example, mined copper 5,000 years ago. In the United States, significant copper mining began in 1845, when the Pittsburgh and Boston Company started a

mine in Michigan's Upper Peninsula. According to Hildebrand and Mangum, there were 25 mining companies located in the Upper Peninsula by 1850. The Calumet and Hecla Mining Company, founded in 1870, quickly became a dominant copper producer. Michigan's Upper Peninsula was the only significant copper-producing region during this period. In the late 1870s, Butte, Montana, experienced a mining bonanza. The copper mines in Butte were the largest underground copper source ever found. The vast Western copper deposits eventually eclipsed the original Michigan mining operations.

Technological innovations changed the nature of copper mining. The early mines were underground operations. Innovations like nitroglycerin, power drills, electric power, and steam shovels increased the productivity of copper mining. Eventually massive open-pit operations replaced underground mines. Milling and smelting technology also improved.

The industry eventually recognized that economies of scale were the key to efficient and profitable copper mining. Hildebrand and Mangum point out that this major innovation resulted from a combination of smaller technological breakthroughs like gravity separation, the Chilean mill (for grinding separated ore), and the steam shovel. In addition, copper mining companies eventually recognized that large initial fixed costs became insignificant, when a copper mine produced a huge output. Following World War II, massive open-pit mining and the consolidation of large integrated companies became the norm in the industry. By the 1990s the U.S. copper industry, dominated by a handful of industry leaders, was the world's second largest copper producer.

With copper prices at historic lows in the late 1990s, a wave of consolidation swept through the U.S. industry, highlighted by several prominent shutdowns and mergers. Australia-based Broken Hill Proprietary, operating as BHP Copper Co. in the United States, had closed all of its U.S. copper operations by 1999, after acquiring them in its ill-timed purchase of Magma Copper Co. just four years earlier. BHP's mines had produced around 10 percent of U.S. copper output, but the company was not one of the low-cost producers and was hit especially hard when copper prices plummeted. Other companies closed individual mines in an effort to cut their losses and ease the glut of copper on the market.

Mergers have been another legacy of rock-bottom copper prices. In 1999 Asarco Inc. and Cyprus Amax Minerals Company began merger talks to form what would have been the world's second largest copper company. The parties estimated that a merger would save some \$200 million a year in operating costs between the two. Then, in a surprise move, the largest U.S. copper firm, Phelps Dodge, made bids for both Asarco and

Cyprus, proposing a three-way merger that would have created the world's largest copper concern. The targeted firms, however, balked at Phelps Dodge's offer on grounds that it was too little and shortchanged their shareholders. While executives at Asarco and Cyprus were determined to fend off Phelps' overtures, some shareholders of the respective companies opposed the Asarco-Cyprus deal. Meanwhile, Phelps continued to make its case aggressively, threatening a lawsuit and a proxy battle and, eventually, increasing its offering price.

As relations between Asarco and Cyprus began to cool, a fourth company, Grupo Mexico S.A. de C.V., entered the fray. Grupo Mexico, a diversified mining company, offered to merge with Asarco at more attractive terms than either of the earlier offers. Phelps chose not to match the new offer. In the end, two mergers were inked: Phelps with Cyprus, and Asarco with Grupo Mexico.

The production cuts during this period of consolidation were expected to help shed the oversupply of copper, although certain producers outside the United States have proven more reluctant to curtail their output. Still, as demand revived in depressed areas like Asia, copper consumption was forecast to catch up with supply. After a devastating first six months of 1999, when copper averaged \$0.65 a pound, prices rebounded modestly in the latter part of the year, to the mid-70 cent range, after several of the closures had been announced.

CURRENT CONDITIONS

Domestic mine production continued a downward trend in 2000 with 1.44 million metric tons and in 2001 with 1.34 million metric tons, representing a 30 percent decrease since 1997. Despite the decline in copper production in the United States, world mining of copper increased by 2 percent in 2001. Although this represents a slowdown from the rapid expansion of copper mining activities during the 1990s, world copper consumption dropped by over 2 percent, thus contributing to the problem of surplus supply that has kept the price of copper depressed. U.S. production of copper is expected to continue to decrease.

Mergers and consolidation of the industry that began in the 1990s resulted in the emergence of three companies that produce over 95 percent of U.S. copper: Phelps Dodge, Inc., Asarco, Inc. (owned by Grupo Mexico S.A. de C.V.) and Kennecott Utah Copper Corp. (owned by Reno Tinto PLC of the United Kingdom). Falling prices, rising inventory, and decreased demand have prompted copper producers in the United States to cut back operations. Following the terrorist attacks of September 11, 2001, the already struggling industry responded by closing facilities and reducing production amounts. For example, Phelps Dodge closed two of its plants in 2002 and halved production in two others. Mine closings and re-

structuring continue to negatively affect the amount of copper production in the United States, as the full impact of the changes has yet to be realized.

INDUSTRY LEADERS

Phelps Dodge. With Cyprus Amax Minerals under its umbrella, Phelps Dodge Corporation is by far the largest copper producer in the United States and second largest in the world. The Phoenix-based company was founded in 1834 as a partnership between Anson Greene Phelps, William Dodge, and Daniel James. The company purchased two copper mines in the 1880s. By 1906 the company's copper mining and smelting operations had become so successful that it moved exclusively into the copper industry. Today, Phelps' Morenci mine, at Greenlee, Arizona, is the largest in the United States. Revenues from all Phelps operations totaled more than \$4 billion in 2001.

Grupo Mexico. Asarco was founded in 1899 by Henry Rogers and Adolph Lewisohn. Originally named the American Smelting and Refining Company, Asarco concerned itself primarily with copper, lead, and silver smelting and refining. By the 1990s Asarco had become a fully integrated copper mining and processing organization, producing an estimated 294,000 metric tons of copper in the United States during 1998. The company's consolidated revenues that year were approximately \$2.3 billion.

Grupo Mexico actually had historical ties to Asarco, originating as Asarco's Mexican operations and later taking the name Asarco Mexicana. The company gradually gained majority control of Mexican business concerns and grew through a series of mergers and acquisitions. In addition to its mining activities, Grupo Mexico operates two railroads by agreement with the Mexican government. Some observers speculated that Asarco's stake in a Peruvian mining company was a major reason for Grupo Mexico's bid for Asarco.

Rio Tinto PLC. Though not a U.S. based company, London-based Rio Tinto PLC is noteworthy within the U.S. copper industry both as the parent company to several U.S. copper concerns and as a major world copper producer. Its biggest U.S. holding is Kennecott Utah Copper, which operates Bingham Canyon, near Salt Lake City, one of the largest copper mines in the United States. The site also includes a major smelting and refining operation that can accommodate all of the mine's output. Among its other global interests, Rio Tinto has a 30 percent stake in Chile's Escondido mine, the world's largest copper mine. Rio Tinto likewise has a minority stake in Freeport-McMoRan Copper & Gold, a U.S.-based holding company with large copper operations in Indonesia.

WORKFORCE

The U.S. copper industry employed an average of 10,000 people in 2001, down slightly from 2000 and reflecting a general downward trend over the previous decade. The United Steelworkers Union represents most employees. Major occupations in the U.S. copper industry include mining managers, mining geologists, valuation engineers, mining engineers, design engineers, shift bosses, blasters, miners, and construction equipment operators. The mean hourly wage in 2001 was \$19.59, according to the U.S. Department of Labor's Bureau of Statistics.

AMERICA AND THE WORLD

Chile is the world's largest producer of copper, mining 35 percent of the world supply or 4.60 million metric tons of copper output in 2000. Chile's production increased by 85 percent from 1995 to 2000, and worldwide production of copper grew 3.5 percent in 2000 and 35 percent between 1995 and 2000. Having relinquished the role as the world's leading copper producer to Chile in the 1990s, the United States was the second largest producer in 2000 with 1.44 million metric tons. Based on U.S. Geological Survey statistics, other major producers in 2000 included Indonesia (1.01 million metric tons), Australia (829,000), Canada (634,000), Russia (570,000), and Peru (554,000). Kazakhstan, which increased production capabilities by more than 40 percent since 1996, produced 430,000 metric tons in 2000. In Chile and in other nations, government ownership of mines is commonplace.

RESEARCH AND TECHNOLOGY

A notable advance in copper mining technology is the solvent extraction-electrowinning (SX-EW) method of production. The SX-EW process involves saturating copper-bearing ores with sulfuric acid solutions. The sulfuric acid dissolves the copper and then recovers it by the electrowinning process, in which the dissolved copper is deposited onto charged cathodes. The process is significantly less expensive than traditional methods because it involves fewer steps. It also reduces air pollution control costs because it avoids the smelting process. Currently, only oxide and secondary sulfide ores can be processed with the SX-EW process. These ores are located close to the surface, where they have been exposed to oxygen. It is estimated that only 15 percent of world copper reserves and 13 percent of U.S. copper reserves can be processed via the SX-EW method. However, coupled with other new lower-cost processing methods, use of the SX-EW process can significantly reduce production costs, and thus large U.S. producers have been quick to adopt it.

SIC 1031

LEAD AND ZINC ORES

This category covers establishments primarily engaged in mining, milling, or other wise preparing lead ores, zinc ores, or lead-zinc ores.

NAICS CODE(S)

212231 (Lead Ore and Zinc Ore Mining)

INDUSTRY SNAPSHOT

According to the U.S. Department of the Interior, U.S. Geological Survey, lead and zinc account for 2 and 3 percent of U.S. nonferrous metals production, respectively. In 2004 approximately 22 establishments were engaged in the production of lead and zinc ores. A lack of capacity in zinc refinery production in the late 1990s and early 2000s resulted in increased exports of zinc concentrates from 531,000 metric tons in 1999 to 830,000 metric tons in 2003, as well as decreased imports of zinc metal from 1.06 million metric tons in 1999 to 780,000 metric tons in 2003. This situation is projected to continue in the United States through 2005.

The special properties of lead, especially its resistance to corrosion, make it extremely useful for nuclear insulation and applications such as X-ray protection. Zinc is also used in the production of nonferrous alloys and is useful as a corrosion inhibitor, especially as a protective coating on steel.

Although global zinc consumption increased 3 percent between 2001 and 2002, U.S. zinc consumption in the U.S. declined. Nevertheless, U.S. consumption continued to account for 13 percent of world consumption. Only China consumed more zinc than that United States in 2002. A total of seven companies operating in five U.S. states produced zinc in 2003; the value of zinc production that year reached \$664 million. Alaska, Missouri, and Tennessee accounted for 97 percent of U.S. zinc production, with the Red Dog Mine in Alaska accounting for 75 percent of that total.

Lead consumption declined roughly 2 percent between 2002 and 2003, while global demand increased 1 percent. Falling consumption in the United States was due in large part to diminished demand for lead by the battery industry. The value of mined lead in 2003 totaled \$435 million. Lead mining is located primarily in Missouri, Alaska, Idaho, and Montana. Ninety-seven percent of U.S. lead product was extracted from nine mines in Alaska and Missouri in 2003; Alaska accounted for about one-half of total U.S. lead production.

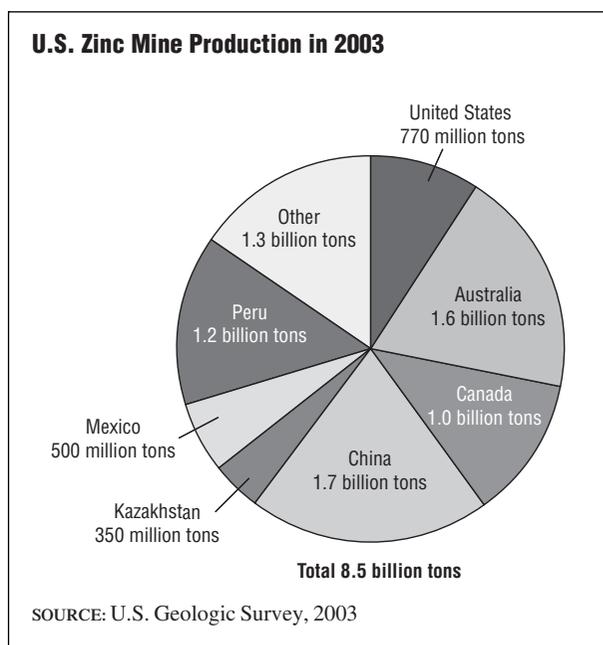

ORGANIZATION AND STRUCTURE

The lead and zinc industry consolidated operations gradually after production peaked in 1970: where 88 establishments existed in 1977, the number fell to 36 firms in 1996, and only 22 remained in 2003. Manufacturers of lead and zinc intermediate products for industrial use are the principal purchasers of lead and zinc.

BACKGROUND AND DEVELOPMENT

The mining of lead and zinc ores originated in Colorado in the early 1800s. The production of these base metals became closely intertwined because both were extracted from the same ores—although in different proportions. After recovery, lead and zinc are separated in the smelting process, whereby the ore is processed and reduced to a metal. Until the beginning of the twentieth century, lead and zinc production was strictly a U.S. affair, and before World War II, the United States was generally not dependent of foreign zinc suppliers. During most of that time, exports exceeded imports by a small margin. After World War II, the United States became a small net importer.

Zinc imports increased from 39,000 tons per year in 1939 to an average of 375,000 tons from 1946 to 1950 and 534,000 for the period from 1951 to 1953. The industry became heavily concentrated during this period, and by 1952 there were 912 lead and zinc mines in the United States, but only 193 of them accounted for 95 percent of the market. A few corporations dominated the industry, with ten companies controlling 65 percent of total U.S. lead output and ten companies controlling 62 percent of the zinc market. Of those corporations, seven

dominated in both groups. Control of the smelting market for zinc and lead ores was even more concentrated.

U.S. firms soon lost their competitive position internationally as the demand for lead and zinc expanded far faster than domestic production. Foreign producers expanded production and sent large quantities of their surpluses to the United States. The market shift coincided with the termination of price controls in the United States in 1946 and the suspension of import duties for several years following World War II. These tactics were needed because the war had depleted the country's stocks, yet demand from the U.S. government increased with the onset of the Korean War.

By the late 1960s imports of zinc exceeded domestic production by more than 50 percent, and domestic production of lead just barely exceeded imports in 1969. Secondary production of lead (essentially from scrap) overtook primary production, reaching more than one-half of total production in the late 1970s.

An overall downturn in lead and zinc mining began in 1970. By 1980 U.S. production of zinc fell to less than 10 percent of total world production, and Soviet and Japanese companies accounted for much of the world market. Total production indexes for the industry as a whole reveal a decline of nearly one-half from 1970 to 1986. During the 1980s lead production declined by more than 10 percent, but zinc production increased by more than 50 percent. The loss of several key markets for lead, including the abandonment of lead as an anti-knocking additive to gasoline and the discontinued use of lead as an insulator in water pipes, contributed to lower demand beginning in the 1970s. The use of lead in

products that might come into contact with humans (such as paints and pipes) was gradually curtailed because of the risk of lead poisoning, and studies suggested that exposure to lead impaired brain development in children. The U.S. Bureau of Mines projected that annual lead demand to fall at a rate of 0.5 percent to 1.5 percent per year in the 1990s.

Tariffs on zinc were phased out gradually as part of the U.S.-Canada Free Trade Agreement of 1989. That situation, combined with the rollback of world trade barriers, encouraged competition on the part Mexican and Peruvian zinc products to seek duty-free markets in the United States. Finally, after the fall of the Soviet Union in 1989, lead and zinc from its former member states flooded the world market, putting downward pressure on prices. The Bureau of Mines estimated world reserve base of zinc at 400 million tons and reserves at 150 million tons, with the United States having the largest reserves. The world reserve base was approximately 120 million tons at the end of 1995.

A series of circumstances caused lead and zinc prices to fluctuate in the early 1990s. Initially, a strike at Doe Run Company, one of the country's primary producers, created a decline in production; but a subsequent strike at the Trail smelter in Canada led to price increases. Later, in 1996, Doe Run experienced a loss of an estimated 5,400 metric tons of lead production as the result of a shutdown for a furnace repair at a secondary lead smelter in Boss, Missouri. Around that same time ASARCO, Incorporated announced the indefinite closing of its Leadville, Colorado zinc-lead-silver mine but reversed that decision in early 1997 and resumed full production. Zinc prices, which had dropped during 1996, turned steadily upward in early 1997 as the U.S. economy began to recover from an earlier recession, and consumption rose by 8 percent.

CURRENT CONDITIONS

Lead. The primary demand for lead in 2003 resulted from growing demand for rechargeable automobile batteries. In fact the transportation industry accounted for 76 percent of U.S. lead consumption in the early 2000s. Additionally, lead-acid storage batteries served as the primary component in uninterruptible power supplies for computer backup systems, a market projected to increase particularly in China. Use of lead shielding for protection from X-ray exposure and lead glass for computer displays and television tubes also contributed to increased demand. The expansion of the secondary (recycled) lead supply—70 percent of total production—combined with improved methods for primary production contributed to a market surplus in the late 1990s. However, by the early 2000s, decreased production at smelters and refineries in the United States, as well as in Europe and Australia,

prompted the International Lead and Zinc Study Group to forecast a balanced supply and demand of lead in 2003.

Zinc. The properties of zinc as a corrosion inhibitor make it valuable for the galvanizing process, and the rubber industry uses zinc oxide in making white paint and pigments. In the early 2000s, low interest rates fueled new home construction in the U.S., which boosted zinc consumption by industries such as construction that use galvanized steel extensively. In fact, this industry proved to be the only consistent U.S. market for zinc in the early 2000s. Although worldwide zinc consumption increased by 3 percent in 2002, weak domestic demand prompted seven zinc mines in the United States to shutter operations in 2001. As a result, zinc production in 2002 declined by 7 percent.

INDUSTRY LEADERS

Nearly all of the leading companies in the industry engage also in other types of metals mining. ASARCO Incorporated of New York is a conglomerate with a major interest in copper as well as lead and zinc and the manufacturing of specialty chemicals. Sales in 2002 totaled \$514 million.

Doe Run Company of St. Louis, owned by New York's Renco Group, is also a major player in the industry. The company led the world in the production of primary lead at the turn of the twenty-first century. Also prominent is Teck Cominco Ltd., formed by the C\$1.5 billion merger between Canada-based Teck Corp. and Cominco Ltd. in 2001. Prior to the merger, Cominco had operated as parent company to Cominco Alaska, operators of Alaska's Red Dog Mine. Red Dog was the largest known zinc ore body worldwide at the close of the 1990s. The total zinc reserves at Red Dog were estimated at 138 million tons at end of 1995, with new deposits discovered in 1999. Total zinc and lead production at Red Dog was reported at 600,000 metric tons annually in 1999. As of 2003, Teck Cominco was the leading zinc producer in the world.

AMERICA AND THE WORLD

World prices for lead and zinc fell during the late 1990s as a result of Asian monetary crises and resultant slowdowns and outright stoppages of production in southeast Asia. The crisis, manifested most severely in Thailand, Malaysia, Korea, and Japan, caused significant reductions in the demand for metals. The countries affected by the crisis accounted collectively for 25 percent of world lead consumption and 30 percent of zinc. Earlier, in 1995, Japan and South Korea alone accounted for 22 percent and 21 percent respectively of U.S. lead and zinc ore exports. The emergence of China into the lead/zinc market just prior to the crisis contributed to an international product deficit in that market as a result of work

stoppage associated with the crisis. The situation was further aggravated when Canada, a major supplier to the United States, experienced a 3 percent reduction in zinc mine output in 1998. In 2002 zinc prices dropped to a 15-year low on the London Metal Exchange.

In 1999 the Asturiana del Zinc in Spain prepared to increase operations by 37 percent, to become the second largest producer of zinc worldwide. Zinc production in Australia, Canada, China, Mexico, and Peru increased between 2002 and 2003, as did lead production in Australia, China, Peru, and Sweden over the same time period.

SIC 1041

GOLD ORES

This category covers establishments primarily engaged in mining gold ores from lode deposits or in the recovery of gold from placer deposits by any method. In addition to ore dressing methods, such as crushing, grinding, gravity concentration, and froth flotation, this industry includes amalgamation, cyanidation, and the production of bullion at the mine, mill, or dredge site.

NAICS CODE(S)

212221 (Gold Ore Mining)

INDUSTRY SNAPSHOT

Mined on every continent except Antarctica, gold is used for a wide variety of applications ranging from jewelry and the arts to dentistry, electronics, and diverse industrial applications. In 2001 U.S. gold mine production was valued at approximately \$2.9 billion. Of that, jewelry and other art-related pursuits accounted for 89 percent of U.S. gold consumption, dental use for 7 percent, and electronics for 4 percent, according to statistics from the U.S. Geological Survey. As a precious metal, gold is traditionally used as a backing for paper currency systems and as a hedge against inflation. Of all the gold produced by the United States in 2001, almost 99 percent came from 30 mines.

An estimated 100,000 tons of gold make up the world's resources, according to the U.S. Geological Survey. South Africa has one half of this total. Brazil and the United States each have 9 percent. Other major producers include Australia, Canada, Russia, and China. Of the 120,000 tons of total mined gold, approximately 33,000 tons are held by central banks as official stocks. The remaining 87,000 are held privately as coin, bullion, and jewelry.

BACKGROUND AND DEVELOPMENT

A Shining Past. Its sparkling character, beautiful hue, and unique metallurgical properties—including resistance to tarnishing and corrosion, and virtual indestructibility—have set gold on the throne of coveted precious metals since early history. Ancient Egyptian, Minoan, Assyrian, and Etruscan artists produced elaborate gold artifacts as early as 3000 B.C. As increasingly complex economic systems evolved, gold was used as a high-denomination currency and eventually as a backing for paper-currency systems.

The Source. Naturally occurring gold is dispersed throughout the earth's crust and is usually combined with other elements such as silver, copper, platinum, and palladium. In addition, small amounts of gold are usually recovered as a by-product in the refining of such base metals as copper and lead. Gold ores, large and rare masses of rock that are very rich in the metal, are usually quartz lodes (also called veins) or deposits that fed off of river bed gravel or quartz conglomerate beds (termed blankets or reefs). One of the best-known reefs is the South African Witwatersrand system in the Transvaal and Orange Free States. Though gold occasionally appears in rock formations as visible flakes, grains, or nuggets, it remains for the most part invisible until separated from ore and refined. The principal ores are calaverite, a telluride (containing tellurium) containing 40 percent gold, and sylvanite, a mixture containing 28 percent gold and variable amounts of silver.

Mining History. Ancient Near Eastern civilizations made profitable use of gold culled from alluvial deposits in and along streams. Egyptian monuments dating back to the first dynasty (c. 3100 to c. 2890 B.C.) depicted the washing of gold ores. Gold deposits were also exploited throughout regions including the Aegean, Libya, Persia (later Iran), India, and China. By the Middle Ages in Europe, gold was mined in Saxony and Austria and, to a lesser extent, Spain.

With the European colonization of the Americas in the sixteenth century, gold production reached unprecedented levels, as output from mines worked by slaves was supplemented by hoards taken from native palaces, temples, and burial sites. Well into the seventeenth and eighteenth centuries, South American mines accounted for

the majority of world gold production. In the early nineteenth century, massive deposits were uncovered in Russia, making it a world leader in gold mining from the 1820s to the late 1830s.

The discovery of gold in California and Australia in the mid-nineteenth century brought a veritable explosion of gold production. Prospectors flocked to California to participate in the gold rush of 1849, earning themselves the name “49ers.” From 1890 to 1915, world production of gold jumped again, with major developments in Alaska, Yukon Territory, and South Africa, as well as Canada in the 1920s. In the early twenty-first century, primary production of gold was carried out in South Africa, Australia, Brazil, Canada, the United States, and several republics of the former Soviet Union, now the Commonwealth of Independent States (C.I.S.). Although gold markets became increasingly convoluted, steady advances in mining and refining technology—such as the development of the heap-leach process in the mid-1980s—continued to increase efficiency and permit mining of less accessible and lower-grade ores.

Mining. Gold is recovered by three basic mining methods: placer mining of alluvial deposits, lode or vein mining, and recovery as a by-product of base-metal mining. In placer mining, the oldest method, the high-density gold is separated from the lighter, siliceous material (called the matrix or gangue) in which it is found. Though the basic principles of placer mining are essentially the same, methods of varying sophistication were developed according to the scale of particular mining operations and the types of terrain exploited. The simplest method of placer mining, practiced by the individual miners in the great American gold strikes of the nineteenth century, was panning—a technique by which several handfuls of siliceous material were placed in a pan or batea (a wooden bowl for washing gold that was commonly used in Mexico) and repeatedly washed with large amounts of water until the denser materials, including gold, were left at the center of the pan. To “sift” greater amounts of material, cradles (also called rockers) were developed in which material was “rocked” with the aid of water, and dense materials were collected in riffle. Pieces of wood or iron were perpendicularly attached to the bottom and sides of the cradle.

Several other large-scale placer methods are used as well. In hydraulic mining, powerful jets of water are directed at thick beds of gravel to break them down and wash the residue through lines of sluices designed to separate gold particles. The subsequent discarding of large amounts of residue into adjacent rivers and farmlands, however, resulted in injunctions in America that limited the practice after 1880. Large-scale placer mining continued to develop, however, with the late nineteenth-century invention of the gold-mining dredge in New

Zealand. Originally used in the rivers of New Zealand, California, and Russia, the dredge technique later evolved into the paddock dredge, developed in the western United States. Here, this technique replaced the need for riverbeds by starting with a dredging pond and continuously shifting the pond by redistributing mining wastes and tailings, as the dredge moved across a designated terrain.

In addition to placer techniques, methods for underground mining of gold lode or vein deposits closely resemble the pit- and shaft-mining methods used for other metals and minerals. In general, a vertical shaft was sunk to gain access to lodes, often at great depths, by designing stopes—underground excavations wherein ore-bearing materials are produced—suitable to specific sites. The basic sequence of activities constituting the mining cycle is as follows: rock breaking (drilling and blasting); mucking (loading); and transporting (hauling and hoisting).

Recovery. After ore is mined, its gold content must be recovered by one or several techniques that vary according to the type and amount of ore. The process of amalgamation, in use since the mid-nineteenth century, applies the principle that gold particles wetted by mercury adhere to each other and to copper plates coated with mercury. Amalgamation remained a commonly used technique for bulk recovery of gold, even as other, more efficient methods evolved.

One such method, the cyanide process, was introduced in South Africa in 1890 and became the industry norm. The process depends on a series of chemical reactions to flux off (remove by heating) base metals contained in the gold ore. Finely ground ore is first treated with dilute solution of sodium cyanide (or calcium cyanide with lime and natural oxygen), yielding a water solution of gold cyanide and sodium cyanoaurite. After being deoxygenated, the mixture was mixed with zinc dust to precipitate the gold and other metals dissolved by the cyanide. The precipitate is then treated with sulfuric acid to remove residual zinc and copper before it is again washed, dried, and melted with fluxes to dissolve any remaining copper, and to fuse gold and silver. The end result, a mixture of gold and silver called dore, is then cast in preparation for assaying (a complex process for determining purity).

The 1980s saw the development of heap leaching, a low-cost technique for recovering gold from low-grade ores, mining waste, or milling tailings, which has resulted in large new supplies of gold. The ore is crushed and “heaped” on large pads, where a process of sprinkling cyanide acid solution leaches the gold in bulk.

Refining. After dore is recovered from ore, various refining processes are then applied to produce gold metal

ready for the market. Two common methods are the Wohlwill process and the Miller process. The Wohlwill process uses direct and alternating currents to electrolyze dore gold in a chloride solution. Gold on the dore anode dissolves and accrues to the cathode, yielding gold of at least 99.95 percent purity. The silver is converted into chloride, while platinum or palladium in the anode dissolves and has to be recovered by further treating the electrolyte. The alternative Miller process is often preferred because of its faster rate of production. Chlorine is bubbled through molten dore, converting the metals into chlorides. Although the purity of gold refined by this method—at least 99.5 percent pure—falls slightly below that of the Wohlwill process, a faster rate of production makes it the preference for most refiners.

Price. After gold peaked in 1987 at \$500 an ounce, the industry was characterized as being on a downtrend that continued into the late 1990s. Worldwide deflationary forces—including stagnant economic growth, tepid money supply growth, and weak commodity prices—threatened to continue dampening new gold prices. Gold prices in 1998 were \$295.24 per troy ounce, well below the \$370 per ounce of 1996.

Declining prices curtailed worldwide exploration spending, which in turn diminished the prospects of new mine supply. In addition, the combination of lower prices and rising production costs precipitated cutbacks at many mines and the closure of numerous others. Production costs in the mid-1990s were estimated at somewhere around \$200 per troy ounce. With many companies implementing cost-saving measures, in 1992, average Western world cash and total costs were reduced by 5 percent to \$247 per ounce, and 4 percent to \$300 per ounce, respectively.

Speculative Demand and World Events. The key swing factor for gold prices has traditionally been speculative demand, arising from the role of gold as a hedge against inflation and backing for currency. Adverse conditions in developed countries intensified deflationary forces in the early 1990s, placing significant downward pressure on gold prices, as recession extended from U.S. to German and Japanese economies by 1992. World events apart from economics, particularly war and political turmoil, also traditionally spur gold price fluctuations, even events in countries thought not to impact industrialized nations.

Money Supply and Gold Speculation. Another key factor in the early 1990s was the indirect effect of money supply growth on gold speculation. Riding on the heels of runaway debt built up in the 1980s, the monetary climate of the early 1990s was characterized by general bank resistance to lending and by wariness or inability of companies and consumers to borrow. By 1992, growth of

the M-2 money supply hovered at 1.6 percent, the lowest in over 30 years. (The M-2 money supply includes the current supply of cash, travelers checks, checking accounts, and savings deposits of \$100,000 or less, and is slightly less liquid than the M-1 supply of money.) According to Standard & Poor's, such a slow rate of money supply growth tended to favor deflation, which in turn, dampened speculation in gold.

Among industrialized nations, a notable exception to stagnant money growth was Germany, which took measures to counteract excessive money supply growth and inflation in 1992, and ended up sending shock waves through European currency markets. After the Bundesbank raised its discount rate in mid-July 1992 to 8.75 percent, the highest since 1931, other countries in the European Monetary System (EMS) were forced to raise their rates to maintain the value of their currencies vis-à-vis the deutsche mark. Artificially high interest rates spurred deflationary measures throughout Europe. Nevertheless, European currency did not stabilize, and the European Monetary System's exchange rate mechanism (ERM) was rocked by turmoil (the Spanish peseta was devalued by 5 percent, and the pound and lira were suspended from ERM to find their own levels in the market).

Given the depth of the European currency crisis, the dollar gold price underwent little change, partly because investors' "flight" funds were largely channeled into the U.S. dollar itself, not its gold equivalent, and partly because foreign exporters kept their dollar-denominated prices steady, at the expense of profit margins, in an attempt to maintain market share in the United States.

Both China and Brazil asserted intentions to gain better control over their national gold industries. The Chinese government in mid-1994 announced intentions to shut down unauthorized markets and give the nation's central bank control of all aspects of gold production and trading; by 1999 China had increased its gold production and mining efficiency. Brazil similarly gained a better grasp of production in the Amazon.

The Official Sector. Constituted by central banks and government agencies, the official sector drew much discussion over the role and influence of its gold holdings. For the better part of the 1980s, official sector institutions were net buyers of gold, becoming marginally net buyers by 1990. Turmoil in the ERM played an additional role in highlighting the importance of reserve liquidity insured by the sales. Influxes of gold to the market by European bank sales in 1992 and again in 1999 and 2000 were not as damaging as many analysts anticipated. Unexpectedly high demand for jewelry fabrication absorbed a good deal, and a significant portion of the Dutch sale circumvented the market to land in several Asian central banks.

Forward Selling. Adapting to the pressure of low prices, many producers received prices much higher than the spot price “fixed” in London by forward selling their gold. By agreeing to deliver gold at a specified future date and price, producers obtained a premium to the spot market price and also hedged against market decline. In late April 1992, North America’s leading gold producer, Newmont Mining, prepaid at \$336 an ounce all remaining 375,000 ounces of a 5-year, 1-million-ounce gold loan for a gain of roughly \$40 million. While many analysts hailed the transaction as establishing a new bottom for the gold market, Standard & Poor’s projected that most producers, forbidden by higher production costs to gamble on future gold prices, would continue to sell at available rallies, contributing to declining prices. In the 1990s fewer companies would make profits by forward selling their production.

Supply. Although Canada, western Europe, the Philippines, and several Latin American countries saw declines in production for 1992, overall world mine production in the early 1990s was sustained by increased output from the three largest producers (South Africa, the United States, and Australia) and such key developing countries as Indonesia, Papua New Guinea, Ghana, and Chile. Consequently, Western world gold production rose by almost 4 percent to 1,841 tons in 1992. Throughout the early 1990s the average world mine production had been about 66 million troy ounces.

Starting in 1991, the dramatic upheavals in the former Soviet Union also contributed to surges in market supplies of gold, as stocks were sold for desperately needed foreign currency. The ability of Russian mines to sustain increased levels of production remained a topic of debate into the mid-1990s. The former Soviet Union produced 12 percent of the world’s gold in 1993. Despite record production levels in 1992, the rate of production growth declined as compared to Western world production increases of 128 metric tons and 51 metric tons in 1989 and 1990, respectively. Many analysts cited diminished increases in production as a sign that mine supply was reaching its peak. The Gold Institute, a trade organization based in Washington, D.C., projected that world gold mine output would eventually taper off.

In 1997 a total of 301 establishments in the industry had sales of \$3.95 billion. The United States imported 257,000 kilograms of bullion and 2,540 kilograms of gold ores and concentrates for consumption in 1998. Conversely, the United States exported 430,000 kilograms of bullion and 401 kilograms of ores and concentrates.

Environmental Issues. The gold ore industry responded on numerous fronts to the environmental concerns of the 1980s and 1990s. Such issues as wastewater,

waste disposal, and land reclamation placed additional planning and economic pressures on mining companies, prompting many to seek development in other countries with less stringent regulations. Three environmental acts carried particular weight. Specifically, the Resource Conservation and Recovery Act (RCRA) required mine owners to comply with terms of the National Pollutant Discharge Elimination System (NPDES), which called for the monitoring and testing of water runoff. The American Mining Congress challenged the rule but was overridden in a 1992 court decision.

Tensions between mining and environmental interests were epitomized in *Colorado v. Idarado Mining Co.*, decided in February of 1989 by a U.S. District Court in Colorado. Pursuant to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), a proposal calling for a 50-cent-per-pound tax on sodium cyanide used in gold mining was considered. These and other environmental issues put the gold ore industry on guard, as it moved into the twenty-first century.

Amending the 1872 Mining Law. From the late 1980s onward, both Houses of Congress focused considerable attention on measures aimed at reforming the 1872 Mining Law governing use of federal lands by mining companies, with emphasis on increasing revenues for leasing or sales of mineral-rich government lands and on environmental protection standards for mining of such lands. Specific controversy revolved around the fee required to patent a claim on federal land; still at \$5 per acre in 1993, critics argued that the country was consequently losing out on the exploitation of precious natural resources. Many experts and mining executives, on the other hand, feared proposed royalty payments of 8.0 to 12.5 percent would adversely affect the gold mining industry. An economic impact study by Evans Economics indicated that an 8 percent royalty on hard-rock mining would cut into U.S. gold and silver mining by 26 and 7 percent, respectively, over a 10-year period.

In the mid-1990s, both the House and the Senate passed bills that would eliminate the ability of mining companies to take title to valuable federal lands containing gold, silver, and other “hard rock” minerals for only a few dollars an acre.

CURRENT CONDITIONS

During 2001 domestic gold production fell by 5 percent to its lowest level since 1996. Domestic gold exploration expenditures declined, continuing a four-year downward trend. In 2000 spending on domestic gold exploration was \$183.4 million; in 2001 that total was cut by 42 percent, to \$107.2 million. The U.S. decline in gold exploration reflects an overall worldwide reduction in explorations expenditures, which fell by 22 percent in 2001. Low gold prices have kept exploration opportuni-

ties to a minimum, but analysts expect activities to increase in the near future, likely to be focused in Latin America.

The U.S. gold industry has been continuing to consolidate, as numerous mines are closed annually. Between 1999 and 2001, 33 U.S. mines ceased operations. An increase in per mine output has helped the United States retain its second-place world ranking for gold production. Larger companies, which continue to buy up smaller operations, are able to replace reserves with new production, whereas smaller companies are struggling to keep a balance of inflow and outflow.

During 2001 the price of gold ranged from a low of \$257 per troy ounce to a high of \$294 per troy ounce, with prices staying around \$270 per troy ounce most of the year. The terrorist attacks of September 11, 2001, helped boost the price of gold, as investors sought out gold as a traditional store of value. According to the World Gold Council, the instability and unease caused by the terrorist attacks, coupled with investors' growing skepticism of the business sector brought on by numerous accounting scandals, have brought gold back to the forefront as an investment option geared toward management of risk. By early 2003 the price of gold stood around \$350 per troy ounce.

INDUSTRY LEADERS

As the world's second largest gold producer behind Canada, the United States produced 335,000 kilograms of gold in 2001, valued at \$2.94 billion. About 30 mines contributed nearly 99 percent of all gold produced in the United States. Nevada, Alaska, Arizona, Colorado, and California are the leading gold mining states.

Nevada has long dominated the production of gold in the United States. In 2001, 14 of the nation's 30 largest mines were located in Nevada and produced 253,000 kilograms of gold or more than 75 percent of the national total of 335,000 kilograms. During 2001 Newmont Gold Company's operations led the nation with 84,000 kilograms, and Barrick Gold Corporation's Betze Post/Goldstrike mines extracted 48,200 kilograms. Placer Dome, Inc.'s Cortez mine, also based in Nevada, was the nation's third largest producer, with 37,000 kilograms.

Whereas Nevada's gold production showed an annual decrease of 6 percent in 2001, Alaska's gold mining operations mines increased 6.5 percent from 15,600 kilograms in 2000 to 16,700 kilograms in 2001. Fairbanks Gold Mining Inc.'s Fort Knox mining operations accounted for 12,800 kilograms, making it the seventh largest mine in the nation. It was also in that state in 1994 that the tenth largest nugget of placer gold in Alaskan mining history was discovered. The Silverado Mines Ltd. unearthed a 41.3-ounce nugget from its Nolan Mine.

Kennecott Utah Mining Corporation's Brigham Canyon mine produced 18,400 kilograms of gold as a by-product of its chief copper mining operations. California's gold mining production fell by 20 percent, from 17,200 kilograms reported in 2000 to 13,800 in 2001. The decrease was caused by the closing of a major mine that ceased to produce and the suspension of operations at another while waiting for expansion permission. Washington State's production fell by more than 40 percent in the same time period, from 2,930 kilograms to 1,700 kilograms.

WORKFORCE

Employment in this sector in the United States dropped to 9,500 employees, comparing unfavorably with the 1997 level of 17,500 employees. According to the U.S. Department of Labor, the industry's mean hourly wage was \$22.64.

AMERICA AND THE WORLD

South Africa. The world's largest producer of gold, producing 402,177 kilograms in 2001, South Africa is also the world's highest-cost producer. Due to deepening mines, an ongoing diminution of ore grades, and labor-intensive practices, South African miners resorted to self-preserving measures including high-grading (i.e., focusing first on those portions of a mine containing high-grade ore) and reductions in operating expenses across the board. The government eased restrictions on some operations to allow work on Sunday, despite continued adherence to the politically sensitive blanket ban on Sunday mining. And allying market demand with production, many houses increased forward positions on the hedging market in attempts to secure upward prices for future output. Some of the country's biggest mines are Freegold, Vaal Reefs, Driefontein, Randfontein, and Elandsrand.

An ongoing research program of the Chamber of Mines of South Africa focused on highly integrated mining systems, incorporating several options to conventional drilling and blasting cycles. The effort, initiated in the mid-1970s, yielded numerous advances, including light, hand-held hydraulic drills with performance characteristics surpassing those of their heavier, immobile counterparts; a portable gold analyzer, developed in cooperation with EG&G Oretec, which scanned faces and blasted muck piles with X-ray fluorescence to measure gold concentrations; and others. Further, as South African mines exhausted easily accessible ores and tended toward deeper levels, new technology was designed to encounter the high stresses of such environments and to maintain acceptable working conditions far underground. Most South African advances would eventually benefit the industry worldwide.

Australia. With production of 285,000 kilograms in 2001, Australia was the third largest world gold supplier. Its leading mines include Super Pit, Boddington, Telfer, and Tick Hill. The territory of western Australia produces about 76 percent of that nation's gold. Traditionally characterized by shallow, open-pit mining—primarily of oxide ores—with relatively short life spans, Australian operations increasingly moved into underground mining of sulfide ores in the mid-1990s. They also began more extensive use of heap-leach recovery methods, a process that contributed to a 13.8 percent rise in production at the Telfer mine in 1992. However, the Australian mine industry found itself embroiled in land tenure disputes linked to court rulings protecting traditional aboriginal lands from mining exploration and development.

Other Nations. Other significant gold-producing nations in 2001 included China (185,000 kilograms), Canada (160,000 kilograms), Russia (152,000 kilograms), Peru (138,000 kilograms), Indonesia (130,000 kilograms), Uzbekistan (87,000 kilograms), Papua New Guinea (74,000 kilograms), and Ghana (68,700 kilograms).

RESEARCH AND TECHNOLOGY

To recover ore from complex deposits that cannot be mined or leached by conventional methods, pressure oxidation and bio-oxidation processes have been developed and patented to extract refractory gold by environmentally friendly methods. A \$3-million investment and five years of study at the Twin Creeks deposit operated by Newmont Gold Co. near Golconda, Nevada, yielded a patented process requiring careful design of the milling process to blend the several types of ore present in the deposit. These oxidation methods are also expected to be adopted by other mining ventures.

SIC 1044

SILVER ORES

This category covers establishments primarily engaged in mining, milling, or otherwise preparing silver ores, including the production of bullion at the mine or mill site.

NAICS CODE(S)

212222 (Silver Ore Mining)

INDUSTRY SNAPSHOT

Most world silver is produced as a byproduct or coproduct in the mining of other metals—such as copper and gold, and, to a lesser degree, lead and zinc. The outlook for silver production tends to overlap with the outlooks for other metals. Primary producers, which account for roughly one-third of world silver supply, are more vulnerable to swings in the historically volatile silver market than diversified metal producers.

Silver entered the new millennium with relatively static prices, fluctuating less than \$1.00 between its high and low prices for the third consecutive year. In early 2001, silver reached a temporary high of \$4.87 per ounce before slipping to a low of \$4.16 per ounce. This drop can be attributed in part to a 10 percent decrease in global industrial silver demand during that period. Worldwide, photographic demand was slightly less than in 2001, whereas the demand for silver in jewelry increased that year. Silver trading remained relatively flat until the September 11, 2001, attacks on the World Trade Center, which closed markets until September 17, causing silver prices to rise to \$4.32 per ounce—eventually reaching \$4.65 in early October—as concerns arose about the vaults of silver buried under the rubble of the World Trade Center. After a brief downward trend, prices rose again in December to \$4.65 as investors looked for a safe haven in a climate of economic uncertainty. Overall, silver was down 12 percent in 2001 from the average price of \$5.00 in 2000.

In 2002, United States mines produced approximately 1,470 tons of silver with an estimated value of \$214 million. There were 21 principal refiners of

commercial-grade silver producing an estimated 2,900 tons of output. Approximately 30 fabricators consumed more than 90 percent of the silver used in the arts and industry. Mainly an industrial metal, industrial and technical uses of silver, including photographic materials and electrical and electronic products, are by far more in demand than aesthetic silver uses, which include jewelry, tableware, and coinage. In 2001, domestic industrial consumption fell by approximately 480 metric tons to 2,450 metric tons. Total 2001 U.S. consumption of silver, estimated at 5,300 metric tons, fell 749 metric tons from the previous year.

ORGANIZATION AND STRUCTURE

Most silver is produced from argentiferous ores—the sulfides of lead, copper, and zinc—which may contain varying amounts of silver, depending on their location. Silver is also found as deposits of native silver (usually in alloy form), as sylvanite (gold and silver telluride) ores, and in many naturally occurring minerals, including galena (lead sulfide), argentite (silver sulfide), cerargyrite (silver chloride), and others.

Extraction and Refining. Various methods are employed to extract silver or a combination of silver and gold from ores, scrap, alloys, and used photographic materials. As most silver is a byproduct of copper, lead, and zinc ore treatment, the precise process differs with each ore. In every case, however, the silver is finally collected in the form of crude silver or silver-gold bullion. The former is refined by a process involving smelting in a furnace with lead oxide, fluxes, and a reducing agent to produce a purer alloy of silver and gold called dore. An oxidized lead residue melts away in the process.

Two methods—electrolysis and parting—are used to separate silver and gold in silver-gold bullion. In electrolysis, electric current is passed through a silver nitrate water solution, with silver, gold bullion, dore serving as the anode. In the parting method, the dore is dissolved in a bath of hot concentrated sulfuric or nitric acid. Gold is recovered from the residue, and the clear solution is treated with ferrous sulfate to precipitate the silver, which is filtered off and melted into bars. In 2001, approximately 1,100 tons of silver were recovered from recycled materials according to the U.S. Geological Survey, Mineral Commodity Summaries.

BACKGROUND AND DEVELOPMENT

For thousands of years, silver's aesthetic and practical value, as well as its relative rarity, have earned it a position among precious metals. As a noble metal, it resists oxidation and demonstrates excellent properties of conductivity, making it particularly useful in both ornamentation and as a practical conductor of electricity and heat for numerous applications. Although it tarnishes

easily in the presence of certain sulfur compounds and scratches easily in its pure form, it is the whitest of all metals and an excellent reflector of light—capable of reflecting up to 95 percent of incident light rays in the visible spectrum. Silver's chemical symbol, Ag, was obtained from the Latin name for silver, *Argentum*, which means bright and shining.

Early History. Silver was one of the first metals after gold and copper to be molded by humans, and silver artifacts have been found in Near Eastern tombs dating back to 4,000 B.C. The Romans developed a method of separating silver from ore by a heating process, which was used into the Middle Ages, when silver-copper mines were exploited in central Europe. By the sixteenth century, the Spaniards had discovered enormous silver and gold deposits in Central and South America. Mexico largely supported Spanish colonial wealth until its independence in the early nineteenth century. Into the 1990s, however, much of the silver remained, leaving Mexico the world leader in silver production. Minas de las Rayas, a mine that began operating in 1558, as well as other mines and general sites, still produced silver into the 1990s. Penoles' Fresnillo Mine, known as the richest silver mine in the world and in operation since 1550, produced 56 percent of Penoles' total silver with a record 893 metric tons in 2001. Until the discovery of the Comstock Lode strike in the Sierra Nevada area of the United States, Central and South America almost exclusively supplied world silver. Moving into the twentieth century, silver leaders in the western world were Mexico, the United States, Canada, Peru, and Bolivia.

Silver in Recent Times. Domestic mine production of silver in the 1980s rose to its highest level in nearly 50 years. One reason is that during this period precious metal prices stayed higher in constant dollars than during the 1970s. Also, in 1979 and 1980, silver and gold prices were unusually high, whereas the prices of other base metals were relatively low. As a result, companies used their exploration budgets to search for precious metals. As a result, new discoveries were developed in producing mines. In the late 1980s, rising prices for metals such as copper, lead, and zinc indirectly contributed to increased domestic silver production. Higher prices were the reason some mines reopened. Other companies increased the capacity of their operations due to the fact that nearly all base metal mines contain some silver.

The Silver Institute, a Washington D.C.-based industry research group, projected that world silver production would reach 14,347 metric tons in 1994, followed by 14,622 metric tons in 1995 and 14,912 metric tons in 1996. (One metric ton is equivalent to 1,000 kilograms and to 32,151 troy ounces.) The actual production, according to the Silver Institute, was 14,266 tons for 1994 and 15,073 for 1995. According to the U.S. Geological

Survey, world silver production was estimated at 16,200 metric tons in 1998, a slight decrease from 1997's 16,400 tons. U.S. silver mine production was valued at \$338 million from about 76 mines in 1998, an increase of more than \$200 million from the previous year. Given the magnitude of price declines, however, silver output remained relatively resilient due to the large portion—up to 70 percent—typically produced as a byproduct of copper, lead, zinc, and gold mining activity. Silver prices averaged \$5.22 in 1999 before dipping to \$4.95 in 2000.

CURRENT CONDITIONS

U.S. silver mine production of about 1,470 tons was valued at \$214 million in 2002, down from 1,740 tons produced by mines in 2001. The Silver Institute reported a slight increase in world silver mine production in 2001 at 18,400 metric tons, up from 18,100 in 2000.

Silver Supply and Stocks. The U.S. Mint safeguards a majority of the country's precious metals and is the caretaker of most of the silver supply of the United States. The values and amounts of silver under the protection of the mint at the end of September, 2001, was 220,062 kilograms (kg) of silver carrying an approximate market value of \$32.422 million (at \$4.5825 per fine troy ounce).

The early 1990s saw dramatic reductions in secondary silver supply. Compared with the early 1980s, silver supply from scrap during the 1990s fell to approximately half its former level and hovered around the 100-million-ounce (3,215-metric-ton) mark. Reasons for the decline included lower prices, the prevalence of lower-content scrap, and restrictive sales policies on official reserves. Most secondary recovery came from photographic scrap materials, which remained economically recoverable even at \$3.50 an ounce, whereas recovery of the lower silver content in electronic scrap became less desirable. Approximately 1,600 tons of silver was recovered from old and new scrap in the United States in 2002, up from a low of 1,100 tons in 2001 but somewhat lower than the year 2000 high of 1,680 tons.

Other secondary sources also declined. Most notably, the U.S. Defense Department's National Stockpile inventory of surplus silver was reduced from nearly 4,300 tons in 1982 to nearly 1,100 tons in 1998. Several regulations were enacted in the early 1990s to control the rate of change and nature of the National Defense Stockpile, including a 1992 law that restricted the disposal of silver from the stockpile to coinage programs or government contractors for use in government projects. Between 1981 and 1992, 65 million ounces of stockpile silver were used for coinage programs and roughly 3.5 million ounces were delegated to contractors, according to the Silver Institute. In 1992 Dennis E. Wheeler of the Idaho-based Coeur D'Alene Mines Corp. predicted that the National Defense Stockpile's supply of silver would be

gone by 1997, at which time the U.S. Mint—which since 1985 has consumed roughly 45 percent of stockpile silver—would buy the metal from domestic producers. In 2002, the Defense Logistics Agency (DLA) transferred the remaining balance of silver, about 200 tons, in the National Defense Stockpile to the U.S. Mint—a unit of the U.S. Department of the Treasury—to manufacture bullion and numismatic coins. The transfer of the remaining silver indicated the termination of silver requirements in the National Defense Stockpile. The Silver Institute forecasts depletion of silver stocks in the first quarter of the twenty-first century if the yearly average reduction continues as previously illustrated.

In July of 2002, silver mining companies got support from Congress, however, as the Senate and the House of Representatives approved the American Silver Eagle Bullion Program Act. The legislation authorized the Treasury Department to buy silver on the open market from domestic sources to produce the Silver Eagle bullion coin after the surplus silver in the National Defense Stockpile had been depleted. The U.S. Mint was expected to purchase some 9 million ounces of silver per year to continue to produce the coin, aiding beleaguered U.S. silver mining companies.

The U.S. Geological Survey (USGS) estimated in 2002 that reserves of silver worldwide in demonstrated resources from producing and nonproducing deposits stood at 280,000 metric tons, with the United States owning 30,000 tons of that figure. The reserve base for the five top silver producing countries—the United States, Canada, Mexico, Australia, and Peru—held an estimated 56 percent of the world total at 240,000 tons. The USGS also reported that total discovered silver resources in the United States were estimated to be 330,000 metric tons and that the amount of silver in undiscovered mineral deposits ranged from 290,000 metric tons to 660,000 metric tons.

Consumption. Silver demand in the early twenty-first century was almost entirely industrial, with electrical, electronic, and photographic applications making up the majority of silver usage. Demand for silver experienced its largest drop in twenty years in the poor economic climate of the early 2000s and as its use in electronic products decreased. The 2001 consumption of silver in the United States, including scrap, was estimated at 5,300 metric tons, down from 6,049 metric tons the previous year. This drop was due, in part, to the decline in domestic industrial consumption, down by 480 metric tons in 2001 to 2,450 metric tons. Photography was the largest end-use application at 2,000 tons, whereas batteries, electrical, and electronic products accounted for 1,060 metric tons. Jewelry, silverplate, sterlingware, and dental and medical usage accounted for the balance of consumption. Globally, demand for silver was estimated at 27,000 metric tons in

2001, down more than 1,400 metric tons from the previous year.

In the fabrication of silverware and jewelry, 2001 worldwide demand amounted to 287.6 million ounces, up slightly from 281.4 in 2000. Demand in this sector was significantly lowered in the late 1990s and dropped 17 percent in 1998 in India alone, where jewelry, silver gift items, and silverware make up two-third's of that nation's demand for the metal; this figure was significant to affect worldwide assessments of demand. The 1998 decline was attributed to silver prices and poor economic conditions in India and East Asia. In the United States, demand for the fabrication sector rose to 214.4 million ounces, a rise of 13 percent. For the tenth year in a row, 1998 fabrication demand was greater than the supply from mine production and recycling. The gap was bridged by supply hedging on the part of suppliers and probably some divestment. Sales of designer jewelry and white metals including sterling silver were strong in the late 1990s, and these fashion trends and the supply of disposable income were expected to continue well past 2000.

Industrial consumption in the United States also continued to grow but at a rate that was not expected to materially affect prices. Worldwide, the industrial sector continued to be the largest consumer of silver in 2001, at 338.5 million ounces. The photography market retained its leading position as a silver end-user with 210.2 million ounces consumed in 2001, for example. This figure was lower than 2000 by 9.5 million ounces and was expected to further decrease as digital imaging became more widespread. The coins and medals sector accounted for 27.2 million ounces in 2001. The metal is also used for hundreds of other applications. Its excellent and long-lasting conductivity, even in high temperatures, makes it the material of choice in batteries requiring little space, long life, and high voltage, as in hearing aids, space technology, submarines, and portable television sets. Silver's germicidal properties make it particularly suitable for medical applications such as bone-replacement plates and sutures, antiseptic drainage tubes, and water purifiers. Its reflectivity also makes silver a perfect coating for high-quality mirrors. Among other uses, it serves as a freeze-resistant alloy in diesel locomotives and airplanes and is used as a colloidal catalyst in various vapor-phase organic chemical reactions. In early 2002, the potential existed for silver to replace toxic chemicals in wood preservatives and marine paints being banned for their toxicity. In early 2003, the growing popularity of the flat panel television—on the market for the past four years—gave silver another boost, as the technology is completely dependent on silver.

The particularly volatile nature of silver prices has been partly attributed to the metal's dual role as both a precious metal and an industrial material. As a precious

metal, silver benefits from the same interests that influence gold prices (and other precious metals) as hedges against inflation. Thus, upturns in gold prices starting in 1993 were accompanied by similar patterns in silver prices; yet silver enjoyed a bigger boost relative to gold because of the notion that, as an industrial metal, it could benefit the most in the event of an economic recovery, according to Bette Raptopoulos, from Prudential Securities Inc. in *American Metal Market*.

Silver-Free Photography. Silver-halide salts (including silver chloride, silver iodide, and silver bromide) darken when they are exposed to light. As a result of this property, silver halide is coated on photographic film, paper, and plates, which makes the photographic industry the largest end-user by far for industrial silver. New developments in photography have some members of the silver industry uneasy. Some analysts fear that new technologies in electronic imaging that do not depend on silver-based chemistry will phase out traditional photographic practices, causing significant losses to the silver industry. Other industry observers, however, feel that such new technologies may actually offer new and related growth opportunities to silver-based imaging.

Further, analysts expect world silver output to be affected by the closing of several zinc mines due to low zinc prices in the early 2000s. A significant amount of silver is a byproduct of zinc mining. Some of the mines will remain permanently closed whereas some are earmarked to reopen when zinc prices rebound. Although these mines together represent a loss of only approximately 80 metric tons of silver per year, another 60 metric tons per year will be lost by cuts in copper mining. Further mining production cuts are expected and may considerably reduce mined silver production in 2002.

Overall, analysts expect silver demand and prices to increase in 2002, due to increases in industrial demand, restocking, and investment silver demand recovery. These estimates proved true in the first half of 2002, as silver prices improved some 20 percent over a low of \$4.07 per ounce in November 2001. By May of 2002, silver prices were between \$4.50 and \$4.75 per ounce, riding a wave of excitement in the gold market. Silver producers announced new, multimillion-dollar financing while their stocks climbed to new heights. Supply of silver is expected to decrease, however, in 2002. This drop is due to a mine supply decrease as a result of mine closings, a lack of new silver mines in production, and lowered byproduct silver production from reduced base-metal production. The resulting silver deficit was estimated to increase further in 2002, causing a further increase in silver prices.

Silver and the Environment. The mining industry in general is not one favored by environmentalists. Gold and

silver mines typically operate in delicate ecosystems, causing environmental damage, disruptions in native populations, and hazards to nearby water systems. Mining companies have primarily relied on insurers offering reclamation bonds pledging to clean up land affected by mining. However, after the attacks of September 11, 2001, insurance companies became wary of such risky bonds. A 2002 rule issued by the Bureau of Land Management required the mining industry to up its bonding requirements, obliging some mining outfits to show more than 100 times as much money as before so that mining cleanup does not come out of taxpayers' pockets. The mining industry reacted unfavorably to the new rule, claiming that some mines would be forced to close. Critics, however, argue that there are thousands of abandoned mines throughout the western United States, causing taxpayers to foot the bill for cleanup to streams and related environmental damage, estimated at \$32 to \$72 billion.

INDUSTRY LEADERS

Nevada was the largest of the 16 silver-producing states in 2002, producing more than 600 tons. According to the United States Geological Survey, 30 fabricators were responsible for 90 percent of the silver used in art and industry.

According to the U.S. Geological Survey, 2000's leaders in silver production were Nevada, with 633,000 kilograms of silver; Idaho, with 416,000 kilograms of silver; and Arizona, with 132,000 kilograms of silver. Alaska, Missouri, Montana, New Mexico, Utah, and other states produced 671,000 kilograms that year. Significant silver producing mines in 2001 included the Greens Creek Mine, near Juneau, Alaska, which produced approximately 342,000 kilograms of silver. Greens Creek—a joint venture with Hecla Mining Company, Kennecott Greens Creek Mining Company, and Kennecott Juneau Mining Company—was expected to produce 93,300 kilograms of silver in 2002. McCoy/Cove Gold-Silver Mine in Lander County, Nevada, produced about 200,000 kilograms of silver in 2001. Silver production at the Galena Mine, in Shoshone County, Idaho, reached 140,000 kilograms in 2001, up 13 percent from 2000.

AMERICA AND THE WORLD

International supply in 2001 was led by Mexico, Peru, Australia, and the United States. China (1,800 metric tons) and Canada (1,270 metric tons) were also major producers according to 2001 figures. Silver mine production increased globally in 2001 to 18,700 metric tons, up 400 tons from 2000 despite lessened silver byproduct from gold mines. This increase in silver production was due to growth in several base-metal mines in Mexico, Chile, and Peru. Central and South America produced more than 6,400 metric tons of silver in 2001—about 34

percent of total world output—led by Mexico, with 2,760 metric tons, and Peru, at 2,353 metric tons. Mexico's San Sebastian silver/gold mine, located in central Mexico, produced more than 31 metric tons of silver in 2001, the year it began operation, and is expected to double that figure in 2002. The number-two silver producer, Peru, enjoyed a 9 percent increase in production largely due to the recent addition of its Antamina Mine where 120 metric tons of silver were mined in 2001.

With the significant political changes in Eastern Europe of the early 1990s, silver production data were available from those regions for the first time. The Silver Institute estimated production in those so-called transitional economies as follows: the Commonwealth of Independent States (CIS—the republics that were formerly the Soviet Union) at 39 million troy ounces from 1992 to 1996; Poland at 28.9 million troy ounces for the same period; China at 6.4 million troy ounces; Bulgaria at 3.1 million troy ounces; and North Korea at 1.6 million troy ounces.

Between 1998 and 2001, Canada accounted for 40 percent of American imports; Mexico accounted for 37 percent, Peru for 7 percent, and the United Kingdom for 3 percent, with the remaining 13 percent from elsewhere. The United States imported 3,310 metric tons of silver and exported 963 tons in 2001. Imports for 2002 were estimated at 3,630 metric tons, whereas 2002 exports were estimated at 885 metric tons.

SIC 1061

FERROALLOY ORES, EXCEPT VANADIUM

This category covers establishments primarily engaged in mining, milling, or otherwise preparing ferroalloy ores, except vanadium. The mining of manganese ores valued chiefly for their iron content is classified in **SIC 1011: Iron Ores**. Establishments primarily engaged in mining vanadium ore are classified in **SIC 1094: Uranium-Radium-Vanadium Ores**, and those mining titanium ore are classified in **SIC 1099: Miscellaneous Metal Ores, Not Elsewhere Classified**. The ferroalloy classification includes the following ores: chromite, chromium, cobalt, columbite, ferberite, huebnerite, manganese, manganite, molybdenite, molybdenum, molybdenite, nickel, psilomelane, pyrolusite, rhodochrosite, scheelite, tantalite, tantalum, tungsten, wolframite, and wulfenite. While production and consumption of particular ores can vary as much as their names, industry-wide trends tend to influence ferroalloys as an overall group of ores serving related applications responding to similar market forces.

NAICS CODE(S)

212234 (Copper Ore and Nickel Ore Mining)

212299 (Other Metal Ore Mining)

INDUSTRY SNAPSHOT

The ferroalloy industry is serviced by dozens of international mining companies, often with special subsidiaries responsible for specific alloys. As ferroalloys are primarily used in the production of steel, the state of worldwide steel production impacts that of the ferroalloy industry. Ferroalloys serve three main functions in steel: they help eliminate undesired elements such as oxygen and sulfur; they impart special characteristics, such as heat- and corrosion-resistance and strength; and they neutralize undesirable elements in the steel. The leading ferroalloy producers are China, South Africa, Ukraine, Kazakhstan, Russia, and Norway.

Starting in 1995, steel production began a decline that has affected prices and demand for many ferroalloys. By 1997 the steel market appeared to have settled down and prices were on the verge of rising, which in turn could have had a domino effect on the ferroalloys industries. However, the U.S. economic recession of the early

2000s pushed both specialty steel and stainless steel consumption down 17 percent in 2001, according to the Specialty Steel Industry of North America. U.S. ferroalloy production declined 10 percent in 2002. Exports declined 18 percent and imports increased 11 percent, according to the U.S. Geological Survey.

From 1989 onward, ferroalloys underwent substantial market decline, largely spurred by a decline in steel production in the United States and other Western nations. Several economic factors placed continued strain on steel—repercussions from the oversupply and price boom of the late 1980s, a flood of exports from Commonwealth of Independent States (CIS) and China, and the lingering effects of worldwide economic recession in the early 1990s. A glut of low-priced imports forced many ferroalloy companies, including world giants, to drastically reduce production and contend with losses and severely reduced profits. Moving into 1993, established market economy countries (EMEC) did not compensate for these factors with sufficient reduction of output, resulting in growing inventories and uncomfortably low commodity prices. From 1993 onward, stainless steel producers in the Western World experienced an annual growth of about 10 percent per year, forcing many to operate at full capacity. However, ferroalloy production forged ahead in anticipation of future demand a little too soon, causing a market flooded by ferroalloys.

By the mid-1990s, industry analysts anticipated a turnaround in the nonfuels minerals industry, particularly in metals. With modernized plants, lower operating costs, and more efficient workforces, producers were poised to capitalize on moderate economic expansion. Although forecasts for the late 1990s indicated increases in commercial building construction, infrastructure projects, and the motor vehicle industry, demand for many types of steel and, consequently, for ferroalloys remained low due to an unanticipated economic recession in the United States, which was worsened by the terrorist attacks of September 11, 2001.

ORGANIZATION AND STRUCTURE

The Market. Like mining in general, the ferroalloy industry is organized along the complex lines of worldwide consumption and supply, with different countries consuming different metals—in varying quantities—according to the demands of their industrial bases and capital goods markets. The London Metal Exchange (LME) served as the general barometer of price fluctuation in metals trading, reflecting the ever-shifting balance between world demand and supply of those commodities.

Ferroalloys and the Former Soviet Union. Due to the complexity of international forces governing consumption and supply, however, the industry's organization

seemed anything but organized, as evidenced by the turmoil following the collapse of the Soviet Union in the early 1990s. Before that event, the metal mining industry was still coping with the adverse effects of a recession taxing the Anglo-Saxon economies and eventually Japan and Germany as well. For the most part, metal mining companies weathered the storm by repairing their balance sheets with high metals prices in the late 1980s. Industry stocks were cautiously maintained at low levels, while the rapid growth of newly-developing countries translated into new demand for most metals minerals and ferroalloys.

The collapse of the Soviet Union, however, placed tremendous strain on the supply side of the metals industry with no apparent let-up in sight. Seeking hard currency to prop up its staggering economy, the Commonwealth of Independent States (CIS) began aggressively exporting any commodities of immediate value, with LME-traded metals and precious metals at the top of the list. The former Soviet Union had been a leading customer for ores as well as the world's leading producer of iron ore, lead, manganese, nickel, and potash. The crisis prompted convulsions in the economies of Russia and other republics and caused severe industrial production problems, effecting a virtual halt to imports of minerals and metals. Consequently, Western stocks soared and prices plummeted, forcing Western mining companies to slash capital spending and exploration expenditure to a minimum and absorb serious short-term losses.

While the CIS may lessen supply of metals exports, Chinese producers fill in the holes, resulting in an abundance of metal on the market. Many analysts predicted that the CIS would not only develop substantial new markets for metals, but that it would become net importers as well. China's ore grades are lower than in Western countries, and mine output is falling, while production costs rise. For example, the worldwide market continues to rely on China and the CIS for most of its tungsten. Still, unknown stockpile levels have left questions in the minds of analysts as to how much and how long an oversupply situation will last for ferroalloys. In mid-1996, it became apparent that production of at least tungsten, and quite possibly other metals, in the CIS, which had declined between 1990 and 1994, was experiencing an increase in global demand. That higher demand is expected to spur additional production. Tungsten production in the CIS totaled 9,500 metric tons in 1995, a 9 percent increase from the 8,800 metric tons of 1994. Any shortfall in Chinese production was expected to be taken care of by CIS producers.

BACKGROUND AND DEVELOPMENT

The mid-nineteenth century saw an explosion in U.S. mining, with the discovery of great mineral deposits, the

development of transcontinental railroads, and a rapidly growing population. Responding to such growth, the American Institute of Mining and Metallurgical Engineers (AIME) was founded in 1871 (it was eventually renamed the American Institute of Mining, Metallurgical and Petroleum Engineers in 1956). Since that time, the ferroalloy industry became fundamentally international in scope, depending on worldwide producers to stabilize the delicate balance between consumption and supply and thereby stabilize prices.

From the mid-1980s onward, several new factors further influenced the industry. Roughly 100 years after the beginning of the industrial revolution that proved so bountiful for ferroalloys, many western countries, particularly the United States, began a trend of deindustrialization, with employment in industrial areas shifting toward service-oriented sectors. In 1986, the U.S. Department of Labor included ferroalloy ores mining on a list of industries that were expected to experience more than a 20 percent decline in output over a 15-year period.

With diminished threat of war with the former Soviet Union, attention shifted to management of the so-called "peace dividend," which included some funds that would have been formerly allotted to ferroalloys in the defense industry. In 1992, the U.S. Department of Defense announced an ambitious plan to sell many of its stockpiles of ferroalloys, including cobalt, nickel, manganese metal and ore, ferromanganese, ferrochrome, chrome ore, and silicon carbide. Debate continued over the wisdom of the sales, however, spurring mixed reactions from legislators and ferroalloy industry groups. The government stockpiles have been severely depleted since that 1992 decision, and sales now have little effect on the market.

Environmental Issues. As world attention shifted increasingly toward environmental issues, the ferroalloy industry responded on numerous fronts. Issues such as waste water, waste disposal, and land reclamation placed additional planning and economic pressures on mining companies, prompting many to seek development in other countries with less stringent regulations. The minerals industry was primarily controlled by three environmental acts: The Resource Conservation and Recovery Act of 1976 (RCRA), regulating both hazardous and non-hazardous solid waste; The Clean Water Act (CWA), regulating surface water discharges; and The Clean Air Act (CAA), regulating air emissions. Many clauses included in these and other environmental acts met with industry resistance due to increased costs of doing business or even prohibition of some practices deemed standard in the past. In 1990, for example, the EPA required mine owners to comply with terms of the National Pollutant Discharge Elimination System, which called for the monitoring and testing of storm water runoff. The Ameri-

can Mining Congress challenged the rule but was overridden in a 1992 court decision. The result of such proposed legislation has been to force companies to take extra environmental precautions, incurring an added expense over the cost of producing the same metals in other countries. The effect has been to put American companies at a slight disadvantage, at least.

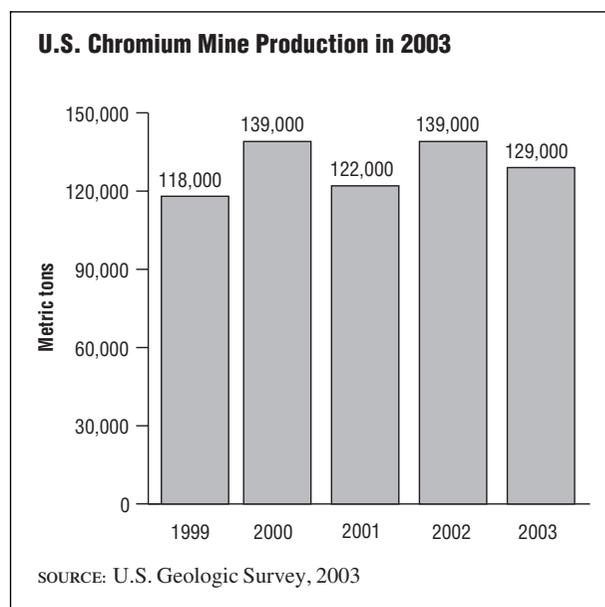

Federal Lands. Another factor affecting the development of the ferroalloy mining industry—and, indeed, mining in general—was the availability of federal lands, which traditionally accounted for about 75 percent of U.S. metals mining. As minerals exploration and mining were dependent on access to these lands, growing efforts to limit or restrict access to federal lands for mining have understandably captured the industry's attention. Natural resource development prescriptions stipulated by the U.S. Forest Service and the Bureau of Land Management grew in scope. From the mid-1960s to mid-1990s, more than 96 million acres of federal lands were withdrawn from mineral entry and placed in the National Wilderness Preservation System. Compounding these debates about mining on federal land were ongoing reinterpretations of key elements in the 1872 Mining Law that determined issues of self-initiation, free access, and security of tenure for mining operations on federal lands.

CURRENT CONDITIONS

The early 2000s saw a deterioration of the domestic ferroalloy industry performance, reflecting a fall in Western world steel production, a sustained flood of exports from the CIS and China, and a backlash from oversupply dating back to the late 1980s. A total of 33 U.S. steel companies declared bankruptcy between 1998 and 2002. Stainless steel production in 2002 declined 18 percent to 1.01 million metric tons. Surveying the specific performances of key metals—nickel, chromium, molybdenum, cobalt, manganese, niobium, and tungsten—yields a clearer picture of the ferroalloy industry in general.

Nickel. A highly ductile and heat- and corrosion-resistant metal, nickel is used primarily in stainless and specialty steel production, plating, and high-temperature superalloys. Global production in the early 1990s was headed by Russia and Canada, followed by Australia, New Caledonia, and Indonesia. When the only U.S. producer, Cominco Resources International Ltd.'s Glenbrook Nickel in Riddle, Oregon, was forced to curtail operations to cope with low metal prices in the late 1990s, the U.S. effectively exited the nickel mining industry. As of 2003, no active nickel mines existed in the United States. U.S. nickel consumption declined from 231,000 tons in 2000 to 218,000 tons in 2003.

Chromium. Resistant to tarnish and corrosion, Chromium—which derives its name from chrome, the

Greek word for color, due to the lustrous nature of its compounds—is primarily used to produce stainless steel and to harden steel alloys. It is also used as corrosion-resistant decorative plating and as a pigment in glass. It is found primarily in chromite, a combination of iron, chromium, and oxygen. Increased demand for chromium in China pushed prices to historic highs in the early 2000s. As a result, both China and India began to export ferrochromium. Domestically, production of chromium declined from 139,000 metric tons to 129,000 metric tons between 2002 and 2003 as imports increased from 263,000 metric tons to 344,000 metric tons.

Molybdenum. First used widely in World War I to toughen armor plating, molybdenum is commonly used as an alloy to strengthen steel and inhibit rust and corrosion. Accounting for approximately 90 percent of world output, the United States, Chile, and Canada were the world's leading producers in the 1990s. The three major molybdenum mines in the United States were the Henderson Mine located in Colorado, the Thompson Creek Mine located in Idaho, and the Questa Mine located in New Mexico. Between 2002 and 2003, molybdenum production in the United States rose from 32,600 metric tons to 34,100 metric tons; however, production remained well below the 1999 total of 42,400 metric tons. The United States exported 32,300 metric tons of Molybdenum in 2003, up from 23,600 metric tons in 2002. Imports over this time period increased from 11,500 metric tons to 11,800 metric tons.

Cobalt. In use since at least 2250 B.C. as a colorant in Persian glass, cobalt is mainly used in high-temperature alloys, magnetic alloys, and hard-facing alloys resistant to abrasion. The largest producers of cobalt are Zaire, Zambia, and Canada, which sold primarily to the United

States because of economic shipping arrangements. Cuba is also a large cobalt producer—one market research firm estimates its holdings at 29 percent of world reserves—but remained unable to sell its materials in the United States. Although a major consumer of cobalt, the United States stopped producing the metal in 1971.

Manganese. In addition to its critical role in steel production, manganese is used in dry-cell batteries, pig iron, animal feed, fertilizers, and other chemicals. South Africa and Russia held more than 80 percent of world resources in the early 1990s. In the early 2000s, the United States, which had no significant manganese mine production of its own, imported supplies primarily from Gabon, Brazil, Australia, and Mexico. Prices for manganese rose in 2003 after France-based Erament SA announced plants to close down its ferromanganese plant in Boulogne.

Niobium. Commonly known as columbium, niobium is one of the refractory metals primarily used as a microalloying element in high-strength and stainless steels. It is also a common ingredient in superalloys, popular in the aerospace industry, and carbide cutting tools. Three mines are almost exclusively responsible for world niobium production: the Araxa mine and smelter of Companhia Brasileira de Metalurgia e Mineralcao (CBMM) and the Catalao mine operated by a subsidiary of the Anglo American Group, both in Brazil, and the Niobec, Quebec, mine in Quebec, Canada.

Tungsten. Also called wolfram, tungsten is found in wolframite and scheelite ores and is primarily used as a carbide to harden metal-cutting tools and as an alloying agent in steel making. Its good thermal and electric conductivity also make it very suitable for electric contact points and lamp filaments. In the 1990s, China led in world tungsten production, followed by Australia, Austria, Bolivia, Brazil, Burma, Canada, North and South Korea, Peru, Portugal, Spain, and Thailand. The United States played a relatively small role in the tungsten industry, with two plants for the production of tungsten concentrated in California and a handful of processors elsewhere. China is the world's largest tungsten exporting country, with a current mine output at almost 80 percent of the world's supply.

RESEARCH AND TECHNOLOGY

Many employment opportunities in the ferroalloy industry involve implementation or operation of new tools and technologies designed for greater efficiency, safety, and environmental benefit. In addition to innovative mine environments to maximize safety, transportation, communication, and yield of large mine operations, companies and specialty metal mining services drew on new computer technology to assist in all phases of indus-

try activity. In the 1990s, for example, Australia's Mount Isa mine used an Integrated Mine Planning system (IMPS)—a computer-aided drafting (CAD) system for geological interpretation and modeling. The system enabled engineers to integrate information from various departments (geology, mine design, and survey) and evaluate complex criteria—such as test clearances, drivers' lines of sight, and mobile equipment specs and compatibility all at once. Other mining companies began using a new system designed to rapidly determine ore contacts and grades in underground metal mining. By measuring differences in the physical characteristics of relatively small mineral samples culled from drill holes, the system vastly reduced the amount of expensive core drilling sampling and assaying required for mine planning. Sandvik Rock Tools made further developments in drilling systems, developing a computer program to simulate drilling conditions through all types of percussive drilling conditions. Graphically displayed results and data are then used to develop optimum rock drilling tools and to maximize drilling energy efficiency in a wide range of tools.

SIC 1081

METAL MINING SERVICES

This classification covers establishments primarily engaged in performing metal mining services for others on a contract or fee basis, such as the removal of overburden, strip mining for metallic ores, prospect and test drilling, and mine exploration and development. Establishments that have complete responsibility for operating mines for others on a contract or fee basis are classified according to the product mined rather than as metal mining services. Establishments primarily performing hauling services are classified under transportation.

NAICS CODE(S)

213114 (Support Activities for Metal Mining)
541360 (Geophysical Surveying and Mapping Services)

INDUSTRY SNAPSHOT

While most large national and international mining companies retain private divisions specially outfitted for mining services, even the largest companies continue to contract specialty mining services companies for jobs requiring particular expertise, extra speed, or outside consultation. The total number of U.S. mining companies totaled 125 in 2002, compared to 179 in 1997.

At the turn of the twenty-first century, two of the leading U.S. companies for metal mining services were Battle Mountain Gold Co., of Houston, Texas, and Newmont Mining Corp. of Denver, Colorado. With sales of nearly \$230 million, Battle Mountain operated as a public, stand-alone company specializing in gold mine exploration and mining of gold and silver and metal mining service. The company produced more than 890,000 ounces of gold per year. Sales at Newmont Mining Corporation hovered near \$1.4 billion, and Newmont's subsidiary, Newmont Gold, was the largest U.S. gold producer. In 2001, Newmont acquired Battle Mountain for \$794.2 million in stock. The deal increased Newmont's gold reserves by 17 percent.

ORGANIZATION AND STRUCTURE

The metal mining services industry offers a wide range of services. Geographically speaking, the state of Nevada has the most companies engaged in mining services. Most of these companies are small operations engaged in the physical tasks involved in mining, as well as in planning, development, and exploration. Some companies specialize in preparing mine shafts and tunnels,

while others offered test boring services. In this age of outsourcing, the metal mining services industry should be growing, but the decline in overall mining is limiting its growth.

CURRENT CONDITIONS

The overriding trend in modern metal mining has been toward the development of improved equipment to ensure better working conditions, the potential exploitation of lower-grade ores, and the design and construction of bigger and deeper mines. Where companies involved in metal mining services did not themselves develop new technologies toward such ends, they made use of a plethora of advances made by other mining companies and associations.

Surface mining in 2001 accounted for 97 percent of all crude industrial ore mined, which totaled 3.3 billion tons, in the United States. Metal consumption declined by 12 percent in 2001 and by another 10 percent in 2002. As a result, production also waned, falling by 21 percent between 1997 and 2002. The number of U.S. metal mines in operation over this time period decreased from 179 to 125, and the number of metal mining employees dropped from 42,202 to 27,230.

MINExpo International, an annual event held in Las Vegas, is a dynamic forum displaying many of the latest mining technologies, including Integrated Mine Planning System (IMPS), a system for geological interpretation and modeling featuring computer-aided drafting (CAD) technology that allows engineers to manipulate plans, design options, and even insert equipment within specific parameters; hydraulic drills that replace pneumatic models; computer-controlled underground drilling jumbos; computer programs to help evaluate and plan ventilation systems and other mine conditions; a variety of communication systems; and other advances that are intended to benefit the metals mining services and their workers.

WORKFORCE

Occupational opportunities in the mining services industry range from those involved in the physical tasks related to mining to those responsible for the planning and development of mining, testing, and prospecting. In the mining, quarrying, and tunneling domain, the industry employs workers as varied as rock splitters—who separate rough dimensions of rock and ore using jackhammers, wedges, and feathers—and mining machine operators, responsible for the operation of equipment including truck-mounted or portable drills, continuous mining machines, channeling machines, and cutting machines for underground excavation.

In the planning and development domain, the metal mining services industry employs a wide variety of

mining engineers trained in locating, extracting, and preparing metals for industry use. In addition to designing and supervising most functional aspects of metal mines, such engineers conceived new plans and equipment to improve safety and health conditions, environmental compatibility, and efficiency of mines.

While more than half of the jobs held by mining engineers in the late 1990s were in the mining industry, a large percentage transferred each year to other occupations, such as engineering consulting, government agencies, and manufacturing. Nevertheless, increasingly stringent environmental standards, as well as moves to increase production capacity and productivity while reducing operating costs, promised new challenges and some new opportunities for mining engineers in the metal mining services industry throughout the twenty-first century.

SIC 1094

URANIUM-RADIUM-VANADIUM ORES

This category covers establishments primarily engaged in mining, milling, or otherwise preparing uranium, radium, or vanadium ores.

NAICS CODE(S)

212291 (Uranium-Radium-Vanadium Ore Mining)

INDUSTRY SNAPSHOT

Domestic uranium mining is essentially a dying industry, no longer kept afloat by the military demand that launched mining in the 1940s, nor the commercial nuclear power industry that provided the major source of more recent demand. In 1992 production of uranium ore from underground mines fell near zero, with any production of uranium coming from by-products. As an indication of the collapse of uranium mining, total mine production peaked in 1980 at 21,850 tons of ore before declining to 1,550 tons in 1995; 1992 marked the first year since 1948—when uranium mining was initiated in the United States—that no new ore was mined from underground mines. In 2001 the United States mined 1,300 tons of uranium. Current U.S. demand for uranium

is about 22,550 tons per year, of which less than 6 percent is met by new domestic production. According to the U.S. Energy Information Administration, in 2001 only three commercial uranium mines were active.

ORGANIZATION AND STRUCTURE

In 1987 approximately 101 establishments were engaged in the extraction of uranium, radium, and vanadium ores from mines in the United States. These establishments employed about 2,300 workers who produced approximately \$268 million worth of ores. The number of employees had dropped to 1,200 by 1992 (48 percent below the 1987 total) and then to about 700 (70 percent below the 1987 total) by 1997. Value added through mining increased in 1997 to \$90 million, as compared with \$69.4 million in 1992; the 1997 figure was a substantial decline, however, from the 1987 value of \$174.7 million. Furthermore, these figures were down sharply from the 1982 census, when output value was \$223.9 million, value added was \$578.8 million, and the industry employed 10,500 workers. Industry shipments totaled \$103.2 million in 1997.

Uranium. The collapse of uranium production in the early to mid-1990s was an intensification of the steady decline of U.S. uranium mining since the late 1970s. Import pressure remained strong. In fact, 83 percent of U.S. demand for uranium was satisfied through imports in 1998—imports as a share of domestic consumption rose from a low of 26 percent in 1983 to 51 percent in 1988, 45 percent in 1989, and 80 percent in 1990—mostly from low-cost producers, such as Canada and Australia. Net imports fluctuated around zero in the 1960s and 1970s, as the government tried to maintain self-sufficiency, but the U.S. market was swamped by imports in the 1980s. In 1998 Canada supplied 34 percent of the United States' foreign-origin uranium, while Russia supplied 14 percent, Australia supplied 13 percent, and South Africa and Uzbekistan both supplied 6 percent. The United States sold 15.1 million pounds of uranium to foreign suppliers and utilities in 1998, 11 percent less than 1997.

In addition to the relatively high cost of mining uranium in the United States, which has hurt the industry's competitive position worldwide, the U.S. uranium industry has always relied heavily on federal government subsidies and protection to keep its markets afloat. Thus, as federal support for the industry was gradually removed, the industry's viability quickly came into question. Because uranium is a one-market commodity, the fall in nuclear-powered electricity generation negatively affected the uranium market. Even uranium inventories held by U.S. utilities continued to fall in the early 1990s. This growing supply-demand gap has sent prices plummeting, creating, from the industry's perspective if

not a social perspective, unwanted additions to inventories from nuclear disarmament.

The federal government remains a primary producer and purchaser of uranium ores. To counteract the import dependency, the United States instituted restrictions on imports from former Eastern Bloc countries—mainly Russia, Kazakhstan, Kyrgyzstan, Tajikistan, Ukraine, and Uzbekistan.

Radium. Radium is a white metal that does not occur in a free state; it must be refined from pitchblende and occurs naturally only as a disintegration product in the radioactive decay of thorium, uranium, or actinium. Radium itself continues to decay into radon, bismuth, polonium, lead, or thallium. Radium was important for radiation treatment of cancer, but it has been replaced by other isotopes that can be produced at a lower cost and have greater effectiveness in treatment. It was also used for petroleum prospecting but has also been replaced in this application. Radium coating of instrument dials and clock faces to make them glow in the dark ceased in the 1930s, when the toxicity of the paint was found to cause cancer and anemia in workers.

Vanadium. Vanadium, a mineral that is found in the same ores as uranium, is primarily a one-market commodity used as an alloy in iron and steel. Small amounts of vanadium can produce high-strength steel for bridges, buildings, pipelines, and automobiles due to the weight savings it brings to these applications. Steel production, which typically accounts for about 90 percent of vanadium demand, began its recovery in the first half of 1992. Vanadium consumption in the United States for the first half of 1995 increased about 10 percent over that in the same period of 1994. Though consumption in the tool steel sector fell 16 percent, consumption in the full alloy sector was up 9 percent. With the cost and mining of vanadium so intertwined with uranium, both industries are strongly affected by U.S. government policy. Vanadium is also seen as a strategic and critical mineral for defense, energy, and transportation industries, and thus import dependence is a perennial concern. According to the U.S. Geological Survey, in 1998 carbon steel accounted for 38 percent of domestic vanadium consumption (an estimated 4,700 metric tons), high-strength low-alloy steel accounted for 20 percent, full alloy steel comprised 19 percent, and tool steel accounted for 10 percent.

Vanadium and uranium are mined together, then separated by liquid extraction techniques. Columbium, manganese, molybdenum, titanium, and tungsten can be substituted for vanadium to some degree and in some applications. While it is difficult to establish specific reserves, the largest reserves of vanadium are found in South Africa, China, the former Soviet Union, Australia,

and the United States. Vanadium resources in the United States are sufficient to satisfy domestic needs. Nevertheless, foreign suppliers met a substantial portion of vanadium demand. In 1998 South Africa controlled 89 percent of the vanadium pentoxide market, China held a 6 percent market share, and Russia had 4 percent of the market.

Eight U.S. companies mined or milled vanadium in 1998. Raw materials used in milling vanadium included Idaho ferrophosphorus slag, petroleum residues, spent catalysts, utility ash, and vanadium-bearing iron slab. End-use distribution of vanadium from U.S. plants goes to transportation, which used 30 percent, the machinery and tools industry bought 27 percent of output, and building and heavy construction, 22 percent, among others. Vanadium averaged \$4.00 per pound in 1998.

In 1997, 29 operations employed about 700 people who were engaged in the production of uranium, radium, and vanadium ores. Per production worker, the average value added in 1997 was \$175,700. By comparison, in 1992, approximately 102 establishments employed 1,011 workers. For the same year, the average value added per production worker was \$57,800. When ranked by the number of establishments per state, the top three were Colorado, Wyoming, and Texas.

In the mid-1990s, it was estimated that the largest 2 companies accounted for \$5.3 million worth of uranium-vanadium industry ore sales, and 10 companies were responsible for nearly all of the output of the industry. Only 3 of the largest 14 companies were publicly traded, and the remainder were subsidiaries or divisions of other corporations. Of the 29 establishments reporting to the U.S. Census Bureau in 1997, only 5 employed 50 or more persons. Of the total of 29 establishments, 23 were producing establishments; 6 operated mines only; 9 operated mines with preparation plants; 2 were separately operated preparation plants; and 6 were nonproducing establishments. From 1972 through 1997, the primary materials consumed in the extraction of uranium compound ores, when ranked by cost, came in the form of other minerals and the use of installed machinery, followed by purchased electric energy.

The product output shipments for the entire industry can be broken down into crude ores and uranium-vanadium concentrates. The largest component of the \$103.2 million of 1997 shipments was uranium concentrates with \$73.9 million; uranium-vanadium ores made up the balance with \$29.3 million. The precise amounts of uranium and vanadium concentrates and ores were not separately reported to the Census Bureau. The decline of these annual shipment figures from 1982 to 1997 is startling—from \$763.2 million to \$103.2 million.

For the industry as a whole, uranium-vanadium-radium miners and milling companies turned a profit in

the early 1990s for the first time since 1983. Though net income in those years was still quite small, translating into a rate of profit of less than 5 percent, peak losses in the mid-1980s ranged from over \$400 million (nominal dollars) to around \$100 million.

Exploration expenditures for new mines peaked at \$626 million in 1978 and continued on a downward slide to \$50.8 million in 1983, to \$14.5 million in 1992, and to a slight increase of \$15.1 million in 1997. In the early 1990s, foreign-controlled companies accounted for 55 percent of exploration in the United States.

BACKGROUND AND DEVELOPMENT

The exploration and mining of radioactive ores began around 1900, when sources of radium were sought for use in luminous paints for instruments, such as watch dials, and for medical purposes. In 1910 Marie and Pierre Curie refined pitchblende to isolate the metal, after Madame Curie had discovered polonium, also in pitchblende. In fact, radium is a radioactive decay product of uranium that was initially perceived to have more uses than uranium and to be more valuable. Uranium was used only as a pigment for coloring glass and painting china until the dawn of the age of atomic weapons and energy.

Radium's chemistry was first understood by the Curies and Andre-Louis Debierne in 1910. Initially, it had more commercial applications than uranium or vanadium, but it has essentially lost its commercial value because it has been replaced in most applications by safer, cheaper, and more effective materials and because it is difficult to isolate.

Because vanadium is often found in the same ores as uranium, its history closely parallels the history of the uranium industry. Originally isolated and discovered in lead ores by Mexican mineralogist Andres Manuel Del Rio in 1801, successful commercial applications wouldn't follow until the beginning of the next century. The basic chemistry was worked out by German chemist F. Wohler.

By 1941 the United States became the largest producer of vanadium. During World War II, stable demand for war output and stable pricing structure from the Office of Production Management helped bolster the industry. Later, production was increased to meet the demand for the Korean War. By 1958, however, the U.S. stockpile reached its limit, so the government reduced its vanadium purchases, focusing more attention on uranium. With its primary market saturated, production declined, and the Atomic Energy Commission stopped purchasing vanadium concentrate—leaving the industry subject to the vagaries of the steel market.

Throughout its history, the uranium industry has been regulated by the federal government. More specifically, the origin of the uranium industry is intimately connected with the heightened U.S. national security following World War II. Originally spawned, nurtured, and subsidized by government programs to develop the atomic bomb, uranium prospecting was encouraged solely for military needs. Later, when the guaranteed military market dried up in the 1960s, the government's industrial policy toward uranium shifted towards helping to foster a new source of demand—commercial nuclear power. Then, when import competition threatened the viability of the industry, the government would impose limits on imports to protect domestic industry.

The U.S. military's explosion of the Trinity device in New Mexico on July 16, 1945, introduced the world to the atomic age. At that time, the United States purchased uranium for military purposes only. In fact, only the U.S. government could legally own uranium ore. (It gradually reduced its purchases until 1970, when it cut its purchases entirely.) Until that time, much of the uranium for the Manhattan Project was purchased overseas. In 1943, however, the Union Mines Development Corporation, assisted by the government, operated mills to process additional uranium for the war effort.

On August 1, 1946, the Atomic Energy Commission (AEC), a civilian agency, was created for the purpose of procuring uranium for military needs. The AEC launched a domestic program to stimulate war production from U.S. deposits. In pursuit of its stated goal to push "nuclear security," the AEC offered bonuses for discoveries of "yellowcake" (as uranium was often called), established prices for ores, offered development and transportation allowances, built miles of access roads and pushed mill construction by subsidizing mill costs. More importantly, the AEC provided a guaranteed market for the ore. The AEC encouraged exploration in the Colorado Plateau region, and many new discoveries led to a number of mining and milling facilities, and new ore mining and processing methods were developed.

The federal government owned 90 percent of the western lands where uranium was sought. Navajo Indians and Mormons did much of the early prospecting of the region during the "uranium rush" unleashed by the AEC. Over 5,500 people took to the plains in pursuit of profits and what was considered patriotic service. At first, large corporations were unconvinced that they could profit over the capital investment required, and the Geiger counter evened out the competition. By the early 1950s, with many small companies generating profits at guaranteed prices, and a guaranteed market with demonstrated large reserves, the industry became less speculative, and larger companies entered the industry, among them large oil interests.

The AEC program was a huge success. Production of uranium oxides in the United States was 100 tons in 1948 and boomed to 8,000 tons in 1965. By the late 1950s, however, falling demand for military purposes and the resultant industry shakeout left the industry in uncertainty. Waiting for a new market required a large capital investment. Smaller companies went out of business, while the larger diversified companies, with their low costs and high-quality reserves, simply shut down their nuclear operations while waiting for the new market to take root. At this time, the oil companies established themselves as the “energy companies” and led new exploration. Reserves at this time were plentiful, but more costly to mine than in other countries. The shakeout of capacity left the industry more concentrated with most of the reserves held by large oil and mining companies. The milling component of the industry was far less concentrated.

The Shift to Commercial Nuclear Power. By the 1960s military demand was declining, and a new source of profitable demand for uranium had to be found, namely commercial nuclear power. The AEC would be involved in a reactor development program for demonstrating the potential use of nuclear power to generate electricity in commercial power plants. It would also provide research and development and technical assistance, encourage property development, and secure stockpiles to meet military needs. Further encouragement of uranium production was provided by the 1964 passage of the Private Ownership of Special Nuclear Materials Act, which privatized many of the government’s roles in the industry. Despite relative privatization, the AEC nonetheless sought to protect the industry to maintain a viable domestic uranium industry.

The program was very successful for industry growth for several decades. U.S. utilities ordered 249 commercial nuclear power plants between 1953 and 1978; more than half of them were built, and 109 were operable by the early 1990s. The decline in demand for nuclear-generated electricity was due primarily to the OPEC oil embargo; the Three Mile Island nuclear power plant disaster; and the increasing costs of building and operating nuclear power plants.

The industry, seduced by prices that increased by over 700 percent from 1972 to 1979, stepped up exploration and production during this period. However, high utility rates and energy conservation efforts slowed utility demand and deterred construction of nuclear plants. These utilities had stockpiled uranium inventories, averaging two-year supplies. Consequently, utilities cut back on uranium orders. Still, many mine producers expanded their activities, knowing that with utilities bleeding off their inventories, the situation could not last.

The boom of this period led to serious oversupply problems. With its high unit labor costs and safety requirements, the U.S. industry was at a competitive disadvantage on the world market, and the U.S. government stepped in to protect the industry, placing an embargo on foreign uranium. Following the sevenfold increase in prices from 1972 to 1976, it was alleged that an international cartel—which included Canada, Australia, South Africa, and England—conspired to fix prices.

By the late 1970s, production was up, demand for nuclear fuel was down, and inventories were high. Prices fell to around \$40 a pound. Even deeper problems led many to question the viability of the industry at the time. One of the contributing factors to declining demand for uranium was the strong antinuclear campaign following the accident at the Three Mile Island plant in the spring of 1979. Because uranium is essentially a one-market metal, any wholesale shift to other energy sources, such as coal, would be disastrous for the industry. Fortunately for the uranium producers, coal had problems of its own, notably its environmental costs.

During this period, declining interest in and direct opposition to the nuclear industry led to more stringent environmental regulations. This increased the cost of nuclear power and reduced the demand for uranium ore. Uranium mill dumping into rivers and wind erosion of exposed tailing piles meant an increased public pressure for additional control measures and cleanup activities. The Uranium Mill Tailings Radiation Control Act (UMTRCA) of 1978 was designed to deal with these problems. The Nuclear Regulatory Commission (NRC) was established, and many mines were shut down or dismantled altogether.

Although the industry as a whole faced severe decline through most of the 1980s and early 1990s, some surviving companies showed signs of strength. One leading mining and milling company, Uranium Resources, Incorporated, posted a 41 percent decline in 1992 net income, but in 1997 the Dallas-based company had revenues of \$12.9 million and had contracts in place with utilities through 1998 worth around \$60 million. Mergers and acquisitions in general increased the profitability of remaining firms by reducing capital stock value.

By the early 1990s, the uranium industry as a whole showed positive rates of profit for the first time since 1982. Following losses as high as 67 percent (net income on total equity in 1988 and 1989) and 21.6 percent (net income on total assets in 1985), the industry scored profit rates of around 3 to 4 percent on total equity and 1 to 2 percent on total assets in the early 1990s. The eight active uranium mines in 1996 were: the Crow Butte mine in Nebraska (operated by Fernet Exploration of Nebraska); the Canon City, Colorado, mine (run by the Cotter Corporation); Nevada’s Apex Deposit (owned by Strathmore

Resources Limited); the Ambrosia Lake, New Mexico, site (operated by the Rio Algom Mining Corporation); the Churchrock, New Mexico, Mine (run by Uranium Resources, Incorporated); the Holiday-El Mesquite mines in Texas (owned by Malapai Resources); and the Sunshine Bridge and Uncle Sam mines located in Louisiana (operated by Freeport Uranium Recovery). Of these facilities, the Freeport Uranium Recovery operation was the sole producer of uranium by-products. The remaining plants used "in situ" leaching (ISL) methods, which involved recovery by chemical leaching of the valuable components of uranium deposits without physical extraction of the mineralized rock. In 1998 Rio Algom Mining Corporation started up an ISL project at Smith Ranch, Wyoming.

Maintaining the industry's viability entailed massive consolidation and concentration of assets, at rock bottom prices, into the hands of fewer companies. Plateau Resources, which operated the Shootaring Canyon uranium mining facility in southern Utah, was acquired by U.S. Energy Corporation, thereby raising its stake in the uranium market. The U.S. Energy Corporation (USEC) was a creation of the U.S. government in the 1960s, when the federal government began to provide uranium enrichment services. Through the Energy Policy Act of 1992, USEC was privatized. In another major deal, Pikes Peak Mining was sold in its entirety by Nerco Minerals to Independence Mining for \$21 million. In another deal, Exxon Corporation sold its Bullfrog uranium deposit in Garfield County, Utah, to Energy Fuels Exploration—with total reserves of 20 million plus pounds of uranium oxide.

Government action in the 1990s hurt the uranium industry, while at the same time protecting it from foreign competition. First, Russia was given most-favored-nation trading status in 1992. The U.S. government agreed to buy bomb-grade uranium from Russia's dismantled nuclear warheads and convert it into fuel for commercial nuclear power plants, an action that further depressed demand for domestic uranium. As a result of the glut of uranium, imports from Russia rose from near zero to over 2,700 tons. Second, the remaining companies sought protection from international competition. This issue focused primarily on the independent republics of the Commonwealth of Independent States.

In July 1992 the U.S. Department of Commerce imposed duties of 115.82 percent against six former Soviet republics—Russia, Kazakhstan, Uzbekistan, Ukraine, Kyrgyzstan, and Tajikistan—all of which posed substantial competitive threats to U.S. uranium. In August 1993 the U.S. International Trade Commission set a 129 percent antidumping duty on uranium imports from Ukraine, excluding highly enriched uranium. Then in October, the U.S. Department of Commerce banned im-

ports from four of the above countries. A two-tier pricing system resulted with U.S. importers paying nearly one-third more—about \$8.75 a pound (in 1998) for uranium concentrates; this compares with \$8.10 per pound (1998 average) of uranium from the former Soviet Union republics. All of these actions, along with an antidumping case brought against the former Soviet bloc nations have been credited with a 25 percent increase in the spot market price for U.S. uranium.

In the 1990s uranium supplied about 6 percent of the world's energy. According to the U.S. Energy Information Administration, 43 percent of Western Europe's electricity came from nuclear facilities. Though world nuclear power has grown since 1973 from 191 billion kilowatt hours to just over 2 trillion, the nuclear energy industry—which is the prime user of uranium—is essentially flat.

The viability of the industry has been uncertain for quite some time. In the early 1980s, the issue was examined by congressional inquiry. Congress passed the U.S. Nuclear Regulatory Commission Authorization Act of 1983 to assess the industry's viability on a periodic basis. World uranium production expanded, while consumption remained steady. Most of this demand was projected to be met by Canadian producers, which accounted for 26 percent of world uranium production in the early 1990s, while U.S. production was projected to fall to around 3.1 million pounds by 1996. Even the once prolific producers fell by the wayside; production in the former East Germany ceased, while elsewhere, such as Czechoslovakia and Bulgaria, production reorganized, and the former Soviet republics jockeyed for some sort of potential cooperative production agreement.

As of 1999, Cameco (based in Saskatchewan, Canada) was the largest producer of uranium in the world with 27.6 million pounds in 1998, and the firm was most likely (according to industry forecasters) to claim the highest share of the world market. Cameco acquired Uranerz in 1998 as part of the ongoing consolidations and closures claiming many members of the industry. Uranerz had been Cameco's partner in the Key Lake, Rabbit Lake, Crow Butte, and McArthur River projects. The McArthur River site, located about 620 km north of Saskatoon, Saskatchewan, is the largest known deposit of high-grade uranium ore in the world. When fully developed by 2002, McArthur River will produce about 18 million pounds per year of commercial-grade uranium. Cameco Corporation operates the mine and owns about 70 percent of the deposit with Cogema Resources as the owner of the remaining 30 percent.

As of 1998, Russia's stockpile of commercial grade uranium continued to control secondary sources of uranium and therefore, to limit worldwide production. The size of the stockpile was not easily assessed primarily

because of questions about Russia's ability to reprocess spent fuel; it is estimated that the stockpile will reach a minimum between 2003 and 2007. Russia has claimed that its Krasnokamensk, Siberia, mine will increase production four times over by 2010, but experts consider this statement inflated. Kazakhstan and Uzbekistan are better positioned for growth despite the fact that their huge, low-grade sources require in-situ leaching; profits from gold mines have generated much-needed capital for the uranium operations.

U.S. government inventories are to be sold off through the U.S. Enrichment Corporation at 20 million pounds per year from 1999 through 2004. Worldwide projections by the U.S. Energy Information Agency suggest that requirements for uranium production will remain flat until 2010.

Meanwhile, environmental cleanup continued with the Environmental Protection Agency (EPA) and the U.S. Department of Energy announcing a cleanup of radioactive uranium mine waste on land controlled by the Energy Department at the Bluewater Mine near Prewitt, New Mexico. Other cleanups in the early 1990s included two sites on Navajo Nation land—an adjacent mine on privately owned land was also cleaned up by private companies in accordance with an EPA order. Radiation levels in these areas posed a serious health threat to people living in the vicinity. The cleanup included sealing mine openings and moving and covering mine waste, with bulldozed areas replanted with grass and sloped to resist erosion. The economic effects of environmental reclamation claimed corporate victims, however. In December 1999 Atlas Corporation of Colorado filed for reorganization, which included the responsibility for remediating its Moab, Utah, uranium tailings piles. International effects of environmental activism include pressure to close nuclear power reactors in Switzerland, Sweden, and Germany despite studies showing that nuclear power is needed to reduce greenhouse gases, global warming, and acid rain.

From the vanadium side of the industry, suppliers continued to be in a situation of oversupply, despite reduced production by the largest producer, Highveld Steel & Vanadium Corporation of the Republic of South Africa. The pattern of vanadium consumption in the United States was not expected to change much in late 1990s to early 2000s, but will remain subject to cycles in domestic and global steel production.

Shipments of concentrated uranium totaled 49.9 million pounds in 1998, and U.S. uranium exploration companies held 825,000 acres. Their expenditures that year totaled \$21.7 million, 29 percent less than 1997 expenditures. Three states (Texas, New Mexico, and Wyoming) had 74 percent of the U.S. \$30-per-pound uranium re-

serves in 1998, according to the Energy Information Administration (EIA).

CURRENT CONDITIONS

Uranium. At the end of 2001, uranium exploration companies in the United States held 683,000 acres, including mineral fee land leases, and patented and unpatented mining claims. Reflecting the continued decline of the industry, total uranium exploration and development costs during 2001 were \$4.8 million for exploration and land development and \$2.7 million for development drilling, a 28 percent decrease from 2000 and an 84 percent decrease from 1997.

Mining of uranium in 2001 totaled 1,300 tons, 15 percent less than 2000 and 45 percent less than 1998. Of the commercial operations engaged in uranium mining during 2001, eight plants were inactive, with one of the eight closing permanently. At the beginning of 2002, the United States had six uranium mills, capable of milling 13,600 tons of ore daily. All mills were inactive at year's end, but one mill was operational during part of 2001, and two others produced uranium concentrate from mine water during the year.

Vanadium. In 2001 fewer than 10 companies engaged in operations related to the refinement of vanadium-related products. U.S. production values of vanadium for both 2000 and 2001 were reported to be zero by the U.S. Geological Survey. South Africa was the major importer to the United States. U.S. demand for vanadium products declined in 2001 for the fourth consecutive year to 3,210 metric tons. Overall, the U.S. Geological Survey predicts that the demand for vanadium will increase in the future, as steels are formulated to be lighter and stronger.

WORKFORCE

Employment figures for 1998 were relatively unchanged from 1997, but significant changes occurred within the industry. Mining employment and processing both had major increases in their workforces (25 percent and 16 percent, respectively), while reclamation and milling employment both had serious decreases (31 percent and 9 percent respectively). Exploration employment was unchanged. Colorado, Texas, and Wyoming accounted for 72 percent of the total U.S. workforce in 1998, according to the EIA.

At the height of uranium mining (1961 and 1962), there were 925 mines with 5,500 miners in 1961 and 1962. From a peak of 12,000 employees in 1977, employment has declined to 2,300 in 1987; 1,200 workers in 1992; and 700 employees in 1997. Value added per employee did increase from 1992 to 1997 to \$175,700 per production employee; the value added was \$57,800 in 1992 and \$76,000 in 1987.

With the mining of ores at a virtual standstill, and output coming mainly from by-product operations, employment for all occupations including mining, exploration, milling, and processing are all projected by the U.S. Energy Information Administration to decline, alongside the decline of the industry in general. Mining employment in 1998 was 518 people.

Health Hazards. It is now well-known that even low levels of radiation cause serious health risks; however, it wasn't until the late 1960s that major health and safety regulations were enacted for uranium mining. In 1967 the Walsh-Healy Act imposed health standards in the mines. From 1979 to 1981, congressional hearings were held to investigate the link between mining in unventilated mines and lung cancer. The EPA instituted regulations dealing specifically with the mining of uranium ores in 1982. Some of the new rules dealt specifically with worker exposure. Mill operators were required to install protective barriers to minimize radioactive exposure and earthen covers to minimize emissions.

In addition, strict cleaning and work rules were established, which meant lower thresholds for the work week in order to minimize exposure. In 1990, after many defeats in the legislative and judiciary branches, the U.S. Congress passed compensatory legislation, called the Radiation Exposure Compensation Act, which called for compensation of uranium miners who were exposed to radioactivity during the peak years of uranium mining. By 1995 the small number of uranium miners who worked in mining or milling were much more closely monitored for health risks.

SIC 1099

MISCELLANEOUS METAL ORES, NOT ELSEWHERE CLASSIFIED

This category covers establishments that are primarily engaged in mining, milling, and preparing miscellaneous metal ores. Production of metallic mercury by furnacing or retorting at the mine site is also included.

NAICS CODE(S)

212299 (Other Metal Ore Mining)

INDUSTRY SNAPSHOT

Metal ores included in this category include: aluminum, antimony, bastnasite, bauxite, beryl, beryllium, cerium, cinnabar, ilmenite, iridium, mercury, microlite, monazite, osmium, palladium, platinum, quicksilver, the rare-earth metals, rhodium, ruthenium, rutile, thorium, tin, titaniferous-magnetite (chiefly for titanium content), titanium, and zirconium. The actual mining of these ores declined for two decades beginning in the 1970s. Production fell by 10.7 percent through the mid-1990s. In addition, environmental pressure for stricter regulation on mining and recycling strained the mining of ores. In the early 2000s metals mining increased slightly, from 53.8 million short tons in 2001 to 57.6 million short tons in 2002, although the value of the mined ore failed to register an increase when adjusted for inflation. In fact, the value of mined metals fell from \$6.51 billion to \$6.38 billion between 2001 and 2002.

United States consumption of the miscellaneous metals overall exceeds production, especially for the platinum-group metals and tin. However, consumption of metals declined steadily throughout the late 1990s and early 2000s, from 93.9 million short tons in 1997 to 72.2 million short tons in 2002. U.S. industry relies on imported product to satisfy its needs, and a trade deficit exists in these areas. Additionally, the U.S. government maintains a strategic stockpile of product, especially of import-dependent metals, that is crucial to the military and to the national security. The stockpile serves to sustain military reserves at adequate levels and creates a small, insulated metals market with limited fluctuation for certain producers. Specific metals in the U.S. government stockpiles include bauxite, titanium, platinum, and tin.

ORGANIZATION AND STRUCTURE

The production of miscellaneous metals is segregated into mining and metal refining according to respective metal product. Individual metal production is subdivided further into primary and secondary production. In the 2000s approximately 14 percent of mining firms in the industry additionally operated preparation plants. Virtually all of the total product output (99 percent) was from primary products. The industry's market structure grew more concentrated during the final decades of the twentieth century, and the number of metal mining establishments fell to under 125 by 2002, after achieving a dramatic peak of 236 in 1982.

In terms of geographic concentration, the largest number of firms mining miscellaneous metal ores is located in the Pacific region of the United States (California, Washington, and Oregon). The second greatest concentration was in the mountainous western region (Montana, Nevada, and Utah). California ranked first among the United States, with ten sites, followed by Montana with five, Arkansas with four, and Florida and Utah with two each.

The principal economic sectors or industries responsible for the purchase of miscellaneous metal ores are manufacturers of intermediate products for industrial use.

BACKGROUND AND DEVELOPMENT

The mining of the miscellaneous metals is very much intertwined because multiple products are frequently extracted from the same ores; separation of the individual metal products occurs in the smelting process whereby reduction of the ores takes place.

Aluminum. Aluminum is the second most abundant metallic element in the earth's crust after silicon. The use of aluminum exceeds that of any other metal except iron, and it is important in nearly all segments of the world economy. The United States is the leading producer of primary aluminum. Aluminum's prime use is in packaging, aerospace, and increasingly in construction. In addition, aluminum competes with other metals and plastics for an increased share of the automobile market. Aluminum experienced a boom in world demand in the early 1980s, then dropped suddenly on the world market until 1986. The industry rebounded after 1986, buoyed by increased applications of aluminum products, and grew by more than 32 percent from 1986 to 1992.

Antimony. Most production of antimony in the United States is the result of a byproduct or is a co-product of mining, smelting, and refining other metals and ores that contain small quantities of antimony. Foreign deposits far outweigh domestic deposits, and U.S. users of antimony depend on suppliers in Bolivia, China, Mexico, and South

Africa. Antimony has a variety of manufacturing applications, but is mainly used in batteries.

Beryllium. Beryllium is important in industrial and defense applications and is known for its high strength, light weight, and high thermal conductivity. It is used in components for aircraft, satellites, electronics, oil drilling equipment, and consumer goods. The U. S. beryllium industry is the largest in the western world.

Bismuth. Bismuth has been replacing lead (which is highly toxic) in many applications. For example, a bismuth and brass alloy was developed to replace leaded brass in some plumbing applications. In the United States, only ASARCO, Incorporated produces primary bismuth, while a number of smaller firms produce secondary bismuth product mainly from scrap.

Mercury. U.S. production of this key metal was a very small percentage of a declining world market. Manufacturers sought substitutes for mercury, especially for its primary use in batteries. New technology enabled reduction of the mercury content of some batteries by as much as 98 percent. A temporary suspension of mercury sales from the National Defense Stockpile in 1994 resulted in dramatically increased quantities of imported mercury in 1995. Sales were prohibited, not to resume until the U.S. Environmental Protection Agency and the Defense Logistics Agency might determine a safe method of selling the mercury to ensure against environmental damage. Consumption as a percentage of supply remained largely unchanged because of the ongoing elimination of mercury from many products and processes, and because of accelerated efforts to recycle product.

Platinum-Group Metals. Six closely related metals comprise the platinum-group metals: platinum, palladium, rhodium, ruthenium, iridium, and osmium. These are among the scarcest of all metal elements and are used in mostly commercial applications. Platinum and palladium (a platinum substitute) dominate this product grouping. These metals are used as emission catalysts for automobiles and in electronics and glass applications. Platinum is highly valued for its corrosion resistance and catalytic activity.

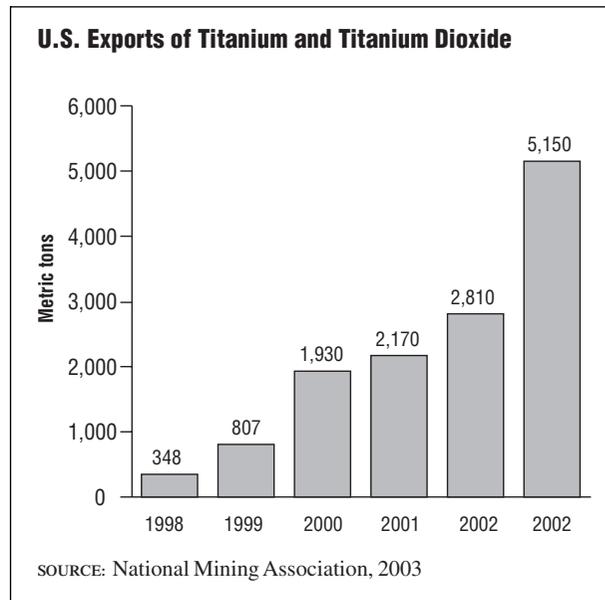

South Africa is the world's largest producer of platinum, furnishing 75 percent of the metal. Russia is also a critical producer in the world market for this metal group. Production of the platinum ores—platinum and palladium—increased in the early 1990s. Platinum production rose from 1,430 kilograms in 1989 to 2,000 kilograms in 1991, while palladium rose from 4,850 kilograms to a high of 6,780 kilograms in 1992, but fell again to 6,000 kilograms by 1994. In terms of revenue, U.S. mine production of platinum and palladium topped \$60 million in 1994, and remained essentially unchanged in 1995.

Rare-Earth Ores: Lanthanides, Yttrium, and Scandium. This group of metals includes 17 elements. In 1995 more than 50 percent of the world total (28,700 metric tons) came from one company in California. The United States was a leading producer and processor of rare-earth ores and continued to be a major exporter and consumer of these products. Domestic ore production was valued at \$82 million in 1995. Three companies refined these ores with plants in Arizona, California, and Tennessee, reaching an estimated value of more than \$500 million. The uses of these metals range from catalysts in petroleum, chemical, and pollution control to metallurgical uses as iron and steel additives, and as alloys to ceramics and glass additives.

Thorium. Thorium is a naturally radioactive element and is extremely expensive to mine—environmental regulations and waste disposal mandate costly extraction and transport procedures. Domestic production of monazite ceased in 1994 as a result of decreased demand for thorium-bearing minerals. Only a small portion of the mined thorium is for consumption, while most is disposed of as waste. Its uses include refractory applications, lamp mantles and lighting, and welding electrodes.

Tin. One of the earliest metals known to humankind, tin is used in a variety of applications. Most known for tin cans, tin is also a component of solder used to weld electronic circuitry. Tin is highly valued for national security purposes by the U.S. military, and is the most collected of all metals in the National Defense Stockpile. Tin production occurs in many countries throughout the world, but U.S. production supplies only a very small percentage of the world market. Domestic consumption of tin exceeds production, and the deficit justifies the high level of defense stockpile.

Titanium. Two firms in Nevada and Oregon produce titanium, most known as a metal alloy used to lighten aircraft and spacecraft. Two titanium sponge producers and nine other firms in seven states produced the total U.S. output in 1995. About 30 companies also produce titanium forgings, mill products, and castings. In 1995 an estimated 65 percent of the titanium metal produced in the United States was used in aerospace applications. The remaining 35 percent was used in the chemical processing industry, mostly as a white pigment in paints, paper, and plastics. It is also used in ceramics, chemicals, welding rod coatings, heavy aggregate, and steel furnace flux. E.I. du Pont de Nemours & Co., Inc. (Du Pont) is the largest integrated producer of titanium products. According to the U.S. Bureau of Mines, U.S. companies own or control almost one-half of the world's productive capacity for titanium pigments. In 1995 titanium dioxide pigment was valued at \$2.6 billion and was produced by five companies in 11 plants in nine states.

Zirconium. U.S. mining interests produced about one-seventh of the total tonnage of zirconium in 1992. Its ore, zircon, is generally recovered from operations in Florida and New Jersey. Zircon is used in refractories, foundry sands, and ceramic opacities. Its ore contains both zirconium and hafnium, two of the mainstay nuclear metals used in reactor cores.

CURRENT CONDITIONS

The actual mining of many of these ores has been in decline since the 1980s. Indeed, U.S. consumption became almost entirely import-dependent in some of these metals categories. Between 1999 and 2002, foreign producers supplied approximately 95 percent of U.S. platinum, along with 100 percent of U.S. bauxite, and 91 percent of U.S. tin.

Aluminum. Aluminum production is a major industry among the miscellaneous metals. Atypical of this industry, the United States was the largest producer of aluminum worldwide at the turn of the twenty-first century. However, aluminum production in the United States declined 28.1 percent in 2001 to 2.63 million tons. That year, global industry leader Alcoa Inc., based in Pittsburgh, Pennsylvania, reported its first quarterly loss since 1994. By the end of 2002, Canada had surpassed the United States in aluminum production due mainly to smelter shutdowns in the Pacific Northwest. Production in Canada was lead by Alcan Inc., the second largest aluminum producer in the world with 2003 sales of \$13.6 billion and a 13 percent share of world aluminum production. Alcoa, which had acquired rival Reynolds Metals Co. in a \$4.4 billion deal in 2000, posted sales of \$21.5 billion in 2003 and accounted for 20 percent of world aluminum production.

Per capita consumption of aluminum in the United States totaled 65 pounds in 2002. To meet demand, the United States imported 41 percent of total aluminum consumed from countries such as Canada, Russia, Venezuela, and Mexico.

Rare Ores. Demand for platinum jewelry consumed approximately one-half of the world market for this precious metal at the onset of the twenty-first century, while the car industry—historically a key consumer of platinum—turned increasingly to palladium catalysts as a substitute. Nevertheless a chronic slump in the production of platinum persisted throughout the 1990s. Russian shipments had declined by more than one-third in 1999, thus aggravating the shortage and curtailing supplies of platinum everywhere through the early 2000s. Record deficits persisted despite unusually high levels of production in South Africa, which produced a record 4.65 million ounces in 2003. Despite the demand growth rate falling to its lowest point in ten years, a platinum shortfall continued to exist. Between 1999 and 2002, the United States relied almost exclusively on platinum from South Africa, the United Kingdom, Germany, and Canada, importing 96 percent of total consumption.

Other Metals. Titanium was described as a roller coaster industry by Myra Pinkham in *American Metal Market*. Volatile fluctuations in demand for the metal are attributed to fashion whims brought about by “designer” sports equipment made from titanium. Emerging industrial markets in gas and oil exploration, combined with traditional aerospace applications maintain the stability of the industry. At the turn of the twenty-first century, more than one-half of product distribution went to the commercial airline industry. Other leading markets were the military, industrial applications, and consumer markets. Exports grew from 348 metric tons to 5,150 metrics tons between 1998 and 2003. To meet consumption demands, the United States imported 73 percent of its titanium between 1999 and 2002 from Japan, Kazakhstan, and Russia.

Environmental Considerations. The momentum toward greater environmental consciousness continued to exert downward pressure on metals demand, especially toxic metals such as mercury. Increasing regulatory controls on mining activities resulted in escalated costs for producers. Incentives abounded for scientists to develop synthetic substitutes for many of the toxic primary metals. Additionally, use of these products was discouraged.

Mercury mining interests, long under scrutiny because of the toxicity of the metal, remained under strict operational guidelines from most governments. The mercury industry not only began to embrace recycling, but also introduced new technology in 1994 to replace mer-

cury battery cells with a new type of membrane cell. U.S. mine production of mercury declined dramatically, by one-third from 1980 to the mid-1990s. Production of the metal virtually collapsed from a level of 1,057 metric tons in 1980 to just 58 metric tons in 1991. Production rose slightly to 64 metric tons in 1994, but political pressure to eliminate the metal from the environment altogether continued through the turn of the century.

Most of the mercury produced in the United States in the early 2000s was from secondary (recovered) product, from such items as obsolete batteries and electrical appliances, and from used fluorescent tubes. The combination of all sources, including the mercury obtained as a by-product of gold mining, brought the total value of U.S. mercury to under \$4 million. The Universal Waste Law of 1995 was amended on July 9, 1999, and became effective on January 6, 2000. The amendment specified proper disposal procedures for fluorescent light bulbs to prevent the mercury-coated tubes from ending up in landfills, and to recycle more product in the process.

INDUSTRY LEADERS

It is difficult to identify precise market shares for individual companies, since nearly all of the leading companies engage in activities classified within other industries. These include **SIC 1041, Gold Ores; SIC 1455, Kaolin and Ball Clay; SIC 1459, Clay, Ceramic, and Refractory Minerals, Not Elsewhere Classified; SIC 3312, Steel Works, Blast Furnaces (Including Coke Ovens), and Rolling Mills; and SIC 3339, Primary Smelting and Refining of Nonferrous Metals, Except Copper and Aluminum.** As of 2003, among the leading companies with interests in the miscellaneous metal ores was the U.S. Steel Group of Pittsburgh, Pennsylvania, with nearly \$9.3 billion total sales in all arenas including production of the miscellaneous metals. The leading company devoted primarily to production of miscellaneous metals ores was Teck Cominco Ltd., formed by the C\$1.5 billion merger between Canada-based Teck Corp. and Cominco Ltd. in 2001. Prior to the merger, Cominco had total sales of \$400 million. As of 2003, Teck Cominco was the leading zinc producer in the world. Other leading firms in the industry included Stillwater Mining Company of Columbus, Montana, with 2002 sales of \$275.4 million.

WORKFORCE

The mining of primary metals is considered to be the most dangerous type of mining. The average occupational injury incident rate per 100 full-time employees for total primary metal production was 16.5 incidents. Overall employment in the industry followed a downward trend through the late 1990s and early 2000s, with metal mining employees declining from 42,202 in 1997 to 27,230 in 2002. The average wage for U.S. miners in

2002 was \$48,609. Alaska was the highest paying state, offering an average annual salary of \$86,000, followed by Louisiana, which paid its miners an average of \$60,308, and Nevada, Wyoming, and Colorado, all of which paid an average of roughly \$59,000.

AMERICA AND THE WORLD

While virtually all of these metals have vital industrial applications in the world economy, the largest reserves, in most cases, are found outside the United States. According to the U.S. Bureau of Mines, the United States only serves as a net exporter of aluminum, beryllium, and rare-earth ores.

The small share and relative descent in U.S. production in this industry has been attributed to several economic pressures. First in most cases, the most productive mines for many of these metals are not located in the United States. Also, the downward pressure on prices and a great degree of uncertainty among producers has led to a U.S. decline in production. Aluminum, platinum, and titanium, for example, experienced severe losses in the face of worldwide competition and a major imbalance in supply and demand. Finally, the demand for many of these metals is directly connected to the world's industrial activity.

In 1999 Russia announced the discovery of a major titanium/zirconium deposit, anticipated to be the largest in the world and totaling seven billion tons of ore. The deposit is anticipated to produce 106 million tons of titanium and 26 million tons of zirconium in the early 2000s. Prior to the discovery, Russia produced no titanium and a maximum of 5,000 tons of zirconium concentrate annually.

SIC 1221

BITUMINOUS COAL AND LIGNITE SURFACE MINING

This classification covers establishments primarily engaged in producing bituminous coal or lignite at surface mines or in developing bituminous coal or lignite surface mines. This industry includes auger mining, strip mining, culm bank mining, and other surface mining, by owners or lessees or by establishments that have complete responsibility for operating bituminous coal and lignite surface mines for others on a contract or fee basis. Bituminous coal and lignite preparation plants performing such activities as cleaning, crushing, screening, or sizing are included if operated in conjunction with a mine site, or if operated independently of any type of mine.

NAICS CODE(S)

212111 (Bituminous Coal and Lignite Surface Mining)

INDUSTRY SNAPSHOT

In 2002 U.S. coal production totaled 1.09 billion short tons, down 3 percent from a record high of 1.12 billion short tons in 2000. A warmer than normal winter during 2002 held down demand, but a hot summer generated increased demand for electricity and thus for coal. In 2002 coal was used to generate 51 percent of U.S. electric power.

In 2001 there were 759 surface coal mines in the United States, which produced 745.3 million short tons of coal. Surface mines accounted for 62 percent of all the nation's coal mines and 66 percent of all coal produced. Wyoming, the country's dominant surface mining state, has 17 surface mines that produced 368.7 million short tons of coal in 2001. This represented 49 percent of all surface-mined coal and 33 percent of all coal mined in the United States. The 11 mines within Campbell County in Wyoming accounted for 329.4 million short tons of the state's coal production.

Surface mining faces many of the same issues as underground coal mining, including regulatory restrictions, environmental concerns, and declining prices. Surface mines must also address reclamation issues of abandoned and depleted mines.

ORGANIZATION AND STRUCTURE

According to the Energy Information Administration, some 1,750 mines operated in 25 states in 1998.

Surface mining was the exclusive mining technique used in 9 of those states. Mines range in size from small facilities that generate several thousand tons of coal per year to mammoth surface operations that extract 10 to 20 million tons per year. The surface and underground mining industry produced more than 1.1 billion tons of coal in 1998.

The Mining Process. Surface mining usually is practiced on relatively flat ground; the coal is recovered from a depth of less than 200 feet. At mines where the coal is located on steep inclines, though, material may be excavated from open pits that can reach depths of several hundred feet.

To reach coal deposits, miners must first remove the overburden, or strata, that covers the coal bed. Between 1 and 30 cubic yards of strata must be excavated for each ton of coal recovered. Dragline excavators, power shovels, bulldozers, front-end loaders, scrapers, and other heavy pieces of equipment are used to move the strata and extract the coal.

The two common methods of surface mining are strip and auger. At strip mines, large drills bore holes in the strata. Explosives are placed in these cavities and detonated. Power shovels or draglines operating at surface level then move the broken strata, while power shovels below dig up the coal and load it into trucks. The strata and coal are removed in long strips. This is done so that the debris from the newest strip can be dumped into an adjacent strip, from which the coal already has been recovered.

Auger mining consists of boring a series of holes that are 2 to 5 feet in diameter and 300 or more feet deep. This parallel and horizontal pattern is carved into a seam of coal that already has been exposed by an outcropping or by strip mining methods. No blasting takes place, and the overburden is left intact. The coal simply is removed and loaded into waiting trucks. Auger mining frequently is used in open-pit mines, where the strata is too thick to economically remove it using strip methods.

Because surface mining is less expensive and more productive than traditional underground mining, new surface extraction technology has allowed this method to dominate U.S. coal production. Moreover, producers are able to remove an estimated 90 percent of the coal at surface mines, while underground mines permit only a 50 to 80 percent extraction rate, depending on the mining method used.

After it is processed, different types of coal are often blended to produce uniform grades of commercial material. Blending also may occur at the point of use. Coal preparation plants can produce anywhere from 200 to 20,000 tons of coal per day. From the preparation plant, 70 percent of the coal is delivered to users by rail. Barges

and ships deliver an additional 20 percent of industry output. Some coal also is stored for future use.

Coal Products. Four grades of coal mined in the coal industry include lignite, subbituminous, bituminous, and anthracite. Each grade differs in moisture content, volatile matter, and fixed carbon content. Anthracite, the highest grade material, accounts for less than one-half of 1 percent of total output and is classified in its own industry (see **SIC 1231: Anthracite Mining**).

Bituminous coal, or soft coal, is the most common type of coal produced in the United States. It represents more than 70 percent of total industry output and accounts for approximately 50 percent of total U.S. reserves. The mineral is composed of 80 to 90 percent carbon and about 10 to 20 percent moisture. A ton of bituminous coal typically generates 19 to 30 million BTUs (British Thermal Units) and ignites at between 700 and 900 degrees Fahrenheit. Bituminous coal possesses a relatively low sulfur content, which causes it to burn more cleanly than some lower grades. Because of its properties, bituminous coal is the principal steam coal used for generating electricity. It also is the primary coking coal used in the steel-making process.

Bituminous coal can be further categorized as low-, medium-, and high-volatile coal, according to its moisture content and heating capacity. Low- and medium-volatility grade bituminous coal typically generates between 26 and 30 million BTUs per ton. High-volatile coal, in contrast, usually produces anywhere from 18 to 29 million BTUs per ton. For comparison, a ton of bituminous coal, assuming an average 22 million BTUs, produces about the same amount of energy as one cord of hardwood, 22,000 cubic feet of natural gas, or 160 gallons of fuel oil.

Subbituminous coal has a 75 to 85 percent carbon content. It produces 16 to 24 million BTUs per ton and is used primarily to generate electricity. In 1995 subbituminous coal represented 31.7 percent of industry output. Although its sulfur content is low relative to lignite, a high moisture content, along with other negative properties, makes it less desirable than higher coal grades for most applications.

Lignite, the lowest ranked coal, is a brownish-black mineral containing a moisture content of 30 to 40 percent. It produces about 9 to 17 million BTUs per ton and ignites at roughly 600 degrees Fahrenheit. Because it deteriorates rapidly in air, has a high sulfur content, and is liable to combust spontaneously, lignite mainly is used to generate electricity in power plants that are close to mines. In 1995 lignite accounted for 8.3 percent of industry production. Lignite also is subject to high royalties charged by the federal government.

Coal Consumers. In 1998, 83 percent of the coal produced in the United States, 912.1 million short tons, was consumed by utilities. Percentage-wise, this was down from 88 percent in 1995. Coal-fired facilities produced approximately 55 percent of the total electricity generated domestically.

The second largest coal customer was the general industry sector, which accounted for 76.5 short tons of coal in 1998. Industry uses for coal include production of materials such as calcium carbide, silicon carbide, refractory bricks, carbon and graphite electrodes, and various food and paper products. Coal also is used to produce gall and stone, primary metals, textiles, and plastics. One of the largest industrial uses of coal is cement production. In fact, 90 percent of U.S. cement plants use coal—at a rate of about 1 ton for each 3.5 tons of cement produced.

Iron and steel manufacturers are the third largest coal consumers. These industries use coal to produce coke—a primary ingredient in the smelting of iron. In 1995 approximately 27.6 million short tons of coal was used in the processing of iron and steel.

BACKGROUND AND DEVELOPMENT

Coal is not a true mineral, but rather an organic compound formed from the remains of living organic material that flourished 250 to 400 million years ago. The Chinese are believed to be the first to have used coal, in about 1000 B.C. The Romans also are believed to have burned the material. The first written history of coal dates back to 1200 A.D., when metalworkers in Europe were observed using it.

Widespread use of coal did not occur in Europe until the fifteenth and sixteenth centuries. Advances that significantly promoted the use of coal during the eighteenth century included Abraham Darby's methods of using coal instead of charcoal in blast furnaces and forges, as well as the coal-burning steam engine developed by James Watt.

Although coal mining was taking place in North America as early as 1701 in Virginia, it was not until 1745 that coal was mined in the colonies on a commercial scale. During the American Revolution, when European sources of coal became inaccessible, the fledgling industry's importance increased. By the early 1830s, many small coal mining operations had sprung up along rivers in Appalachian regions. In the 1840s the industry mined its first 1 million tons.

The advent of the steam locomotive in the middle and late 1800s prompted a huge expansion of the coal industry, as producers took advantage of that important new channel of distribution. This development, in conjunction with the start of the Industrial Revolution, resulted in huge industry growth. Between 1865 and 1905,

for instance, production ballooned from 182 million tons to 928 million tons. Although the United Kingdom led world coal production throughout the nineteenth century, the United States surpassed that country as the leading producer in 1900. In that year, U.S. companies mined 250 million tons of coal. By 1935 world output stood at 1.18 billion tons.

Growth in the use of coal, mostly to generate energy and to create iron and steel, continued at a moderate pace until the middle 1900s in most industrialized countries. By 1958 annual demand for coal in the United States stood at about 400 million tons. However, massive growth in demand in previously undeveloped regions, such as the former U.S.S.R. and China, had pushed global consumption past 2.5 billion tons by the 1950s.

In the 1950s and 1960s demand for coal realized solid growth in the United States, despite the increasing popularity of alternative energy sources, such as petroleum and hydropower. During those decades, a booming postwar economy spurred demand for coal by utilities and iron and steel makers, as well as other commercial industrial sectors.

Growth of Strip and Auger Mining. Coal was first taken directly from exposed ledges and outcroppings. When this meager supply was consumed, however, miners began to scratch beneath the earth's crust using surface, or open-cut, mining equipment. After easily accessible surface coal had been extracted, and the strata became too thick to remove, companies were forced to mine for coal using costly underground operations. Underground mines, though, could not safely access coal that was close to the earth's surface because the risk of the mine collapsing was too great. For this reason, much of the coal that lay just beneath the earth's surface, but also under thick strata, remained inaccessible.

In the 1960s and 1970s, improved earth-moving equipment catapulted the surface, or strip mining, industry to center stage. New tools allowed miners to remove overburden more than 200 feet thick. Massive power shovels, many taller than a 12-story building, were developed that could remove up to 115 cubic yards of debris in a single bite. New earth hauling trucks had equivalent capacities. Similar advancements propelled auger-mining technology, which originated in the 1940s. Indeed, massive drills, conveyors, and haulers made auger mining, like strip mining, preferable to many forms of underground mining.

Coal companies were finding that, in most cases, they could extract coal using new surface mining techniques more cheaply and efficiently than they could using even the latest underground mining technology. Surface mining accounted for only 35 percent of total U.S. coal production in 1965. By the late 1970s, however, auger

and strip mining operations accounted for a full 60 percent of industry output. Because surface mining is not always applicable in mountainous regions, such as Appalachia, coal extracted from underground mines accounted for 38 percent by 1995.

Labor Influence. The early mining industry in the United States and Europe was characterized by a history of worker exploitation as well as dismal and dangerous working conditions. For these reasons, the impetus to form and maintain strong labor unions has played an integral role in the development of the industry.

The first U.S. coal labor union appeared in Illinois in the 1890s. By 1900 unions were present in five other states. Eventually, the United Mine Workers of America (UMW), a national organization, became the dominant labor influence in the industry; by 1940 the UMW represented more than 800,000 mine workers. Federal and state governments also became active in the protection of mine workers in the first half of the century. Following a succession of mine explosions in 1907 that killed thousands of miners, the Bureau of Mines (BOM) was created. Several states also began requiring mine safety inspections.

The industry death toll continued to rise, however, prompting the federal government to establish mine safety standards in 1941, although these regulations were not enforced until 1946. In 1969 Congress passed the important Coal Mine Health & Safety Act (CMHSA). Adding to federal and state efforts were international organizations, such as the Coal Mining Industrial Committee, which was formed in 1945 to improve mine workers' conditions on a global scale. Between 1968 and 1991, mine fatalities decreased from .27 fatalities per 200,000 man-hours to .05—a reduction of 81 percent. Injures declined as well, by about 29 percent.

By the 1960s labor organizations had become so strong in the mining industry that about 75 percent of all coal was produced by UMW members. Furthermore, several other unions appeared, including the Progressive Mine Workers of America, the International Brotherhood of Electrical Workers, and the International Union of Operating Engineers. These combined labor forces vastly improved wages and working conditions for miners in the 1960s, 1970s, and 1980s. Critics, however, argued that labor unions had become too strong and were sapping coal industry productivity and health.

The 1970s and 1980s. Many coal producers fell on hard times during the 1970s—a result of several factors. A principal reason for the industry's decline was a marked decrease in productivity and an increase in salaries and benefits. Federal safety regulations, for instance, were blamed for slashing productivity by almost 50 percent between 1969 and 1978—from 1.95 miner hours per ton

to 1.04. The Coal Mine Health & Safety Act (CMHSA) regulations forced companies to hire more personnel and alter existing labor practices that were deemed unsafe or unfair.

Of critical importance to the coal mining industry in the 1970s, as well as in the 1980s and 1990s, were federal environmental regulations that cut into the profits of industry players. A series of state and federal bills dealing with land reclamation, for instance, were blamed for decreased productivity at surface mines—down to 3.03 tons produced per man hour in 1977 from 4.74 tons in 1974. The Surface Mining Control and Reclamation Act (SMCRA) of 1977 also set up a provision for cleaning up old mining sites. That provision, which among other things instituted a tax of 35 cents per ton on all surface-mined bituminous coal, generated \$256 million in 1996.

Another factor that hurt producers in both the 1970s and 1980s was a decrease in the growth of coal demand. Hydro, nuclear, natural gas, and oil sources continued to reduce coal's total contribution to domestic energy consumption. Although coal production grew at a rate of 5.7 percent in the 1970s and 3.8 percent in the 1980s, this was down from a 7.3 percent annual growth rate in the 1950s and 6.6 percent average annual growth during the 1960s.

During the 1980s, however, many coal producers succeeded in overcoming the profit barriers that arose during the 1970s. Although total growth in demand for coal declined in the 1980s, the industry was able to increase its contribution to total U.S. energy consumption from a low of 17.6 percent in 1973 to more than 25 percent in the late 1980s. Even a significant reduction in the use of coal by iron and steel producers was not enough to offset increased consumption by utilities, which were seeking less expensive alternatives to oil.

Coal companies also enjoyed growing success in increasing productivity and extracting labor concessions in the 1980s. Technological advancements in automation and mining techniques allowed producers to realize massive productivity gains between 1980 and 1990. Productivity at surface mines shot up from about 3 tons per man hour in the late 1970s to more than 6 tons per hour by 1990, and continued to rise. As a result, total industry employment declined from about 240,000 workers in 1978, when 665 million tons of coal was shipped, to 81,000 workers in 1995, when 1.12 billion tons of coal were produced.

As industry employment diminished and new surface mining plants opened in western states, labor's influence on the industry declined. Indeed, the portion of coal produced at UMW mines had declined to about 30 percent of the total by 1990, while the percentage of U.S. coal mined by members of all labor unions had fallen to

only 55 percent. By 1995 about 27 percent of miners at surface mines belonged to the UMW, and another 11 percent belonged to other unions.

Industry participants also insisted that they had made strides in meeting environmental challenges, pointing to new mining, processing, and coal burning technologies. Environmental groups, however, remained opposed to many aspects of the coal mining industry.

Despite successes in the 1980s, industry profit growth was held in check by relatively stagnant demand growth and declining prices. Production outpaced demand, forcing prices down. Between 1992 and 1995, for instance, the price of coal dropped from \$21.03 per ton to \$17.52 per ton, using constant 1992 dollars.

Overall coal production realized very modest gains from 1991 to 1998, averaging less than 1 percent annual growth. There was a slight decrease from 1994 to 1995, but figures for 1996 indicated growth of more than 2 percent. Surface mining, however, grew steadily. While coal production east of the Mississippi, where most underground mines were located, fell 3.9 percent from 1994 to 1995 to 544 million short tons, coal production in the western states, where surface mines predominate, increased by 4.6 percent to a record 489 million short tons. In 1998 surface production stood at 686.6 million short tons. Prices continued to decline, though, at the same time that production costs were rising.

Mines continued to close, and employment continued to decline across the whole coal mining industry, with a net loss in 1995 of 250 mines and about 7,000 miners. Employment at surface mines declined by 9.9 percent from 1994 to 1995, to about 32,000 miners. However, productivity continued to increase. Miner productivity east of the Mississippi grew to 3.45 short tons per miner per hour, while in the West productivity rose 7 percent to 14.18 short tons.

Phase one of the Clean Air Amendment Act of 1990, which set a goal of cutting sulfur dioxide emissions nationwide by 10 million tons by the year 2000, went into effect on January 1, 1995. The law required electrical generating plants to lower smokestack emissions of sulfur compounds, but gave utilities wide latitude in how this might be accomplished. Plants that exceeded requirements received allowances that could be sold or exchanged on the open market. Because of this market-based approach, the legislation had not, by the time phase one went into effect, had the calamitous effect that some analysts had feared. Most utilities had not found it necessary to install expensive scrubbers, but had found switching to low-sulfur coals and purchasing allowances adequate to meet the law's requirements. Midwestern mines that produced coal with a higher sulfur content felt the impact of the legislation most severely, while western

low-sulfur coal producers experienced some relative benefit. The threat of increased environmental controls related to carbon dioxide emissions and land reclamation was, however, a source of concern for many producers.

Electric utilities continued to consume the vast majority of surface-mined coal and lignite. In 1998 electric utilities used 912 million short tons. A study by Resource Data International Inc., reported in July 1996, projected continued domination of electricity generation by coal through the year 2015. Annual increases of 1.3 to 2.1 percent were forecast.

Another segment in the energy market that held promise for coal producers was nonutility power producers. Since passage of the Public Utility Regulatory Policies Act (PURPA) of 1978, several new types of nonregulated power facilities had developed. These entities usually sold their output to public utilities. Nonregulated facilities included nonutility generators, independent power producers, and cogenerators.

The domestic demand for coking coal was expected to continue its decline. Accounting for 25 percent of industry output in 1950, the demand for coking coal to produce iron and steel in the United States commanded only 3.4 percent of production in 1991. In 1993 consumption of coking coal hit a low of 31 million short tons, but had risen to 33 million tons in 1995. By 1998 that figure had declined to 27.6 million.

CURRENT CONDITIONS

Coal prices rebounded slightly during 2002, after numerous years of decline. The average price of delivered coal was \$24.68 per short ton, a 2 percent increase from 2001. Coking coal prices averaged \$46.42 per short ton, a 5 percent increase, and industrial steam coal prices averaged \$32.26 per short ton, a 3 percent increase. Coal prices are determined by a number of factors that are beyond the industry's control, including weather patterns and enactment of environmental regulations concerning smokestack emissions and mine cleanup and restoration.

Surface mining evokes particular reactions from environmentalists due to the large land areas that are altered by surface mining operations. Previously abandoned surface mines that were not properly restored led to the industry's negative image. The Department of the Interior's Office of Surface Mining oversees land recovery of mines that were abandoned or depleted prior to 1977. According to the Office of Surface Mining, during 2002 over 5.8 million acres were under permit for land mining, including nearly 116,000 new acres awarded permits during the year. Within the year about 73,500 acres completed Phase Three of reclamation and were released from the reclamation program. Out of 32 surface mining states and tribal reservations, 23 states and reservations

reported 862,500 acres of disturbed lands that were in need of reclamation.

Despite a sluggish economy, coal mining remains stable for the foreseeable future. Energy usage is expected to increase, and coal prices and production should benefit from growing demand. Although natural gas continues to increase its market share, coal is a long-time stable of the American energy landscape and is expected to remain an inexpensive, readily available energy source for the United States. However, long-term questions regarding ecological sustainability and environmental pollutants released by burning coal will continue to shadow the industry.

INDUSTRY LEADERS

The coal industry has undergone a period of consolidation that began in the mid-1970s. Since that time, the number of coal producers declined from 2,300 to about 1,500 by 1993. The number of mines those companies operated fell during the same period from 6,200 to 3,200. In the 1970s a number of energy companies such as Exxon, Shell, and Sun Oil had acquired coal properties in an attempt to diversify, but soft prices for both coal and oil encouraged many of these companies to sell off some or all of these acquisitions. Large coal operators such as Peabody Holding, Zeigler Coal, and Cyprus AMAX Minerals purchased many of these existing mines.

The largest U.S. producer of coal in 2002 was Peabody Energy Corp., which had 33 U.S. mines and produced over 190 million short tons. Peabody had sales in fiscal 2002 of \$2.71 billion, resulting in a net income of \$105.6 million. The second largest producer of coal in the United States was Arch Coal, Inc., which produces more than 115 million tons of coal per year. The company had 2002 sales of \$1.5 billion, resulting in a net loss of \$2.6 million. The third biggest producer was CONSOL Energy, Inc., with net income of \$10.6 million in 2002 on sales of \$2.1 billion. Horizon Natural Resources (formerly AEI Resources) is another major coal mining operation in the United States. Although Horizon posted revenues in excess of \$1.4 billion in 2001, the company's heavy debt load—a result of numerous acquisitions in the 1990s—required the company to declare Chapter 11 bankruptcy twice during 2002, leaving its future uncertain.

The eight largest mines in the nation were all surface mines located in Wyoming. The North Antelope Rochelle Compe, owned by the Powder River Coal Company, was the largest, producing 77.8 million short tons in 2001. Black Thunder, owned by Thunder Basin Coal Company, was second with 67.6 million short tons. Other top-producing mines included Cordero Mine, owned by Cordero Mining Co. (43.4 million short tons); Jacobs Ranch Mine, owned by Jacobs Ranch Coal Company

(29.3 million short tons); Caballo Mine, owned by Caballo Coal Company (27.1 million short tons); and Eagle Butte Mine, owned by Rag Coal West, Inc. (24.8 million short tons).

WORKFORCE

The number of workers employed by U.S. coal producers continued declining in 2001 to about 78,600. Although surface mining operations are less susceptible to labor cutbacks than underground mining facilities, surface mines are considerably less labor intensive and provide fewer job opportunities per ton of coal produced than do underground mines. Labor positions in the surface mining industry are concentrated in the maintenance and operation of heavy machinery. In addition, surface mining companies have a higher proportion of management and clerical workers than the overall coal industry.

Employment opportunities in the surface mining industry have been limited. Labor unions have pushed hard to get companies that have opened new surface mining operations to employ workers who were displaced from underground mining jobs. This factor, in addition to constantly rising automation and productivity, make coal industry employment highly competitive. Even new positions in management remained limited in the early 1990s—a result of generally tepid industry growth.

AMERICA AND THE WORLD

Of the estimated 490 billion tons of coal reserves in the United States, only about 150 billion tons are accessible through surface mining. Nevertheless, this reserve ensures a dominant U.S. position in the future global coal mining industry. In addition to healthy reserves, U.S. coal companies have achieved the highest productivity of any coal-producing nation. While the United States places second to Australia as the largest coal exporter, America remained the largest total coal producer until the early 1990s, when China assumed the lead.

The amount of coal exported from the United States has increased. In 1998 exports stood at 76.2 million tons. The primary reason for the increase was the substantial growth in the demand for U.S. steam coal. Exports to Europe more than doubled between 1994 and 1995. At the same time, the United States imported less than 1 percent of its coal needs. Canada overtook Japan as the single largest consumer of U.S. coal in 1998, absorbing 19.2 million tons to Japan's 7.7 tons. Other countries importing U.S. coal include Brazil (6.5 million tons in 1998), the United Kingdom (5.9 million tons), and Italy (5.3 million tons).

Despite its strong export position, the 1998 figure represents only 7 percent of total U.S. production for the year. The price per exported ton fell from \$44.36 in 1996 to \$34.30 in 1998. In fact, U.S. share of the world coal

market has fallen dramatically since the 1950s. From 1960 to 1990 the country's global market share fell from 50 percent to approximately 25 percent. This decline was a result of increased production by several other countries, many of which are not subject to environmental regulations and labor controls that constrain U.S. producers. South Africa and Australia, particularly, have proven themselves effective competitors for global market share. Other countries with a small but growing output of coal include Indonesia, Colombia, and Venezuela.

Producers also have kept a close eye on China, which produced 1.2 billion tons in 1998—and which boasts massive coal reserves in excess of 800 billion tons. China's export potential clearly is formidable. The country has continued to strive to upgrade its production and distribution infrastructure with the help of Japanese investment capital and has embarked on an ambitious nuclear energy program. China hoped that increased domestic use of nuclear energy would allow it to divert more of its coal production to the export market. Other countries that were striving to garner global coal market share in the early 1990s included Columbia, Venezuela, and Indonesia. These three, along with Canada, make up the major exporters to the United States.

RESEARCH AND TECHNOLOGY

To maintain economic viability and their position in the global export market, U.S. surface mining firms have continued to rely on technological advances to overcome imposing barriers that face them. Of great importance were projects to improve the cleanliness and efficiency of coal-fired electric power plants. The U.S. Department of Energy was developing five categories of research. Low-emission boiler systems incorporated advanced combustion and innovative flue gas cleaning systems in the initial design for new power plants. Pressurized fluidized bed combustion captured sulfur pollutants inside the boiler instead of in the stack and allowed combustion at temperatures below the point at which most nitrogen pollutants form. The integrated gasification combined cycle (IGCC) employed coal gasification rather than traditional combustion and combined a steam turbine driven by exhaust heat with the gas turbine driven by the coal gas. Indirectly fired cycles employed a design that heated a working fluid, such as air, to turn the turbine rather than the hot gases of combustion. Finally, integrated gasification-fuel cell combinations would link a coal gasifier with a fuel cell. By 1995 pressurized fluidized bed combustion systems and integrated gasification combined cycle (IGCC) systems were in commercial use. The primary goals of the industry at present are to produce coal more efficiently and more safely, as well as to encourage scientists to find cleaner ways in which it can be used.

SIC 1222

BITUMINOUS COAL UNDERGROUND MINING

This classification includes establishments primarily engaged in producing bituminous coal in underground mines or in developing bituminous coal underground mines. This industry includes underground mining by owners or lessees or by establishments that have complete responsibility for operating bituminous coal underground mines for others on a contract or fee basis. Bituminous coal preparation plants performing such activities as cleaning, crushing, screening, or sizing are included if operated in conjunction with a mine. Independent bituminous coal preparation plants are classified in **SIC 1221: Bituminous Coal and Lignite Surface Mining**.

NAICS CODE(S)

212112 (Bituminous Coal Underground Mining)

INDUSTRY SNAPSHOT

In 2001 there were 719 underground coal mines in the United States, which produced 380.6 million metric short tons. Of total U.S. coal mines—underground and surface—48 percent were underground mines, which contributed 34 percent of all coal. West Virginia leads the nation in underground coal mining with 193 underground mines that produced 99.6 million metric short tons in 2001. Other leading underground coaling states include Kentucky (264 mines, 80.9 million short tons), Virginia (109 mines, 22.5 million short tons), and Pennsylvania (73 underground mines, 58.1 million short tons).

Despite its large size and its importance to energy and industrial markets, the U.S. underground coal mining industry is in some fundamental ways a troubled one. These difficulties first manifested themselves in the late 1960s and have continued unabated into the 2000s. A primary threat to industry participants has been the rapid proliferation of relatively efficient surface mines. Other detriments include increasing environmental constraints, labor problems, stagnant growth, and foreign competition.

ORGANIZATION AND STRUCTURE

In 1998 there were about 860 underground coal mines in operation. By 2001 that number had declined to 719 underground mines. Underground mines were more prevalent in the East, accounting for 64 percent of production. The majority of these mines were located in the Appalachian region. Surface coal mines were located primarily in the West, with the largest surface mines in the world found in the Powder River Basin, located in Montana and Wyoming. (See **SIC 1221: Bituminous Coal Surface Mining**).

Steam coal, which represents the large majority of industry output, is most often used to power electric utilities. General industry, such as glass making and cement production, accounts for the next large portion of coal consumption. Metallurgical coal, or coking coal, is used for iron and steel production. Although they are classified as part of the same industry, these three segments differ in their reserve base, production facilities, distribution channels, and marketing requirements.

Besides regional distinctions and differences in mining techniques, underground mines differ in the quality and type of bituminous coal they produce. Eastern underground coal, for instance, is more likely to exhibit coking properties. Coal mined from underground operations in the Northeast typically has a high energy content and contains a widely varying amount of sulfur, a pollutant that is believed to be a major source of acid rain. Eastern Appalachian coal is most likely to have a very high sulfur content, while central Appalachian coal is comparatively low in sulfur. Much of the underground

coal mined in the Midwest, such as Illinois Basin coal, is also high in sulfur.

Because it has a higher energy content and costs much more to produce, coal extracted from underground mines is more expensive than surface-mined coal. Appalachian coal, for instance, was priced at \$28.24 per ton in 1995. In contrast, western surface mined coal was selling at \$9.63 per ton. High transportation costs associated with western-mined coal tend to reduce this great disparity though.

Underground Mining Methods. Companies engaged in this industry extract coal that lies 200 to 1,000 feet below the earth's surface, though some mines are as deep as 2,000 feet. Underground mines consist of a series of parallel and interconnecting tunnels from which the coal is cut and removed with special machinery. The process is complex and sometimes dangerous. The mine must be adequately ventilated to protect miners from dust and explosive methane gas that is released by the coal. In addition, careful ground control must be practiced to prevent the roof of the mine from collapsing on workers and equipment.

Three types of underground operations are distinguished by the method used to access the coal mine. Drift mines are characterized by the use of a level tunnel leading into the mine, while slope mines have an inclined tunnel, and shaft mines utilize a vertical tunnel. The primary methods of extracting coal from all of these mines are room-and-pillar, long-wall, and shortwall.

Room-and-pillar mining is often the least efficient method. It often allows recovery of only about 50 percent of the coal, although there are occasions when this methodology can achieve a much greater recovery percentage. Long-wall and shortwall mining, in comparison, extract up to 80 percent of the usable coal. In a room-and-pillar operation, coal is mined in a series of rooms cut into the coalbed. Pillars of unmined coal are left intact and serve to support the mine roof, as miners advance through the coal seam. Sometimes the coal in the pillars can be extracted later in the "retreat" phase.

The two basic types of room-and-pillar mining are conventional and continuous. Conventional mining consists of a series of operations that involves cutting and breaking up the coalbed, blasting the bed, and then removing the shattered coal. Continuous mining, on the other hand, uses a machine that digs and loads coal in one operation, without blasting. The majority of room-and-pillar coal was extracted using continuous mining in the 1990s.

Long-wall mines use huge machines with cutting heads. The heads are pulled back and forth across a block of coal up to about 600 feet long. Coal is sheared and plowed into slices that are removed by a conveyor. Mov-

able roof supports allow mined-out areas to cave in behind the advancing machine. In the mid-1990s, long-wall systems accounted for about half of all coal mined underground. Shortwall mining is similar to long-wall operations, but the continuous mining machine shears smaller blocks of coal, generally less than 150 feet long.

BACKGROUND AND DEVELOPMENT

Bituminous underground coal was created during a 250- to 400-million-year process in which the ocean covered and compressed organic deposits. Low-grade coal material that eventually developed below the ocean floor was further compacted into higher grade bituminous coal. More extreme pressure, resulting from the folding of the earth's surface into great mountain ranges, such as the Appalachians, produced the highest grade coal. This high-grade coal is most likely to be found in the United States in underground mines along the eastern seaboard.

The first coal mined from the famous Appalachian bituminous coal field, which is more than 90 miles long and covers 63,000 square miles, occurred in the mid-1700s. Most of this coal, though, was simply dug from exposed coal seams on the earth's surface. During the 1800s, after the easily removable surface coal had diminished, underground mining became the industry standard. By the early 1830s in fact, underground mines were operating in many parts of Appalachia, as well as in several areas along the Mississippi River. In 1840 the U.S. coal industry mined its first 1 million tons.

As the coal industry gained strength in the 1850s and 1860s, the federal government began to play an increasingly important role in its development. Concerned about the loss of valuable federal coal reserves, Congress enacted the first legislation dealing specifically with federal coal resources in 1864. The legislation provided for the sale of coal lands at public auction for a minimum of \$20 per acre, compared to \$1.25 per acre for other types of land. The law was modified in 1865 to require that purchasers be miners, and that one buyer could acquire no more than 160 acres.

The Coal Lands Act of 1873 added further regulations to the sale of lands with coal reserves by stipulating new prices for federal lands that were located near railroads. This act remained the dominant law regulating federal coal reserves until the 1920s, when The Mineral Leasing Act was passed. The Mineral Leasing Act of 1920 essentially ended an era of federal coal disposal. By requiring mining companies to lease, rather than purchase, coal reserves, the act instituted an ideology of close government planning and supervision of federal coal production.

The Industrial Revolution. By the late 1800s, U.S. coal production had reached a staggering 250 million

tons per year. As the industry expanded, huge numbers of miners were employed to work underground. Besides suffering dismal working conditions for relatively low pay, miners were also exposed to serious hazards. Unsafe mining practices often resulted in cave-ins or explosions that killed hundreds of workers at a time, and poor ventilation gave many miners "black lung," an ailment caused by inhaling large amounts of coal dust.

To relieve the plight of underground miners, federal and state government bodies began regulating and mandating safety standards in the early 1900s. In addition, workers succeeded in forming powerful labor unions that forced improvements in working conditions and higher salary scales. Although workers began forming state unions as early as the 1890s, the United Mine Workers of America (UMW) had become the dominant force for change in the industry by the 1930s. By 1960 UMW members were responsible for 75 percent of industry output.

At the same time that industry workers were making gains, underground coal mining companies were also realizing successes. Industrial growth in the early 1900s pushed U.S. coal production to more than 500 million tons per year in the early 1920s, the large majority of which was extracted from underground mines. International demand for U.S. coal following World War II further aided the companies; exports reached a record 80 million tons per year in the mid-1950s. Furthermore, the introduction of long-wall systems in the 1950s rapidly increased industry productivity. These factors combined to enable many coal companies to reap huge profits between 1900 and 1950.

Total demand for U.S. coal subsided after World War II—a result of the proliferation of alternative fuels, such as natural gas and oil. Nevertheless, coal producers benefited from the huge productivity gains achieved in the 1950s and 1960s because of the introduction of new mining techniques and advances in machinery. Although coal production fell to about 400 million tons per year by the late 1950s, worker productivity increased 50 percent, and payroll costs declined between 1940 and 1960. In addition, an increase in the demand for underground-mined metallurgical coal helped offset decreasing demand in other areas. The United States became a major supplier to Japan and Europe, who were trying to rebuild their countries. Until the late 1970s in fact, the United States supplied 30 to 50 percent of those regions' import demand. Many underground coal mining companies were thus able to maintain profit growth throughout the 1960s.

Industry Downturn. In the late 1960s and early 1970s, the underground bituminous coal industry suffered serious setbacks. Most importantly, coal production in the United States rapidly shifted from underground mines in

the East to surface mines in the West. New surface mining technology and machinery, which allowed companies to surface-mine coal at drastically reduced costs, accelerated this trend in the 1970s and 1980s. Furthermore, western mine operators were able to employ mostly nonunion labor—a factor that eventually weakened organized labor's influence on underground mining companies across the country.

Also during the 1970s and 1980s, domestic demand for metallurgical coal, which is primarily supplied by eastern underground mines, dropped from about 10 percent of total industry production to 4 percent. Because metallurgical coal is usually of a higher grade than steam coal, the loss of this high-income domestic segment constituted a serious blow to many Appalachian mine companies. The drop reflected the overall decline in the late 1960s and 1970s of the U.S. iron and steel industry, which was battered by foreign competition and productivity losses, among other problems.

Adding to industry turmoil in the 1970s and 1980s were stringent new environmental regulations and an increase in foreign competition in the export market. The loss of world export market share hit underground mining companies particularly hard, as they produced a proportionately larger share of export coal than do surface mining firms. Because of new safety and environmental requirements, moreover, underground mine productivity fell from 1.95 tons per miner hour in 1969 to just 1.04 tons by 1978.

As producers battled on several fronts, total demand for underground coal rose only 2 percent between 1980 and 1990. New legislation, much of it intended to protect the environment from both surface and underground mining operations, further pressured the industry. The Surface Mining Control and Reclamation Act (SMCRA) of 1977, the 1988 National Bituminous Coal Wage Agreement (NBCWA), the Ford-Wallop Agreement, parts of the Comprehensive National Energy Policy Act, and several other legislative efforts increased downward pressure on coal industry profits, although environmental groups continued to protest that the measures were insufficient.

The net effect of western mining growth, diminished demand in some high-margin markets, and new regulations contributed to the decline of underground mining. Despite an overall rise in coal consumption to more than 950 million tons by 1990, the share of U.S. coal produced by underground miners plummeted from 65 percent in 1965 to about 40 percent by 1985. Even massive gains in productivity during the 1980s, to 2.54 tons per miner hour, were unable to restore profits for many ailing companies.

Though the number of underground mines dropped in the 1990s—in 1993 there were more than 1,100 U.S.

mines, but in 1998 there were only about 860—underground mining production increased through the 1990s, rising from about 351 million tons in 1993 to 430 million tons in 1998. The increase in production was due primarily to the trend toward larger and more efficient mines. The increasing use of long-wall and continuous mining methods also helped boost productivity.

1998 was a banner year for overall coal production, which reached a record 1.12 billion tons, according to an estimate from the Energy Information Administration. This amount, which was the fifth straight year U.S. coal production output was more than a billion tons, reflected an increase of 2.6 percent over 1997 numbers and 18.3 percent over 1993 figures. Output in the East accounted for 51 percent, or 570.6 million tons of the total, while production in the West reached a record 547.6 million tons, 49 percent of the total. Though coal production continued to migrate to the West, underground operations continued to dominate production in the East. Data from the Energy Information Administration revealed that productivity levels, when calculated in terms of tons per miner, had more than doubled since 1985. However, the number of miners employed as underground miners had declined. While more than 64,000 underground miners had been employed in 1993, this figure dropped to 51,000 in 1998.

According to a 1998 survey by the National Mining Association, the four top-producing underground mines included the Enlow Fork Mine in Pennsylvania, the Twentymile Mine in Colorado, the Bailey Mine in Pennsylvania, and the Mountaineer Mine located in West Virginia. Wyoming and West Virginia were the top coal-producing states in the nation, producing about 314 million and 171 million tons, respectively, in 1998. However, West Virginia was the leader in 1997, in terms of shipments of processed bituminous coal from underground mining operations, followed by Kentucky and Pennsylvania.

The federal government owned about a third of the U.S. coal resources in 1998, according to estimates by the Bureau of Land Management. The government's reserves consisted of about 92 billion short tons of recoverable coal reserves, considerably more than the 20 billion tons held by the next largest holder of reserves, the Great Northern Limited Partnership. The Peabody Group came in third with an estimated 10.3 billion tons, followed by CONSOL Energy Inc., and Arch Coal Inc. Each had less than 4 billion tons of coal reserves.

Phase One of the Clean Air Amendment Act of 1990, which set a goal of cutting sulfur dioxide emissions nationwide by 10 million tons by the year 2000, went into effect on January 1, 1995. The law required electrical generating plants to lower smokestack emissions of sulfur compounds, but gave utilities wide lati-

tude in how this might be accomplished. Plants that exceeded requirements received allowances that could be sold or exchanged on the open market. Because of this market-based approach, the legislation had not, by the time Phase One went into effect, had the calamitous effect that some analysts had feared. Most utilities had not found it necessary to install expensive scrubbers, but had found switching to low-sulfur coals and purchasing allowances adequate to meet the law's requirements. Midwestern mines that produce coal with a higher sulfur content felt the impact of the legislation most severely, while western low-sulfur coal producers experienced some relative benefit. The threat of increased environmental controls related to carbon-dioxide emissions and land reclamation was, however, a source of concern for many producers.

The Clean Coal Technology Program, a partnership between the U.S. government and private industry, began in 1986 with the goal of developing options for controlling hazardous emissions. With an investment of more than \$6 billion, by the late 1990s the program had about 40 projects either completed or in development. These projects included advanced power generation systems designed to increase coal-to-electricity efficiencies, environmental control devices to reduce pollution in a cost-effective manner, and efficient coal processing and cleaning processes.

CURRENT CONDITIONS

Underground coal mining came into national focus during the summer of 2002, when nine coal miners were amazingly rescued after being trapped 250 feet below the earth's surface in a coal mining accident in Quecreek, Pennsylvania. The incident sparked numerous lengthy accounts by journalists and a made-for-television movie, which highlighted the significant dangers faced by underground coal miners.

Underground coal mining is facing significant challenges in the twenty-first century, one of which is struggling with increasingly stiff competition from very efficient surface mines, primarily located in the Western region. For example, Pennsylvania, the nation's leading underground coal mining state, has 193 surface mines. However, these 193 mines produce just 16 million metric tons of coal, compared with 17 surface mines in Wyoming that produce almost 369 million metric tons of coal, making Wyoming the nation's top coal-producing state.

Found primarily in the East, underground mining produces more coal that is denser in sulfur than coal found in the Western region, causing high-sulfur coal to emit more environmentally undesirable pollutants when burned. Although coal industry experts expect the Bush administration to leave room for coal mining firms to operate with few new environmental regulations, smoke-

stack emissions will continue to be a problem that will need to be addressed. Despite environmental concerns, coal remains a very viable source of energy in the United States because it is both abundant and inexpensive, albeit heavy (up to 70 percent of coal's cost is related to transportation expenses).

Coal consumption is expected to increase during the first 25 years of the twenty-first century in conjunction with increased energy usage. Although natural gas is expected to siphon off a portion of coal's market share, increased energy consumption should keep coal mining operations busy. After falling for the last three decades of the twentieth century, coal prices stabilized during the first years of the 2000s, as production decreased slightly and demand increased slightly. Prices are not expected to change dramatically, unless new environmental rulings are instituted that would increase the cost of production. Earnings growth will also come from cost-cutting measures, including increased automation to lessen workforce expenditures.

INDUSTRY LEADERS

Consolidation among coal companies was extensive during the late 1990s. Arch Coal purchased the U.S. coal interests of ARCO, and Horizon Natural Resources (formerly AEI Holding Company, Inc.) acquired the coal interests of both Zeigler Coal Holding Company and Kindill Mining, as well as the Martiki Coal Company, a subsidiary of MAPCO Coal Inc. In addition, AEI secured a portion of the coal properties of Cyprus-Amox Coal Company. Other acquisitions included the Kennecott Energy Company purchase of Kerr-McGee's Jacobs Ranch Mine, the American Coal Corporation's buyout of Kerr-McGee's Galatia Mine, and MAPCO Coal Inc.'s purchase of the Cimarron Division of Andalex Resources.

The largest U.S. producer of coal in 2002 was Peabody Energy Corp., which had 33 U.S. mines and produced over 190 million short tons. Peabody had sales in fiscal 2002 of \$2.71 billion, resulting in a net income of \$105.6 million. The second largest producer of coal in the United States was Arch Coal, Inc., which produces more than 115 million tons of coal per year. The company had 2002 sales of \$1.5 billion, resulting in a net loss of \$2.6 million. The third biggest producer was CONSOL Energy, Inc., with net income of \$10.6 million in 2002 on sales of \$2.1 billion. Horizon Natural Resources is another major coal mining operation in the United States. Although Horizon posted revenues in excess of \$1.4 billion in 2001, the company's heavy debt load—a result of numerous acquisitions in the 1990s—caused the company to declare Chapter 11 bankruptcy twice during 2002, leaving its future uncertain.

WORKFORCE

Unions were increasingly concerned about job security in the 1990s. Coal companies argued that rising costs were pinching profit margins. Union leaders pointed out that coal production had increased 200 percent over the past two decades, while costs had been reduced by 50 percent, largely through payroll savings. Labor negotiators also charged mine companies with shifting production to nonunion facilities. By the end of 1993, however, the United Mine Workers union had agreed to terms with both the Bituminous Coal Operators Association and the Independent Coal Bargaining Alliance, the multiemployer bargaining groups of the industry, and had signed five-year contracts. This was only accomplished, however, after bitter strike actions and negotiations with the association.

Job opportunities are expected to continue to degenerate in the underground coal mining industry. According to the Bureau of Labor Statistics, employment in the coal mining industry was expected to decline about 35 percent from 1998 to 2008. In 2001 about 76,800 people worked in the coal mining industry, down from about 91,600 people in 1998. By 2008 the number employed in the coal mining industry was expected to drop to about 59,400 overall, with 12,078 in mining, quarrying, and tunneling occupations.

AMERICA AND THE WORLD

The United States was the second largest coal exporting nation in the world in the mid-1990s, accounting for approximately 24 percent of the global export market. In 1998 U.S. companies exported about 76 million tons. More than 59 percent of U.S. coal exports were metallurgical grade in the mid-1990s, which was primarily produced in eastern underground mines. Much of the high-grade steam coal exported was also produced in that region. West Virginia alone distributed 49 percent of U.S. coal exports in 1995. The leading customers for U.S. bituminous coal in the late 1990s were Canada, Japan, Brazil, and the United Kingdom, in that order.

Foreign Investment. A weak foreign dollar, the exit of traditional steel, oil, and utility interests, and the decline of European coal industries combined to generate an influx of capital into the U.S. coal industry in the early 1990s. The most significant move was made in 1990, when U.K.-based Hanson PLC acquired Peabody Holding (for which it paid \$1.25 billion), America's largest coal producer. Similarly, Rheinbraun A.G., of Germany, paid \$890 million for a stake in CONSOL Energy, the nation's second largest producer. Kennecott Energy was also acquired by the British conglomerate RTZ. At the same time, U.S. companies such as Cyprus AMAX, ARCO, and Peabody, were involved in coal mining ventures in Australia and South America.

RESEARCH AND TECHNOLOGY

To combat regulatory entanglement, stagnant prices, and increased competition, underground coal companies were increasingly looking to advanced mining and coal burning technologies for help. In addition, the industry was seeking new uses for its products that could open new markets.

Of critical and immediate importance to the underground coal mining industry was clean-burning coal technology that could reduce sulfur emissions and allow utilities to comply with new Clean Air Amendment Act standards. Failure to achieve success in this area will likely result in many power plants converting to alternative fuels, a development that would devastate high-sulfur underground mining regions. The U.S. Department of Energy, working with researchers in coal companies and utilities, was developing five categories of research. Low-emission boiler systems incorporated advanced combustion and innovative flue gas cleaning systems in the initial design for new power plants. Pressurized fluidized bed combustion captured sulfur pollutants inside the boiler instead of in the stack and allowed combustion at temperatures below the point at which most nitrogen pollutants form. The integrated gasification combined cycle (IGCC) employed coal gasification rather than traditional combustion and combined a steam turbine driven by exhaust heat with the gas turbine driven by the coal gas. Indirectly fired cycles employed a design that heated a working fluid such as air to turn the turbine rather than the hot gases of combustion. Finally, integrated gasification-fuel cell combinations would link a coal gasifier with a fuel cell.

The Wabash River coal gasification repowering project in Terre Haute, Indiana, demonstrated on a commercial scale and in a commercial utility environment that IGCC technology can effectively meet both energy and environmental needs. Wabash River, a joint venture of Destec Energy Inc. and PSI Energy Inc., was selected as a Department of Energy demonstration project in September 1991 and went online in August 1995. The plant was built in the 1950s, but the project replaced one of six original coal fired units with a new gasification process and combined cycle power block.

Several more unusual approaches to meeting government regulations were being explored. Microterra Inc., of Florida, was trying to patent a system that utilized genetically engineered bacteria that lived on a diet of sulfur. A prototype system was already being used by Freeport McMoran Inc. Porter's system differed from past efforts by other researchers in that it consumed sulfur in 36 to 48 hours, compared to 10 to 48 days for similar systems.

Another approach reported in the mid-1990s used pellets of zinc titanate to absorb the sulfur. The advantage being tested was that the hot coal gas produced in the coal

gasification process has to be cooled only to about 1,000 degrees Fahrenheit to remove the sulfur instead of to room temperature, as in other processes. The zinc pellets are dropped through the column of hot gas, absorbing sulfur as they fall, and then returned to the top of the column in an elevator. In another project, researchers were striving to replace coke used in processing iron and steel with "formcoke," made from less expensive and more abundant nonmetallurgical grade coals.

SIC 1231

ANTHRACITE MINING

This category covers establishments primarily engaged in producing anthracite or in developing anthracite mines. All establishments in the United States that are classified in this industry are located in Pennsylvania. This industry includes mining by owners or lessees, or by establishments that have complete responsibility for op-

erating anthracite mines for others on a contract or fee basis. Also included are anthracite preparation plants, whether or not operated in conjunction with a mine.

NAICS CODE(S)

212113 (Anthracite Mining)

INDUSTRY SNAPSHOT

Anthracite is a hard coal containing a high percentage of fixed carbon and a low percentage of volatile matter, such as sulfur and ash, containing more than 90 percent of fixed carbon, less than 5 percent of volatile matter (gases), and a very small percentage of moisture (usually less than 5 percent). With these desirable qualities, anthracite coal is ranked higher than other, more commonly used coals like bituminous and lignite because it has more than twice the energy content of these other coals. Thus, it provides a longer burning potential and is, accordingly, a higher energy fuel.

Almost all of the U.S. supply of anthracite coal is located in eastern Pennsylvania and is often referred to as Pennsylvania anthracite. Pennsylvania has about 7 billion tons of minable anthracite coal reserves. In 2002 anthracite mined in Pennsylvania totaled 1.2 million short tons. Showing a steady and significant decline, anthracite production was 4.8 million short tons in 1999, 4.6 million short tons in 2000, and 1.5 million short tons in 2001. Most of the original markets for anthracite were relinquished long ago to natural gas, fuel oil, and other coals, such as bituminous and lignite coal. Anthracite maintains a small share of a niche market, consisting primarily of coal-fired home-heating units. In fact, anthracite mining has been declining steadily for many years, from peak production in 1918, when anthracite mines produced 99.6 million short tons.

ORGANIZATION AND STRUCTURE

Both surface and underground methods were used in the extraction of anthracite. In 1995, some 270,000 short tons were produced by underground mines and 4.1 million tons by surface mines. Surface mining is usually practiced on relatively flat ground; the coal is recovered from a depth of less than 200 feet. To reach coal deposits, miners must first remove the overburden, or strata, that covers the coal bed. Between 1 and 30 cubic yards of strata must be excavated for each ton of coal recovered. Dragline excavators, power shovels, bulldozers, front-end loaders, scrapers, and other heavy pieces of equipment are used to move the strata and extract the coal.

The two common methods of surface mining are strip and auger. At strip mines, large drills bore holes in the strata. Explosives are placed in these cavities and detonated. Power shovels or draglines operating at surface level then move the broken strata, while power

shovels below dig up the coal and load it into trucks. The strata and coal are removed in long strips. This is done so that the debris from the newest strip can be dumped into an adjacent strip, from which the coal has already been recovered.

Auger mining consists of boring a series of holes that are 2 feet to 5 feet in diameter and 300 or more feet deep. This parallel and horizontal pattern is carved into a seam of coal that has already been exposed by an outcropping or by strip mining methods. No blasting takes place, and the overburden is left intact. The coal is simply removed and loaded into waiting trucks. Auger mining is frequently used in open-pit mines, where the strata is too thick to economically remove the coal using strip methods.

Underground mines consist of a series of parallel and interconnecting tunnels from which the coal is cut and removed with special machinery. The process is complex and sometimes dangerous. The mine must be adequately ventilated to protect miners from dust and explosive methane gas that is released by the coal. In addition, careful ground control must be practiced to prevent the roof of the mine from collapsing on workers and equipment.

Three types of underground operations are distinguished by the method used to access the coal mine. Drift mines are characterized by the use of a level tunnel leading into the mine, while slope mines have an inclined tunnel, and shaft mines utilize a vertical tunnel. The primary methods of extracting coal from all of these mines are room-and-pillar, longwall, and shortwall, but no anthracite mines used longwall systems.

Room-and-pillar mining is often the least efficient method. It allows recovery of only about 50 percent of the coal, although there are occasions when this methodology can achieve a much greater recovery percentage. Longwall and shortwall mining, in comparison, extracts up to 80 percent of the usable coal. In a room-and-pillar operation, coal is mined in a series of rooms cut into the coalbed. Pillars of unmined coal are left intact, and serve to support the mine roof, as miners advance through the coal seam. Sometimes the coal in the pillars can be extracted later in the "retreat" phase.

The two basic types of room-and-pillar mining are conventional and continuous. Conventional mining consists of a series of operations that involve cutting and breaking up the coalbed, blasting the bed, and then removing the shattered coal. Continuous mining, on the other hand, uses a machine that digs and loads coal in one operation, without blasting.

Longwall and shortwall mines use huge machines with cutting heads. The heads are pulled back and forth across a block of coal up to about 150 feet long in

shortwall mining, though much longer in longwall. Coal is sheared and plowed into slices that are removed by a conveyor. Movable roof supports allow mined-out areas to cave in behind the advancing machine.

Anthracite reserves totaled more than 7 billion short tons in Pennsylvania in 1990, with smaller amounts (less than 300 short tons) existing in Colorado, Virginia, Arkansas, and New Mexico. By far the greatest concentration of anthracite reserves were in several counties in northeastern Pennsylvania, specifically Lackawanna, Luzerne, Carbon, Columbia, Northumberland, Dauphin, Schuylkill, and Lebanon, with more than one-third of the reserves lying in Schuylkill County.

BACKGROUND AND DEVELOPMENT

The history of anthracite mining in the United States dates back to before the industrialization of the country, when material needs were largely met through subsistence agriculture, and craft-type production methods dominated the economy. The shift to an economy dominated by factory production methods was accompanied by growth in anthracite mining, providing a striking case study of the origins of industry in the United States. Historian Alfred Chandler argued that anthracite was a primary factor in facilitating factory production methods in the northeastern United States, suggesting that anthracite mining played a key role in the timing and pattern of economic development in the United States during the mid- to late 1800s.

Well before it was mined for profit, anthracite was discovered by Native Americans near Nazareth, Pennsylvania, around 1750. By the 1790s settlers began exploring the possibility of using anthracite for commercial and industrial purposes.

During the Revolutionary War, anthracite was burned in forges for the production of weapons. When the war ended, the population of the country was less than 4 million, and most of the output of the country was agricultural. A profitable market for anthracite would emerge, as merchants sought higher levels of profitability, bringing forth factory production methods and a rise in demand for mineral production.

One impediment to coal production was the lack of transportation infrastructure, which made the cost of getting coal to market prohibitive. Part of the rise of anthracite production can thus be tied to the construction of canal and railway systems, which lowered the cost of transportation. By the War of 1812, demand for coal by the government led to shortages in Baltimore, Philadelphia, and New York, which hastened the decision to develop additional anthracite sources.

Much of the early mining was undertaken by small-scale entrepreneurs. Development would be intertwined

with the development of extensive canal systems constructed in the 1820s and 1830s, and later the railroad, eventually leading to the union of the most successful anthracite firms with railroad companies.

The development of canal systems between 1815 and 1834 enabled coal to reach expanding textile markets on the East Coast. In fact, between 1815 and 1834, \$10 million was spent by the government and private interests to construct canals to bring anthracite deposits of northeast Pennsylvania to the Atlantic seaboard, thereby providing a way for a cheap fuel to reach expanding markets. The Erie Canal, the Delaware Canal, and the Hudson Canal were all developed specifically for the purpose of allowing growing anthracite companies like the Lehigh Coal and Navigation Company and the Schuylkill Navigation Company to haul anthracite.

The Industrial Revolution. As the industry advanced, early mining methods were rapidly replaced by more machine-intensive methods of production, which raised productivity and reduced labor time. Mines became much more productive, but along with this trend, mining accidents increased, leading to many worker casualties from explosions, fires, floods, and collapsing ceilings and walls. Consequently, workers began organizing to fight against increasingly intolerable work conditions.

From the 1830s to the 1870s, Pennsylvania produced more anthracite than bituminous coal. Anthracite had specific applications in steel production and was the most used of all types of coal at the time. By the early 1860s, anthracite fueled booming iron production in Pennsylvania and became a primary fuel for the textile industry in New England. The boom years of 1863 and 1864 in the northeastern United States were driven by the need for blankets, firearms, and other goods needed for carrying through with the Civil War. Other contributing factors during this period were tariffs placed on imported manufactured goods and the creation of a national currency and a national banking system.

With the increasing growth of the railroad industry, the demand for pig iron and iron production rose as well, which meant more anthracite coal was needed. Total coal production leaped from just under 17 million tons in 1861 to nearly 72 million tons in 1880. At this time, competition in the highly profitable anthracite industry was fierce. Not only were many capitalists entering the industry to take advantage of the higher than average profit rates and low wages, but firms were also guaranteed a relatively controlled workforce.

Labor Disputes. At this time, the federal government was fostering manufacturing activity, but was hardly a friend of labor in the Pennsylvania anthracite mines. With the industry expanding vigorously in the post-Civil War boom era, miners were being pushed to their physical

limits for very low wages. Paid low piece-wages while working long hours under extremely hazardous conditions, miners also had to pay exorbitant prices at company-owned stores. In addition, 600 workers had died in mining accidents in the Pennsylvania mines from 1863 to 1870. As labor organized, the government called in the army to crush strikes in 1864. Strike leaders were arrested, and martial law was declared in the Pennsylvania coal towns. The miners responded by organizing under the Workingmen's Benevolent Association (WBA). Due partly to fierce competition in the coal industry, which prevented coal owners from uniting against the miners, the WBA was able to forge a unified force of all miners, skilled and unskilled, throughout the industry, as opposed to separate "craft" unions that were the dominant form of labor organization at the time. As a result of this collective action, the WBA, after a bitter six-month strike, won better working conditions, a "sliding scale" wage system by which wages rose or fell according to the market price of coal, and a mining inspection law from the Pennsylvania legislature.

As the country slipped into a prolonged depression in the 1870s, anthracite prices and profits collapsed, and workers struggled to maintain their living standards. A wave of strikes swept the nation in the mid-1870s, with the Long Strike in eastern Pennsylvania standing as one of the most dramatic and important. The conflict plagued eastern Pennsylvania, with many firms using private police forces to infiltrate and suppress unions. The conflict was often violent.

Despite intense competition among mining companies, management's response to the labor movement was much more organized and aggressive this time around. The anthracite mining industry was changing, becoming more concentrated as a result of competition, which engendered far more failing companies than profitable companies. A leading company was Reading Railroad, an anthracite and railroad concern headed by Franklin Gowen, which became the largest coal operator in eastern Pennsylvania. Gowen circled the wagons of other coal operators and took on the WBA.

Responding to a five-month strike in 1874, Gowen stockpiled coal, then, in the winter of 1874-1875, shut down his mines, inflicting tremendous hardship on the miners and their families. Following a long, violent struggle—with Gowen's private police firing indiscriminately into crowds of workers, and strikers often attacking scab workers and strike breakers with clubs and stones—workers eventually succumbed, conceding a 20 percent wage cut, and returned to work in nonunion mines. Several miners were tried for alleged violent attack and convicted, despite questions about testimony of security agents for the companies. The union was decimated and would not emerge again until the end of the

century, when the United Mine Workers of America (UMWA) came into existence.

The depression dragged on for many years. The UMWA was involved in strikes across the country, including a key strike in Pennsylvania in 1894, but with the union severely weakened from the impact of the prolonged depression, the coal miners lost a battle of attrition.

Many more strikes would rock the industry around the turn of the twentieth century. One major 1901 strike in the anthracite fields of Pennsylvania drew the attention of President Theodore Roosevelt, who, after threatening to order U.S. troops to seize the mines, convinced the mine owners to settle with the UMWA. Roosevelt had taken on the owners, who were being particularly strident in the struggle, and won support as a populist.

By the end of the nineteenth century, Pennsylvania anthracite was shipped by boat and rail to almost every major city in the country, becoming the most important domestic fuel for industrializing America. By the turn of the century, Luzerne County ranked as the third most populous county in the state, while Lackawanna County ranked as the fourth largest. These counties were growing up on coal, a resource that made the region a major commercial center.

Entering the twentieth century, use of anthracite was clearly on the rise, when production reached 57.3 million tons and grew to more than 100 million tons by World War I. Output increased every year in the late nineteenth and early twentieth century, reaching its peak in 1917, when the industry employed more than 150,000 anthracite miners. From 1870 to 1920, more than 50 percent of all hard coal produced came from the northern Pennsylvania fields. Profitability was very high, with mining costs at the point of extraction only 75 cents, while the selling price ranged from \$15 to \$18. At this time, anthracite was used as a bunker fuel during World War I, but this was less than 20 percent of all end uses. Most anthracite was used as space heating fuel for industrial, commercial, and residential purposes. In addition, a small portion of anthracite was used for electrical power generation and by the steel industry. Most anthracite was used domestically with little being exported.

The value of anthracite properties was estimated by the U.S. Coal Commission to be almost \$1 billion. However, coal costs began to rise, while prices remained constant. Other troubles arose because of changes in steel production. Coke, which has many of the advantages of anthracite but is derived from soft coal, increasingly came into competition with anthracite. The harder anthracite could not compete, primarily because production costs were too high.

To exacerbate the situation, the highly centralized industry also was accused of operating as a monopoly, with a small number of firms regulating pricing and controlling 90 percent of the market. There had been a close connection between the mining and distribution of anthracite and the control of these companies by "anthracite railroads." Suits were brought against the Lehigh Valley and Reading companies.

In 1923 seven large companies owned and controlled an estimated 75 to 80 percent of the mining, transportation, and hauling of anthracite, each of which was controlled by the railroads. The remaining anthracite producers were considered small independent miners who leased coal mines. The large interests were accused of price collusion. The debate raged over whether these large interests should be allowed to operate as railroads, coal miners, or both. Some of the large companies were: The Reading Company, Philadelphia and Reading Railroad Company, Philadelphia and Reading Coal and Iron Company, Lehigh Valley Railroad Company, Lehigh Valley Coal Company, and Coxe Brothers Co.

In a ruling similar to the Supreme Court decision that broke up Standard Oil in 1911, the seven large companies were forced to dissolve in accordance with the Sherman Anti-Trust Act. By 1922 profit rates for the industry fell to around 12.1 percent, while the debate on price fixing and regulation continued. Meanwhile, the costs to the smaller independent companies rose, as rents charged by land owners increased. With the tendency of coal prices to reflect the cost of the largest company, the price of anthracite rose.

In addition, strike and labor resistance continued to plague the mining industry. Several long and costly strikes occurring after World War I that involved the complete cessation of anthracite production lent support, from the mine owners' perspective, to promoting substitute fuels. Major strikes were carried out during the 1920s and 1930s.

Anthracite production began to decline before the Great Depression. Following the expansion of mining, which came with the high profitability enjoyed during World War I, demand for coal fell, and more cost-efficient oil and natural gas were used. Supply for all types of coal was outrunning demand by two to one, and prices were plummeting, eroding profits, and consequently production was cut back. Companies were going under, closing some union mines, and labor was severely hurt, with working conditions becoming harsher, wages falling, and the intensity of labor increasing. The UMWA was completely demoralized following an important strike in 1927.

Market demand continued to shift away from anthracite and oil, while natural gas became more attractive and

more widely distributed. Space heating applications, which had been a major portion of anthracite consumption at the turn of the century, also declined. Production fell precipitously, from 69.4 million tons in 1930 to 9.7 million tons in 1970. A slight resurgence in the demand for anthracite occurred in the late 1970s because of an increase in home heating units in New England and from a switch to coal as a consequence of rising oil and natural gas prices.

Though it did not lead to a major rejuvenation of the industry, one of the salvations for anthracite producers in the 1970s was the use of anthracite for space-heating purposes in U.S. military installations overseas. The Defense Department's space heating equipment, originally designed to burn coke, accommodated only anthracite rather than bituminous coal.

The 1980s saw a brief surge in the demand for anthracite primarily because of a rise in the purchase of coal stoves, as homeowners sought alternatives to rising oil and natural gas prices. But the industry had trouble meeting the demand because of its inflexibility, leading to huge price increases. The industry tried to remedy this by increasing mining capacity to ensure protection of its key market, the residential space-heating market. By this time anthracite composed less than 1 percent of the coal market. In 1977 the federal government gave brief attention to the industry, forming the Anthracite Task Force in 1977 and the Office of Anthracite within the U.S. Department of Energy. This was more appearance than action, however, as very little federal assistance was forthcoming.

The anthracite coal mining industry remained in a basically stagnant condition in the mid-1990s. The number of operating mines fell by 24 percent and the number of miners by about 8 percent. Productivity per miner increased during this same period, but was still well below that of bituminous miners. Expressed in 1997 dollars, the price for anthracite averaged \$31.24 per ton, while the average price for all U.S. coal was \$16.14.

The outlook for real growth in the industry was grim. With the market for anthracite flat, there was little incentive for mining companies to open new mines or install production enhancing technology such as longwall systems. In 1997 there were only 68 establishments with 1,094 employees.

CURRENT CONDITIONS

The anthracite coal industry has not recovered from its long decline. Production amounts in 2002 were just one-fourth of 1999 levels, which stood at just 4.8 million short tons. The number of workers employed in surface mining of anthracite fell from 980 in 2000 to 683 in 2001, a decrease of more than 30 percent. Over the same time period, the number of workers at underground anthracite

mines declined by nearly 7 percent, from 292 to 272. The price per ton of anthracite rose from \$23.33 in 2000 to \$25.07 in 2001. Pennsylvania had 31 anthracite mines in 2001. Leading anthracite-mining firms included Bradford Coal Company (2002 revenues, \$19 million), Anthracite Industries, Inc. (2002 revenues, \$8.2 million), and Reading Anthracite (2002 revenues, \$3.4 million).

SIC 1241

COAL MINING SERVICES

This category covers establishments primarily engaged in performing coal mining services for others on a contract or fee basis. Establishments that have complete responsibility for operating mines for others on a contract or fee basis are classified according to the product mined, rather than as mining services.

NAICS CODE(S)

213113 (Support Activities for Coal Mining)

INDUSTRY SNAPSHOT

The companies classified in this category are a small but growing part of the overall coal industry. According to the most recent data from the Bureau of Labor Statistics, the industry employed 4,790 workers in 2001, down slightly from the figure for 1997. Construction and extraction workers accounted for more than half of these employees, who earned an annual salary of \$34,000 on average. Although coal mining services as an industry has grown in absolute terms (relative to total coal production), its share of total coal production, which reached 1.09 million short tons in 2002, was less than 2 percent. The total number of coal mines in operation in 2002 totaled 1,426, compared to 2,746 a decade prior.

ORGANIZATION AND STRUCTURE

The increase of mining services as an industry in its own right largely reflected cost-cutting measures on the

part of the coal mining industry. They often cut costs by increasing use of nonunion workers to perform many of the tasks previously performed by union workers. Contract mining services also grew due to the fact that many larger coal interests simply diversified their operations or got out of certain aspects of coal mining.

With specific services contracted out, firms can avoid a large commitment of capital investment and small entrepreneurs have seen a profitable opening. Thus, faced with erratic demand conditions, the industry has seen an increase in flexible conditions of production, including just-in-time methods, which create smooth production, reduce turnover times, and thereby reduce downtime. Flexible work rules involving eradication of union work rules—or at the very least, union cooperation—have contributed to mine efficiency. In any case, with various degrees of contract services, the number of large independent operators continues to decline according to some industry observers, with efficiency forcing the competition process.

Approximately 300 establishments provide services to the coal industry on a contract basis. These companies provide services ranging from removal of overburden, stripping the mine face, auguring or culm bank mining, drilling services, mine tunneling, and shaft sinking. Most of these establishments and multi-establishment firms are small; only 50 have more than 19 employees and, of these, only 14 have 100 or more.

The most significant revenue source in the coal mining services industry is strip mining, followed by stripping overburden, sinking mine shafts, driving mine tunnels and drilling and blasting. In terms of major area of geographic concentration, the larger companies engaged in coal mining services (with 20 or more employees) are concentrated in West Virginia, Kentucky, Pennsylvania, and Ohio. These firms accounted for approximately three-fourths of the workforce and more than half of the value of shipments and receipts.

BACKGROUND AND DEVELOPMENT

Coal mining services are defined more according to company organization rather than by type of activity. In other words, for a given technique of extracting coal, a number of activities are undertaken including sinking shafts, stripping, tunneling, drilling, coal recovery, transportation, and others. For any particular mine, these activities may take place under the auspices of one establishment, or some of the services may be outsourced to a contracting company for a fee. In the case where one particular establishment has complete responsibility for the operation of the mine, the activities are classified according to the product mined, whereas specific activities performed by contracting companies on a fee basis are counted as part of the coal mining services industry.

The specific types of services that may fall under coal mining services, for all types of coal—anthracite, bituminous, and lignite—include anthracite mining, auger mining services, bituminous coal mining, draining or pumping of coal, drilling, lignite mining, overburden removal of coal, sinking shafts, stripping services, and tunneling.

The Commerce Department, at one point, classified coal mining services according to the product mined. Thus, anthracite mining services and bituminous coal and lignite mining services were classified separately. When the number of anthracite mining service companies went to 57, however, the Commerce Department created a SIC classification for coal mining services in general.

Historical Precedents. With its small but integral connection to the coal industry in general, the coal services industry rises and falls with coal mining. Mining services have been an integral part of the rise of coal in the United States, whether they were part of the mining companies operations or provided through companies that contracted with the mine owners and operators. In general, the evolution of mining services connected with coal mining and the rise of separate companies providing these services relates to the changes in production techniques in the extraction of coals and the efficiency of production methods. Thus, the separation of the industry called mining services is somewhat artificial, or at the very least, a changing one.

In fact, the early techniques of coal mining were exceedingly simple—simply carrying coal from the exposed vein. Of course, these primitive methods were rapidly replaced by a more refined division of labor, and eventually, by machinery, which rationalized the production processes and reduced the total labor time required per unit of coal mined.

In the early years of coal mining, primitive production methods meant individual workers owned and operated their own tools and were paid piece-wages, according to the amount of coal mined. This involved the simple act of shoveling coal into a pile, then throwing it into an empty mine car—human muscle. According to Keith Dix, as late as 1948, one-third of the nation's underground coal was still loaded by hand. The early miners used their own tools, paid the company blacksmith to keep them sharp, and worked the mines and railroad track owned by the company. The miner also bought his own blasting powder, lamp oil, and other supplies, and even purchased his means of subsistence from the company stores. Thus, the early miner was an independent crafts-person combining a high level of knowledge and skill.

While increases in productivity came fast and furious in coal mining, the labor process in mining coal, during any period, involved essentially five tasks: sinking

a shaft for an underground mine, penetrating a slope, or uncovering a surface vein; undercutting the coal vein face; drilling the face; blasting the coal; and shoveling the broken coal into cars.

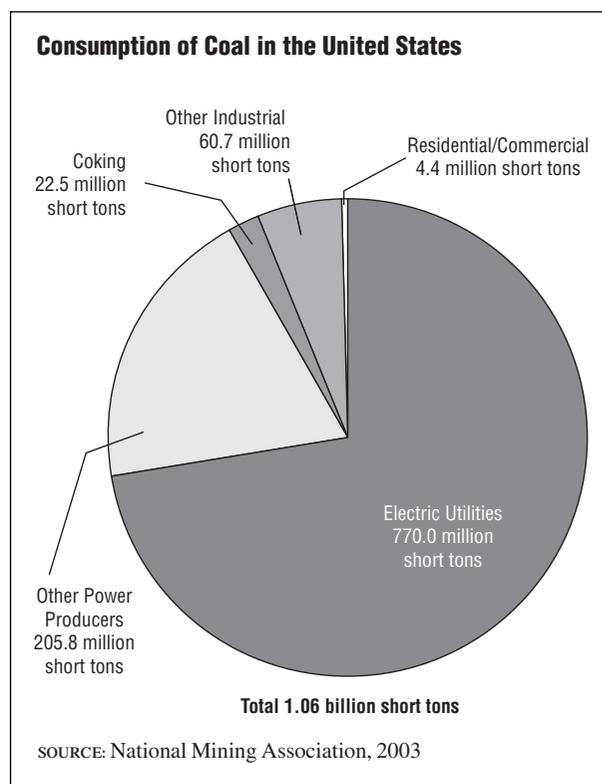

Mechanization to reduce costs, and to overcome the resistance of an increasingly militant mine workers union, proceeded quickly. First, undercutting machines developed, and eventually, the mechanization of hauling, drilling, and cleaning followed. The result was higher capital equipment requirement per worker, vast improvements in labor productivity, and a decline in labor requirements. Impediments in transportation to markets were overcome by agreements with the developing railroad industry near the turn of the century.

The Ups and Downs of the Coal Industry. While precise records of coal mining services as an industry were not kept by the government until the late 1960s, coal mining services has undoubtedly been a part of coal mining from the time of its inception. The railroads provided the impetus for the coal boom during the first two decades of this century, but when the railroads switched to the oil burning diesel engine, coal lost a major customer. This, accompanied by the switch of home heating to oil and gas, deflated the coal industry in the post-World War II period. Following the protracted boom immediately following World War II, by 1961 coal output declined to 1939 levels.

In the early 1960s, mechanization (which reduced unit costs), the decline in general transportation costs, and the surge in demand for electricity brought the industry to life. The rise in electricity demand between 1962 and 1966 produced a boom in the coal industry of over 26 percent. Smaller, more efficient, continuous mining companies also increased the intensity of labor, further reducing costs. The surge in demand from electrical utilities, which comprised over 50 percent of coal industry sales, led to two of the most dynamic decades in U.S. coal history in the 1960s and 1970s. This dynamic led to concentration and consolidation of industry capital and to the rise of small contracting companies.

The number of mining service establishments more than doubled from 191 in 1972 to 422 in 1982. The massive rise in productivity allowed for relatively high wages in the industry and exports boomed, with foreign customers seeking low-cost, high-quality U.S. coal. The markets for steel (coal's second largest customer) also came to life in the postwar boom. Nuclear power was a small, but growing, government-subsidized industry at this time.

Though the 1970s witnessed a slowdown in coal productivity, this trend reversed in the 1980s. After an austerity campaign, the introduction of continuous mining techniques, and further advances in mechaniza-

tion in cutting, drilling, and loading, the 1980s witnessed a resurgence in productivity growth and a reduction in necessary workers. This shakeout in the industry also led to a decline in the proportion of union mines. In the non-union shop, mine operators implemented work rule changes—allowing flexible work teams, cross-training, and fewer and longer shifts. In addition to the relative hardship of laborers, industry leaders faced a highly uncertain and sluggish demand in an industry where many firms struggled to finance the large scale capital investment that was required to compete.

CURRENT CONDITIONS

The U.S. coal industry was still strong in the early 2000s, second only to China in terms of coal production, but growth was sluggish and prices continued to fall. Between 1994 and 2002, U.S. coal production hovered between 1.0 and 1.1 billion short tons. Electric utilities remained by far the largest consumers of coal, and demand from this sector was expected to remain steady well into the future. More than half the electricity used in the United States is generated by coal.

The industry was marked by consolidation as smaller, less efficient mines closed and some large non-mining corporations who had acquired coal mines during the seventies sold withdrew. Large mining companies expanded by acquiring these existing operations more often than by opening new mines. Between 1998 and 2002 the number of U.S. mines in operation declined

from 1,828 to 1,426. Production shifted west where economies of scale could be brought to bear on operating costs, and where large deposits of the low-sulfur coals desired by the utilities were located. Surface mines, most of which were located in western states, accounted for 66 percent of U.S. production in the early 2000s. Wyoming, the leading state in terms of coal production, mined 373 million short tons of coal in the United States, accounting for 34 percent of coal production in 2002.

Given these conditions, in which narrow profit margins forced coal operators to seek every possible means of lowering operating costs, expanding opportunities existed for mining service companies, which were able to accomplish some aspects of the mining process at a lower cost. Companies in this industry segment provided much needed flexibility to mine operators.

INDUSTRY LEADERS

Although there were a fairly large number of firms classified in this industry in the early 2000s, the consolidation and influx of foreign companies that marked the coal industry at large were evident in coal mining services also. The largest companies in the field in the late 2000s were subsidiaries of major corporations, such as Texas Utilities Mining Co., a subsidiary of TXU Corp., which reported 2003 sales of \$11 billion. The North American Coal Corporation operates as a subsidiary of NACCO, a diversified conglomerate that reported 2002 revenues of \$2.5 billion. Other large operators included several subsidiaries of Tenneco Inc., First Mississippi Corporation, and Flour Corporation.

SIC 1311

CRUDE PETROLEUM AND NATURAL GAS

This industry consists of companies that are primarily engaged in the operation of properties for the recovery of hydrocarbon liquids and natural gas. These companies may perform any or all of a broad range of activities.

They may explore tracts onshore and offshore for crude petroleum and natural gas; drill and complete wells; equip wells for production; supply services to increase or maintain the recovery of oil and gas; or provide any of the other services necessary to prepare the product for shipment from the production site. This industry includes companies that produce oil and gas from oil shale and oil sands, or that recover hydrocarbon liquids and natural gas through the gasification and liquefaction of coal. The industry also encompasses firms that are responsible for operating oil and gas wells for others on a contract basis. Oil field service companies that perform services for operators are classified in **SIC 1382: Oil & Gas Exploration Services**.

NAICS CODE(S)

211111 (Crude Petroleum and Natural Gas Extraction)

INDUSTRY SNAPSHOT

The crude petroleum and natural gas industry was highly volatile during the late 1990s, which has directly impacted the industry in the early 2000s. Between 1998 and 2001, natural gas prices doubled—for a brief time, quintupled—and then returned to 1998 levels. During the same time the number of natural gas drilling rigs fell off by 40 percent, rebounded to produce at record levels, and then declined again. The petroleum industry also felt effects from the events of the late 1990s. Asia, a large importer of petroleum, underwent an economic crisis that curtailed demand. At the same time, petroleum production worldwide was increasing, causing an oversupply that pushed prices down.

By 1999 production had been curtailed, and prices rebounded, but the fallout from the situation remained. In the United States 35,000 jobs were lost, but only 7,000 were replaced, when balance returned to supply and demand, and of the 331 oil rigs that had ceased production, only 67 were put back on-line. This, in turn, led to a decrease in reserves, which, coupled with an increase in demand, drove prices higher.

During the early 2000s, the U.S. oil and gas industry was being affected by several other current conditions. First, the sluggish economy and unusually warm weather caused a decrease in demand. Second, on December 2, 2001, Venezuela's exports fell off drastically due to a strike. Finally, the U.S. war with Iraq in 2003 caused market volatility that put the industry on edge.

ORGANIZATION AND STRUCTURE

Two types of companies are involved in the crude petroleum and natural gas business: the independents and the majors. The majors are large, vertically integrated companies that explore, produce, refine, and sell oil and gas to end consumers. These companies benefit most

from the economies of scale. In contrast, the independent operators produce oil and gas to sell to others who then refine and distribute it.

While major oil companies usually funded drilling programs out of their own resources, independents relied heavily on outside investors. Favorable tax treatment for investors in oil and gas limited partnerships helped fuel an unprecedented boom of exploration and drilling in the late 1970s and early 1980s. In a limited partnership there are two kinds of partners, limited and general. General partners, like limited partners, invest money and share the risk of drilling programs. Unlike limited partners, general partners handle the day-to-day management of the business. Usually, there are several limited partners, but only one general partner.

Company Size. The companies in the crude petroleum and natural gas industry range from enormous conglomerates that employ 100,000 people and generate revenue of more than \$100 billion, to companies reporting less than \$1 million in revenue with few employees. Despite the fact that some firms are very large, 53 percent have fewer than five employees and report revenues of \$50 million or less. The industry reported 325,900 employees in 1998.

Regulatory Climate. Historically, the federal government has both helped and hindered the industry. The 1990 Omnibus Budget Reconciliation Act encouraged production by granting a tax credit for projects using enhanced recovery. It expanded the use of deductions for intangible drilling costs and the percentage depletion allowances, and provided a special deduction for independent oil and gas producers to apply against the alternative minimum tax. The decision to cancel the 1990 sale of leases for exploration on the outer continental shelf off California, the Gulf Coast of Florida, and the Northeast, however, hindered the discovery of new oil. The Oil Pollution and Liability Act of 1990 prohibited oil and gas exploration off the coast of North Carolina. That same law also hampered production by imposing federal liabilities on vessels and facilities for oil spills. In addition, the act allowed states to impose their own forms of liability independently. As a result, drillers paid higher insurance rates for their offshore activities.

BACKGROUND AND DEVELOPMENT

Crude petroleum has been used since ancient times. It has caulked boats, cured ailments and aches, and lit the lamps of home and the fires of war. But it was the demand for lamp oil that triggered the creation of the oil and gas industry. In the mid-nineteenth century, overfishing had decimated the whale population, the primary source of lamp oil. Experts speculated that the supply of kerosene, made from petroleum collected at ground seepages, could be increased and solve the problem. A group of investors,

led by George Bissell, a New York attorney, and James Townsend, a banker from New Haven, Connecticut, decided to finance the drilling of the first petroleum well.

Boom and Bust. On August 27, 1859, the well was completed in Titusville, Pennsylvania, by Edwin L. Drake. Drake's success triggered a frantic search for oil in the area, and boomtowns sprang up quickly. While the first wells required that petroleum be pumped from the ground like water, it wasn't long until the first flowing well, producing 3,000 barrels per day, was discovered several miles from Drake's well. New refineries were built closer to the wells, and existing refineries increased capacity. Soon, hundreds of small companies were involved in drilling for oil.

Seven years later, however, the once-bustling streets of Titusville were nearly deserted. A legal loophole, "the rule of capture," led the fledgling oil companies to take as much oil as possible from the ground as quickly as possible. This practice promptly ruined the oil-producing capabilities of the underground field, and the wells ceased to produce. The industry had completed its first boom/bust cycle.

The cycle was a phenomenon that the industry has been unable to shake for more than 100 years. After the Civil War, the United States began a period of massive economic expansion and development. The need for petroleum and its products greatly increased.

Standard Oil Trust. In 1871 the industry was in a panic; too many wells were producing too much oil. The price of kerosene fell by more than half, and many refineries were losing money. This alarmed a commodities trader-turned-refiner named John D. Rockefeller. He decided that the best way to save the industry was to limit the intense competition by combining most of the refineries into one company. Eventually, Rockefeller's Standard Oil Trust controlled 90 percent of the refining capacity in the United States. But the company's questionable business practices came to light and, in 1890, the Sherman Antitrust Act was passed by Congress. In 1911 the U.S. Supreme Court ordered that Standard Oil be dissolved. The trust was divided into 33 independent companies. Among these were Standard Oil of New Jersey (which later became Exxon); Socony and Vacuum Oil Co., Inc. (the two later merged to form Socony-Vacuum, which became Socony-Mobil Co., Inc., and finally the Mobil Corporation); Standard Oil of California (later known as Chevron Corporation); Standard Oil of Ohio (which became Sohio and later was bought by the British Petroleum Company p.l.c. as part of its BP America subsidiary); Standard Oil of Indiana (which became Amoco Corporation); and Atlantic Petroleum (which merged with Richfield to become Atlantic Richfield Company, also known as ARCO).

The quest for oil led westward. The first large find in California was made in the 1890s. By 1903 that state was leading the nation in oil production. But to the east lay a larger discovery. In the Texas town of Corsicana, south of Dallas, civic leaders were upset when they discovered oil while drilling for water in 1893. The new well marked the beginning of the Texas oil industry.

It was south of Corsicana, however, that the Texas oil industry had one of its grandest openings. On January 10, 1901, Lucas No. 1 on Spindletop Hill near Beaumont blew in at 75,000 barrels per day, a real Texas gusher. Spindletop was followed by other major discoveries in Texas, Oklahoma, and Louisiana. The result was a surplus of U.S. oil that would last for nearly 70 years.

New Market. Originally, the quest for petroleum was driven by the need for kerosene, a cheap lamp fuel. Yet when Thomas A. Edison invented the electric light, the need for kerosene decreased. The budding auto industry, however, needed gasoline. By 1910 gasoline sales exceeded kerosene sales. William Burton, a Standard Oil scientist, was working on a new process—thermal cracking—that more than doubled the yield of gasoline from a barrel of oil. When Standard Oil was dissolved, Burton's new employer, Standard Oil of Indiana, began using his discovery. Soon the process was licensed at refineries across the country, and petroleum production soared.

Natural Gas. After World War II, the nation implemented the lessons it had learned: petroleum had figured mightily in the success of the Allies. It was clear that measures to conserve the resource had to be taken, and exploring the possibilities of natural gas seemed a logical avenue. In the Southwest, where it was produced, natural gas was used to heat communities near the gas fields. Most of it, however, was burned in bright flares on the high plains. Transporting natural gas to the major markets in the industrial Northeast required a 1,300-mile pipeline.

In 1947 the government sold the "Big Inch" and the "Little Inch," two petroleum pipelines that had carried crude oil and gasoline from the Southwest to the Northeast during World War II. Texas Eastern Transmission Co. immediately converted them to gas pipelines. El Paso Natural Gas brought gas to Los Angeles, California, through another pipeline called the "Biggest Inch." In 1950 gas consumption rose to 2.5 trillion cubic feet (tcf), more than doubling the consumption of four years earlier.

Offshore Exploration. While most oil men were busy drilling on land, some saw the potential off the coast of the United States—especially Louisiana. Because of their state's abundance of marshes, Louisiana oil men had been drilling over water since the early 1900s. The first over-water rigs were land derricks built on wooden platforms supported by creosoted pilings. It was a costly

method, but the rewards from the rich Louisiana reservoirs could be worth the expense.

In 1945 a controversy arose over whether the southern states or the federal government owned the rich oil fields on the continental shelf in the Gulf of Mexico. At stake were billions of dollars in potential revenue. If the land belonged to the states, as they claimed, the taxes, royalties, and other revenue would make them among the wealthiest in the nation. On November 14, 1947, the first deep offshore oil well was completed in the Gulf of Mexico, 45 miles south of Morgan City, Louisiana. Three years later, the value of the area was confirmed, as five more major oil fields were discovered.

In 1950 the U.S. Supreme Court declared the offshore waters the province of the federal government. The question of how the lands would be managed was settled by Congress. It passed two acts, the Submerged Lands Act and the Outer Continental Shelf Lands Act, firmly establishing the federal government as the owner, yet allowing leasing of the land for exploration. The Court decision created a major revenue source for the federal government. Between 1970 and 1989, the federal government received a total of \$55 trillion from its offshore oil and gas leases. In 1983 alone, the offshore oil industry turned over more than \$6 trillion to the U.S. Treasury.

Although oil had been discovered and produced off the shores of other states, Louisiana remained the undisputed U.S. leader in offshore oil wells. In 1990 there were 3,612 oil and gas platforms in federal waters off Louisiana. Marathon Oil and Texaco announced in December 1996 that they made a new oil discovery 130 miles south of New Orleans in the Gulf, and this single well field was expected to recover about 10 million barrels of oil equivalent. The Vermilion 279 property was producing 979 barrels of oil and 4.2 million cubic feet of gas per day from two wells. The Gulf of Mexico was the only place where production was slated to increase in the United States.

Using the Oil Weapon. On October 6, 1973, the high holy day of Yom Kippur, Egypt and Syria launched surprise attacks against Israel. When the Soviet Union resupplied Egypt and Syria with weapons, it was clear that Israel was in danger. When the United States sent supplies, the Organization of Petroleum Exporting Countries (OPEC) retaliated with an oil embargo. Other countries were granted varying amounts of oil, depending on their relations with OPEC. For those who could buy OPEC oil, the price jumped from \$2.90 per barrel in September to \$11.65 in December. Non-OPEC nations also raised their prices. The nations of the world faced a global recession that rivaled the Great Depression.

New Era. By mid-1974, the Yom Kippur War was over. The effects of the embargo lingered for a long time, however. Besides forcing a settlement in the war, the

embargo signaled that the OPEC nations controlled their own oil. Soon after the fighting ended, the OPEC countries nationalized their petroleum industries. The OPEC-member countries would pay the oil companies for operating the oil fields and refineries, but those companies no longer had an equity interest in the oil.

This shift in control forced the companies to rethink where and how they would obtain their oil. What they decided shifted the balance of petroleum power again. By the late 1970s, the U.S. demand for oil began to drop for the first time since the 1930s. Stringent conservation measures, especially a mandatory increase in automobile fuel efficiency, had made the nation less dependent on OPEC oil. Moreover, new non-OPEC fields in Alaska, Mexico, and the North Sea were coming on stream. The surge in prices brought in a great deal of money for the oil companies, creating an exploration boom. At the peak of the boom, more than 4,000 rigs drilled for oil both onshore and offshore the United States.

High energy prices intensified the search for more secure sources of petroleum in oil shale and tar sands. Oil shale contains kerogen, an organic material that forms oil when the shale is heated to high temperatures. An estimated 550 billion barrels of recoverable oil existed in the oil shale deposits of the western United States. Researchers realized that if the cost of recovering it compared favorably with the price of crude oil, it would ensure the energy security of the nation. Experiments were initiated in the 1960s, but were shelved when energy prices dropped in the 1980s. Nonetheless, the federal government continued low-level research in the area. Another area of exploration was tar sands, deposits of very thick crude petroleum. Three experimental projects in tar sand production were successful, but additional research was funded at a very low level.

Coal gasification was used to make almost all the fuel gas sold for residential and commercial use from the late 1800s to the 1940s. As natural gas became more available, the market for coal gas diminished to near zero. Yet, interest in gasification was revived after the 1973 oil embargo. The high crude oil prices made the cost of gas made from coal competitive again. Out of all the projects, only one actively produced synthetic natural gas for pipeline distribution in the early 1990s—the Great Plains Synfuels Plant in North Dakota. In another project of the early 1990s, the federal government funded an experimental coal liquefaction plant in Wyoming to produce synthetic fuel gas and formcoke—made from coal char and much like ordinary coke.

After nationalization, OPEC's announced strategy was to stabilize prices by persuading its members to reduce production. But decreased production meant less income, and the OPEC countries had become accustomed to large profits. One by one, the members of OPEC broke

ranks, selling more oil than the agreed-upon amount. As a result, prices began to tumble. When the price of oil hit bottom, it was less than \$10 per barrel, a far cry from the \$30 per barrel OPEC had commanded at the peak of its power. In the United States, the number of rigs drilling for oil plummeted, until they were counted by the hundreds instead of the thousands.

Even in their disagreement, the OPEC oil ministers controlled prices. If they lowered their income, they also seriously slowed the discovery of new sources of oil outside OPEC. Steadily rising consumption would eventually increase the world's dependence on their oil.

Shifting Sites. The U.S. crude petroleum and natural gas industry moved into a period of decline after 1986, when production hit 8.35 million barrels per day. Three major factors figured in the decline: a shift away from petroleum as an energy source, low crude oil prices, and increasingly stringent environmental regulations—including drilling bans in some of the most promising areas of development. The number of rotary rigs drilling in the United States in 1995 was 723, a decrease of 52 rigs from 1994. This was the second-lowest count since World War II, and a drastic decrease from the nearly 4,000 that were in operation in 1981. But in the first nine months of 1996, the number rose to 761, with 39 percent drilling for oil, 60 percent for gas, and 1 percent miscellaneous. As a result, the major thrust of drilling and exploration moved outside of the United States. Low crude oil prices also curbed the development of other sources of hydrocarbon liquids, such as oil shale, tar sands, and coal liquefaction.

Despite the fact that oil supplied a smaller percentage of the total U.S. energy demand, that demand increased significantly. As a result, the absolute amount of oil used by the United States continued growing (at a time when worldwide use remained stable). By 1992 nearly 2 million miles of gas pipelines linked wells with consumers. Dependence on foreign oil imports reached a record-high 48.2 percent of domestic demand in 1993, up from 31.5 percent in 1985. In 1992 the amount of natural gas consumed rose 4.1 percent to 19.83 trillion cubic feet (tcf). The figure rose to 21.99 tcf in 1996, and consumption for 1998 was estimated at 23.25 tcf.

Americans increased their dependence on foreign oil, from 45 percent in 1993 to 53 percent in 1998. In 1998 the United States imported an average of 8.55 million barrels of crude petroleum per day. After remaining flat for a few years, in 1998 crude oil production in the United States began to fall, from 6.45 million barrels per day in 1997 to 6.24 million barrels per day in 1998. By February 1999 the production levels were the lowest in 50 years, dropping from 6.38 million barrels per day in February 1998 to 5.94 million barrels per day. While

production declined, the reserves of crude oil rose, to 222.5 billion barrels in 1997, an increase of 2.4 percent.

The industry in the United States also changed where it got its petroleum. In 1974 the United States produced 8.8 billion barrels per day, with 81 percent from the lower 48 states, 2 percent from Alaska, and 17 percent from offshore. In 1998 the output was 6.4 billion barrels per day, and the percentages were: the lower 48 with 57 percent, Alaska with 19 percent, and offshore with 24 percent. The forecast for the year 2005 was 5.8 billion barrels per day, with 54 percent from the lower 48, 16 percent from Alaska, and 30 percent coming from offshore drilling. The Gulf of Mexico was the area where nearly all offshore drilling occurred in the United States. The increase in offshore drilling was attributed to advances in deepwater production and drilling, and legislation aimed at providing royalty relief to the crude oil companies.

In the first six months of 1999, the large integrated oil companies of the United States cut back spending on exploration and production by 10 percent, compared to the same time in 1998. Companies had cut back their upstream spending in the United States by a quarter, while maintaining or increasing the spending in foreign countries. Some analysts, noting total upstream budgets, expected the spending to rise dramatically in the second half of 1999. Some smaller firms were being more aggressive in upstream investment, with some spending more than 75 percent of their yearly upstream budget in the first six months of 1999, with the implication that they would go over budget by the end of the year.

While natural gas production rose in the United States—averaging 18.97 trillion cubic feet in 1998, up from 18.90 tcf in 1997—imports rose 4 percent during that period, due to increased demand. Production was expected to increase in the United States over the next few years, with improved technologies for recovery and storage. The forecasts for natural gas production were 20.27 tcf in 2000 and 22.25 tcf by the year 2005.

Consumers are demanding ever more efficient energy sources, and this will push demand for natural gas to about 2 percent per year. With more Americans choosing products based on environmental considerations, natural gas wins over petroleum products. The combination of deregulation and plans for more electricity generation plants to be powered by gas will lead to increased demand.

For the industry as a whole, the rotary rig count declined to 502 as of March 1999, the lowest ever. Of those 502 rigs, 78 percent drilled for natural gas and 22 percent for oil. In 1998 there was a drop of 13 percent in well completions—10,711 for gas, 8,720 for oil, and 5,453 dry wells.

CURRENT CONDITIONS

Crude petroleum. At the end of 2002, workers at Petroleos de Venezuela, the national oil company, went on strike, causing the nation's oil exports to fall from 3 million barrels a day to around 400,000. Venezuela supplies 14 percent of U.S. imports—about nine times as much crude oil as Iraq. With the United States on the brink of war with Iraq, the situation in Venezuela helped to further destabilize an already volatile market.

The U.S. war with Iraq in early 2003 caused continued uncertainty in the market, in both worldwide production levels and price. As the war approached, prices jumped from \$20 a barrel to \$40 a barrel, before declining to the mid-\$20 range. In April 2003 crude oil prices fell to a five-month low, and inventory was running high. "We're getting a huge influx of crude," Marshall Steeve, an analyst with Refco Group Ltd., told *The America's Intelligence Wire*. "It's obvious that the big producers are pumping as much as they can." U.S. inventories stood at 286.2 million barrels, and the Energy Department was concerned that another oil glut could occur over the next months.

In 2001 the United States imported 55 percent of petroleum consumed domestically. In 2000 domestic crude petroleum production totaled 2.1 trillion barrels, with a value of \$56.9 billion. The U.S. Department of Energy's Energy Information Administration (EIA) predicts that dependence on petroleum imports will reach 68 percent by 2025. Crude oil production in the United States is expected to increase slowly over the next several years, before beginning to decline in 2008. Increases in production will mostly be driven by offshore rigs. According to the EIA, U.S. production of crude petroleum will grow from 4.8 billion barrels per day in 2001 to 5.3 billion barrels per day in 2007 and then decline to 4.2 billion barrels per day by 2025. As consumption increases and domestic supply decreases, the United States will become more dependent on petroleum imports.

Natural gas. The natural gas industry is expected to see growth in exploratory and development drilling that should lead to increases in domestic production levels. According to the EIA, additions to natural gas reserves are expected to peak in 2018 at 25.8 trillion cubic feet, before gradually declining to 22.4 trillion cubic feet in 2025. Improved technology will drive natural gas production from unconventional sources (tight sands, shale, and coalbed methane), with production from these sources jumping from 5.4 trillion cubic feet in 2001 to 9.5 tcf in 2025.

With natural gas increasingly fueling the generation of electricity, the sector is posed for significant growth in the coming years. Whereas the United States produced under one-tenth of the world's crude petroleum at the turn

of the century, domestic production of natural gas totaled one-fifth of the world's dry, marketable gas. Natural gas liquids produced domestically accounted for one-third of the world's supply. In 2000 domestic production of natural gas totaled 20 tcf, valued at \$73.6 billion.

INDUSTRY LEADERS

In 2002 the top production companies were Exxon Mobile Corporation, with sales of \$178.9 billion; BP p.l.c. (formerly BP Amoco), with sales of \$178.7 billion; Royal Dutch/Shell, with \$179.4 billion; and Chevron Texaco, with \$91.7 billion.

Exxon was the flagship of the Standard Oil Trust and was incorporated in 1882. It was the world's largest publicly owned integrated oil company. Mobil Oil, the second largest in the United States and third largest worldwide, started in 1866 in Rochester, New York, as Vacuum Oil Co. and was also part of the Standard Oil Trust. It merged with Socony in 1931, became Socony-Mobil in 1955, and Mobil Oil in 1966. In 1998 Exxon and Mobil agreed to merge into a new company called Exxon Mobil.

BP was a result of a merger in 1998, the world's largest between industrial companies. William Knox D'Arcy founded BP in the early 1900s. D'Arcy was convinced (and eventually proven right) that there were large oil deposits in Iran (then Persia). BP remained a heavy presence in the Middle East for 60 years, before concentrating in the United Kingdom and the United States. Amoco was founded by John D. Rockefeller in 1889 and folded into his giant Standard Oil. In 1911 Amoco became an independent company. Scientists at Amoco developed the process that increased octane levels in gasoline in 1912.

Shell had humble beginnings as a bric-a-brac shop in 1833, with part of its enterprise the sale of exotic sea shells. When owner Marcus Samuel died, the thriving business was continued by his sons, and had its first foray into the oil industry in 1878, handling consignments of cased kerosene, and eventually became Shell Transport. Standard Oil made several unsuccessful attempts to buy or control Shell, and in 1907 Shell and Royal Dutch merged, with Royal Dutch holding 60-percent ownership and Shell Transport 40-percent ownership—exactly as it stands today. The Royal Dutch/Shell Group is the second-largest petroleum company in the world.

The industry was being held to an increasingly higher environmental standard, especially offshore. Drilling and production wastes once held acceptable were declared toxic. For example, a machine shop that removed scale from the inside of drilling pipes found out the scale was radioactive. The oil companies that sent the pipe to the shop agreed to a multimillion-dollar settlement out of court. Early estimates were that thousands of

workers and their families might have been exposed to harmful radiation, and clean-up costs might reach several hundred million dollars.

Environmentally related situations continue to plague petroleum companies. In 1989 the largest oil spill in U.S. history took place in Prince William Sound, Alaska. Seven years later, a U.S. District Court judge ordered Exxon to pay compensatory damages of more than \$5 billion. Exxon filed an appeal. In January 1997, Ecuador's attorney general stated that Texaco Oil was responsible for unprecedented and continuing damage to the health and well-being of Ecuadorian Indians. They joined a \$1 billion class-action lawsuit against Texaco. Shell Petroleum in Nigeria was accused of environmental devastation and exploitation in Ogoni, a small, highly populated area of the Niger Delta. There have been several well-publicized incidents and community disruption to Shell Nigeria's operations.

The bad publicity from environmental disasters continues to afflict the oil industry. Russell Mokhiber of *Corporate Crime Reporter* and Robert Weissman of *Multinational Monitor* compiled a list called the "Top 100 Corporate Criminals." The list appeared in an article written by Michelle Bier in the *Oil Daily*, and oil companies were featured prominently. Exxon, in making the list twice at numbers 5 and 96, was called a "criminal recidivist corporation." The two incidents involving Exxon were the spill in Prince William Sound and a spill of 567,000 gallons of home heating oil. The latter spill occurred in Arthur Kill, a waterway between New York and New Jersey, and resulted in Exxon pleading guilty to federal charges in 1991 and paying a \$200,000 fine.

But Exxon had company on the list. Chevron Corporation was placed at number 41, when it pleaded guilty to discharging oil and grease off a drilling platform in Santa Barbara, California. The company was fined \$8 million. At number 77 was Unocal Corporation, which leaked oil at its field in Guadalupe, California. It was estimated that the company leaked as much as 8.5 million gallons. Five other oil or petroleum-related companies made the list.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, the oil and gas industry employed 125,370 people in 2001. Among the job titles were administrators, accountants, civil engineers, insurance specialists, human resource specialists, public relations practitioners, and marketing and sales managers. Peculiar to the industry are gas engineers, geologists, geophysicists, seismic surveyors, derrick men, drillers, floormen, mud engineers, mud loggers, mud men, nipple chasers, petroleum engineers, roughnecks, roustabouts, swamper, tank strappers, and wildcatters.

Wages in the industry ranked above average. The mean annual salaries in 2001 for those who worked in the United States were: petroleum engineer—\$90,240; roustabout—\$26,710; surveyor—\$61,740; rotary drill operators—\$32,950; and derrick operators—\$33,010. Whereas most professionals were not unionized, other employees were often represented. Two prominent unions in the industry were the Associated Petroleum Employees Union and the Oil, Chemical, and Atomic Workers International Union.

Job opportunities remained fair to poor, due to industry restructuring and consistently low prices for crude petroleum. Restructuring produced layoffs from the rig floor to the boardroom. Long-term oil prices, however, were expected to rise, as reservoirs were depleted and the need for additional exploration increased, possibly necessitating more workers. Because the number of degrees granted in the field has traditionally been low, the number of job seekers was not likely to exceed the number of positions available in the early 2000s. Recent setbacks were offset by the increased demand for these professionals in environmental protection, reclamation, cleaning up contaminated sites, and in assisting private companies and government comply with more numerous and complex regulations. Job prospects for geoscientists were expected to grow 10 to 20 percent through 2005. In addition, overseas opportunities existed for many of the skilled and technical professions.

AMERICA AND THE WORLD

The United States has been a leader in international oil exploration and production. U.S. companies have played roles in the discovery and production of oil in major fields in Mexico, Venezuela, Saudi Arabia, Kuwait, and Libya. While exploration and oil drilling have decreased in the continental United States and Alaska, all of the major American oil companies have increased their presence overseas. It is important to note that more than 75 percent of proven oil reserves are controlled by OPEC, although the vast majority of oil is consumed by non-OPEC nations—therefore giving OPEC a tremendous influence on the world oil and gas market.

American oil exploration, and that of other non-OPEC countries, slowed in contrast to OPEC exploration. Meanwhile, the major U.S.-based petroleum companies became increasingly involved in foreign exploration. In the early 1990s, money allocated to foreign exploration and development topped 50 percent of all exploration spending, as compared to 27 percent in the mid-1980s. In 1998, for example, Exxon spent about 45 percent on production in the United States and about 55 percent in the rest of the world. World political and economic developments of the 1990s made it more feasible and profitable to increase American investment in foreign

exploration. U.S. companies increased their investment in many areas of the world, particularly in Latin America. The natural gas industry in Central and South America presented great potential. With the exception of Argentina and Venezuela, the industry was underdeveloped, with reserves equivalent to those found in North America.

The dissolution of the Soviet Union provided increased opportunities for investment in that area's oil reserves. The CIS (Commonwealth of Independent States) saw the rise of joint exploration and drilling ventures, especially in Russia, between U.S. and Russian companies. While instability in the former Soviet Union slowed the natural gas industry, this was seen as a short-term problem.

Another area of increasing American investment was Southeast Asia, where U.S. exploration spending grew the most from the mid-1980s to the mid-1990s. The economies of Asian countries have become increasingly industrialized since the late 1990s, and many governments in Asia, including China and Vietnam, actively courted foreign investment and participation in local drilling by outside companies. Deepwater fields offshore in the Philippines showed great promise as well.

After decades of being a net exporter of petroleum, the United States crossed the line into international interdependency sometime in 1970, when production hit its peak and the last of the oil surplus that had guaranteed energy independence had been pumped into the pipeline. Other countries, particularly South Africa and Canada, were leaders in developing technology for the use of coal as a source of petroleum and gas. South Africa had the largest commercial coal gasification plant and the only commercial coal liquefaction plant in the world. But while oil production decreased, natural gas production in America was increasing and was expected to remain on an upward swing until 2015. As the largest supplier of natural gas after Russia, American companies were putting more effort into drilling for gas domestically rather than petroleum.

RESEARCH AND TECHNOLOGY

In the crude petroleum and natural gas industry, research and development occurs in both the laboratory and on the drilling rig. Directional drilling and enhanced oil recovery have been two of the latest areas of research and development. Directional drilling rapidly gained importance by allowing several wells to be drilled into different areas from a single derrick. The technique proved especially valuable offshore, where the cost of establishing a platform ran into the hundreds of millions of dollars. Onshore, directional drilling also limited environmental damage by reducing the number of rig locations needed.

Another advantage to directional drilling was the ability to drill a well horizontally across the top of a formation to maximize oil or gas recovery. Directional drilling is done with steerable drill bits that allow drillers to change the direction of the hole from the surface at any depth specified. A turbine motor, powered by the pressurized drilling mud circulating through the well, provides a high-speed twist to the drill bit.

Enhanced oil recovery—the third phase of oil recovery—became increasingly important as oil fields matured. In primary recovery, natural gas or water pressure drives the oil through the rock formation into the well. Sometimes the pressure is high enough to raise the crude to the surface, but often it must be pumped out. Production reduces the pressure until the driving force can no longer push the oil through the formation fast enough for economical recovery.

In secondary recovery, gas or water pressure is added to push the oil to the well. Enhanced, or tertiary, recovery begins when secondary recovery methods no longer produce enough oil to make the well profitable. Tertiary recovery uses a variety of techniques to wring the last bit of recoverable oil from the rock formation. The techniques fall into four categories: thermal—combustion, steam soak, steam drive, steam flood, hot water drive, and electromagnetic; gas—hydrocarbon gas, carbon dioxide, nitrogen or flue gas; chemical—alkaline, foam, and polymer; and other—microbial.

Oil Shale, Tar Sands. In the early 1990s the attempt to produce liquids from oil shale involved several steps. The shale was mined, crushed, and heated in a retort to produce shale oil. Major problems with the technique included how to dispose of spent shale. In an oddity of nature, when oil is recovered from shale, the shale expands. Research in oil shale technology, like that for tar sands technology, had been all but completely shelved because of low oil prices.

Coal Gasification, Liquefaction. In the early 1990s, the \$2.1 billion Great Plains Synfuels Plant in North Dakota produced more than 171 million cubic feet of synthetic natural gas per day using lignite (soft) coal mined in the state. The gas was then sold to a pipeline company for distribution in the eastern United States. Design of the plant began in 1973 as an effort to reduce the nation's dependence on foreign energy.

The success of the plant was costly. The federal government guaranteed \$2.02 billion in loans to build the plant, and private sector partners agreed to provide up to \$740 million of their own funds. Four years after construction began, the private sector sponsors withdrew and defaulted on the loans, despite the fact that the plant was earning revenue in excess of operating costs. The plant

was sold in 1988 with \$84 million and a share of future profits going to the federal government.

Coproducts had become important sources of revenue for the Great Plains Synfuels Plant. The plant produced 35 million pounds of phenol annually for plywood and chipboard resins. From the facility's oxygen plant, commercial quantities of xenon and krypton gases were being recovered and sold to lighting manufacturers. Other products included anhydrous ammonia, sulfur, and liquid nitrogen.

Coal liquefaction, also called mild gasification, began to emerge from the purely experimental stage in the early 1990s. While promising technologies had been discovered, they required crude oil prices in the \$38-per-barrel range to be feasible. The price of crude ranged between \$12.50 per barrel (1986) to about \$20 per barrel in the early 1990s. Commercialization may depend on making commercial quantities of high-value chemical coproducts. The solid product of mild gasification can be made into formcoke and used in blast furnaces. Because the product would come from new plants meeting the most stringent environmental standards, instead of traditional coke ovens, the environment would benefit as well.

Also in the early 1990s, a Wyoming project that received federal funding under the U.S. Department of Energy Clean Coal Technology Program was to produce two products, one solid, the other liquid. The solid product was a low-sulfur, high-energy, coal-like fuel able to be burned in power plants and meet strict emissions standards. The liquid fuel could be used directly as a boiler fuel or as a refinery feedstock to produce gasoline and diesel. When fully operational, the plant was expected to produce 180,000 tons of high-energy solid fuel and 150,000 barrels of liquid each year using 1,000 tons of subbituminous coal per day. In all, 32 coal gasification and liquefaction projects were in various stages of development across the United States. But as crude oil prices increased, the economic benefits of coal liquefaction were beginning to attract attention. The Sierra Pacific Power Company's Pinon Pine Project was a showcase demonstration plant, showing how clean, affordable electricity could be generated from coal, one of America's most abundant resources. In its gaseous form, coal can be cleaned of more than 95 percent of its sulfur pollutants and virtually all of its ash impurities. The project began in 1992 and was scheduled to run until 2000. By 2010 technological improvements will be able to lower the cost to 75 percent of what it is today.

SIC 1321

NATURAL GAS LIQUIDS

This category includes establishments primarily engaged in the production of liquid hydrocarbons from oil and gas field gases. Establishments recovering helium from natural gas and establishments recovering liquefied petroleum gases incidental to petroleum refining or to the

manufacturing of chemicals are classified in a range of chemical and allied product manufacturing industries.

NAICS CODE(S)

211112 (Natural Gas Liquid Extraction)

Natural gas liquids (NGL) are found in natural gas, often in association with crude oil production. NGL is a reservoir portion of natural gas that is stripped out as a liquid at the surface by special processing facilities. NGL typically contains 35 percent ethane, 30 percent propane, 17 percent natural gasoline, 12 percent butane, and 6 percent isobutane. NGL should not be confused with natural gas, which is composed primarily of methane. NGL is denser than natural gas and becomes combustible at different concentrations than methane, according to the American Gas Association. Also, NGL is not liquefied natural gas, which is condensed natural gas that is compact and therefore convenient for overseas shipping.

NGL appears in a gaseous state at normal temperatures and pressures. NGL is removed from the gas stream at an extraction plant when the gas is processed. Using the most modern extraction technique, up to 90 percent of the NGL can be recovered from the gas stream. After the NGL is extracted, it is mixed together and transported to a fractionation center, where it is divided into individual gas products. The two largest centers are located in Texas and Kansas. Furthermore, Texas, the Gulf of Mexico Federal Offshore, New Mexico, Oklahoma, Louisiana, and Wyoming together accounted for 87 percent of all NGL production throughout the early 2000s. In addition, the 20 largest gas processing companies controlled 75 percent of NGL production.

The chemical industry accounts for roughly half of the total demand for NGL products ethane and propane. NGL is used as feedstock to produce chemicals and plastics. One common product called ethylene is composed of 75 percent NGL. Analysts expect worldwide demand for NGL should rise significantly through the year 2010 because of feedstock usage, especially in the manufacturing of ethylene.

The Clean Air Act bolstered butane demand by requiring gasoline composition to include a 12 to 15 percent greater oxygen content. Methyl tertiary butyl ether (MTBE), which has a high oxygenate content, has been the most highly regarded oxygenate to be used. MTBE is composed of 75 percent butane. The retail industry accounts for 30 percent of NGL demand. Propane is used for home heating, cooking, and transportation purposes.

The U.S. Department of Energy reported that 884 million barrels of NGL were produced in 2002, compared to 690 million barrels in 1998. Most of the domestic supply of more than 70 percent of NGL was derived from natural gas processing plants. Refiners accounted for about 20 percent, and the rest of the supply came from imports, according to the *Oil and Gas Journal*.

In 2002, the United States increased its NGL reserves by 1 million barrels to 7.9 billion barrels. Total discoveries of NGL reserves decreased 26 percent to 738 million barrels, with the largest share of the discoveries (34 percent) in Texas. Utah and Wyoming accounted for another 19 percent of discoveries. Despite waning discoveries, the NGL future looks promising as the Gas Processors Association predicts strong demand for NGL in the future as industrial and developing countries increase their use of cleaner burning fuels.

A leading producer of NGL throughout the early 2000s in the United States has been ChevronTexaco Corp. formed by the 2001 merger of Chevron Corp. and Texaco Inc. With 2003 sales of \$112.9 billion, ChevronTexaco is the second largest energy company in the United States. Its domestic natural gas production in 2002 totaled 2.9 billion cubic feet per day. Another NGL powerhouse is Houston, Texas-based ConocoPhillips, formed by the 2002 merger of Phillips Petroleum Company and Conoco Inc. Gathering, processing, and marketing natural gas is one of four key activities of the firm, which is the third-largest U.S. energy concern with 2003 sales of \$104 billion.

SIC 1381

DRILLING OIL AND GAS WELLS

The category includes establishments primarily engaged in drilling wells for oil and gas field operations for others on a contract or fee basis. This industry includes contractors that specialize in spudding in, drilling in, redrilling, and directional drilling.

NAICS CODE(S)

213111 (Drilling Oil and Gas Wells)

INDUSTRY SNAPSHOT

Oil and natural gas drilling is expected to be a growing industry during the 2000s. In the late 1990s, worldwide production increases led to a glut of oil and natural gas on the market, which resulted in price declines. Consequently, many wells were idled. In the early 2000s, with demand once again pushing supply, drilling companies were undertaking new drilling opportunities as well as refurbishing idled drills to get them running again.

Drilling is an inherently volatile business that follows trends in the overall worldwide oil and natural gas markets. For example, rising oil and gas prices in 2001 led to nearly 1,300 active wells, the highest count since 1986. Within the following nine months, well activity plummeted 43 percent, to 743 active wells in April 2002. By mid-2003, active well totals approached 850. Because 80 percent of all U.S. drilling is related to natural gas, natural gas prices will likely dictate drilling activity, which is primarily inland based.

ORGANIZATION AND STRUCTURE

In the mid-1980s when Saudi Arabian crude oil flooded the market, the price of crude oil fell to \$10 a barrel. American crude oil producers were hurt, but the rest of the domestic industry remained profitable, primarily due to strong consumption rates for refined petroleum products and chemical sales. The operators and producers of crude oil who survived the 1980s confronted an industry-wide collapse in 1991 and 1992.

The fall of natural gas prices sent the rig count plummeting to the lowest number in 50 years; drillers were most affected. Intense gasoline price competition led to the collapse of refining and marketing margins. An economic slump in the United States and a surplus of gas also contributed to weak prices.

Industry analysts continued to offer conflicting views regarding the future of the oil and gas industry through the mid-1990s—eventual recovery, little or no recovery, growth in the natural gas sector only. For the

drilling sector of the industry, economic recovery was contingent on many factors, all related to the supply and demand for oil and its related products. Various indicators included economic growth in the United States, consumption rates, oil and gas prices, Organization of Petroleum Exporting Countries (OPEC) production and export rates, and the development of new markets for exploration.

Earlier in the 1990s, Standard & Poor's (S&P) anticipated U.S. oil consumption to approximate one-half of real growth in Gross Domestic Product (GDP). With long-term real GDP growth forecast at 2.5 percent annually, S&P predicted oil consumption to increase approximately 1.0 percent annually during the 1990s. Oil consumption did, in fact, rise from 17.979 million barrels a day in 1992 to 19.653 million barrels a day in 1999.

Gasoline consumption remained the largest component of total domestic petroleum use, with home heating oil in second place. Market analysts asserted that as Americans purchased more sports vehicles, which consume more gasoline than conventional automobiles, U.S. consumption of gasoline would increase. Increased consumption was also attributable to industrial and utility users who had dual burning capacity and switched from heavy fuel to natural gas. Natural gas consumption increased 4 percent over 1992 to capture approximately 25 percent of the U.S. energy market in 1993.

Natural gas can be found by itself or in association with crude oil. Natural gas is one of the cleanest burning fuels, producing primarily carbon dioxide, water vapor, and small amounts of nitrogen oxides. Prices of natural gas averaged \$1.86 per thousand cubic feet in 1992, up 13 percent from the 1991 average of \$1.59. According to the Independent Petroleum Association of America (IPAA), 1991 prices were abnormally low due to the warmer weather and the early release of gas from storage. By 1997, however, prices had risen to \$2.42. Preference for natural gas continued to grow throughout the 1990s. The IPAA projected an annual growth rate of 1.7 percent through 2010.

By late 1995 the natural gas industry faced numerous challenges attributable to increased demand for natural gas, limited sources of new gas supplies domestically and in Canada, and record low levels of gas storage. The industry also faced low average natural gas prices in 1995, which discouraged exploration drilling activity. As a result, producers cut capital expenditures; productive capacity, subsequently, was reduced during the 1995-96 heating season. Although market analysts projected continued low capacity through 1997 and projected natural gas prices in major regional hubs to nearly double from 1995 prices, prices only rose to \$2.42 per thousand cubic feet.

From 1989 through 1991, oil consumption fell. According to the *Oil & Gas Journal*, this continued decline was a result of a depressed level of drilling activity, the natural production decline rate of mature reservoirs, and a lack of access to prospective onshore and offshore areas. According to IPAA, crude oil production averaged 7.2 million barrels per day in 1992, which was the lowest level in 30 years. The trend continued and fell to 6.3 million barrels per day by 1998.

Oil prices averaged \$12.12 per barrel in 1998, rose to \$17.21 in 1999, and the U.S. Department of Energy (DOE) projected that they would continue to rise to an average of \$21.86 per barrel in 2000. Natural gas prices also rose from \$2.38 per million BTU (British thermal unit) in 1998, to \$2.64 in 1999, and were expected to rise to an average of \$2.89 in 2000.

Perhaps reflecting the price increase in crude oil, the U.S. rig count rose to 763 in November 1999, compared to 696 in 1998. The Canadian rig count was 336 in 1999, almost double the 183 operating in 1998. Only international drilling activity showed a decrease from 724 rigs in September 1998, compared to 557 in September 1999.

Saudi Arabia has been the dominant member of OPEC and maintained the highest share of OPEC oil export revenues. Other top OPEC oil exporters included Iran, Venezuela, Iraq, and Nigeria.

In the first half of the 1990s, U.S. exploration was centered in the Gulf of Mexico. As consumption of natural gas increased at the end of the twentieth century, companies continued to search for new sources of crude oil. Opportunities for international petroleum companies to explore, develop, and produce crude oil and natural gas in many areas of the world increased rapidly, particularly in the Asia-Pacific region.

Contract Drilling Firms. Contract drilling firms work with the well operators. Operators are the companies that decide what kind of well to drill and determine its specifications. Operators hold the lease rights and operate the lease as well. According to the *Fundamentals of Petroleum*, almost 98 percent of all gas and oil wells in the United States have been drilled by contract drilling firms. The drilling contractor usually is assisted by other companies, or subcontractors, that furnish specialized well services, such as casing and cementing (**see SIC 1389: Oil and Gas Field Services, Not Elsewhere Classified**).

To remain financially viable, drilling contractors began to diversify their businesses to include other oil-related services. Rowan Companies Inc., for example, diversified into an international aviation organization operating helicopters and fixed-wing aircraft. Between 1983 and 1995, while the drilling industry was in a state of turmoil and a period in which Rowan lost \$342 million, its aviation division contributed more than \$178 million

in earnings. To diversify, Rowan Companies also operated another division, LeTourneau, Inc., a mini-steel mill and manufacturing facility that produces heavy equipment for the mining, timber and transportation industries, an international aviation service business operating helicopters and fixed-wing aircraft, and a marine division that has built more than one-third of all mobile offshore jack-up drilling rigs.

Drilling contractors are primarily responsible for drilling wells, re-drilling, reworking wells, and spudding (or startup) services. During 1995 Rowan Companies conducted offshore drilling operations in the Gulf of Mexico, the North Sea, offshore eastern Canada, and offshore Trinidad. The overall activity rate of its 21 offshore rigs in 1995 was 90 percent, up from 85 percent in 1994. Its drilling operations yielded an operating profit of \$2.3 million, down \$2.7 million from 1995.

Varco International, Inc., a manufacturer of products used in the oil and gas well drilling industry worldwide, reported that sales for 1999 totaled \$80 million, down from \$96.1 million in 1998. The reduced level of incoming orders in 1999 as compared to 1998 reflected the continued low level of worldwide drilling activity and the absence of new rig construction.

Drilling contracts specify a drilling contractor's obligations to the operating company. The drilling contract is important to both the drilling contractor and the operating company because it details responsibilities and expectations, such as the depth of the well, start date, and sizes of the hole and casing. Operating companies rely primarily on two kinds of drilling contracts: turnkey and footage, or daywork. Using a turnkey contract, the operating company is required to pay a set fee to the drilling contractor upon completion of the well. The contractor furnishes all the materials and labor, controlling the entire drilling process independently. Under a footage contract, a rate per-foot-drilled is established. This contract usually includes a daywork payment to compensate the drilling contractor for days when drilling has been suspended. This payment covers situations when the drilling rig is on site but has to perform nondrilling duties that are vital to well completion.

Drilling Rigs. All drilling rigs are designed to extract a significant amount of petroleum, which is trapped underground in a porous or permeable rock formation. The most common form of drilling rig has been the rotary rig. With rotary drilling, the rock formation is penetrated by a rotating bit connected to a hollow drill pipe. Fluid is pumped through the pipe, so that the rock cuttings can be brought to the surface. Two or more diesel or gas engines provide the required 1,000 to 3,000 horsepower, depending upon well depth and rig design. Rotary rigs are usually portable, so the contractor can be relatively mobile.

The operating equipment of a rotary rig can be divided into three systems: hoisting, rotating, and circulation. Wells are drilled using tremendous amounts of pipe and drill collars, sometimes weighing as much as 500,000 pounds. In order to move these items, the rig must have a hoisting system. The rotating system provides the power to the bit by turning it in the well bore. The rotary method spins the bit further and further into the ground, while the drill is lubricated to keep it cool and to flush out excess matter. The drill collar is heavier than the drill pipe and is used on the bottom of the string to put weight on the bit. The bit chews up the rock formation and dislodges it. The hardness of the formations determines the type of bit to be used. The circulating system is used to remove rock cutting and to cool the bit. Drilling fluid, often called mud, is a mixture of clays, chemicals, and water or oil, and is circulated in the drill hole.

Preparing a drill site requires many steps. The contractor must first clear and level the land, build access roads, make water available, and dig a pit to serve as a waste protector. At the site of the borehole, the contractor moves in the rig and other necessary equipment. Once the rig is in position over the conductor hole, the drilling begins to create the surface hole. The first drilling is accomplished by using a large bit attached to a drill collar, which is lowered into the conductor hole, with sections of the drill pipe added until the bit is on the bottom. Additional joints of drill pipe are added to the drill stem every 30-40 feet. At some depth, when the hole has been created beyond the gravel beds and other near-surface materials, the drilling subsides, and the drill stem is lifted out of the hole.

Pulling out the entire drill stem and bit is known as tripping out. Once the pipe is out, a casing crew moves in and runs the surface casing. Casing is a steel or iron pipe lowered into the well to prevent the walls from caving in during drilling and to keep gas and water from entering the well. Casing services are usually provided by an oil and gas field services subcontractor. Once in place, the casing is cemented by a subcontractor.

To resume drilling, or to trip into a hole, the drill stem with a new, smaller bit has to fit inside the casing. The bit, along with the drill collar, and each stand of pipe, is attached to the drill stem and is lowered into the hole. The drill bit continues to drill through the cement inside the casing. At some point, the drilling stops again, and another string of casing is set into the hole.

After the hole has been drilled to its determined depth, the operating company completes all evaluations regarding the economic viability of the hole. The company decides whether to set the production casing or plug the well. If it is determined that the well cannot produce enough oil or gas to compensate the costly completion services, then the well is considered to be "dry," and it is

plugged and abandoned. If the production casing is to be set, it will be set by a contract casing crew. The drilling contractor's job is completed when the hole has reached final depth, and the casing has been set and cemented.

BACKGROUND AND DEVELOPMENT

The petroleum pioneers based their drilling methods on the process of drilling for water: digging by hand. In 1857 operator Edward L. Drake and driller Billy Smith in Titusville, Pennsylvania, decided to try drilling for oil by hammering a pipe into the ground. The citizens of Titusville thought the project was foolishness and called the contraption "Drake's Folly." Even the financial backers of the venture gave up on the scheme and wanted Drake to abandon the project. But the driller, Billy Smith, did not give up, and soon enough the drill pipe struck oil. By the start of the 1860s, Titusville was covered with derricks, and the first oil boom had begun.

Early drilling methods relied on the cable-tool method, which was a rope or chain that suspended drilling tools into the well bore. Various methods were used to actually pound the drill bit into the ground. The tool's strings were relatively light, and the bit "looked something like a funnel." The process allowed the drill to penetrate one to two feet before the bit became dull. The drilling tools had to be removed from the well, the bit sharpened, and attached to a larger reaming instrument. If necessary the hole was pumped out, and the entire process began again. Versions of cable-tool drilling have been modernized and used in shallow wells. The cable-tool drilling system does not use injecting fluid or mud. Thus, the hole still has to be bailed out in order to remove cuttings produced during the drilling process.

Unlike the impact action of the cable system, in rotary drilling, the power of the bit comes from a rotating motion that turns the bit in the well bore. The circulation of fluid was an innovation by the Baker brothers in the 1880s. Fluid circulation allows particles of soft rock to float up the shaft and out of the way of the drill bit. The Bakers used their rig for drilling water wells in the Great Plains. The technique was also successful in the soft soil of Texas, where the great Corsicana oil field was discovered.

The petroleum industry's offshore operations began in the 1930s. Drilling in the shallow bays of the Louisiana and Texas Gulf coasts was conducted on wooden platforms mounted on timber piles. Most of the early activities in water-covered areas were designed to recover oil from reservoirs already defined on shore.

The offshore industry grew with the development of submersible and semisubmersible rigs, drill ships, and barges. Each year, independents dramatically increased their presence offshore, in both traditional production areas and in frontier deepwater leases. In 1999 more than

400 independents were active in the Gulf of Mexico, with at least 60 independents participating in the development of deepwater leases.

As the rig counts in American waters have declined, offshore drilling in other parts of the world has steadily increased. According to *Oil & Gas Journal*, a report by Infield Systems Ltd. noted that more than 1,400 new oil and gas fields will be developed prior to 2010. According to the *New York Times*, rig operators pulled their equipment out of the Gulf and hauled it to areas with more oil, including Venezuela, West Africa, and the North Sea.

According to IPAA, there were 835 U.S. rigs in operation in 1992. IPAA attributed the decrease in the number of operating rigs to the expiration of Section 29 tax credits and warm weather patterns. Some analysts predicted that the industry would pick up by 1993, estimating an average of 1,200 wells. Yet, the rig count stood at an average of 827 during the first half of 1998.

Environmental Issues. Industry leaders, such as those present at the 1992 Offshore Technology Conference, complained that the rapid decline in rig count has been due to rising costs and also to excessive environmental regulations. As these and other drilling experts have commented, the petroleum industry has been increasingly subjected to environmental considerations, a trend that continued throughout the decade.

The industry was mainly concerned with U.S. national energy policies. The Clean Air Act promoted the development and use of natural gas, which burns cleaner than other fuels. Although this legislation seemed to boost the natural gas market, it also included more stringent emission standards for offshore drilling, which directly affected well completion costs for drilling contractors. As new environmental laws and regulations were introduced, drilling contractors had to spend capital to meet standards set by these laws.

To meet demand, crude oil and petroleum products were imported at the all-time high rate of 10.4 million barrels per day in 1998, while exports measured 0.9 million barrels per day. Between 1985 and 1998, the rate of net importation of crude oil and products more than doubled from 4.3 million barrels per day to 9.5 million barrels per day. The share of U.S. net imports that came from OPEC nations reached 72 percent in 1977, subsided to 42 percent in 1985, and climbed back to 51 percent in 1998. Total net imports as a share of petroleum consumption reached a record high of 51 percent in 1998. The five leading suppliers of petroleum to the United States in 1998 were Venezuela, Canada, Saudi Arabia, Mexico, and Nigeria.

The price paid by refiners for crude oil in 1998 averaged \$12.57 per barrel. When adjusted for inflation, the price was \$11.15, fully 35 percent below the previous

year's price and 79 percent lower than 1981's record inflation-adjusted price of \$53.39 per barrel.

Up from less than \$15 in early June of 1999, a jump in September of world oil prices put crude back to above \$21 a barrel, the highest since 1997. The jump came on top of hefty fuel duty increases. The signs of a strengthening recovery in Japan and Southeast Asia drove the upward twist in oil prices.

The United States produced 19.0 trillion cubic feet of natural gas in 1998, well below the record-high 21.7 trillion cubic feet in 1973. Gas well productivity peaked at 435 thousand cubic feet per well per day in 1971, then fell steeply through the mid-1980s before stabilizing. Productivity in 1998 was 146 thousand cubic feet per well per day.

Annual petroleum consumption rose in the United States until 1973, when the Arab OPEC embargo stalled the annual increases for two years. Consumption peaked in 1978 at 18.9 million barrels per day. Rising prices over the next few years lowered consumption, which fell to 15.2 million barrels per day in 1983. Consumption began to rebound the following year and was boosted by plummeting crude oil prices in 1986. By 1998 it had reached 18.7 million barrels per day, close to the all-time high.

The resurgent U.S. natural gas market and new opportunities for work abroad should provide growth in the industry. Operators are expected to use more turnkey operations, risk sharing, partnerships, and to seek outside sources for certain services rather than developing them in-house, explained Sam Albright, of Howard, Weil, Labouisse, Friedrich, Inc., at the International Association of Drilling Contractors' (IADC) annual meeting. In *Drilling Contractor*, Albright added that the oil industry is restructuring, and consolidation will continue for the next few years.

CURRENT CONDITIONS

During the early 2000s, world oil production and prices were quite volatile. Tensions in the Middle East rose after the terrorist attacks on the New York World Trade Center on September 11, 2001. As the United States was preparing for war with Iraq in late 2002, workers at the national oil company in Venezuela, which provides 14 percent of U.S. petroleum imports, went on strike. Venezuela's production fell from an average 3 million barrels per day to just 400,000 barrels per day, driving prices up. Then, in 2003 the United States engaged Iraq in war, causing oil prices to spike to \$40 per barrel early in the year, before falling into the range of the mid-\$20s in March 2003.

Crude petroleum drilling is expected to provide a gradual increase in production through 2007, before lev-

els begin to decline. Most new growth in the drilling for petroleum will occur offshore, most often coming from existing idled platforms that could come back on-line as the economy recovers. Many of these platforms will have received upgrades during recent periods of downtime. Technological advances will provide advances in automation, as well as increase the speed and depth of the drilling.

Most opportunities in the well drilling industry will come from the natural gas sector. However, during the early 2000s high levels of reserves and unusually warm winters kept natural gas prices down, which directly impacted the utilization of drilling rigs. As supply tightened during 2002 and prices edged up, the drilling industry was looking hopefully toward recovery. In a fall 2002 issue of *The Oil & Gas Journal*, Marshall Adkins and Jim Rollyson predicted: "U.S. natural gas supply is falling at a record pace. . . . As a result, natural gas prices are setting up for an extremely robust 2003 and beyond. Since about 80 percent of all U.S. drilling is now natural gas driven, natural gas prices will be the key variable to watch to predict future US drilling activity levels."

INDUSTRY LEADERS

On July 13, 1999, Schlumberger Ltd. announced that it had agreed to merge the offshore drilling operation, Sedco Forex, with Transocean Offshore, to create the world's largest offshore drilling company. The merged company was named Transocean. Both companies said the spinoff was in response to the increasing costs and technological demands of offshore drilling, which is taking place in deeper waters than in previous years. Transocean reported revenues of \$2.7 billion in 2002.

GlobalSantaFe Corporation, a leading offshore drilling contractor, has drilling operations around the world. Its operations include 57 offshore rigs and 31 land rigs. GlobalSantaFe was formed in 2001, after Santa Fe International purchased Global Marine. Kuwait Petroleum, owned by the government, has a 29 percent share in GlobalSantaFe. The company reported a net income of \$278 million on revenues of \$2 billion in 2002.

Halliburton is one of the largest oil field services providers. Its Energy Services Group, which accounts for about 55 percent of revenues, provides well drilling services. Halliburton reported sales of \$12.5 billion in 2002. Schlumberger Limited is another giant in the oil field services industry. The company reported revenues of \$13.5 billion in 2002.

WORKFORCE

In 2001 the U.S. Department of Labor, Bureau of Labor Statistics, reported that the oil and gas field services industry employed 204,010 people. Over 50 percent

of jobs were related to construction and extraction. The mean annual salary for a drill operator was \$36,790.

AMERICA AND THE WORLD

The Department of Energy (DOE) has forecast strong opportunities for the export of U.S. energy services and technology through 2010. The international market for oil and gas exploration, excluding former Eastern Bloc nations and China, has been predicted to increase to \$1.3 trillion per year from 1991 through 2010, as reported in *Oil & Gas Journal*. The DOE has estimated that U.S. vendors can capture \$955 billion or 74 percent of that market.

According to the International Trade Administration, Department of Commerce, the Middle East and North Africa are of vital strategic interest to the United States and are of economic importance as a major source of the world's energy supplies. Export figures from the region support that assessment—Persian Gulf countries (Bahrain, Iran, Iraq, Kuwait, Qatar, Saudi Arabia, and the United Arab Emirates), as of February 1998, produced 26 percent of the world's oil and held 65 percent of the world's oil reserves. Saudi Arabia and Kuwait alone accounted for about 12 percent of total U.S. crude oil imports.

Canada was the world's fifth largest energy producer, after the United States, Russia, China, and Saudi Arabia. The United States is Canada's major trade market for energy products, accounting for 91 percent of all Canadian energy exports (including nearly all of Canada's oil, natural gas, and electricity exports). Despite low oil prices in 1998, Canada's overall energy outlook was good. The country possessed abundant quantities of gas, coal, uranium, and oil, and was a major net energy exporter.

Latin America is also a promising market, especially Venezuela and Columbia. Although both have political risks, a joint venture has already begun between Benton Oil & Gas Co. and Vincler CA, producing 2,100 barrels a day in Venezuela. According to the *Wall Street Journal*, this has been the first Venezuelan oil field operated by a U.S. company since the industry was nationalized in the mid-1970s. Southeast Asia has also become a lead target for development by U.S. firms.

Although overseas work can prove to be lucrative, it is not without its problems, most of which are not related to the task of drilling. Instead, contractors will have to learn about customs, work habits, and social behaviors for each country. Also, each market is decisively different, so what is known about one market will not be easily transferred to the next. Moreover, some overseas markets have grown to expect contract drillers to provide integrated services, "where the driller's participation in the planning and the management of the drilling programs

are the norm rather than the exception," reported Luigs in *Oil & Gas Journal*.

RESEARCH AND TECHNOLOGY

Advances in research and technology in the contract drilling industry will continue to be the most critical factor to keep companies competitive. Continual improvements in technology and procedures have resulted in lower drilling costs and improved safety. At an annual meeting of the International Association of Drilling Contractors, both Suzanne Cook, industry analyst and first vice president of Merrill Lynch and Co., and Matt Simmons, president of Simmons and Co., International, agreed that "savvy exploitation of technology is one of the keys to repositioning for the future." Technological issues boil down to how to drill a well more efficiently and cost effectively.

Other technological advancements already in use are rig computerization and automation for daily drilling operations, such as Microsoft's Project Manager software. As reported in *Drilling Contractor*, Global Marine has developed a Rig Efficiency Program and has used the Microsoft program to monitor and analyze the performance of all its operations on every company rig around the world. Simmons added that while technology has profoundly changed the drilling industry, few advances have threatened to replace the rig itself.

Horizontal drilling uses drill bits driven by motors actually in the bits, instead of aboveground motors, and can be directed with the help of computers and detailed mapping. Drillers use horizontal drilling in aging fields, where earlier attempts might have missed oil trapped in narrow, vertical rock formations. Texas has remained the dominant region for horizontal drilling, with 81 percent of all horizontal wells. Some companies have begun to use the technique to search for new discoveries in North Dakota, Wyoming, and Colorado, where rock layers are similar to the ones in Texas fields, according to *The New York Times*.

According to the *1997 Swift Energy Annual Report*, while horizontal drilling was still a small segment of the total drilling activity in the United States, its percentage of the total drilling activity increased sharply during the 1990s. Between 1991 and 1996, the number of horizontal wells drilled rose by 28 percent, while the total number of drilled wells fell by 23 percent.

In the field of exploration and production, technology revolutionized the way oil was found and gas was produced. Mobile Oil developed a new software that mimicked the way the human brain's neural network processes information. Using supercomputers, this tool integrated signs of gas, oil, or water from well measurements into a "big picture," provided by high-definition seismic readings taken over hundreds of square miles.

Predictions could then be made regarding a reservoir's hydrocarbon locations. With this detailed reservoir picture as a guide, zones could be tested using flexible drilling technologies.

OIL AND GAS FIELD EXPLORATION SERVICES

This category covers establishments engaged primarily in performing geophysical, geological, and other exploration services for oil and gas on a contract or fee basis.

NAICS CODE(S)

541360 (Geophysical Surveying and Map Services)

213112 (Support Activities for Oil and Gas Field Exploration)

INDUSTRY SNAPSHOT

Companies performing oil and gas exploration services are most often divisions or subsidiaries of major oil companies, although the industry also boasts several significant independent contractors. Many of the industry's leaders are known as integrated companies, which cover the entire oil and gas industry, from exploration to refining to distribution. As such, the exploration branch of the industry is affected by trends in the field as a whole.

For example, in 1998 a drop in world oil prices led to a collapse in exploration and drilling activity. During that time the number of natural gas drilling rigs fell off by 40 percent, but rebounded by 2001 to produce at record levels, and then declined again. When oil and gas prices are suppressed, companies tighten their purse strings, often cutting costs by idling explorative drilling. During 2003 the U.S. war against Iraq, as well as a workers' strike in Venezuela, pushed oil prices back up. As a result, oil companies had revenues to once again pursue increased exploration activities.

Partly because the United States is considered a mature oil region, the major American companies—Exxon/Mobil, Texaco, and Chevron (which, along with the European giants British Petroleum/Amoco/Arco and Royal Dutch/Shell, control the American market)—focused their exploration efforts elsewhere. The Energy Information Administration (EIA) reported that the increases in the U.S. majors' exploration and development expenditures have mostly been directed toward the North Sea and Southeast Asia.

ORGANIZATION AND STRUCTURE

Much of the exploration process is done before wells are actually drilled. Once a company obtains the mineral rights to the land it wishes to drill, three-dimensional (3-D) seismography, aboveground sonic sampling, and other methodologies are utilized to determine where oil is most likely to be found. Once seismographic data about either underground or sea floor rock is collected, it is analyzed for signs of oil or gas deposits, a process that takes several months. A likely area is then selected, and exploratory or "wildcat" wells are drilled to confirm suspicions. If the area is known to have oil, "development" wells are drilled. There are legal regulations on the number of wells that can be drilled in a given area by "infill drilling." Drilling to test the possibilities for expanding an oil field is done with "stepout" wells. Finally, wells that turn up no product, or too little to make continued drilling feasible, are called "dry holes."

While drilling, a rig (made up of a derrick and surface equipment) is set up over the target area, and a bit attached to a drill stem is lowered into the earth. In the most common setup—rotary drilling—a rotating bit con-

nected to a hollow pipe breaks up the earth. Fluids (“mud”) made up of clay, water, and other ingredients are injected through the pipe to cool the rotating bit and carry broken rock back to the surface. Often a hollow casing is placed in the well to keep the walls from caving in and to protect the contents of the well from outside influences of water or gas. Both oil and gas are removed through narrow tubing implements that bring the substances to the surface.

The crude oil that wells up without pumping is culled using primary recovery methods, during which time most of the available oil is recovered. In secondary recovery, additional effort must be expended to remove the oil. Most often, the well is flooded with water to flush out the oil. Finally, in some wells, tertiary recovery methods, such as injecting steam or gases into the well, help flush out the heaviest, most viscous oil. Wells may be “shut in,” their valves closed, during the wait for a pipeline connection or even when the oil and gas market is depressed and further drilling becomes financially difficult. Once a well is dry, it is plugged—filled with cement or mud—and abandoned.

Drilling for natural gas is similar to drilling for oil, but gas must be liquefied before it can be shipped. Apart from the natural gas liquids (NGL) that occur naturally at a well, all gas obtained must be cooled and pressurized into liquid natural gas (LNG) for transportation. NGL is mainly ethane, propane, butane, and natural gasoline; the gas from LNG is mainly composed of propane, propylene, butanes, and butylenes.

The amount of oil obtained is measured in barrels (bbls.), one of which is equal to 42 U.S. gallons. Natural gas is measured in thousand cubic feet (mcf), one of which equals 1 million BTUs (British thermal unit) of energy at one atmosphere of pressure. One barrel of oil is equal to six mcf.

BACKGROUND AND DEVELOPMENT

Field exploration in the petroleum industry began in earnest in 1859, when Edwin Drake drilled the first successful oil well in Titusville, Pennsylvania. Previously, oil was obtained only where it seeped from the ground. Drake’s discovery went to feed the burgeoning need for kerosene for lamps; soon, lamp oil made from oil replaced that made from coal.

Among the rash of speculators who entered the exploration business was John D. Rockefeller, who soon turned away from exploration (which he considered too much of a financial risk) and moved toward refining and transporting the fuel already obtained. For the next 50 years, Rockefeller’s Standard Oil Company expanded by any means necessary, engaging competitors in price wars or buying them out when they became a threat. Standard Oil remained unchallenged until exploration in Texas,

Louisiana, and Oklahoma led to the rise of companies such as Gulf and Texaco. While Standard’s oil fields were in the United States, it began exporting its products to the European and Far Eastern markets, competing with both Shell (then the Shell Transport and Trading Company) and the Royal Dutch Petroleum Company. Standard Oil made several unsuccessful attempts to buy or control Shell. Royal Dutch and Shell began cooperating with each other, partly in an attempt to compete with Standard Oil and eventually united into one company, today the second largest worldwide. In 1909 the Standard Oil Trust was deemed illegal under antitrust charges, and the U.S. Supreme Court ordered it to be dissolved. Broken up into over 30 companies, the offshoots of Standard Oil still retained immense industry influence, eventually spawning Jersey Standard (later Exxon), Socony and Vacuum (later Mobil), Standard of California (later Chevron), Atlantic (later ARCO), and Standard of Indiana (Amoco), among others.

U.S. exploration on the part of the major American oil companies (known as the Seven Sisters) produced what for a while seemed to be a never-ending stream of resources. It was not until the 1920s that they began foreign exploration and then mostly to check the power of British companies drilling in the Middle East. But foreign exploration came with a price; in the 1940s Venezuela demanded half of the income generated from drilling within its borders. Other countries followed suit, stemming in part from the huge profits flowing into U.S. companies from overseas. Challenges also came from smaller independent oil companies such as Marathon and Getty. At the same time, exploration efforts uncovered new sources of revenues in natural gas, often found with oil deposits. Once it was discovered how to trap and transport the gas, it became another focus of exploration.

Another challenge to American oil companies came with the 1960 formation of the Organization of Petroleum Exporting Countries (OPEC), consisting of eight Middle Eastern countries that were heavy producers of oil. This cartel used its power to push up the price of oil from \$1.80 a barrel in the 1960s to more than \$3.00 a barrel in 1973. Prices rose further when a 1973 OPEC embargo aimed at punishing U.S. support of Israel led to a national energy crisis in which America was made aware of its dependence on foreign oil. Meanwhile, American oil companies came under attack for profiting unfairly from the embargo. The state of the oil and gas exploration industry was further impacted by increased emphasis on alternative energy sources, such as hydroelectric, nuclear, and solar energy.

In the late twentieth century, the oil industry made significant cutbacks in exploration, production, and corporate staffs. Slim profits, surplus inventories, and low prices cooled the fever to explore for new oil and gas

fields. In some cases, such as with the 1984 purchase of Gulf Oil by Chevron, companies were bought out or restructured. By the early 1990s, the industry had still not reattained boom status; it entered 1994 with several years of cutbacks, employee layoffs, and flat earnings behind it. By the mid-1990s, though, the downhill slump did an extraordinary turnaround. U.S. oil companies experienced strong profits during the second quarter of 1996. Compared to the same period only one year earlier, Mobil's profits were up 337 percent, Texaco's 154 percent, Chevron's 44 percent, Amoco's 13 percent, and ARCO's 11 percent. Exxon experienced a 4 percent decrease in profits, but showed a strong net income in the fourth quarter, which was 49 percent higher than the same period in 1995. For the year in total, all showed strong profits, including Exxon, whose 1996 income was up 16 percent from that reported in 1995. ARCO announced that 1996 was one of the most successful years in the company's 130-year history. The increase in profits has been credited to high crude oil and natural gas prices, and also to strong margins in refining and marketing operations. Mergers and acquisitions reached \$14.5 billion in the first half of 1996, up from \$11.5 billion for all of 1995. Among the largest of these moves was Tenneco's \$4.0 billion sale of its pipeline to El Paso Natural Gas Co.; Mobil's planned merger of its European refining and marketing operations with British Petroleum; and Mobil's \$1.4 billion takeover of Australia's Ampolex Ltd.

Natural gas prices fell to record lows in the early part of the 1990s, and oil companies spent approximately 10 percent less in 1992 on new well exploration than they had the previous year. U.S. production fell to 9.0 million barrels per day (b/d) in 1992, down from 10.0 million b/d in 1987, continuing its slow slide, as more companies pursued international drilling at the expense of U.S.-based exploration. Despite the gains in the industry, U.S. production had fallen below 7.0 million b/d, a low not seen since the 1950s.

In 1996 production was 6.7 million b/d, with 1.4 million b/d from Alaska and the remainder from the lower 48. Alaska was seen as the only U.S. state with the possibility of harboring large, untapped oil and gas reserves, but new exploration on federally owned lands has been forbidden by Congress, spurred on by a growing environmental movement. The only real growth sector was offshore, primarily in the Gulf of Mexico. For example, the Federal Energy Regulatory Commission (FERC) had approved the Gulf of Mexico Discovery Project for Discovery partners MAPCO and Texaco, a 150-mile offshore Gulf pipeline accessing deepwater production from existing and planned locations. Ashland Oil began production on Vermillion Block 410 offshore Louisiana, and a second platform with four wells was scheduled for production in 1997. At the beginning of 1997, Amoco

announced that it would develop the deep water Gulf of Mexico Marlin prospect with Shell Deepwater Development, Inc. It was expected to cost \$500 million to develop and ultimately would produce 250 cubic feet of gas and 40,000 barrels of oil per day.

Environmental concerns had also increased the cost of local drilling, further spurring American exploration firms to turn their attention to drilling outside of the United States, where regulation was sometimes slack and the possibility of untapped reserves significant. While exploration services underwent shifts in fortune prior to the 1990s, those changes were most often due to economic or political factors (such as the OPEC oil embargo of the mid-1970s) rather than environmental ones. However, The Oil Pollution Liability and Compensation Act of 1990 and the Clean Air Act of 1990 had some direct effect on exploration practices (the latter, among other things, tightened emission standards for offshore drilling activity). But most effects on exploration remained indirect—most new regulation and fines applied to vehicles, oil refineries, ships, and pipeline operations, the costs of which would reach oil and gas companies in general and then trickle down to exploration expenditures. With government rewarding the use of diesel fuel alternatives, more energy was being put into natural gas exploration and production than into crude oil.

In the late 1990s, U.S. drilling activity took a major dive, due to plummeting world oil prices, but made a remarkable recovery by the end of 1999. Oil drilling in the United States hit an historic low in 1999, with one of the smallest number of total well completions in the modern petroleum era. Operators drilled 18,600 wells in 1999, off from an estimated 23,900 drilled in 1998, the lowest number in six decades. Slack profits in oil and gas production operations accounted for the decline in investment in U.S. exploration and development. Oil prices bottomed out at \$11.26 a barrel in February of 1998, but rebounded to \$25.70 a barrel in December of 1999.

In 1998 there were a total of 24,884 wells in the United States, an increase of 2,703 from 1995; of these 8,720 were completed for oil; 10,711 for gas; and 5,453 were dry holes. Baker Hughes, Inc., an oil field service company, reported a dramatic drop in domestic drilling since late 1997. The September 1997 U.S. rig count topped 1,000; by December 1998, it dropped to 647, reaching the lowest level since 1950.

After peaking in 1970, domestic crude oil production has fallen by an average of 1.5 percent per year. In 1997 crude oil production in the United States declined by 56,000 barrels a day to an average of 6.4 million barrels per day (MMb/d), down from 6.5 MMb/d during the same period in 1996. Alaska, which produced 1.3 MMb/d, accounted for 20 percent of total U.S. production in 1997. The lower 48 states averaged 5.1 MMb/d. Total

natural gas production in 1997 was estimated at 19.0 trillion cubic feet (Tcf), compared to 18.7 Tcf in 1996. Domestic crude oil production was expected to increase by only 0.1 percent in 1998 and decline by 2 percent in 1999.

Since 1986, the U.S. petroleum industry has shrunk: higher-cost companies have left the industry and big-budget projects have been scrapped. Despite the slow growth, U.S. companies have made significant efficiency gains, as the cost of adding reserves (finding costs) has declined. A general reduction in activity combined with more selective drilling (often called “prospect high grading”) account for this drop. Moreover, technological advances in exploration and drilling have made many projects more profitable. Finally, corporate downsizing and industry mergers have reduced operating costs by streamlining resources and eliminating redundancies.

CURRENT CONDITIONS

The market volatility of the 1990s saw little improvement during the early 2000s. A general strike by workers at Venezuela’s national petroleum plant in December 2002 caused the country’s production to fall from 3 million barrels per day to just 400,000 barrels per day. Venezuela provides approximately 14 percent of U.S. imports, and the mayhem in that country caused oil prices to spike in late 2002. On the heels of the strike came the U.S. war against Iraq, which resulted in per-barrel prices jumping briefly to \$40 before dropping back to \$28 in March 2003. Elevated prices put money back in the pockets of petroleum companies, paving the way for increased exploration activities.

Continued exploration will be necessary to meet future demands for both petroleum and natural gas. In 2003 global consumption of crude oil stood at 76 to 78 million barrels per day. The demand is expected to increase to 90 to 110 million barrels per day by 2025. Natural gas consumption in 2003 averaged 90 trillion cubic feet per day and is expected to increase to 135 trillion cubic feet per day by 2025. Exploration will be driven by new technology that will allow deeper wells, and in offshore locations, in deeper waters.

Whereas natural gas exploration and drilling, which accounts for 80 percent of all U.S. drilling activity, will be focused inland, petroleum exploration is shifting toward more offshore locations. In 2003, U.S. companies operated 4,194 offshore platforms. In 1984, 84 percent of acreage awarded exploration privileges was onshore, with 3 percent onshore with offshore extensions, and 22 percent offshore. By 2002 offshore exploration awards had grown to 53 percent, and onshore awards had fallen off to 42 percent. The increase in offshore exploration has not gone unnoticed or uncontested by environmental groups. For example, during 2002 Florida protested ex-

ploration releases off its coast, resulting in the federal government buying the leasing rights from oil companies to compensate them for the loss of potential oil. Likewise, California was waging a battle to keep exploration leases in water north of Los Angeles from being renewed by the federal government.

INDUSTRY LEADERS

The *Financial Times* reported that the petroleum industry has been transformed by what it called a new order of mega-majors. Impelled by low oil prices and a desire to cut costs, petroleum corporations stepped up their merger activity in the late 1990s. The largest industry marriages occurred between BP and Amoco, Exxon and Mobil, and Total and PetroFina. In addition, on April 1, 1999, BP Amoco agreed to purchase Arco.

Exxon’s merger with Mobil, completed in the third quarter of 1999, created the world’s largest company, with 2002 revenues of \$178.9 billion. The company has 55.7 trillion cubic feet of natural gas and 11.8 billion barrels of oil in proven reserves. The consolidation also gave the company key access to some of the world’s most lucrative oil basins, including offshore West Africa and the Caspian Sea, as well as a strong position in natural gas markets in North America, Europe, and Asia-Pacific.

Smaller companies had also been gaining ground in the development of U.S. oil and gas resources. The share of oil and gas production from non-majors (also known as “independents”) increased from 40 percent of total U.S. production in the late 1980s to nearly 50 percent in 1996. Non-majors accounted for 60 percent of total U.S. production of natural gas from U.S. offshore areas in 1996. Nonmajor companies tended to drill smaller fields that had faster depletion rates than those of the majors. But like the majors, the smaller companies were able to reduce their finding costs to levels equivalent to the majors’.

WORKFORCE

Corporate mergers have not boded well for the job market in oil and gas exploration. However, streamlining has not affected skilled exploration workers. With prospects beckoning overseas, the demand for technical experts was expected to rise.

Oil and gas exploration teams require a variety of subject expertise. Geophysicists, who apply the principles of physics to the science of geology, and geologists, who study the formation of the earth, evaluate incoming data from seismic vessels and onshore data collection. Then, they use sophisticated computer systems to interpret the data and make recommendations for when and where to drill. Engineers are needed to design oil and gas rigs and to oversee their use on site. Oil rig workers, who may live for weeks at a time on offshore rigs, are needed

to operate the equipment. The oil companies themselves employ executive and clerical staff on the corporate level, but in the wake of increased cutbacks in the 1990s, these jobs were increasingly difficult to obtain. Companies were relying more and more on contract or freelance workers instead of large, permanent staffs.

AMERICA AND THE WORLD

The American oil and gas industry is inextricably linked to the world industry. In 1997 to 1998, financial crises spread throughout the world—from Southeast Asia to Brazil to Russia—causing a huge drop in worldwide petroleum demand; hence the collapse of oil prices.

Because decisions about exploration are linked to the proven reserves of oil and gas available, it is important to note that more than 75 percent of proven oil reserves are controlled by OPEC, although the vast majority of oil is consumed by non-OPEC nations, giving OPEC a tremendous influence on the world oil and gas market. In 1998 OPEC countries decided to raise their production quotas, flooding the market with excess supplies and driving prices downward. However, in April of 1999 the OPEC consortium agreed to cut their production to drive up world demand, and oil prices soon rebounded.

American oil exploration, and that of other non-OPEC countries, has slowed in contrast to OPEC exploration. With the end of the Gulf War, members of OPEC followed the lead of relatively moderate Saudi Arabia and stabilized their pricing while increasing both exploration and production.

Meanwhile, the major U.S.-based petroleum companies were becoming increasingly involved in foreign exploration. In the early 1990s, money allocated to foreign exploration and development topped 50 percent of all exploration spending, as compared to 27 percent in the mid-1980s. In 1996 Exxon spent twice as much on foreign exploration as for domestic. Mobil Co. spent \$830 million on domestic exploration and \$1.8 billion on overseas. In addition to the many reasons for decreasing domestic exploration mentioned earlier, world political and economic developments of the 1990s made it more feasible and profitable to increase American investment in foreign exploration. Along with maintaining an already strong presence in the Mexican and Latin American markets, U.S. companies have increased investments in other areas of the world.

The dissolution of the Soviet Union provided increased opportunities for investment in that area's oil reserves. The Commonwealth of Independent States (CIS) has seen the rise of joint exploration and drilling ventures, especially between U.S. and Russian companies. The Caspian Sea, which borders Russia, Azerbaijan, Iran, Turkmenistan, and Kazakhstan, is one of the world's hottest new investment zones, with estimates of

oil reserves ranging from 30 billion barrels to 200 billion barrels, according to Steve LeVine of the *New York Times*. Another area of increasing American investment is Southeast Asia, where U.S. exploration spending grew the most from the mid-1980s to the mid-1990s. The economies of Asian countries have become increasingly industrialized in recent years, and many governments in Asia, including China and Vietnam, have actively courted foreign investment and participation in local drilling by outside companies.

However, U.S. companies do not have a free rein to invest anywhere they choose. Politics trumps economics in petroleum-rich countries whose governments have offended the United States. Sanctions continue to Iran and Libya, putting U.S. companies at a disadvantage to their foreign competitors. U.S. companies must also adhere to relatively stringent environmental and labor codes compared to their competitors.

RESEARCH AND TECHNOLOGY

Fortune magazine reported on the dramatic strides in oil exploration technology. In 1965 drillers could only operate in water up to 300 feet deep. By the late 1990s, Chevron was leasing blocks of land in the Gulf of Mexico 9,000 feet underwater. Some experts said that drilling in 10,000 feet was imminent. Chevron and other companies were developing a technique called subsea mud-lift drilling, which enabled drillers to leave residue on the ocean floor instead of sucking it up through a pipe. This method could save drillers \$5 million to \$10 million per well.

New tools like three-dimensional seismic analysis allow oil companies to bounce sound waves off oil-bearing deposits and translate the patterns into 3-D models. Drilling rigs using the technique find productive wells more than 70 percent of the time, compared to a 40 percent success rate with conventional seismic analysis, according to *Fortune*. In addition, producers could extract more oil from existing wells. *Oil & Gas Journal* reported on a new fracturing technique that allowed gas drillers to stimulate existing wells rather than drilling new wells. Major U.S. producers could pump as much as 50 percent of the oil from a given pool, compared to a worldwide average of less than 35 percent.

As the large oil companies cut back on domestic exploration through the 1990s, it became even more important to make as certain as possible the profitability of those explorations that were undertaken. Technology for assessing the shape of underground earth formations, and oil and gas deposits was introduced as early as 1927 by Schlumberger Ltd., which maintained a hold on the industry through 1996, with nearly \$9 billion in annual revenues. Schlumberger's Maxis service, which assesses the characteristics of earth around a well, was introduced in the early 1990s. At a time when profits were flat and

downsizing common, Schlumberger doubled its jobs in 1992, testament to the industry's ever-increasing reliance on high technology.

But Maxis was only one of many high-technology innovations that reduced oil exploration costs and more than halved finding costs for natural gas in the late 1980s and early 1990s. Other innovations included horizontal drilling, three-dimensional (3-D) seismography, and improvements in drilling in light sands. The majority of innovation was in offshore drilling, which required much technological innovation in both the exploration and drilling stages. The Machar project in the North Sea used both advanced technology and an innovative system to tap a difficult oil well. Discovered in 1972 and estimated to hold 55 million barrels of recoverable oil, the reservoir was too complex to confidently evaluate with the technology of the day and considered too marginal economically. In 1994 British Petroleum enlisted what became the Turnkey Additional Production (TAP) alliance, which drew together contractors to supply the best possible solutions, one of them being Schlumberger Integrated Project Management (IPM), managing well engineering and well construction. All parties participated in risk and reward, so all focused on reducing risk, maximizing efficiency, and maximizing return. Decisions were made rapidly by those nearest the action, instead of relying on a chain of management. The results were quick and impressive; instead of the usual one to two years typical when using the conventional approach, appraisal oil flowed in just 19 weeks. At the end of the 25-month project, there had been no work loss due to accidents, no leaks or spills, and an overall efficiency 7 percent above plan.

Although invented in the 1960s, three-dimensional (3-D) seismography only became viable in the 1980s with advances in the computer and acoustical industries. Ships equipped with two cables each carrying two source arrays (or "seismic streamers") cruise areas of suspected undersea oil and gas deposits. The streamers give off electric or air detonations, whose waves are reflected off underwater rock formations below the level of the sea floor. Data is then processed onshore and the undersea floor mapped. Although ships covered much terrain, it could take as much as a year and a half to interpret the data gained from 100 square miles. Because of the presence of aboveground structures, 3-D seismography was impractical on land. Instead, trucks called "thumpers" sent sonic waves through the ground by hammering the earth at specific sites; the wave data was then collected and interpreted.

Data interpretation is highly technical and involved; it uses excessive amounts of computer storage space, plus specialized computer software that sorts and analyzes the streams of incoming data. However, advances in proprietary hardware and software were speeding up the process.

SIC 1389

OIL AND GAS FIELD SERVICES, NOT ELSEWHERE CLASSIFIED

This industry includes establishments primarily engaged in performing oil and gas field services, not elsewhere classified, for others on a contract or fee basis. Services included are excavating slush pits and cellars; grading and building of foundations at well locations; well surveying; running, cutting, and pulling casings, tubes, and rods; cementing wells; shooting wells, perfo-

rating well casings; chemically treating wells; and cleaning out, bailing and swabbing wells.

Establishments that have complete responsibility for operating oil and gas wells for others on a contract or fee basis are classified according to the product extracted rather than as oil and gas field services. Establishments primarily engaged in hauling oil and gas field supplies and equipment are classified in a range of Transportation and Public Utilities Standard Industrial Classifications. Establishments primarily engaged in oil and gas machine shop work are classified in **SIC 3599: Industrial and Commercial Machinery and Equipment, Not Elsewhere Classified**.

NAICS CODE(S)

213112 (Support Activities for Oil and Gas Field Exploration)

INDUSTRY SNAPSHOT

Companies categorized in this industry provide specialized services to assist in the excavation of oil and gas. These companies are used by drilling contractors to provide services in producing new wells and maintaining existing wells. The economic condition of oil field service companies is predicated on that of the oil and gas industry in general. Service-related work has been contingent on the number of rigs in operation, the price of oil and gas, and the demand for energy.

At the end of 2003, the number of rotary rigs drilling for oil and natural gas totaled 1,111, of which 109 were offshore and 1,002 were onshore. While this reflected an increase from the average annual active rig count of 830 in 2002, it remained below the 1,156 average active rig count in 2001.

Crude oil prices in 2002 averaged \$22.51 per barrel, an increase from \$21.84 in 2001. Natural gas prices declined between 2001 and 2002, falling from \$4.07 per thousand cubic feet to \$2.95 per thousand cubic feet.

Domestic demand for energy continued to grow in the early 2000s as the United States used 97.35 quadrillion Btu of energy, compared to 96.32 quadrillion Btu in 2001. Petroleum and natural gas accounted for 63 percent of U.S. consumption, with crude oil and natural gas liquids accounting for 39 percent and natural gas accounting for 24 percent. To meet demand, the United States relied on imports for 61 percent of its crude oil supply and 19 percent of its gas supply.

ORGANIZATION AND STRUCTURE

Companies classified in this industry provide services intended to increase or improve well production. Services are provided throughout the life of the well, including the initial drilling, the completion phase that

sets production, and the maintenance or stimulation of existing wells.

Casing and Cementing. Casing and cementing services are provided when the well is drilled. Casing is a large steel pipe, inserted into the wellhole and cemented into place. Oil well cementing is a mixture of water and cement that is pumped into the space between the casing and the wellbore, known as the annular space. The cement bonds the casing to the formation, providing structural support and directing fluid movement. Cementing also limits pipe corrosion, prevents natural gas blowouts, and aids in maximizing production circulation.

Testing Services. After the well has been drilled to its determined depth, evaluations are made to determine if the hole will produce a sufficient amount of oil and gas. Downhole formations can be analyzed by five different methods: well logging, drill stem testing, potential testing, bottomhole pressure testing, and productivity testing.

Completion Services. If it is determined that the well should be completed, the service company will lay production casing and complete the well, bringing the flow of liquid to the surface. Specific types of completion services depend upon the formation of the hole. The open-hole and liner methods are available, although the perforated casing technique has become the most commonly used completion method.

Using perforated casing, the casing wall is pierced to provide holes through which formation fluids may enter the wellbore. These holes are created either by bullet or jet perforating. Bullet perforators are lowered into the hole and fired electronically from the surface. However, jet perforating, using shape-charge explosives, has become more widely used because it produces maximum penetration, especially in hard rock.

Well Stimulation Services. Additional treatment to increase fluid flow rates may be needed to make existing and producing wells commercially viable. These treatments include hydraulic fracturing, acidizing the reservoir, and explosives. The rock type and the existing formation structure determine the selected approach.

Hydraulic fracturing is the use of specialized fracturing fluids blended with water to form a gel that is pumped downhole. This gel forces the petroleum reservoir to split open along the bedding surfaces and fracture zones extending beyond the wellbore. A greater reservoir drainage area is exposed to the wellbore, enhancing the flow of liquid. Reservoir rocks with poor permeability can be treated with acids in order to increase the wellbore's drainage area. Depending upon the structure of the reservoir, acidizing and hydraulic fracturing can be used together.

Originally used in the 1880s, explosives have reappeared as a modern well service method. Explosives are used with certain kinds of tight formations that do not respond to the other treatments. Explosive fracturing enlarges the wellbore by detonation either in the borehole or away from the wellbore.

Establishments engaged in this industry also often provide routine maintenance work on wells already in production. One of the most common well servicing operations is the artificial lift installation. When a well is first drilled, the fluid is expected to flow to the surface. In order to maintain maximum recovery from the well, however, most need some form of artificial lift to help raise the fluid to the surface. Types of artificial lifts include gas lifts, sucker rod pumps, hydraulic pumps, and submersible pumps. Maintenance service also includes replacing parts, repairing tubing leaks, working on malfunctioning downhole equipment, and providing well clean-out services.

BACKGROUND AND DEVELOPMENT

When the price of natural gas fell in the United States during the early 1990s, operators reduced most of their drilling plans, which adversely affected the oil field service companies already suffering due to the decline in the overall U.S. market. Many service companies began to diversify into other oil field services not directly related to production or well completion. Halliburton Company, a leader in the oil field services industry, purchased both 60 percent of Texas Instruments' Geophysical Services (GSI) and Geosource, another geophysical service company. The company also bought Gearhart Industries, a wireline service company, and merged it with Welex to form Halliburton Logging Services. In the second quarter of 1996, Halliburton announced plans to acquire Landmark Graphics Corporation, the leading supplier of integrated exploration and production information systems and professional consulting services for the petroleum industry. Schlumberger Ltd., another industry leader, had also been investing in artificial intelligence technology. The company bought GECO to provide marine seismic analysis and acquired Prakla Seismos for onshore seismic operations. Schlumberger also entered a joint venture in a smart card and pay phone plant in China. At the end of January 1997, barely two months after beginning production, its factory in Hunan shipped its one millionth smart card. Pay phone production also reached volume status with an output of 1,000 units per month. Schlumberger Electronic Transactions, a unit of Schlumberger Ltd., supplied cards, terminals, and management systems across the entire range of magnetic and chip card applications and was considered the industry's leading single source supplier.

With nearly all of the world's major energy fields already found, according to *The Value Line Investment*

Survey in 1993, the future of oil and gas excavation would be dependent on the search for smaller pools. This effort, in addition to the extension of production from existing wells, increased the demand for oil field service companies. Therefore, those companies providing high tech services, such as three-dimensional seismography, extensive data gathering methods, seismic exploration services, and enhanced oil recovery skills found a competitive but productive market in the 1990s.

CURRENT CONDITIONS

Rig Count. In the early 1980s, the number of operating rigs in the United States rose to more than 4,500. By 2001, this had decreased to 1,156, and the number fell further in 2002 to 830. While this number rebounded in 2003, it remained well below that of the early 1980s. In 2003, 15 percent of rigs were drilling oil, while 85 percent were drilling for gas. Per exploratory well, the average volume of oil discoveries in 2002 declined 47 percent, and the average volume of gas discoveries increased 16 percent. According to the Energy Information Administration, crude oil production in 2002 declined 2 percent to 1.87 billion barrels. This trend is expected to continue declining, as levels in the early 2000s were 12 percent lower than average levels in the 1990s. Although the natural gas industry had been growing in the late 1990s, by the early 2000s production began to decline. Dry natural gas production declined 2 percent between 2001 and 2002, while production of natural gas liquids declined 1 percent during that time period.

Price for Oil and Gas. Natural gas prices fell to \$2.95 per thousand cubic feet in 2002, compared to \$4.07 per thousand cubic feet in 2001. After starting at \$2.36 per thousand cubic feet in January of 2002, gas prices fluctuated for most of the year until October, when they began climbing consistently. By December of 2002, gas prices had reached \$3.81 per thousand cubic feet.

The well head price for crude oil has fluctuated dramatically in the early 2000s due to unstable economic and political conditions in both the United States and the Middle East. Compared to a high of \$23.02 in the fourth quarter of 1996, crude oil prices were down to \$15.54 per barrel in December of 2001. The average price per barrel of \$21.84 in 2001 rose slightly in 2002 to \$22.51. Gasoline prices, as well, continued to fluctuate in the 2000s.

Demand for Oil and Gas. Faster economic growth in the United States boosted the demand for energy, including oil and natural gas. Energy consumption in 2002 grew by 1.03 quadrillion Btu to 97.35 quadrillion Btu. The United States remains the leading consumer of energy in the world. Daily oil consumption reached 19.8 million

barrels, and daily dry gas consumption reached 62.7 billion cubic feet in the early 2000s.

Consumption of natural gas had increased throughout the 1990s, gaining 3.8 percent over 1992's rate to capture approximately 25 percent of the U.S. energy market in 1993. However, by 2002, natural gas accounted for only 24 percent of the U.S. energy market. Crude oil and natural gas liquids made up 39 percent of the market.

In addition to the domestic market, service companies based in the United States will likely encounter a variety of overseas market opportunities, particularly as the United States continues to rely heavily on energy imports. High-potential countries include those in the Commonwealth of Independent States (CIS) and the Asia-Pacific region.

INDUSTRY LEADERS

Halliburton Co. Dallas-based Halliburton Company provides oil field services, construction services, and insurance as an underwriter of property and casualty insurance. Its oil field service and products group provides start-to-finish service in the drilling and production of oil and gas wells. One of the many companies within this group is Halliburton Services, the world's largest supplier of cementing, stimulation, water and sand-control services and related downhole tools.

Erle Halliburton founded his company in 1919, then called the Better Method Oil Well Cementing Company. He provided a service using cement to hold a steel pipe in a well, which assisted in the drilling and production process. Although this technique was not initially accepted, it has become a common practice throughout the industry. In 1921 Erle Halliburton moved to Duncan, Oklahoma, and in 1924 he incorporated the company as Halliburton Oil Well Cementing Company.

With the purchase of other companies experienced in the oil and gas markets, Halliburton built up its oilfield service business from the 1950s to 1970s. Two particularly important acquisitions were the addition of Welex, a well-logging company, in 1957, and Brown & Root, experts in the construction of offshore and drilling platforms, in 1966.

Halliburton has operations in 100 countries providing construction, drilling, and well maintenance services. It reported 2003 sales of \$16.2 billion and 83,000 employees.

Schlumberger Ltd. New York-based Schlumberger Ltd. provides oilfield services, exploration services, well site and contract drilling, and computer-aided engineering services in more than 100 countries. In January 1993, Schlumberger purchased Dow Chemical's 50-percent interest in the Dowell Schlumberger group of companies.

This group provides various oil and gas field services and is divided into the following entities: coil tubing, drilling fluids services, cementing, design and evaluation, and industrial cleaning.

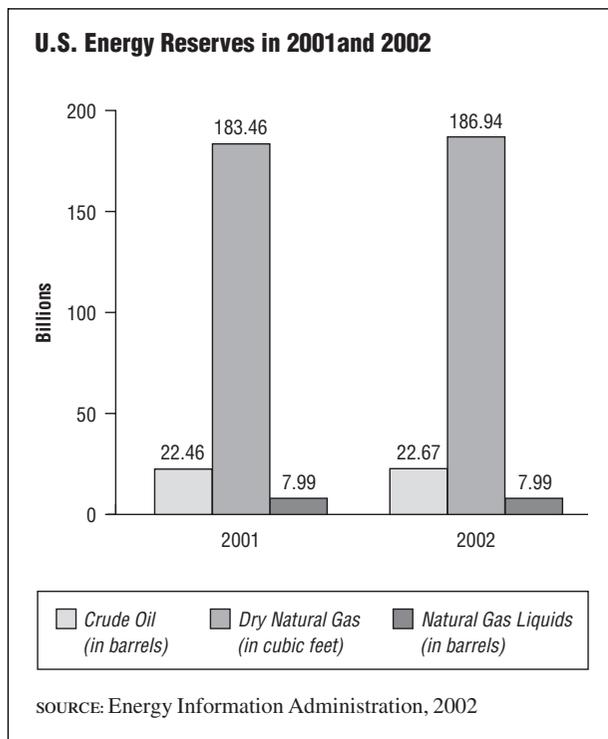

Schlumberger was created by two brothers, Conrad and Marcel Schlumberger, who believed that the earth's surface could be measured by electrical resistance. The company began in 1927, when the Schlumberger brothers lowered an instrument down a well to assess the surrounding rock formation.

The company's oilfield services unit provides 75 percent of total revenues. Schlumberger reported 2002 sales of \$13.4 billion and 78,500 employees.

AMERICA AND THE WORLD

Companies from the United States have played roles in the discovery and production of oil in major fields in Mexico, Venezuela, Saudi Arabia, Kuwait, and Libya. While exploration and oil drilling have decreased in the continental United States and Alaska, all of the major American oil companies have increased their presence overseas. The American oil and gas industry is inextricably linked to the world industry. Overseas operations have been particularly interested in service companies because of their ability to provide well workover and stimulation services to existing wells. Many countries have numerous wells in existence, but due to a lack of technology, have not been able to maximize production. The DOE has stated that the worldwide market for oil and gas exploration services was \$38.2 billion in 1990 and will grow to \$1.3 trillion per year to 2010. Moreover, the DOE has calculated that American vendors can capture \$995 billion, or 74 percent of that market. This will likely translate into substantial opportunities for companies providing support services to oil and gas exploration services.

The CIS holds an estimated 6 percent of the world's proven oil reserves and 37 percent of the natural gas reserves. According to *Oil & Gas Journal*, the older fields should offer tremendous opportunities for Western service firms to achieve considerable production improvements through the use of relatively straightforward procedures such as well workovers, equipment repairs, and regular preventive maintenance programs. Estimates of the number of wells in need of workover have been as high as 20,000. Area instability since the early 1990s has slowed progress somewhat, both in renovating old wells and in new drilling and pipelines. But it is predicted that the region will experience enormous growth in the long term, and that by 2010 the CIS will be the largest supplier of natural gas. The Yamal pipeline project, if successful, will run 4,000 km connecting Siberia with Western Europe. It's scheduled completion is 2010.

The Department of Energy (DOE) also regards China as an enormous growth market for oilfield service companies. Other areas of Asia show great potential as well for the service companies. Spending by American oil companies was highest in Southeast Asia during the 1990s, indicating a vested interest in the region. Vietnam and the Philippines also show great promise for oil exploration offshore, which in turn will be a profitable opportunity for service companies.

Latin America and Africa also are growing markets. The natural gas resources in South America are largely underdeveloped but the industry is expected to undergo increased development, incurring a need for skilled personnel to build and maintain rigs and pipelines. The oil wells of Columbia and Peru are expected to double their production by the end of the century. Several natural gas pipeline projects are also planned in South America, the two most ambitious being the Bolivia-Brazil pipeline and the Argentina-Chile pipeline. In the early 2000s, the African nations of Chad, the Ivory Coast, and Somalia, among others, were expected to join the market as oil producers.

SIC 1411

DIMENSION STONE

This category covers establishments primarily engaged in mining or quarrying dimension stone. Also included are establishments engaged in producing rough blocks and slabs. Establishments primarily engaged in mining dimension soapstone or in mining or quarrying and shaping grindstones, pulpstones, millstones, burrstones, and sharpening stones are classified in **SIC 1499: Miscellaneous Nonmetallic Minerals, Except Fuels**. Establishments primarily engaged in dressing (shaping, polishing, or otherwise finishing) blocks and slabs are classified in **SIC 3281: Cut Stone and Stone Products**. Nepheline syenite mining operations are classified in **SIC 1459: Clay, Ceramic, and Refractory Minerals, Not Elsewhere Classified**.

NAICS CODE(S)

212311 (Dimension Stone Mining and Quarry)

INDUSTRY SNAPSHOT

In 2003, 132 U.S. companies produced 1.35 million tons of dimension stone for use in building, monuments, and curbing with a total value of \$236 million. Roughly 176 quarries operated in 2003 in 34 states, with those in Indiana, Wisconsin, Georgia, Vermont, and Massachusetts accounting for 53 percent of the national output. Of the total industry tonnage, 34 percent was granite dimension stone, 28 percent limestone, 16 percent sandstone, 5 percent marble, 1 percent slate, and 16 percent other types of dimension stone.

The use of dimension stone in the high-end single-family housing sector was bolstered by an increase in residential construction in the early 2000s. Despite a weak U.S. economy, historically low interest rates fueled new housing starts. Increased use of granite and marble dimension stone in residential kitchens and bathrooms, limestone dimension stone in landscaping stone and ledges, and "worked" or hand-carved dimension stone and roofing slate in residential homes indicated that the residential segment would continue to be an expanding market for U.S. dimension stone producers.

ORGANIZATION AND STRUCTURE

The U.S. quarrying industry as a whole encompasses two major sectors: crushed stone and dimension stone. Within the dimension stone segment, companies mine, cut, and in some instances prepare stone blocks for such uses as building stone, monument stone, paving stone, and curbing. The dimension stone industry traditionally has accounted for only 0.5 to 1.0 percent of the 1 billion total tons of stone produced annually.

Dimension stone consists of both rough block and dressed stone. Rough stone accounted for 52 percent of all dimension stone produced by U.S. firms in 2003. Roughly 45 percent of rough block was used in building, and 23 percent was used in irregular shaped stone applications. The largest uses of dressed stone were flagging, curbing, and ashlar (a squared cut of stone used as facing material).

Among the many minerals mined for use as dimension stone by U.S. producers are basalt and diabase. Although these minerals, known collectively as trap rock or "trap," are primarily used in crushed stone, small amounts are quarried, cut, and polished as "black granite" for dimension stone. Because traprock dimension products are low-cost commodities in the stone market, they become less profitable as they are transported farther from mining locations. As a result, proximity to end-use markets or inexpensive modes of transportation are considered more important than their properties as minerals.

Another material commonly used as dimension stone is granite. The granite category includes "true" granite, granite gneiss, syenite and diorite, and some forms of granite-gabbro. Dimension granite is used in monuments and memorials; in heavy construction as large blocks; in residential and other buildings as foundation blocks, steps, and columns known as ashlar (when cut to regular shapes and sizes); and as paving stones and curbstones. Factors influencing the value of dimension granite deposits include color, uniformity of texture, and hardness. Besides final appearance, these factors also affect the cost of quarrying, cutting, and "dressing" or processing the rock.

The production of dimension granite historically has occurred in three regions: New England, the Southeast, and the midwestern states of Minnesota, Wisconsin, and South Dakota. Smaller amounts of dimension granite were produced in 14 other states.

Limestone is another material with numerous applications as dimension stone. Mines in Indiana traditionally have accounted for 60 percent of the dimension limestone produced in the United States. Dimension limestone is used nationally for the exteriors of commercial and institutional buildings as "Indiana" or "Bedford stone." Valuable properties of dimension limestone include uniformity of color and texture as well as the absence of elements such as stain-forming iron sulfide and quartz or chert, which impeded extraction of the stone.

Dolomite is a geologically recrystallized form of limestone used for dimension stone, and polished crystalline limestone is sold as "orthomarble." When first quarried, orthomarble is soft and easily worked and can be readily planed and carved into desired shapes. Orthomarble mines in eastern Tennessee produce a lime-

stone known as "Tennessee marble" that ranges in color from light gray to pink, red, and brown, and is used in interior floors, panels, wainscoting, windowsills, and to a lesser extent in exterior construction.

Another popular material used as dimension stone is marble. The term marble applies commercially to any stone, other than granite, that had an attractive appearance and takes a polish. Most rock marketed as marble is not true marble but metamorphic marble, crystallized limestone, cave onyx, travertine, or verde antique (or serpentine). The most common element in true marbles is calcite, although the highest grades of statuary stone are more than 99 percent calcium carbonate. Pure marble is white, but common color variations include light gray, green, red, cream, and black.

Major uses for cut and polished marble are as architectural and statuary stone. More than 50 percent of marble production is utilized in constructing building exteriors as well as interior floors, steps, sills, wainscoting, columns, and trim. Most of the remainder became memorial or statuary stone. Important properties affecting the value of dimension marble include color, texture, hardness, porosity, solubility, and strength. Marble can be worked profitably only on a large scale, and new quarries cannot be economically opened or old ones extended without positive indications that a large bed of stone is present.

The states of Vermont and Georgia produce the bulk of building and monument marble, but other producing states include Alabama, Colorado, Maryland, and North Carolina. Vermont marble quarries are often as deep as 400 feet, and single blocks of Vermont marble weighing as much as 65 tons are used for such purposes as fountain base stones. Georgia marble is used in buildings, monuments, and memorials. Well-known marble structures include the Buckingham Fountain in Chicago and the face of the New York Stock Exchange.

Sandstone provides another material appropriate for use as dimension stone. Dimension stone is used for exterior facing and trim on large buildings, for "ashlar" in residential construction, as flagstones and curbstones, and in retaining walls and bridge abutments. Dimension sandstone ranges in texture from very fine to coarse and in deposit depth from a few inches to 200 feet. Some of the most desired colors in sandstones include shades of gray and tan. Uniformity of color in dimension stone is typically favored, but some producers market dimension stones that oxidized during weathering to produce aesthetically appealing spotted and streaked patterns.

Dimension slate is widely used for roofing purposes because it is easily prepared and fixed, weatherproof and durable, and often cheaper than and superior to other roofing materials. An average roofing tile of the highest

grade of rock is only about five millimeters thick, which reduces strain on walls and roof supports. In addition to its use in roofing and flagstones, much dimension slate historically was produced as “mill stock” for switchboards and electrical panels, blackboards, mantels, baseboards, steps, sills, and grave vaults. Colored slate, which included red, purple, green, black, and gray, was favored for flagstone.

BACKGROUND AND DEVELOPMENT

Techniques for quarrying dimension stone varied according to the type of rock, the depth of the deposit, and the end-use of the mined stone. Unlike some other minerals, which were processed into their marketable form at processing plants and simply extracted from the ground in the most economical fashion possible, the specific end-use of a dimension stone product determined the procedure used to quarry it. Ideal end-products—large, solid, relatively flawless blocks of stone of attractive texture and color—were carefully cut from quarries one by one.

The exact type of quarry excavated by industry firms depended on the nature of the terrain in which the deposit was located. A deposit extending into a hill, for example, could be entered from the side by digging a “bench” quarry. Such quarries provided long, high faces from which the granite could be blasted, as well as direct approaches to the quarry for removal of the mined rock. When granite deposits were located under flat ground, a pit quarry had to be excavated—either wide and shallow quarries for deposits of uniform quality extending over large areas, or deep quarries extending from 20 to 300 feet for narrow deposits of great depth.

Most dimension stone was cut from the quarry face into large blocks, undercut at quarry “floor” level, and pried free by wedging. The stone was then cut into “mill blocks” of the desired size (typically from 10 to 60 feet long, 4 feet wide, and 4 to 12 feet thick) by drilling and wedging, and then hoisted from the quarry by derricks. Although light blasting was sometimes used to loosen deposits, explosives were usually avoided because they could damage the rock.

Granite and sandstone quarrying usually involved “broaching,” wire sawing, or jet piercing mining methods after the covering rock and silt were removed by scrapers or steam shovels. Broaching consisted of drilling a row of closely aligned holes in the rock face with tungsten carbide drill bits, then removing the blocks between the holes with broaching tools. Wire sawing involved the application of tensioned single- or triple-strand wire cables up to 16,000 feet long, which were drawn through pulleys. The cables formed a “saw” that was held against the rock and fed with a mixture of water and sand, cutting the stone by abrasion at a rate of about two inches per hour (in hard granite). When cutting was

completed, channels of about a quarter of an inch wide and 50 to 70 feet deep remained from which the mill blocks could be extracted.

In sandstone and granite deposits with inherent strains or internal pressure, the drilled holes sometimes closed around the drill bit, rendering it ineffective. In such cases, a jet-piercing drill—in which a combustible mixture of oxygen and fuel from the drill’s nozzle was used to blast the rock into fragments—could be employed to cut an eight-inch channel through the deposit face. Blocks could then be cut into the desired dimensions and lifted from the quarry by derricks into rail cars for transport to the dressing or preparation mill.

Another method traditionally used by dimension granite miners in shallow quarries involved drilling six- to eight-foot holes (depending on the desired size of the block) and placing small explosive charges into them to create a “parting” in the rock. Compressed air then was forced into pipes cemented in the holes, separating the desired sheet from the rock below. Using this method, granite miners could peel off segments of stone in desired sizes as they were needed.

In marble, limestone, and soft sandstone quarries, electrically powered channeling machines with steel chisels—which moved in a chopping motion back and forth on a track—could be used to cut through the stone. Such machines usually left channels about 2 inches wide, 10 to 12 feet deep, and 4 feet apart. After these initial cuts, drill holes were made into the rock and blocks were loosened from the quarry floor by wedges inserted in the holes. These loosened blocks could then be fashioned into smaller blocks using the “plug and feather” method. Feathers were elongated strips of iron, which were inserted in rows of drill holes. Plugs, or steel wedges, were driven between the “feathers” and alternately struck until a fracture appeared, forcing the feathers and loosening the stone.

Marble quarrying was typically affected by such factors as the “dip” or shape of the marble beds, the quality of the deposit, the expected price of the mined rock, the thickness of the overburden, and the uniformity of the marble. The chief goal of marble quarrying was to produce sound blocks of uniform quality, and quarrying procedures were tailored to each deposit. Marble beds of high value could be worked laterally or vertically through deep cuts made in the marble, while gently dipping layers of marble between solid walls of earth could be worked in deep open quarries.

In a typical marble mining operation, channel cuts were made six feet apart and eight feet deep across the quarry floor. The ends of the resulting strips were cut away from the walls, leaving blocks free to be drilled, wedged,

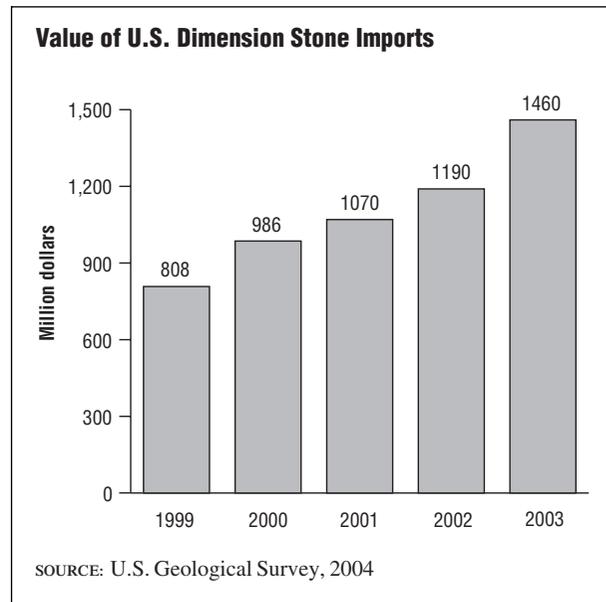

and lifted out. Using this technique, the quarry floor was gradually lowered by successive eight-foot “benches.”

Since most dimension stone was mined and dressed through contracts for specific jobs, preparation plants or mills operated by industry firms kept extensive drafting and pattern-making departments to anticipate required stone sizes. Drawings were prepared that detailed the exact dimensions of the requested stone, which were then referred to regularly during the stone finishing or dressing stage. Sawing, planing, rubbing, and polishing with stoneworking machines were among the processes employed in the finishing stage. Finished stones were then carefully marked and packed for shipment.

Between 1987 and 1992, employment in the U.S. dimension stone industry increased 8 percent to 1,400. Companies with five or fewer employees comprised more than one-third of the industry’s total shipments in dollar terms, and the number of industry establishments employing twenty or more employees fell from 13 percent in 1987 to only 10 percent in 1992. In 1992, nearly 79 percent of the industry’s work force was involved in production, development, and exploration activities at an average income of \$19,455. Nonproduction workers averaged annual wages of \$30,333.

Major dimension stone industry events in the mid-1990s included major new industry projects, expanding reliance on foreign sources, and new technologies. In 1995, after many delays, the Denver International Airport opened a massive construction project that featured 20,000 square feet of two-centimeter thick marble slabs from the Colorado quarry that had supplied marble for the Lincoln Memorial and the Tomb of the Unknown Soldier. In July 1995, the Korean War Veterans Memorial was also unveiled, in which 41 panels of granite formed a 164-foot-long reflective wall on which were etched photographic images of the conflict. Although exports of U.S. dimension stone (primarily to Italy) decreased slightly in 1995, imports (mostly of dimension granite) rose to \$476 million, primarily from Italy, Spain, India, and Canada. Indian green marble found growing use for kitchen countertops, and low-priced Chinese marble emerged as a new product in the U.S. market.

Also in 1995, the National Mining Association (NMA) was formed from the union of the National Coal Association and the American Mining Congress. The group, which represented the entire mining industry, said its initiatives would include advocating for policy and legislation that will promote the health of the industry. Specifically, the group was concerned with, in the words of 1995 association president Richard Lawson, the perception of the “environmental lobby [that] argues that ‘public’ land must be forever held virtually as wilderness in the public interest.” The NMA expressed concern that such environmental initiatives could make resources, in-

cluding lands which were home to mineral resources, available only to select “special interests.”

New technologies in the late 1990s included “thermally stable” waterjet stone-cutting drill bits for increased penetration rates and extended bit life and computerized wire saws that could cut complex images on monument faces. The images etched on the surface of the Korean War Veterans Memorial, for example, were made by high-precision etching and contour-cutting laser technology made possible by advances in computerized design. A 1997 industry periodical described a new extraction method that used diamond wire sawing machinery (as opposed to traditional hydraulic and mechanized drilling, smooth blasting, and wheel loading). The new technique, manufactured by Blue Pearl, reportedly resulted in smoother surfaces and reduced waste. Such new ways of extracting granite were tested in the United States, as well as Japan, Finland, Italy, and South Africa.

Fueled by the growing demand for “natural stone” finishes, new quarry and processing technologies emerged that permitted the fabrication of very thin stone products. Computers also aided the marketing efforts of industry firms. The explosion of the World Wide Web as a marketing tool in the mid-1990s enabled some dimension stone producers to display their wares through digitized images of their stone products on their own Web pages.

CURRENT CONDITIONS

As consumption of dimension stone increased in the United States, so did reliance on imports. By 2003, imports accounted for roughly 86 percent of dimension stone used in the United States. This figure had grown steadily since 1999, when imports accounted for 75 percent of domestic consumption. The value of dimension

stone imports grew 23 percent in 2003, from \$1.19 billion to \$1.46 billion, while the value of exports declined by 6 percent, from \$64 million to \$60 million.

Consumption of U.S. dimension stone has grown steadily since 1999, when it was valued at \$1.01 billion. By 2003, consumption was valued at \$1.63 billion. To offset competition from substitute materials such as steel, aluminum, reinforced concrete, lightweight and low-cost facing materials, plastics, glass, aluminum, and porcelain-enameled steel, industry firms had looked to the development of niche markets in granite and marble dimension stone for kitchens and bathrooms; limestone for landscaping, ledges, and tiles; and worked or hand-carved stone for custom-built houses. According to 2004 estimates by the U.S. Geological Survey, demand for dimension stone is expected to grow through 2014 due to the rising prices of substitute materials, as well as expanded varieties of stone and advances in dimension stone processing technology.

INDUSTRY LEADERS

Cold Spring Granite Company, Rock of Ages Corporation, Fletcher Granite, Indiana Limestone, Georgia Marble, and Halquist Stone were among the industry's leading companies in the early 2000s. In 2003, Rock of Ages, which maintained nearly 40 granite quarries, billed itself as the "world's leading supplier of granite products" for memorials, mausoleums, and estate pieces. Primarily a supplier of granite blocks to other manufacturers, Rock of Ages was capable of producing 63,000 cubic meters of granite every year from its quarries. By the end of 2003, Rock of Ages had 100 retail outlets in 14 states and sold wholesale products through 160 independent retailers in the United States and Canada. Company sales during 2002 were \$92.5 million, falling roughly 2 percent from the previous year, and employees totaled 860.

Georgia Marble was founded in 1835 by an Irish immigrant stone cutter. By 1997, the company was a subsidiary of IMETAL and the largest producer of marble products in the world, with more than 300 marble products produced by its industrial, consumer, and dimension stone divisions. Its dimension stone operations produced structural (panels, columns, and floor tiles) and memorial dimension stone, and its marble stones have been used in the memorials of such prominent Americans as Warren Harding, Thomas Jefferson, and Martin Luther King Jr. In the late 1990s the company had a sales range of \$50 to \$100 million. In 2003, Georgia Marble continued to operate as a subsidiary of IMERYS, the result of a merger between IMETAL and English China Clays.

SIC 1422

CRUSHED AND BROKEN LIMESTONE

This industry consists of establishments primarily engaged in mining or quarrying crushed and broken limestone, including related rocks, such as dolomite, cement rock, marl, travertine and calcareous tufa. Also included are establishments primarily engaged in the grinding or pulverizing of limestone, but establishments primarily engaged in producing lime are classified in **SIC 3274: Lime**.

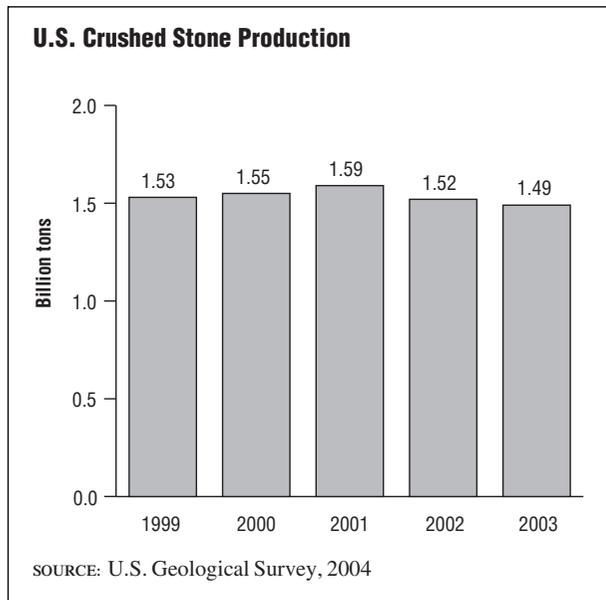

NAICS CODE(S)

212312 (Crushed and Broken Limestone Mining and Quarrying)

Crushed limestone production is the largest of three related industries that extract and process nonfuel, non-metallic minerals. Primarily employed as aggregate, which refers to a wide number of sand, gravel, and stone mixtures, crushed stone is an essential component of the U.S. infrastructure because of its use in the construction of highways, airports, river locks and dams, railroad ballast, and breakwaters. It is, however, considered a "high-volume, low-value commodity" with relatively stable prices since the 1970s, according to the U.S. Geological Survey.

The crushed stone industry is the largest nonfuel mining industry in the United States, with 3,300 quarries in 49 states as of 2003. Limestone and related rocks account for the vast majority—71 percent in 2003—of crushed stone production and sales in the United States. The essential make-up of limestone is calcium carbonate (CaCO₃). If 10 percent or more of magnesium carbonate is present it is called "magnesian" or "dolomitic" limestone. Usually the term "limestone" acknowledges the presence of dolomite.

After growing by an average of 3 percent in the late 1990s, crushed stone production began to decline in the early 2000s, falling by 2 percent to 1.49 billion tons in 2003. However, a 3.2 percent increase in production was

expected for 2004. Total crushed stone output in 2003 was valued at \$8.6 billion.

In the past most crushed and broken stone has been mined from open quarries. Today, the trend has been more toward underground mining. Underground room-and-pillar mines are operated on a year round basis and do not require as much material removal. Additionally, underground mining requires less surface space and consequently avoids the ever-increasing cost of land. Another benefit for the underground mine operator is the availability of valuable storage space.

The high cost of transporting crushed stone has dictated that stone be mined and quarried as near as possible to the market centers or manufacturing plants that use it. However, increasing land values and environmental concerns have made it necessary to move crushed stone quarries further away from customers and have driven up the cost of the delivered material for some producers. Overall, however, prices have remained stable since the 1970s, growing just over the rate of inflation due in part to productivity gains and competition.

The average unit value of crushed stone is also expected to increase as a result of rising costs of labor, energy, and the rising costs of processing equipment. In the area of environmental concern, most states are now requiring crushed stone operations to submit environmental impact reports, and soon a reclamation plan and a use permit application will be required.

In the early 2000s, ten states accounted for more than half of the total U.S. output of crushed limestone and dolomite: Texas, Florida, Pennsylvania, Missouri, Illinois, Georgia, Ohio, North Carolina, Virginia, and California. The central and eastern regions of the United

States contain its largest reserves of limestone. Two of the leading U.S. producers in 2003 were Martin Marietta Materials Inc., which had strengthened its limestone operations by purchasing Redland Stone Products Company in 1999 and the limestone assets of Brauntex Materials Inc. in 2001 and Florida Crushed Stone Company, which was acquired by CSR America in 2000 and later sold to Pinker Materials Corp.

Among market economy countries, the United States is far and away the largest producer of crushed and broken stone. Major international producers include Australia, Canada, Germany, France, Japan, and the United Kingdom. Because of high transportation costs, the international crushed stone trade remains quite minor. Nearly 86 percent of the tiny U.S. crushed stone import market is held by Canada and Mexico.

The outlook for limestone, and crushed stone in general, was generally favorable in the early 2000s. The U.S. Geological Survey predicted in 2004 that increased spending on infrastructure, largely the result of a recovering U.S. economy and legislation such as the Safe, Accountable, Flexible, and Efficient Transportation Equity Act of 2003, would boost demand for crushed stone and other construction aggregates.

SIC 1423

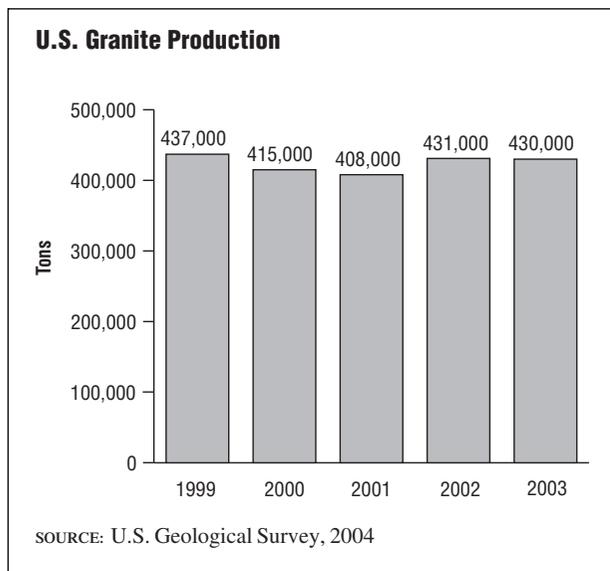

CRUSHED AND BROKEN GRANITE

This classification covers establishments primarily engaged in mining or quarrying crushed and broken granite, including related rocks, such as gneiss, syenite, and diorite.

NAICS CODE(S)

212313 (Crushed and Broken Limestone Mining and Quarrying)

The top crushed and broken granite producer in the early 2000s was the family-owned Luck Stone Corp. of Richmond, Virginia, with more than 900 employees in 2004. The company, founded in 1923 and now run by the third generation of the Luck family, was the twelfth

largest producer of crushed stone in the United States, operating nearly 20 crushed stone and sand-and-gravel plants, and eight retail stores in Virginia and North Carolina. Its automated, noise-controlled crushers had the capacity to produce and ship over 600,000 tons of stone daily, as compared to its 1923 capacity of 100 tons produced manually by men with sledgehammers, loading mule-drawn carts by hand. Retail stores, part of the Architectural Stone division, offered crushed stone to construction professionals as well as the general public for diverse uses such as in fireplaces and garden pathways.

The industry is composed primarily of small independent operators, with a few large companies producing a significant percent of total granite output. Approximately 150 companies operate 365 granite quarries in 34 states. Leading states include Georgia, North Carolina, Virginia, South Carolina, and Arkansas. Together, these five states make up nearly three-fourths of total production.

A small but healthy segment of the U.S. crushed stone industry, crushed granite accounted for approximately 15 percent of U.S. production as of 2003. That year, the United States produced nearly 430,000 tons, down from 437,000 tons in 1999. In general, granite production growth and prices have exceeded the average for crushed stone in the early 2000s. As with most types of crushed stone, the majority of crushed granite—roughly 56 percent—is used as construction aggregate. Leading importers of granite include Italy, which accounts for 41 percent of granite imports; Brazil, which accounts for 17 percent; India, which accounts for 13 percent, and Canada, which accounts for 11 percent. Exports of granite declined from 166,000 tons in 1999 to 140,000 tons in 2003.

Civil engineers found granite as early as 1871 along the main coastal line of the Southern Pacific railroad. As track was laid throughout California, engineers discovered that granite was the perfect ballast material for railroad beds. With the inception of automated, steam-powered crushers, the mining and production of granite improved significantly.

When crushed to powder, tiny fragments of separate substances can be picked out of granite. These secondary or compositional particles include quartz, feldspar, and mica. As the most common igneous rock in the earth's crust, granite has been mined voluminously for decades.

The introduction of giant, mobile primary crushers in mining operations at granite quarries unleashed enormous production and profit potential. Other recent technological innovations used in granite mining include conveyors that move rock from the primary crusher to wash plants and secondary crushers; state-of-the-art, computer-controlled automated trucks and rail car loading systems; and the complete control and monitoring of all quarry operations by large computer systems.

SIC 1429

CRUSHED AND BROKEN STONE, NOT ELSEWHERE CLASSIFIED

This classification covers establishments primarily engaged in mining or quarrying crushed and broken stone, not elsewhere classified. Types of stone processed by this industry include basalt, diabase, dolomitic marble, gabbro, marble, mica schist, onyx marble, quartzite, sandstone, and volcanic rock.

NAICS CODE(S)

212319 (Other Crushed and Broken Stone Mining and Quarrying)

In 2003, about 71 percent of the crushed stone produced in the United States was limestone and dolomite (see **SIC 1422: Crushed and Broken Limestone**), followed by granite at 15 percent (see **SIC 1423: Crushed and Broken Granite**), traprock at 7 percent, as well as

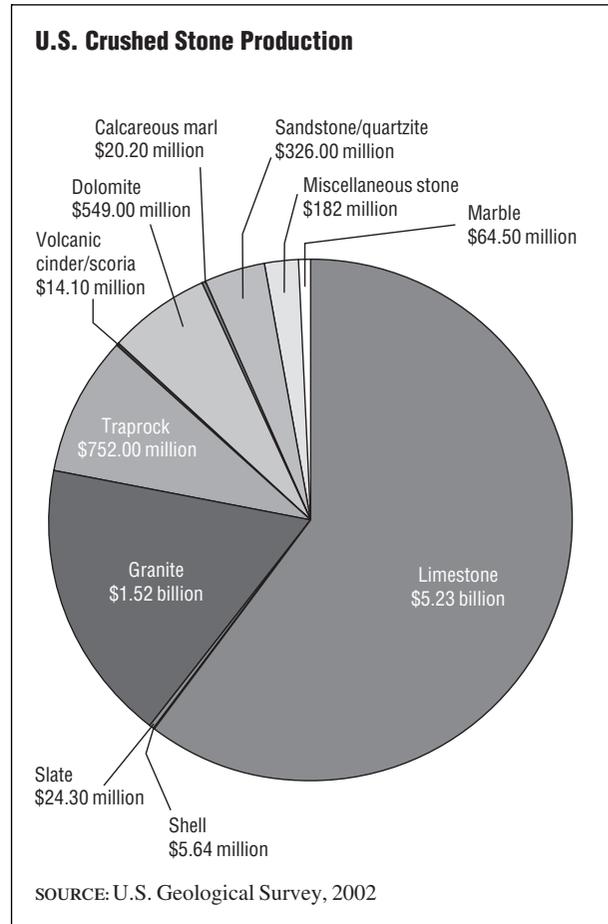

sandstone, quartzite, shell, marble, calcareous marl, volcanic cinder and scoria, and slate, which combined to account for the remaining 7 percent of stone production. Only the latter 14 percent of crushed stone production is included in this industry.

After output declined in both 2002 and 2003, the crushed stone industry was expected to enjoy modest growth in 2004, fueled in part by increased federal spending on highway construction and maintenance. For example, the Safe, Accountable, Flexible, and Efficient Transportation Equity Act of 2003 is expected to boost demand for crushed stone.

The mining of aggregate was relatively unorganized and undocumented in the nineteenth century. It was not until 1882, when the U.S. Geological Survey began compiling an annual *Mineral Resources of the United States* publication, that the classification, method, and organization of the aggregate industry began to take shape. The *Mineral Resources of the United States* added its first chapter on stone in 1889. Aggregate production was originally reported in dollar amounts of product sold but has since been assessed in terms of both tons and dollar value of product sold or used. Production volume of crushed stone has escalated dramatically throughout the twentieth century. The dollar value of crushed stone in 1900 was \$24 million. In 1950, this increased to \$422 million, representing 325 million tons of crushed stone. The crushed stone industry in 2003 was valued at more than \$8 billion, representing nearly 1.5 billion metric tons produced.

The crushed stone industry has been labor intensive since its inception in the late 1800s. Early production advancements came in the first decade of the twentieth century when company-owned steam locomotives and quarry cars replaced steam tractors and mule-powered carts in quarry operations. Characterized by innovation and inventiveness, the stone crushing industry also improved the quantity and quality of production when it began incorporating sophisticated processing equipment and quarry machines in the 1940s. Product quality and quality control have increased steadily throughout the twentieth century as technology has continued to keep pace with the production demands of the stone crushing industry. The largest association concerned with the health of this and other nonmetallic mineral mining and quarrying industries is the National Stone Association, which was founded in Columbus, Ohio in 1918 by a group of concerned quarry operators.

Valued at \$752 million, production of traprock totaled 112 million metric tons in 2002, reflecting a 9.2 decline from 2001. A total of 222 businesses produced traprock in 2002, and the majority of them were located in Oregon, Virginia, Washington, New Jersey, and Cali-

fornia. In fact, these five states accounted for roughly 55 percent of U.S. traprock production.

Sandstone and quartzite operations are centered in Pennsylvania, Arkansas, California, South Dakota, and Oklahoma. In 2002 sandstone production grew 2.6 percent to 39.7 million metric tons, valued at \$249.7 million, while quartzite production declined 7 percent to 13.2 million metric tons, valued at \$76.8 million. Crushed quartzite and sandstone companies numbered 35 and 110, respectively.

The industry is comprised of many small companies and a few large corporations. In 2002, a total of 405 trap rock quarries operated in the United States, as did 185 sandstone and quartzite quarries, 13 slate quarries, and 41 volcanic cinder and scoria quarries. Vulcan Materials Co. of Birmingham, Alabama was the leading crushed stone producer by output in 2003, with 220 active crushed stone operations and \$2.6 billion in total sales (including nonstone sales). Other leaders included Martin Marietta Materials Inc., and Trap Rock Industries Inc.

SIC 1442

CONSTRUCTION SAND AND GRAVEL

This category covers establishments primarily engaged in operating sand and gravel pits and dredges and in washing, screening, or otherwise preparing sand and gravel for construction uses.

NAICS CODE(S)

212321 (Construction Sand and Gravel Mining)

INDUSTRY SNAPSHOT

Construction sand and gravel is a fundamental raw material used primarily by the construction industry. It is among the most accessible of natural resources. Sand and gravel production benefited from growth in the construction industry in the 1990s, but growth diminished into the 2000s as the economy slowed. As a result, construction sand and gravel production in 2002 was approximately 1.13 billion tons, roughly the same as 2001 production. It is estimated that 2003 output will be approximately 1.2 billion tons, up slightly from the previous year. In 2002, about 4,000 companies in 50 states produced 1.3 billion metric tons of construction sand and gravel worth an estimated \$5.8 billion. Nine states accounted for about 51 percent of U.S. output of construction sand and gravel. In order of volume, the leading states were California, Texas, Michigan, Arizona, Ohio, Minnesota, Washington, Colorado, and Wisconsin. About 51 percent of the total output was used for unspecified purposes. Of the remainder, 45 percent was used as aggregate in concrete; 22 percent for road stabilization and road base and coverings; 13 percent as aggregate in asphaltic and other bituminous mixtures; 13 percent as construction fill; 2 percent for concrete products, including bricks, blocks, and pipes; 1 percent for plaster and gunite sands; and 4 percent for roofing granules, snow and ice control, railroad ballast, filtration, and related uses.

ORGANIZATION AND STRUCTURE

Sand is composed of particles of feldspar, limestone, slag, gypsum, coral, or quartz formed by such natural processes as erosion and weathering. Gravel consists of pebbles, stones, and rock fragments broken from larger deposits of such minerals as shale, quartz, granite, or sandstone by water or ice erosion. Gravel occurs geologi-

cally in riverbeds and seas but is more commonly found in dried-up streambeds formed by glaciers during the Ice Age. Sand is graded for commercial use by passing the grains through standardized sieves, which yield such classifications as very fine, fine, medium, coarse, and very coarse. The five standard gravel sizes are also classified according to the sieves through which they pass. Acceptable sizes for commercial sand and gravel vary with the engineering organization, highway department, or government agency setting the standard and are occasionally revised.

Sand and gravel are primarily used by private construction firms and government agencies in the construction and paving industries. Combined, they take the form of "aggregate" in concrete, portland cement, asphalt, mortar, and plaster, or can be used alone as "fill" in the construction of building foundations, runways, highways, dams, and a wide range of other applications. The commercial use of sand and gravel is so extensive that the growth or decline of production by industry firms is considered a reliable indicator of the country's economic activity.

Roughly 80 to 85 percent of the weight of concrete is typically contained in its sand and gravel aggregate content. In other words, one ton of concrete usually contains about 1,700 pounds of sand and gravel. An estimated 54,000 pounds of sand and gravel are used in the construction of a typical new American home. Traditionally, roughly twice as much gravel is used as sand in the United States. The term *fine aggregate* is often used to describe commercial sand and *coarse aggregate* to describe gravel. (In addition to sand and gravel, aggregate might also contain crushed stone.)

In the 1990s firms in the sand and gravel mining industry shared a number of characteristics with other U.S. mining industries, including equivalent production methods for blasting, drilling, loading, transporting, crushing, screening, and "beneficiation" (removal of impurities) of the mineral. Firms in sand and gravel and other mining industries also placed great emphasis on geological, management, and fundamental technical expertise and shared the same environmental, safety, and land rehabilitation concerns.

The sand and gravel mining industry is distinguished from other mining industries, however, by the number and size of its mining operations. Mining firms outside the industry generally operate fewer mines, which are on average much larger than sand and gravel operations. Whereas the market for sand and gravel and other aggregates is highly localized (generally within 40 miles of the quarry), the market for metals and their derivative minerals is much wider (approximately 300 miles for some industrial minerals) and in many cases international in scope. Finally, the amount of capital investment, time,

and financial risk required to develop a metal mine is substantially larger than is common in the sand and gravel industry.

In the 1990s the aggregates industry as a whole was a mature industry tied closely to general economic cycles. The range of firms in the sand and gravel industry extended from small, temporary roadside pits working deposits of 20,000 cubic yards with portable equipment to major facilities extracting thousands of tons per day and maintaining stockpiles of processed sand and gravel in excess of 100,000 cubic yards. In the late 1990s the trend in the industry was a continued shift from the small, "family-run" mining operations toward consolidation of industry activities among a few large companies. One factor fueling this trend was the requirement by government environmental agencies that firms entering the industry file environmental impact statements beforehand, which eliminated many prospective small firms with limited start-up capital. Although the majority of industry firms were private establishments, by the mid-1990s more than 50 percent of aggregates consumed went to public construction projects.

BACKGROUND AND DEVELOPMENT

Before sand and gravel deposits can be mined, they first have to be located, thoroughly analyzed, and mapped. Geologists, engineers, or other exploratory personnel first consult geologic maps and reports on topography, hydrology, and geology for the potential site, then visually inspect places where the deposits protrude to the surface or are exposed in streambeds and highway "cuts." Samples of the subsurface deposit can be extracted using soil augurs or test borings; electrical resistivity tests or other geophysical tests might also be conducted from the surface to analyze the deposits.

"Petrographic" analyses of deposits supply information about the average shape, hardness, and size of the sand and gravel particles; the amount of sand relative to the amount of gravel; the presence of "coatings" on the rock particles; and the existence of any chemically reactive properties or impurities in the particles. After these analyses are completed, a thorough three-dimensional map of the deposit is prepared indicating the extent, depth, and variation of the deposit.

The optimal sand and gravel deposit contains a wide range of particle sizes, from fine to coarse. It consists of particles that are round, hard, solid, resistant to temperature and moisture changes, chemically inert, and "clean" (free of organic matter, mica, and soil), in sufficient quantities to justify extraction. The ideal deposit is also located near transportation routes to a permanent source of demand for the processed product. Factors such as compressibility, elasticity, thermal conductivity, chemical alkali reactivity, or specific gravity also might be

important for sand and gravel intended for special-purpose concretes. In large or laterally extensive deposits, "exploration" by geologists or engineers often continues after mining of the deposit begins. These experts constantly update the levels of overburden (overlying soil) and grades and supplies of remaining sand and gravel as the deposit is worked.

Because sand and gravel is a readily available commodity of low unit value, the economic viability and final market price of a deposit is determined by such factors as the costs of labor, extraction, and shipment to end-use markets. Transportation costs in the aggregates industry as a whole traditionally average about 50 percent of the price paid by customers, so a deposit located far from transportation or sizable markets might be economically worthless regardless of its extent and quality.

Transportation of the mined sand and gravel to the processing or preparation plant is usually accomplished by conveyor belt, truck, or railcar. The processes employed at the preparation plant to ready the sand and gravel for shipment depend on the nature of the specific deposit and the intended end use. In general, it is washed to remove soil and other impurities, screened or otherwise "classified" to divide it into its various grades, crushed to remove oversized particles, and subjected to various separation techniques to remove remaining impurities and undesirable minerals.

If the sand and gravel mined from a deposit are not of a grade adequate for a market's needs, they can be upgraded artificially at the processing plant by washing, screening, and combining particles until they become the required size. Separation techniques include "sink-float" solutions, in which unwanted impurities sink to the bottom of a receptacle or settling pond while the sand and gravel float, or "heavy-heavy-media" methods, in which gravitational or other forces are used to differentiate the sand and gravel from the impurities. In other methods, separation of sand and gravel from impurities is accomplished using inertial, aerodynamic, or centrifugal principles.

History. Between 1945 and 1966 the sand and gravel industry experienced uninterrupted growth, with combined tonnage of aggregates increasing from 266,000 tons to 1.5 billion tons. Following the completion of the federal government's massive highway construction project begun in the 1950s, industry growth leveled off at roughly 7 percent annually between 1973 and 1988. By 1990, however, the industry was growing by only about 2.5 to 4 percent annually, and it fell off even further during the recessionary years of the early 1990s.

In the mid-1990s the sand and gravel mining industry continued to be affected by fluctuations in demand by the home-building industry, federal construction-oriented

legislation such as the Intermodal Surface Transportation and Infrastructure Act, continuing expenses for compliance with environmental regulations (such as the Clean Water Act and Federal Water Pollution Control Act), and cost increases stemming from the longer distances industry firms were forced to cover to bring sand and gravel from their quarries to the end market.

In 1993, however, the sand and gravel industry began to show signs of a recovery from the recession of the early 1990s, its worst period since the Great Depression. Although construction of apartments and office buildings, which traditionally required much larger amounts of sand and gravel than single-family homes, had been stagnant in the early 1990s, construction of highways, power plants, and electrical utility structures rose markedly in 1993. Together with the rise in residential housing starts, this construction spurt contributed to a boom period for the industry that continued through the late 1990s.

In the 1990s trends in the U.S. construction sand and gravel industry centered on three basic factors: consolidation, transportation, and automation and new operating methods. The wave of consolidation that struck the industry in the 1980s continued into the late 1990s as the larger producers gobbled up smaller operations at the rate of about 130 acquisitions a year. As the number of unexhausted quarries near major markets continued to decline, industry firms were also faced with higher costs of hauling their products from increasingly remote quarries. Rail transportation, which had traditionally been reserved for hauls of 300 miles or more, began to edge into the trucking industry's historical hold over the aggregates transport business, and experts predicted that by the year 2046 most sand and gravel would be shipped by railcars.

The industry also began to rely increasingly on automation and innovative methods to streamline the rock extraction and preparation process and cut costs. Underground mining, for example, enabled some industry firms to sidestep the controversial issue of the environmental impact of surface strip mining on unspoiled land. More fuel-efficient equipment, electric rather than gas-powered machinery, and the operation of sand and gravel mines at night promised to reduce the industry's energy costs. Enhanced rock-blasting technology offered improved efficiency and better rock fragmentation, and driverless rock-hauling trucks guided remotely by global positioning satellites promised to reduce employee accidents and personnel costs. Industry leaders increasingly envisioned a future in which highly automated sand and gravel "industrial centers" would incorporate asphalt, ready mix, and pipe production facilities within the traditional quarry. A new emphasis on quality management techniques, customer-driven "value-added" business approaches, and the introduction of new, specifically sized

and hybrid aggregate products also hinted at the future shape of the industry.

The passage of the Transportation Equity Act for the 21st Century in 1998 led to an increase in funding for highway construction and maintenance, which in turn assured continued demand for aggregates. In addition, the Balanced Budget Act of 1997 included a provision to increase appropriations to the Highway Trust Fund. This additional yearly amount of \$6 to \$7 billion was expected to fuel road construction and thereby provide steady demand for construction sand and gravel.

Construction sand and gravel production continued to increase in 1999, and the total outlay for the first nine months of 1999 reached 816 million metric tons, a 2.8 percent increase over the comparable period in 1998. The top five producing states in the third quarter of 1999 were California, Michigan, Ohio, Texas, and Minnesota. Together, the states produced 36.4 percent of the total U.S. output of construction sand and gravel. Among geographic regions, the leading area was East North Central, producing 21.7 percent of the U.S. total. Ranking second among sand and gravel producing regions was the Pacific, which contributed 18.8 percent, followed by the Mountain area, which produced 17.2 percent.

Though the late 1990s were a positive period for the construction sand and gravel segment, construction spending was expected to decline in the early part of the twenty-first century, resulting in lower demand for aggregates, according to the CIT Group, Inc. Public works projects such as road and highway construction were expected to remain steady, whereas residential and non-residential construction were expected to decrease somewhat in 2000. The CIT Group expected that production of sand and gravel would reach record levels in 1999 but fall by 5 million short tons in 2000. Actual output of sand and gravel in 2000 was about 1.12 billion tons worth approximately \$5.4 billion.

CURRENT CONDITIONS

Construction sand and gravel was a \$5.8 billion industry during 2002 with an output of roughly 1.13 billion tons, a total virtually unchanged from 2001. Estimates for 2003 construction sand and gravel production and U.S. consumption were 1.2 billion tons, up only slightly from the previous year. Average unit prices rose about 4.4 percent in 2001 to \$5.02 per metric tons over the previous year. Unit prices by usage ranged from a high of \$8.86 per ton for roofing granules to a low of \$3.30 per ton for fill. The largest increases recorded was for road stabilization, up 33 percent, while the only sector to decline was roofing granules, by 28.3 percent over the previous year. In 2001, some 6,280 construction sand and gravel operations were active in the United States.

Expectations for growth in the industry were meager, due to a sluggish economy and a decrease in spending in road and other construction. The health of construction and related industries are generally indicators of the economy as a whole, and when the economy suffers, so do these areas of commerce. Construction sand and gravel prices were likely to experience a similar trend, estimated to be up only slightly in 2002. With sand and gravel being transported great distances due to local zoning laws, however, delivered prices were expected to rise.

Although mergers, once rampant in the late 1990s, had slowed considerably in 2001, the industry was expected to continue its consolidation in 2002 and beyond. Increasing local resistance to mining—pushing production to rural areas—caused a rise in transportation and other costs. The difficulty for new companies to acquire zoning and permit approvals and install equipment also made acquiring existing, active companies much more desirable. The cost to acquire such companies would likely rise due to these factors.

Recycling had been a trend in the aggregates industry for many years, with a continuously growing number added to the total each year. This type of recycling involved crushing, screening, and reusing cement and asphalt concretes. Aggregates companies were frequently collecting and reusing the materials on construction projects in which they were involved. Some 5.46 million tons of asphalt concrete was recycled in 2001 valued at \$25.5 million, a 15 percent increase from the previous year. States leading these recycling efforts, in descending order of tonnage recycled, were Minnesota, California, and Michigan. Company leaders in recycling in order of tonnage produced were Martin Marietta Aggregates, Weber Sand and Gravel, Inc., J.A. Jones, Inc., Midwest Asphalt Corp., and Red Flint Group, LLC.

Safety, health, and environmental restrictions also topped the list of concerns for the construction sand and gravel industry in the early 2000s. The trend toward local zoning and land development regulations discouraging sand and gravel operations was expected to continue to facilitate the movement of sand and gravel operation away from urban and industrialized areas. Thus, shortages were expected to increase in these areas. Environmental issues continued in 2001, as the state Department of Ecology's November rules issued for shoreline protection to prevent further erosion in the state of Washington sparked debate from the industry that argued such laws could completely obliterate the state's sand and gravel industry. The opposition argued that such rules would not ban mining. Other environmental issues in 2002 included whether to renew permits to allow commercial dredging in the Allegheny and Ohio Rivers. Opponents to dredging argued that it affected water supply, caused erosion, and

damaged mussel beds, among other things. The majority, however, favored continued dredging, which had been done for a century.

INDUSTRY LEADERS

The leading U.S. aggregate-producing firms (including crushed stone) in 2001 were Vulcan Materials Company, with 291 active operations; Martin Marietta Aggregates, with 384 operations; Hanson Building Materials America/Hanson Aggregates, with 181 operations; Oldcastle, Inc./Materials Group, with 173 operations; Lafarge North America, Inc., with 95 operations; and Rinker Materials Corp., with 37 operations. Among construction sand and gravel producers, the leading companies in order of output in 2001 were Hanson Building Materials America/Hanson Aggregates; Oldcastle, Inc./Materials Group; Vulcan Materials Co.; Martin Marietta Aggregates; Aggregate Industries, Inc.; and Kiewit Materials Co.

Consolidation and acquisitions continued to be the trend in the late 1990s. In 1997 Martin Marietta Materials acquired several operations of American Aggregates Corp. from CSR America. This purchase included more than 25 production facilities. The company also bought Nuckolls Aggregates, with operations primarily in north central Iowa. Lafarge's acquisition of Redland Plc transformed Lafarge into one of the largest aggregates producers in the world. It also made Lafarge the fourth largest producer of aggregates in the United States, up considerably from 36th place in 1996. Lafarge's 2001 purchase of the Salt Lake City-based U.S. Aggregates, Inc., made it the largest producer of sand and gravel in Utah. In early 1999 Vulcan acquired Calmat, the leading producer of aggregates in California. Oldcastle Materials bought Hallett Material and Des Moines Asphalt and Paving in 2001, making it the fourth largest producer of sand and gravel in the United States. By 2001, however, mergers had declined by some 23 percent.

AMERICA AND THE WORLD

Beginning in the late 1970s, foreign acquisitions of U.S. sand and gravel mining firms began an upward spiral that would see thirty major purchases of U.S. aggregate producers concluded between 1979 and 1990 alone. Firms from the United Kingdom, France, Belgium, Ireland, and Australia were among the many foreign owners of U.S. construction sand and gravel producers in the early 1990s. Led by the United States, the North American sand and gravel market was the world's largest in the 1990s, but import-export activity was relatively low. In 1997, for example, U.S. imports and exports accounted for less than 1 percent of domestic consumption. The U.S. exported about 1.43 million tons of construction sand in 1997, primarily to Mexico and Canada. Exports of construction gravel in 1997 dropped 15 percent from

1996 amounts. About 81 percent of total exports of gravel went to Canada. Imports in 1997 reached 1.61 million tons, an increase of about 28 percent from 1996 imports. About 73.9 percent of imported construction sand and gravel was from Canada, and 15.1 percent came from the Bahamas.

In 2001, foreign trade of construction sand and gravel remained slight. Exports grew to 3.05 metric tons, a 27 percent jump from the previous year, but the value dropped to \$19.1 million, 21 percent lower than 2000. Imports grew to 3.82 metric tons in 2001, a 33 percent increase with a value of \$40.8 million, also an increase from the previous year by 23 percent. Between 1998 and 2001, Canada accounted for 66 percent of American imports, Mexico for 19 percent, and the Bahamas for 4 percent, with the remaining 11 percent from elsewhere.

SIC 1446

INDUSTRIAL SAND

This category covers establishments primarily engaged in operating sand pits and dredges, and in washing, screening, and otherwise preparing sand for uses other than construction, such as glass making, molding, and abrasives.

NAICS CODE(S)

212322 (Industrial Sand Mining)

INDUSTRY SNAPSHOT

In 2003, 67 U.S. companies in 34 states produced an estimated 28.3 million metric tons of industrial sand and gravel with a total value of \$566 million. Illinois, Michigan, California, North Carolina, Texas, Wisconsin, New Jersey, and Oklahoma accounted for 59 percent of the national industrial sand and gravel total that year. U.S. consumption of industrial sand and gravel grew from 26.1 million metric tons in 2002 to 27.2 million metric tons in 2003.

ORGANIZATION AND STRUCTURE

Glass Sand. The single most common use of industrial sand (38 percent of total tonnage in 2003) is in glass making, where glass or quartz sand constitutes 52 to 65 percent of the weight of finished glass. Glass sand requires a high percentage of silica—the principal ingredient of sand—because the presence of other elements such as iron oxide and clay introduces visible impurities that mar the glass’s transparency. Few sandstones or natural sands (such as beach or dune sand) are pure enough to yield glass without “beneficiation,” or the removal of impurities through processing. Glass sands are graded according to average grain size, which can be determined by passing them through sieves of varying calibers.

The container glass industry was one of the largest consumers of silica-based glass sand in the United States in the late 1990s, but the trend toward glass recycling, as well as increased plastic bottle and aluminum can packaging, weakened demand for silica sand. Some states require that 35 percent of container glass be comprised of recycled glass, with the potential for increases of as high as 65 percent recycled glass content by 2005. This trend was partly offset in the late 1990s, however, by heightened demand for flat glass, special-purpose glass, glass microwave packages, and glass containers for sparkling and flavored waters.

Molding Sand. Molding or foundry sand is traditionally the second most common use (20 percent in 2003) of industrial sand. Sand is used in these applications to make molds into which molten metal is poured in metal casting and as the “core” sand used in such molds to produce hollow areas in the final casted product. Sand needs to contain several properties to be used in foundry or molding applications. Internal cohesiveness and heat resistance—or refractoriness—enable the mold to withstand the high temperatures of the metal casting process (in steel applications, temperatures of 1340 to 1500 degrees Fahrenheit). Second, the sand’s moisture content, and the type and amount of bonding agent (such as clay) within it, govern its ability to withstand the pressure

exerted by the cast metal during heating. A third requirement is the sand's permeability, or its ability to allow water vapor and gases from the molten metal to escape during the casting process for cooling. Finally, the sand's composition and texture determine whether it will react chemically with the casted metal and whether it will create a smooth surface on the metal when it cooled.

While so-called naturally bonded molding sand contains enough clay and other bonding material to be used in metal casting without the addition of other bonding ingredients, synthetic molding sand consists of silica sand to which a specific amount (about 5 to 10 percent) of fire clay, bentonite, or other bonding material is added artificially. The trend toward greater use of these synthetic molding sands continues. Spurred by government regulations governing the disposal of used industrial sand, the use of recycled or reclaimed foundry sand is also increasing.

Fracturing Sand. Fracturing or hydraulic "frac" sand, also known as "proppant" sand, accounted for 5 percent of U.S. industrial sand production in 2003. It is comprised of washed and graded high silica-content quartz sand with a grain size of between 0.84 and 0.42 millimeters and is used in high-pressure fluids pumped into oil and gas wells to enlarge or scour out openings in oil- or gas-bearing rock or to create new fractures from which oil or gas can be recovered. Traditionally, the "fracture treatment" at an average well uses 26,000 pounds of fracture sand, and annual demand for fracture sand increases or decreases with the level of activity in the oil and gas industry.

Abrasive Sand. Abrasive sand and blast sand, which accounted for 5 percent of total industrial sand tonnage in 2003, include quartz-based silica sand used in sandpaper, glass grinding, stone sawing (as in dimension stone manufacturing), metal polishing and metal casting cleaning, and in sandblasting to remove paint, stain, and rust. While sands with angular-shaped grains are often used because they cut faster, sands with rounded grains last longer and yield a smoother finish.

Other Uses. Other traditional applications of industrial sand include engine sand, fire or furnace sand, and filtration sand, which together comprised 32 percent of the industry's total tonnage in 2003. Engine sand is laid on railroad tracks to provide traction for train engines in wet or slippery conditions. Fire or furnace sand is generally coarser than the sand used in metal molding. It is used in building floors for acid open-hearth furnaces and in lining the cupolas and ladles that contain molten metal in the foundry industries.

Filtration sand is used by municipal water departments to remove bacteria and sediment from water supplies. Although filtration sand is generally mined from

the same quarries as molding and glass sands, it has to be free of clay, lime, and organic matter as well as insoluble in hydrochloric acid. Other industrial uses include enamel manufacture, various metallurgical applications, and the production of phosphoric acid for the fertilizer industry.

Producing Regions. The sand used in industrial applications is mined from silica sand and sandstone deposits in 35 states. Approximately 75 percent of the sand derived from dunes and glacial lake beds is sandstone. Silica sand is composed almost exclusively of grains of quartz and includes between 95 and 99 percent (or more) silicate.

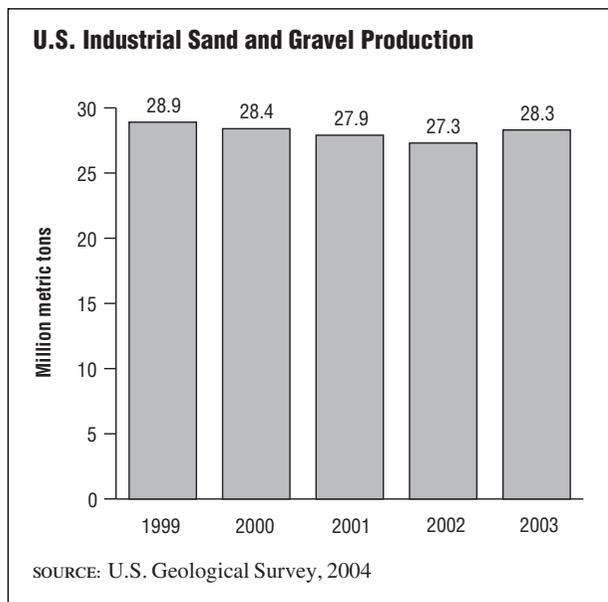

Industry firms in New Jersey traditionally supply special-purpose industrial sand (abrasives, fire sand, etc.), while silica miners in Pennsylvania provide sand for refractory bricks. Deposits in eastern Ohio are a source of sandstone sand that, when finished and sized, is used for clay-free molding sand and high-purity glass sand. Sandstone pebbles from the same region are often crushed and used in the production of ferrosilicon and silica brick. Industry mines in northwestern Ohio and southeastern Michigan historically produce very pure quartz sandstone for high-quality glass sand, and industrial sand mines in California have provided materials for superduty silica brick and glass-making applications since the mid-1950s.

BACKGROUND AND DEVELOPMENT

Mining Methods. The method by which industrial sand deposits are mined depends on the solidity or degree of "cementation" of the mineral. Natural sand deposits such as dunes and coastal beaches can be worked simply by using loading and hauling equipment. However, in deposits where the "overburden" or covering deposits are unusually deep—as in some locations in Missouri—underground mining uses the traditional "room-and-pillar" method, in which sections of the deposit are mined around supporting "pillars" of the mineral.

By far the most common means of extraction, however, is the mining of open pits or quarries. The term *quarry* is traditionally assigned to hard mineral deposits—such as the harder varieties of sandstone—requiring blasting or crushing, while *pit* technically refers to softer mineral deposits that can be mined using digging techniques.

Firms involved in quarrying operations use drills to make "shotholes" spaced at calculated intervals parallel to the rock face and with a diameter, depth, and angle sufficient to dislodge a specific volume of rock when explosive charges are detonated in them. The explosives are of a quantity and type needed to shatter the rock face and break the sand deposit into sizes convenient for loading.

Firms mine deep sand deposits in dry pits in progressive steps or terraces connected by ramps. They use light blasting, mechanical excavators, or high-pressure jets of water to dislodge the lighter earthy material and expose the heavy sand rock for mining. In some low-lying sand deposits, water naturally seeps into the pit as material is removed, so sand can be extracted as in riverbeds using “drag lines,” chain buckets, “grab dredgers,” or suction pumps. In pits with sufficiently deep water levels, floating grab dredgers and drag lines can be used to haul the sand to the surface.

Processing. While molding or foundry sand may be marketed without preparation other than crushing, glass sand is washed, dried, and screened, and may also be treated by electromagnetic, electrostatic, flotation, or other techniques to remove heavy mineral impurities like clay. Blast sand may be processed by breaking large sand grains into marketable grades using a high-speed rotary impact mill. Quartzite sandstone used to make silica bricks is crushed and screened into particle sizes of about 0.132 inches.

Developments in the late 1990s. In 1995 the U.S. industrial sand industry experienced several facility closures as well as a few major mergers and acquisitions, including Fairmount Minerals’ purchase of two Ohio companies to fortify its third-place position in the industry. The biggest corporate news, however, was the announcement by U.S. Borax, the parent company of the industry’s largest producer, U.S. Silica, that it planned to divest its subsidiary from its corporate stable.

Major changes in the end uses for industrial sand continued to affect the demand for the industrial sand mining industry’s products. The greatest new product advances in 1995 occurred in the silica chemicals and

glass and advanced materials industries. Rhône-Poulenc Basic Chemicals and PPG Industries announced new precipitated silica plants in Illinois and Louisiana, respectively; Dow Corning launched a new line of “resin modifiers” based on silicone powder for use in flame-retardant thermoplastics; and Ford Motor Company announced the development of an all-fiber, glass-reinforced composite car body design that if adopted by the auto industry would increase the demand for the industrial sand industry’s glass sand products. By using silica as an ingredient in the ceramic portion of such aluminum-and-ceramic composites, manufacturers could produce industrial materials with the strength of steel but with a fraction of its weight and cost. The growing importance of the semiconductor industry also promised to expand the silica sand industry’s sales, and Samsung Electronics and Intel Corporation announced major new plants in Texas and Arizona, respectively.

CURRENT CONDITIONS

In 2004 the United States remained the world’s largest producer and consumer of industrial sand and gravel due to the wide range and high quality of its deposits and the advanced processing techniques used to mine them. After the United States, which accounted for 28.3 million metric tons of the 94 million metric tons of industrial sand and gravel produced worldwide, the leading producers in 2003 were Germany, Austria, France, and Spain.

After increasing for several consecutive years to meet growing demand, production of industrial sand declined 3.7 percent between 2001 and 2002. Analysts pointed to recessionary economic conditions in the United States as the reason behind slowing demand. Production of industrial sand and gravel combined grew from 27.3 million metric tons in 2002 to 28.3 million metric tons in 2003; however, production levels remained below those of the late 1990s.

The United States exported 1.4 million metric tons of industrial sand and gravel in 2003, primarily to Canada and Mexico. Exports had declined steadily since their 1999 total of 1.4 million metric tons, despite increased demand from Mexico. U.S. industrial sand imports were much smaller than exports, totaling 250,000 metric tons in 2003, with Canada accounting for 48 percent of this total and Mexico accounting for 47 percent.

Health and environmental issues continued to have a major impact on the industrial sand mining industry in 2004. In 1992 the International Agency for Research on Cancer had identified crystalline silica as a probable human carcinogen, and the U.S. Occupational Safety and Health Administration (OSHA) therefore required that industrial sites using or receiving more than 0.1 percent of crystalline silica notify workers of its potential health dangers. Industry firms began labeling bags and filing

Material Safety Data Sheets to comply with federal, state, and local regulations regarding crystalline silica content, and garnet and granular slag were investigated as alternative sources of blasting and filtration sand. Establishments were expected to continue moving into lower-population zones in the early 2000s.

INDUSTRY LEADERS

The largest producer of industrial sand in the United States in the early 2000s was J.M. Huber Corporation of Edison, New Jersey, which posted 2002 sales of \$1.23 billion and 3,278 employees. Second was Unimin Corporation of Connecticut, which produced the broadest range of ceramic grade silica, nepheline syenite (**SIC 1459: Clay, Ceramic, and Refractory Minerals, Not Elsewhere Classified**), feldspar (**SIC 1459: Clay, Ceramic, and Refractory Minerals, Not Elsewhere Classified**), and micron-sized silica. Its trademarked "QIP" quality assurance program enabled it to offer minerals of the highest grades of chemical purity and uniformity. In 2002, Unimin garnered sales of \$550 million. Other leaders included U.S. Silica of West Virginia, which was sold by its corporate parent U.S. Borax and Chemical Corporation of California to D. George Harris and Associates, a New York industrial management and advisory firm, in late 1995. By 2003, U.S. Silica operated processing plants in 14 states.

SIC 1455

KAOLIN AND BALL CLAY

This category covers establishments primarily engaged in mining, milling, or otherwise preparing kaolin or ball clay, including china clay, paper clay, and slip clay. Establishments primarily engaged in grinding, pulverizing, or otherwise treating clay, ceramic, and refractory minerals not in conjunction with mining or quarrying operations are classified in **SIC 3295: Minerals and Earths, Ground or Otherwise Treated**.

NAICS CODE(S)

212324 (Kaolin and Ball Clay Mining)

INDUSTRY SNAPSHOT

In the early 2000s, a total of 28 U.S. firms operating 124 mines produced 9.13 million metric tons of kaolin and ball clay. Of the total U.S. production of clay and shale in 2003, which reached 39.3 million metric tons with a value of \$1.6 billion, kaolin accounted for about 20 percent. Ten states, led by Georgia, produced kaolin in the early 2000s. Kaolin's primary uses are for paper coating and filling (54 percent), refractories (17 percent), and other uses (29 percent).

The ball clay segment of the industry was rather small and consisted of four companies in four states in 2002. Tennessee was the leading supplier of ball clay, producing 59 percent of total U.S. output. Following Tennessee were Texas, Kentucky, and Mississippi. U.S. production of ball clay in 2002 reached 1.12 million metric tons with an approximate value of \$47 million. The major ball clay markets in the United States were floor and wall tile (41 percent), sanitary ware (25 percent), and other uses (34 percent).

ORGANIZATION AND STRUCTURE

Clays are classified according to their relative plasticity or malleability, their strength when moist (green strength), their strength after drying (dry strength), their air shrinkage properties, and their vitrification range. Vitrification refers to the process by which clay molecules begin to fuse when exposed to heat. A clay's vitrification range therefore describes the temperature levels between which the clay begins to fuse and when it achieves its final fusion or hardness.

Clays are often mixed or blended to achieve the desired properties dictated by their end use. Thus, whiteware ceramic consists of kaolin, ball clay, feldspar, and ground silica. Kaolin, or china clay, derived its name from the hill where it was first extracted in Kao-Ling, China. Historically, more than half the annual U.S. production of kaolin was used as filler and coating material in high-quality paper. Along with wood pulp, kaolin traditionally constituted a large percentage of the paper's content. The properties that recommend kaolin as a paper clay include natural brightness, ink absorption characteristics, chemical inertness, and superior dispersability when introduced into the water solutions from which the final paper mixture is derived.

There are no commercial substitutes for kaolin as an ingredient in coated paper. The increasing scarcity of wood pulp and the high costs of transporting kaolin outside the southeastern United States however, spurred the papermaking industry to develop alternatives to kaolin as a paper filler in the 1980s. The invention of lime- and calcium carbonate-based alkaline paper manufacturing techniques meant that papermakers would require less wood pulp for paper production. It also meant that

they could avoid the high transportation costs associated with kaolin paper fillers—resulting in a potentially long-term loss of demand for the industry’s kaolin mining firms.

However, in addition to its uses in papermaking, kaolin is also favored as a filler in rubber production for its low cost and stiffening or reinforcing characteristics, as well as for the properties that recommended it in papermaking. Comparatively smaller amounts of kaolin have been used as extenders and fillers in the manufacture of paint, linoleum, leather, wallpaper, textiles, and fertilizers. Other uses of kaolin include the production of fungicides and insecticides and the manufacturing of porcelain, chinaware, and other ceramic products. Highly refined kaolin has also been used in cosmetics and pharmaceutical products.

Although kaolin as a commodity is relatively inexpensive, it is less common than other clays and therefore has a higher unit price compared to them. Because kaolin has a low per ton price compared to other nonclay commodities, it yields its producers only slim profit margins—unless it could be extracted and processed in greater bulk without added cost or offered to the market in a refined, higher-priced form. For example, in the late 1980s, Georgia-based Nord Kaolin Company introduced a line of customized kaolin-based pigments to act as “opacifiers” to reduce the transparency of paper and to augment the printing quality and whiteness of premium or “glossy” magazine paper, lightweight periodicals paper, and uncoated copier paper. The firm sold more than 12,000 tons of such kaolin-based pigment paper products in 1992.

Historically, about 90 percent of U.S. kaolin production came from mines in Georgia and South Carolina, but North Carolina provided another source of workable deposits. The United States and Great Britain historically led world production of kaolin. In the late 1960s, the kaolin production by Germany, India, and France combined amounted to less than one-third the kaolin production of Great Britain alone.

Ball clay, a light-burning, high-grade ceramic clay, derived its name from the shape it took when it was removed from open pit mines in the early days of the clay mining industry in Great Britain. More than 89 percent of U.S. ball clay originated in western Tennessee and Kentucky, but other mined deposits existed in California, Maryland, Mississippi, and New Jersey. Ball clays differ in color, plasticity, strength, and firing properties, but almost all their uses are ceramic. High-grade ball clay is used in the manufacture of dinnerware, porcelain, and ceramic-based bathroom fixtures. Ball clay is also used to produce “wad” and “sagger” clays used in ceramic kilns to protect and support the clay being baked. Ball clay is shipped in bags and bulk carload lots—in ground,

“air floated,” lump, or shredded form. Like kaolin, ball clays are produced in relatively small quantities compared to other clays and thus have a generally higher unit price.

BACKGROUND AND DEVELOPMENT

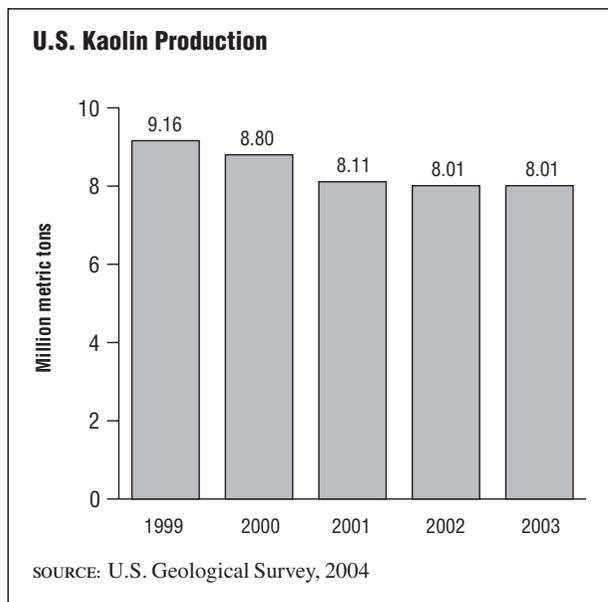

Kaolin and ball clays were most often mined by directing hydraulic high-pressure jets of water on the clay faces of open pits, loosening the soft clay from the deposit. The liquefied clay mixture or “slip” was then raised by bucket elevator to a flume or chute that transported it to the preparation plant. In other methods, the clay was mined by removing the overburden (or overlay of soil or rock) by power shovel or dredging “dragline” machine. The exposed clay was then mined by a power shovel and delivered to the preparation plant by conveyer belt, truck, or rail.

At the preparation plant, the clay mixture was refined and “de-watered” by mechanical drying equipment and filter presses. The undesired grit minerals (such as sand, rutile, or mica) were separated from the clay by such processes as grinding, washing, screening, settling, and/or flotation (in which the extracted mixture was immersed in a solution that caused the undesired elements to sink to the bottom while the clay rose to the surface).

The mining industry as a whole has traditionally faced very high capital costs associated with its exposure to weather-related work interruptions, the cost of exploration activities and preparation of feasibility studies, the expense of acquiring and holding rights to mineral properties, the cost of purchasing and maintaining equipment, and the expense of developing and operating the mines and preparation plants. The mining operations of kaolin and ball clay producers were also governed by environmental regulations that required them to control dust emissions, reclaim strip-mined sites, and purify production waste materials.

CURRENT CONDITIONS

Kaolin. The United States remained the world leader in kaolin production in the early 2000s. In 2002, 78 quarries in 10 states produced 8.01 million metric tons of kaolin, down from 9.45 million metric tons produced in 1998. About half of the kaolin produced was water washed. U.S. exports of kaolin in 2003, according to the U.S. Geological Survey, were estimated at about 3.40 million metric tons, and imports from foreign sources totaled approximately 275,000 metric tons. The primary supplier of kaolin imports was Brazil, which supplied 61 percent of the total despite the fact that it had just become a major supplier of kaolin in the late 1990s. In fact, imports from Brazil accounted for nearly all of the 117,000 metric ton increase in imports realized by the United States between

2002 and 2003. In 2003, total world production of kaolin was estimated at 45.1 million metric tons, with the Commonwealth of Independent States ranking as the leading producer worldwide after the United States.

Demand for kaolin, which is used primarily for paper coating and filler, was undermined by waning demand for paper, which had increased dramatically in price throughout the late 1990s and early 2000s; during this time period the paper industry had also suffered from the shift toward paperless transactions in the business world. At the same time, competition from calcium carbonate lessened demand for kaolin-based paper coating and filler products.

The leading U.S. producers of specialty clays in the early 2000s included Engelhard Corporation, which produced both kaolin and fuller's earth and posted 2003 sales of \$3.7 billion and employed 6,650 workers, and J.M. Huber Corp., which secured revenues of \$1.23 billion in 2002 and employed a workforce of 3,278. Other industry leaders included ECC International LTD; Thiele Kaolin Co.; and Dry Branch Kaolin Co.

Ball Clay. In 2002, the U.S. ball clay mining industry produced an estimated 1.12 million metric tons, up slightly from 1.11 million metric tons in 2001. The largest increase in demand and consumption was for sanitaryware. Positive sales for ball clay were attributed largely to the steady growth in construction, both commercial and residential, and home renovations. The construction segment provided consistent demand for sanitaryware, tile, and whiteware. However, competition from clay-based ceramic imports began to weaken this demand in the early 2000s. Ball clay exports in 2003 were 150,000 tons, according to the U.S. Geological Survey.

SIC 1459

CLAY, CERAMIC, AND REFRACTORY MINERALS, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in mining, milling, or otherwise preparing clay, ceramic, or refractory (heat-resistant) minerals, not elsewhere classified. Establishments producing clay in conjunction with the manufacture of refractory or structural clay and pottery products are classified in manufacturing in the major group for stone, clay, glass, and concrete products.

NAICS CODE(S)

212325 (Clay and Ceramic and Refractory Minerals Mining)

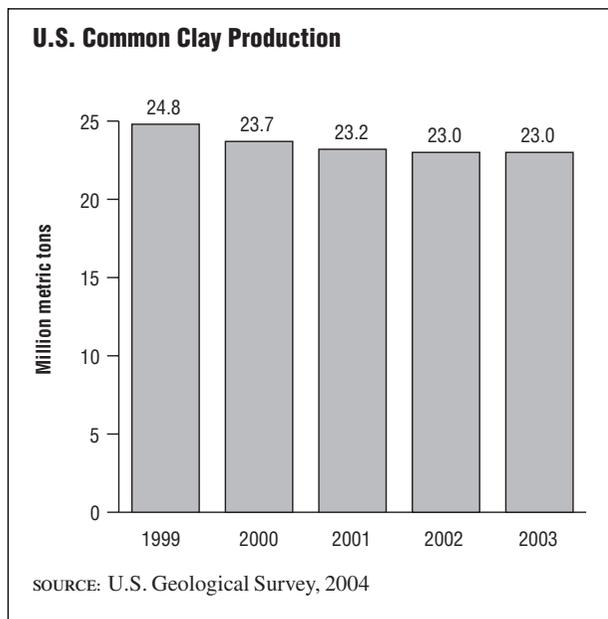

INDUSTRY SNAPSHOT

Firms in this industry extract raw minerals used in a wide variety of industrial and consumer applications with the most common end use being refractory materials for the manufacture of glass, ceramics, and industrial uses.

ORGANIZATION AND STRUCTURE

Common Clay and Shale. Industry firms produced 39.3 million metric tons of common clay and shale in 2003. In 2003, common clay and shale accounted for 58.5 percent of the total output of all clay minerals (including those produced by firms not classified in this industry) sold or used in the United States.

Common clay alone was used to manufacture bricks (56 percent of output), cement (17 percent), and in lightweight aggregate (17 percent). Other uses for common clay alone include such heavy clay products as building brick, flue linings, sewer pipe, drain tile, structural tile, terra cotta, and portland cement clinker (slag). In descending order of output, the leading producers of common clay in 2002 were North Carolina, Texas, Alabama, Georgia, Ohio, Missouri, Oklahoma, California, South Carolina, Kentucky, Arkansas, Virginia, and Pennsylvania.

Shale is one of the most common sedimentary rocks and thus usually has a lower unit price than rarer clays such as kaolin and ball clay. Shale's industrial applications include heavy ceramic ware, portland cement manufacture, and lightweight construction aggregate. The choice of shale as an ingredient in these applications is governed by such factors as its suitability compared with other industrial minerals, the presence of other useful minerals in the market for which it is to be produced (i.e., pumice, sand and gravel, slag, or crushed stone in the lightweight aggregate industry), and its economic viability with respect to other competing minerals such as clay.

Bentonite. The United States was the world leader in the production of bentonite throughout the early 2000s, and the 21 industry companies operating as of 2002 produced an estimated 3.97 million metric tons, valued at \$180 million, in 12 states. In 2002, bentonite's specific end uses were as a foundry sand-bonding agent (25.4 percent), as a clumping agent in pet waste litter (22.7 percent), as a drilling mud (20.6 percent), and in iron ore pelletizing (15.1 percent). Bentonite's other uses included the manufacture of decolorizing oils; catalysts for the production of polymers, plastics, and resins in the petrochemical industry; absorbent materials for industrial plants; cattle feeds; and a thickening agent for the production of paints, hand lotions, and pencil lead.

As ingredients in the drilling mud used in the oil-well drilling industry, bentonite-based products aid in the removal of drill cuttings, thicken drilling fluids, stabilize well walls, and reduce friction. Bentonite is also used as an ingredient and preblend in the production of metal casting products for automobiles, kitchen appliances, and other products; as a binding agent in iron ore pelletizing

processes in the steel industry; and as a water-absorbing sealant or liner in underground or waterproofed structures.

Fuller's Earth. The United States was the world leader in fuller's earth production throughout the 1990s and early 2000s with 16 companies producing a total of 2.73 million metric tons. Fuller's earth derived its name from the ancient practice of using earth to clean wool—a process known as “fulling.” Fuller's earth became a generic name for clay- and earth-based minerals that had the property of chemically coloring vegetable oils and minerals. The product is used to decolorize soy oils, petroleum products, tallow, and cottonseed oil, as well as in such applications as insecticide production, oil well drilling, mud, manufacture, and as a filler. Fuller's earth is also used in the manufacture of traditional or nonclumping cat litter products. In 2002, the majority of all fuller's earth mined in the United States was for use as an absorbent; a minor amount of total output served as a dispersant in insecticide.

Feldspar. Feldspar is the most common igneous rock mineral and the most plentiful mineral in the earth's crust. In the early 2000s, roughly 70 percent of all feldspar (including aplite) sold or consumed in the United States is in the glass-making industry, including the manufacture of glass fibers and glass containers in which it enhances glass's durability, hardness, and resistance to erosion. Feldspar is also commonly used as a flux in the manufacture of ceramics and its other end uses include the manufacture of pottery, plumbing fixtures, electrical porcelain, ceramic wall and floor tiles, glass, dinnerware, television picture tubes, and glass fiber insulation.

Nepheline syenite is a feldspathic mineral that provides alumina and alkali used in glass making and serves as a flux in ceramic product manufacturing to lower melting temperature. Pegmatites are the minerals from which feldspar is mined; feldspar is the most plentiful mineral present in pegmatites.

Fire Clay. In 2002, a total of seven businesses produced 446,000 metric tons of fire clay, the majority of which was used in refractory products such as calcines (metal oxides produced by roasting or calcination), firebrick, grogs (crushed material used to make refractory products, such as crucibles, to limit shrinkage), high-alumina brick, saggars (fireclay boxes for firing more delicate ceramics), refractory mortars and mixes, and ramming and gunning mixes. Other uses include lightweight aggregates, portland cement, and pottery. Roughly 12 percent of fire clay production is used as a dispersant in insecticides. In 2002, Missouri produced the most fire clay for the United States, followed by South Carolina, Ohio, and California.

Magnesite. The United States has been the world's biggest producer of metallic magnesium since World

War II. Magnesium is the third most abundant element in seawater and the eighth most abundant element in the Earth's crust. Magnesium and its compounds are recovered from seawater and from mineral deposits of magnesite, dolomite, and olivine. Magnesium is employed primarily as an alloy in the aluminum used to make everything from beverage cans, aircraft, automobiles, and machinery. It has also found uses in the desulfurization of iron and steel and in the chemical, agricultural, and construction industries. In 2002, more than half of U.S. magnesium compounds were used in refractories, as for example, in the linings of iron and steel furnaces; thus, the magnesite mining segment of the industry is strongly affected by economic trends in the iron and steel industry. Magnesium compounds are also used in agricultural, chemical, environmental, and industrial capacities.

Kyanite. Kyanite and its two related minerals, andalusite and sillimanite, are used primarily in the glass-making, metallurgy, refractory, and ceramic industries. With most mines located in Georgia, Virginia, and North and South Carolina, the American kyanite mining segment is the world's second largest producer. South Africa ranks first with more than half of the world total. Andalusite is mined from deposits in California and used in the manufacture of spark plugs and other porcelain requiring high heat-resistant properties in electrical and chemical applications.

Kaolin. Kaolin is a clay mineral that is used as a pigment in the production of paint, paper, plastic, ink, polish, ceramics, cement, fiberglass, adhesives, and rubber. Kaolin is distinguished from other clay minerals like illite, montmorillonite, vermiculite, and several other groups by chemistry, particle shape and structure, and properties like conductivity and light refraction. All clays are very fine in structure, and their differences require techniques like electron microscopy or X-ray diffraction to measure. These same differences, however, greatly affect the behavior of kaolin (or any of the other clays) in product applications. Kaolin is also used as a paper coating (100,000 tons) and in refractories (210,000 tons).

In 2002, 24 firms in 10 states produced 8.01 million metric tons valued at \$951 million. This was a slight decrease from the 8.11 million metric tons produced the previous year. Georgia is the leading state in kaolin production, followed by Alabama, South Carolina, and California.

CURRENT CONDITIONS

Common Clay and Shale. In 2002, the 162 firms in the common clay and shale segment of the industry mined these minerals for use in the manufacture of their own products, and only about 10 percent of the estimated 23

million metric tons of common clay and shale produced in 2002 was sold to other firms. A significant trend in this portion of the industry was the consolidation of industry firms in reaction to the prohibitive costs of transporting mined clay and shale. Thus, many smaller industry firms operated through local ownership companies, while larger firms contained transportation costs by owning and operating a number of strategically located pits and fabricating facilities.

In 2002, 23 million metric tons of common clay and shale was sold by the United States. More than 55 percent is used as brick, with 17 percent being used as cement, and 17 percent being used as lightweight aggregate.

Bentonite. A total of 21 companies produced bentonite in 12 states in 2002. While production of swelling bentonite increased to 3.62 million metric tons valued at \$166 million, production of nonswelling bentonite decreased to 354,000 metric tons, valued at \$14 million. Alabama was the leading producer of nonswelling bentonite; Wyoming led the nation in swelling bentonite production.

Fuller's Earth. Sixteen companies operating 31 quarries in 10 states produced 2.7 million metric tons of fuller's earth in 2002. World production of fuller's earth, 3.9 million tons in 2003, was led by the United States and Germany.

Feldspar. In 2003, nine U.S. firms produced an estimated 800,000 metric tons of feldspar and aplite with a value of \$44 million. The three largest producers supplied nearly 70 percent of this total. In the mid-1990s industry leader Feldspar Corporation had expanded its North Carolina production capacity by 120,000 tons and opened a new mine in Georgia. In 2003, the United States only imported 9,000 metric tons for consumption, 96 percent of which was supplied by Mexico. Glass was the largest end use for feldspar in the United States as of the early 2000s; as a result, the booming U.S. housing market, which bolstered the U.S. glass market, impacted the feldspar industry favorably.

Fire Clay. In 2002, seven U.S. firms operating 44 quarries in 4 states produced 446,000 metric tons valued at \$10.5 million, up from 383,000 metric tons in 2001, but considerably lower than the 583,000 metric tons produced in 1995. Most producers were refractory manufacturers that used the clay in the fabrication of firebrick and other refractory materials.

Magnesite. In 2003, two companies in Delaware and Florida extracted magnesium compounds from seawater; three companies in Michigan extracted magnesium compounds from brine wells; and two companies in Utah recovered magnesium compounds from lake brine. U.S. production of magnesium compounds fell to 285,000

metric tons in 2003, down from 395,000 metric tons in 1999. Domestic production wasn't enough to satisfy demand, as 350,000 metric tons were imported, 66 percent of which came from China. In 2003, the Ludington, Michigan-based brine producer shuttered its magnesium hydroxide plant, which resulted in the eventual shutdown of a dead-burned magnesia plant located nearby, which had relied on the Ludington plant for magnesium hydroxide. As a result, only one dead-burned magnesia producer continues to operate in the United States.

Kyanite. In the mid-1990s the kyanite industry was positively affected by new developments in the refractory market. So-called monolithic refractories, that is, refractories that are made of a single piece, found expanded uses in new high-temperature manufacturing processes being adopted in the iron and steel, cement, glass, and other refractories industries. In particular, industry firms like Kyanite Mining Corporation of Virginia, C-E Minerals of Georgia, and North American Refractories are expected to benefit from the emergence of new refractory materials that help the steel industry in its quest to produce ever purer grades of steel. In 2003, U.S. consumption of kyanite reached 102,000 metric tons. Refractories accounted for 90 percent of use. The U.S. exported 35,000 metric tons of kyanite and imported 7,000 metric tons, all from South Africa.

INDUSTRY LEADERS

Leading the clay, ceramic, and refractory minerals industry in the early 2000s was Amcol International (formerly American Colloid) of Illinois, which posted sales of \$364 million in 2003. Minerals accounted for more than half of total revenues for Amcol, which is the leader in the manufacture of such clay-based products as scoopable cat litter. Other top players include Oil-Dri Corp., which posted 2003 sales of \$173 million, and Martin Marietta Magnesia of Michigan.

In 1999 Utah Clay Technology (UCT), a firm that makes high-quality kaolin, had leased 7,000 acres of land in southern Utah from Utah Kaolin Corporation. UCT's kaolin reserves are estimated to have increased by over 200 million tons through this mining lease. Hecla Mining Company of Coeur d'Alene, Idaho, was also a key supplier of kaolin and other clay mineral from mines in Mexico, Venezuela, and the United States as of 1999. However, in 2003, Hecla divested the last of its industrial minerals operations, effectively exiting the industry.

SIC 1474

POTASH, SODA, AND BORATE MINERALS

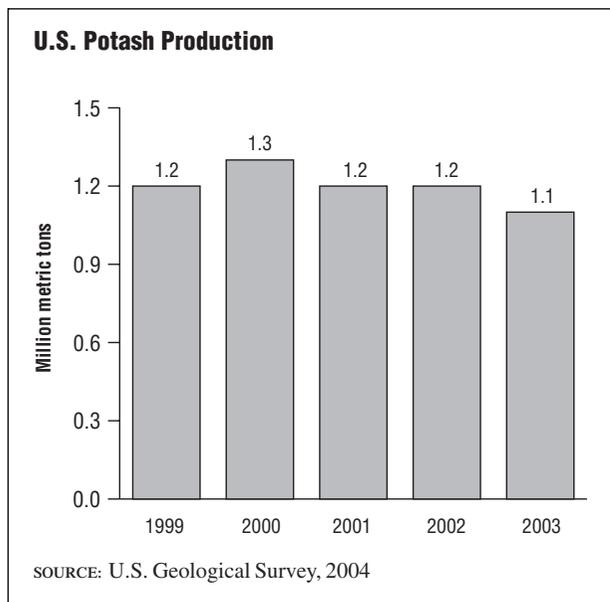

This category covers establishments primarily engaged in mining, milling, or otherwise preparing natural potassium, sodium, or boron compounds. Establishments primarily engaged in mining common salt are classified in **SIC 1479: Chemical and Fertilizer Mineral Mining, Not Elsewhere Classified**.

NAICS CODE(S)

212391 (Potash, Soda, and Borate Mineral Mining)

In 2003 the majority of potash production took place in New Mexico, where three mines were in operation. Michigan and Utah also had potash production facilities. In the 2003 crop year, about 1.1 million metric tons of potash were produced in the United States, down from 1.2 million metric tons the previous year. The fertilizer industry accounted for about 85 percent of U.S. potash sales, and the chemical industry used about 15 percent. Roughly 60 percent of the potash extracted in 2003 was produced as potassium chloride, with potassium sulfate and potassium magnesium sulfate—both for fertilizing certain crops and soils—representing the remainder of potash production. Of the world's potash reserves, the largest percentage was located in Canada and Russia. Canada accounted for 93 percent of U.S. potash imports, which totaled 4.5 million metric tons in 2003. The United States relied on imports for roughly 80 percent of its total consumption.

As a fertilizer, potash was used for such crops as soybeans, tobacco, potatoes, sugar beets, and corn, and the potash mining industry was thus subject to the sea-

sonal fluctuations of the agricultural market. Before the Civil War, U.S. production of potash involved removing it from wood ashes through a leaching process. In 1916 potash began to be extracted through crystallization from saltwater lake brines in southern California, and later potash was mined from deposits discovered in New Mexico, which became the primary source of domestic potash in the United States. Following the oil crisis of 1979, demand for potash in developed nations declined, but in 1986 began a steady climb of 140,000 short tons a year.

By the 1990s the world's potash markets were in oversupply, and in the late 1990s and early 2000s, potash producers were forced to operate at reduced capacity. In addition, potash production was affected by economic crises afflicting Asia, as demand from Asia for imported grains declined. In fact Potash consumption in Asia was expected to decline 9 percent in 2003. Based on data from the U.S. Geological Survey, U.S. consumption of potash declined from 5.6 million metric tons in 2001 to 5.3 million metric tons in 2003. Exports over that time period rose from 366,000 metric tons to 370,000 metric tons, with the majority going to Latin America.

By 2003 there were only four potash-producing companies in operation in the United States, down from 10 companies in 1996. These four companies worked a total of seven production facilities. One of these firms, Mississippi Chemical Corp., filed for Chapter 11 bankruptcy protection in May of 2003 due to rising raw materials costs, which made it difficult to turn a profit on nitrogen and phosphorus. In March of 2004, Mississippi Chemical agreed to sell its two remaining potash mines in New Mexico. Another potash producer, IMC Global Inc., had acquired Western Ag-Mineral in 1997 and Harris Chemical Group, Inc. in 1998. IMC posted sales of \$2.19

billion in 2003; by then, the firm operated six potash mines. In January of 2004 Cargill Inc. announced its intent to purchase IMC. Other consolidations in the late 1990s had led to Canadian-based Potash Corporation's ownership of the Moab Salt Company in Utah and Reilly Industries, Inc.'s ownership of the Reilly-Wendover potash site.

The soda ash mining segment of the industry, the world's largest, consisted of six U.S. companies in Wyoming and California, which in 2003 produced 10.6 million metric tons of soda ash. Soda ash, a form of sodium carbonate, is used in the production of such chemicals as sodium bicarbonate, sodium sulfate, sodium chromate, sodium phosphate, sodium silicate, potassium chloride, potassium sulfate, sodium sulfite, sodium tripolyphosphate, and chemical caustic soda. In 2003 the most common end uses of these soda ash products were glass (49 percent); chemicals (26 percent); soap and detergents (11 percent); distributors (5 percent); flue gas desulfurization (2 percent), pulp and paper and miscellaneous (2 percent each); and water treatment (1 percent). Other applications of this "non-table salt" group of sodium or saline minerals were the production of photographic darkroom materials and wood fibers for the manufacture of wrapping paper and carton board, and the processing of textile fibers, dye manufacture, and leather tanning. Alum, Glauber's salt, and trona were other forms of sodium salts mined by industry firms. Sodium sulfate in particular was used as a substitute for salt in the dyeing processes of the textiles industry and in the glass, powdered laundry detergent, and pulp and paper industries.

After struggling with the impact of economic turmoil in Asia in the late 1990s, global demand for soda ash began to climb in the early part of the twenty-first century; as a result, U.S. production grew steadily, rising from 10.2 million metric tons in 2000 to 10.6 million metric tons in 2003. U.S. soda ash exports also increased from 3.9 million metric tons to 4.4 million metric tons over the same time period. In the early 2000s, China revealed plans to boost capacity at its soda ash facility in Weifang by 600,000 tons and to build a synthetic soda ash plant in Zhejiang with an annual capacity of 900,000 tons. Analysts predict that China will supercede the United States as the largest soda ash producer in the world by 2004.

Foreign investment in the U.S. soda ash industry increased throughout the 1990s. In 1981 foreign investment accounted for only 10 percent of soda ash production, but by 1998 foreign investment was 46 percent of capacity. European companies owned about 22 percent of soda ash production operations in Wyoming in 1998. The percentage had been higher—35 percent—in 1995, before Rhone Poulenc SA of France sold its Wyoming plant to Korea's Oriental Chemical Industries. In late 2003

Belgium-based Solvay S.A., the leading soda ash producer in the world, bought American Soda, a soda ash joint venture formed between Williams Companies Inc. and American Alkali in 2000. The deal gave Solvay soda ash capacity in excess of 9 million tons, roughly 20 percent of worldwide soda ash capacity.

The term *borate minerals* encompasses such boron-producing minerals as borax and kernite and includes colemanite, ulexite, and probertite. Boron was used in gasoline, jet and rocket fuel, and as an ingredient in industrial plasticizing and dehydrating processes. Borax was used in the production of enamel for bathtubs, stoves, refrigerators, and metal signs, and as an agent for ensuring brilliance and clarity in the manufacture of glass. Other uses for borax included disinfectants, preservatives, starches, lumber treatment, detergents, fertilizers, weed killers, and metallurgical applications. Borax and other borate compounds were also used as intermediate chemicals in a wide variety of industrial processes. Colemanite and ulexite were used in glass manufacturing and in the production of glass wool used for insulation.

U.S. production of boron minerals was centered in California and handled by four companies. The three regions responsible for much of the production were Kern County, San Bernardino, and Inyo County. The four borate mineral producers were American Borate Co., Fort Cady Minerals Corp., North American Chemical Co., which was owned by IMC Global, and U.S. Borax, Inc. The United States was the largest producer of boron compounds globally in 2003 and exported roughly 50 percent of its output. The largest producer of boron ore globally was Turkey. The United States continued to import borates, primarily from Turkey and Chile. The principal end uses of boron compounds in 2003 were glass and ceramic products (78 percent), soaps and detergents (6 percent), agriculture (4 percent), fire retardants (4 percent), and other uses (9 percent).

SIC 1475

PHOSPHATE ROCK

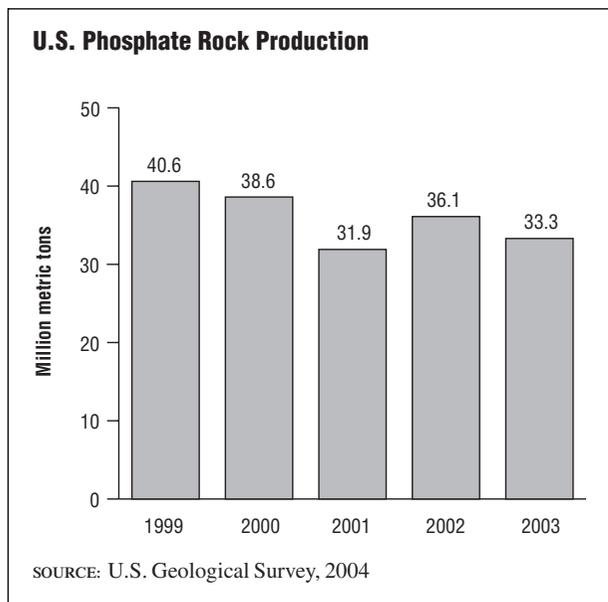

This category covers establishments primarily engaged in mining, milling, drying, calcining, sintering (heating without melting), or otherwise preparing phosphate rock, including apatite.

NAICS CODE(S)

212392 (Phosphate Rock Mining)

In 2003, nine U.S. firms in four states mined phosphate rock ore, compared to 20 firms in 1997. In 2003 mines produced an estimated 33.3 million metric tons of phosphate rock, with a value of \$895 million f.o.b. mine. The United States is the world's leading producer and consumer of phosphate rock, over 90 percent of which is used to produce chemical fertilizers and animal feed supplements. In 2003, it accounted for about one-fourth of total global production, down from one-third in the late 1990s. The states of Florida and North Carolina produced 85 percent of the total U.S. phosphate rock output, with Idaho and Utah contributing the rest. After growing for seven consecutive years in the late 1990s, phosphate rock production in the United States began to wane, plunging from 40.6 million metric tons in 1999 to 31.9 million metric tons, its lowest point in 30 years, in 2001. Although production rebounded somewhat to 36.1 million metric tons in 2002, it dipped to 33.3 million metric tons in 2003. This decline was due in large part to reduced exports to China, where the market for diammonium phosphate (DAP) had weakened considerably. Between 2000 and 2001, U.S. phosphate rock exports had plunged from 299,000 metric tons to 9,000 metric tons. By 2003, exports were down to a mere 5,000 metric tons.

The mineral phosphate took over 150 natural forms and was required by all plant and animal life for existence. All of the U.S. production of phosphate minerals—and 90 percent of worldwide production—was the sedimentary phosphate rock known as phosphorite, which was largely comprised of carbonite apatite. The phosphate rock mining and preparation industry produced the phosphorus that comprised one of three primary ingredients of agricultural fertilizers.

A substantial percentage of mined low-grade phosphate was used in an untreated state as soil fertilizer. This natural phosphate released its phosphorus content into soils relatively slowly, however, so greater volumes had to be extracted to achieve the same effects as more concentrated processed phosphate fertilizers. Common forms of treated or processed phosphate compounds include phosphoric acid, triple superphosphate, ammonium phosphate, and superphosphate. The harvesting of one ton of wheat required the application of about 18 pounds of phosphoric acid fertilizer, which was usually applied to the soil through irrigation water.

In addition to its use as a fertilizer, phosphate rock provided orthophosphoric acid and elemental phosphorus, which were used in applications such as leavening agents, photographic chemicals, water softeners, oil refining, beverages, insecticides, ceramics, detergents, plasticizing chemicals, and scouring powders. Phosphate rock was also widely used as a source of fluorine for making plastics and resins, laboratory dies, refrigerants, solvents, lubricants, and aerosol propellants. Phosphorus also played a role in the production of explosives and fireworks and in steel production. Phosphate rock found in Idaho contained vanadium, which was used as a bonding agent in the manufacture of titanium steel, as a stabilizing agent in steel production, and as a rust-resistant element in high-speed tools.

The extremely high costs of acquiring and holding mineral properties, conducting feasibility studies and exploration operations, purchasing and maintaining mining equipment, and developing and operating the mines themselves, made the mining industry one of the most capital-intensive in the United States. Historically, the majority of phosphate rock mined in the United States

was extracted from open pits, but the number of underground mining operations gradually increased. Open pit mining was performed by large excavating machines, which stripped the “overburden” (nonproductive overlay) and removed it from the site. A typical operation involved washing the mined phosphate with a hydraulic jet and then pumping it in liquefied “slurry” form to a washing plant. The phosphate was then mechanically graded by size, concentrated, and dried.

Phosphate mining began in Idaho in 1906 and in Montana in 1920. The use of phosphate fertilizers in sugar beet fields first occurred in the western United States in the mid-1930s. The production of phosphate rock grew rapidly during World War II and reached 10.7 million metric tons by 1950. And by 1964, 23.3 million metric tons were produced in the United States alone. Although worldwide consumption of phosphate fertilizers increased from the 1970s to the 1990s, its rate of growth steadily fell off, from 5 percent a year to 2 percent or lower by the mid-1990s. The International Fertilizer Industry Association predicts phosphate fertilizer consumption to grow an average of 2.7 percent between 2003 and 2008.

One of the most important trends in the U.S. phosphate mining industry in the late 1990s and early 2000s was industry consolidation. Grain surpluses, an excess supply of phosphate fertilizer worldwide, and depressed prices between 1981 and 1986 forced North American phosphate producers to begin seeking greater efficiencies. For example, Potash Corporation of Saskatchewan (PCS) bought two phosphate mines and chemical plants in Florida to complement its existing phosphate complex in North Carolina. The 1996 purchase gave PCS control of approximately 39 percent of U.S. phosphate reserves, the largest in the industry, and made PCS the third-largest phosphate producer in the world. Similar consolidation activities by U.S. phosphate mining firms—such as the merger of IMC Global and Vigoro—created significant economies of scale within the industry. Several idle mines were purchased and reopened. IMC Global paid \$16 million to Agrifos Fertilizer LLC for its Florida-based Nichols Mine, including 6.6 million metric tons of phosphate rock reserves, in 2002. As of 2004, the firm operated five phosphate mines in Florida.

Industry firms also turned to advanced mineral processing technologies such as the WPPA manufacturing process. As a result, coupled with increased global demand for phosphate-based agricultural fertilizer, the outlook for the U.S. phosphate mining industry in the early 2000s was favorable. Asia, Oceania, and South America are all expected to see significant increases in phosphate consumption, and U.S. exports to those areas are forecasted to increase, according to the U.S. Geological Survey.

SIC 1479

CHEMICAL AND FERTILIZER MINERAL MINING, NOT ELSEWHERE CLASSIFIED

This category covers establishments primarily engaged in mining, milling, or otherwise preparing chemical or fertilizer mineral raw materials, not elsewhere classified. Establishments primarily engaged in milling, grinding, or otherwise preparing barite not in conjunction with mining or quarry operations are classified in **SIC 3295: Minerals and Earths, Ground or Otherwise Treated**; similar establishments preparing other minerals of this industry are included here. Establishments primarily engaged in producing salt by evaporation of sea water or brine are classified in **SIC 2899: Chemicals and Chemical Preparations, Not Elsewhere Classified**.

NAICS CODE(S)

212393 (Other Chemical and Fertilizer Mineral Mining)

INDUSTRY SNAPSHOT

Salt represents nearly half of all industry chemical and fertilizer mineral industry shipments. Consequently, the performance of the salt industry tends to reflect overall industry conditions. U.S. salt production between 2000 and 2003 declined from 45.6 million metric tons to 41.2 million metric tons, while consumption declined from 51.6 million metric tons to 50.1 million metric tons over the same time period. Because production was declining faster than production, the United States increased its reliance on imports to 23 percent of domestic consumption in 2003, compared to 16 percent of consumption in 2000. At the same time, exports declined from 1.12 million metric tons in 2001 to 500,000 metric tons in 2003.

ORGANIZATION AND STRUCTURE

The major products mined by the chemical and fertilizer minerals industry included salt, sulfur, barite, fluor spar, lithium, and strontium. Salt represents approximately 50 percent of the value of all industry shipments and is primarily produced in Louisiana, Texas, and New York. The second largest segment of the miscellaneous

chemicals and fertilizer minerals mining industry is sulfur, which comprises roughly one-third of the value of all industry products. The third largest product in the miscellaneous chemical and fertilizer mineral mining industry is barite, although it represents less than 5 percent of the value of all industry shipments.

CURRENT CONDITIONS

Salt. The United States was the world's largest producer of salt in the early 2000s, followed by China, India, Germany, and Canada. Twenty-nine U.S. companies operated 69 salt-producing plants in 15 states in 2003, producing salt in four basic forms: salt in brine (51 percent of all salt sold or used), rock salt (30 percent), vacuum pan salt (11 percent), and solar salt (8 percent).

There were roughly 14,000 end uses for salts, with the largest being chemicals (45 percent), road de-icing/ice control salt (31 percent), salt sold to distributors (8 percent), industrial uses (8 percent), agricultural salt (6 percent), food (including table salt, 4 percent), primary water treatment applications (2 percent), and exports/other uses (less than 1 percent). Along with limestone, coal, and sulfur, salt was one of the four most important minerals used by the chemicals industry. As early as 1939, salt was being used in the production of 74 industrial chemicals in the form of sodium and chlorine, and the largest U.S. salt mining or producing firms historically were operated by chemical companies that processed the extracted salt into commercial products. Salt was used by the chemical industries as a feedstock in the manufacture of chlorine and caustic soda, which was used to make everything from soap, dyes, and dairy products to glass, pulp, and paper. Other uses included water conditioning and treatment processes, textiles and rayon manufacturing, metallurgical applications, leather treatment, agriculture, refrigeration, meat packing, and fish curing.

U.S. salt producers accounted for 19.6 percent of the world's total production in 2003, and six industry firms accounted for the majority of all salt sold overseas: Akzo Nobel Salt Inc., Cargill Salt Co. and its affiliate Leslie Salt Co., North American Salt Co., Morton Salt Co., Western Salt Co., and United Salt Co.

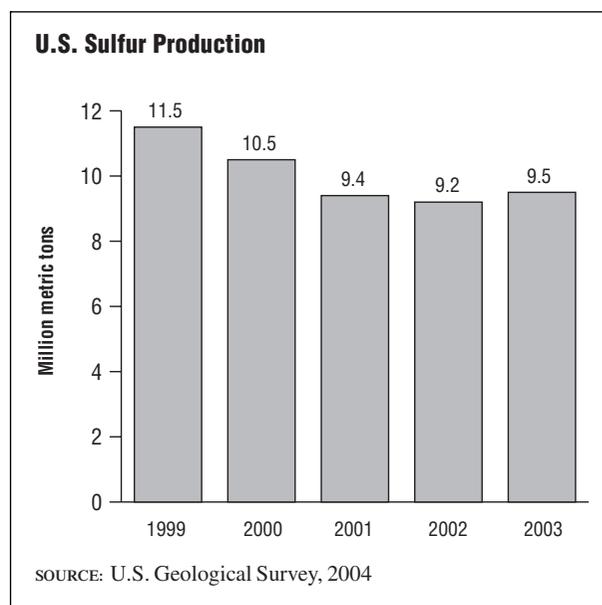

In 2003, 50.1 million metric tons of domestic and imported salt was used in the United States. In 1970, a total of 50 salt-producing companies had operated 95 plants in the United States. By 2003, several factors had reduced this industry segment to 29 companies and 69 plants. Among these factors were cheaper salt imports, intensified market competition, surplus production capacity, and high energy and labor costs. Among the major salt industry events of 1990s were the announcement of a joint venture between Continental Salt, Eastern Cargill Inc., and Petroquaimica de Venezuela, S.A. to produce

solar salt, and the decision by Akzo Nobel Salt Inc. not to replace its collapsed and flooded rock salt mine in Retsof, New York—the largest underground room-and-pillar salt mine in the hemisphere—with a new mine. Instead Akzo decided to sell virtually all its North American and Caribbean salt operations (valued at \$450 million) to agricultural giant Cargill Inc., strengthening Cargill in its struggle with Morton Salt for industry dominance. With sales of \$708 million, Morton Salt was the retail salt industry leader as of 2003.

In early 2000s, the United States remained the world's largest producer and consumer of sulfur, one of the four most widely used industrial minerals in the chemical industry. Unlike most other major mineral commodities, sulfur is primarily used not as part of a finished product but as a chemical reagent, namely, sulfuric acid, the most widely produced chemical in the United States. In 2003, 90 percent of all sulfur output was consumed in the form of sulfuric acid (**SIC 2819: Industrial Inorganic Chemical Manufacturing**), and it was used to make everything from insecticides, soaps, leather, and textiles to artificial fertilizers, paints, dyes, and paper. Roughly 70 percent of all sulfur consumed in the United States in 2003 was used in agricultural chemicals, mainly fertilizers, but also in the manufacture of a myriad of industrial products.

Sulfur. The world sulfur industry was divided into two categories: producers who extracted sulfur or pyrites as their primary mining objective, and those who extracted it solely as a byproduct of the mining of other minerals. In the early 2000s this indirect or “involuntary” production of sulfur accounted for almost three-quarters of the world's sulfur production. In 2003, 8.8 million metric tons of elemental or unrefined sulfur was produced by more than 160 operations in 32 states and U.S. territories. Three-quarters of the world's output of elemental sulfur was recovered from natural gas processing, petroleum refining, and coking plants. Thirty-nine U.S. companies in 26 states and U.S. territories produced recovered sulfur in 2002; they were led by ExxonMobil Corp., BP plc, ConocoPhillips Co., ChevronTexaco Corp., Shell Oil Co., Valery Energy Corp., and CITGO Petroleum Corp. Elemental sulfur was also produced using the Frasch hot-water method, in which native sulfur found in salt domes and sediment was melted underground and brought to the surface with compressed air. In 2000, however, Freeport-McMoRan Sulphur Inc. had shut down the last operational U.S. Frasch mine.

Barite. Barite production grew 14 percent in 2003 to 480,000 metric tons valued at \$14 million, compared to 540,000 tons valued at \$30 million in 1996. Barite mines operated primarily in Nevada and Georgia. Almost 95 percent of the barite sold in the United States in the early 2000s was used as a weighing agent in oil- and gas-well-

drilling fluids to maintain pressure and prevent blowouts. It was also used as a weighing additive in cement, rubber, and urethane foam and for metal protection and gloss in automobile paint primer and leaded glass, as well as a raw material in barium chemicals. It has found uses in everything from automobile brake and clutch pads, concrete vessels for holding radioactive materials, cathode-ray tube faceplates and funnelglass, as a filler in linoleum, paper, and rubber, as an ingredient in the manufacture of white pigment, inks, oil cloth, and leather, and in the production of glaze, enamels, detonators, and signal flares.

The United States increasingly relied on barium imports in the late 1990s and early 2000s. Between 1999 and 2003, barium imports grew from 66 percent of domestic consumption to 81 percent of domestic consumption. U.S. barium producers found it difficult to compete with the high-grade, low cost imports of foreign rivals. Nevertheless, U.S. production continued to grow as the onshore drill rig count climbed from 790 in July 1996 to 965 in August of 2002, fueling a need for fresh barium. However, most exploratory and development oil drilling occurred outside the United States in the early 2000s, and because it was not cost-effective to ship a low-unit-value commodity like barium overseas, the barium mining industry's future growth depended on the discovery of new gas reserves in the United States.

Other Minerals. Other minerals mined by industry firms in the 2000s included pyrites, fluor spar, lithium carbonate, strontium, wollastonite, natural wollastonite, and natural iron oxide pigments. Major end uses for fluor spar included lead, silver, copper and gold smelting, aluminum manufacturing, high-octane gasoline production, enamel manufacturing, refrigerant, plastics, and in-

secticide production, the manufacture of opaque glass and colored cathedral glass, and steel production (a single ton of steel requires approximately seven pounds of fluorspar). Lithium compounds have historically been used in roughly 20 industrial applications, including the production of synthetic vitamins, the manufacture of special-purpose alloys, use in aluminum lithium composite alloys for commercial and military aircraft, and in nuclear energy applications, among other uses. Spodumene, lepidolite, and amblygonite were mined by industry firms primarily for their lithium content. Almost 70 percent of strontium consumed in the United States was used in the manufacture of X-ray-blocking faceplate glass for television picture tubes. Celestite and strontiate were strontium-based minerals also mined by this segment of the industry. Other minerals mined in comparatively small quantities by industry firms included arsenic, brimstone, alunite, guano, marcasite, mineral pigment, ocher, pyrrhotite, and umber.

INDUSTRY LEADERS

The leader in the chemical and fertilizer minerals industry in the 2000s was Freeport-McMoran Inc., of Louisiana, with close to 15,000 employees and \$2.2 billion in 2003 sales. In addition to producing, distributing, and selling phosphate fertilizers—in which it was the leading U.S. firm—the company also explored for, mined, developed, produced, processed, transported, and marketed sulfur and other minerals, owned and operated laboratory and pilot plant facilities for analyzing minerals, performed metallurgical work, and conducted testing and research activities. Freeport-McMoran was founded in 1981 through the merger of Freeport Minerals Co. and McMoran Oil & Gas. To strengthen its mineral assets while lessening its dependence on the fertilizer market, in the 1980s CEO James Moffet had begun diversifying and expanding, investing more than \$1 billion in new sulfur reserves, adding geothermal properties and oil and gas assets, and opening phosphate mines in Florida. In 1988, however, two major mineral discoveries—a gold, silver, and copper mine in New Guinea and the world's second-largest sulfur discovery in history in the Gulf of Mexico—compelled Moffet to change course. To pay for the development of these sites, it sold its geothermal properties and part of its oil and gas, fertilizer, and gold properties, betting that the two discoveries were worth the risk in company capital. Moffet's bold move depended for its success on a resurgence in mineral prices, however, that, by 1996, had not yet arrived, and a lawsuit filed by New Guinea tribesmen claiming Freeport-McMoran had violated their land and culture put a crimp in Moffet's strategy. One investment firm had downgraded Freeport-McMoran to a "neutral" rating over the company's "high-risk" strategy, and Rene L. Latiolais had replaced Moffet as the company's CEO. In 1997

Freeport-McMoran was acquired by IMC Global Inc. at a value of \$748 million. The companies had collaborated in a prior partnership (IMC-Agrico) which made phosphate fertilizers. By the late 1990s, IMC Global was the third largest world producer of salt, behind Morgan Salt and Cargill. However, IMC Global, which posted 2003 sales of \$2.2 billion, agreed to merge with Cargill in early 2004.

SIC 1481

NONMETALLIC MINERALS SERVICES, EXCEPT FUELS

This category covers establishments primarily engaged in the removal of overburden, strip mining, and other services for nonmetallic minerals, except fuels, for others on a contract or fee basis. Establishments primarily engaged in providing geophysical exploration services for metal mines are covered in **SIC 1081: Metal Mining Services**. Establishments primarily engaged in performing oil and gas field geological exploration services are covered in **SIC 1382: Oil and Gas Field Exploration Services**.

NAICS CODE(S)

213115 (Support Activities for Non-metallic Minerals, (except Fuels))

541360 (Geophysical Surveying and Mapping Services)

In addition to performing contracted strip mining and overburden removal, industry firms perform general non-testing drilling and blasting, miscellaneous mining services, and prospect and test drilling. Industry firms also offer geophysical exploration services, sink mine shafts, and drain and pump mines—all on a contract basis and all within the nonmetallic minerals mining industry.

However, almost 60 percent of the industry's total receipts derive from for-contract mineral services performed by firms classified as mining rather than mining services companies and from industry firms too small to be canvassed by the Bureau of the Census. Among the largest firms in the industry in 2004 was GZA Drilling Inc. of Brockton, Massachusetts, a subsidiary of privately owned GZA GeoEnvironmental Technologies Inc.

The U.S. nonmetallic minerals mining industry was traditionally considered highly capital intensive. Before a mining firm could begin to consider establishing a mine at a site suggested as potentially viable by geological literature and maps, a complex range of activities had to be undertaken to ensure that a workable deposit of economically viable mineral existed at the location. Extensive exploratory and assessment activities were conducted; highly detailed maps were made of the prospective deposit; and costly and sophisticated equipment was brought in to test, dig, develop, work, and maintain the mining operation. Because most costs at a mine are fixed, the more ore that can be processed lowers the producer's total cost per ton. High-volume, highly efficient mineral extraction is thus crucial, and contractors in the mineral services industry play a key role in this process. Because smaller mining firms either did not have the capital resources to perform exploration and extraction activities or wished to restrict themselves to the operational side of mining, they turned to independent contractors who specialized in the techniques and technologies of mineral geophysics and mine engineering to perform a broad range of mining support activities.

Projects performed by these nonmetallic minerals service contractors prior to the actual working of a mine included analyzing the surface geology for outcroppings or other indications of the underlying mineral, as well as conducting geophysical surveying or mapping operations using aerial photography, satellite imagery, or seismic, gravitational, magnetic, electric, or other methods of geological analysis. Drilling or boring test shafts (usually with an electrical, gas-powered, or pneumatic diamond drill) helped determine if a "showing" of a desired mineral was actually and extensively located at the site. The extracted cores or "cuttings" from these tests were used to gauge the quality, subsurface shape and variation, depth of overburden (unwanted mineral, soil, or rock covering the deposit), geographical extent, and potential processability of the mineral at a deposit.

When the precise range and nature of the deposit was documented, nonmetallic minerals service firms might also be contracted to develop the mine by sinking shafts, boring mine tunnels, stripping and removing overburden, or blasting the deposit face with explosives to dislodge the mineral from underground, an open pit, or a shallow strip mine. Industry firms might also be retained to per-

form the actual mining of the mineral or to develop or maintain the mine.

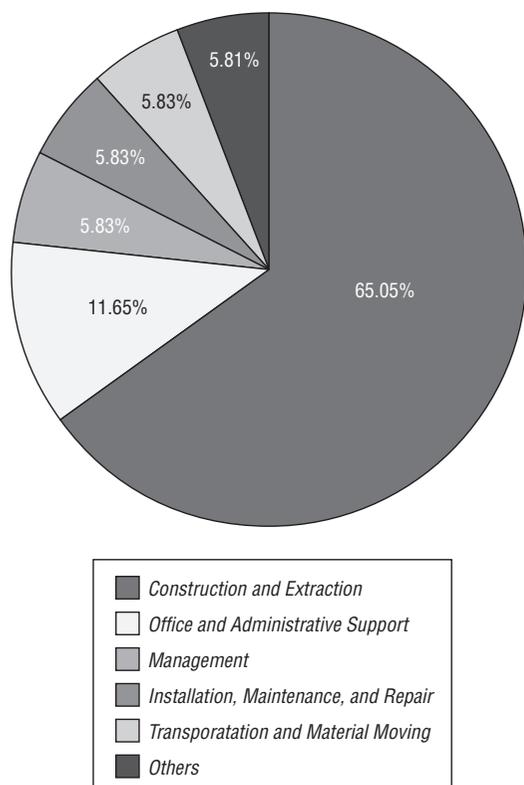

For example, many mines suffered from accumulation of subsurface water, surface runoff, or water associated with the mining operation itself. Industry contractors were often hired to install the draining or pumping infrastructure to prevent water from entering the operation and clear the mine of existing water levels. This facet of the industry activity alone could necessitate the installation and operation of a drainage system so complex that computer planning software would be required to assess the viability of networks containing as many as 20 drainage pumps, 50 regulators, and numerous line segments, valves, and fittings.

In the late 1990s and early 2000s, the nonmetallic minerals services industry continued to benefit from advances in sensing, automation, and computer technology. New unmanned "walking machines" loaded with cameras, sensors, and measuring equipment have enabled researchers to explore inhospitable terrain remotely and may prove to have applications in the field of mineral exploration. Space-age sensing and mapping technology have also enabled scientists to search for mineral deposits with much greater sensitivity and speed. The staggering growth in the power of computer microprocessors has also allowed scientists to collate and analyze enormous volumes of data about mineral structures, hazards, and resources that previously would have taken years to gather. Computer-controlled X-ray diffractometers can now determine a mineral's structure within a matter of minutes. The rapid advances in laser range-finding technology, three-dimensional digital mapping software, computer-aided design programs, and data acquisition and processing systems promised to give the mineral services industry new opportunities to provide the mining industry with precise data about the volume of material extracted, scrap volumes, topographical features of a deposit, and a host of other factors.

According to the U.S. Bureau of Labor Statistics, the nonmetallic minerals services industry employed approximately 1,030 people in the early 2000s. Employees earned an average wage of \$15.15 per hour. Construction and extraction workers made up the largest segment of employees, accounting for 65 percent and earning an average hourly wage of \$15.28. Office and administrative support personnel accounted for nearly 12 percent of industry employees and earned an average hourly wage of \$12.49. Managers accounted for another 6 percent of total industry employees, as did both transportation and material moving workers and installation, maintenance, and repair workers. Managers earned an average of \$29.61 per hour; installation maintenance and repair workers, \$14.40 per hour; and transportation and material moving workers, \$12.51 per hour.

SIC 1499

MISCELLANEOUS NONMETALLIC MINERALS, EXCEPT FUELS

This category covers establishments that primarily mine, quarry, mill, or otherwise prepare nonmetallic minerals, except fuels. This industry includes shaping natural abrasive stones at the quarry. Establishments that primarily produce blast, grinding, or polishing sand are classi-

fied in **SIC 1446: Industrial Sand**, and those calcining gypsum are classified in **SIC 3275: Gypsum Products**.

NAICS CODE(S)

212319 (Other Crushed and Broken Stone Mining and Quarrying)

212399 (All Other Non-Metallic Mineral Mining)

Some of the most economically significant minerals mined by industry firms included garnet, gemstones, graphite, gypsum, industrial diamonds, perlite, and quartz. Other minerals produced include asbestos, asphalt, burrstone, calcite, catlinite, corundum, cryolite, diatomite, emery, fill dirt, gilsonite, greensand, Iceland spar, meerschaum, mica, millstone, oilstone, ozokerite, peat, pipestone, pozzolana, pumice, pyrophyllite, rubbing stone, scoria, scythestone, vermiculite, whetstone, wollastonite, and wurtzilite.

Garnet was used primarily for industrial applications, particularly as an abrasive or as a filtration medium. Between 1999 and 2003, the United States shifted from a net exporter to a net importer of industrial garnet. Although consumption over this time period grew from 33.7 million metric tons to 58.9 million metric tons, production declined from 60.7 million metric tons to 38.7 million metric tons. Consequently, the United States became increasingly reliant on imports, which more than doubled between 1999 and 2003, growing from 12 million metric tons to 28.4 million metric tons. Australia accounted for 47 percent of U.S. imports; India, 35 percent; and China, 17 percent.

Three U.S. companies—two in New York and one in Idaho—produced garnet as of 2003. Production was valued at \$3.9 million that year. The United States was the largest consumer of industrial garnet in the world, and garnet was used for air/water blasting media (35 percent); water jet cutting (30 percent), which used concentrated, high-pressure water jets for precision cutting of metals; water filtration (15 percent); abrasive powders (10 percent); and composite materials, fabrics, and fiberglass. Demand for industrial garnet was expected to remain strong through the early part of the twenty-first century, due partly to growing demand in blasting markets.

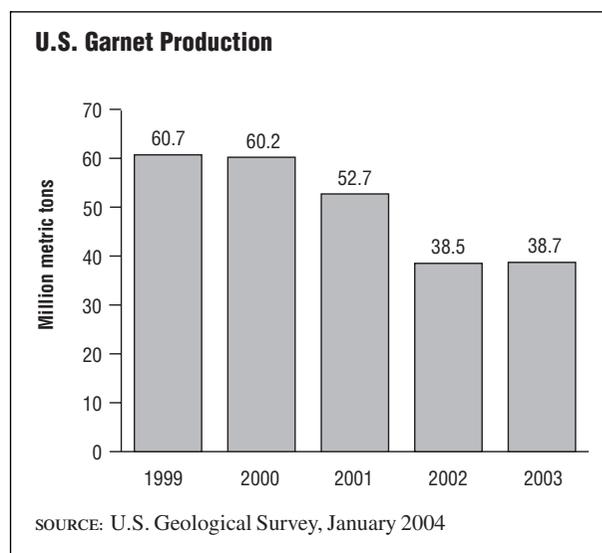

Minerals were defined as gemstones less by geological properties than by end use—any mineral or other material whose aesthetic qualities recommended it for decorative or ornamental uses could be called a gem stone. The terms precious and semiprecious described the relative economic value of gemstones and other minerals, and most gemstones fell into the precious stone category, including: jade, corundum (rubies and sapphires), diamond, quartz (including amethyst and agate), garnet, turquoise, and several stones not mined by industry firms.

U.S. production of natural gemstones was valued to be \$10.9 million in 2003, down from a high of \$17.2 million in 2000. Production declines were due in large part to decreased pearl and opal production, as well as to reduced domestic demand, the result of sluggish economic conditions. Though production of natural gem materials took place in every U.S. state, eight states produced 80 percent of the total output in 2003: Tennessee, Arizona, Oregon, California, Arkansas, Nevada, Idaho, and Montana. The United States produced less than 1 percent of total global output; however, it was the largest market for gemstones in the world, accounting for about 33 percent of world demand. Gem stone diamond production in the United States was virtually nil in the late 1990s as the nation's only commercial diamond mine, Kelsey Lake in Colorado, had stopped production. Eventually, the Kelsey Lake mine was sold to Toronto-based McKenzie Bay International.

Graphite is a soft, carbon-based mineral that is classified into two general types: natural and synthetic. Natural graphite is further subdivided into three types: flake, high-crystalline, and amorphous. In 2003, natural graphite was used for refractory applications (25 percent), brake linings (13 percent), dressings and molds in foundry operations (9 percent), lubricants (8 percent), and miscellaneous uses such as steelmaking (45 percent). Graphite consumption in the United States increased from 24,000 metric tons to 32,000 metric tons between 2002 and 2003. The United States relied on imports from China (33 percent), Mexico (24 percent), Canada (21 percent) and Brazil (6 percent) for its natural graphite supply, since it was not mined domestically in 2003. The majority of amorphous graphite came from Mexico.

The United States was the largest producer and consumer of gypsum in the world, contributing 15.2 percent of world output in 2003. Of the estimated 16 million tons produced domestically, the majority was used for the manufacture of wallboard and plaster products. Gypsum was also used for cement production, agricultural applications, smelting, and glassmaking. Growth in the construction industry led to increased demand for wallboard in the late 1990s and early 2000s. The majority of crude gypsum was mined by three companies—USG Corp., which filed for Chapter 11 bankruptcy protection in 2003 due to asbestos litigation costs, National Gypsum Co., and Georgia-Pacific Corp.

Industrial diamonds were crystallized carbon of a quality and color unsuitable for decorative gem stone use. Industrial diamonds generally ranged from yellow-brown to black in color and because of their hardness, diamonds found applications in virtually every major manufacturing industry. The United States produced about 236 million carats in 2003, compared to 140 million carats in 1998, and was a leading producer of synthetic industrial

diamonds. Du Pont Industrial Diamond Division and GE Superabrasives were the only two U.S. companies that produced synthetic industrial diamonds in 2003. The United States was also the leading consumer of industrial diamonds, and in 2001 consumption increased to a record high of 405 million carats, although this had declined to 398 million carats by 2003. Industrial diamonds were used by such U.S. industries as construction, computer chip production, mining services, transportation systems, and machinery production.

In 2003, domestic processed perlite production was 512,000 metric tons with a value of \$19.2 million. Since the 1999 peak of 711,000 metric tons, perlite production had decreased steadily in the United States. Imports of perlite increased from 144,000 metric tons in 1999 to 240,000 in 2003, which helped to offset declining domestic production. Eight companies operating 10 mines in seven states in the West produced crude ore, with the majority of domestic production coming from New Mexico. Processed ore was produced at 63 facilities spanning 30 states. The primary uses of perlite in the early 2000s included building construction (64 percent), horticultural aggregate (13 percent), filter aids (9 percent), and fillers (9 percent).

Quartz was one of the most common minerals that found many industrial and decorative applications. Large flawless quartz crystals were used to make radio circuits, radar, television, telephone circuits, ultrasonic equipment, and quartz oscillator plates in electronic products; as prisms, wedges, and lenses in optical spectrographs, microscopes, and other optical instruments; and as an abrasive in glass and refractory brick production. Crystalline quartz, including clear quartz, rose quartz, and yellow quartz, was used for decorative carvings and semi-precious stones. Amethyst and agate were quartzes used as gemstones.

Most of the quartz crystal used in the manufacture of electronics goods were cultured quartz crystals as opposed to natural crystals. The United States stopped mining lascar, which was used to produce cultured quartz crystals, in late 1997; however, four domestic companies continued to produce cultured quartz crystals using imported, mostly from Brazil, and reserved lascar. The continued growth of the U.S. consumer electronics market was expected to keep demand for quartz crystal strong.

CONSTRUCTION INDUSTRIES

SIC 1521

GENERAL CONTRACTORS—SINGLE-FAMILY HOUSES

The category covers general contractors primarily engaged in construction activities (including new work, additions, alterations, remodeling, and repair) of single-family houses.

NAICS CODE(S)

233210 (Single-Family Housing Construction)

INDUSTRY SNAPSHOT

Traditionally quite fragmented, in 2000 the single-family housing construction industry consisted of 151,296 establishments that employed 713,300 workers, according to the U.S. Census Bureau's *Statistical Abstract of the United States*. The top 400 housing construction contractors accounted for less than 33 percent of the national market. In 2000 there were 1.2 million new housing starts. A boom in the housing industry pushed new housing starts up in 2003 to an estimated 1.6 million.

The single-family home construction industry comprises general contractors who are primarily engaged in building, remodeling, and repairing houses. Included in this industry classification are prefabricated housing assembled on-site and town-house construction. The single-family home construction industry is vital to the U.S. economy; it supplies jobs, tax revenue, and housing for Americans. During the early 2000s, the U.S. economy slumped into recession. However, low interest rates and the value of real estate as a relatively safe investment spurred housing construction. Although all other con-

struction was sluggish at best, housing construction remained robust.

The rate of home ownership reached a record 67 percent of U.S. households in 1999, a figure that was expected to reach 70 percent by 2010. However, declining numbers of people will be entering the prime home-buying ages of 25 to 45 following the aging of the baby boomers during that period. Moreover, a decreasing proportion of this age bracket was purchasing homes; despite rising income levels among those 25 to 45, more people than ever opted to live in apartments. This shift was attributed mostly to lifestyle changes among younger people entering the housing market, who tended to prefer living in proximity to entertainment venues and shopping.

Furthermore, the rising costs of land, labor, and materials were among the primary challenges to single-family homebuilders at the beginning of the twenty-first century. Drywall and lumber prices, which tend to be somewhat unstable, were particularly inflated, while increases in land costs have been less pronounced, though some strong markets, especially in southern cities, have experienced significant escalation. Meanwhile, the shortage of skilled labor was viewed by some analysts as the most pressing concern facing the industry as it entered the twenty-first century.

ORGANIZATION AND STRUCTURE

The single-family housing construction industry is unique for an industry of its size because it is highly fragmented and dispersed. The typical home is built by a contractor who produces fewer than 25 houses each year, while about half of all industry employees work at firms with less than 20 workers. While some larger contractors maintain building operations in a number of sectors, about 75 percent of establishments engage only in single-

family housing construction. These firms also account for 55 percent of industry employees.

Nonetheless, in alignment with most industries in the 1990s, single-family construction was rapidly consolidating. The top construction firms on *Builder* magazine's "Builder 100" list have continued to expand their market share throughout the decade, particularly toward the late 1990s. The top five single-family contractors have accelerated their market share the fastest, achieving 30 percent of the top 100's share in 1997, compared with 21 percent two years earlier. Altogether, the five largest contractors generated revenues of \$14.9 billion in 1998, up from \$11.3 billion in 1997.

The relative, though diminishing, lack of concentration in the industry reflects the labor intensity and logistical complexity characteristic of on-site homebuilding. Regional and state building codes, trade unions, demographics, and environmental regulations combine to make the competitive structure of each local market unique. Many workers from various trades must be coordinated to complete a home. Moreover, many construction materials are less expensive when purchased regionally. Finally, the localized nature of housing markets prohibits many national economies of scale.

Since the 1980s, the South and West have proved the most fertile ground for new housing construction. The leading states for single-family construction in 1997 were California, with 13,000 establishments generating sales of \$18.1 billion; and Florida, with 6,740 establishments engaging in work valued at \$12.1 billion. Other leading states included Michigan, New York, and Texas.

Large contracting companies that do compete nationally are often relatively decentralized—consisting of generally autonomous regional operating companies. The various units of the corporation benefit from financial strength, as well as geographic and market diversification. The few contractors that compete overseas usually do so through foreign-owned subsidiaries. Although U.S. manufacturers sell and ship significant amounts of manufactured housing to countries such as Mexico, the homes themselves are usually assembled and finished by foreign contractors.

General contractors in the industry operate in a variety of ways. Some contractors actually purchase property and perform all construction work themselves. In other cases, a general contractor may be hired by a developer or landowner to provide construction services. General contractors commonly subcontract some or a majority of building activities to other firms. In any case, the general contractor is ultimately responsible for the finished product.

Products and Services. Two broad categories of homes are constructed or assembled on-site by the industry—

attached and detached. Attached homes, commonly called town houses, can be owned by their occupants rather than rented. They are similar in construction to some apartment rental complexes, but town houses are separated from adjoining units by a ground-to-roof wall. In contrast to rental facilities, attached homes also have completely separate utilities and do not share infrastructure.

Detached homes are usually built on a lot that is owned by the same party that possesses the house. They typically have front, back, and side yards and are more expensive than attached homes. In 1998, 1.03 million detached homes were constructed, accounting for more than 90 percent of the single-family market. Approximately 8 percent of these homes were manufactured houses, which means that they were almost completely manufactured off-site, shipped to a lot, and assembled by a general contractor. Only the on-site assemblage of the home is classified as a single-family home construction activity.

Manufactured homes are typically smaller and less expensive than site-built homes. Because of federal manufacturing regulations, however, these units must conform to building codes that are stricter than those imposed by many local governments for site-built housing in a similar price range. Furthermore, quality control is often higher for manufactured homes, because they are built in a controlled, factory environment. Though they were conceived by the mobile home industry, manufactured homes in the 1990s bear little resemblance to earlier mobile homes—which were often temporary-sited and cheaply constructed.

Many builders of both detached and attached homes employ a systems approach to building, which represents a hybrid of site-built and manufactured housing. This type of housing is also referred to as component or prefabricated housing, because large components of the home are built in a factory and designed for quick and easy assembly on-site. The four types of systems-built housing include pre-cut homes, for which all lumber and materials are shipped to the site already cut; panelized homes, for which the main wall panels are shipped to the site—often with plumbing and wiring already installed; sectional homes, which are more than 90 percent complete when they leave the factory, and have cabinets and flooring already installed; and log homes, which are essentially factory-made kit homes. Furthermore, half of the new, larger manufactured homes currently built are placed on privately owned, scattered building sites, and into housing subdivisions.

In addition to new home construction, single-family home contractors also are engaged in maintenance-and-repair and home improvement work. Maintenance and repair included painting, mudjacking, replacement of ap-

pliances, and similar work. Improvements consisted of additions and alterations to existing structures involving major interior and exterior changes. Replacement of major items, such as furnaces and water heaters, is also considered home improvement. Americans spent a record \$121 billion on home improvements in 1998. As baby boomers reach middle age, Americans are staying in their homes longer than they did previously. The median number of years Americans remain in one home in 2003 is 13 versus 10 a decade ago. Nearly two-thirds of the dollars Americans spend on home improvements is targeted for optional upgrades, such as kitchens, bathrooms, and family rooms, rather than for repair work. In 1989 the split was approximately 50-50.

Financial Market Influence. The single-family home construction industry is extremely susceptible to changes in economic factors and financial markets. There is a significant and direct negative correlation, for example, between federally controlled interest rates and the volume of new homes under construction. When the interest rate attainable on mortgage loans is low, housing starts are relatively high because of increased affordability. For example, a \$100,000, 15-year home loan requires a buyer to make monthly payments of \$899 per month, when the interest rate is fixed at 7 percent. When the interest rate rises to 12 percent, however, that monthly payment jumps to \$1,200. In such an environment, builders will have to offer incentives to increase sales. As a result, the housing industry, like mortgage rates, is highly cyclical.

In addition to interest rates, contractors are also affected by consumers' access to capital. For this reason, several government sponsored enterprises, as well as private companies, make up the secondary mortgage market. This market consists of investors who buy mortgages from primary lenders, such as banks and thrifts, so that the lenders can use that money to make new loans. By backing mortgage loans, as well as mortgage securities created from pools of loans, the government helps to insure a steady supply of capital to build, maintain, and improve housing.

BACKGROUND AND DEVELOPMENT

During the nineteenth and early twentieth centuries, when a large majority of Americans lived in rural areas, people who could afford to build a home often acted as the general contractors in the construction of their own home. They hired local builders and tradesmen with money that they had saved or borrowed from family members. Few regulations existed to insure structural soundness or safety of new homes, and little long-term financing existed for prospective homeowners. Indeed, by the time the Great Depression hit, less than half of all U.S. families owned a home.

In an effort to increase home ownership, the Federal Housing Administration (FHA) was created in 1934. By insuring home mortgages, the FHA made it possible for banks to make relatively low interest loans to home buyers. By the early 1940s, Americans were building about 100,000 new homes each year. Outdated and often lacking basics, such as indoor plumbing and electricity, however, nearly half of the homes in the nation were considered substandard. Furthermore, most families still could not afford to buy a home, choosing instead to rent housing or live with family members. In 1942 the United States home ownership rate stood at approximately 46 percent.

The housing environment began a radical transformation in the mid-1940s for several reasons. Most important, much of the demand that had existed for new housing during World War II had gone unmet, as the country poured its resources into fighting a war. When soldiers returned home and started families, housing demand ballooned even further. The number of U.S. births leapt from less than 3 million in 1945 to about 3.75 million in 1947.

Coinciding with the jump in demand was the development of the Veterans Administration Home Loan Guaranty Program in 1944. Using a Veterans Administration (VA) loan, war veterans were able to obtain mortgage loans with little or no down payment. Besides insuring VA and FHA loans, the federal government also set a maximum interest rate that lenders could charge. Credit and tax policies, such as tax-deductible mortgage interest payments, were also used by the government to spur home ownership. Furthermore, the National Housing Act of 1949 set a national goal of providing "a decent home and suitable living environment for every U.S. family." As a result of government incentives and strong demand, both single and multi-family housing starts boomed—skyrocketing from 139,000 in 1944 to 1.9 million by 1950.

Throughout the 1950s and 1960s, as the postwar economy flourished, families flocked to the housing market in a buying frenzy. Thousands of tract subdivisions were built on the perimeter of urban America—typically offering quality detached homes for less than \$10,000 in the 1950s, with mortgage payments of less than \$100 per month. Indeed, during the 1950s and 1960s an entire suburban culture emerged. Enormous street grids with identical homes in the early 1950s soon gave way to more elaborate and attractive neighborhood layouts that offered a variety of Cape Cod and ranch style home designs. Split-level homes and garages also became dominant features in many communities.

In addition to the rise in the number of U.S. homes in the 1950s and 1960s, housing quality improved. Besides new federal and state regulations that mandated structural integrity and uniform infrastructure, new construction

techniques increased home quality and affordability. Component construction, for instance, let builders efficiently erect large numbers of units. Plywood replaced expensive boards, and drywall was introduced as an improvement to lath and plaster construction. Portable generators, power trowels, backhoes, and other heavy equipment allowed contractors to realize massive productivity gains. Although less than 2 percent of homes in 1960 had air-conditioning, almost all new homes sported indoor plumbing, central heat, electricity, and gas. Furthermore, most newer homes in the 1960s had more than one bathroom.

Despite cyclical downturns caused by interest rates and energy prices, the housing industry remained healthy throughout the 1960s and 1970s. For instance, although single-family housing starts dropped by 50 percent in 1966 to about 800,000, they peaked in 1972 at about 1.3 million. After falling to approximately 850,000 in 1975, housing starts rose to more than 1.4 million in 1977. Despite increasing land and construction costs, housing starts in general surged in the 1970s, as baby boomers matured and began buying homes. In the 1970s housing prices outran inflation by an average of 3 percent per year. By 1980 the U.S. home ownership rate had risen to more than 65 percent.

While the number of Americans owning their own home had steadily risen during the 1970s, housing quality and construction productivity also advanced. Fiberglass and plastic products—used for everything from bathroom fixtures and plumbing to siding—helped to allay the impact of rising material and energy costs. Furthermore, by 1979 the share of new homes that offered central air-conditioning had risen to more than 60 percent. Most important, rising energy costs had caused builders to increase the efficiency of their products with better windows and doors, insulation, and heating and cooling equipment.

The 1980s and 1990s. Although contractors began construction on nearly 1.2 million new homes in 1979, the industry was devastated in the early 1980s by soaring interest rates. As mortgage rates skyrocketed past 16 percent, housing starts collapsed to 705,000 in 1981 and then to only 663,000 during 1982. Many builders filed for bankruptcy in the severely depressed market. Contractors who survived the shakeout, however, were greeted by falling interest rates in 1983 that continued through 1987. Single-family housing starts lurched 62 percent in 1983, to about 1.1 million. Throughout the mid-1980s, in fact, new home construction inched upward to nearly 1.2 million starts by 1986.

Despite apparently healthy construction activity in the 1980s, single-family home contractors were failing to achieve growth rates attained in the three previous dec-

ades. Several factors indicated that the industry was declining. Of immense importance, the affordability of housing for younger buyers began slipping—after peaking in 1980. Although the total home ownership rate only declined from 65.6 percent in 1980 to 63.9 percent in 1990, the rate for the population in the 30 to 34 age bracket plummeted from 61.1 percent to 51.8 percent. Furthermore, the ownership rate for 35- to 39-year-olds fell from 70.9 percent to 69.8 percent during the 1980s. The ownership rate for the 25- to 29-year-old age bracket recessed even more.

To make matters worse, housing starts began slowly declining in 1987, as interest rates edged upward, and the U.S. economy began to fall into a recession. Despite the government's lowering of mortgage rates in 1990, housing starts quickly plummeted to 895,000 in 1990 and to only 840,000 in 1991. In addition, contractors were also battling rising expenses associated with burdensome regulations and material costs. Although the generally distressed industry forced many builders across the nation into bankruptcy, contractors in some regions of the country fared much worse than others.

After a five-year decline in housing starts—one of the longest in U.S. history—the single-family home construction industry experienced a relatively weak recovery in 1992. The early 1990s housing slump differed from past slowdowns, since the recession in the early 1990s hit upper- and middle-income white-collar wage earners—the bulk of the housing market—the hardest. Earlier recessions had a greater impact on blue-collar workers (who are more likely to rent). In addition to job losses, construction loans for builders remained suppressed throughout the early 1990s. Total construction lending by commercial banks, for instance, declined more than 40 percent between 1989 and 1992. Small construction companies that supply the large majority of U.S. homes were especially crunched by tight credit.

Contractors were especially disappointed by weak growth in 1991 and 1992 in the area of remodeling and repair expenditures, which are traditionally relatively impervious to cyclical downturns. Although new home construction generally drives the industry, remodeling and repair contracts had grown during the 1980s to account for more than 45 percent of the value of all single-family home construction.

One impetus for the rapid consolidation of the single-family home-contracting industry was the parallel consolidation that has characterized lumber and building material (LBM) dealers. Builders recognized that by pooling resources they were more easily able to demand better pricing deals, thus maintaining leverage over suppliers. LBM dealers followed suit using the same logic, thus producing a self-replicating trend. While small, localized contractors tend to enjoy relative stability in their

immediate markets, mid-sized contractors found it increasingly difficult to establish economies of scale. Thus the mid- and late 1990s witnessed these firms' increasing absorption into their larger competitors, who were more capable of hedging against increases in material and labor costs, the prime factors holding the single-family home construction market in check in the late 1990s. Analysts agree that the wave of consolidation is not likely to break in the near future. Smaller and niche custom builders can remain healthy, however, only when the economy continues to grow.

The industry's previous stabs at consolidation were less than spectacular, with firms quickly realizing diminishing returns after 10,000 homes built. Leading firms in the late 1990s combated this tendency by decentralizing managerial structures to allow for greater autonomy at the local levels within the organization.

The market for professional remodeling continued its strong showing for the 1990s, worth \$40 billion in 1998 and expected to reach \$45 billion by 2003. A good portion of this success was owed to demographic trends. Whereas the home building market of the early 1990s was driven by the tendency for consumers to "downsize" to smaller homes, particularly as baby boomers' "empty nests" led them to abandon their larger homes, the strong economy of the late 1990s produced many more customers for building additions and remodeling.

Factory-built homes also registered strong growth. These buildings, alternately called systems-built or modular homes, incorporate building methods that are virtually identical to those of standard detached homes, but that occur in a factory, thus avoiding weather-related delays. Modular homes are shipped to the site in fewer than 10 pieces before construction is finished on-site. Modular homes often weigh as much as 30 percent more than conventional homes. Most modular homes can be completed in 30 to 60 days; however, they are still a small market sector, totaling only 8 percent of all homes built in 1997.

In 1998 the average interest rates on 30-year fixed-rate mortgages fell to 6.94 percent, down from 8.36 percent in 1994 to reach the lowest level since the early 1960s. Mortgage originations reached a record \$1.5 trillion. As a result, more households could claim the income necessary to purchase their own home. The housing market has thus responded in kind. Meanwhile, houses themselves continued to grow. The average new home in 1999 covered 2,190 square feet, compared to 1,645 square feet in 1975 and 2,095 in 1995. An estimated 31 million homes exceeded 2,400 square feet or larger by 1998. The average size of a single-family home lot was 13,795 square feet. The median home price in 2000 was \$135,000.

Finally, the growing numbers of new homes also included a greater range of features. In 1997 about 82 percent of new homes had central air-conditioning, and 78 percent had at least a two-car garage; 50 percent of the homes had at least 2.5 bathrooms, and about 69 percent had fewer than four bedrooms; about 80 percent of all new homes were built in metropolitan areas. Thirteen percent lacked garages or car ports, but 61 percent were equipped with a fireplace, 37 percent with a basement, and half had two or more floors. Nearly two-thirds were fueled by gas, 32.2 percent by electricity, and only 2.7 percent by oil.

Regional Differences. Despite strong overall business in the single-family housing industry, some regions experienced stronger growth rates in housing starts in the late 1990s. In 1999 sales increased in all regions except the Northeast. Midwest housing sales increased by 5 percent, while those in the South and West experienced a 2 percent growth. Total housing starts in 1997 were broken down by region as follows: the South started 630,000 new home projects, the West 335,000, the Midwest 292,000, and the Northeast 127,000. The generally more built northeastern market faced higher taxes relating to land development and building. Seventy-five percent of households in the rural United States are homeowners.

Rising Costs. Escalating construction costs, attributable to a variety of factors, were a primary cause of declining home ownership among younger Americans in the mid- and late 1990s. One reason that costs were rising was a jump in the price of land, materials, and labor necessary to build homes. The cost of materials for single-family home contractors totaled \$42 billion in 1997. In addition, more restrictive land regulations increased land costs, largely a result of emerging antigrowth initiatives to combat urban sprawl and environmental degradation that have reached U.S. legislatures. In general, land prices have increased less dramatically than those for building materials, though stronger markets have achieved double-digit growth. Meanwhile, indeed, costs associated with new impact fees, building codes, environmental rules, safety laws, and other regulations were increasingly squeezing contractors, especially mid-sized firms.

Builders also suffered from bloated costs associated with the tight labor market and the scramble to find a shrinking number of skilled laborers, including managerial workers. In addition to wages, the cost of complying with federal worker safety regulations in the late 1990s often exceeded \$1,000 for a 2,200-square-foot home.

After the deregulation of the thrifts, the traditional source of financing for home builders, culminated in the Savings & Loan crisis of the 1980s and 1990s, home builders were forced to seek alternative financial sources. In recent years, they have tended to settle on the stock and

bond mortgages, where the lucrative business in the 1990s is expected to cool but remain stable in the early 2000s. This development has been particularly beneficial to large firms with greater capital pools and the geographic reach to concentrate business in regions with strong local economies.

While an aging population was expected to prove a boon to housing construction well into the 2000s, fewer younger people were entering the single-family housing market. Moreover, younger professionals were increasingly opting to live in apartment complexes. The homeownership rate among those aged 25 to 34 was expected to remain fixed at about 45.6 percent until 2010. For those between the ages of 35 to 44, the rate was likely to increase only marginally, from 66.1 percent in 2000 to 67.9 percent in 2010. The expected rate improves among older demographics. Meanwhile, minority groups watched their homeownership rate increase; about 45 percent of all African-American households were homeowners in 1998, up from 43 percent in 1994, while Hispanics' homeownership rate increased from 42 percent to 45 percent in that period.

With fewer households forming, it would seem likely that housing starts would, in turn, be affected negatively. While the new household projections from the Census Bureau seem to justify a lower level of housing starts, the housing market is more complicated than a simple one-to-one relationship with household formations. For example, regional shifts in the population require that homes be constructed where the population is moving. In the 1990s there was a dramatic population shift toward the South and West, a trend expected to accelerate well into the 2000s. This movement will justify a larger number of starts in these areas than the national household statistics might suggest.

CURRENT CONDITIONS

New housing construction remained a bright spot in the economy during the early 2000s. While industrial and commercial activity declined, housing construction continued to grow. Extremely low mortgage rates, combined with the safety of real estate investments, provided fertile ground for the industry during a period of time marked by economic recession and instability caused by political volatility in the Middle East.

Housing starts increased from 1.2 million in 2000 to an estimated 1.6 million in 2003. Growth in the industry is expected to level off after 2003. Even under improving economic conditions, a modest reduction can be expected because demand has been eased by the high number of new starts, and mortgage rates are expected to inch back up. Nonetheless, forgoing any unforeseen economic events, such as a large increase in interest rates or a

sudden jump in unemployment, housing construction should remain a healthy industry in the near future.

A very fragmented industry, the single-family housing construction industry is showing signs of consolidation, as large building contractors target smaller operations. Although *Professional Builder* rejected as outlandish Andersen Corporate Finance analyst Paul F. DeCain's prediction that by 2011 the top 20 builders would control 75 percent of the housing market, the publication did predict that the industry would continue growing through acquisitions and mergers, noting: "For most of the past decade, the public Masters of the Universe—especially the big five at the top, all with more than 25,000 completions a year—have grown by acquiring smaller local or regional production builders that offered strong share positions in new markets, often hot markets with impressive annual housing starts."

Despite continuing consolidation, the contracting market continues to remain highly diversified. Most residential building companies are considered small by Wall Street standards. Of the top 20 companies, 17 are publicly traded. Centex, Pulte, and Lennar, each of which generate more than \$7 billion in revenues and 30,000 closings annually stand above the crowd at the top three positions in market share.

INDUSTRY LEADERS

The largest builder of single-family detached homes in the United States in 2002 was Centex Corporation, which reported revenues of \$9.1 billion in 2002, though not all of this derived from the single-family homebuilding sector. Established in 1950, Centex employs 16,200 workers and also engages in financial services related to construction.

The second largest homebuilder was Pulte Homes, headquartered in Arlington, Virginia. Although the company also builds duplexes, townhouses, and condominiums, single-family homes account for 85 percent of revenues. In 2002 Pulte reported revenues of \$7.5 billion and employed 9,200 employees.

Lennar Corporation, with \$7.3 billion in sales and 9,400 workers, ranks just behind Pulte Homes. Other leading single-family home contractors in 2002 included D. R. Horton, with revenues of \$6.7 billion; KB Home (formerly Kaufman & Broad Home Corporation), with revenues of \$4.9 billion; and Ryland Group, with sales of \$2.9 billion.

WORKFORCE

About 768,000 workers were involved in general contracting for single-family construction in 2001, including 246,800 carpenters, who earned an average of \$16.75 an hour. Construction laborers totaled over 84,000 and earned a mean hourly wage of \$12.50. Gen-

eral operations managers, numbering 21,750, earned a mean annual salary of \$74,160.

RESEARCH AND TECHNOLOGY

Housing contractors have been quick to incorporate the latest technology into their operations. In the late 1990s, the use of computer-aided design (CAD) and "virtual models" to optimize design and construction greatly streamlined the building process.

Steel producers were aggressively positioning themselves to establish inroads in the construction market. While only 50,000 steel-framed homes were built in 1997, the steel industry is aiming for a 25 percent market share by 2003. Steel costs are generally higher than those for wood (about \$3,000 more for a 2,000 square-foot home). However, while wood prices were rising quickly in the late 1990s and generally tend to fluctuate, steel prices remain fairly stable.

Industry advances in productivity and technology since World War II created vast improvements in the quality, integrity, and comfort of housing. The percentage of new homes with more than 2,400 square feet, for example, increased from 11 percent in 1977 to 31 percent by 1997. During the same period, the percentage of new houses with a garage for two or more cars jumped from 60 percent to 78 percent. Likewise, 50 percent of all new homes had two-and-a-half or more bathrooms in 1995, compared to 23 percent in 1977, while central air-conditioning was featured in 82 percent of new homes, up from 54 percent in 1977.

Builders have also been able to improve housing through the use of cheaper and stronger materials, such as plastics and alloys. Bathtubs and sinks made of cultured marble generated huge savings for buyers. Integrated energy and communications systems have allowed significant gains in energy efficiency. Between 1980 and 1987, new systems and insulation helped to decrease average household energy consumption from about 140 million BTUs to less than 120. Other amenities, such as electric garage openers and security systems, have added to home quality as well.

GENERAL CONTRACTORS— RESIDENTIAL BUILDINGS, OTHER THAN SINGLE-FAMILY

This industry consists of general contractors primarily engaged in the construction of residential buildings other than single family homes. This type of construction includes new work, additions, alterations, remodeling, and repair of such establishments as apartment buildings, dormitories, and hotels and motels.

NAICS CODE(S)

233320 (Commercial and Institutional Building Construction)

233220 (Multi-Family Housing Construction)

INDUSTRY SNAPSHOT

Multifamily residential construction enjoyed strong sales and a promising market for new projects in the late 1990s as the U.S. economy maintained its voracious ex-

pansion. And even when the economy began to falter at the turn of the twenty-first century, multifamily residential construction continued to do well, despite the increase in home ownership spurred by low interest rates. Demand for multifamily housing was expected to increase by 1 percent annually until 2010.

After apartment construction had outpaced demand through the early and mid-1990s, resulting in increased vacancy rates, contractors were forced to scale back new starts and derive greater shares of revenue from remodeling and repairs, a market that was expected to maintain its strong growth for years to come. By the end of the decade, however, demand had resurfaced, leading to a resurgence of new building activity. This activity continued into the early 2000s. New apartment starts in 2003 increased by 2.8 percent to 316,000 units, although this paled in comparison to the record 1.49 million single-family housing starts, which reflected 10.3 percent growth that year.

Hotel construction, meanwhile, remained a notoriously volatile sector. In the early 1990s, construction spending had reeled from a recession, dropping 35 percent in 1991 and another 47 percent in 1992. By 1995 the sector had dusted itself off and regained its healthy position in the construction industry, reaching \$6.4 billion. Total spending for hotel construction reached \$17.0 billion in 1999, up from \$14.9 billion in 1998, and was particularly strong in the luxury hotel market. Analysts familiar with gluts in this market sector, however, had expected that hotel building would cool, as did the U.S. economic expansion, and they proved correct. Along with the impact of the economic slowdown, the terrorist attacks of September 11 drastically reduced U.S. travel, and by 2003, hotel construction had reached its lowest point in industry history, a full 53 percent below its record high in the late 1990s. According to a PricewaterhouseCoopers report, hotel occupancy rates will increase from 59.1 percent in 2002 to 61.6 percent in 2005 as the U.S. economy recovers.

Leading multifamily construction markets in 2004 were located mostly in the South or West: Dallas, Texas; Orlando, Florida; Houston, Texas; Atlanta, Georgia; and Seattle, Washington. Hotel construction, meanwhile, has been strongest in the Pacific and mid-Atlantic regions, while trailing off in the south, central, and mountain regions. The states with the greatest concentration of multifamily construction companies include New York, California, Florida, and Texas. Of the 295,429 multifamily permits issued in 2001, the south Atlantic region of the United States accounted for 92,200 of them, while the Pacific Coast accounted for 44,287. The Rocky Mountain states saw a 16.6 percent growth in the number of permits issued, which grew to 37,912. The New England states experienced 13 percent growth, reaching 4,948 permits.

The rising costs of land, labor, and materials were among the primary challenges to multifamily contractors at the onset of the 2000s. Drywall and lumber prices were particularly alarming, while increases in land costs have been less pronounced, though some strong markets, especially in southern cities, have experienced significant escalation.

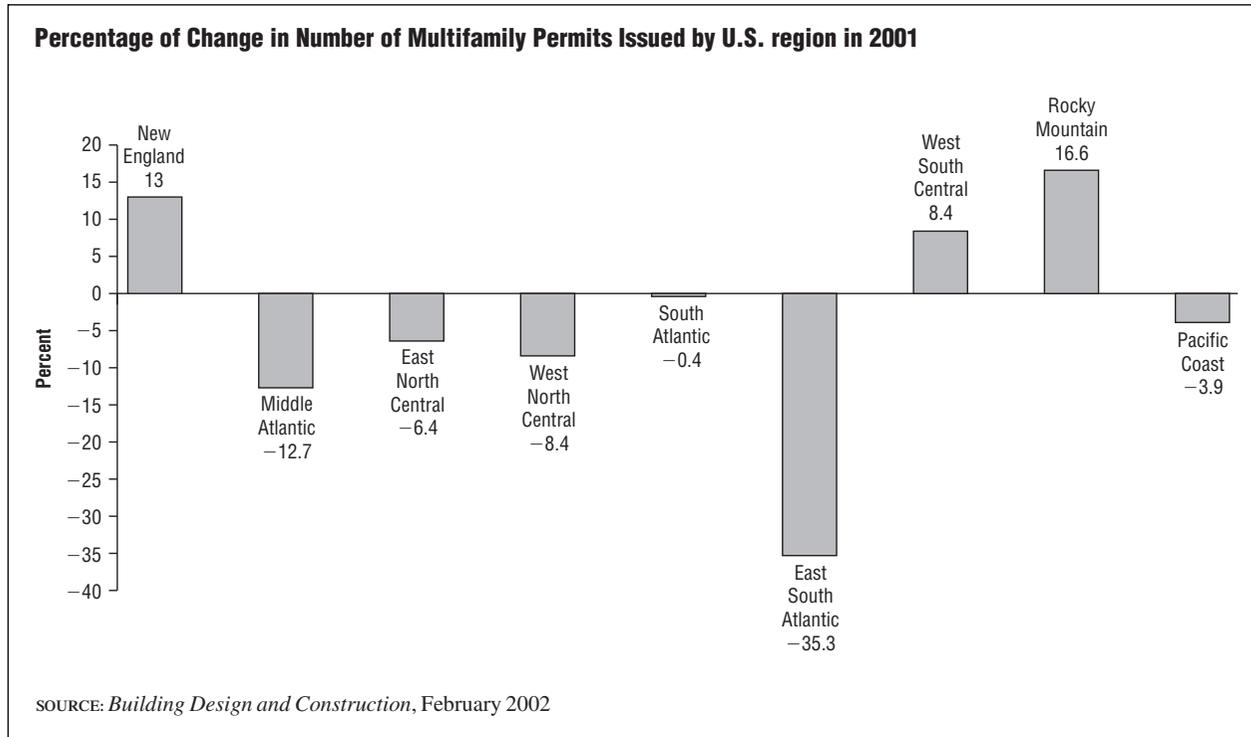

ORGANIZATION AND STRUCTURE

General contractors are licensed professionals who agree to arrange a project in agreement with certain plans, specifications, and other related documents. A written contract usually documents the specific terms. The responsibility of a general contractor extends to every aspect of construction, except those items so designated within the contract documents. General contractors are frequently referred to as builders; however, a developer or owner is also commonly referred to as a builder. Therefore, for purposes of understanding, a general contractor is one who contracts with owners to construct the owners' projects.

Multi-unit housing consists of two or more unit structures and includes apartment buildings, dormitories, condominiums, and some townhouses. Apartments constitute approximately 90 percent of all multi-unit construction. Multi-unit construction experienced unexpectedly strong sales in the late 1990s relative to single-family detached homes, despite a strong economy that would normally favor single-family home purchases. The weaker economy of the early 2000s also helped bolster multi-unit construction, despite record low interest rates, which would also normally favor single-family home purchases. This trend toward multi-unit living was due at least in part to the aging of the U.S. population, as retirees typically opt to downsize into multi-unit residences.

This industry also includes companies that provide maintenance and repairs, as well as new construction improvements to existing buildings. In general, improvement refers to additions and alterations involving major interior and exterior changes to existing residential structures, and the replacement of major individual items such as furnaces and water heaters.

Establishments engaged in the erection of residential prefabricated buildings (except single-family structures) are also included in this industry. Prefabricated buildings are those that are built with various forms of factory-made items, ranging from simple components (for example, roof trusses, wall panels, and prehung doors and windows) to three-dimensional, 95-percent complete modular units. These buildings are constructed from wood **SIC 2452: Prefabricated Wood Buildings and Components** or metal **SIC 3448: Prefabricated Metal Buildings and Components**. Such structures were gaining popularity in the mid- and late 1990s and early 2000s

as improved technology, materials, and building processes eliminated much of the negative public perception formerly associated with pre-fabricated housing.

A knowledge of the legal aspect of the construction business is a critical component in understanding this complex industry. Construction contractors operate under a significant amount of federal, state, and local regulation, and thus often utilize members of the legal profession. The attorney a contractor selects must be experienced and have complete knowledge of contract law with particular reference to laws that affect contracts between general contractors, owners, and subcontractors. In fact, due to the complex and diversified components inherent in the general contracting business, one attorney often cannot handle all legal requirements of a general contractor. The various arenas of law that impact general contractors that may require legal representation include negotiations, preparing and reviewing contracts, labor law, lien laws, bankruptcy laws, litigation, corporate structure, and general counsel. The extent of the contractor's general business operations and the legal issues regarding individual projects should be the determining factors when a contractor elects to use more than one legal firm or attorney. Attorney services are needed for almost every step of the construction process. Therefore, the choice of a competent general contracting attorney is often one of the most crucial decisions a general contractor can make.

Another aspect of the legal portion of general contracting is the vast array of government laws. These laws

include both local and area laws. Examples of such laws include laws relating to the inspection and approval of works, the acceptance of plans, the use of certain materials, the conditions under which labor may be employed, and health and safety regulations. Moreover, equipment that comes on site has to be certified safe for use under the conditions of use.

Many large contractors have organized their own legal department, usually employing lawyers that are experts in construction law. These legal departments will often perform many of the functions described above that are necessary for a general contractor to operate their business.

CURRENT CONDITIONS

Demographic and lifestyle trends favored the multifamily residential construction industry in the late 1990s and early 2000s. Despite rising income levels among the prime home-buying age group (25 to 45), more people than ever opted to live in apartments; in fact, the fastest-growing financial-demographic group for apartments was made up of individuals who earn more than \$50,000 per year. This shift is attributed mostly to lifestyle changes among younger people entering the housing market, who tended to prefer living in proximity to entertainment venues and shopping. Moreover, the faster pace of living among young professionals helped spark a preference to avoid the continuous upkeep associated with detached homes. To accommodate these developments, multifamily housing facilities increasingly feature such ameni-

ties as swimming pools, fitness centers, and gardens. Apartment starts totaled 333,000 units in 2001, compared to 261,000 units in 1998.

Older customers also wielded tremendous influence on construction activity, as assisted-living housing facilities exploded in the late 1990s. In 1998, construction reached 32,600 units, up 46 percent from 1997; an additional 31,300 units were produced in 1999. However, most analysts expected that the boom was at an end by 2000. Prices per unit skyrocketed as well, from a median of \$39,755 in 1993 to \$86,667 in 1995. However, by 2002, the median price had fallen to \$65,000 due to a glut of units on the market. Most of the units sold in 2002 (60 percent) had been constructed during the development frenzy of the late 1990s. However, analysts believe the market will recover and eventually flourish as roughly 20 percent of the U.S. population will be in the 65 and older age bracket by 2030.

Another market fueling multifamily residential housing construction was low-income housing, spurred by tax-exempt municipal bonds and housing tax credits, which finance multifamily building. Private-activity multifamily housing bond issues skyrocketed from \$322.0 million in 1992 to \$2.3 billion in 1998. This trend continued into the early 2000s as bond issues grew further to \$5.6 billion in 2002. Meanwhile, helping to hedge against some of the more dramatic market swings, particularly those relating to land costs and occupancy rates, was the growing popularity of real estate investment trusts (REITs).

INDUSTRY LEADERS

While contractors in this industry tend to be rather small with limited market reach, a few firms stood out as clear market leaders. A.G. Spanos Construction of California, one of the largest apartment builders with nearly 12,000 in annual starts, boosted its revenues 21.4 percent to \$1.7 billion in 2003, while maintaining a payroll of 600 employees. JPI of Irving, Texas, achieved revenues of roughly \$500 million in early 2000s. Trammell Crow Residential of Atlanta, Georgia, garnered \$692.1 million from residential starts in 2003, and employed 6,300 workers. Colson & Colson Construction of Salem, Oregon, brought in revenues of \$900 million in 2002 and employed a total of 7,300 individuals.

WORKFORCE

The construction industry has always been labor intensive. This fact has not cheered contractors in the late 1990s and early 2000s as an extremely tight labor market has led to wage pressures, causing many industry players to fear further inflation of construction prices. Some analysts suggest that the shortage of skilled labor was the most serious problem facing the industry at the start of

the twenty-first century. The Bureau of Labor Statistics named construction as one of the most promising industries for job seekers in the early 2000s.

Construction workers in 2002 earned an average of \$18.51 per hour. Craftsmen generally acquire skills during an apprenticeship, usually over a period of four years.

SIC 1531

OPERATIVE BUILDERS

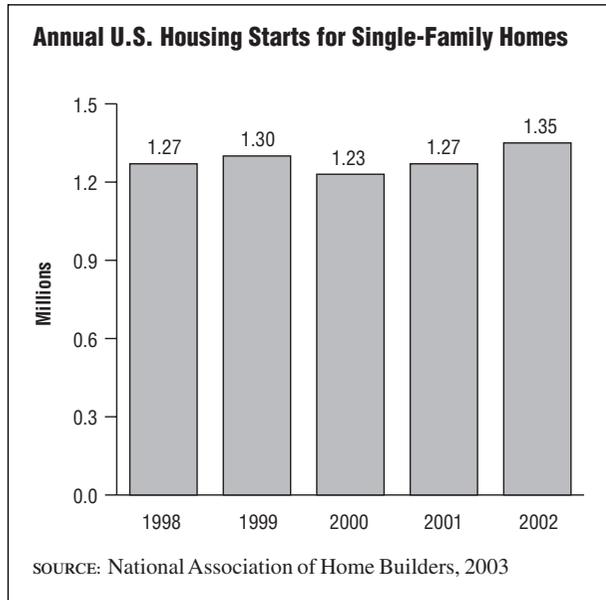

This category covers builders primarily engaged in the construction of single-family houses and other buildings for sale on their own account rather than as contractors. Establishments primarily engaged in the construction (including renovation) of buildings for lease or rental on their own account are classified in the Real Estate Operators (Except Developers) and Lessors industries.

NAICS CODE(S)

- 233210 (Single-Family Housing Construction)
- 233220 (Multi-Family Housing Construction)
- 233310 (Manufacturing and Light Industrial Building Construction)
- 233320 (Commercial and Industrial Building Construction)

INDUSTRY SNAPSHOT

Historically low interest rates in the early 2000s fueled an unprecedented housing boom in the United States. In 2003, new home sales exceeded 1 million for the first time in industry history. All segments of the residential construction industry, including operative builders, benefited from brisk new home sales. According to the National Association of Home Builders, the outlook for the U.S. housing industry remained favorable through at least 2005.

ORGANIZATION AND STRUCTURE

Unlike general contractors who perform construction work on a for-hire basis for the owner or owners of a development, operative builders are the owners of the structures they erect and act as their own general contractor. In addition to construction, operative builders also engage in land acquisition, sales, and a host of other non-construction activities associated with developing and selling properties. Historically, operative building has traditionally accounted for a comparatively small percentage of construction. Typically during the 1990s, operative builders employed fewer construction workers than general contractors and employed a higher proportion of non-construction employees such as executives, salespeople, administrative staff, and other professional categories, reflective of their wider involvement in site development, property sales, and other activities not performed by general contractors.

Although operative builders were primarily involved in construction, their principal industry activities also included subdivider and site development work, real estate management activities, land sales, construction-related activities, and miscellaneous operations. The vast majority (95 percent) of the construction performed by industry firms involved the erection of new buildings and service facilities and the installation of equipment such as elevators, heating and air conditioning, and plumbing. A small proportion of construction activities involved renovation work, such as additions, alterations, or reconstruction, and maintenance and repair.

An important component of the industry's non-construction-related activities was the acquisition of land for development of its own properties or for resale in developed, undeveloped, or partially developed form to

purchasers such as other builders. Industry firms considering the purchase of a tract of land evaluated it on its cost, or based on marketing and demographic studies conducted by the operative builder or by consultants. Other criteria included financial and legal considerations, governmental approvals and entitlements, environmental factors, the firm's experience in a particular market, real estate market trends and the health of the economy in general. Engle Homes of Florida, for example, primarily purchased land already "improved" for building construction, land requiring site improvements, and "options" on improved land permitting the company to buy the site when market demand warranted construction. Firms that can afford to carry the costs of a large undeveloped "land inventory" may ultimately benefit from having purchased large tracts rather than several smaller, more expensive parcels when it comes time to construct a large master-planned community on the site. It generally takes five years to develop purchased land into master-planned communities or subdivisions, while smaller, more conventional residential projects take two to three years to complete. The purchase of land tracts involves a "contingency period" while zoning, environmental, and other governmental and infrastructure requirements are met.

In the 1980s and early 1990s, several factors had compelled the building industry to seek new means for acquiring financing for land purchases: the federal Tax Reform Act of 1986, the revision of commercial banks' loan underwriting standards, and the decline of the U.S. savings and loan industry. One such approach was the formation of "land bank partnerships" in which investors pooled their resources to purchase land and used provisions in the tax code to avoid the costs associated with carrying the debt from the purchase of land on their balance sheets.

After purchasing land for a master-planned community, industry firms must determine the layout, size, and style of each of the site's lots, as well as the design of the overall community. A product line is then developed, based on such factors as existing housing, the expenditure for the lots, and the projected needs of the specific market. Once these general guidelines are established, the firm seeks the necessary governmental approvals, performs specific site planning, constructs or contracts for the construction of roads, sewers, water and drainage facilities, and, if necessary, conducts other engineering operations.

The development of the "balloon frame" building technique in the 1830s, with which homes could be constructed by laborers rather than skilled carpenters, represented the birth of modern, industrialized home construction methods in the United States. Contemporary two-story homes are generally constructed using a "platform frame" method in which the studs that support the roof rest on the

second story rather than extending all the way to the ground floor as in traditional balloon frames. Single-family homes—both detached and attached—were the most common structures erected by operative builders during the late 1980s. The modern home is much more than a frame, floor, roof, and walls, however; home builders must install pipes for plumbing, fiberglass for insulation, ductwork for heating and air conditioning, special flooring for bathrooms and kitchens, and conduits for electrical wiring, as well as a wide range of building components.

Office buildings, industrial buildings and warehouses, and commercial buildings such as stores, restaurants, and service stations represent a not insubstantial amount of construction activity. Industry firms also developed and constructed condominiums, defined as townhouses, apartments, or any other structures in which the purchaser owns title to the three-dimensional space occupied by the unit as well as an undivided interest in the building's common property. Industry firms also developed cooperative apartments, which have the same physical form as condominiums but in which purchasers hold stock in the company that owns the apartment rather than owning a unit of space. Industry firms also engage in speculative building—structures built in the expectation of future demand without prearranged purchasers.

The operative building market, like other construction markets, is “counter cyclical.” Operative builders are significantly dependent on the freeing up of credit from lending institutions that occurs when depressed economic conditions limit the number of industrial or manufacturing borrowers seeking loans for expansion. Because money loaned by banks and other financial institutions is more readily available to home-buyers and construction firms when the economy is in the trough of an economic cycle, the home building industry generally begins to improve when economic conditions are at their worst, thus earning the designation “counter cyclical.” Home builders also are strongly affected by interest rate levels and general consumer confidence. Other economic factors affecting the home building industry include demographic trends, such as the number of adults in the prime home-buying years (ages 25-44), changes in the mortgage financing industry, increases in energy costs and property taxes, labor and building materials costs, and changes in consumer preferences.

The residential building industry during the 1990s and 2000s, was highly competitive, with only a few firms competing at the national level. Builders compete on the basis of location, reputation, quality of construction, price, design quality, and amenities, among other factors. Builders with strong administrative and paperwork processing operations, superior on-site management, and sound construction systems were generally the most competitive.

Most residential building firms (including operative builders) were small, with the number of units constructed by a single establishment averaging 25 or less per year, although industry giants such as Centex, Pulte, Ryland, Lennar, and Beazer far exceeded this total. Such firms often started out by building a small number of homes, acquiring additional land, and then gradually expanding their market geographically and perhaps demographically as well, offering, for example, “first home” residential construction, then moving up to expensive high-end home construction. Among the preliminary activities that may be conducted by start-up builders before beginning their first construction project were: market research of the communities in which they intend to sell, prearrangement of financing for their initial construction activities, analysis of competition, exploration of business relationships with construction suppliers, installation of computer-aided design computer systems for floor plan design and modification, or consultations with area realtors and investors. Using specialized formulas, builders conducting market research were able to determine with some accuracy how many homes of a certain type would be purchased in a particular subdivision or development.

Builders may finance their construction activities through revolving lines of credit offered by commercial banks using the firm's inventory of homes as collateral. The actual amount of credit extended to the builder may be based on the value of the homes the builder has sold and may be about 50 percent of the home's intended sale price. Builders can expect profits of perhaps 15 percent of the sale price of a home. Larger home builders tend to have the financial resources to survive housing downturns and exploit emerging housing trends.

An important initial decision for the operative builder during the 1990s and 2000s was the choice between constructing and marketing individually designed homes or offering so-called “market units,” a choice between unique home specifications and floor plans or more generic housing specifications keyed to a specific demographic market, master-planned development, or architectural style. Some firms offer a “personal builder” program in which home buyers can modify the builder's design plans to arrive at a “semi-customized” home. Other builders may purchase pre-designed house plans from “plan service” firms, thus eliminating design and architectural costs from their budgets. In fact, many builders use the elevations provided in catalogs of home plans such as *Sweet's Catalogue Files* rather than incur the expense of retaining an architect.

The types of homes built by industry firms during the 2000s were as diverse as the U.S. housing market itself, ranging from government subsidized lower-income developments to customized, high-end estate homes. Hous-

ing markets can be classified according to taste, race, family status, location (neighborhood as well as region), employment patterns, income, or age. Across all housing levels several trends have merged since the late 1970s. Mean home size has continued to increase and the percentage of new homes with 2,400 square feet of space or more has risen notably. Between 1978 and 1995 the percentage of homes with central air conditioning grew from 58 percent to 80 percent, those with two-car garages or larger increased from 52 percent to 76 percent, and homes with two and one-half baths or more nearly doubled, growing from 25 percent to 48 percent. By 2003, over 52 percent of homes were two-story and 37 percent were larger than 2,400 square feet. Roughly 55 percent contained two and one-half baths, while 36 percent had four or more bedrooms.

One of the largest hurdles faced by prospective operative builders was arranging financing through banks, which are much more inclined to lend money to established builders. In some markets construction financing was provided to builders by their suppliers (such as lumber companies) which could monitor the builder's financing needs and construction progress by observing how much materials they had ordered or used. Other sources of residential building loans include pension funds and insurance companies. Because construction costs can vary significantly over a two-month period, some builders planned to construct only the number of homes projected by their monthly research, then concentrated on selling the homes before beginning actual construction.

Industry firms generally sell their homes through independent brokers or by employing salespeople retained on commission. These salespeople operated out of model homes and conducted tours, providing floor-plans and describing prices and design options. Available homes were advertised in newspapers, magazines, billboards, brochures, on radio, through out-of-state home shows, direct mail, video tapes, or special promotional events. Major sources of sales include referrals from customers or members of a region's home-building, real estate, architectural, or financial community, from traffic through model homes, and through bidding on planned residential development projects in competition with other builders.

Operative building firms may also maintain customer service departments that conduct home orientation tours for buyers before the final sale as well as resolving problems occurring after the sale is final. In the early 2000s, the largest costs incurred by operative builders were construction on work subcontracted to other builders; materials, components, and supplies; and payroll. Industry firms took advantage of a number of strategies to control their costs including using subcontractors to per-

form home construction and site improvement on a fixed-price basis, obtaining volume discounts on construction materials and other special pricing arrangements from subcontractors, obtaining zoning entitlements before making land purchases, and minimizing their inventories of unsold homes by building a limited number of speculative homes in order to meet short-term demand. Some larger home-builders elected to lessen the financial risk inherent in residential construction by having a range of projects under development in several communities in each market at one time, thus minimizing their dependence on the success of any single project.

Among the range of secondary activities engaged in by industry firms in the 1990s were the sale of improved lots, mortgage origination and title insurance services, cement aggregate and gypsum wallboard manufacture, and the purchasing and selling of undeveloped land. Other activities included the sale and asset management of commercial properties and sites, residential and commercial property rental, real estate investment trust (REIT) management, development and marketing of vacation ownership resort communities, savings and loan operation, and aluminum and wood building component manufacturing.

CURRENT CONDITIONS

The states with the largest number of operative builders (single-family construction) in the early 2000s were California and Florida, followed by New York, Pennsylvania, and Michigan. North Dakota, Alaska, South Dakota, Hawaii, and Wyoming have the lowest number of firms operating in this industry.

Most operative building industry establishments specialize in detached single-family housing construction, while about 10 percent specialize in attached single-family housing construction, and a minimal number specialize in apartment building construction, office building construction, and other commercial building construction.

Trends in the operative building industry in the 2000s included the continuing increase in the use of prefabricated and component parts, such as pre-finished walls, partitions, and stairs. Also, operative builders used a greater amount of non-wood construction materials in response to rising lumber costs and increased their reliance on computer-aided design and other software for home design and business tracking activities. Other characteristics of the industry in the early 2000s included a continuation of the trend toward larger homes (the average square footage of a new home in 2002 was 2,230, according to the National Association of Home Builders); improved construction tools and equipment; decreasing union representation among construction workers; a continuation of the rise in average home prices and land

costs; an increase in the number of mergers and acquisitions among the largest national home-builders; increases in the amount of remodeling activities performed by industry firms; and gradual increases in the percentage of U.S. households owning homes, which totaled 68 percent in 2002.

Despite recessionary economic conditions in the United States at the start of the twenty-first century, more people bought new homes, and the new homes they bought became increasingly lavish. This was due in large part to record low interest rates, which made housing more affordable, as well as to increases in the amount of financing available to individuals.

According to the most recent statistics from the U.S. Bureau of Labor Statistics, the operative building industry (including single-family, multi-family, industrial, and office buildings) included 31,280 employees who earned an average of \$40,950 per year. Roughly 36 percent of these employees worked in construction, while 21 percent worked in office and administrative support positions, 15 percent were in management, and 10 percent were in sales.

INDUSTRY LEADERS

Dallas-based Centex Corporation was the largest operative builder in 2003, with sales of \$9.1 billion, reflecting 17.7 percent growth from the year prior, and 17,540 employees. Centex builds homes in 20 states and also in the United Kingdom. It also owns 80 percent of manufactured-housing producer Cavco Industries. Other companies with a strong presence include Pulte Corporation, based in Bloomfield Hills, Michigan. Pulte, which builds single-family homes across several price ranges, saw sales in 2003 grow 21.1 percent to \$9.0 billion and employed 10,800 workers. The Ryland Group, based in Columbia, Maryland, focuses on the "typical" middle-class home; it had 2003 sales of \$3.4 billion, reflecting 19.7 percent growth from 2002, and employed 2,558 people. Toll Brothers, which focuses on luxury housing, operates in 18 states. The Huntington Valley, Pennsylvania-based company had 2003 sales of \$2.7 billion and 3,416 employees.

The Rouse Company, based in Columbia, Maryland, is a real estate investment trust (REIT) that specializes in retail properties such as shopping centers; its 2003 sales were \$1.2 billion and the company had 3,696 employees.

Other companies include Engle Homes, Inc., based in Boca Raton, Florida (sales in 2003 were roughly \$1 billion); Atlanta-based Beazer Homes (\$3.1 billion in 2003 sales and 2,986 employees); and Hovonian Enterprises, Inc. of Red Bank, New Jersey (2003 sales of \$3.2 billion; 3,249 employees).

SIC 1541

GENERAL CONTRACTORS—INDUSTRIAL BUILDINGS AND WAREHOUSES

This category covers general contractors primarily engaged in the construction, alteration, remodeling, repair, and renovation of industrial buildings and warehouses, including aluminum plants, automobile assembly plants, food processing plants, pharmaceutical manufacturing plants, and commercial warehouses. General contractors working on nonresidential buildings other than industrial buildings and warehouses are classified in **SIC 1542: General Contractors—Nonresidential Buildings, Other Than Industrial Buildings and Warehouses**.

NAICS CODE(S)

233320 (Commercial and Institutional Building Construction)

233310 (Manufacturing and Light Industrial Building Construction)

INDUSTRY SNAPSHOT

Like all construction activity, this category of nonresidential construction is crucially dependent on overall U.S. and regional economic health. Specifically, construction of industrial building and warehouses is intimately tied to trends and conditions in the U.S. manufacturing sector; individual projects are, moreover, bound to the economic health of whichever industries are sponsoring those projects.

Therefore, when the U.S. economic bubble of the late 1990s burst, spending on industrial buildings and warehouses began to wane. Employment in the manufacturing sector fell throughout 2001 and 2002, as did industrial production. As a result, spending on new manufacturing plants and warehouses experienced a dramatic slowdown. This downward trend was expected to continue through 2002, according to a May 2002 issue of *Building Design and Construction*.

ORGANIZATION AND STRUCTURE

In this sector of the construction industry general contractors generally bid for a project, assuming responsibility for the project's planning and overall development. Often, however, the general contractor delegates performance of many specific tasks to specialty subcontractors.

Once a contractor is chosen to undertake a given project, he or she often remains in close communication with its owner over many aspects of construction detail while at the same time coordinating the work of various subcontractors and teams of employees. Given the inherent complexity of this arrangement, successful management proved one of the industry's greatest challenges. Project often fail due to miscalculation of budgets and missed deadlines, often attributed to the lack of an efficient communication process between contractors and owners.

BACKGROUND AND DEVELOPMENT

Contractors benefited from the booming U.S. economy in the late 1990s, in particular the raging stock market, which encouraged investment in new buildings and modernization schemes as manufacturing industries attempted to increase efficiency through technological innovation. Contractors were called in for building and remodeling projects to accommodate the new production methods and equipment.

Manufacturers that expanded or relocated in the mid- and late 1990s at the greatest rate were those involved in semiconductor manufacturing, pharmaceuticals, food and kindred products, and paper and allied products. Companies within the pharmaceutical industry as well as semiconductor manufacturers are particularly in constant need of new research, development, and production facilities since their products face ever-shortening product life cycles. In order to be competitive, many manufacturers also need to upgrade into facilities fully equipped to provide advanced telecommunications and computer systems. Moreover, the importance increasingly attached by companies around the world to reducing hazards to the environment was expected to create further remodeling and new construction opportunities.

The food industry, for instance, demanded the construction, expansion, or renovation of a record 867 plants in 1998, an increase of 14.7 percent from the year before. Analysts attributed the bulk of this growth to increasing automation in production. Companies such as Coca-Cola, ConAgra, and Frito-Lay all had a number of projects underway in 1999, with Kraft leading the sector with 24 projects. The food industry in general was leaning toward larger facilities in which automation could be most economically applied.

Also impacting the industry in the 1990s was the increasingly stringent loan requirements set up by banks in the wake of the savings and loan crisis. To counter banks taking a risk position in these projects, developers and their subsequent construction firms were often asked to take an equity position or become a part owner in projects they design or build. Meanwhile, however, the growing strength and popularity of real estate investment trusts (REITs) helped maintain healthy funding for construction in this sector, even in the face of concerns over oversupply or pending interest-rate increases.

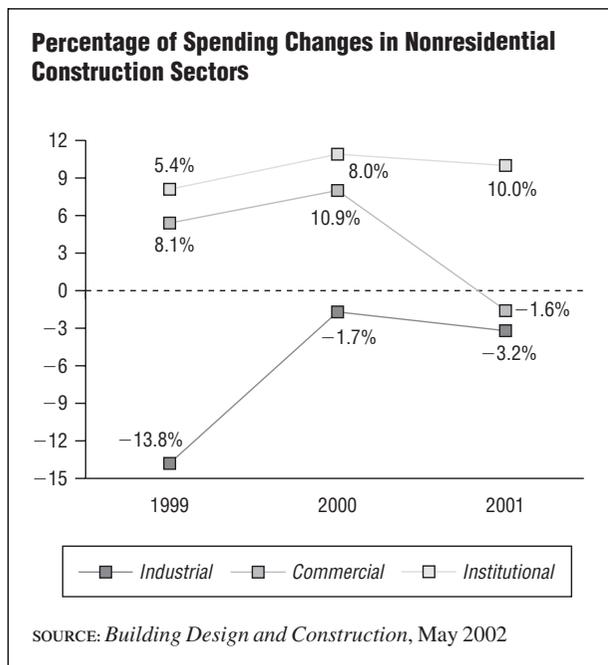

The nonresidential repair and renovation market, in general, was seen as having a more secure future than that of new construction. The commercial building boom of the 1980s produced, among other results, record vacancy rates for warehouses, and this over-supply was expected to diminish the market for new warehouse construction for some time. Instead, manufacturers were generally trying to reflect their industries' tightening concentration by expanding their capacities—in short, fewer but larger facilities.

Contractors in this construction sector remained somewhat wary, however, over the increased international presence of the U.S. manufacturing industries. With relaxed trade and investment restrictions, a strong dollar relative to foreign currencies, and the lure of cheaper labor and materials costs overseas, larger firms with capacity to move production facilities to foreign markets began seeing increasing reasons to do so. However, such practices were also expected to lead to a rise in warehouse construction, as goods produced abroad would be shipped to the U.S. and readied for domestic distribution.

CURRENT CONDITIONS

After experiencing substantial growth in the mid-1990s, the industrial building industry experienced a dramatic slowdown beginning in 1999. Spending on industrial buildings in the United States declined 13.8 percent in 1999 to \$32.6 billion, and then continued to deteriorate at a slower pace, falling 1.7 percent in 2000 and another 3.2 percent in 2001 to \$31.1 billion. According to a May 2000 issue of *Building Design and Construction*, the decline in spending was related to the slowdown in U.S. industry in general. "Medium- and long-term demand for new industrial space is closely correlated with industrial output, export growth, and capacity utilization rates—all factors that have weakened dramatically during the past 18 months."

Despite continued economic weakness into 2004, the residential construction sector continued to perform well, bolstered by historically low interest rates; however, the nonresidential construction sector, which includes industrial buildings and warehouses, continued to falter. Even

the institutional sector, which flourished in 2000 and 2001 due in large part to the strength of the healthcare industry, had started seeing a slowdown in construction spending by 2002. However, analysts note that the decline in nonresidential construction had begun to level off in 2003, prompting some to predict a turnaround by the end of 2004.

INDUSTRY LEADERS

The top contractors in this category in the early 2000s were generally engaged in other construction sectors as well. Fluor Corporation of Irvine, California, posted sales of \$8.8 billion in 2003, down 11.6 percent from 2002, and employed 29,011 people. Bechtel Corporation of San Francisco, a private company founded in 1898 and still run by its founding family, employed 47,000 people and generated worldwide sales of \$11.6 billion in 2003, down 13.4 percent from the previous year. Kellogg Brown & Root, based in Houston, Texas, was the construction unit of Haliburton Company, with sales of \$9.2 billion and 64,000 employees. In 2003 Kellogg Brown & Root filed for Chapter 11 bankruptcy protection after being saddled with a \$4.4 billion asbestos-related settlement. JA Jones Construction Co. of Charlotte, North Carolina, maintained a payroll of roughly 10,000 workers and generated about \$1.5 billion in revenues. A unit of bankrupt Philipp Holzmann Group, the firm's plan to be acquired by Balfour Beatty fell apart in 2003.

There were large numbers of generally small firms tackling a wide variety of projects within a frequently confined geographical area. Nearly half of all establishments in this category employed fewer than 5 workers,

while 85 percent employed fewer than 20. With the exception of the giants undertaking business not only nationally but also internationally, even those contractors doing business in more than one state typically relied overwhelmingly on contracts in the state in which they were headquartered for the bulk of their profits.

WORKFORCE

About 5 percent of the U.S. labor force is employed by one branch or another of the construction industry. The industrial building and warehouse sector employed about 139,000 individuals at the turn of the twenty-first century. Construction workers in this category earned an average of \$16.50 per hour. The states employing the greatest number of construction workers were Texas, Alabama, and California.

Despite its size, this workforce was by no means monolithic. Employment in construction was seasonal, leading to pronounced swings in the number of workers employed over the course of a year. Moreover, the skilled members of the workforce engaged in a wide variety of different crafts or specialties. As a result, no single voice could adequately represent the various needs and interests of all of these workers. Such considerations were particularly important because labor and management are more intimately tied than in many other industries. That is, in addition to wages and working conditions, unions must negotiate with contractors on issues such as training procedures and hiring practices. Especially in the late 1990s, when skilled labor was in exceptionally short supply, employers and unions were increasingly forced to negotiate to preserve job opportunities. Skilled labor in this category earned about \$29 per hour.

Further adding to the lack of uniformity in the workforce were the tendencies for skilled workers to identify with their specialties rather than with a particular employer, as well as for all employees to change employers often, to switch frequently from site to site, to work beside teams hired by other employers, and to engage to an unusual extent in self-supervision.

Supervising contractors typically worked their way into that position from a beginning in some particular craft or specialty. Traditionally, academic training has played a minor role in preparing contractors for their career, though the inherent complexity of managing construction projects—especially the larger ones—seemed likely to make higher levels of education increasingly desirable.

ters.” *Indianapolis Business Journal*, 17 February 2003.

SIC 1542

GENERAL CONTRACTORS— NONRESIDENTIAL BUILDINGS, OTHER THAN INDUSTRIAL BUILDINGS AND WAREHOUSES

This category covers general contractors primarily engaged in the construction, alteration, remodeling, repair, and renovation of nonresidential buildings, other than industrial buildings and warehouses. Included are nonresidential buildings of commercial, institutional, religious, or recreational nature, such as office buildings, churches and synagogues, hospitals, museums and schools, restaurants and shopping centers, and stadiums. General contractors primarily engaged in the construction of industrial buildings and warehouses are classified in **SIC 1541: General Contractors—Industrial Buildings and Warehouses**.

NAICS CODE(S)

233320 (Commercial and Institutional Building Construction)

As with the construction industry in general, nonresidential construction had benefited from a surging U.S. economy in the late 1990s. The demand and spending for all types of construction in this sector was commensurate with general economic strength, measured by gross domestic product and interest rates. When the economy began to falter at the turn of the twenty-first century, the nonresidential construction began to feel the pinch. Although residential construction was bolstered by interest rates that dipped to lows not seen since the 1950s, nonresidential construction experienced no such cushion. Businesses of all kinds began to curb spending on new and existing construction projects.

Along with economic strength, the specific construction categories of this sector are further affected by a range of variables, such as demographic trends, legislation regarding public expenditures and business developments, and social trends. Private nonresidential construction in the United States has fluctuated according to the success of key sectors such as office buildings and institutions. Nonresidential construction spending dropped by 6 percent in 2003 as even the strongest sectors, such as healthcare construction, began to see previously rapid growth rates slow.

The states that experienced the greatest levels of construction activity in this sector included California and Texas.

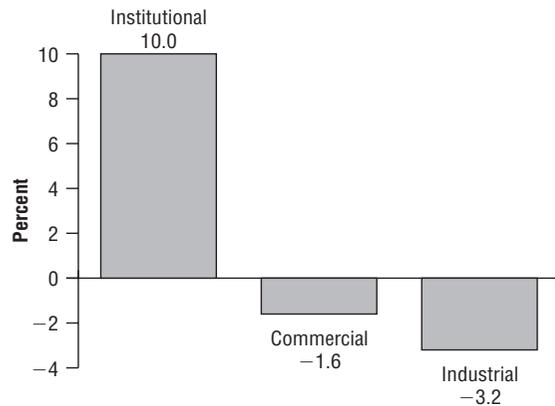

Office Construction. The 1980s saw tremendous growth in new office construction, but the overproduction and subsequent economic recession resulted in such a glut that vacancy rates became a nationwide problem. In 1983, the national metropolitan office vacancy rate stood at approximately 12 percent; by 1990, that rate had risen to 17 percent and peaked at 19 percent two years later. In 1998 the rate was at its lowest mark since the early 1980s, at 8.9 percent. However, by early 2003, the office vacancy rate had jumped back up to 16.5 percent.

Office construction spending experienced a long-awaited resurgence in the late 1990s, from \$36.2 billion in 1997 to \$47.5 billion in 1999. While this was excellent news for contractors, 1999 revenues were still 35 percent below their record 1985 level. As the economy as a whole cooled off from its late 1990s surge, the rate of office building construction growth slowed considerably to roughly \$43 billion in 2002 and to \$39 billion in 2003. Meanwhile, lending institutions, which had eased some of their restrictions on commercial real estate loans, began to tighten up lending requirements. Eyeing the slower growth rate for white collar employment, as well as the economic trend toward downsizing, builders wary of a repeat of the late 1980s disaster were expected to try and rein in runaway construction.

Retail Construction. In contrast to office construction, the retail construction market has remained strong since the 1980s. Spending on retail construction rose steadily during the late 1990s, from \$42 billion in 1996 to \$55.4 billion in 1999. About half the value in this category is related to the construction of shopping centers. Especially in recent years, such construction was geared toward big box stores—large non-mall discount stores specializing in focused product categories.

According to a December 2002 issue of *Chain Store Age*, the 25 largest U.S. retailers opened a total of 5,935 new stores in 2002, compared to 5,843 in 2001. In addition, square footage in these new stores reflected a 6.4 percent increase over the size of existing stores. Leading U.S. retailers also continued to spend construction dollars on remodeling existing stores. Supermarkets, in particular, were investing more capital into improving existing stores than on opening new units. Supermarket companies engaged in store remodeling grew from 22 percent to 38 percent between 1997 and 2001. In fact, supermarket store openings fell to a ten-year low in 2001. Offsetting the impact of this decline, however, was the fact that store closings had also reached a decade low rate. The new supermarkets that did open in 2001 boasted square footage of 46,750, compared to 44,072 a year earlier.

2001 Percentage of Spending Changes in Nonresidential Construction Sectors

SOURCE: *Building Design and Construction*, May 2002

Institutional Construction. This sector includes a wide range of building types, including hospitals, schools, prisons, government buildings, and others. This type of construction has generally been more stable than all other sectors of nonresidential construction. As a result, it commands an increasing share—more than 60 percent as of the early 2000s—of total industry spending. Compared to industrial construction spending, which declined by 3.2 percent in 2001, and to commercial construction spending, which dipped 1.6 percent that year, spending on institutional construction grew 10 percent in 2001.

Educational building construction was very healthy in the late 1990s, with optimistic forecasts into the following decade. Sales in 1998 reached \$39.5 billion and were expected to increase to \$44.0 billion by 2000. Furthermore, as more schools placed a priority on full Internet service and technological facilities, the construction of new buildings and remodeling of existing ones was expected to follow. However, drastic cuts in educational funding in the early 2000s curtailed construction considerably in this sector. Seventy percent of this construction was of primary and secondary schooling facilities, while colleges, universities, and other educational institutions accounted for the remainder. The vast majority of this construction (80 percent) was for public institutions, though that figure was likely to diminish as state and local budgets continued to be strained while calls for voucher programs and other shifts toward private schooling increased.

The construction of healthcare facilities was largely dependent on legislative activity, which was in an uncertain state of limbo in the late 1990s. As a result, spending was down slightly in this sector, though much less for private hospitals than for public care facilities. Seventy

percent of spending in this sector went toward hospitals and clinics, though nursing homes and outpatient centers claimed an increasing proportion of the market. More optimistically, however, analysts expect healthcare facilities to be among the fastest-growing sectors in the entire construction industry in the early 2000s. An aging population is a prime factor for this projected growth, especially as nursing homes and similar facilities flourish. Another indicator for growth is the age of existing facilities. According to an August 2002 issue of *Health Care Strategic Management*, “In many cities, hospital plants are decaying beneath the surface, with out-of-date chillers and boilers, asbestos in the walls, and outdated signage . . . now it’s time for hospital to play catch-up.”

INDUSTRY LEADERS

While the majority of companies engaged in nonresidential construction other than industrial buildings and warehouses employed fewer than 8 workers, a handful of firms commanded a substantial market share; however, most of those firms’ operations included construction activity that extended beyond what fits into this industry.

HBE Corporation was established in 1960 and employed 9,100 workers in 2002. Its flagship operation is HBE Hospital Building and Equipment Company, which designs, plans, and builds healthcare facilities. HBE also performs construction activity for the financial services industry, building banks and credit unions. Sales totaled \$625 million in 2002, compared to \$1.3 billion in 1998.

Hellmuth, Obeta, and Kassabaum, otherwise known as HOK Group, Inc., engaged in a wide range of construction activities, including commercial, recreational, and institutional facilities, including U.S. government buildings. The firm maintains a payroll of more than 1,600 workers and posted sales of \$309 million in 2002.

Other leading firms in 2002 included: Clark Construction Group of Bethesda, Maryland, with 4,000 employees and sales of \$2 billion; Perini Corporation of Framingham, Massachusetts, with 2,400 employees and sales of \$1.4 billion; and Turner Corporation of New York, New York, with 4,700 employees and \$6.0 billion in sales.

SIC 1611**HIGHWAY AND STREET CONSTRUCTION**

This industry covers general and special trade contractors primarily engaged in the construction of roads, streets, alleys, public sidewalks, guardrails, parkways, and airports. Special trade contractors primarily engaged in the construction of private driveways and sidewalks are classified in **SIC 1771: Concrete Work**.

NAICS CODE(S)

234110 (Highway and Street Construction)

INDUSTRY SNAPSHOT

In 2001 the United States maintained 3.95 million miles of highways, the vast majority of which were under the control of local entities. Highway-user revenues totaled \$128.7 billion. In 2001 highway systems were also helped by federal aid amounting to \$26.5 billion from the highway trust fund and \$7.6 billion from the Federal Transportation Administration. According to the U.S. Census Bureau's *Statistical Abstract of the United States*, in 2001 there were 10,889 contractors involved in highway and street construction that employed over 265,000 workers. The value of new construction put in place during 2001 totaled \$54 billion.

Three-quarters of highway construction is for roads, called flatwork. In 1998 the Transportation Equity Act for the 21st Century (TEA-21) was signed into law, allowing nearly \$200 billion for highway construction and maintenance from 1998 to 2003. Most of the money for federally subsidized highway and airport projects comes from excise taxes on fuel, airplane fares, trucks, and related products. Americans also spend more than \$1 billion annually on tolls. In 2003 the Bush administration was working with Congress to develop a replacement package for TEA-21, which expired in September 2003.

These numbers reflect the significant impact the industry has on the nation's economy. For instance, the U.S. Department of Commerce estimates that every \$1 spent on construction results in \$2.23 generated in the economy on a short-term basis. In terms of the specific contribution to the economy from investment in road construction, each \$1 million generates 63 jobs (13 at job sites, 13 by suppliers, and 37 through related service industry jobs created).

The total impact of the highway and street construction industry ranks it as one of the major industries in the country. According to the American Road & Transportation Builders Association (ARTBA), in 2002 the industry generated more than \$200 billion annually in U.S. eco-

nomics activity and provided jobs for approximately 2.2 million workers.

ORGANIZATION AND STRUCTURE

There are a number of different categories of independent contractors that make up the highway and street construction industry. Each of these specializes in a different facet of the industry. The employment change for highway maintenance workers was expected to decline into 2006, but employment prospects were expected to grow rapidly. The total number of highway and street construction employees is estimated at more than 302,100. There are more than 100,000 firms in the construction industry, a figure that far outnumbers the total aggregate of firms in all other manufacturing sectors.

Despite the vast number of firms, the average size of most firms is relatively small. Many of these, in fact, are comprised of only one individual performing a specialized task in the construction project. Although there are a number of exceptions to this, the overwhelming majority of contract construction firms have no employees at all, except for the self-employed owner and operator of the firm. Despite this, small firms in the industry account for only 6 percent of the industry's total volume, according to available statistics. Most of the construction activity in the industry, about two-thirds, is carried out by small to medium-size contracting firms having less than 100 employees.

Construction contractors typically limit their activity to a specific, local jurisdiction. These are, more often than not, the states in which they are located. In fact, only one out of eight contractors performs out-of-state work.

The construction contracting business can be a precarious one. Contractors hire employees on an ad hoc basis after securing contracts; very rarely are two contracting jobs the same, and contractors have to meet the labor and material requirements of each job and its particular specifications. Also, contractors have very little control over the development of new business or increased demand for their services. The industry and nature of the work also demand that contractors adhere to strict completion schedules. The nature of the industry mandates that contractors and the heavy construction machinery they need to do the job must be mobile. Each contracting firm must be able to restructure and equip his organization according to the requirements of the contract, and transport crew and materials to the construction site. Inevitably, this leads to increased management problems and expense, and requires specific organizational skills on the part of the contractor.

Of the contracting businesses that fail, the most common reason is that individual contractors have to cover the cost of labor and machinery rentals—usually within 10 to 30 days. This leaves most contractors oper-

ating with a minimum of working capital. As a result, most contractors show a lower profit margin than other major industries. Because of the risk involved in underwriting the construction project, most general contractors subcontract different aspects of the project to specialty contractors. This minimizes their investment and risk, and increases the likelihood they will earn a reasonable profit from each job. Street and highway construction contractors, however, use their own equipment and underwrite the job when they can, thus maximizing the profit margin, although this increases the financial risk of the project.

The highway and road construction industry is labor sensitive and intensive. Most of the costs in other construction fields incur increased material expenses. Because highway and road construction is more labor sensitive, it tends not to be as affected by increased material costs. For instance, where material costs account for 42.9 percent of residential construction, they consume only 32.6 percent of highway and street construction. Overall, 37 cents of every construction dollar is spent on materials, 40 cents on labor, and 23 cents for miscellaneous expenses, such as equipment, services and supplies, rentals, and overhead. Whatever is left after these expenses constitutes profit.

Contractors have had limited success in passing rising labor and material costs on to customers because demand for their product has not kept pace with inflationary trends of labor and material required to manufacture the product. This is especially the case with highway and street construction.

The primary federal agency concerned with this industry is the Department of Transportation's Federal Highway Administration (FHWA). The FHWA administers an annual, multibillion dollar program of financial assistance to the states. The estimated budget for the FHWA in 1999 was \$28.7 billion.

The agency is also responsible for the development and distribution of the latest technology to meet the need of federally financed road programs. It serves as the highway design and construction agent for the U.S. federal government, and regulates and enforces federal requirements relating to the safety of operation and equipment of commercial motor carriers engaged in interstate or foreign commerce.

Through cooperation with major financial and developmental institutions, such as the International Bank for Reconstruction and Development, the Inter-American Development Bank, the Export-Import Bank, the United Nations, the Organization of American States, and the Agency for International Development, FHWA provides technical help in highway technology nationally and internationally.

BACKGROUND AND DEVELOPMENT

The history of the road and highway construction industry can be traced back to the invention of the automobile in 1892. The number of cars, buses, and trucks escalated quickly, and today there are more than 200 million vehicles on the roads. But it became apparent, even in 1900, that the nation's road system would soon see a period of major expansion.

Road and highway builders organized an association in 1902 that represented them as an industry. It evolved from a bicycle group founded 22 years earlier called the League of American Wheelmen. The history and growth of the American Road and Transportation Builders Association (ARTBA) parallels that of the construction of roads and highways that exploded in the early twentieth century and has continued ever since.

ARTBA, based in Washington, D.C., is a federation of private firms, public agencies, and associations. It is the only national association to represent all sectors of the transportation construction industry to the executive and legislative branches of government as well as federal agencies. Its primary goal is to advocate strong federal investment in transportation infrastructure. Its more than 5,000 members as of 2000 include the chief executive officers of large transportation construction firms in the United States, owners and partners of planning, engineering, and design firms, and heavy equipment purchasing directors with all 50 state departments of transportation, major public works departments, and county transportation departments.

The Office of Road Inquiry, which became the Office of Public Roads, was formed in 1905. With the inception of highway departments in 16 states by 1906, road construction escalated dramatically. The Federal-Aid Road Act of 1916 was the harbinger of voluminous road construction across America. It has fueled transportation construction, from single-lane roads in rural America to the super interstate highways that traverse the nation. The act was officially signed into law by President Woodrow Wilson on July 11, 1916. This made substantial money available for heavy construction of roads and ratified several principles and objectives that have remained in place to the present. The legislation established the federal-state relationship that determined that federal help would be channeled through the states, which were responsible for implementation of heavy construction projects. The act also provided for the institution of a state matching requirement that would operate in tandem with federal contributions to highway and road construction. Finally, the act put forth financial distribution formulas that would determine the distribution of money, based on demographics such as population, area, and road mileage.

Although this program was supposed to promote and support the federal-aid highway program for three years, it was extended for two more years because of the onset of World War I. In 1921 Congress once again set out to create an ambitious highway development program, using the 1916 law as a paradigm that would set the pace and structure for completion of the federal highway program. The pace at which the industry has subsequently developed has been largely determined by the categories of funding established by the 1921 legislation, which established the principle of contract authority; this allowed highway money to be obligated to the states, even if they had not been appropriated. Basically, this meant that construction could begin with the apportionment of money becoming a financial obligation of the federal government. Soon, numerous contractors began major construction projects before the money was in hand, knowing that the federal government would eventually pay for it.

It was only a few years after this revolution in highway legislation, 1925, that the U.S. Numbered Highway System became a reality. The entire street and highway development program leaped forward when Col. H. L. Bowlby, Chief of the War Materials Division of the U.S. Bureau of Public Roads, was elected ARTBA president. This led to further organization of the heavy construction industry, coordinated with the federal government's ambition to build an arterial transportation infrastructure throughout the nation. The creation of the Highway Research Board of the National Academy of Sciences was another watershed event that escalated quality road construction in America.

In the meantime, ARTBA elected J. H. Cranford as president in 1924. This was the first time a contractor had been elected to head the organization and increased the association's efficacy in promoting and lobbying for work and money from the federal government. ARTBA also established a Manufacturers Division. This was created as the result of affiliation with the Highway Industries Association, today's Construction Industry Manufacturers Association. This and other divisions created by ARTBA served to increase the specialized focus of the group and organized street and highway contractors in a way that increased their credibility and productivity as an industry.

Road construction, similar to most other industrial initiatives, slowed during the Depression era. States began leveraging gas taxes and vehicle registration charges as a way to underwrite the cost of highway construction. Prodded by the industry to use creative means to stimulate the economy, and increase and improve the nation's streets and highways, Congress initiated huge public works programs that included substantial highway construction projects. The industry continued to lobby on

Capitol Hill, urging continued highway development projects, even as the Depression abated and the Second World War drained the nation's manpower, and financial and material resources. As the industry argued, a well-constructed and maintained road and highway system was needed to facilitate the nation's war effort.

Highway construction that was needed to move men and material during World War II took precedence over all other heavy construction during the war. It was during this period, however, that more emphasis was placed on road and highway safety, and engineers and designers threw themselves into these efforts with a vengeance.

It became evident by the mid-1950s that an expanded highway construction program was urgently needed. Increased motor traffic and reliance on the automobile as the primary mode of conveyance throughout the United States, civil defense plans during the Cold War, and the deferral of highway construction during the World War II years placed the industry at the center of the nation's economic stage. The industry surged forward after Congress authorized a 40,000-mile national highway network in 1944, named the "Interstate" system three years later. Appropriation of money proved difficult, however, and financing of the bill had to compete with other federal-aid highways at a 50-50 matching ration.

The situation changed drastically, however, in favor of the industry in 1956. This is when the government enacted the federal-aid Highway Act of 1956, which represented a redesign of the interstate system. The Highway Trust Fund was set up to pay for this initiative, and it was decreed that the federal government would pay 90 percent of the cost. This put the industry at the forefront of major government initiatives aimed at mobilizing America. The "Golden Years of Road Building" were at hand.

Building the interstate system took precedence over all other heavy road construction activities and was the primary focus of the highway construction industry for the next 10 years. As the project neared completion, the industry began to focus more on other modes of transportation. Councils were established throughout the country to advise governments and industry on construction of airports, public transit, rail, and highway maintenance and improvement.

Federally funded highway construction and improvement projects, and mass transit programs all felt the impact of the Surface Transportation Assistance Act as the result of a congressional decision made in 1978. Shortly after this, the industry met one of its biggest challenges to date: support of the reauthorization of the federal-aid highway program in 1982. The Reagan administration announced it would support increased highway user fees to back funding for highway construction

and maintenance programs, and the jobs they would create. After much congressional debate and negotiations, the bill was finally passed in January 1983. This led to a five cents per gallon increase on the gas tax. One cent of this tax was set aside for funding mass transit programs.

Another battle ensued in 1986 when reauthorization of highway and mass transit programs was addressed by Congress. After an adjournment late in the year, Congress declared the legislation a high priority in January 1987. The industry lobbied heavily, as money for highway and mass transit programs began to dry up. Although Reagan vetoed the measure, he was overridden by Congress, and road building moved into high gear once again.

The federal surface transportation program would be overhauled in 1991, and this consumed the industry's attention in the late 1980s. Completion of the interstate system, coupled with fiscal restraints and tight budgets in government, did not bode well for the road and highway construction industry.

Congress developed the Intermodal Surface Transportation Efficiency Act (ISTEA), and The House Public Works and Transportation Committee recommended a five cents per gallon fuel tax. Debate and lobbying continued, much of which was focused on the prevention of using federal fuel taxes to decrease the federal deficit. In 1991 Congress enacted the massive and complex ISTEA, which changed and rewrote the federal highway law for the first time since 1916. Authorizations of funding equal to \$155 billion were provided over the next six years for federal highway and mass transit programs. President George Bush signed ISTEA into law on December 18, 1991. In 1997 President Bill Clinton offered the National Economic Crossroads Transportation Efficiency Act (NEXTEA) as a guideline for highway construction spending over the following six years.

Public investment in the nation's network of roads and bridges has been declining steadily, according to an analysis by Apogee Research, Inc., of Bethesda, Maryland. Investment that was 1.4 percent of the gross national product in 1958 had declined to 0.7 percent in 1988.

The fiscal health of the Highway Trust Fund could meet the need of an immediate requirement for highway improvement expenditures. The balance in the federal Highway Trust Fund at the end of fiscal year 1987 was \$9.4 billion. Revenue accruing to the Highway Trust Fund during that fiscal year totaled \$12.7 billion, and expenditures equaled \$12.8 billion. Federally aided highway program obligations totaled \$12.9 billion during fiscal year 1987.

Several states have committed themselves to substantial road building programs, despite the fact that total state government spending on road construction has in-

creased only slightly faster than the inflation rate. Voters in California approved a relatively large gasoline tax to pay for billions of dollars in road improvements. The California legislature, in the meantime, approved the implementation of four toll roads. The state suffered a tremendous blow in January 1994, however, when a massive earthquake crippled the highway system of Los Angeles, its most populous city. Repairs to the area's highways and bridges cost billions of dollars and took years to complete.

The Highway Bill, passed in December 1992, provided more money for highway maintenance. Industry skeptics were discouraged by the fact that the allotment was to be spent over a five-year period. Moreover, the bill had no incremental spending built into it. Nevertheless, industry was encouraged by the aspect of the bill that allows states and municipalities to own stretches of road and bridges they build and to collect tolls for their use. It was hoped that this may inspire the issuance of tax-free bonds to initially finance construction of local roads and highways, given that revenue would be generated from their construction and use.

About 25 percent of highway construction in 1992 was in the areas of bridge construction, overpasses, and tunnels. Flatwork (primarily roads) accounted for the remaining 75 percent of the work. Analysts believe bridge work will grow faster than road work in the coming years, mainly because of the need to replace aging, unsafe bridges. Federal Highway Administration reports indicate that 23 percent of the highway bridges in the United States were structurally deficient, and an additional 21 percent were functionally or structurally obsolete in 1990. This will naturally require that the industry put a great deal of work into repairing and rebuilding these structures.

Due to the limited lifespan of most highways and roads, maintenance and repair expenditures have continued to grow since the 1970s. This reflects the increase in the number of these structures as well as their age.

According to President Bill Clinton's statement of March 12, 1997, concerning NEXTEA, there were approximately 12 million people employed in transportation and transportation-related industries. One million of those jobs had been created since 1994. This represented just over 10 percent of the total civilian workforce. The NEXTEA program proposed about \$175 billion be spent between 1998 and 2003 for the improvement of bridges, highways, and transit systems. NEXTEA authorized an 11 percent increase over the Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991. It concentrated on improving border crossings and developing major trade corridors within the United States. According to President Clinton, this bill would create tens of thousands of jobs. From another angle, an analysis by the

ARTBA found that Clinton's 1998-2002 transportation budget would "throw 106,000 transportation construction industry employees out of work over the next five years."

On June 9, 1998, the Transportation Act for the 21st Century (TEA-21) was signed into law. Nearly \$200 billion was allocated for highway construction and maintenance from 1998-2003, picking up where ISTEA left off.

Although spending on operations and maintenance has remained relatively stable since completion of the interstate system, there has been a steady trend toward disinvestment on the part of the federal government. Although capital investment has been declining, highway use in this country has increased dramatically, according to the report. In 1962 the United States spent \$42 for every 1,000 vehicle miles traveled (VMT) on highway infrastructure. Expenditures leveled off at around \$16 per 1,000 VMT in the mid-1990s.

From 1970 to 1990, VMT averaged a growth of 3.3 percent compounded annually. But for the first five years of the 1990s, growth slowed to 2.3 percent. A statement issued by the U.S. Department of Transportation in May 1996 found lower growth rates consistent with Highway Performance Monitoring System forecasts, which showed nationally 2.37 percent compound annual growth over the next 20 years. The report reasoned that vehicle ownership rates may have reached a saturation point, with ownership at one vehicle for personal use per household driver in 1990.

Driver licensing rates have approached saturation, as men are at 93 percent and women at 83 percent of the driving age population. Women have closed this gap since the 1970s and are near men's licensing rates in the high driving age groups. Also, the age structure of the population had a great effect on travel with the baby boom generation entering the high driving age groups during the late 1970s and 1980s. A decline in the number of new drivers is evident now that the baby boom phenomena has passed.

The highway and street construction industry was also hurt by the recession at the beginning of the 1990s. Federal and local governments, burdened with tightened budgets and swelling deficits, had difficulty maintaining existing highway, airport, and street construction projects; new street construction initiatives were sparse as well.

Despite this, road and bridge construction increased slightly during 1992. The demand for improvement of essential arterial transportation systems necessitated work on major roads and highways, and this helped to keep contractors working. New construction suffered, as money was directed toward highway maintenance and repair.

CURRENT CONDITIONS

For financial year 2001 under TEA-21, federal investment in highways exceeded \$30 billion for the first time, reaching \$30.4 billion. This marks a 5.7 percent increase from 2000's \$28.8 billion. A large part of this increase is the result of higher-than-expected gas tax revenues that contribute money to the Highway Trust Fund (HTF). Core highway spending in this plan was \$872 million for 2001, an increase of 3.2 percent over the previous year.

TEA-21 doled out \$31.8 billion in 2002 and is set to expire on September 30, 2003. However, the TEA-21 mathematical formula includes the "revenue-aligned budget authority" (RABA). Because TEA-21 expenditures are linked to the HTF's Highway Account, the actual money available through TEA-21 depends on the amount of funding states receive from incoming highway user fees. Because of the economic recession of the early 2000s, revenues were down, causing the RABA formula to dictate an \$8.6 billion decrease in TEA-21 funding. Compromise among Congress, the Bush administration, and industry advocates led to a \$4.4 billion reduction in highway funding in 2002.

In April 2003 the Bush administration proposed the Safe and Flexible Transportation Efficiency Act of 2003 (SAFETEA) to replace TEA-21. Whereas TEA-21 authorized \$218 billion over six years, SAFETEA would provide a modest increase to \$247 billion. SAFETEA would also contain adjustments to the RABA formula to prevent large swings in funding. At the same time the Senate Budget Committee was proposing a spending level of \$311.5 billion, and the House Transportation and Infrastructure Committee was looking at an even higher appropriation of \$375 billion. In May the new highway funding plan was worked out to approximately \$320 billion, which becomes effective in October 2003.

INDUSTRY LEADERS

Street and highway construction leaders in 2002 included Kiewit Construction Group, Inc., of Omaha, Nebraska, with \$3.7 billion in revenue and 15,000 employees, and Granite Construction Inc., of Watsonville, California, with \$1.8 billion in revenue and 5,000 employees.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, the street and highway construction industry employed nearly 320,000 people in 2001. Operating engineers and other construction equipment operators, totaling 51,680, earned a mean annual salary of \$40,760; construction laborers, totaling over 77,000, earned a mean annual salary of \$31,870; and paving and surface workers, totaling 22,390, earned a mean annual salary of \$33,960.

AMERICA AND THE WORLD

The U.S. highway and road system has not kept pace with those of competitors throughout the world. Highway capital investment relative to the economies in Japan, Korea, and Germany, for instance, has been significantly higher over recent years than similar investment in America. In 1988, for example, Japan spent more than 1.8 percent of its Gross National Product (GNP) on highway infrastructure. That's almost triple the amount that the United States invested in highways, 0.7 percent of its GNP.

Comparing capital spending per vehicle miles traveled (VMT), it is obvious Japan is substantially outspending other nations in highway development and maintenance. In 1988 Japan invested \$150 for every 1,000 VMT—nine times the U.S. investment. In the same year, Korea spent \$95 per 1,000 VMT, and Germany expended \$30 per 1,000 VMT. The U.S. spent only \$16 per 1,000 VMT.

Despite lagging investment, America's road building technology remains strong. In fact, although the United States comes up short in terms of highway infrastructure investment, it continues to export highway technology to other nations through the Department of Transportation's FHWA.

RESEARCH AND TECHNOLOGY

New technology in highway construction and maintenance offers significant opportunities to the industry in terms of the ability to meet safety concerns, energy concerns, and other transportation challenges. Computerization has already changed the automobile and promises to revolutionize the mechanical and physical aspects of the car as we know it. Computerization and telecommunications, industry visionaries say, may result in completely automated vehicles traveling automated highways. This would result in improved travel-time, energy conservation, lower operating costs, reduced environmental pollution, and improved highway safety.

Addressing the subject of technology, and highway construction and administration, Thomas D. Larson, U.S. Federal Highway Administrator, said "The research and technology component of a potential future highway program will provide the expanded level of funding necessary to support a long-term aggressive commitment to improving highway productivity through the development, demonstration, and deployment of available and evolving technology for both operations and construction."

Proposed legislation envisions a program with the following components:

- Attention to long-range fundamental and applied research and development activities for pavement and structure materials and construction methods, safety

and traffic research, and improved techniques and technologies for environmental management.

- A focus on intelligent vehicle/highway systems programs in four key areas—advanced traffic management systems, advanced driver information systems, automated vehicle control systems, and advanced commercial vehicle operations.
- A program for motor carrier research activities, including vehicle characteristics, human factors studies, regulatory and program analysis, and other motor carrier-related research.

The highway construction industry has already instituted high-tech methods of dealing with traffic management and safety throughout the United States. One example of this approach is the INFORM system on Long Island, New York. Conceived as an FHWA research and development project, the system features variable message signs that inform motorists of unusual congestion, and also implements ramp metering and signal control on affected freeways and arterials.

The Smart Corridor in California is a 12.3 mile stretch of the Santa Monica Freeway that features coordinated traffic data and management strategies with the California Department of Transportation, the California Highway Patrol, the City of Los Angeles Department of Transportation, and the City of Los Angeles Police Department. By linking traffic control centers and developing a common database of information, the coordination of strategies, such as ramp metering policies, parking enforcement, signal timing, and detours around congested areas will be possible.

In Philadelphia, I-95 is being transformed into a high-tech, traffic management superhighway. An elaborate traffic management plan with advanced technologies, such as integrated ramp metering and signal control, will be used to alleviate traffic congestion, integrate public transit and automobile traffic, and mitigate air and noise pollution.

A new technology to highway construction in 1996 was the use of rubberized asphalt. Roads made with recycled tire chips showed less frost heave than conventional roads. Tire chips also proved much better than soil as an insulator, limiting the depth of frost and therefore the damage of winter. Using rubber in retaining walls reduced the pressure on those walls, allowing them to be lighter, thinner, and less expensive.

Studies by FHWA and university research programs in 1995 aimed to use robotics in highway construction. These included the development of an Automatic Pavement Crack-Sealing Machine and a Pothole-Repairing Machine. Another area of research was directed at improving work zone safety and minimizing traffic congestion with the use of robotic aids.

One of the most environmentally sound research strategies in the highway construction industry was for the use of waste materials and by-products in place of conventional asphalt. In 1994 research was done to help implement materials, such as blast furnace and steel slags, carpet fibers, coal ash by-products, including fly ash and bottom ash, glass, municipal solid waste combustion ash, recycled plastic, roofing shingle wastes, and rubber tires into roads and highways.

highways; and highway, pedestrian, and railway tunnels. General contractors engaged in subway construction are classified in **SIC 1629: Heavy Construction, Not Elsewhere Classified**. Special trade contractors primarily engaged in guardrail construction or installation of highway signs are classified in **SIC 1611: Highway and Street Construction, Except Elevated Highways**.

NAICS CODE(S)

234120 (Bridge and Tunnel Construction)

INDUSTRY SNAPSHOT

According to the U.S. Census Bureau's *Statistical Abstract of the United States*, in 2000 there were 906 bridge, tunnel, and elevated highway construction contractors, down from 1,171 in 1997. These firms employed more than 39,000 people. The value of state and local government construction in 2001 totaled \$1 billion for tunnels and \$10.2 billion for bridges. According to the U.S. National Bridge Inventory, in 2002 there were 617,935 bridges in the United States. Of this total, 266,476 were on county roads, and 144,917 were on state highways. Interstates supported approximately 60,000 bridges. The number of structurally deficient bridges totaled 82,636, and the number of functionally obsolete totaled 79,869.

ORGANIZATION AND STRUCTURE

Roughly 25 percent of the money spent on highway construction in the United States is used for bridge, tunnel, and elevated highway construction, with the remainder spent on "flatwork," such as highways and interstates. The vast majority of the construction work performed by industry firms in 1992 (72 percent) was for bridge and elevated highway construction, while tunnel construction composed only about 12 percent of industry construction. The remaining 17 percent of the industry's construction work encompassed highway, street, and related facilities construction; sewage treatment and water treatment plant construction; and sewer, water main, and related facilities construction. In 1992, 884 industry establishments specialized in bridge and elevated highway construction, while only 122 firms specialized in tunnel construction.

Like general contractors in residential and building construction, general contractors in the bridge, tunnel, and elevated highway construction industry generally assume responsibility for managing an entire construction project, but they may subcontract all or part of a project to various subcontractors. The design and construction of some construction projects may be awarded to a prime contractor and several subcontractors or to a single prime contractor, or the project may be awarded to two or more firms operating in a joint venture. Contractors bid on jobs based on estimates, and the difference between the lowest and

SIC 1622

BRIDGE, TUNNEL, AND ELEVATED HIGHWAY CONSTRUCTION

This category covers general contractors primarily engaged in the construction of bridges; viaducts; elevated

highest bids depends on the accuracy of the estimates made of the job's cost. For example, the six bids received by the Florida Department of Transportation in 1994 for the construction of a bridge—a \$7 million project—differed by only several hundred thousand dollars. Boston's mammoth Central Artery/Tunnel Project (known as "the Big Dig") involved more than 200 design and construction contracts encompassing tens of thousands of intercontract and intracontract dependencies. Typically, bid prices for highway construction projects tend to go up, as the number of bidders declines on any given project.

In cost-reimbursement contracts, builders were paid for justifiable costs incurred during the project, while fixed-price contracts required builders to absorb any cost overruns themselves. Incentive and performance-based construction contracts rewarded contractors who completed projects by prescribed deadlines or ahead of schedule.

Any construction projects using federal funds were required by law to be awarded on the basis of competitive bids, except in the case of emergencies or if the highway agency could demonstrate a more cost-effective way of assigning contracts. Government agencies also considered service, contractor guarantees, past experience with particular contractors, and options offered by individual bidders when evaluating bids. In order to avoid the appearance of relying on "sole sourcing" for public construction projects, some government agencies wrote project specifications in language general enough to attract several potential bidders. Some government public works agencies held "pre-bid" conferences with prospective contractors to make possible the dissemination of information on a project. Such conferences enabled local contractors or experts with specialized knowledge to add input that could help either the agency formulate specifications on the job or assist contractors in modifying their bids.

In the 1990s federal highway and public works agencies increasingly involved themselves in the execution of construction projects. Known as "partnering," this trend changed the way bridge, tunnel, and elevated highway construction projects were conducted. In the early 1990s, the distinction between private and public construction—at one time determined by which sector paid for the construction work—was determined by which sector owned the project. Industry projects were funded by a combination of federal and state funds. In a typical example from the early 1990s, the Federal Highway Administration (FHWA) paid 80 percent for a cable-stayed bridge across the Mississippi River, while the Illinois Department of Transportation paid the remaining 20 percent.

Driven by their need to find alternative funding sources, a growing number of public agencies developed

new financing strategies, such as public-private joint ventures, that allowed state agencies to take advantage of bond market investment funds. The 1991 federal transportation bill also enabled private construction firms for the first time to operate toll collection facilities, while they repaired bridges, tunnels, or highways in order to finance their work without having to invest as much of their own capital up front.

By the early 1990s, 89 percent of state highway agencies were using some form of "team building" or partnering process, and 85 percent incorporated partnering directly into their construction projects. Private and public partnering took several forms, including committing to a joint-mission statement or project charter, reaching agreements on quantifiable objectives of performance, creating an issue-resolution "ladder" to streamline decision making, and jointly developing team-building and problem-solving skills to enhance "team" productivity. An advantage of public-private partnering is that it allows private contractors to review a construction project with a state administrator and, if necessary, adjust a project's specifications, so that contractor capabilities and project requirements meshed.

Almost 67 percent of the value of all industry construction work in 1997 was new construction, with the remainder divided between additions, alterations, and reconstruction—which accounted for 26 percent of the value of the industry's construction work—and maintenance and repair, which represented almost 7 percent.

The public-private partnership funding mechanism flourished in the late 1990s, as construction costs continued to spiral upward, and resistance increased to full public funding of transportation projects. In 1999 Bechtel Group and Kiewit Pacific entered into a contract with the state of Washington, forming a nonprofit corporation to finance and build a companion bridge to the existing Tacoma Narrows bridge. This new bridge is the first major suspension bridge to be constructed in the United State since the 1970s.

The public-private agreement is also an excellent way for a community to acquire a much larger dollar value of improvements for a given amount of public money. This improves the transportation infrastructure and provides many more jobs than a project built solely with public money. In addition to the \$350 million used to build the bridge, the state of Washington will invest another \$350 million for approaches to the new bridge and to Interstate 5.

Although public-private partnerships have been successful in smoothing the resistance to new bridge and highway projects, it is usually necessary for these new facilities to charge tolls. This presents another avenue of resistance to highway improvements. In addition to the new

Tacoma Narrows suspension bridge, Washington State had five other projects on its wish list; these projects failed to go forward because of resistance from antitoll activists.

BACKGROUND AND DEVELOPMENT

Although ancient Roman techniques for constructing stone bridges were sophisticated, it was not until the principles of physics were applied to bridge construction in the nineteenth century that bridge building made the transition from craft to a technical and scientific profession. In 1816 the first suspension bridge in the world was constructed over the Schuylkill River near Philadelphia by U.S. builders. American bridge construction firms erected the country's first iron arch bridge in Pennsylvania between 1836 and 1839, the first all-metal truss bridge in 1840, the first iron girder railroad bridge in 1845, and the first U.S. bridge with concrete piers or foundations in 1848. In the mid-1850s wrought iron began to replace stone in some bridges, increasing their length and durability, and private U.S. firms began to manufacture "proprietary" bridges to be marketed to railroads and government agencies, a practice that continued until the turn of the century. After 1856 the invention of the Bessemer process for producing steel by reducing the carbon content of iron made possible the incorporation of steel into bridge construction. In 1855 John Roebling designed the first stiffened suspension bridge in Niagara Falls, New York, and 28 years later introduced the use of high-strength steel wire in the supporting cables of the famous Brooklyn Bridge. Civil engineering bridge science came into its own in the 1880s, when poor bridge design and cheap building materials led to rail bridge collapses that called attention to the need for systematic analysis of bridge design and construction methods. In the United States, a premium was placed on inexpensive design, which led to the predominance of the simple triangulated truss design (first used with wooden bridges and later for iron bridges).

Although systematic tunneling for military and other purposes dates back at least to the Roman Empire, the first tunnel in the United States was the Erie Canal, constructed between 1817 and 1825. Because early locomotives did not have the power to climb steep slopes, blasting tunnels through mountains was a necessity. The first such railroad tunnel, constructed for the Allegheny Portage Railroad in Pennsylvania, was completed in 1832 and extended the distance record for rail tunnels from 850 feet to four miles. By 1850, 29 railway tunnels had been built in the United States using only picks, shovels, and explosives. The first steam-operated percussion rock drill was patented in 1849. Compressed air percussion drills came into use in 1851.

Nitroglycerin first was used for blasting purposes in the construction of the Hoosac Tunnel in Massachusetts

in the mid-1850s, but by 1865 the excavation of a single cubic yard of rock still required almost four man-hours of labor. The invention of a stable form of nitroglycerin, dynamite, in 1869 made the construction of tunnels for such historic rail lines as the Union-Pacific transcontinental route more practicable. The first underwater railroad tunnel was constructed in 1890, connecting Michigan and Ontario, Canada, and in the same year the first underwater tunnel for horse-drawn carriages was built in Chicago. Although few early tunnels had any linings at all, when used, linings consisted of cast iron rings. This lining method was gradually replaced by such early tunnel-lining materials as timber, brick, and mortar. Tunneling technology was greatly advanced with the development of the Greathead "shield" excavator around the turn of the century, which used air pressure to hold back walls of water, so workers could tunnel underwater.

In 1956 President Dwight Eisenhower initiated a mammoth federally funded program to create a national interstate highway system, later named the Dwight D. Eisenhower System of Interstate and Defense Highways. The system offered industry firms enormous new revenue sources in the construction of bridges, tunnels, and elevated highways. By the mid-1990s, the system, renamed the National Highway System (NHS), encompassed more than 225,000 miles of roads nationwide.

The longest railroad tunnel in North America, measuring 7.7 miles, was constructed in the state of Washington in 1929. As the century progressed, new tunneling techniques began to see wider application. For example, the immersed tube tunnel, also known as the build-and-sink method, enabled underwater tunnels to be built from the surface by lowering prefabricated sections into trenches excavated from the river floor. The first such tunnel was built under the Detroit River between 1906 and 1910 and a second on the West Coast in 1925. In the second half of the twentieth century, tunneling methods, materials, and excavating tools continued to evolve in sophistication and versatility, culminating in the construction of the Channel Tunnel (Chunnel) between Great Britain and France in the 1980s and 1990s. Although the construction of the Chunnel required no radical new departures in tunneling science, its sheer scale, expense, and technical success made it perhaps the single most important tunneling project in history. The engineering success of the tunnel (though marred by its great expense and a major tunnel fire in 1996) led some engineers in the mid-1990s to explore the idea of tunnels connecting Russia and Alaska across the Bering Straits and Morocco and Spain across the Straits of Gibraltar.

About 25 percent of the value of highway construction consisted of bridges, overpasses, and tunnels in 1993, while flatwork (primarily roads) accounted for the remaining 75 percent. According to a U.S. Department of

Transportation report on the status of the nation's highways, bridges, and transit systems, \$49.9 billion was required to maintain the condition and performance of the nation's highways and bridges in 1994. In 1991 it was estimated that approximately 72 percent of existing U.S. bridges were built before 1935, and estimates of the nation's roughly 575,000 bridges that were structurally or functionally deficient in the early 1990s ranged from 14 to 40 percent, with those in New York in most need of repair. In addition, the Federal Highway Administration estimated that another 21 percent of U.S. bridges were not only deficient but obsolete, leaving a grand total of 225,000 to 231,000 below-par bridges nationwide. Roughly 42 percent of the backlog for bridge rehabilitation in the early 1990s involved pavement costs, and the remaining 58 percent was for constructing additional capacity. By 1996 the estimated cost of upgrading the backlog of deficient U.S. bridges had risen to about \$72 billion. By 1998 the value of new construction for highways, including elevated highways and bridges, was expected to increase to almost \$39 billion.

Perhaps the largest single bridge, tunnel, and elevated highway construction project in the United States in the mid-1990s was the \$7.7 billion Central Artery/Third Harbor Tunnel project in Boston, which consisted of an immersed three-quarter-mile tube tunnel and elevated highway system designed to connect several Boston neighborhoods with the rest of the city. With roughly 22 percent finished by mid-1996, the project was expected to be completed in 2004. A total of 100 contractors, subcontractors, and government agencies were involved in the Boston project, led by the Bechtel Group and Parsons Brinckerhoff.

Other major U.S. construction projects in the mid-1990s included the widening of the George P. Coleman Bridge in Virginia (the second-largest double-swing span bridge in the world) by Tidewater Construction; the construction of the Des Plaines River section of Chicago's deep tunnel and reservoir plan by Kenny Construction, Kiewit Construction Group, and J. F. Shea; the completion of the Cumberland Gap Highway Tunnel project between Kentucky and Virginia (including two-lane tunnels and seven roadway bridges); and a \$3 billion deep tunnel wastewater collection, treatment, and disposal system in Singapore by CH2M Hill and Parsons Brinckerhoff. In the mid-1990s New York City mayor Rudolf Guiliani began pushing the construction of a multibillion dollar water tunnel to supplement New York's water supply.

In November 1995 President Clinton signed the National Highway System Designation Act of 1995, which injected an additional \$5.4 billion into the federal contribution set aside for the NHS. By one estimate each \$1 billion of federal highway aid created roughly 7,900 full-

time, on-site construction jobs in the United States. One provision of the act also raised the maximum federal share for toll project funding to 80 percent, up from a variable 50 to 80 percent previously.

The Intermodal Surface Transportation Efficiency Act (ISTEA)—an annually budgeted omnibus transportation legislation package—and FHWA funds accounted for a large percentage of the revenues of industry firms. In 1991 ISTEA provided \$130 billion in transportation funding. In mid-1998 President Clinton signed a funding bill that was a follow-up to the 1991 ISTEA legislation. Called the "Transportation Equity Act for the 21st Century" (TEA-21), it provides \$217 billion through the year 2003 for all types of surface transportation. It is the largest public works legislation in U.S. history. Since it was signed into law, implementation of the act was passed to each state's transportation agency along with the state's share of the funding. The state is responsible for parceling out its share of the funds for use in highway, bridge, and tunnel projects. The transportation industry is watching carefully how the money is distributed and how well transportation contractors and government are prepared to fill the transportation needs of the century.

States have received this funding with mixed blessings. For instance, California's share of the TEA-21 funding is more than \$14 billion; this money filled a large void in funding caused by the voters' rejection of \$4 billion in transportation bond issues in the late 1990s. Although Illinois's allocation is expected to be \$5.3 billion, the state ranks first in truck traffic, yet it only has the sixth highest level of funding in the TEA-21 package. New York's \$8 billion allocation is music to the state's ears—with this money New York will be able to complete even the smaller projects that usually get pushed aside when transportation priorities are assigned.

CURRENT CONDITIONS

Of the more than 600,000 bridges in the United States, 45 percent are under the financial jurisdiction of state governments, and 38 percent are controlled by county authorities. The remainder are maintained by cities, and a small number are under the control of other agencies. The development, construction, and maintenance of these bridges, along with the handful of tunnels in the United States, are dependent on the funding priorities of local, state, and federal legislative bodies. The sluggish economy of the early 2000s pushed many state governments, in particular, to the brink of financial disaster. With the coffers nearing empty, new and upgraded bridge and tunnel projects were stalled.

In April 2003 the Bush administration proposed the Safe and Flexible Transportation Efficiency Act of 2003 (SAFETEA) to replace TEA-21. Whereas TEA-21 authorized \$218 billion over six years, SAFETEA would pro-

vide a modest increase to \$247 billion. At the same time the Senate Budget Committee was proposing a spending level of \$311.5 billion, and the House Transportation and Infrastructure Committee was looking at an even higher appropriation of \$375 billion. In May the new highway funding plan was worked out to approximately \$320 billion, which becomes effective in October 2003. A portion of the funding will go toward upgrading and building new tunnels and bridges to attempt to ease historically high traffic congestion levels. New projects will likely include new bridges to serve the ports of Charleston, South Carolina, and New Orleans.

INDUSTRY LEADERS

The leading bridge-building firms in 2002 were Peter Kiewit Sons, Inc. (with \$3.7 billion in sales), Granite Construction (\$1.8 billion), and Skanska USA (\$1.4 million). Peter Kiewit Sons was formed in the 1880s by a Dutch immigrant brick maker, and under the founder's son the firm built dams, power plants, and canals during the New Deal and highways after World War II. In the mid-1990s Kiewit formed a joint venture with the Bechtel Group called United Infrastructure Co. to design, build, finance, and operate private toll roads, bridges, water pipelines, and treatment facilities.

WORKFORCE

The bridge, tunnel, and elevated highway industry encompasses a wide diversity of engineering specializations. A typical advertisement placed in the jobs section of the World Wide Web site of *Road and Bridges* (a leading industry trade magazine), for example, called for an "engineering project analyst" to join up with a state's department of transportation and "assist in contracting for engineering consultant services for highway design projects." His or her responsibilities included determining fees and statistical measures and assisting in the development of agreements with consulting engineers. In addition to requiring state licensure as an engineer, the job required "experience in planning and design of highway improvement projects and knowledge of state government procurement practices." The pay range was \$41,800 to \$54,725. For an annual salary between \$45,470 and \$64,230, an engineering design manager for a municipal construction agency might be required to review private construction development projects, resolve right-of-way issues (i.e., legal arrangements allowing highway projects to be built on specified lands), and oversee municipal permit work.

Structural engineers might be called on to design multispan concrete bridges; to have expertise in designing drilled piers, analyzing soil reports, and driving piles, caissons, abutments, and mats for bridge foundations; and to have experience drafting plans and sections with computer-aided design (CAD) software. With a B.S. de-

gree and two years of specific experience, an entry-level engineer who qualified for this position might expect to be paid at least \$35,000 per year. The majority of the states in the country did not require engineers to possess a degree to practice the profession in the mid-1990s.

Project managers for a freeway construction firm could be expected to prepare design reports, environmental assessments, traffic management analyses, or bridge condition reports and be able to assume overall control of a project involving professionals from several firms. Geotechnical engineers conducted soil analyses to determine the suitability of a site for heavy construction foundations. Other engineers were required to have experience in traffic-flow theory and related modeling software, and to have thorough knowledge of such industry manuals as the *Highway Capacity Manual*. A senior bridge and highway engineer acted as a technical reviewer for quality assurance of bridge and highway designs, plans and construction documents, and condition inspection procedures and reports.

Project schedulers are generally required to utilize such project scheduling software systems as Primavera System Inc.'s P3, and to have experience analyzing the impact of change orders, tracking delays, and scheduling large, complicated, heavy construction projects. So-called special trade contractors perform such tasks as painting and electrical work, and general superintendents directed all functions of large construction operations according to established schedules and procedures. Estimators gather basic data on proposed construction projects from engineering or architectural plans and site inspection, and computed the cost of construction, factoring in profit and overhead. Other integral industry positions included expeditors, materials purchasing agents, marketing managers, drafters, construction inspectors, job-site safety directors, office managers, and foremen.

Construction occupations in the bridge, tunnel, and elevated highway industry were similar to positions in the construction industry as a whole but also included mining industry-related positions, such as mining or tunneling machine operators and drainage constructors. The most important construction occupations included electricians, cement masons, painters, reinforcing ironworkers, structural ironworkers, heavy construction and highway laborers, crane operating engineers, operating engineers of light equipment, operating engineers of heavy equipment, sheet metal workers, and carpenters.

Union efforts in the 1990s to increase membership levels in the heavy construction and highway industries included strategies carried out by the American Federation of Labor and Congress of Industrial Organizations (AFL-CIO) and its building and construction trades department to challenge contractors on their compliance with environmental regulations, membership campaigns targeting specific corporations, political pressure, and

agreements for union-only representation in major government and private projects. Highway and heavy construction work, such as bridge, tunnel, and elevated highway construction, has historically been one of the most dangerous occupations in the United States. In the early 1990s, the National Transportation Safety Board (NTSB) issued reports calling for safeguards in highway construction sites, such as separating traffic lanes in detoured highway construction areas and redesigning highway work zones. Another area of concern stemmed from the unique hazards associated with working in confined spaces, such as sewer and tunnel construction projects. Historically, about 50 workers per year died in confined space construction accidents and another 5,000 suffered serious injuries. In 1993 the Occupational Health and Safety Administration (OSHA) issued new rules governing the safety of workers in confined spaces, requiring employers to warn employees about potential hazards, provide them with protective and emergency equipment, and ensure they follow specific procedures before entering confined work spaces.

AMERICA AND THE WORLD

Beginning in the early 1970s, the world's construction industry became increasingly international in scope, and early on U.S. contractors dominated the global scene. In 1992 U.S. firms were awarded about 49 percent of all international construction contracts, including contracts awarded to foreign subsidiaries of U.S. firms. Beginning at least in the 1980s, however, U.S. construction firms began to fall behind Japanese and European contractors in the development of new construction technologies and building methods, and by 1992 were losing market share in international contracts at a rapid clip. By one estimate, U.S. firms were 10 years behind the pace in construction technology and took twice as long on average as the Japanese to erect a structure. And according to a study by the U.S. Department of Commerce, American construction firms could no longer bring either "strong technological or management advantage" to the bidding process for international infrastructure contracts.

Construction firms in Japan—the world's largest market at \$700 billion in 1995—were the world leaders in the use of high-performance steel, automated equipment, and intelligent buildings and systems, and European firms were the leaders in high-performance asphalt, tunneling, high-speed rail work, and marine construction. The leading U.S. construction firm with more than 50 percent of its revenues from transportation construction work (including bridges, tunnels, and elevated highways) was Kiewit Construction Group of Omaha, Nebraska (52 percent), which, however, only ranked 59th worldwide in 1995 revenues.

In the mid-1990s the largest foreign construction firms with more than 50 percent of their revenues deriv-

ing from transportation construction work were Bouygues SA of France, Toa Corporation of Japan, China Railway Construction Corporation, China Harbor Engineering Co., and Ret-Ser Engineering Agency of Taiwan. Although lagging in the global bridge, tunnel, and elevated highway market, U.S. construction firms in general continued to be the leaders in the Middle East, Latin America, and Canada.

The most promising international markets for industry firms during the early 1990s were located in developing countries, where anticipated transportation infrastructure needs were estimated to cost as much as \$100 billion a year. Nations in the Far East and Pacific Rim, particularly Vietnam, Cambodia, and China, were expected to be the site of much of the international bridge and tunnel industry's most significant projects in the 1990s and beyond. In the mid-1990s an increasing number of major international infrastructure projects were being developed on a "build-own-operate-transfer" (BOOT) basis. In BOOT contracts, which were invented by the Turkish government in the 1980s, the construction firm not only performed the construction work but also operated the finished facility until it became profitable, at which point it transferred ownership to the local government. Another international trend that had just begun to have an effect on the bridge, tunnel, and elevated highway industry was the privatization of international infrastructure work, especially in developing countries with little capital to spend on huge projects. In these arrangements, the builder itself offered to supply the project funding—for a power plant or toll road, for example—and expected to recoup its investment from the income generated by the project when it was operational.

Of the 50 largest U.S. construction contractors in the mid-1990s, the vast majority earned significant portions of their business from international work. Although U.S. construction firms did not have a strong presence in international transportation construction work in the mid-1990s, several major U.S. construction firms did a substantial amount of transportation construction work overseas (which in addition to bridges, roads, and tunnels included airports, canals, locks, marine facilities, dredging work, and railroad construction). Kiewit Construction Group, for example, derived 36 percent of its revenues—its largest segment—from transportation-related construction projects. Morrison Knudson of Boise, Idaho, derived 35 percent of its total market from such construction work, and the Parsons Corporation and Ellis-Don Construction Inc. derived 12 and 22 percent, respectively, of their revenues from international transportation projects.

RESEARCH AND TECHNOLOGY

Innovations in bridge, tunnel, and elevated highway construction technology in the 1990s occurred in three

broad areas: improvements in construction materials, improvements in construction tools and equipment, and wider use of sophisticated engineering and management computer software and automation technologies.

Materials. Although steel has been a highly popular material for bridge and tunnel construction and continued to prove its usefulness in new weathered and improved grades, industry researchers in the 1990s continued to look for other suitable materials. One such alternative was aluminum, which the American Association of State Highway and Transportation (AASHT) officials began recommending as a practical substitute for steel girders and subfloors in bridges. Because of its light weight, anticorrosive properties, and favorable weight-to-strength ratio, aluminum was also used for bridge decks in place of other construction materials.

Although steel has been used almost exclusively as the material for liner plates along the walls of tunnels, plastic polymers offered cost savings in construction time, labor, and equipment in certain tunneling operations. Similarly, the search for alternatives to the traditional welded wire highway concrete reinforcement led to the development of fiber-reinforced concrete, using acrylic, nylon, carbon, and polyethylene materials among others to create stronger, more sound, and cheaper concrete reinforcing materials. Another reinforcement alternative, glass-fiber-reinforced concrete, was also comparatively inexpensive and offered versatility and light weight. Concrete reinforcement using steel fiber has been in use since the late 1950s and was also gaining wider use as an alternative to traditional reinforcing materials in the early 1990s. Plates made of carbon steel were also introduced as a reinforcing element in highway and bridge construction. Other innovations in bridge, tunnel, and elevated highway construction materials included the use of electrical current—called cathodic protection—to counter corrosion of concrete by road salts, as well as new technology for making and installing buried segmental precast arch structures for use in road and rail bridges and tunnels.

Between 1988 and mid-1993, the FHWA's Strategic Highway Research Program developed 130 products aimed at improving highway construction and operation methods, including new pavement engineering techniques and concrete and asphalt with enhanced performance characteristics. By 1996 more than 100 case studies reporting the program's development of successfully implemented technologies had been documented. These included a new road-surfacing material known as Superpave, spray-injection technologies for filling potholes, bridge management software, and concrete anticorrosion technologies. Similarly, the FHWA's Geotechnical Research program developed improvements for bridge foundations, retaining walls, and embankments and maintained experimentation sites for assessing new methods for quantifying the proper-

ties and behavior of soils to predict their suitability for highway and bridge construction.

According to a July 1999 article in *ENR*, a leading industry journal, cable-stays and composites represent the future of bridge-building materials. Bridges will last longer and will require less maintenance. In the traditional suspension bridge, thick cables are strung from the support towers, and the bridge deck hangs from smaller cables attached to the thicker cable. Cable-stayed bridges are similar, except that the cables that hold the bridge deck are attached directly to the support towers. Along with new technology in the manufacture and composition of the towers and cables, it is believed that bridges of the future will also have traffic monitoring and de-icing systems to help with operation and maintenance.

Equipment. Among the many advances in bridge, tunnel, and elevated highway construction equipment in the 1980s and 1990s was the increased use of highway and bridge surface groovers and grinders using diamond-tipped saw blades to cut grooves into pavement for vehicle traction and water drainage. Also utilized more frequently was an underground excavating machine for cutting two-lane road arch tunnels through hard granite. The machine formerly had been used only in underground mining, offering an alternative to drilling and breaking rock by hydraulic wedge or nonexplosive demolition.

Software and Automation. The introduction of engineering/design and project management software had a profound effect on the way bridge, tunnel, and elevated highway construction firms conducted their business. Among the advantages such packages offered were the capability to produce clean and accurate technical drawings by users without drafting skills, correct and replot drawings in a fraction of the time required by manual methods, quickly optimize designs to explore alternative approaches to a project, and better understand a project's total design features through three-dimensional visualization and imaging features.

On the project management and administrative side of construction operations, software programs like "AutoProject" or Primavera's P3 facilitated easy scheduling and project monitoring, time/cost trade-off analyses, and customized reports. Packages like "WinEst" provided building construction estimating features for the Windows operating system and allowed construction managers to create detailed project estimates. Quick scheduling also was completed with Critical Path Method software programs to monitor the progress of individual contracts and an entire construction project.

In the 1990s Japanese firms began dominating the global construction market by integrating automated construction systems and robotics into their construction projects. Systems like Obayashi Corporation's Automated

Building Construction System enabled structures to rise up in half the time as traditional methods. Automated machines delivered the building materials, from columns and beams to floor panels and interior fittings, to the floor under construction, which was enclosed in a climate-controlled "factory-like" environment. Robots then precisely positioned the materials at their appropriate points on the construction floor, and automatic welding machines welded the columns and beams. When the floor was finished, an integrated hydraulic system lifted the entire "shop" up one level to start the process anew. Such systems not only shortened construction schedules by allowing around-the-clock construction, they ensured that the structure was of uniform quality and reduced labor costs and construction site injuries. Using such technologies, by the mid-1990s the Japanese construction firms had become the world's most competitive.

As in many other U.S. industries, the emergence of the Internet and the World Wide Web in the mid-1990s gave industry firms new opportunities to market themselves inexpensively through company Web sites and links to construction industry organizations, journals, and databases. By mid-decade the construction industry was also experimenting with processing federal construction grants remotely through the Web.

SIC 1623

WATER, SEWER, AND UTILITY LINES

This industry covers general and special trade contractors primarily engaged in the construction of water and sewer mains, pipelines, and communications and power lines.

NAICS CODE(S)

234910 (Water, Sewer, and Pipeline Construction)

234920 (Power and Communication Transmission Line Construction)

INDUSTRY SNAPSHOT

According to the U.S. Census Bureau's *Statistical Abstract of the United States*, in 2001 there were 7,483 companies involved in water, sewer, and pipeline construction, down from 8,042 in 1997. Their 165,800 employees earned over \$7 million. Although the number of contracting companies declined, the number of employees increased, reflecting consolidation within the industry.

The three segments of the water, sewer, and utility lines construction industry share a common trait: project-based organizational structure. To facilitate project completion, various general contractors and subcontractors form transitory networks that sometimes last for several years. Nevertheless, the three segments of the industry are distinguished from each other by their key stakeholders, market segments, and projected growth rates.

The utility construction industry is exceptionally sensitive to fluctuations in tax legislation and the investment community, and it experienced a decline during the early 2000s, caused by a decline in overall spending in the United States during a time of economic downturn. The pipeline construction industry, however, benefited from declining spot market prices and increased consumer demand for natural gas. As a result, there was a dramatic increase in building for that sector. The water and sewer construction segments respond to legislative actions and government spending. Decreased federal outlays and financially strapped state and local governments slowed growth for this segment of the industry. Legislative mandates that foster modernization and re-

placement of older aqueduct systems were expected to create long-term growth, however.

Private Electrical Utility Construction. This segment of the heavy construction industry includes the building of new power plants, transmission lines, pollution control facilities, conversion of existing power plants from oil/gas to coal, and modernization of existing power plants. Spending on utility construction slowed considerably after the passage of the 1986 Tax Reform Act. According to a U.S. Industry and Trade Commission report, the inflation-adjusted value of electrical utility construction dropped by 47 percent during the 1980s. Other factors that contributed to the slowdown included excess capacity, changing regulatory policies, dissatisfaction in the investment community, and overseas nuclear-generation disasters.

By the early to mid-1990s, however, demand for electrical energy was increasing rapidly, which encouraged the industry to consider building more electrical generation facilities. DRI/McGraw-Hill estimated in *Electrical World* that one-third of the nation's growth in electrical generation capacity through 2001 would come from retooling and reconfiguring existing power plants rather than new construction, which tends to be far riskier and requires more regulatory permits. In addition, pollution control spending was expected to increase because of environmental restrictions and a federal government program aimed at subsidizing "clean coal" technology.

During 2001 California underwent a serious energy crisis that interrupted service and caused prices to soar. The event highlighted the stress on the country's power lines during high-usage conditions. The average number of megawatts transmitted through power lines during peak summer months increased 22 percent and are expected to increase another 14 percent by 2009. "The grid is literally heating up—when lines are heavily loaded, they get hot, expand, and sag," explained David Stipp in *Fortune*. "Wires drooping onto branches on sweltering days are a major cause of voltage sags and blackouts."

Despite the need for additional power lines in many heavily populated areas, public resistance to new lines, as well as the enormous cost, is prohibitive. The cost of expanding the transmission system to keep pace with increased use has an estimated price tag of at least \$50 billion over the next 10 years.

Oil and Natural Gas Pipeline Construction. The oil/natural gas industry uses pipelines primarily to acquire and transport natural gas. Long-distance, high-pressure "trunk lines" are the most efficient and economical method of transporting gas from areas of production to areas of consumption. Due to seasonal fluctuations in gas demand, transmission companies and large distributors maintain storage facilities near final markets and production markets. At "city-gate" facilities (located as the

pipelines near consumer markets), pressure in the pipeline is reduced and an odorant is added to the gas to make any leaks more noticeable. Finally, end-use pipelines distribute gas to homes and businesses.

During the mid-1990s, recently completed construction projects and system expansions were consolidated into the interstate pipeline grid. The construction of new long-line pipeline systems slowed as the industry moved toward projects such as mainline extensions and lateral facilities to reach specific customers.

Gas pipeline companies reported an industry gas-plant investment of more than \$59.8 billion in 1995, up from \$55.5 billion in 1992. Despite nearly stagnant operating revenues, natural gas and petroleum liquids pipeline companies increased their net incomes slightly in 1995 by improving their efficiency. Oil and gas pipelines were highly volatile during the late 1990s, as production levels and prices swung widely. During the early 2000s, as oil and gas prices rebounded, the pipeline industry was looking toward a brighter future. Natural gas drives 80 percent of pipeline activity in the United States.

New natural gas pipelines from Canada and the Gulf of Mexico began coming online in the late 1990s. The increased supply caused some dips in the price of natural gas, but these fluctuations were generally offset by increased demand for energy. In contrast to the utility construction segment of the industry, world pipeline construction is a rapidly expanding industry.

Water and Sewer System Construction. Water and sewer construction is heavily influenced by growth or decline in the construction industry, since new homes require a water supply and sewage treatment facilities. Developers and local utilities usually pay for water and sewer systems for new subdivisions. During the early and mid-1990s the industry grew moderately, but some projects were postponed because of problems with financing by local governments. This was particularly true of sewer projects. The industry did benefit, however, from federal legislation. The Safe Drinking Water Act Amendments of 1996 required system upgrades, and the Water Resources Act of 1991 increased federal funding for water supply construction.

In 1998 *Forbes* magazine reported that there were almost 60,000 U.S. water companies owned by cities or private enterprises, and many cities were placing their water supply services up for bid. Some U.S. waterworks projects were being taken over by foreign companies.

In the early 2000s, many municipal water and sewer systems were faced with significant problems in maintaining and upgrading aging pipes. The Environmental Protection Agency (EPA) began pressuring municipalities to cut down on combined sewer overflows. These systems, used by some 770 cities, have combined sewer systems that use the same pipe to collect sanitary sewage,

wastewater, and storm water. Other cities have replaced defective pipes to meet EPA guidelines. According to the EPA, to meet new environmental standards, cities will need to spend between \$93 and \$123.5 million per year.

Leading companies in the water, sewer, and utility line construction industry in 2002 included Qwest Communications International Inc., of Denver, Colorado; Morrison Knudsen Corp., of Boise, Idaho; MasTec Inc., of Miami, Florida; and Perini Corp., of Framingham, Massachusetts. One of the largest companies operating in this segment was EMCOR Group Inc., of Norwalk, Connecticut. Previously known as Jamaica Water Power, EMCOR had declared bankruptcy in 1993, was restructured, sold some of its businesses, and acquired others, including Marelich Mechanical Company in 1998 and Poole & Kent in 1999. In 2002 EMCOR recorded a net income of \$62.9 million on \$4 billion in sales.

Another huge company in the industry, Suez (formerly known as Lyonnaise des Eaux), was based in France but expanded its global operations in 1998 by bidding successfully for the contract to supply water to Atlanta, Georgia. In 2002 the company reported revenues of \$37.8 billion.

HEAVY CONSTRUCTION, NOT ELSEWHERE CLASSIFIED

This classification covers general and special trade contractors primarily engaged in the construction of heavy projects, not elsewhere classified.

NAICS CODE(S)

234930 (Industrial Nonbuilding Structure Construction)
234990 (All Other Heavy Construction)

INDUSTRY SNAPSHOT

The heavy construction business is divided into several specific categories that represent separate building and development industries. There remain, however, multiple specialty construction activities that cannot be easily classified. Consequently, this miscellaneous heavy construction industry was named to encompass and represent these specialties. This industry is composed of companies primarily engaged in the construction of heavy projects not classified elsewhere. The array of categories in this group include athletic field and golf course construction, clearing of brush and land, land drainage, canal and channel construction, chemical complex or facilities construction, dam and dike construction, hydroelectric plant and petrochemical plant construction, missile facilities construction, pier, wharf and waterway construction, pond construction, power plant construction, and railroad construction.

The structure, history, and current status of this industry is closely related to, and often overlaps, the major divisions of the overall construction industry. Therefore, this entry stresses many of the unique specialties that are considered miscellaneous, and serves to tie-up loose ends of the heavy construction market that are not addressed in other standard industrial classifications. For more information on the structure and history of this industry, see related entries in the heavy construction industry.

The U.S. construction industry overall continued to grow throughout the late 1990s, largely as a result of a strong economy, which drove building in both residential and nonresidential markets. However, by the early 2000s, as the U.S. economy weakened considerably, this trend had reversed. Based on a 2003 *ENR* survey of the top 400 contractors, revenues fell by 3.2 percent in 2001 and by another 2.9 percent in 2002. Estimated 2002 domestic revenues for all establishments in this classification were \$174.79 billion, compared to \$200.93 billion in 2001. International revenues declined by 10.9 percent to \$19.6 billion in 2002.

Apart from a weak economy, factors influencing the decline in this industry were the terrorist attacks of September 11, which devastated the U.S. insurance industry, and the Enron scandal and subsequent bankruptcy, as well as various other highly publicized discoveries of corporate fraud and accounting irregularities. As the economy worsened, declining tax revenues and funding cuts prompted state and local governments to tighten their construction budgets.

Despite the troubles of the early 2000s, prospects for the near future in this industry were generally considered favorable by industry analysts and insiders. The opening of foreign markets to American construction companies created great potential for further international growth, while domestic funding for government-based initiatives was expected to increase as the economy slowly recovered. The transportation sector is expected to perform particularly well.

ORGANIZATION AND STRUCTURE

Because the miscellaneous heavy construction industry is actually a conglomeration of many distinct activities performed by diverse companies, there is not a formal structure by which it is characterized. Likewise, few statistics exist that provide a representative picture of the companies within the industry or the markets that they serve. Many of the firms in this industry are active in several areas, while others are highly specialized. Furthermore, it is difficult to distinguish this classification from other sectors of the overall construction industry because many of the miscellaneous activities are closely related to other markets. For instance, aqueduct construction is not part of this industry, but both canal building and waterway development are included. Similarly, subway tunnel construction is part of the industry, but highway tunnel work is not encompassed by this classification.

Most companies in this industry usually act as general contractors for specific construction projects. This means that they sign a contract with the entity for whom the job is being done and are responsible for seeing that all work pertaining to the job is accomplished. Responsibilities of general contractors include hiring and managing sub-contractors. In some cases, however, companies in this industry act merely as sub-contractors, serving as part of a team of companies working to construct a project rather than orchestrating and managing the entire job.

Although huge multinationals dominate the top 10 lists of industry leaders, most companies in this industry are quite small. According to the latest U.S. Census Bureau statistics available, 15,475 establishments were classified as Heavy Construction, n.e.c., with a total of 192,974 employees—an average of 12.5 employees per establishment, which marks a decline from the average of 19.2 in 1992. The vast majority of establishments indicated that at least 51 percent of their business was specialized; taking into consideration both the number of establishments and the size of those establishments, the most common areas of specialization included conservation and development, sewage and water treatment plants, and mass transit construction. Larger corporations may achieve specialization through divisions and subsid-

aries, or through joint ventures with more specialized firms.

Industry Divisions. Many of the miscellaneous projects in the heavy construction industry are so irregular that they cannot be comfortably categorized with a significant number of other activities. For instance, removing underwater timber and extinguishing oil well fires are both relatively distinctive enterprises. On the other hand, a few broad categories exist that encompass many of the miscellaneous activities, and thus bring some order to this industry classification.

A 2003 survey of the top 400 contractors broke down as follows: 50.6 percent of 2002 revenues in the construction industry came under the general category of building, most of which does not fit into this classification. The remaining 49.4 percent was split among various specialties, including several in this classification.

Transportation took 13.3 percent of the market, with \$25.8 billion in revenues. Some of the projects included in this miscellaneous heavy construction field are subways, railroads, and canal construction, including repair work on existing projects. Nearly 400 companies specialized to some degree in mass transit construction alone.

Power-related construction had 9.7 percent of revenues, with \$18.8 billion dollars. Construction projects that fall under this category include new power plants, conversion of existing power plants from oil and gas to coal, modernization of power plant buildings, and myriad modern, unconventional power plant projects, which are spurred by technological advances. With the inclusion of power and telephone lines, roughly 500 establishments specialized to some degree in this sector of the industry.

Sewage and wastewater treatment, and related projects, took 1.7 percent of the market, with \$3.3 billion in revenues. Work in this category primarily entails contracts related to water and sewage treatment plant construction and renovation, including filtration and desalination plants. Sewer and water line development is not considered part of the miscellaneous heavy construction industry. Nearly 700 establishments considered this one of their specialties.

Other water projects, such as reservoirs and dams, represented 1.6 percent of the market, with \$3.0 billion in revenues. Spending on water construction remained relatively steady through the late 1990s, although it also felt the effects of the economic downturn in the early 2000s.

The “Other” category had 2.0 percent of the total market, with \$3.7 billion dollars. A few of these activities include furnace construction for industrial plants, kiln construction, missile facilities development, pile driving, underwater rock removal, construction of industrial baking ovens, and development of chemical complexes and

facilities. Sports and recreation facilities, such as golf courses, racing speedways, tennis courts, or ice rinks, also fall under this classification.

A category of construction that split among these and other categories was conservation. Some of the jobs included in this heavy construction industry include breakwater construction, brush clearing and cutting, land clearing, drainage project construction, dredging, earth moving (not related to building construction), flood control project development, land and sea reclamation, pond construction, and water power plant development. Over 3,000 establishments considered this their specialty to some degree; more than 2,146 specialized completely in this area.

BACKGROUND AND DEVELOPMENT

Although the success of individual specialties within the industry varied widely in the 1980s and early 1990s, the industry followed the same economic pattern as the general construction market. Most commercial construction sectors boomed during the mid-1980s but became recessed in the late 1980s and early 1990s. In contrast, industrial and public construction remained comparatively stable.

The health of the miscellaneous heavy construction industry was similar to that of the overall construction industry in the mid-1990s. However, a greater proportion of these miscellaneous projects were related to public works (except military installations) and industrial activity, rather than commercial construction. Because the commercial sector was the most depressed segment of the construction industry, the market for miscellaneous projects was not as adversely affected as other construction markets by the economic downturn of the late 1980s and early 1990s.

For example, total expenditures for commercial construction plummeted about 40 percent between 1985 and 1992, falling from approximately \$87 billion to \$54 billion. During the same period, however, the value of all work done in the construction industry fell about 13 percent, to an annual rate of just under \$410 billion by the end of 1991. Furthermore, spending in several sectors that represented disproportionately large amounts of miscellaneous construction actually increased. Spending on water supplies increased from \$3.5 billion in 1989 to about \$4.8 billion in 1992. Similarly, spending on all miscellaneous private structures increased from about \$2.3 billion in 1989 to about \$2.9 billion during 1992.

Despite the industry's resilience, most contractors that offered miscellaneous heavy construction services were still striving to recover from unfavorable market conditions which began in the late 1980s and lingered into the mid-1990s. Several factors contributed to these conditions: increased competition from global competi-

tors, as well as from domestic contractors that were fleeing from depressed market segments; lower profit margins caused by increased competition; a weak economy, which was resulting in a general reduction in the demand for new construction and was generating fewer tax dollars for public improvement projects, and; a lack of capital available to finance new projects.

Conservation. In 1992 the value of new conservation construction amounted to approximately \$4.5 billion, reflecting a growth of 5 percent. This figure excluded repair work on existing facilities, but included some work classified in other construction industries.

In 1993, federal expenditures accounted for more than 80 percent of the activity in the conservation category and were administered by three federal agencies: The Army Corps of Engineers, the Bureau of Reclamation, and the Tennessee Valley Authority (TVA). The Army Corps of Engineers' hydropower facilities accounted for 30 percent of the U.S. power generating capacity in 1993.

Although the last of the Bureau of Land Reclamation's "mega-dams" were put into place in Arizona and Utah in 1993, several new smaller projects were planned. The Army Corps of Engineers was planning significant rehabilitation expenditures for major repairs of its dams, many of which were built in the 1940s and 1950s. Other conservation construction spending was slated by the TVA, which launched a \$100-million redevelopment program in 1991 for dam repairs. Furthermore, more than \$1 billion of spending was earmarked for flood control projects in such states as California and New Jersey.

One of the more ambitious conservation projects proposed in 1993 was an effluent diversion plan in the San Francisco Bay area. This \$3-billion proposal, developed by the city's Department of Public Works, called for treating, storing, and delivering municipal wastewater to farmers nearly 50 miles away. Part of the plan proposed spending an additional \$200 million to construct a seven-mile tunnel across the city that would transport effluence to the ocean.

Utilities. Although the inflation-adjusted value of electric utility construction (excluding water power) dipped by 47 percent during the 1980s, the decline appeared to have leveled off in the early 1990s. The market for power plant retrofits, which increase plant efficiency or convert plants to run on different fuels, was especially promising. In fact, expenditures for the maintenance and repair of electric utilities were almost as great as new utility construction spending in the mid-1990s. This phenomenon was due in part to increased regulatory requirements and financial risks associated with building new utility facilities.

Transportation. Growth in mass transit construction activity, much of which falls into the miscellaneous heavy construction industry, received a significant boost by the Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991. ISTEA was created to generate as much as \$90 billion in additional funds for new mass transit projects between 1992 and 1997. ISTEA was also responsible for much of the projected 21 percent growth in the Department of Transportation's mass transit spending for 1994. The Federal Highway Administration recognized that economic and environmental constraints of the 1990s would make it impossible to build the 34,000 lane miles needed to meet U.S. traffic demand, and consequently focused on boosting rail industry prospects.

Although traditional railroad construction, which is also part of the industry, was relatively stagnant in the early 1990s, there was growth in the rehabilitation of commuter and intercity tracks. For instance, Amtrak was electrifying a line between New Haven and Boston under a \$300-million construction contract. At least \$500 million of additional spending would improve other areas of Amtrak's Northeast corridor. Additionally, Los Angeles was continuing construction of a multi-billion dollar, 400-mile regional rail system in 1993.

Using trains for airport transportation was a growing trend in the late 1990s: as of 1998, 166 cities worldwide either had or were planning or building such systems. An expansion project underway for San Francisco International Airport carried a price tag of \$1.1 billion; a new system for JFK in New York was projected to cost \$1.5 billion. Parsons Brinckerhoff was the general engineering consultant for the San Francisco project, while the JFK project was a joint venture of Bombardier Transportation, Skanska USA, STV, Inc., Alcatel Canada, and Perini Corp.

Traditional rail was on the rise in the late 1990s as well, for both passengers and freight, as infrastructure investments reached record highs. Capital spending by "Class I" railroads was over \$6.26 billion in 1997, as railroads increased capacity to compete directly with the trucking industry. Several railroad companies announced plans in 1998 to spend even more: Union Pacific planned to spend \$1.4 billion, CSX Corp. announced nearly \$320 million in construction projects, and Dakota, Minnesota & Eastern Railroad was seeking federal approval for a \$1.2 billion expansion.

Water and Sewage. Spending on new water and sewage projects in 1992 was approximately \$13.4 billion, up from \$11.7 billion in 1989. Much of that amount, however, was spent on activities such as pipeline and man-hole construction, which are classified in other industries.

Most of the growth in this division of the industry was dependent on increased federal spending on municipi-

pal water supply construction allocated by The Safe Water Drinking Act and The Water Resources Act. For instance, in 1993 the Environmental Protection Agency (EPA) estimated that it would take \$110.6 billion over 20 years to deal with U.S. water pollution.

Aside from wastewater treatment and water supply facilities, filtration was a growing market, as the federal government forced localities to improve their water supplies. In 1992, San Francisco was ordered to initiate a \$500-million surface water filtration program. The city of New York was facing a potential \$5 billion investment in filtration systems. Other domestic opportunities for water and sewage facilities contractors existed in the West and Southwest, where disappearing or contaminated water supplies were forcing many cities to resort to desalinization to supplement drinking water supplies.

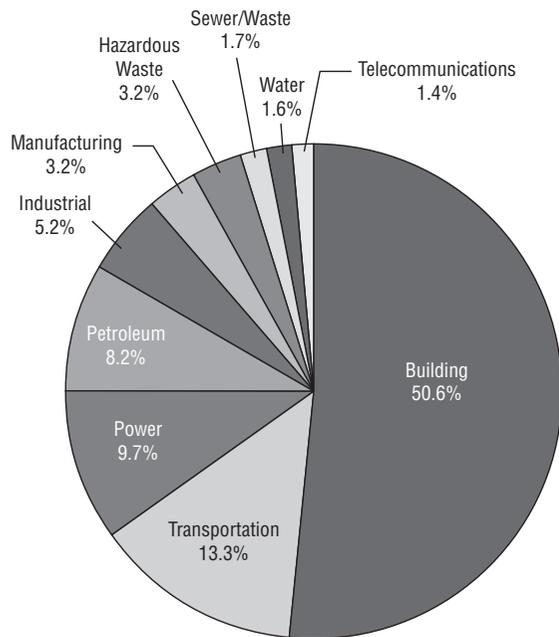

In general, increasing concerns about the environment were a boon for firms specializing in these areas of the industry. According to a 1999 report in *ENR*, "municipalities face the twin challenges of expanding populations and ever-stricter state and federal standards for water and wastewater treatment." The top 200 firms focusing on environmental engineering earned \$26.7 billion in revenue in 1998, marking an 11 percent increase from the year before. Forty-seven percent of that revenue came from water, wastewater, and solid waste projects. The potential for profits from this sector spurred heavy competition among contractors, with many larger firms acquiring smaller niche businesses to expand their footprint in this area.

CURRENT CONDITIONS

The top 400 construction contractors saw domestic revenues decline by 2.9 percent in 2002 as the value of new domestic contracts declined 10.9 percent to \$172.8 billion. However, while international revenues declined 10.9 percent, the value of new international contracts rose 7 percent to \$24.4 billion. Some industry analysts believe that emerging international markets will offer the most growth potential to U.S. contractors through the first decade of the twenty-first century.

Conservation and Water. The Water Resources Development Act of 1999 (WRDA) was expected to make available over \$4.3 billion dollars for 45 major conservation projects, including flood control and dredging. That federal money was expected to be matched by local money, bringing the total to \$6.3 billion. One goal of the bill was to develop nonstructural methods of flood control, including the restoration of wetlands and floodplains. "Challenge 21," as the project was called, was slated to receive \$200 million of the federal WRDA money. Major dredging projects included Oakland Harbor (receiving \$128.1 in federal money) and Savannah Harbor (\$145.2 million); beach-rebuilding projects were

Percentage of Top 400 U.S. Contractors Engaged in Heavy Construction Industry Sectors

SOURCE: ENR, May 2003

planned for mid-Atlantic states including Delaware and New Jersey. Congressional members also mentioned the possibility of a similar act in the year 2000, which might include significant funding for the restoration of the Florida Everglades.

In late 1999, the House considered reauthorizing the Clean Water State Revolving Loan Fund program, which expired in 1994. A bill co-sponsored by Rep. Sue Kelly (R-N.Y.) and Rep. Ellen Tauscher (D-Calif.) would fund the program at \$3 billion per year for five years. Part of that money would be earmarked for smaller projects in less populated areas.

Transportation. The passage of the Transportation Equity Act for the 21st Century (TEA-21) in year 1998 was expected to boost this sector of the heavy construction industry through the year 2005. The Act, which was the largest public works measure ever authorized by Congress, set aside \$217 billion for transportation construction, at an average of \$26.2 billion per year over five years. Important areas for growth in transportation construction included light rail projects—representing at least 10 percent of TEA-21 projects—and airport construction. Cities considering building commuter lines included Cleveland, Minneapolis-St. Paul, Madison, Seattle, and Salt Lake City. Areas with existing commuter rail—including Long Island, Miami, Boston, and Chicago—were also making plans to extend services. In

March of 2004, the House Transportation and Infrastructure Committee approved a \$275 billion version of TEA-21, dubbed the Transportation Equity Act—a Legacy for Users (TEA-LU). TEA-LU was drafted as a compromise between the \$318-billion version of TEA approved by the U.S. Senate and the \$256 billion version of TEA advanced by the Bush administration. If enacted, the bill will authorize the spending of \$275 billion on transportation-related projects through 2010.

High-speed rail was another beneficiary of TEA-21 funding, with \$121.5 million in earmarked funds from 1998 to 2004—plus another \$1 billion to study magnetic levitation technology. High-speed rail, which travels at speeds from 150 to 300 mph, was primarily considered for areas with high population density and heavily touristed areas, including lines from Anaheim, California, to Las Vegas, Nevada; from Orlando International Airport to Disney World; between Dallas, Houston, and San Antonio; and between San Francisco, Los Angeles, and San Diego. If passed, TEA-LU will earmark \$69 billion for transit projects of all kinds, including high-speed rail, through 2010.

Utilities. “Utilities and independents are building power plants again,” according to a year 2000 report in *Forbes*. Deregulation was one of the main factors in the increase in power plant construction, especially renovating existing facilities. However, by the early 2000s, this segment of the industry proved to be one of the hardest hit. According to a May 2003 article in *ENR*, “The surge and then collapse of the power market has been well documented particularly in California. Starting with California’s deregulation of power, then the Enron debacle, followed by the state’s regulation of the industry, the market has been poor.” Adding to industry woes, particularly in California, are the highly publicized financial troubles experienced by both Southern California Edison and Pacific Gas and Electric Co.

INDUSTRY LEADERS

Because miscellaneous heavy construction markets are so fragmented, no companies that are engaged primarily in this industry dominate it. Although some of the largest construction companies in the world complete numerous projects within the industry, these companies are not dedicated to projects included in the miscellaneous heavy construction market. Rather, the industry is mainly composed of thousands of unique small and mid-size companies. Many of these companies specialize in a single activity, such as brush-clearing or pier construction. According to Katherine Grieder of Insurance Marketing Research, “Approximately \$4.1 billion in premium, or 75 percent of the total, is in small and medium sized accounts. The average premium per account of \$12,300 for small firms and \$124,000 for medium sized

firms makes this a much sought after area for independent agents.”

Ranked by total sales (which may include projects not included in this classification), the top five companies in this industry in 2002 were Bechtel Group Inc. (\$11.6 billion, which reflects a percent decline from 2001); Fluor Corp. (\$8.8 billion, which reflects an 11.6 percent decline); Turner Corp. (\$6.05 billion, which reflects a 3.9 percent decline); Skanska USA Building Inc. (\$4.8 billion, which reflects a 3.7 percent decline); and Kellogg Brown and Root, Inc. (\$3.7 billion).

Rankings within particular classifications give a clearer picture of who leads the industry in each sector. Light rail leaders include Skanska USA, Peter Kiewit Sons', and Raytheon Engineers and Constructors. Power plants leaders include Bechtel Group Inc., Black & Veatch, and Raytheon Engineers and Constructors. Leading the list for wastewater treatment are Skanska USA Inc., TIC-The Industrial Company, and Danis Environmental Industries Inc., although Danis was expected to shutter operations by the end of 2004.

WORKFORCE

Although employment in the entire construction industry dropped from over 5 million to less than 4.5 million during the recession of the late 1980s and early 1990s, the miscellaneous heavy construction industry fared better than most other segments of the construction market. In fact, certain areas of this industry were realizing significant employment growth in the 1990s. Most growth was expected to occur in sectors that benefited from increased federal spending or from federal mandates requiring businesses and localities to invest in construction. By 2002, despite a waning economy, employment in construction had recovered to 6.7 million workers, due in large part to booming residential construction, which was far outstripping miscellaneous heavy construction by then.

Significant growth was expected to occur in miscellaneous activities related to environmental construction such as wastewater treatment, retrofits of energy producing facilities that were polluting the atmosphere, and land reclamation. When these sectors bottomed out in the early 2000s, however, analysts began pointing to international markets, where the largest growth was expected to occur.

Job positions in the miscellaneous heavy construction industry were similar to those available in related heavy construction industries. Jobs in construction management, skilled trade work, physical labor, equipment operation, and sales were representative of the overall construction industry. Growth was most likely to occur in positions that required technical knowledge, as more firms were relying on advanced technology to reduce

costs and become more competitive in the crowded market.

A multitude of niche opportunities existed in miscellaneous projects, as well. For instance, high-paying jobs in weapons disarmament and battlefield reclamation were on the rise as foreign governments increasingly sought U.S. expertise in removing and detonating live explosives that remained after armed conflicts. Another growing field was removal of underground storage tanks, many of which were leaking hazardous residues and were contaminating surrounding soil and water tables.

AMERICA AND THE WORLD

Through the early 2000s, the United States was the world's largest construction market, surpassing economically depressed Japan, which was the largest market in the mid-1990s. China was a distant third. Other markets expecting to see growth rates of 8 percent or higher in the early 2000s included Italy, Spain, Australia, Mexico, India, and Switzerland. The market with the highest predicted growth was Korea. Only Brazil was expected to show a slight decline in growth.

Based on growth in the early 1990s, industry watchers had anticipated an even larger Asian market, but the collapse of several Asian economies in the late 1990s changed the forecast. Particularly for U.S. construction firms on the West Coast, soft spending in former growth leaders Japan and Korea affected all areas of the construction industry. Bart Eberwien, vice president of Hoffman Construction Co., told *ENR* “Even for a bunch of concrete pourers like us, it's a worldwide economy. Once the world's second-largest economy [Japan] went into a nosedive, it affected all of our customers.” Temporary instability caused by the introduction of the Euro (the European Union's common currency) slowed the growth of markets in Europe as well.

Decreased restrictions on foreign involvement and increased privatization in public works projects created opportunities for U.S. construction firms. In February 2000, India announced plans to build the world's largest hydroelectric power plant, at an estimated cost of \$23 billion (U.S.). The plant was planned to have a capacity of 21,000 megawatts, and to be built on the river Brahmaputra, in northeast India. The National Hydroelectric Power Corporation encouraged U.S. construction companies to pursue contract opportunities on the project through the U.S.-Asia Environmental Partnership.

Contracts in light rail increased overseas as well as domestically. China announced plans to start an extensive light rail development in 2001, including a subway line in the Northeastern city of Shenyang, and above-ground commuter rail in Changchun and Harbin. Competition for the projects was expected to be intense; only 30 percent of total project value was open to foreign partici-

pation. U.S. companies with investments in Chinese concerns, however, would be considered domestic, giving heavily globalized companies a significant advantage.

Environmental and Utility Opportunities. As in U.S. markets, the greatest area of growth for miscellaneous contractors overseas was in the area of environmental construction. American specialty contractors have dominated this industry segment. For example, U.S. firms took the lead in extinguishing more than 900 oil well blazes in Kuwait following the Gulf War of 1991. Growing markets in waste cleanup and water treatment abroad were likely to lure more U.S. companies overseas. Another potential area for international growth was in flood control, as several Asian nations announced plans for major flood control efforts in the second half of 1999. Clean-up in Iraq following U.S. attacks there in 2003 was also expected to require the work of U.S. contractors.

A characteristic of many foreign environmental projects in the industry is immensity. The average overseas utility project in the late 1990s and early 2000s was 4.5 times larger than the typical U.S. project. An example of one of these massive projects was in progress in Pakistan in the mid-1990s. This multi-billion-dollar plan would eventually create an entirely new river system that would allow more efficient and environmentally safe irrigation. The master plan called for the construction of over 2,500 miles of channels, drains, and irrigation canals. In addition to irrigating soil, the system would carry 2,700 cubic feet of refuse water per second to the Arabian Sea. More Western firms were expected to receive contracts for the project as the amount of work exceeded the capacity of Pakistan's construction industry.

The construction of the Katse Dam and two massive accompanying diversion tunnels in Africa was another example of projects that were increasing the foreign market for U.S. firms in the industry. The project, which started in the tiny mountain country of Lesotho in 1991, will carry water and generate power for the Republic of South Africa. The \$5-billion effort, which will provide 29 years worth of construction activity, will result in the continent's tallest dam.

In 1999, Bechtel, already a leader in international construction, announced expansion of its relationship with Royal Dutch/Shell Group, an alliance expected to enhance their competitiveness in seeking contracts to build power plants abroad. The joint venture is known as InterGen, based in Houston. One of its biggest projects as of 1999 was China's largest private coal-fired power plant, built to provide power for most of southern China. The global trend toward the privatization of power plants previously run by national governments—particularly in Latin America and Asia—drove the market for power plant construction up; strategic alliances with key players

in foreign markets became essential for U.S. companies like Bechtel to compete.

RESEARCH AND TECHNOLOGY

An area of growth that has been of particular interest to specialty contractors is alternative energy production facilities. For instance, the first compressed air energy storage unit was completed in 1991. In addition, Hawaii's National Energy Laboratory launched construction of an ocean thermal energy conversion unit in 1992, which was designed to generate electricity by exploiting temperature variations of seawater at different depths.

Other advances in technology offered the potential for growth in wind power plant construction, development of large-scale solar-thermal facilities, and construction of onsite "fuel cell" generation facilities. Fuel cell power plants employ clean electrochemical reactions that generate the useful by-products of steam and heat. New waste-to-energy projects were also beginning to increase, following a lull in the early 1990s. Delaware, for example, unveiled a plan for a \$275 million, 2,400-ton-a-day plant that would burn virtually all the state's combustible, non-recyclable waste.

U.S. dollars began moving from defense to private industry, particularly environmental industries, in the early 1990s. Nevertheless, U.S. construction companies lagged behind many other industrialized nations in the percentage of revenues invested in research and technology in the mid-1990s. In sharp contrast, Japan's construction contractors spent about \$100 million on research in 1992, almost twice as much as their U.S. counterparts. Japanese firms also were forming more joint research ventures between government agencies and other industries. As a result, Japanese miscellaneous heavy construction contractors were setting the pace in three critical growth areas: mass transit, automation, and tunneling. For instance, Japan had already developed an automated rail setter by the mid-1990s, which could lay rail for subway systems. Furthermore, it was nearing completion of an automated tunneling system.

Despite Japanese advances, U.S. firms were breaking new ground and innovating at a record pace, particularly in wastewater and water treatment. For instance, the National Environmental Technology Applications Corp. (NETAC) in Pittsburgh was working with contractors to use X-ray fluorescence technology to analyze soils and sludge for heavy metals. In another breakthrough, the company designed a portable system for screening soil and water samples for volatile organic compounds. NETAC also had developed a biotreatment system that used proprietary microbes and enzymes to cleanse wastewater.

American construction firms were also leading the global industry in development of new software that

served miscellaneous heavy construction firms. One of the newest software breakthroughs was 3-D computer modeling. This process allowed construction managers and job site engineers to construct projects on their computers, piece by piece, before implementing the construction on the ground, thereby reducing completion time and costs. This 3-D modeling technology had already been used in the construction of cogeneration plants, where animated diagrams showed exactly how the projects would come together and how they would later function. In the early 2000s, U.S. researchers continued working on integrating laser imaging, global positioning systems, and sensor technology in an effort to increase automation on construction sites.

In addition to increasing research expenditures, the U.S. government was trying to increase industry awareness of new research and technology being developed. Northwestern University, with an \$18-million grant made possible by ISTEPA, was striving toward this goal through development of the Infrastructure Technology Institute. The purpose of the Institute was to transfer knowledge from research to practical applications in the field.

SIC 1711

PLUMBING, HEATING, AND AIR CONDITIONING

This industry classification covers special trade contractors primarily engaged in plumbing, heating, air conditioning, and similar work. Sheet metal work performed by plumbing, heating, and air conditioning contractors in conjunction with the installation of plumbing, heating, and air conditioning equipment is included here, but roofing and sheet metal work contractors are classified in **SIC 1761: Roofing, Siding, and Sheet Metal Work**. Special trade contractors primarily engaged in electrical work are classified in **SIC 1731: Electrical Work**.

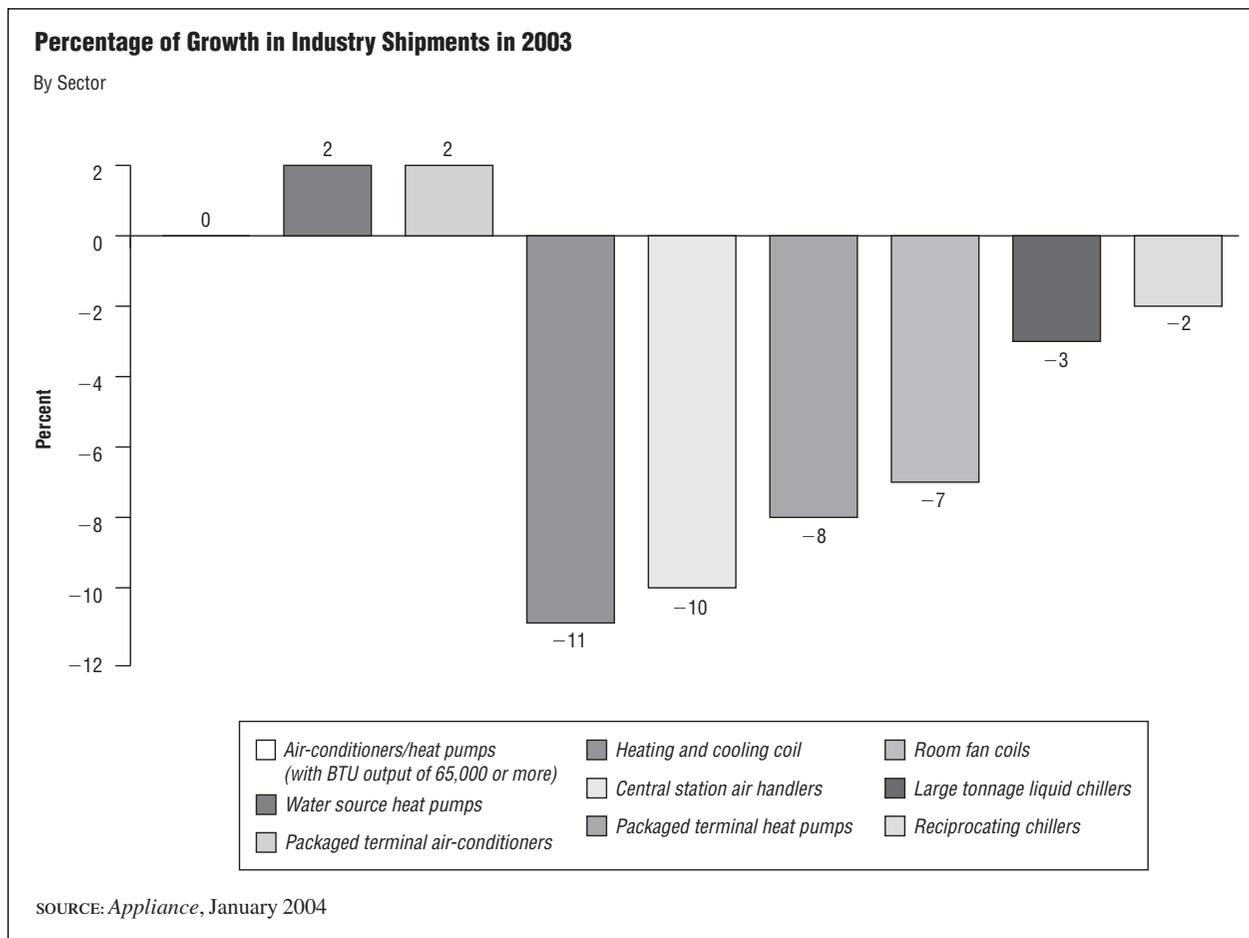

NAICS CODE(S)

235110 (Plumbing, Heating and Air-Conditioning)

The U.S. heating, ventilation, and air-conditioning (HVAC) industry employed about 249,000 workers in 2002, according to the U.S. Bureau of Labor Statistics. Roughly 50 percent of these individuals worked for heating and cooling contractors, and roughly 15 percent were self-employed. Plumbers accounted for nearly 550,000 jobs in 2002. Average hourly earnings for HVAC mechanics and installers were \$16.78 in 2002, with a yearly wage of \$34,902. Plumbers earned an average of \$13.70 per hour, or \$28,475 per year, in 2002. Generally, apprentices earned half the wage paid to their more experienced counterparts.

The plumbing, heating, and air-conditioning industry was benefiting from the growing U.S. housing market in the early 2000s. Despite a weak economy, housing construction continued its record growth in response to low interest rates. There were approximately 1.51 million building permits issued for single family housing in 2003 and 315,000 building permits issued for multi-family units. This was vital for the plumbing, heating, and air-conditioning industry, since more than one-quarter of its construction work was done on detached single-family houses in the early 2000s. Industrial buildings accounted for another 15 percent of its work, followed by office buildings and other commercial buildings at roughly 10 percent each. While sales of industrial and commercial units waned as construction in those sectors slowed in the early 2000s, the booming home construction market pushed shipments of central air-conditioning units and heat pumps to 6.7 million in 2002 and slightly higher yet in 2003. However, the industry did not remain immune to the effects of the recession. According to a January 2004 issue of *Appliance*, “It’s been a difficult few years for the HVAC/R industry, despite the welcome new record shipments of central air-conditioners and heat pumps. The loss of millions of jobs, especially the cutbacks in manufacturing employment, took its toll as indicated by the slowdown in shipments in many sectors of this industry.”

Severe winter weather in some areas of the country in 2004 proved to be a good business opportunity for this industry. Water damage from frozen pipes and frozen water mains required expensive repairs. Also, the nation’s aging housing stock meant that many homes built during the building boom that followed World War II needed replacement heating and air conditioning systems, as well as plumbing repairs, which helped to boost industry sales. In the air-conditioning sector alone, roughly 65 million air-conditioning units were in use as of early 2003, a figure that boded well for future replacement needs.

One trend affecting the plumbing, heating, and air conditioning industry in the early 2000s was the continuing shortage of skilled tradespeople. Jobs in construction continued to suffer an image problem with high school students. The labor shortage was causing firms involved in construction to increase wages, stretch schedules, and, in some cases, reduce the quality of construction. The U.S. Department of Labor named construction as one of the most promising industries for those seeking employment in the early 2000s. The job market for HVAC workers is projected to grow 37.5 percent between 2002 and 2012; for plumbers it is expected to grow 22.5 percent.

While there are thousands of small, independent contractors in this industry, there are also very sizable major companies leading the industry. The top companies in 2003 in the plumbing, heating and air conditioning industry were Comfort Systems USA Incorporated, which posted sales in 2003 of \$785 million; Vivendi North America Management Services; American Residential Service Incorporated, a subsidiary of ServiceMaster; Monumental Investment Corporation, a subsidiary of EMCOR Group Inc.; and ACCO Engineered Systems, formerly known as Air Conditioning Company.

Global demand for HVAC equipment is expected to grow 5 percent annually through 2006, according to the Freedonia Group. Heat transfer equipment is expected to lead the industry with \$20.2 billion in sales by 2006, accounting for a significant portion of the \$110 billion in total industry sales forecasted for that year. Asian countries other than Japan are expected to offer the largest growth potential.

SIC 1721**PAINTING AND PAPER HANGING**

This classification includes special trade contractors primarily engaged in painting and paper hanging. Special trade contractors primarily engaged in roof painting are classified in **SIC 1761: Roofing, Siding, and Sheet Metal Work**.

NAICS CODE(S)

235210 (Painting and Wall Covering Contractors)

Painting and paper hanging is a diverse, highly fragmented industry. In 2002, there were more than 468,000 individuals working in this industry, according to the U.S. Bureau of Labor Statistics.

The painting and paper hanging industry is worth an estimated \$13 billion in income, as per the latest statistics released by the U.S. Census Bureau. Nearly all of this amount was for construction work. While most of the establishments in this industry are small, independent contracting companies, there are several large corporations. In 2003, leading companies included privately owned Brock Enterprises, of Beaumont, Texas, and Long Painting Company, of Seattle, Washington, which posted sales of roughly \$400 million per year.

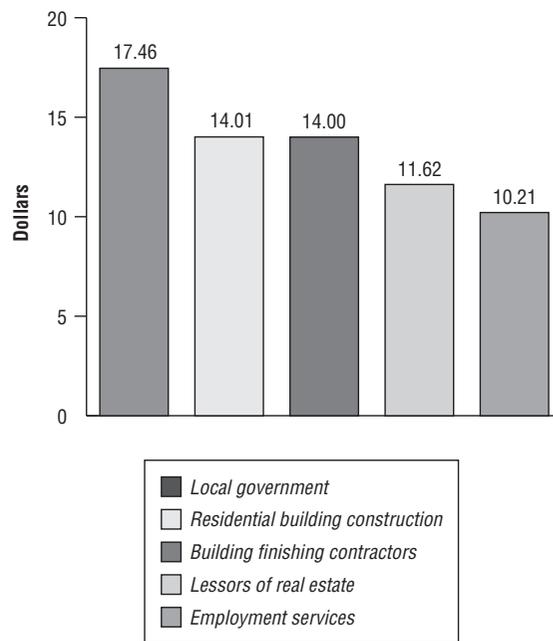

In most regions of the United States, individual contractors and contracting companies are available and handle most industrial and residential contracts. Contractors involved in painting and paper hanging are often represented by one of several industry groups or associations, such as the Painting and Decorating Contractors of America. The 600 top specialty contractors in the United States produced \$612.2 million in revenues for the painting industry in 2001, according to *ENR*.

The painting and paper hanging industry is closely linked with overall trends in the construction industry, since the painting of new and remodeled buildings account for most of the industry's business. For that reason, the painting and paper hanging industry saw sustained growth in the early 2000s. Despite an economic slowdown in the United States, historically low interest rates kept housing starts growing steadily through the early 2000s. The number of single family housing starts reached 1.848 million in 2003, their highest level since 1978. Though expected to decline in 2004, starts still were expected to be at a high enough level to sustain growth in many construction industries, including painting and paper hanging. Consequently, the employment outlook in this industry was expected to grow by 14 percent between 2002 and 2012.

The type of work done by painting and paper hanging firms varies by the type of construction being done.

Median Hourly Wages for Painters and Paperhangers in 2002

By Industry

SOURCE: Bureau of Labor Statistics, 2004

For example, new detached single family houses accounted for more than one-quarter of all work done by this industry. New office buildings were the next largest category of work done, followed by industrial buildings and warehouses and commercial buildings. While the painting and paper hanging industry benefited from the record level of housing starts in the early 2000s, it also felt the pinch of reduced commercial and industrial construction.

Workers earned an average of \$16.49 per hour in 2002. One negative trend in the late 1990s and early 2000s was the shortage of skilled laborers. The construction boom during that time period meant that painting and paper hanging firms had to compete more intensively for skilled labor and increase compensation for their employees. The shortage produced quality problems, increased prices, and stretched schedules for many firms.

SIC 1731

ELECTRICAL WORK

This category covers special trade contractors primarily engaged in electrical work at the site. The construction of transmission lines is classified in **SIC 1623: Water, Sewer, Pipeline, and Communications and Power Line Construction**, and electrical work carried on in repair shops is classified in **SIC 7622: Radio and Television Repair Shops; SIC 7623: Refrigeration and Air-Conditioning Service and Repair Shops; or SIC 7629: Electrical and Electronic Repair Shops, Not Elsewhere Classified**. Establishments primarily engaged in monitoring of burglar and fire alarms with incidental installation are classified in **SIC 7382: Security Systems Services**.

NAICS CODE(S)

561621 (Security Systems Services (except Locksmiths))

235310 (Electrical Contractors)

INDUSTRY SNAPSHOT

The electrical contracting industry in the United States is made up of a few large firms doing business in many regions and a large number of small companies that generally serve customers in their local vicinities. Many of these smaller firms are family owned. Most work in this industry depends on intense competitive bidding, and the obtaining and completing of contracts makes for fluctuating needs for skilled electricians. Most electrical contract work companies are nonunion, but there is a strong union that is influential in some parts of the industry.

In 2002 the industry had approximately 61,400 establishments with 642,000 electricians. After experiencing growth in the mid- and late-1990s, due to nationwide economic improvement and a boom in housing construction, the bottom fell out of the commercial and industrial building industry. Although residential building continued, fueled by low interest rates, commercial development projects fell during 2002 to the lowest levels since

1996. After peaking in 2000 at 66,800 firms with 698,000 employees, the number of electricians and electrical firms declined over the next years to reflect 1997 employment levels. Although the industry stabilized slightly in 2003, many electricians are diversifying their skills and their client base to adjust to the changing economy. New focuses include home networking and security system installation.

ORGANIZATION AND STRUCTURE

While the wide range of company sizes and large number of firms in electrical contracting make for diversity of operations, there are certain patterns relating to the types of customers and jobs, internal functions, costs, union and nonunion conditions, trade associations, training, and governmental regulations and standards.

Customers and Jobs. Electrical contracting firms, as well as other trade contractors, generally do their work at the construction or facility site, though some specialty work may be done in their own shops. When a new building is constructed, these trade contractors are retained by a general contractor who is responsible for the entire building's construction. The specialty contractors, however, are sometimes subcontractors of other subcontractors and, at other times, especially with repair and maintenance jobs, may deal directly with the facility's owners. The ultimate customers are individual homeowners, businesses, institutions, and governmental agencies, each of which has its own manner of dealing with contractors and subcontractors.

Size of Operating Units. About 10 percent of electrical contracting establishments in 1997 had 20 or more employees, and these establishments controlled 60 percent of all business. Only 9 establishments had 1,000 or more employees. Establishments are considered to be generally permanent places, where estimating, procurement, and management of work is done for one or more sites. Larger firms may have a number of such establishments.

Internal Functions. Whether an electrical contracting firm is an individual or a company with 500 employees, it performs the necessary business functions of marketing, estimating, planning, scheduling, purchasing, accounting, and training. The estimating function is especially important in the electrical contracting industry because many jobs are obtained on the basis of competitive bids. Jobs bid too low result in losses, and bids that are too high result in business lost to lower bidding competitors.

Costs. Principal costs are materials and labor. In 1997 the cost of materials and supplies amounted to 36.6 percent of the total value of electrical contractors' work, and their payrolls came to 33.5 percent of that total. Other costs included subcontracted work, rentals for machinery and facilities, fuel, and other overhead and administrative costs.

Unions. The International Brotherhood of Electrical Workers (IBEW) is an American Federation of Labor-Congress of Industrial Organizations (AFL-CIO) affiliate that dates back to the 1890s. Generally, the electrical contractors in larger cities have had larger numbers of union employees. The number of nonunion shops increased during the 1980s, and the IBEW launched a campaign to strengthen its membership. Membership is still down from its high of more than 1 million. In the late 1990s, the IBEW counted 750,000 members in more than 1,100 local unions in both the United States and Canada.

Standards and Regulations. The National Electrical Code (NEC) was established to provide electrical work guidelines to assure avoidance of hazards. The code was fostered by the American National Standards Institute and by the National Fire Protection Association. The code is revised and updated every three years to meet changing technology and improve safety features. In 1996 the National Electrical Contractors Association introduced the National Electrical Installation Standards (NEIS) for electrical products and systems. Not intended for regulatory use, they are voluntary standards intended to create a more specific definition for what is meant by the “neat and workmanlike” standards that the NEC refers to, creating a baseline level for quality and workmanship in electrical construction. Other specifications under development by NEIS at the end of the 1990s included standards for electrical symbols, industrial lighting systems, motor control systems, raceways, cables, hazardous locations, industrial heat tracing systems, and telecommunications.

Regulation. Local and state authorities generally require adherence to code, and most have set up their own supplementary procedures and regulations to monitor its enforcement. Most localities require that electricians performing commercial and industrial work be licensed as journeymen, and some localities provide a “residential wireman’s” license for residential work only. Work permits and inspections are required for new construction, and most cities require yearly code inspections for commercial buildings. In addition, the Underwriters Laboratory has provided a service to manufacturers of electrical and other products to analyze and certify approval to those products that the laboratory has determined meet its minimum safety standards.

BACKGROUND AND DEVELOPMENT

Commercial use of electrical products and services developed rapidly in the late 1880s after Thomas Edison’s invention of the incandescent lamp and other applications. Electrical products and service businesses grew along with related organizations, associations of electrical contractors, and electricians’ unions. Although growth has been quite continuous, there have been cycles with downswings, as in the early 1990s.

One measure of the continuing growth in the electric industries is the fact that the amount of electricity used in American homes tripled in the four decades after 1950. Other data showed growth and change in the structure of the electrical contracting industry in the years between 1972 and 1999. The number of employees reached an all-time high in 1999, and the number of establishments continually increased.

Electrical contracting firms, however, like all construction businesses, have always been subject to significant up and down cycles according to economic conditions. The late 1980s and early 1990s were a period of decline in new construction, and electrical contractors were affected accordingly, as the specialty contracting business in general had lower revenues than in prior years. Most recently, the addition of “limited energy systems,” such as voice-data lines and fiber optics, has expanded the work of electrical contractors.

Unions and Associations. The National Electrical Contractors Association was founded in 1901 and by 1999 boasted 118 local groups and 4,000 contractor members. It has traditionally worked with union leaders in developing training programs and negotiating relationships. Independent Electrical Contractors, Inc. (IEC), formed in 1958, represents primarily open-shop electrical contractors and also administers apprentice training activities. By the year 2000, the IEC grew to a 76-chapter association representing more than 3,500 electrical contractors and nearly 70,000 electrical workers. The International Brotherhood of Electrical Workers (IBEW), founded in 1891, is an affiliate of the AFL-CIO.

During the second half of the 1990s, an ever increasing number of electrical contractors branched into the quickly expanding systems work, which included low voltage applications, such as building alarm systems, automatic building controls, and voice-data communications lines. An increasing number of customers hired electrical contractors solely for their installations of telecommunications wiring and infrastructure. By 1999 standard electrical work accounted for only 60 percent of industry sales, with systems work accounting for 33.5 percent, and the remaining 6.5 percent classed as other.

To stay competitive, many firms sought business in the adaptation of old facilities to meet current and future computer needs, such as installation of systems for new technologies. More and more firms also offered design services to customers. Moreover, a large percentage of homes built before 1970 had electrical systems that were inadequate for their current and future needs, indicating continuing business potential for electrical contracting firms in that area. Maintenance and building modernization accounted for nearly 25 percent of industry sales by the end of the 1990s.

CURRENT CONDITIONS

During the economic recession of the early 2000s, electricians were buoyed by strong residential construction, although industrial and commercial new starts were hit hard by an economic downturn. The electrical contracting sector remained flat during 2002, which was taken as a rather strong stance, considering the state of the economy. Slight improvement was expected for 2003, but the industry expected to see no widespread growth until at least 2004.

In an effort to insulate themselves against downturns in the construction industry, electricians are adding new skills to their resumes. Two top trends for electricians in the early 2000s are home networking and security system installation. Home networking provides a user-friendly interface that connects residential subsystems, such as computer networks, telecommunications, entertainment, and security systems. Electricians can obtain additional training to receive certification as a home technology integrator. According to In-Stat/MDR, as reported by *EC&M Electrical Construction & Maintenance*, the home networking equipment market nearly quadrupled in size from 1999 to the end of 2001, growing from \$150 million to \$585 million. The journal also reported that the magazine *Archi-Tech* predicted that the number of U.S. networked homes would jump from 650,000 in 2000 to more than 1.7 billion by 2005.

Another fast-growing market for low-voltage applications is security systems. In the wake of the terrorist attacks of September 11, 2001, Americans have become increasingly concerned regarding the matter of monitoring physical access to facilities. Although special government contracts will obtain a large portion of the federal push to update security systems at government facilities, electricians will benefit from an increase in security installations across the board, from schools, hospitals, small businesses, and corporate and industrial facilities, as well as residential installations. Digital and remote monitoring are the established standards in security maintenance, but more widespread use of many new applications could be on the horizon, including iris scanning, retinal scanning, hand scanning, and face recognition.

INDUSTRY LEADERS

Most electrical contracting firms were quite small and were limited to a specific geographical area. Also, most such firms provided electrical contracting services only, whereas other outfits engaged in additional contracting work, such as carpentry or masonry. Quite a few construction companies specializing in other fields performed electrical work as well. In the late 1990s, the top three electrical contracting firms in terms of revenue, according to *Electrical Contractor Magazine*, were EM-

COR Group Inc., Integrated Electrical Services Inc., and Building One Services Corp.

EMCOR Group. Based in Norwalk, Connecticut, EMCOR Group reported \$4 billion in revenue in 2002, resulting in a net income of \$62.9 million. The EMCOR Group acquired several large industry leader firms, such as Dynalectric. EMCOR boasted 70 subsidiaries and more than 26,000 employees, with more than a third of its business outside the United States. The company worked with a wide variety of industries and offered complete project design and construction in all phases of mechanical and electrical construction.

Integrated Electrical Services. Based in Houston, Texas, Integrated Electrical Services grew rapidly since going public in January 1997. With 2002 sales of more than \$1.5 billion, it was ranked second in the industry. Integrated Electrical managed rapid growth by acquiring a large number of smaller companies, totaling approximately 170, and by offering services in every aspect of electrical contracting, including commercial, industrial, residential, service, power line and information technology.

WORKFORCE

The principal technicians in the electrical contracting industry were journeyman electricians who had the skills, training, and experience to perform the demanding work. The union status of a contractor had a significant effect on the relationships between management and the electricians, as well as the individual firms' apprentice training approach. Wages varied with job requirements and were influenced significantly by the wage levels in the locality. Jobs for electricians were found in all areas of the country and at all times of the day.

Approximately 50 percent of electricians were employed in the construction industry, and 10 percent were self-employed. The remaining 40 percent worked in a wide variety of other industries and provided a broad range of business functions, including estimating, engineering, planning and scheduling, purchasing, material control, and accounting.

Unions. The share of construction work undertaken by union shops has decreased. In 1997 approximately 18.6 percent of construction workers were represented by unions, according to the U.S. Bureau of Labor Statistics. The International Brotherhood of Electrical Workers (IBEW) began a campaign to increase union membership among electrical contracting firms that had been open-shop firms. This campaign was part of an AFL-CIO construction-worker crusade called COMET (Construction Organizing Membership Educational Training). It was expected that the members of Independent Electrical Contractors (IEC), which are open-shop firms, would

carry on various efforts to maintain their open-shop status. Union membership was heaviest among larger firms and in the major urban areas.

In the union apprentice training program, contractors and the union collaborated in organizing and administering training courses. IBEW and the National Electric Contractors Association had a joint committee that established training standards for the local groups' guidance and promoted journeyman and apprenticeship training. In open-shop localities, training programs were run by the IEC.

Pay. The rates of pay for electricians varied considerably, affected by supply and demand, union presence, and historical wage levels in particular geographic regions. In 2001 the average income for full-time electricians was approximately \$43,300, according to the U.S. Bureau of Labor Statistics. Electricians' helpers earned a mean annual income of \$23,390.

AMERICA AND THE WORLD

The various elements of the American construction industry increasingly looked to international opportunities since around 1980. Despite difficulties gaining entry into foreign markets, demand grew most strongly in the Pacific Rim. The largest market for U.S. contractors was Europe. American-based design firms received \$7 billion in international billings in 1997, and American general contractors received \$25 billion in foreign contracts that same year, according to the U.S. Department of Commerce. In 1997 the United States held the largest percentage, slightly less than 25 percent, of the international contractors market share. U.S. construction exports were predicted to continue to grow by 2 to 5 percent in the coming years, despite the downturn in the Asian economy.

RESEARCH AND TECHNOLOGY

Electrical contractors, as well as construction firms in general, continued to rely on computer programs, such as computer-aided design (CAD), for a variety of functions. According to a survey conducted by the Electrical Contracting Foundation, from 1995 to 1996 the use of CAD for design and development in the electrical contracting industry rose 8 percent and continued to rise. Through the use of CAD 3-D modeling, construction companies could now detect design interferences and problems earlier in the development of a project. Also, the rapid development of the Internet dramatically increased the need for systems work involving upgraded building wiring and fiber-optic cable work.

Deregulation. Since the passage of the Energy Policy Act of 1992, the door opened to deregulation of the electric utility industry. Various states passed legislation that required deregulation in the late 1990s and early

twenty-first century. Industry analysts predicted nationwide deregulation of the utility industry, and it began in several states. While the majority of the impact of this regulation would be felt by utility providers, it remains to be seen how this would effect the status of electrical contractors.

SIC 1741

MASONRY, STONE SETTING, AND OTHER STONE WORK

This category covers special trade contractors primarily engaged in masonry work, stone setting, and other stone work. Special trade contractors primarily engaged in concrete work are classified in **SIC 1771: Concrete Work**; those engaged in digging foundations are classified in **SIC 1794: Excavation Work**; and those engaged in the construction of streets, highways, and alleys are classified in **SIC 1611: Highway and Street Construction, Except Elevated Highways**.

NAICS CODE(S)

235410 (Masonry and Stone Contractors)

INDUSTRY SNAPSHOT

The masonry, stone setting, and other stone work industry includes the laying of cement blocks and bricks, chimney construction, and stone and marble work, both utilitarian and decorative. While some contractors use techniques in existence for centuries, others rely on the latest advances in method and machinery. For example, buildings of rough stone or brick remain dependent on construction techniques developed thousands of years ago, while the cutting and polishing of stone was accomplished in the early 2000s with highly accurate and sometimes electronically controlled machinery.

As a business, masonry remained a relatively small part of the construction specialty trades group. Masonry contractors often worked as subcontractors to general contractors on construction projects, but some also worked for the facility owners on repair and maintenance jobs, or on projects such as the installation of a new marble floor in an old building.

ORGANIZATION AND STRUCTURE

Masonry contracting establishments are considered offices managing work at one or more construction sites. While some of the larger masonry contractors serve customers from several offices over a wide territory, most firms are relatively small, privately or family-owned businesses serving local customers. Most masonry work is performed by specialists, with only about 6 percent contracted to firms primarily engaged in other construction specialties. Furthermore, some masonry specialists limit the scope of their business to specific materials such as brick, cement blocks, or stone. One of the largest masonry firms, The Western Group, works primarily in restoration and renovation projects.

Masonry contract work is done on a variety of structures. According to the latest figures available from the U.S. Census Bureau, the industry is broken down by revenue as follows: single-family houses (26.0 percent), office buildings (12.5 percent), stores, restaurants, and gas stations (12.5 percent), industrial buildings (8.7 percent), schools (6.2 percent), apartment buildings (5.7 percent), houses (5.4 percent), hospitals (3.9 percent), other institutions (3.6 percent), warehouses (3.5 percent), heavy industrial facilities (2.2 percent), churches (2.0 percent), and other construction (7.8 percent). Of the total construction amounts, about 76 percent represented new construction, 24 percent additional alterations or reconstruction, and 10 percent maintenance and repair.

Masonry contracting companies all performed the necessary business functions of marketing, estimating, planning, scheduling, purchasing, accounting, and training. Since most contracts were secured on the basis of competitive bids, the estimation function was regarded as one of the most important in the business, requiring

special skills and experience. Bids that were too high resulted in losing contracts to competitors, whereas jobs bid too low could result in losses for the contractor. Masonry was also subject to national, state, and city building codes, which required the full understanding and compliance of the masonry firm management and technicians.

In the early 2000s, payroll represented the main cost of operating masonry contractor businesses, representing roughly one-third of total revenues. The cost of building materials represented another one-third, and work subcontracted to other firms represented less than 10 percent of revenues. The balance went toward overhead and administrative costs.

BACKGROUND AND DEVELOPMENT

Masonry had its origins in Mesopotamia around 4000 B.C., when mud or clay bricks were used in construction. In Egypt, around 2600 B.C., cut stone was introduced in the construction of religious facilities and monuments. These early stone works exhibited remarkable engineering skills as they included stone pieces of several tons in size which were fitted with exacting tolerances. In the Americas, dry stone construction was also used, primarily for religious edifices, by the early Aztec, Mayan, and Inca civilizations.

The Romans brought several innovations to stone construction techniques. They used mortar extensively and developed vaults and domes in large structures with buttresses to reinforce large-scale buildings. These features were later incorporated into Gothic cathedrals, which represented an unsurpassed artistic achievement in masonry workmanship.

The development of steel and reinforced concrete in the nineteenth century rendered stone arches and vaulting obsolete and led to the development of the modern skyscraper. In the twentieth century, the most common masonry application involved the use of concrete blocks, which proved both economical and durable. Moreover, concrete blocks provided excellent insulation against extreme temperatures and noise, were fire-resistant, stood up well in earthquakes, and needed little maintenance. In the United States, an industry standard developed in which concrete blocks, with mortar, measured 8 inches by 8 inches by 20 inches.

Much of the stone used in American masonry projects—granite, limestone, marble, sandstone, and slate—was purchased from foreign sources, and a lesser amount of stone quarried in the United States was sold overseas. In 1991, domestic stone production was valued at \$197 million, with the following six states as the highest producers: Georgia, Vermont, Minnesota, North Carolina, Texas, and Indiana. Stone imports for domestic use that year were valued at \$475 million, with Italy

serving as the source of about half the worldwide stone production.

CURRENT CONDITIONS

A booming U.S. construction industry revitalized the masonry industry in the late 1990s and early 2000s. Not only were homes being built at a rate unmatched in 25 years, buyers were also demanding more upgrades that required tile, stone, and brick in their new homes. The industry employed 165,000 workers in 2002, and employment between 2002 and 2012 was predicted to grow 17.4 percent. Average hourly wages for stonemasons were \$16.36 in 2002. Brickmasons and block masons earned an average of \$20.11 that year.

The early 2000s were not without trouble for masonry contractors, as well as for other construction specialties. The U.S. economic slowdown caused high office vacancy rates, which slowed office construction. At the same time, a slowdown in manufacturing pushed industrial and warehouse construction down as well. However, analysts predicted that commercial and industrial construction would rebound as early as 2004 thanks in part to the passage of the TEA-21 Reauthorization Bill, introduced by the House Transportation and Infrastructure Committee, which earmarked funding for masonry structures.

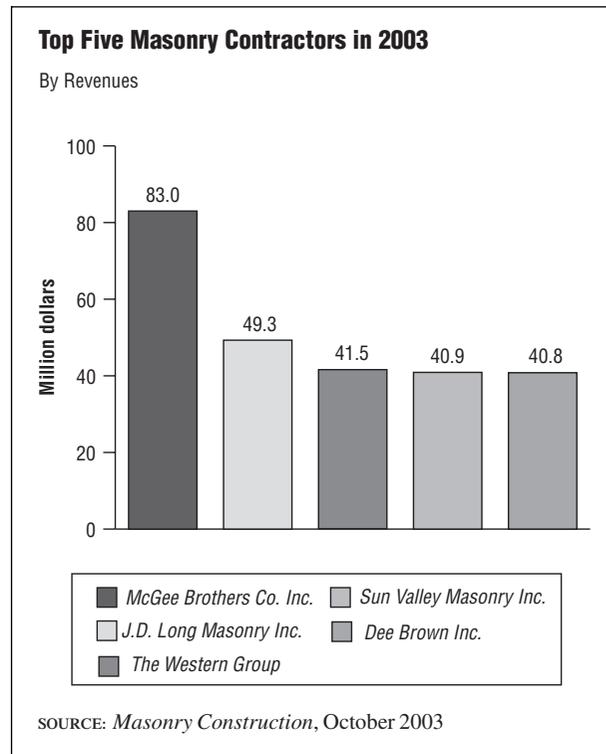

INDUSTRY LEADERS

The industry leaders as of 2003 included McGee Brothers Co., based in Monroe, North Carolina, which posted \$83 million in masonry sales, 80 percent of which were residential. In a distance second place was J.D. Long Masonry Inc., based in Lorton, Virginia, with sales of \$49.3 million. St. Louis, Missouri-based The Western Group, secured sales of \$130 million, \$41.5 of which came from masonry operations. Western employed 1,000 workers in 2003. Close on Western's heels were Sun Valley Masonry, located in Phoenix, Arizona, with \$40.9 million in sales and Dee Brown Inc. of Garland, Texas, with \$40.8 million in sales.

WORKFORCE

Steeped in centuries of tradition, masonry work required specialized skills and often, artistry. The homes, cathedrals, and other buildings masons helped produce prompted a high esteem for the profession and many masons derived considerable personal satisfaction from their creative efforts.

Formal apprenticeship and training programs for the industry were administered by the International Masonry Institute, an organization formed jointly by contractors in the masonry industry and the International Union of Bricklayers and Allied Craftsmen. Less formal training

was also available through on-the-job guidance by senior, experienced masonry craftsmen.

In the early 2000s, construction workers comprised the majority of the industry's work force, while about 10 percent performed a broader range of business functions including estimating, engineering, planning and scheduling, purchasing, material control, and accounting. Although some seasoned masons had a broad range of skills and experience, from laying cement blocks to carving or repairing stone ornamentation, most specialized in one skill. Considerable physical strength was required for laying cement blocks, while stone work was more precise and therefore, required more patience and an eye for detail.

Most masonry contractors' employees are members of the International Union of Bricklayers and Allied Craftsmen. Others belong to the Laborers International Union. Both unions are affiliated with the AFL-CIO and membership remains particularly strong in urban areas.

AMERICA AND THE WORLD

While some of the larger masonry companies had branch operations throughout the United States, few were engaged in business on a global scale. American general contractors that performed construction overseas generally subcontracted work to established local masonry firms or acquired foreign operations near the job site. Foreign general contracting companies performing construction work in the United States were more common.

RESEARCH AND TECHNOLOGY

Several masonry methods and techniques led to changes in the industry. The development of modular stone wall panels for high-rise buildings, which consisted of steel frames, anchoring devices, and stone, glass, and other exterior materials, made construction of walls more speedy and economical. The modular process also enabled the use of thinner stone panels, leading to lighter and less costly materials.

An injection system for applying epoxy—used to secure threaded rods to reinforced brick masonry walls—helped make the walls better equipped to withstand the effects of an earthquake. Moreover, aqueous silicon solutions were introduced to new water repellents to help prevent damage to walls from the freezing and thawing of absorbed moisture. Improved durability in concrete was achieved by adding supplementary materials made from industrial by-products, thereby conserving natural resources. Technological developments also resulted in using robots in the industry for excavating, pipe mapping, and building masonry walls and wall partitions.

SIC 1742

PLASTERING, DRYWALL, ACOUSTICAL, AND INSULATION

This category is comprised of special trade contractors primarily engaged in applying plain or ornamental plaster, or in the installation of drywall and insulation. Activities include taping and finishing drywall, applying solar-reflecting insulation film, installing lathing, and constructing ceilings.

NAICS CODE(S)

235420 (Drywall, Plastering, Acoustical and Insulation Contractors)

Hourly Earnings of Drywall and Ceiling Tile Installers and Tapers in 2002

Drywall and Ceiling Tile Installers	
Highest 10%	\$28.03 or more per hour
Middle 50%	\$12.43 to \$21.50 per hour
Lowest 10%	less than \$9.76 per hour
Tapers	
Highest 10%	\$29.32 or more per hour
Middle 50%	\$14.57 to \$24.68 per hour
Lowest 10%	less than \$11.07 per hour

SOURCE: Bureau of Labor Statistics, 2004

The U.S. plastering, drywall, acoustical, and insulation industry includes more than 20,000 establishments, according to the latest figures available from the U.S. Census Bureau. Drywall installers, ceiling tile installers, and tapers numbered roughly 176,000 in 2002. Average hourly earnings for dry wall and ceiling tile installers totaled \$16.21, while tapers earned an average of \$18.75 per hour.

This industry changed markedly in the twentieth century. In the early 1900s most walls and ceilings were constructed with wood lath and plaster. Homeowners commonly performed much of the work themselves. Thermal and acoustical insulation, if any, generally consisted of natural materials. After World War II, gypsum wallboard began to displace the lath and plaster, and various synthetic insulation products were introduced. New construction materials, along with a massive demand for plaster and insulation during the post-war building boom, created a specialized industry.

Because of its heavy dependence on new construction, the industry is cyclical. Commercial and residential construction growth during the mid-1980s generated a steady demand for specialty plaster contractors as gypsum wallboard sales surged past \$2.6 billion. Conversely, a depression in commercial development and a recession in housing starts quashed industry growth from the late 1980s through the early 1990s. As the demand for gypsum products slipped to about \$2 billion in 1992, many wallboard contractors suffered major setbacks, but sustained growth in housing starts gave the industry a strong boost in the mid-1990s. After dropping to 1.01 million in 1991, housing starts rose to 1.45 million in 1996.

Reflecting the performance of the residential construction industry in the early 2000s, the plastering, drywall, acoustical, and insulation industry performed well in the early 2000s. Although economic conditions in the United States were weak, historically low interest rates bolstered housing starts through the early 2000s. In fact, by 2003 single family housing starts had reached 1.848 million, their highest level since 1978. Although

starts were expected to decline a bit in 2004, analysts believed they would remain high enough to sustain growth in many construction industries, including the plastering, drywall, acoustical, and insulation sectors. As a result, employment for this industry was expected to grow 34.3 percent between 2002 and 2012.

In the late 1990s a shortage of drywall had pushed prices up substantially; at the same time, construction projects fell behind schedule, and some retail outlets limited drywall purchases to 20 sheets per customer. Drywall manufacturers responded by building new factories, re-opening facilities that had been closed, and increasing production at existing plants. Some companies hoped to import drywall from Canada, Mexico, and other foreign sources; this was a difficult proposition, though, since drywall cannot survive accidental contact with rain or other dampness and it is so brittle that it tends to break in transit.

The plastering and insulation contracting business was comprised mainly of thousands of small, privately owned firms. Some of the industry leaders, however, were large contracting companies with additional operations in other segments of the construction industry. The top five firms in the plastering and insulation contracting business by revenue, as of 2003, were Rust Industrial Services Inc. of Westchester, Illinois (\$750 million); APi Group Inc. of St. Paul, Minnesota (\$675 million); Performance Contracting Group Inc. of Lenexa, Kansas (\$509.8 million); Pacific Coast Building Products Inc. of Sacramento, California (\$360 million); and Irex Corp. of Lancaster, Pennsylvania, which placed its AC and S subsidiary under Chapter 11 bankruptcy protection in 2002 due to asbestos litigation.

SIC 1743

TERRAZZO, TILE, MARBLE, AND MOSAIC WORK

This category covers special trade contractors that primarily set and install ceramic tile, marble, and mosaic, and those that mix marble particles and cement to make

Number of Tile and Other Flooring Installers and Finishers in 2002

SOURCE: Bureau of Labor Statistics, 2004

terrazzo at construction sites. Companies that primarily make pre-cast terrazzo steps, benches, and other terrazzo objects are in **SIC 3272: Concrete Products, Except Block and Brick**.

NAICS CODE(S)

235420 (Drywall, Plastering, Acoustical and Insulation Contractors)

235430 (Tile, Marble, Terrazzo and Mosaic Contractors)

Terrazzo, tiles, marble, and mosaic have been used in construction for centuries, lending charm and elegance to houses, churches, and public buildings. This respected craft requires skill but offers the opportunity for artistic expression, particularly in the use of terrazzo and mosaic materials.

The U.S. Department of Labor reported that approximately 33,000 tilesetters were employed in 2002. Those who were employed by contractors tended to be assigned to nonresidential construction projects. Almost half were self-employed and worked primarily on residential projects. During the early 2000s, the industry included many companies that served customers locally, although some firms covered broader areas.

Much of the marble and other material used in this industry is imported from countries such as Italy. In fact, imports from Italy account for nearly 27 percent of U.S. domestic tile consumption. Terrazzo originated hundreds of years ago when Venetian craftsmen discovered a new use for discarded marble chips. Terrazzo is made by mixing pebbles or chips of stone or glass in cement, then

polishing the surface to make it smooth. Terrazzo is one of the most durable flooring surfaces, and it can also have aesthetic qualities.

Tiles traditionally are square pieces of fired clay used to cover exterior or interior surfaces such as floors, walls, or roofs. Craftsmen in this trade also use thin slabs of vinyl, wood, cork, and other materials in a similar way. Most civilizations since 3000 B.C. have used ceramic tiles, often for decorative purposes. Because they are durable and easy to clean, tiles are commonly used in areas such as bathrooms, swimming pools, and medical operating rooms.

Marble is a metamorphic rock often with irregular markings from impurities, which add to its appeal and beauty. It has been used in many architectural landmarks including the Parthenon and the Taj Mahal.

Mosaic is a decorative surface made by setting small colored pieces, such as tile, in mortar or other adhesive. Employed in architecture since 3000 B.C., mosaic is still used in places where a waterproof, hygienic surface is required, especially if decoration is also desired.

Although this industry is based on a craft that is centuries old, some new methods have been developed to make the work easier or less expensive. In contrast to the traditional methods of setting and polishing terrazzo or laying out tile and mosaic at the construction site, some manufacturers began selling prefabricated materials. Other innovations included vinyl tile designed to look like natural formations, as well as new lightweight panels and bonding materials that made tile more suitable for exterior surfaces, even on high-rise buildings.

After experiencing sluggish sales in 2001, U.S. tile factories produced a record 638 million square feet of tile in 2002. Domestic factory revenues climbed 8 percent. Factory shipments, including imports, grew 15.7 percent to 2.63 billion square feet. According to the Tile Council of America, factory shipments will grow to 2.71 billion square feet in 2004. This growth was fueled by brisk sales in the residential construction market, which saw new housing starts reach a 25-year high in 2003. Larger-sized glazed tile accounted for roughly 90 percent of total ceramic tile sales in the United States.

Exports, which were primarily to Canada and Mexico, increased by 25.2 percent to 41.7 million square feet in 2002. The United States ranks ninth among the leading tile exporters in the world. Imports increased by 18.5 percent. The United States is the world's largest importer of tile, based on square footage. After Italy, the leading exporters to the United States are Spain and Mexico.

Several trade associations serve contractors and manufacturers in this industry. They include the National Terrazzo and Mosaic Association, the Ceramic Tile Institute of America, the Marble Institute of America, the

National Tile Contractors Association, the International Brotherhood of Painters and Allied Trades, and the International Union of Bricklayers and Allied Craftsmen.

SIC 1751

CARPENTRY WORK

This category includes special trade contractors primarily engaged in carpentry work. Establishments primarily engaged in building and installing cabinets at the job site are classified in this industry. Establishments primarily engaged in building custom cabinets for individuals in a shop are classified in **SIC 5712: Furniture Stores**. Carpentry work performed by general contractors engaged in building construction is classified in **SIC 1500: General Building Contractors**.

NAICS CODE(S)

235510 (Carpentry Contractors)

INDUSTRY SNAPSHOT

Carpentry is the work of cutting and joining timber to create frames for housing and items such as doors, windows, cabinets, and staircases. Work in this industry includes cabinet work performed at the construction site, carpentry work, folding door installation, framing, garage door installation, ship joinery, store fixture installation, trim and finish, and prefabricated window and door installation. It is a very strenuous occupation due to long periods of standing, climbing, bending, and kneeling.

Carpenters rely heavily on the health of the economy and especially the success of the housing industry, since their work consists mainly of building or renovating residential structures. The housing industry can be positively or negatively affected by factors such as interest rate fluctuations and availability of mortgage funds.

Carpenters make up one of the largest building trade groups in the United States, holding approximately 1.2 million jobs in 2000. Of these, about 25 percent are self-employed, about 33 percent are employed by general building contractors, 20 percent are employed by specialty trade contractors, and 12 percent are employed in

heavy construction. The remainder work in the manufacturing, government, retail, and education sectors.

ORGANIZATION AND STRUCTURE

Nearly 500,000 carpenters belong to the United Brotherhood of Carpenters and Joiners, a labor organization located in Washington, D.C., which is actively involved in the construction industry. The union supports building contractors who work with union carpenters. The union also studies health and safety aspects of carpentry work, which has the highest serious injuries rate in the United States. The union has been studying the ergonomics of carpentry in hopes of reducing workplace accidents by developing preventive on-the-job techniques.

The union, in conjunction with contractor trade associations, also provides training and apprenticeship programs, which are greatly needed in this industry. As carpentry work becomes more specialized and involves potentially dangerous materials such as asbestos removal, formal training will become increasingly necessary.

Other groups primarily interested in carpentry are the Associated Builders and Contractors, of Rosslyn, Virginia; the Associated General Contractors of America, Inc., of Washington, D.C.; and the National Association of Home Builders, also located in Washington, D.C.

The construction industry can be divided into three major contract divisions: general building contractors, heavy construction contractors, and special trade contractors (including carpenters). General building contractors build residential, industrial, and commercial buildings, while heavy construction contractors build structures like roads, highways, and bridges.

Special trade contractors usually focus on one trade and work under the direction of general contractors, architects, or property owners. Beyond completing their work to specification, special trade contractors have no responsibility for building the structure in its entirety.

BACKGROUND AND DEVELOPMENT

When both commercial and residential buildings were made primarily from timber, the carpenter was the critical element needed for construction. Over time, the scope of the carpenter's work has changed. As the materials for commercial buildings switched to primarily concrete and steel, the demand for carpenters has shifted to the framework for houses and commercial structures, and residential remodeling. A carpenter's work also may extend to interior jobs, requiring some of the skills of a joiner. These skills include making door frames, cabinets, countertops, and assorted molding and trim.

The standard tools used by a carpenter have been hammers, pliers, screwdrivers, awls, planes (handheld

blades), crosscut saws, rip saws, dovetail saws, and levels, in addition to an assortment of power tools. Lightweight cordless pneumatic and combustion tools like nailers and drills, and sanders with electric speed controls are being used increasingly more. These help carpenters to be more efficient and work faster; they also reduce fatigue. Carpenters have used wood as a building material for centuries; however, as the world's supply of wood continues to shrink, alternative building materials, such as partial-wood products, have begun to be developed and used in residential construction.

For carpenters who work predominately in residential construction, the state of the housing industry is critical. The recession of the early 1990s hit the housing market particularly hard. With weak employment trends, potential buyers postponed purchasing new homes. The housing market's recovery was stalled by a lingering and severe credit crunch, an unanticipated rise in lumber costs, and low consumer confidence levels. Fueled by lower interest rates, the housing industry began a slow but steady rebound in 1994. Although the pace of economic growth stalled during the first quarter of 1994, a surge in housing sales at the end of 1993 forecasted a strong performance for 1994. In 1993 the construction of 100,000 new single-family homes generated over 200,000 construction jobs and \$4.4 billion in wages, according to the National Association of Home Builders (NAHB). The NAHB predicted a 4 percent rise in single-family housing starts for 1994.

Carpenters work closely with, and are greatly affected by, the remodeling industry. Once thought to be recession-proof, the residential repair and remodeling (R&R) market declined by 8.7 percent during 1991. Spending for additions and alterations dropped the most, by 17 percent. Despite this fall, the remodeling sector should continue to provide carpenters with steady work. Remodeling totaled approximately \$113.5 billion in 1993.

Carpenters who work in the remodeling sector should benefit from two major demographic factors. First, as baby boomers enter their high income-producing years, they will be purchasing new or existing homes. Also, the aging U.S. housing stock will need to be updated or replaced. Out of the 100 million homes in the United States, nearly 60 percent are at least 22 years old.

Impact of the High Cost of Lumber. Despite the increased number of jobs available for carpenters in the mid-1990s, the construction and housing industry continued to be burdened by the high cost of lumber. When logging stopped in the national forests of the Pacific Northwest, a lumber shortage ensued. Home builders and remodelers have been the primary users of lumber, accounting for nearly 65 percent of all framing timber.

After hovering at just over \$200 per 1,000-board-feet throughout the 1980s, the price of framing lumber rose and dropped sporadically during 1992 and 1993, according to NAHB. The price increase was blamed on the cessation of virtually all logging in the national forests of the Pacific Northwest. Logging was halted by court order, as environmental organizations fought to protect the habitat of the Northern Spotted Owl, a threatened species in Washington, Oregon, and Northern California.

A near-instantaneous shortage of lumber from national forestland, one of three major sources of timber, caused a 74 percent price increase between October 1992 and 1994. This price increase added between \$4,000 and \$5,000 to the cost of building a typical 2,000-square-foot home, according to NAHB. Although lumber prices fell somewhat from a high of \$510 per 1,000-board-feet, the Northern Spotted Owl issue has yet to be resolved.

Impact of Labor Union Activity. In an effort to get contractors to use union workers, labor groups have been subsidizing organized labor by using a tactic called "job targeting." Although some contractors have aggressively opposed job targeting, smaller operators have welcomed the arrangement because it allows them to gain market share by underbidding their nonunion contractor. By late 1992 more than 500 local unions nationwide had begun to implement this practice, according to the *Wall Street Journal*.

When a construction job comes up for bid, a local union will "target" a contractor and offer to make a payment. This allows the union contractor to come in with a lower bid than a nonunion competitor. Targeting was originally intended to stem the flow of jobs to non-union workers.

Health and Safety Issues. With the highest serious injury rate in the United States, health and safety concerns continue to be a major issue both to carpenters and the contractors who employ them. Because over half of all workers' compensation dollars have been used for the treatment of musculoskeletal injuries, the United Brotherhood of Carpenters launched a pilot program to address the ergonomics of carpentry by exploring how job-related tasks impact the worker and provide preventive training at the apprenticeship level, according to *Engineering News Record*. An ergonomist and a health and safety team will study carpenters at job sites to better understand the contributing factors to the most prevalent injuries. The team will compare workers' compensation data from state and area health and welfare funds, according to *Engineering News Record*.

The union also has begun to study carpentry in relation to health implications for its workers. Carpenters have been dying an average of six years younger than other Americans, reported Hazel Bradford in *Engineer-*

ing News Record. Carpenters have a 150 times greater chance of dying from mesothelioma, an asbestos-related disease. Cancer deaths for carpenters have been 50 percent higher than the general population, while deaths from emphysema, bronchitis, and asthma have been three times higher. From its findings, the union hopes to establish medical screenings and early warning programs for its members. The union also plans an educational campaign aimed at reaching both apprentices and journeymen (trained union workers) through educational programs. Special attention will be given to work regarding asbestos, lead, and hazardous wastes.

CURRENT CONDITIONS

In the early 2000s, the carpentry industry was sustained by strong growth in new housing starts, spurred on by extremely low interest rates despite an overall weak economy. The boom in the housing industry pushed new housing starts up in 2003 to an estimated 1.6 million, compared to 1.2 million new starts in 2000. Although new housing construction continued unabated, construction in the commercial and industry sectors fell off dramatically during 2001 and remained stagnant in 2003.

Carpenters with a diversity of skills will fair the best, until the U.S. economy works its way slowly out of the doldrums. New housing starts are expected to slow, as pent up demand has been fulfilled, and interest rates are predicted to take an upward swing again. One area of growth for the carpentry industry is in home improvement and home repair.

More than 50 percent of all U.S. homes are more than 25 years old, and the aging baby boom population is shifting from do-it-yourself to do-it-for-me, providing a growing market for skilled carpenters. According to the National Association of Home Builders, home maintenance and repair expenditures jumped 14 percent from 2001 to 2002.

INDUSTRY LEADERS

It is difficult to determine exactly how many carpentry contractors exist in the United States because carpentry contractors generally are small establishments, and many self-employed carpenters serve as their own contractors. Plus, the housing industry is highly fragmented, lacking national general contractors or specialty trade contractors. A typical American home builder is a local contractor who constructs fewer than 25 houses each year and works with local subcontractors, labor, and suppliers. The largest companies involved in carpentry, according to *Ward's Business Directory of U.S. Private and Public Companies* (1999) were BT Mancini Company Inc., Center Brothers Inc., Door Systems Inc., and J Mar and Sons Inc.

WORKFORCE

According to the U.S. Census Bureau, in 2000 1.2 million people were employed in the carpentry industry. Approximately 80 percent of those worked for contractors; they built, remodeled, and repaired buildings and other structures. The others worked for manufacturing firms, government agencies, wholesale and retail establishments, and schools. Over 25 percent were self-employed. According to the Bureau of Labor Statistics, \$17.06 per hour was the mean pay for carpenters who were not self-employed in 2001.

Carpenters learn their trade through both on-the-job training and formal education. Most employers recommend an apprenticeship, but the number of available programs, usually administered by local chapters of Associated Builders and Contractors, Associated General Contractors, and the United Brotherhood of Carpenters, has been limited.

As skilled workers become scarce, and jobs become more demanding, the need for more training programs will increase. The industry will demand more knowledgeable workers. Computer and math skills in addition to special new skills, such as hazardous waste cleanup, will be in demand.

Some organizations have begun to provide additional training programs, starting in high school and offering apprenticeships upon graduation. Associated Builders and Contractors has begun four-year training courses in five construction specialties. The group works with both employers and high school students in 19 school districts in Texas. The Laborers International Union and Associated General Contractors trained about 33,000 U.S. and Canadian workers in construction skills in 1992. The group also planned to train another 29,000 workers in hazardous waste cleanup.

RESEARCH AND TECHNOLOGY

With rising timber costs, the construction industry continues to look for alternative building materials to use instead of lumber and plywood in residential construction. Some viable options have been engineered wood products, concrete, structural foam sandwich panels, and laminated fiberboard structural sheathing. Engineered wood products (EWPs) have been on the market for years. These products are a combination of wood fibers with adhesives and have been used to form beams, headers, joints, and other structural framing products. EWPs do not use raw materials from the U.S. timber supply. Instead, these products have been made from smaller trees and inferior species once thought to be unsuitable for building materials.

Laminated fiberboard and foam core structural sandwich panels are two other alternative building products.

Fiberglass sheathing is a lightweight panel made from wood and agricultural by-products. The panel consists of fibrous plies laminated under pressure and covered with aluminum foil or polyethylene. Foam sandwich panels are made of two strong, stiff skins, usually strand board or plywood, and separated by a lightweight, but thick, core of polystyrene. The fiberboard can be used in place of plywood sheathing on exterior walls, and the foam core panels can be used instead of wooden wall and roof systems.

SIC 1752

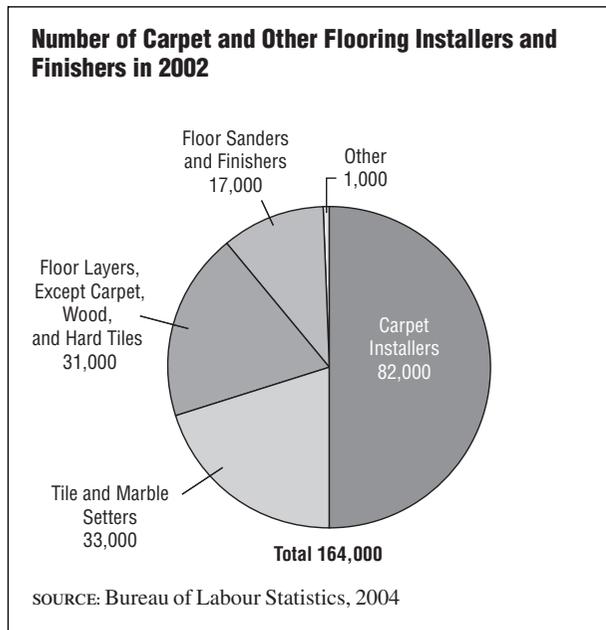

FLOOR LAYING AND OTHER FLOOR WORK, NOT ELSEWHERE CLASSIFIED

This category includes special trade contractors primarily engaged in the installation of asphalt tile, carpeting, linoleum, and resilient flooring. The industry also includes special trade contractors engaged in laying, scraping, and finishing parquet and other hardwood flooring. Establishments primarily engaged in installing stone and ceramic floor tile are classified in the Masonry, Stonework, Tile Setting, and Plastering industries; those installing or finishing concrete floors are classified in **SIC 1771: Concrete Work**; and those installing artificial turf are classified in **SIC 1799: Special Trade Contractors, Not Elsewhere Classified**.

NAICS CODE(S)

235520 (Floor Laying and Other Floor Contractors)

The U.S. floor-laying industry is characterized by a large number of special trade contractors who perform work for a general contractor or an architect. According

to the latest figures available from the U.S. Census Bureau, roughly 12,000 of these establishments operate in the United States. Carpet installers may also install other types of flooring, such as tile and/or vinyl and linoleum.

Much of the floor-laying industry works in the residential repair and remodeling (R&R) market. Renovation and repair had increased dramatically in the mid-1990s, reaching an all-time high of \$69.5 billion in total revenue in 1995. New installations, however, were the key to industry growth in the late 1990s and early 2000s. Fueled by lower interest rates, the residential construction industry continued to boom well into the early 2000s, despite a weak economy. According to the National Association of Home Builders (NAHB), new housing starts reached a 25-year high of more than 1.8 million in 2003.

The health of the floor-laying industry is closely tied to that of the housing and construction industry; when housing starts increase, as they did in the early 2000s, floor layers see increased work. The rate of employment for carpet layers, however, generally remains stable, since so much of their work involves the replacement of carpet. By 2002, carpet, flooring, and tile installers numbered 164,000. Approximately 82,000 of those workers were employed in carpet installation, compared to 50,000 in the mid-1990s, according to the U.S. Bureau of Labor Statistics. Floor layers, except for carpet, wood, and hard tiles, accounted for 31,000 workers in 2002, while floor sanders and finishers numbered 17,000. While some flooring installers worked for flooring contractors or floor covering retailers, more than 40 percent were self-employed in 2002. Employment in this industry was expected to grow by nearly 17 percent between 2002 and

2012 due to the continued need to renovate and refurbish existing structures and a growing demand for carpet in new industrial plants, schools, hospitals, and other commercial buildings.

Carpet and other flooring installers may belong to either the United Brotherhood of Carpenters and Joiners of America or the International Brotherhood of Painters and Allied Trades.

Of all floor coverings, carpet continues to be the most popular product for both residential and commercial buildings. Carpet industry shipments reached 1.88 billion square yards in 2001, compared to 97 million square yards shipped in 1950. In the late 1990s and early 2000s, carpet accounted for the majority of the total flooring market (both residential and commercial). For houses built with plywood rather than hardwood floors, wall-to-wall carpet is a necessity. Commercial properties, such as offices and shopping centers, also use carpet to cover concrete floors. And, as previously stated, carpet continues to be used largely in renovation work. As new fibers are developed, particularly those that are stain and crush resistant, more durable, and in a wider range of colors, the demand for carpet will continue to grow. Over the past decade, however, hardwood floors have experienced a resurgence in popularity and usage. Laminate flooring, which looks and feels like hardwood but is typically less expensive and more resistant to scratching, also gained in popularity. Vinyl and linoleum manufacturers also continue to improve their products: the newer vinyls come with a glossed finish, requiring less maintenance to retain original appearance. Most are available without patterns (they may have a fleck or pebble-grain design), but more are becoming available with stylish patterns, in order to compete with the commercial carpet market.

Industry leaders in the early 2000s included Continental Flooring Company, based in Scottsdale, Arizona, which sold flooring mainly to government agencies, as well as Evergreen, Colorado-based Kalman Floor Company.

SIC 1761**ROOFING, SIDING, AND SHEET METAL WORK**

Special trade contractors primarily engaged in the installation of roofing, siding, and sheet metal work. Sheet metal work performed by plumbing, heating, and air-conditioning contractors in conjunction with the installation of plumbing, heating, and air-conditioning equipment are classified in **SIC 1711: Plumbing, Heating, and Air-Conditioning**.

NAICS CODE(S)

235610 (Roofing, Siding, and Sheet Metal Contractors)

INDUSTRY SNAPSHOT

Construction services offered by the roofing, siding, and sheet metal industry include architectural sheet metal work; erection and repair of metal ceilings; copper smithing in connection with construction work; metal downspout installation; sheet metal duct work; metal gutter installation; roof spraying, painting, or coating; all roofing work, including repairs; siding installation; skylight installation; and tin smithing in connection with construction work.

ORGANIZATION AND STRUCTURE

The construction industry can be divided into three major divisions: general building contractors, heavy construction contractors, and special trade contractors, which include those who install roofing. General building contractors build residential, industrial, and commercial buildings, while heavy construction contractors build structures such as roads, highways, and bridges.

Special trade contractors usually focus on one trade and work under the direction of general contractors, architects, or property owners. Beyond completing their work to specification, special trade contractors have no responsibility for building the structure in its entirety.

Besides new installations or re-roofing, the market can be divided by type of roof, either low-slope or steep-slope. The low-slope market includes commercial and industrial buildings and some apartment houses. The steep-slope market is primarily residential.

Sometimes working in conjunction with architects, roofing contractors choose from a selection of materials that include thermoset single plies (e.g., EPDM, CSPE/Hypalon, PVC), built-up roofing (BUR), and fiberglass, and organic asphalt shingles. In the re-roofing industry the contractor decides what type of roofing system to use and which manufacturer's product to install. With new installations the architect usually decides which roof sys-

tem to use, and, most of the time, the contractor still chooses the manufacturer.

BACKGROUND AND DEVELOPMENT

For roofers who work predominantly on newly built homes, the state of the housing industry is crucial. The recession of the early 1990s hit the housing market and roofing contractors particularly hard. Renovation and repair increased slowly but steadily during the mid-1990s, reaching \$69.5 billion by 1995. The recovery of the housing market led to significant increases in both re-roofing and new construction in the West (86.4 percent), with moderate increases in the Northeast (36.0 percent) and Midwest (16.8 percent). In the South, however, there was a 17.4 percent decline.

The state of the home remodeling industry also greatly affected roofing contractors, since a large percentage of their business derives from re-roofing projects. The residential repair and remodeling (R&R) market was once thought to be recession-proof. The recession of the early 1990s proved that theory wrong, but the market recovered and increased to about \$113.5 billion by 1993.

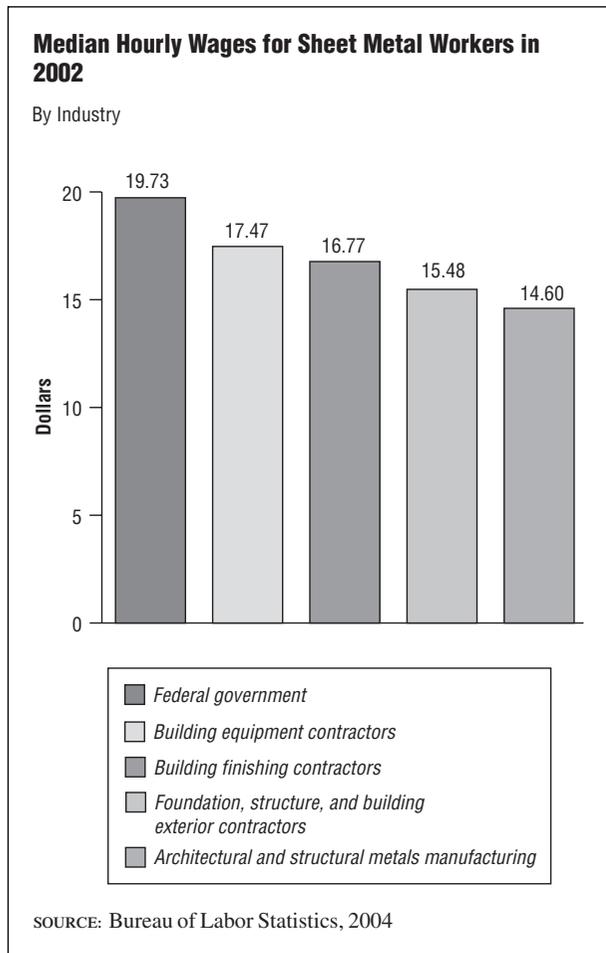

Roofing contractors who worked in the remodeling sector stood to benefit from two major demographic factors. First, as baby boomers entered their high income-producing years, they would be purchasing new or existing homes. Also, the U.S. housing stock became fairly old. Of the 100 million homes in the United States, nearly 60 percent were at least 22 years old.

Some roofing contractors rebounded from the recession with a booming roofing business. These contractors were re-roofing faulty plywood that was widely used in the eastern and southern United States in the 1980s. The chemically treated, fire-resistant roofing substance known as FRT deteriorated and lost strength when subjected to high heat and humidity, causing roofs to sag and leak. It was estimated that between 250,000 and 1 million roofs would need to be replaced.

CURRENT CONDITIONS

According to the latest figures available from the U.S. Census Bureau, the U.S. roofing, siding, and sheet metal contracting industry comprises more than 30,000 companies and earns more than \$24 billion in total revenues, the largest portion of which is generated by architectural sheet metal contractors, followed by carpentry contractors; heating, ventilation, and air-conditioning contractors; roofing contractors; siding contractors; and specialty sheet metal contractors.

Due to the economic downturn of the early 2000s, both the roofing and the siding industries felt the pinch of reduced commercial and industrial construction, despite the frenetic pace of residential construction. Based on estimates released by the Freedomia Group, demand for

siding between 2002 and 2005 will grow less than 1 percent, reaching 109 million squares, worth \$9.2 billion, in 2005. Fiber cement siding is expected to lead industry growth with 5 percent gains each year due to its increasingly popularity over wood siding products. However, due to booming residential construction and remodeling, vinyl siding will likely remain the leading industry segment in terms of volume. Due to signs of recovery in the U.S. economy, the roofing industry expects increased sales in 2004, according to the National Roofing Contractors Association.

INDUSTRY LEADERS

The roofing industry typically consists of numerous small roofing firms and a few larger companies, which often operate additional construction and manufacturing businesses. Among the largest companies involved in the roofing, siding, and sheet metal industry, Bradco Supply Corp. of Avenel, New Jersey, employed 2,000 people in 2003 and had estimated annual sales of \$995 million, reflecting 17 percent growths from 2002. Privately owned Pacific Coast Building Products Inc. of Sacramento, California, had roughly 2,500 employees and approximate sales of \$400 million. Bryant Universal Roof-

ing Inc. of Phoenix, Arizona, had 1,200 employees and sales of \$110 million.

WORKFORCE

Workers in the sheet metal industry typically learn their trade through apprenticeship, including four or five years of hands-on training at job sites and at least 144 hours per year of classroom education. Others start as helpers, learning informally from experienced workers on the job and progressing gradually to more skilled tasks. They often study at vocational schools to supplement their practical experience.

On-the-job training is the most common way of entering the roofing industry, but some people learn the trade through a three-year apprenticeship that typically includes 144 hours of classroom education and at least 2,000 hours of hands-on training at job sites. Labor unions usually offer roofing and sheet metal work apprenticeship programs, often under the auspices of local union-management joint training committees.

According to the *Occupational Outlook Handbook*, roofers held approximately 166,000 jobs in 2002. Self-employed roofers represented one out of every three jobs and mainly specialized in residential work. Some roofers were members of the United Union of Roofers, Waterproofers & Allied Workers. Average hourly earnings for roofers in 2002 were \$14.51.

Sheet metal workers held approximately 205,000 jobs in 2002. Roughly 66 percent were employed in the construction industry, half of whom worked for plumbing, heating, and air-conditioning contractors. Most of the others worked for roofing and sheet metal contractors, and a few worked for other general or special trade contractors. Relatively few sheet metal workers were self-employed. Most were members of the Sheet Metal Workers' International Association. Average hourly earnings in 2002 were \$16.62.

Between 2002 and 2012, employment in the roofing and sheet metal industries was expected to grow by 18.8 percent and 22.8 percent, respectively, according to the Bureau of Labor Statistics.

SIC 1771**CONCRETE WORK**

Special trade contractors primarily engaged in concrete work, including portland cement and asphalt. This industry includes the construction of private driveways and walks of all materials. Concrete work incidental to the construction of foundations and concrete work included in an excavation contract are classified in **SIC 1794: Excavation Work**; and those engaged in construction or paving of streets, highways, and public sidewalks are classified in **SIC 1611: Highway and Street Construction, Except Elevated Highways**.

NAICS CODE(S)

235420 (Drywall, Plastering, Acoustical and Insulation Contractors)

235710 (Concrete Contractors)

INDUSTRY SNAPSHOT

Concrete—a mixture of portland cement, sand, gravel, and water—is used for the construction of everything from patios and floors to dams and highways. Special trade contractors involved in concrete work provide the following products and services: private asphalt parking areas; blacktop work; concrete work for private driveways, sidewalks, and parking lots; culvert construction; curb construction; pouring concrete to build foundations; grouting work; parking lot construction; patio construction; sidewalk construction, except public; and stucco construction.

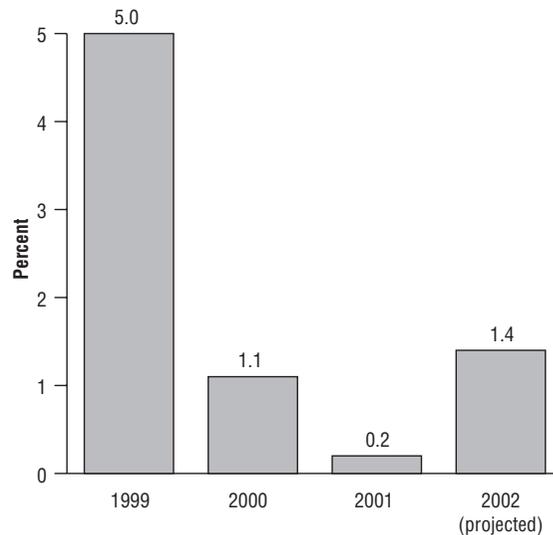

The most recent U.S. Census Bureau reports indicated that more than 30,000 establishments are involved in concrete contracting. These companies employed 190,000 cement masons, concrete finishers, and terrazzo workers in 2002, according to the U.S. Bureau of Labor Statistics. Portland cement consumption declined in the Northeastern and Mountain states in 2001, due in large part to the economic recession—exacerbated by the September 11 terrorist attacks—which prompted a slowdown in commercial and industrial construction and transportation expenditures. Compared to a 5 percent growth rate in 1999, portland cement consumption grew by only 0.2 percent in 2001. However, consumption was expected to grow 1.4 percent in 2002 as every region of the United States saw gains.

ORGANIZATION AND STRUCTURE

The construction industry can be divided into three segments: general building contractors, heavy construction contractors, and special trade contractors, which includes those engaged in concrete work. General building contractors build residential, industrial, commercial, and other buildings, while heavy construction contractors

Portland Cement Consumption in the United States

Annual Percentage Change

SOURCE: *Concrete Products* December 2001

build structures such as roads, highways, and bridges. Special trade contractors usually focus on one trade and work under the direction of general contractors, architects, or property owners. Beyond completing their work to specification, special trade contractors have no responsibility for building the structure in its entirety.

Concrete can be classified by the type of aggregate or cement used, by specific characteristics, or by production methods. Ordinary structural concrete is characterized by its water-to-cement ratio. The lower the water content, all else being equal, the stronger the concrete. For concrete to set properly, however, the mixture needs to have enough water to ensure that the aggregate particles are encompassed by the cement paste, that the space surrounding the aggregate is filled, and that the concrete is liquid enough to be poured and spread effectively. The composition of concrete varies because different aggregates are used from market to market, depending upon what kind of sand and rock is available and least expensive.

Concrete's range of durability is determined by the amount of cement in relation to the aggregate, with relatively less aggregate present in strong cement. The strength of concrete is measured in pounds per square inch (psi) of force needed to crush a concrete sample of a given age or hardness. Concrete's strength can be affected by environmental factors, especially temperature and moisture.

Cement, through its use in concrete, is used in all types of construction. The Portland Cement Association esti-

mated that in the mid-1990s about 55 percent of cement shipments in the United States was consumed in building construction, with 22 percent used for residential and 19 percent for commercial construction. Public works construction consumed about 42 percent of cement shipments, with most going to the building of streets and highways.

By far the largest customer for portland cement at that time was the ready-mix concrete industry, which purchased about 71 percent of the total shipments. Another 13 percent went to concrete producers of blocks, pipes, precasts, and prestressed products; 5 percent to highway contractors; 4 percent to building materials dealers; 3 percent to other contractors; and 4 percent to all others, including the government.

BACKGROUND AND DEVELOPMENT

Long before the discovery of cement, ancient civilizations used clay as a bonding substance. The Egyptians used a material made from lime and gypsum that resembled modern-day cement. Derived from limestone, chalk, or oyster shells, lime continued to be the primary cementing agent until the early 1800s.

In 1824 English inventor Joseph Aspdin burned and ground together a mixture of limestone and clay. This concoction, called portland cement, became the cementing agent used in concrete from that time on.

In 1867 Joseph Monier, a Parisian gardener who made pots of concrete reinforced with iron mesh, received a patent for reinforced concrete. This product, sometimes called ferroconcrete, consisted of concrete hardened onto imbedded metal, usually steel. The reinforcing steel contributed tensile strength.

A later innovation in masonry construction was the use of prestressed concrete, which neutralized the stretching forces that would rupture ordinary concrete. Because it achieved its strength without heavy reinforcements, prestressed concrete could be used to build light, shallow structures such as bridges and roofs.

During the 1980s cement imports became a significant part of the domestic supply, peaking in 1987 at more than 17 million short tons. The reason for this rise in imports was weak worldwide demand combined with strong U.S. demand, which made the United States a target for excess supplies produced by foreign cement manufacturers. Low water transportation costs during the 1980s also was a key. Canada was the largest supplier of cement to the United States through 1985. Mexico became the primary source from 1986 through 1989, supplying 28 percent of total U.S. imports in 1989.

U.S. consumption of cement (the major component of concrete) was 84 million short tons in 1993. Cement was used to build highways and other public works and to rebuild structures damaged by natural disasters, such as

the hurricane in southern Florida, the earthquake in Los Angeles, and the flood in Midwest river basins. During the mid-1990s the concrete industry benefitted from a slow but steady recovery in the housing industry. New home building traditionally used about one-third of the cement consumed annually in the United States.

Prices for concrete varied widely and depended on the proximity of the nearest mill. Transportation costs continued to be a major factor in determining costs, because concrete was so heavy and had to be delivered on a timely basis. In 1994 the U.S. Justice Department began investigating possible price fixing, since the average cost of cement had jumped from \$5 to about \$50 a ton within one year.

CURRENT CONDITIONS

New construction accounts for the lion's share of work done by concrete contractors, although firms also engage in reconstruction, maintenance and repair. Building construction includes work on single-family houses. Nonbuilding construction includes work done on private driveways and parking areas, as well as work done on projects such as highways and streets.

Ready-mixed concrete producers in North America numbered more than 2,700 in 2002. A total of 13 U.S. concrete contracts secured more than \$1 billion in sales in 2002. Concrete contractors were primarily concentrated in California, Texas, and Florida. Other states with a high concentration of firms in this industry included Illinois, Michigan, Missouri, New York, Ohio, and Pennsylvania. Concrete contractors tended to cluster around those states producing the most construction sand and gravel.

Throughout the early 2000s, the \$90 billion construction industry grew rapidly as the nation experienced a surge in housing starts. The construction boom happened in spite of a sluggish economy, due in large part to historically low interest rates. For the residential building industry, 2003 was one of the best years on record. The economic conditions of the early 2000s proved to be a mixed blessing for the concrete industry. While residential construction reached levels not seen since the 1970s, commercial and industrial construction, as well as in nonbuilding sectors such as transportation, saw significant slowdowns. These declines were reflected in the growth rate of portland cement consumption, which dipped from 5 percent in 1999 to less than 1 percent in 2001. Although consumption increased by 1.4 percent in 2002, growth remained well below the 1999 level.

INDUSTRY LEADERS

During the early 2000s the residential and commercial concrete industry was a mixture of large public companies, such as cement manufacturers, and small independent concrete contractors and laborers. Among the largest compa-

nies involved in the industry was Houston, Texas-based Cemex USA, Inc., which operated 85 ready-mix plants and 12 cement plants throughout the United States. Other industry leaders (those with sales of \$1 billion or more) included Lafarge North America Inc. (Herdon, Virginia); Oldcastle Inc. (Atlanta, Georgia); Vulcan Materials Co. (Birmingham, Alabama); Rinker Materials (West Palm Beach, Florida); Aggregate Industries Inc. (Saugus, Massachusetts); A. Teichert and Son Inc. (Sacramento, California); Granite Construction Inc. (Watsonville, California); Lehigh Cement Co. (Allentown, Pennsylvania); and RMC Industries Corp. (Decatur, Georgia).

WORKFORCE

Most concrete masons worked for concrete contractors or for general contractors on projects such as highways, bridges, shopping malls or large buildings such as factories, schools, and hospitals. A small number were employed by firms that manufactured concrete products. Fewer than 1 out of 10 concrete masons were self-employed, a smaller percentage than in other building trades. Most self-employed masons specialized in small jobs, such as driveways, sidewalks, and patios.

Cement masons and concrete finishers earned an average hourly wage of \$14.74, while terrazzo workers earned \$13.42 per hour. Many workers in this industry tend to work overtime, because a job must be completed once the concrete has been placed. Overtime tends to be paid at premium rates.

As the construction industry boomed, contractors had trouble finding enough workers and building supplies. The widespread labor shortage ran from 1997 into the early 2000s. To attract workers, companies increased wages and overtime pay, but many were nevertheless forced to settle for laborers who were inexperienced or insufficiently trained. The shortage of workers stemmed from a trend among young people to attend college instead of entering the skilled trades. In addition, many construction workers had left the industry during the slump of the early 1990s.

Concrete masons generally learned their trade through on-the-job training or apprenticeship programs. Many concrete workers belonged either to the Operative Plasterers' and Cement Masons' International Association of the United States and Canada or to the International Union of Bricklayers and Allied Craftsmen.

RESEARCH AND TECHNOLOGY

The future of the concrete industry lay in continued development of high-performance concrete products. Since the start of the 1980s, concrete formulations changed to create an entirely new generation of high-strength products. What was once considered strong was 7,000 to 9,000 psi, but new products reached 15,000 to

20,000 psi. These concrete products became popular for use in tall buildings, bridges, offshore structures, and pavements.

SIC 1781

WATER WELL DRILLING

This category covers special trade contractors primarily engaged in water well drilling. Establishments primarily engaged in drilling oil or gas field water intake wells on a contract or fee basis are classified in **SIC 1381: Drilling Oil and Gas Wells**.

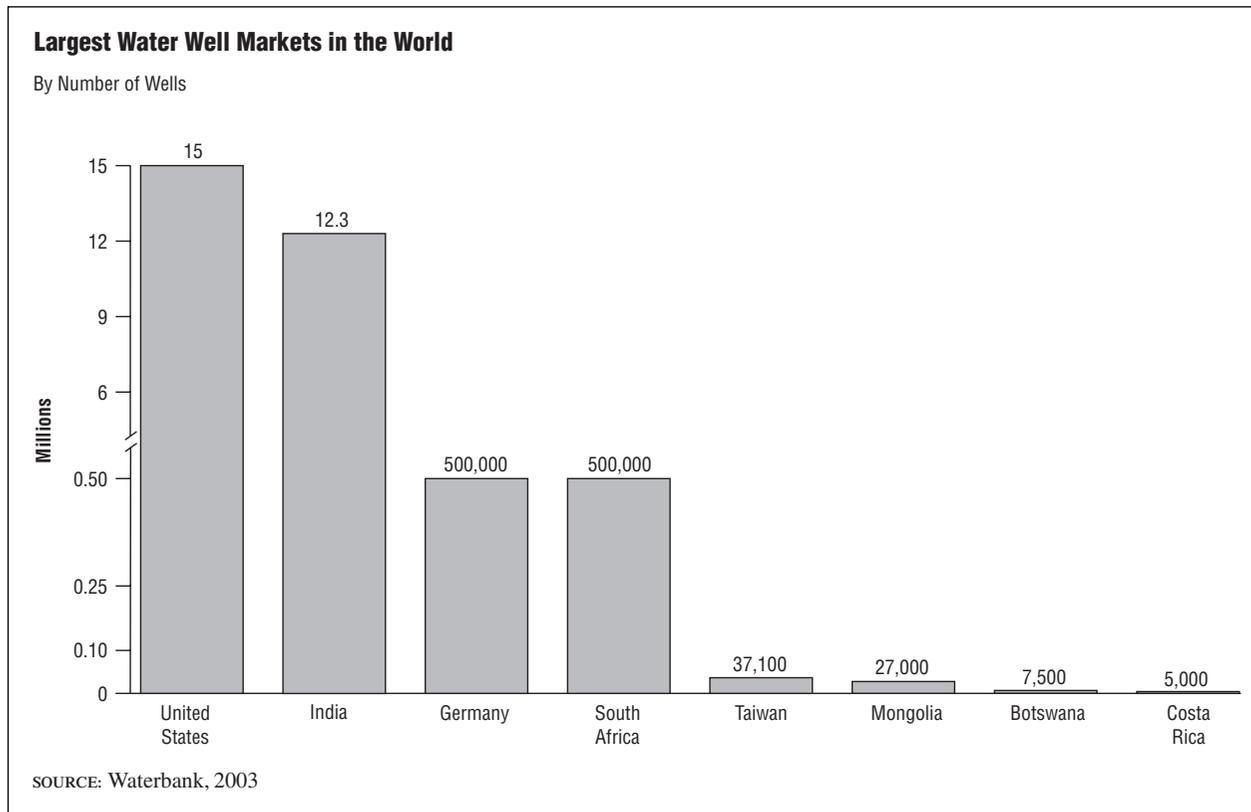

NAICS CODE(S)

235810 (Water Well Drilling Contractors)

The U.S. water well drilling industry includes more than 8,000 establishments operating roughly 19,000 drilling rigs in the early 2000s. These establishments had total employment of 25,539 in 2002, according to the U.S. Bureau of Labor Statistics. Average hourly wages for water well drillers totaled \$12.77 in 2002.

Establishments engaged in water well drilling in the United States tend to be small, independent contractors. Even the industry leaders tend to be small, seldom generating more than \$20 million in annual revenues. Some of the largest companies have diversified into other areas of construction or other types of drilling projects, such as oil, natural gas, and geothermal wells.

The nation's water supply comes from surface sources such as lakes, rivers, and streams, in addition to vast underground aquifers. Groundwater has often been preferred over surface water for use in homes and industry because it is relatively inexpensive to develop and treat, it contains no sediment, its chemical quality remains constant, and facilities to develop it can be situated on small plots of ground. Of the 408 trillion gallons of water consumed daily in the United States in the early 2000s, nearly 20 percent was ground water.

Contractors who drill wells to tap into underground water are largely dependent on new construction. In fact, community water mains and wells for single-family houses account for the vast majority of all business done by this industry. More than 15 million water wells provide 79.4 billion gallons of ground water daily to U.S. residents for community and single-family use, irrigation, livestock, and other agricultural, commercial, and industrial purposes. Irrigation accounted for the largest portion (60 billion gallons) of ground water usage.

Housing starts in the early 2003 remained strong, despite a weakening economy. In fact, housing starts rose to more than 1.8 million in 2003, reaching their highest point since the 1970s. The water well drilling industry was mature and somewhat overserved from both a manufacturing and distribution standpoint. Manufacturers had excess capacity, and distributors were readily available to serve contractors. The environmental business had been the source of most growth for some years. Drillers who offered new and differentiated products were seeing success in their marketing efforts. Increasing emphasis on service and quick responses to customer needs was separating the firms that were growing from those that were merely retaining their market share.

The U.S. drilled roughly 800,000 water wells in the United States each year as of the early 2000s. Michigan was the leading state in terms of number of households

served by private water wells, with 1.12 million. Pennsylvania followed with 987,202 households, while North Carolina had 912,113; New York had 824,342; and Florida had 794,557. California housed the largest number of irrigation wells, with 71,544. Texas followed with 57,881, while Nebraska had 57,369, Arkansas had 32,555; Kansas had 19,213; and Florida had 18,993.

Industries engaged in the supply of water are expected to be among the fastest-growing public utilities because of factors such as the nation's expanding population and the increasing number of new housing projects connected to community water sources. The construction industry is expected to grow faster than average for all the nation's industries throughout the early 2000s.

As of 2003 the industry leaders in well drilling were Beylik Drilling Inc., based in Santa Ana, California; Honolulu, Hawaii-based Barnwell Industries Inc., which operates Water Resources International Inc.; and Charles Sargent Irrigation Inc., based in Broken Bow, Nebraska. Other industry leaders included True Geothermal Energy Company, Raba-Kistner Consultants Inc., R. E. Chapman Company, Weeks Drilling and Pump Company Inc., and Grabow Well Drilling Company.

SIC 1791

STRUCTURAL STEEL ERECTION

This category covers special trade contractors primarily engaged in the erection of structural steel and of similar products of prestressed or precast concrete.

NAICS CODE(S)

235910 (Structural Steel Erection Contractors)

INDUSTRY SNAPSHOT

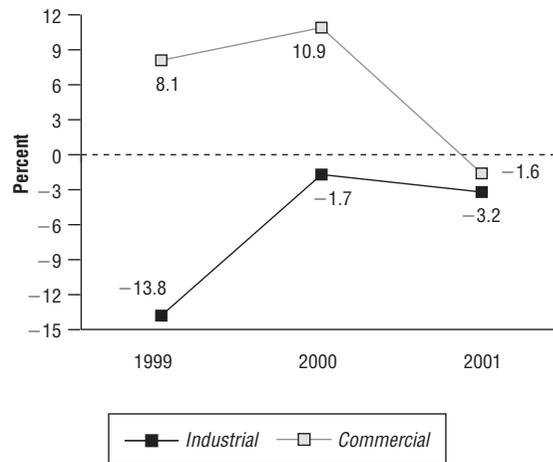

According to the latest figures available from the U.S. Census Bureau, more than 4,238 establishments are engaged in structural steel erection, generating an estimated \$8 billion worth of business. Major uses of structural steel include office and industrial buildings; commercial buildings, including retail stores, restaurants, and service stations; apartment buildings, hotels, and motels; warehouses; and highways, bridges, tunnels, and other transportation facilities. Single-family homes accounted for a very small percentage of the structural steel used in the United States.

The structural steel erection industry felt the effects of the U.S. economic downturn more than other construction related industries because it relied so heavily on commercial and industrial construction, both which saw growth slow dramatically in the early 2000s. Spending on commercial construction declined 1.6 percent in 2001, while spending on industrial construction declined 3.2 percent. The lone bright spot in the U.S. economy—residential construction—had little impact on the structural steel sector. Transportation spending had also been trimmed in various rounds of budget cutting during the early 2000s, although increased funding was expected to gain governmental approval in 2004.

BACKGROUND AND DEVELOPMENT

French architects began using iron to form the framework of their roofs about 1780. By the 1830s they also were using a form of masonry reinforced with imbedded iron bars that is regarded as the precursor of reinforced concrete. English builders began relying on iron in the construction of factories about 1850, primarily in an effort to make the buildings fireproof. Columns, beams, and window frames were made of cast iron, while exterior walls were made of brick or stone. Many commercial

Percentage of Spending Changes in Nonresidential Construction Sectors

SOURCE: *Building Design and Construction*, May 2002

buildings also used iron, with elaborate facades often constructed entirely of cast iron and glass.

Builders in the mid-1800s also used wrought iron, which could be hammered into a sheet and laid between wooden beams, or vice versa, for added strength. Iron plates also were sometimes riveted to the ends of these beams to create an early I-beam. The first I-beams made entirely of wrought iron were produced in Paris about 1847. The Trenton Iron Works in Trenton, New Jersey, began rolling wrought-iron I-beams in 1854. The first wrought iron I-beams produced in Trenton were shipped to New York where they were used to rebuild the six-story Harper Building, which had burned in 1853. The building also had a cast-iron front.

Bridge builders also began using iron to replace wood and stone in the late eighteenth century. Abraham Darby, an Englishman credited with originating the coke blast furnace, designed and built the famous Coalbrookdale Bridge over the Severn River in 1779, using wedged-shaped sections of cast iron to form the arch. The 100-foot bridge was still standing more than 200 years later. The first bridge in the United States made entirely of cast iron was built in 1840 and spanned the Erie Canal at Frankfurt, New York. The first railroad bridge made entirely of cast iron was built in 1845 at Manayunk, Pennsylvania.

In 1886, a bridge being built across the St. Lawrence River near Montreal needed to pass through part of the Caughnawaga Indian reservation. To obtain permission, the bridge builder agreed to hire local Indians. The Indians proved adept at the work, and several tribes, espe-

cially the Iroquois, later earned reputations for high-steel construction work.

However, bridges made of cast iron often shattered and collapsed under the tremendous weight of the steam locomotives, so bridge builders turned to wrought iron, which has greater elasticity under stress. Later, bridge builders turned to steel for even greater strength. The first bridge to use arches made of steel was built at Kuelenberg, Holland, in 1868, and spanned the Rhine River. The Eads Bridge, which was built in 1874 and spanned the Mississippi River at St. Louis, was the first bridge to use steel arches in the United States. The rest of the bridge was made of wrought iron. The first all-steel bridge was built over the Missouri River at Glasgow, Montana, in 1879.

Besides being used in bridges, steel was crucial to the erection of the world's first tall buildings. In the early 1850s, Elisha Graves Otis, an American inventor, developed an improved elevator with safety devices to keep it from falling. About the same time, Henry Bessemer in England and William Kelly in the United States developed a process that made it possible to produce large quantities of inexpensive steel. Together, the Bessemer process and the Otis elevator gave rise to the modern structural steel erection industry. Safe elevators made it practical to build taller structures, and cheap steel provided architects with a way to support taller buildings without relying on thick, windowless walls of masonry.

William Le Baron Jenney, a Chicago architect, built the first metal-frame skyscraper, the 12-story Home Insurance Building, in the mid-1880s. Jenney used an iron framework for the first six floors to carry the weight of the building into the foundation. He used steel beams for the top six floors. According to Douglas Alan Fisher in *The Epic of Steel*, the first building with a frame made entirely of steel probably was the Rand McNally Building completed in Chicago in 1890. By 1900, buildings had reached 30 stories. The Empire State Building, built in 1931, was originally 86 stories. It was later raised to 102 and remained the United States' tallest building until the Sears Tower in Chicago was built in 1972.

CURRENT CONDITIONS

The structural steel erection industry reflected general economic trends in the United States. With an economic downturn in the early 2000s, there was less construction of new factories and office buildings, which depressed the industry. In fact, by early 2003 the office vacancy rate had jumped to 16.5 percent, compared to 8.9 percent in 1998. Between 2002 and 2003 spending on office building construction declined from \$43 billion to \$39 billion. However, structural steel and prestressed or precast concrete remained the primary construction materials for large-scale projects, and the industry was expect-

ed to rebound with another spurt in new construction as the economy recovered in 2004 and 2005.

In the early 2000s, the United States also was becoming increasingly concerned with the deteriorating transportation infrastructure. With thousands of railroad and highway bridges needing repair, the outlook for the structural steel erection industry was strong, particularly with the likely passage of the TEA-21 Reauthorization Bill, introduced by the House Transportation and Infrastructure Committee, which earmarked billions of dollars for transportation. As a result, the employment outlook for this industry was also better than average.

INDUSTRY LEADERS

The leading company in this industry in 2003 was Pitt-Des Moines Steel Service Centers Inc., which was sold to Reliance Steel and Aluminum Co. in 2001. Operating as a subsidiary of Reliance, Pitt-Des Moines reported revenues of \$215 million in 2001. Second was Schuff International Inc., of Phoenix, Arizona, which reported \$174 million in revenue in 2003.

WORKFORCE

Structural steel erection workers held approximately 107,000 jobs in 2002. Nearly 4 of every 5 worked for the construction industry. Very few were self-employed. Many were members of the International Association of Bridge, Structural and Ornamental Ironworkers. Hourly wages for structural steel erection workers in the early 2000s averaged \$19.55 an hour, according to the Bureau of Labor Statistics. Earnings of these workers can be reduced due to poor weather and the short-term nature of the work in the construction industry.

SIC 1793

GLASS AND GLAZING WORK

This category is comprised of establishments primarily engaged in cutting, coating, tinting, and installing

glass. Companies that install automotive glass are described in **SIC 7536: Automotive Glass Replacement Shops**.

NAICS CODE(S)

235920 (Glass and Glazing Contractors)

This industry consists of a few companies offering a range of services. Common industry activities include installing plate glass in storefronts and other commercial buildings, cutting and installing windowpanes for homes, and tinting windows. Other niche markets exist for firms that install revolving glass doors; cut and install mirrors and safety glass; create custom glass doors, signs, shelves, and glass tabletops; or cut and install architectural and ornamental custom glass work.

The U.S. glass and glazing work industry includes roughly 4,700 establishments according to the latest figures available from the U.S. Census Bureau. Most of these firms employ less than 10 workers, and the total employee count for this industry ranges from 35,000 to 40,000. According to an April 2002 issue of *Glass Magazine*, attracting skilled workers will be the industry's most pressing challenge throughout 2010.

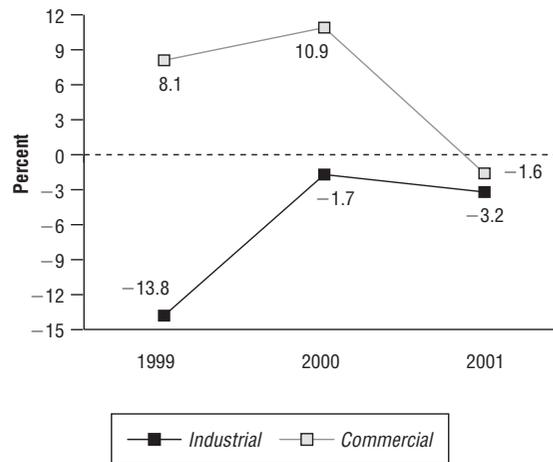

Although glass was invented in about 4000 B.C., it wasn't until the early twentieth century that advancements in manufacturing technology made it inexpensive and widely available. In 1900, the use of glass was primarily limited to windows, mirrors, optical lenses, and containers. During the early and mid-1900s, however, glass applications proliferated. As the U.S. economy boomed after World War II, the demand for glass by commercial, institutional, and residential sectors ballooned, spurring growth in the glass installation and glazing industry.

By the mid-1980s, the United States was consuming about \$2 billion worth of non-automotive flat glass, much of which was installed by contractors in the glass and glazing industry. Approximately 80 percent of that glass was used by construction industries, with the remainder used to make signs, mirrors, solar panels, and other specialty products.

A recession in commercial and residential building markets in the early 1990s curtailed glass shipments and cut the need for glass installation contractors. U.S. glass demand plummeted 8 percent per year between 1990 and 1992, to less than \$1.5 billion, as building contractors faced a major economic setback. Glass contractors also suffered as trends in architectural design moved away from the expensive glass office enclosures and stoic glass buildings so popular the decade before.

However, the sustained economic recovery in residential housing that began in 1992 continued past the middle part of the decade, spurring renewed demand for

Percentage of Spending Changes in Nonresidential Construction Sectors

SOURCE: *Building Design and Construction*, May 2002

glass contractors. Single-family houses accounted for 16.3 percent of the value of construction work done by this industry in 1992, up sharply from 10.6 percent in 1987, according to the U.S. Economic Census. However, the leading category of construction work done by the glass and glazing work industry in 1992 was "other commercial buildings," such as stores and restaurants, with 28 percent of the total (up from 21.7 percent in 1987). Office buildings accounted for another 21.5 percent of the industry's work in 1992, but this was down sharply from 28.8 percent in 1987.

The economic recession of the early 2000s prompted a slowdown in commercial and industrial construction, undercutting the performance of the glass industry as a whole. Nonresidential construction spending dropped by 6 percent in 2003 as even the strongest sectors, such as healthcare construction, began to see previously rapid growth rates slow. Spending on office building construction slowed considerably to roughly \$43 billion in 2002 and to \$39 billion in 2003. Spending on industrial buildings in the United States had declined 13.8 percent in 1999 to \$32.6 billion, and then continued to deteriorate at a slower pace, falling 1.7 percent in 2000 and another 3.2 percent in 2001 to \$31.1 billion. However, strong residential construction, spurred by record low interest rates, did help to offset this decline somewhat for glass manufacturers.

Industry trends included greater use of riot- and bulletproof glass, more skylights and windows in residences, and greater use of metal frames and finishes. By the mid-1990s many successful glass and glazing contractors had started concentrating on developing niche

markets, including the installation of energy-saving glass and safety glass. Some also expanded their services to include such activities related to glass installation as designing and building window frames. Technological advances that affected the glass and glazing work industry included a new "two-phase" adhesive glazing technique that lowered costs and enhanced aesthetics. In the wake of the September 11 terrorist attacks, many glass manufacturers began to offer security glazing. In fact, the U.S. Department of Justice issued a report in 2003 advocating the use of protective glazing on glass used in government buildings.

This industry has supported several thousand small contractors, but there are several large firms that lead the industry. In 2003, the top two companies in the industry were Harmon Contract, of Bloomington, Minnesota, and Benson Industries, Inc., of Portland, Oregon.

SIC 1794

EXCAVATION WORK

This category covers special trade contractors primarily engaged in excavation work and digging foundations, including digging and loading. Contractors in this industry may also perform incidental concrete work. Contractors primarily engaged in concrete work are classified in **SIC 1771: Concrete Work**. Those primarily engaged in trenching or in earth moving and land clearing not related to building construction are classified in the major group for heavy construction other than building construction, contractors.

NAICS CODE(S)

235930 (Excavation Contractors)

The U.S. excavation work industry includes more than 18,000 establishments employing more than 116,000 workers according to the latest figures published

by the U.S. Department of Commerce. Larger establishments (defined as those with 20 or more employees), account for less than 10 percent of the total number of establishments while taking in roughly 25 percent of all business done by this industry.

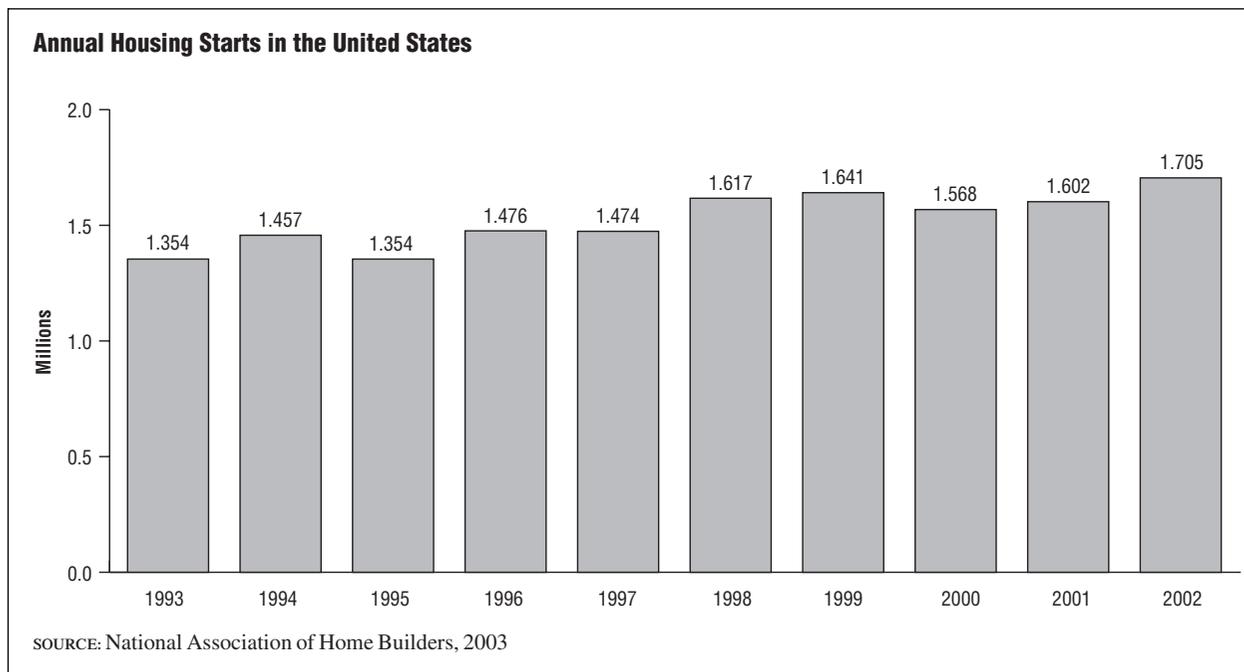

The two dominant costs of doing business in the excavation work industry are materials components and supplies, as well as payroll. Other costs include electricity; rental cost for machinery, equipment, and buildings; and cost of repairs to machinery and equipment.

The status of the U.S. excavation industry generally mirrors the country's economic climate, in particular the demand for construction of detached single-family homes. Typically single-family homes accounted for more than one-third of the value of all excavation work in the United States, while other commercial buildings represent less than one-fifth and educational buildings less than one-tenth.

The U.S. excavation work industry benefited from the sustained demand for single- and multi-family housing in the early 2000s. The recession of the early 1990s dropped housing starts to just 1.01 million in 1991, but the economic recovery that began in 1992 helped housing starts rise each year to a peak of 1.46 million in 1994. While starts dropped back to 1.35 million in 1995, they rose again to 1.45 million in 1996. In 1998 housing starts matched the 1996 number of 1.45 million, down slightly from the previous year. By 2002, however, housing starts had reached 1.70 million, 1.36 million of which were single-family, and 346,900 of which were multifamily. The National Association of Home Builders expects continued growth through at least 2005.

Because residential construction trends were up throughout the United States in the early 2000s, excavation work in these areas was booming despite a sluggish economy. Not surprisingly, most growth occurred in southern and southwestern states, which have experienced the strongest population growth in the United States during the 1990s and early 2000s. Among the top 50 markets, many of which experienced annual growth of 20 percent or better, were Dallas, Texas; Houston, Texas; Phoenix, Arizona; Atlanta, Georgia; and Las Vegas, Nevada. Florida leads the way in growth, attracting aging baby boomers who are looking for retirement homes or communities in warmer climates.

Small, independent operators remain the backbone of the excavation work industry. They generally work as subcontractors to home building companies, commercial construction firms, and others. Still, several large companies hold dominant market positions in this industry, though they tend to be regional and not national in scope. In 2003 the top companies in the excavation work industry included Freesen Inc., Springfield, Illinois (\$130 mil-

lion); Glasgow Inc., Glenside, Pennsylvania (\$100 million); George J. Igel and Company, Inc. Columbus, Ohio (\$50 million); and Beaver Excavating Company, Dresden, Ohio (\$40 million).

SIC 1795

WRECKING AND DEMOLITION WORK

This category covers special contractors that primarily wreck and demolish buildings and other structures, except marine property. They may or may not sell material salvaged from demolition sites. Businesses that do marine wrecking are in **SIC 4499: Water Transportation Services, Not Elsewhere Classified**.

NAICS CODE(S)

235940 (Wrecking and Demolition Contractors)

Despite opposite objectives, wrecking firms are grouped in the larger trade construction industry. This is due to the similar physical and economic nature of demo-

lition and construction work; they use many of the same tools, and the former activity often precedes the latter.

The wrecking and demolition industry is grouped into two sections: building and non-building demolition. The first category destroys houses, commercial establishments, and office buildings; the second removes highways, streets, and other non-inhabitable construction projects. Companies in the wrecking and demolition industry may specialize in one type of task—for example, demolishing small single-family homes.

According to the National Association of Demolition Contractors, roughly 1,000 firms operate in this industry. These companies employ nearly 19,000 workers and secure more than \$3.5 billion in sales. Many of these firms are small, family-owned companies already in business for a generation or two.

Before the 1930s, buildings were usually demolished by hand tools, which could take many months for an average-sized building. Newer building techniques developed in the early twentieth century gave rise to larger, sturdier buildings. This development, coupled with methods developed in post-World War II Britain to clear building debris, brought new demolition techniques. Because the German air force bombed so much of London, civilian and army units mobilized to help clear the destroyed buildings. These first methods were primitive, but the need to clear large sections of rubble and debris eventually led to quicker and more large-scale building removal techniques.

Another effect of World War II on the wrecking industry was a U.S. construction boom in the prosperous

years afterward. The returning troops, a population shift away from urban and industrial areas, and a baby boom led to severe housing shortages in many parts of the country. It also was necessary to clear older sections of cities to make room for new apartments and houses. The push toward urban renewal also played a role in the development of the industry. This idea began in the 1930s, when Roosevelt's administration tried to improve living conditions in poor urban areas where old tenements housed people in crowded, unsanitary conditions. The U.S. Housing Authority, the forerunner of the Department of Housing and Urban Development (HUD), began in 1937 to clear large tracts of slums and erect federally-subsidized housing. More wrecking and demolition firms set up shop to meet the higher demand. Urban renewal continued to effect the demographics of American cities well into the 1970s.

The decline of American manufacturing since the 1970s showed in the number of related edifices torn down in 1987—15 percent were former industrial buildings. The next largest group was commercial structures, such as stores and restaurants, which made up 12.4 percent of the buildings demolished. Office buildings were next, with 10.1 percent of the total, followed by single-family homes at 5.8 percent. The rest of the structures torn down by the industry in 1987 were, in descending order, highways and streets, blast furnaces, petroleum refineries or other heavy industrial complexes, hospitals and other institutional buildings, apartment buildings, and warehouses.

Various demolition methods, ranging from the traditional wrecking ball to explosives, were often used in conjunction. The largest expense for industry firms was often payroll costs. Generally these costs took one-third of the wrecking or demolition company's operating budget. Supplies and materials were the next biggest expense, while other pre- or post-demolition work, if contracted out to other companies, was an additional cost. Many smaller firms could not afford to own their own heavy equipment because the purchase price and maintenance costs were prohibitive. A thriving sister industry in equipment rental was another segment of the wrecking and demolition business. Insurance costs were also high, due to the relative danger of demolition work.

In 2003, the industry leader was Walsh Group Limited, of Chicago, Illinois, with \$1.7 billion in revenue. Following Walsh were Cleveland Wrecking Company, of Los Angeles, with \$64 million, and Brandenburg Industrial Service Company, also of Chicago, with \$60 million. D.H. Griffin Wrecking Co. and Gateway Demolition Corp. were among those firms that gained national recognition in 2001 and 2002 for their demolition work following the September 11 terrorist attacks. The four largest contracts for the clean-up were secured by three New

York City-based firms—Bovis Lend Lease, Tully Construction Co. and Amec Construction Management—as well as Turner Construction Co., located in Chicago, Illinois. The Federal Emergency Management Agency awarded each of these firms contracts for up to \$250 million apiece.

Issues concerning the industry in 2003 included the environmental impact of various activities, such as demolishing buildings with lead-based paint. In fact, the U.S. Army Corps of Engineers conducted a study, funded by the Construction Materials Recycling Association and the National Association of Demolition Contractors, on lead dust levels during such practices in California. Results were pending as of 2003.

SIC 1796

INSTALLATION OR ERECTION OF BUILDING EQUIPMENT, NOT ELSEWHERE CLASSIFIED

Special trade contractors primarily engaged in the installation, erection, or dismantling of miscellaneous building equipment make up this industry, which encompasses numerous firms that offer a wide range of services. Common activities include the installation, repair, and dismantling of conveyor systems, dumbwaiters, dust collecting equipment, elevators, incinerators, industrial machinery, power generation devices, revolving doors, and vacuum cleaning systems.

NAICS CODE(S)

235950 (Building Equipment and other Machinery Installation Contracts)

Businesses classified in this industry include more than 4,400 establishments, according to the latest figures available from the U.S. Census Bureau. The installation or erection of building equipment industry produces nearly \$10 billion in total revenues.

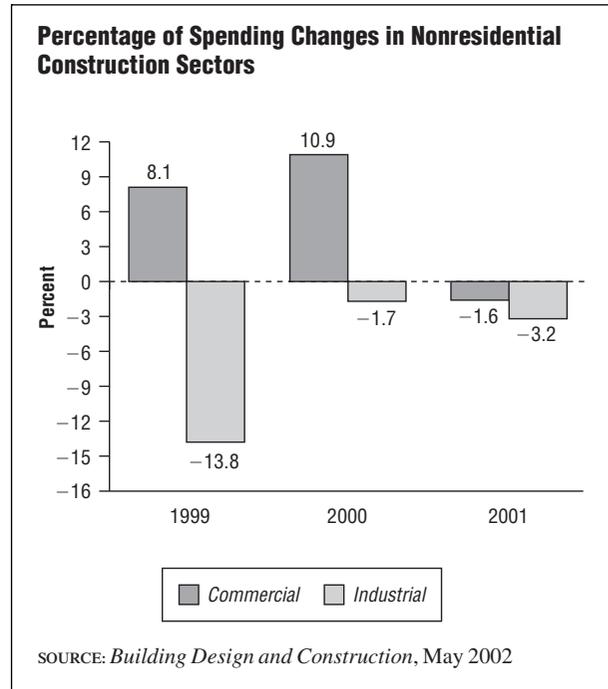

Most contractors in this industry rely heavily on new commercial, industrial, and institutional construction. Industrial buildings account for nearly one-third of the value of construction work done by this industry, followed by office buildings and other commercial buildings.

When building markets boomed during the mid-1980s, most specialty contractors realized healthy growth in billings and profits, and demand for items such as industrial machinery, elevators, and revolving doors increased. Contractors in this business, however, have to cope with the extremely cyclical nature of the nonresidential construction market, and this fluctuating cycle was most clearly evident during the late 1980s and early to mid-1990s. For example, industrial building construction expenditures in the United States advanced from \$15 billion in 1987 to \$23.8 billion in 1990. In 1991, however, construction in this category fell to \$22.3 billion and continued falling to \$20.7 billion in 1992 and to \$19.5 billion in 1993. Nonetheless, the industrial building market bounced back in 1994, to \$21.1 billion and \$24.1 billion in 1995.

The cycle in office building construction, the second largest market for contractors in SIC 1796, has been even more pronounced. Construction in this category peaked in 1989 at \$31.5 billion. By 1993, however, construction expenditures in this category had dropped by half, to just \$15.4 billion, before recovering slightly to \$17.0 billion in 1994 and \$19.4 billion in 1995.

This cycle has a profound impact on contractors in this industry category. During good times, specialty contractors enjoy healthy profit margins, expanding business, and steady demand for their services. In bad times, many contractors manage to stay afloat only by taking on installation and repair jobs at very low profit margins. In the early to mid-1990s, for example, elevator contractors were emphasizing elevator retrofits that integrated advanced technology. They were also striving to increase their share of the airport and health care elevator markets.

The long-term outlook for this industry appears to be mixed. While commercial construction benefited from the extended economic expansion of the late-1990s, overbuilding in many regions dampened the industry's performance in the early 2000s when the economy weakened considerably. While residential construction was boosted by interest rates that dipped to rates not seen since the 1950s, nonresidential construction experienced no such cushion. Businesses of all kinds began to curb spending on new and existing construction projects. Particularly hard hit was office construction. Spending on office building construction slowed considerably, from \$47.5 billion in 1999 to roughly \$43 billion in 2002 and

to \$39 billion in 2003. Between 1999 and 2003, office vacancy rates jumped from 8.9 percent to 16.5 percent.

One bright spot in this downturn was institutional construction, fueled in large part by healthcare facility construction, which didn't begin to wane until 2003. Compared to industrial construction spending, which declined by 3.2 percent in 2001, and to commercial construction spending, which dipped 1.6 percent that year, spending on institutional construction grew 10 percent. In 2003, however, total nonresidential construction spending dropped by 6 percent, as even the strongest sectors, such as healthcare construction, began to see previously rapid growth rates slow.

Privately owned companies dominate this diverse industry. The largest companies in the industry tend to be diversified contractors that have interests in many different areas. As a result, their activities in this industry category are just a small part of their overall business. Industry leaders include Millar Elevator Service Company, of Holland, Ohio, which was acquired by Morristown, New Jersey-based Schindler Elevator Corp. in 2002, and Harco Technologies Corp. of Medina, Ohio.

SIC 1799**SPECIAL TRADE CONTRACTORS, NOT ELSEWHERE CLASSIFIED**

The special trade contractors, not elsewhere classified industry is comprised of a plethora of firms that provide a broad range of miscellaneous construction services. Examples of industry activities include bathtub refinishing, gasoline pump installation, grave excavation, swimming pool construction, post hole digging, wallpaper stripping, mobile home setup, house moving, fire escape installation, bowling alley construction, artificial turf installation, and sandblasting.

NAICS CODE(S)

235210 (Painting and Wall Covering Contractors)

235920 (Glass and Glazing Contractors)

562910 (Remediation Services)

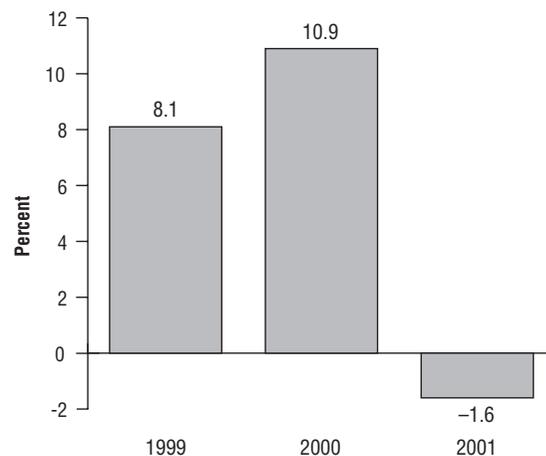

235990 (All Other Special Trade Contractors)

The special trade contractors industry includes roughly 25,000 establishments according to the most recent data available from the U.S. Census Bureau. The average firm is small, employing less than 10 people. Annual industry revenues total roughly \$20 billion.

While this diverse industry is hard to classify, a Department of Commerce survey notes that the industry's leading business category (based on value of construction work) is other commercial buildings, such as stores, restaurants, and auto service stations. This category is followed closely by outdoor swimming pools, industrial buildings and warehouses, fencing, single-family houses, and office buildings. A variety of other construction work accounts for the remainder of the total.

Although each sector of the industry is impacted by different factors, most specialty contractors are heavily dependent upon housing starts or new commercial and institutional construction. During the mid-1980s most contractors enjoyed steady expansion as commercial and residential building flourished. Likewise, when housing starts and commercial development stalled in the late 1980s and early 1990s, many contractors suffered immense setbacks. Total U.S. construction expenditures, in fact, actually declined 10 percent in inflation adjusted dollars between 1986 and 1992.

However, the construction industry saw strong growth between 1992 and 1999, as the general economy recovered, interest rates stayed relatively low, and housing starts boomed. For example, after dropping to just 1.01 million in 1991, single family and multi-family housing starts in the United States rose every year to 1.46 million in 1994. While starts dropped back to 1.35 million in 1995, they rose again to 1.45 million in 1996 and

Percentage of Growth in Commercial Construction Spending

SOURCE: *Building Design and Construction*, May 2002

were about 1.64 billion in 1999, a two-decade high. By 2002, U.S. housing starts had climbed to 1.7 billion, 1.35 billion of which were for single-family homes.

Another industry sector, home remodeling, had grown into a \$153 billion industry by 2002. Growth in this segment was expected to average roughly 5 percent per year, due in part to rising home values, against which consumers could borrow. This forecast boded well for special trade contractors, many of whom served this market segment.

However, nonresidential construction began to slow considerably in the early 2000s in response to recessionary economic conditions in the United States. Spending on industrial construction declined by 3.2 percent in 2001, and commercial construction spending dipped 1.6 percent that year; institutional construction, bolstered by a few strong segments such as healthcare construction, grew 10 percent in 2001. However, even institutional construction spending had started to wane by 2003; in fact, total nonresidential construction spending dropped by 6 percent that year. Particularly hard hit throughout the early 2000s was office construction due to the overbuilding that took place during the late 1990s. Spending on office building construction declined from \$47.5 billion in 1999 to \$39 billion in 2003. During this time period, the office vacancy rate nearly doubled from 8.9 percent to 16.5 percent.

Most companies in this industry were small, privately held, local enterprises. There were several industry leaders, though many of them also had interests in other industries. As of 2003, leaders in the specialty contractors industry were REXX Environmental Corporation, of

New York, New York, with nearly \$1.4 billion in sales; Anco Industries Inc., of Baton Rouge, Louisiana, with roughly \$140 million; and Western Group Inc., of St. Louis, Missouri, with \$130 million.

TRANSPORTATION, COMMUNICATIONS, ELECTRIC, GAS, & SANITARY SERVICES

SIC 4011

RAILROADS, LINE-HAUL OPERATING

This category covers establishments engaged primarily in line-haul railroad passenger and freight operations. Railways primarily engaged in furnishing passenger transportation confined principally to a single municipality, contiguous municipalities, or a municipality and its suburban areas are classified in **SIC 4111: Local and Suburban Transit** and **SIC 4119: Local Passenger Transportation, Not Elsewhere Classified**.

NAICS CODE(S)

482111 (Line-Haul Railroads)

INDUSTRY SNAPSHOT

Line-haul is defined as “the movement of freight between terminals.” More generally, line-haul railroads are those that transport passengers or freight long distances on a network of tracks that disperse goods and passengers across the United States. According to the Association of American Railroads, there were 571 common carrier freight railroads operating in the United States in 2001. Of those, eight were Class 1: The Burlington Northern and Santa Fe Railway, CSX Transportation, Grand Trunk Western Railroad, Illinois Central Railroad, Kansas City Southern Railway, Norfolk Southern Combined Railroad Subsidiaries, Soo Line Railroad, and Union Pacific Railroad. Although Class 1 accounted for only 1 percent of U.S. freight railroads, they generate 92 percent of the industry’s revenues. Regional, local line-haul, and switching-and-terminal operations rounded out the industry.

American railroads are experiencing a revival of sorts. Once the lifeblood of the U.S. transportation sys-

tem, the rail system fell out of favor as trucks took over the roads and the shipping industry. However, as highway congestion continues to pose environmental, safety, and energy conservation concerns in the twenty-first century, railroads are being revisited as a viable means of transporting goods across the nation.

ORGANIZATION AND STRUCTURE

In the years from 1987 to 1992, the railroad industry began to pull out of the slump it had seen in the 1970s and 1980s. In 1995 railroads realized significant productivity gains with freight revenue ton-miles per employee rising to seven million, up 11.1 percent over 1994 figures, and a dramatic 233 percent increase over the 1980 totals. In 1995 the industry’s fleet expanded for the third year in a row to 69.4 million, up 7 percent from 1994 and twice the comparable 1980 level. Meanwhile, rail freight rates fell sharply and steadily, lagging behind the overall inflation rate every year since 1983, with the exception of 1998, when rates rose more than 1 percent. Costs, however, also declined since the early 1980s, resulting in widening margins for the railroads.

Rail traffic increased steadily in the 1990s, growing by 30 percent between 1990 and 1997. In 1998 rail traffic increased 2.1 percent to 1.38 trillion ton-miles, due in part to a 3.7 percent increase in U.S. industrial output. Demand for rail service was influenced by several factors, including retail sales, general manufacturing levels, export and import trade, and housing and commercial construction. Coal was the industry’s largest source of traffic, accounting for 44 percent of volume and 22 percent of revenues in 1997. Grain, another major source of traffic, accounted for 8 percent of the industry’s volume and revenues.

Nearly 70 percent of all rail freight was transported under contract relationships between railroads and ship-

pers. Meanwhile, railroads would operate almost exclusively on privately owned rights-of-way, and would spend large sums of money on restoration of these rights-of-way, maintenance, and equipment investment.

One of the most notable investments in new equipment came in 1984 with the advent of double-stack containers—boxcar containers that fit on a lowered platform and could be stacked one on top of the other, doubling the amount a single train could carry. These immediately improved the feasibility and profitability of rail transport.

Another important innovation was the increase in intermodal transport, a system in which freight containers are attached to truck beds for shipments to rail yards, then transported by rail to a distribution “hub,” where they were again picked up by trucks for the final leg of their journey. These containers could also be transported by ship to port locations where they were transferred to rail for the journey inland. Intermodal transport allowed for both speed and low cost when transporting goods; due to decreased wind resistance of the lower-stacked cars, it cut fuel consumption by 20 percent. More importantly, the system changed the relationship between rail and trucking companies—once intense rivals for the same business—by encouraging cooperation and new business collaboration for the benefit of both industries. Between 1980 and 1997, intermodal traffic grew from 3 million containers to 8.7 million. By 1997, intermodal transport accounted for more than 17 percent of rail revenues, second only to coal, which accounted for 22 percent.

A side effect of intermodal shipping was the adoption of a hub-and-spoke network for shipping, in which fewer cities (hubs) served as drop-off points for goods initially shipped by truck. This system reduced the number of stops that had to be made by a single train, speeding up travel time for many routes and reducing overall customer costs.

BACKGROUND AND DEVELOPMENT

Railroads, defined as vehicles that move along a track on flanged wheels, have been in use since the sixteenth century, when human- or horse-pulled carts on tracks were used in Europe to haul ore out of mines. The first mechanically self-propelled railroad system was created in 1681 by Ferdinand Verbeist, a French Jesuit missionary in Peking, China. It was not until 1804, however, when the steam locomotive was invented in Wales, that the railroad’s potential as a system of mass transportation was realized. In the westward expansion of the United States, the railroad industry became significant both as a key factor in national growth, and as a formidable economic force in its own right.

In 1825 John Stephens of Hoboken, New Jersey, built the first American steam locomotive, ushering in an

era of development that would make the railroad industry an integral part of the expansion of America. Only two years later, the Baltimore and Ohio Railroad Company (B&O) was created to carry passengers and goods from Baltimore to Ellicott City, Maryland, 13 miles away. As B&O expanded in the following years (its tracks reached West Virginia by 1834), railway companies sprang up in other areas of the country during the 1830s, many of which were to become the Class 1 railways of the present.

Railroad building continued at an amazing pace between 1830 and 1860. With their ability to connect places previously separated by prohibitive distance, the railroads made possible the settlement of the western half of the continent. Railroads also liberated the country from its reliance on water transportation and made it possible for cities to grow away from rivers and canals, as the new lines could deliver goods and building materials to new homesteaders and carry raw materials to other cities. It became physically and economically possible to tap the continent’s huge reserves of raw materials such as lumber. New cities and towns were formed due to their proximity to railroad lines; in some ways the industry determined the political and social geography of westward expansion. In 1869 the first transcontinental railroad was created when the tracks of the Union Pacific from the East met those of the Central Pacific from the West at Promontory, Utah. America had entered the Railway Age.

By the beginning of the Civil War, 30,000 miles of track had been laid across the country. Railroads played an important strategic role in that conflict, as they were a means of delivering crucial supplies and troops. The Union army’s control of railroads—the owners of which were located mainly in the industry-rich North—was a significant factor in its eventual victory.

Big Business. From the end of the war in 1865 until the turn of the twentieth century, the industry grew at a fantastic rate, becoming America’s first “big business.” Although the railroad expanded the possibilities for agricultural sales, it did so at a price. Future conflicts between industry and agriculture were foreshadowed when, during the economic depression of the 1870s, a farmers’ group called the Grange protested the high rates charged by railroad “middlemen” to ship their goods. The case went to the Supreme Court. Its decision of 1877, *Munn v Illinois*, gave states the power to regulate business with a strong public aspect like that of the railroads. National (long haul) rates remained unregulated, however, leaving the industry open for control by businesses of national stature.

The development of the railroads was inextricably linked to that of other industries. Andrew Carnegie’s innovations in steel allowed the creation of rails that were

much more durable than the previous ones made of more malleable iron. The increase in anthracite coal mining in the late nineteenth century reduced the price of coal and made coal-fueled steam engines cheaper and more feasible; the railroads, in turn, made it possible to transport and distribute coal and steel to new towns and cities, many of which were centered around mills and factories needing these goods. The railroad thus became an essential link in the cycle of industrialization of the 1870s and 1880s that made mass production and mass marketing a way of life for a growing nation.

It took a new organization of business on a greater scale to support all this growth; in the last quarter of the century, the rise of big business was seen nowhere more clearly than in the railroads. Initially the competing companies fought rate wars to lure customers, but bankruptcy followed for many. In the late 1870s, railroad executives set up "pools," informal rate-setting agreements that fixed rates in a market. They also cut wages, which eventually led to the formation of unions to protect worker rights.

The railroads' profit margins, coupled with their workers' unstable and often dangerous working conditions, created an increasingly explosive atmosphere in the industry. In 1877 railroad workers staged what was to become the first nationwide strike, a conflict that required military and police intervention. In the years between 1881 and 1905, the country witnessed 36,757 strikes, a situation that resulted in the creation of unions such as the Knights of Labor and the American Federation of Labor. These unions forced the railroads, among other businesses, to improve working conditions, reduce hours, and pay wages negotiated by the unions and company management.

The growth of the rail industry continued unchecked through the beginning of the next century. Despite the Sherman Antitrust Act of 1890, industry saw the formation of several huge trusts, made up of formerly competing companies that controlled certain industries almost exclusively and made competition by smaller rivals nearly impossible. In 1902 President Theodore Roosevelt directed that a suit be filed against the railroad monopoly established by James J. Hill and J. P. Morgan. When that succeeded, he gave the Interstate Commerce Commission (ICC), which had been established in 1887, the authority to regulate monopolies and enforce rates. Although it did not end the tendency in the industry toward establishing trusts, the ICC did serve as a regulatory eye until it was abolished in 1995 and replaced with the Surface Transportation Board.

Profits Level Off. Railroads continued to expand their business and their track miles until well into the 1920s, at which point the industry reached a level of maturity that

was reflected in a leveling off of profits and growth that continued for the next few decades. As passenger air travel, and later air shipping, became more common and less expensive in the 1950s and 1960s, the railroads entered a period of decline that would not change until the 1980s. As it was still used to ship raw materials such as coal, grain, and lumber, the industry did little to reflect the nation's shift from a service and industrial economy to an information economy in the 1970s and 1980s.

The railroad industry suffered in the 1980s as increased reliance on trucking and other modes of transportation and the perception of railroads as antiquated, contributed to slow growth. The advent of innovations, however, such as double-stack containers, intermodal shipping, and computer-controlled dispatching, changed both perceptions and profits.

Deregulation. Another boon to the freight rail industry was industry deregulation. The Staggers Rail Act of 1980 reduced the ICC's regulation of rates and service, and in the following year the ICC exempted all intermodal traffic from rate controls. In addition, the ICC exempted boxcar and trailer-on-flatcar traffic and the transport of some agricultural products, lumber, and transportation equipment. Industry analysts credited this loosening of regulations with rail companies' increased investment in equipment, especially intermodal containers.

Deregulation also spurred Class 1 railroads' sales of branch lines to smaller companies. In contrast to the mergers of the 1980s, which analysts said left the largest railroads weighted down by debt and property, the sales of the early 1990s helped the industry as a whole. Smaller lines were able to offer improved local service, while still maintaining connection to the larger lines' nationwide network of tracks. In addition, smaller railroads often hired nonunion employees, who generally were unable to bargain for higher wages. Without union regulations, lines were also able to staff trains more lightly; they could rely on improved computer tracking and monitoring that could be handled by a two-person crew. Shorter lines also had the advantage of being able to offer more personal service to smaller customers.

In 1994 the ICC approved the merger of Burlington Northern (BN) with the Atchison, Topeka and Santa Fe Railway Company. This created the country's biggest railroad, with \$7 billion in combined revenues and 33,000 miles of track. BN already operated the longest rail system in North America, with 24,500 miles of track spanning 25 states and two Canadian provinces.

In late 1996 CSX Corp. attempted to take over Conrail with an \$8.4 billion offer. Norfolk Southern immediately countered with a \$9.1 billion hostile takeover bid. After several months of wrangling and opposition from several sources over the proposed takeover, the

two railroad giants agreed to divide Conrail's assets between themselves. After two years of planning, CSX and Norfolk Southern finally divided Conrail in 1999. CSX acquired 4,000 miles of track for \$4.2 billion, while Norfolk Southern took 7,200 miles of track for \$5.8 billion. The deal left most of the railroad traffic in the eastern half of the United States under the control of the two companies.

Another major consolidation in the railroad industry took place late in 1996, when Union Pacific acquired Southern Pacific. Following the acquisition, Union Pacific experienced two years of service interruptions as it tried to integrate the two rail systems. It was estimated that the interruptions cost shippers \$2 billion and Union Pacific \$1 billion.

While the merger of Union Pacific and Southern Pacific resulted in two years of service interruptions, it was hoped that the acquisition of Conrail by CSX and Norfolk Southern would go more smoothly. Service delays and misdirected freight cars, however, were reported in the months following the Conrail breakup in mid-1999. Because of these delays, United Parcel Service of America Inc.—one of the nation's largest rail shippers—diverted part of its Conrail business to trucks.

By 1999 Union Pacific appeared to have successfully integrated the Southern Pacific system into its operations. Through mid-1999 the company reported a 7 percent gain in rail traffic, the most of any major rail line.

The railroad industry enjoyed growing margins, as costs fell faster than rail rates during the 1990s. In addition, favorable economic conditions and a robust economy have contributed to steady increases in rail traffic. Following a 0.5 percent decline in rail traffic in 1997—due to factors such as the Asian financial crisis, traffic problems at Union Pacific, and soft demand from the coal and grain industries—rail traffic rebounded in 1998, rising 2.7 percent as the overall economy increased industrial output by 3.7 percent.

The future of the rail industry is affected heavily by industries that produce the goods being shipped. Those industries relying most heavily on rail transportation for shipping their products included steel, coal, chemicals, pulp and paper, automobiles, construction, and agriculture. Coal alone made up approximately 40 percent of rail shipments, so the coal industry's economic status had a strong effect on the fortunes of the railroads.

CURRENT CONDITIONS

In 2002 Class 1 railroads operated on over 121,000 miles of tracks and had nearly 500,000 freight cars in service. These eight major railroads reported total revenues of \$33.5 billion in 2001. Coal accounted for 47 percent of commodities shipped via rail and generated 23

percent of revenues. Total revenue for all railroad classes in 2001 was \$36.7 billion. That year, railroads shipped 1.5 trillion ton-miles and carried 9.5 percent of all inter-city goods (trucks carried the vast majority, at 80.4 percent).

Railroads' renewed life is being based on the rapid growth of the fast-freight, or intermodal, sector. Unlike the traditional loose cars that are dominated by coal transportation, as well as other low-value per-weight goods, fast-freight uses containers that carry higher-valued goods with a much keener need for quick and timely service. During the first years of the twenty-first century, railroads have worked hard to prove their old reputation for unreliable service is unfounded. To that end, trains carrying fast-freight, which may include time-sensitive goods, are given the right-of-way on the tracks, with trains pulling loose cars pulling over to make way for the intermodal freight carriers. Between 1980 and 1999 coal ton-miles grew a very respectable 43 percent, but intermodal ton-miles jumped up 98 percent.

The largest problem facing the railroads' revival is service capacity. At the beginning of the twenty-first century, railroads were putting approximately 20 percent of revenues into capital expenditures. Railroads are very expensive to build, and construction must be coordinated within existing, and often already congested, transportation infrastructure. Therefore, it remains unclear how the industry will underwrite the cost to increase capacity, as well as maintain existing structures to once again become a dominant player in the freight-hauling industry.

INDUSTRY LEADERS

The top Class 1 freight railroads of 2002, generally considered to be the industry giants, included Union Pacific, with \$12.5 billion in revenues; Burlington Northern Santa Fe, \$9 billion; CSX, \$8.2 billion; and Norfolk Southern, \$6.3 billion.

Illinois Central was acquired by Canadian National Railway Co. for \$2.4 billion in a deal that was approved by the Surface Transportation Board in March 1999. The acquisition added 2,600 miles of U.S. track, ranging from Chicago to the Gulf of Mexico, to Canadian National's 13,750-mile system in Canada and six northern U.S. states. Following the acquisition, Canadian National reported \$3.9 billion in revenues for 2002.

Through a series of acquisitions, RailAmerica, Inc. emerged as the largest regional and short-line operator. Toward the end of 1999 the company acquired RailTex of San Antonio for \$325 million. The deal gave RailAmerica ownership or an interest in 51 railroads with 12,500 miles of track in the United States, Canada, Mexico, Chile, and Australia. In 2002 RailAmerica reported revenues of \$428 million.

National Railroad Passenger Corporation, better known as Amtrak, was established by Congress in 1971. Operating with the benefit of government subsidies and federal grants for equipment, Amtrak reported 2002 revenues of \$2.1 billion. In 1997 Congress passed the Amtrak Reauthorization Act, which among other things created the Amtrak Reform Council (ARC). The ARC was responsible for monitoring how Amtrak would use the \$2.2 billion it received as a result of the Taxpayer Relief Act of 1997. With Wisconsin Governor Tommy G. Thompson appointed the new board chairman in 1998, Amtrak attempted to become self-sufficient by 2002, when Congress would end its operating subsidies. For 1999 Amtrak projected an operating loss of \$930 million, followed by a loss of \$908 million for 2000. Congress set aside \$609 million for Amtrak's use in fiscal 1999 and \$571 million for fiscal 2000.

In the 1990s Amtrak's challenge was to become profitable while improving travel time by incorporating high-speed passenger trains that would create competition with commuter air flights, especially in the congested Northeast. This goal is helped by rail travel's role in reducing traffic congestion and pollution when used as an alternative to automobile travel—trains emit 10 to 30 percent less pollution than do autos and trucks. Amtrak's first high-speed train, called Acela, was scheduled to debut in spring 2000. The 150-mile-an-hour train was expected to add \$180 million in annual profits and help Amtrak compete against airline shuttles in the northeast corridor.

WORKFORCE

According to the Association of American Railroads' Policy and Economics Department, in 2001 the railroad industry employed 184,368 people, with 162,155 being employed by Class 1 railroads. Average annual wages were approximately \$58,000. Rail workers have long been unionized, and the unions have made rail employees as a group one of the highest-paid segments of the working population. But the increasing automation of trains, centralized dispatching, and company mergers, combined with companies' desire to cut operating costs as much as possible, have endangered several key employment positions. In addition, faster trains mean that crews, who are paid bonuses for miles traveled over a set limit, often earn bonuses of up to 70 percent of a day's wages for an 8- or 10-hour day. Companies are eager to cut these bonuses, but the power of the unions is strong.

Collective bargaining occurred throughout 1991 between the freight railroads, Amtrak, and the railroad employees' unions (most notably the International Association of Machinists, or IAM), with most disputes being settled that year. Yet by June 1992, IAM and the freight rail companies had still not reached an agreement. This

situation, combined with Amtrak's stalled negotiations with two of its unions, led to a strike and a national rail shutdown on June 24, 1992. After Congressional intervention forced binding arbitration, all disputes were resolved by August 2, 1992. It is likely that labor disputes will continue to mark the rail industry, as technical advances shift emphasis from physical labor such as brake operation to more technical and managerial jobs such as engineering.

Each train is run by an engineer, who holds the highest rank on a train and is in charge of the train and its crew. The engineer checks the train for mechanical and safety problems before each run, starts and stops the train, and monitors its progress throughout a trip. Trained as "firers" (a term surviving from the days of steam locomotives) or assistant engineers, engineers must learn how to run and monitor all trains owned by their employer and must be familiar with tracks, signals, and hazards of each route. In 1993 starting engineers earned an average of \$35,000 to \$45,000 per year, reflecting the job's status as the highest-paid railroad worker.

All trains also employ a conductor who is responsible for the train crew and the passengers or freight. On freight trains, the conductor logs the contents of each freight car and ensures that the contents are deposited at their destinations along the route. On passenger trains, the conductor collects passenger fares, helps passengers with any needs or requests, and alerts the engineer when all passengers at a given stop have left the train. Conductors also act as an information conduit between the dispatchers, station managers, etc., and the engineer. In 1993 the average annual starting salary for a conductor was \$32,000 to \$35,000.

Some trains employ an assistant engineer ("fireman" or "firer"), who aids the engineer in running and monitoring the trains. This position is being phased out due to the increasing computerization and mechanization of trains, terminals, and freight yards. Firers perform engine maintenance and repair and serve as emergency replacements for engineers. Brake operators (previously called "brakemen") maintain braking equipment and lights and add and remove cars at station stops. Brake operators also are disappearing from trains due to railroad-union negotiations; they are being eliminated mainly through attrition and early-retirement incentives. In 1993 firers earned an average yearly starting salary of \$16,000 to \$25,000, and brake operators had a starting salary of \$30,000.

AMERICA AND THE WORLD

Regional trade agreements, railroad cooperation, railroad mergers, and transportation innovations have all had an impact on the growth and development of rail transportation. The U.S.-Canadian Free Trade Agree-

ment, signed in 1988, resulted in Class 1 railroads on both sides of the border accelerating their connections into each other's territory. The North American Free Trade Agreement (NAFTA), which diminished most trade barriers, and a wave of rail mergers in the United States in 1994 and 1995 further hastened this trend.

With trade between the United States and Canada forcing a north-south orientation, railroads shifted their east-west systems accordingly. Both shared track, rail beds, and operations on both sides of the border. U.S. railroads gained entry to Canada through interline agreements with Canadian railroads. The Atchison, Topeka and Santa Fe Railway Company, for example, entered into an interline connection with the Canadian National Railway Company's Grand Trunk line at Chicago. This enabled the railroad to provide service between Mexico and Canada.

NAFTA resulted in U.S., Canadian, and Mexican rail carriers capitalizing on increased trans-border trade. Rail traffic to Mexico began growing when the country first began easing trade barriers in 1988, and reached new highs in 1993 with NAFTA. In 1994 cargo volumes for Canadian railroads accounted for about one-quarter of the southbound export tonnage moving across the U.S. border. The pact particularly benefited U.S. producers of grain, automobiles, lumber, and other goods suited for transport by rail.

American companies worked especially hard with the Mexican national rail system, FNM (Ferrocarriles Nacionales de Mexico), to simplify border regulations and increase rail traffic between the two countries. For example, FNM adopted Union Pacific's computerized monitoring and tracking system, while Concaril, a Mexican company, began building cars for the Atchison, Topeka, and Santa Fe Railway. Shipments of goods between the two countries had already increased in the early 1990s, even before the implementation of NAFTA, with more American-made automobiles and Pacific Rim imports being shipped by train to Mexico.

In 1994 Union Pacific derived \$348 million in revenues from Mexico traffic, up 20 percent from the previous year, and handled 55 percent of cross-border rail traffic. Southern Pacific, the largest double-stack carrier to Mexico, handled the second-largest amount of cargo. Southern Pacific invested directly in Mexico's infrastructure and developed a network of distribution centers at Mexican rail ports that enabled timely unloading. In 1993 it completed construction on an intermodal facility at Monterrey, operated by Mexican firms. Union Pacific expanded its presence in Mexico in 1997 by entering into a joint venture to operate the Pacific-North Railway. In 1999 it increased its ownership to 26 percent of Grupo Ferroviario Mexicana, parent company of Ferrocarril

Mexicano, the operator of the privatized former Pacific-North region of the Mexican National Railway.

RESEARCH AND TECHNOLOGY

Among the newest innovations in the railroad industry was EDI, or electronic data interchange, which allowed the railways to track goods and trains more closely and quickly than in the past. The primary EDI system, ATCS (advanced train control systems), controlled trains using telecommunications technology and computer tracking. With ATCS, train crews could stay informed of all train operations, a development that could improve safety and reliability and reduce costs.

Norfolk Southern established an EDI system called Thoroughbred, which allowed the carrier to closely track cargo, gave customers up-to-the-minute status reports on their shipments, and provided delivery schedules. Likewise, the Atchison, Topeka and Santa Fe Railway launched Santa Fe Direct, a real-time EDI system to track shipments that went beyond its rail service. Union Pacific's computerized car locator system, on which all U.S. and Canadian locator systems were based, installed its system at 10 rail yards in Mexico. In 1994 data was integrated into the U.S. and Canadian systems making it possible for a Canadian shipper to send freight out on a Canadian National or Canadian Pacific car all the way to Mexico City without the car being opened, and know where the goods were anytime and anywhere.

Technology refinements in the use of intermodal containerized freight, the means by which containers could be interchanged between rail, seagoing, and trucking modes, resulted in railroads moving freight faster and more efficiently. Statistics from the Association of American Railroads indicated that the use of intermodal peaked in 1994 with 8.13 million trailers and containers in use, then slacked off in 1995 to 8.07 million, only to rebound to 8.7 million in 1997. The engineering of double-stack trains, a means by which one container is literally stacked on top of another, also made it possible for a train to carry the equivalent of 200 trucks, thereby saving fuel and labor costs while improving efficiencies. Platforms on which the containers were secured provided a smoother ride for materials and products.

Once industry standards became hammered out, some industry observers felt that ATCS would provide near-instantaneous data on car location, switching records, car scheduling, and other factors that affected the smooth synchronization of a vast network of trains. Of course, the up-front costs were great, but ATCS was one step toward further computerizing a large and complex industry.

Other innovations included ISS (Interline Settlement System) and REN (Rate EDI Network), industry-wide standards of computerized data management that would

manage revenue sharing among railroads when goods were shipped on more than one line, as was often the case, and speed billing and dispute resolution within the industry. An information system called Railinc, used widely in the industry, already sped customer service and tracking. Finally, it was predicted that the rail industry would take advantage of handheld "slate" computers that would allow crews to forward information to central schedulers "on the fly," or as it was taken down. All of this automation, based on smaller networked computer systems rather than large central mainframe machines, could lead to a continuing decentralization of control and information that would allow greater flexibility and improved response on the part of each company and the industry as a whole.

A major development affecting passenger rail service, and especially Amtrak, was high-speed rail passenger systems, which ran at 125 miles or more per hour and brought train travel to a speed where it could compete with air travel over shorter distances, both in regard to cost and convenience.

High-speed rail systems fell into two categories, steel-wheel-on-steel-rail and magnetic levitation systems. Among the more traditional wheel-on-rail trains, the fastest of which could reach 187 miles per hour, France's TGV train was the most successful. As of 1993, a privately financed TGV system was planned by the Texas High-Speed Rail Authority to link Dallas/Fort Worth, Houston, San Antonio, and Austin by 1999. Privately financed for \$7 billion, the system would be the first of its kind in the United States.

Magnetic levitation (maglev) technology, which used magnetic forces to propel, brake, and control trains traveling up to 300 miles per hour, was tested in Germany and Japan. The trains, which were separated from the tracks by a magnetic field, were not yet in commercial use. A planned maglev system, however, that would connect the Orlando, Florida, airport and the Disney World complex, was planned, with backing from American, German, and Japanese investors.

Among other developments in the industry were new fuels for locomotives. In 1991 Burlington Northern, in conjunction with Air Products & Chemicals, Inc., developed a locomotive that could be run on refrigerated liquid methane, a natural gas derivative. The use of such fuels could reduce fuel costs for rail companies, as well as cut down on polluting emissions.

Railroads invest heavily in technologies that would improve safety and efficiency. By July 1997 railroads had two-way end-of-train braking devices installed on all trains that routinely traveled at speeds greater than 30 miles per hour. Railroads replaced older wheels with heat-treated curved plate wheels, which were developed

following research in the late 1980s. Positive train separation systems were being tested to reduce the chance of mainline collisions. The latest rail transport and safety improvements were tested at the Transportation Technology Center, a 52-square-mile facility operated by the Association of American Railroads.

SIC 4013**RAILROAD SWITCHING AND TERMINAL ESTABLISHMENTS**

This category covers establishments engaged primarily in the furnishing of terminal facilities for rail passenger or freight traffic for line-haul service and in the movement of railroad cars between terminal yards, industrial sidings, and other local sites. Terminal companies do not necessarily operate any vehicles themselves, but they may operate the stations and terminals. Lessors of railway property are classified in **SIC 6517: Lessors of Railroad Property**.

INDUSTRY SNAPSHOT

The roughly 3,000 stations and track terminals in the United States during the 2000s served about 15 large freight railroads and more than 600 small, regional railroads. As mass transit systems continued to spread across America, rail tracks and terminals shared by more than one railroad company became an increasing concern. A train going just 30 mph needs two-thirds of a mile to stop; a train going 50 mph needs 1.5 miles. High-speed trains traveling in excess of 125 mph also were being placed into the rail system.

The human error factor, which accounted for the majority of train switching accidents, was being eliminated from the industry. As trains became more electronically controlled, safety for passenger and freight cargo rose dramatically. Approximately 80 percent of railroad tracks in the United States used a technology employing electromechanical relay signal systems. However, wireless microprocessors that used computer signals were rapidly replacing the relay systems. The remote control technology was touted by proponents as a way to reduce miscommunication and the accidents resulting from human error. Switching to remote control was expected to save the industry upwards of \$250 million annually, and the technology was able to be upgraded continually. The result was a less expensive and more safety-oriented rail system that was expected to grow through 2006. According to Florida East Coast Railway President and CEO John McPherson, quoted in *Railway Age*, the technology was “the most productive implementation in our industry since we were able to eliminate the caboose.”

BACKGROUND AND DEVELOPMENT

Railroad switching and terminal establishments for line-haul railroads are connection points facilitating the

movement of tons of goods on and off trains, as well as the assembly and tracking of those trains. Closely tied to the railroads’ increased profitability in the 1990s was tighter scheduling and dispatching made possible by high-tech tracking systems that aided crews in train turnover, which can reach hundreds of trains a day.

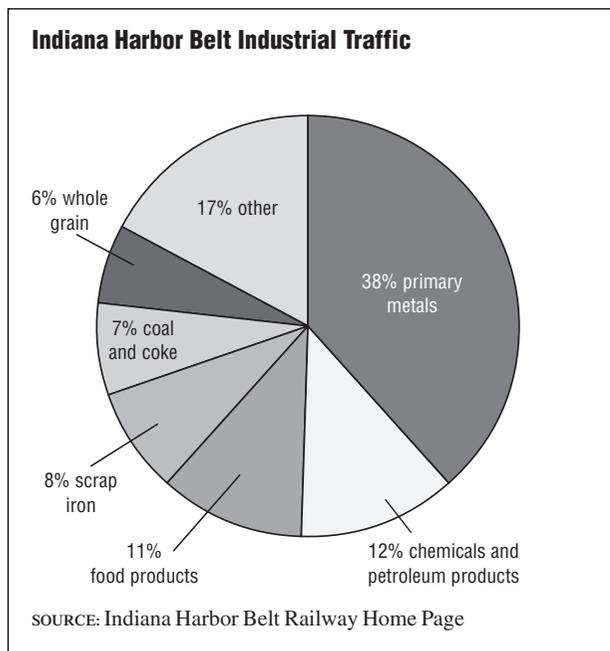

In order to cut costs and attract new truck-to-rail business, railroad companies have begun to upgrade their transfer terminals. At the heart of this activity was a desire to facilitate the movement of intermodal traffic. In 1997 Illinois Central upgraded its transfer terminal at Harvey outside of Chicago to increase its intermodal business. Norfolk International Terminals constructed a new intermodal transfer container facility to increase the facility’s intermodal rail handling capacity.

With the merger of major railroad companies in the United States, railroad executives anticipate a potential bottleneck at terminals with some railroads not having easy access to switching. In 1997 the issue became heated with the potential of some form of re-regulation coming to the industry.

The biggest technological advance affecting railroad terminals was the use of computer networking and scheduling to speed jobs that were once handled by paperwork and tracked by human operators. These advances, which in the long run save money for railroads and make them able to compete with other forms of transportation, have shaken up the industry and reduced the number of workers necessary for a task. Automatic Train Control System (ATCS) networks, used by most Class 1 (large railroad) lines, are based on transponders attached to tracks at certain intervals and triggered by passing trains.

With ATCS, information gained from the transponders is sent via fiber-optic cable or telephone line to a regional data center or directly to the switching yard to which a passing train is headed. Once gathered, this information allows switching establishments to react more quickly to changes on the line, as well as to assign incoming trains to certain tracks in the yard. Switching establishments, which may or may not be run by the railroads that use them, can use up to 100 track segments on which cars and locomotives are coupled and uncoupled, loaded and unloaded.

ATCS was being implemented in four areas: work order reporting, locomotive performance monitoring, track force equipment management, and positive train separation and control. The U.S. Department of Transportation’s (DOT) Federal Railroad Administration (FRA), in cooperation with the industry, conducted a safety inquiry into this new technology and reported to Congress the feasibility of implementing ATCS in a way that would enhance the safety, efficiency, productivity, and customer service capabilities in the railroad industry.

Union Pacific's rail complex in North Platte, Nebraska, the world's largest, can deal with up to 700 trains in a day by way of its computerized command center. Outside Albany, New York, Conrail's Selkirk Yard sorts 3,200 freight cars per day, thanks to computer scheduling and track assignment. Finally, a move by the railroads to a hub-and-spoke system of organization reduces local stops and focuses time and money on larger, more centralized switching establishments (see **SIC 4011: Railroads, Line-Haul Operating**).

To meet the new demand, corollary industries also were experiencing commensurate growth. For example, Harmon Industries, manufacturer of signaling and safety systems, posted a record \$265 million in sales for 1998. The company offered a six-week training program to train switch operators in crisis situations, which are simulated in its 3,500-square-foot lab, complete with two full-size switching machines and three railroad crossing gates.

Another corollary industry was that of renovating and refurbishing train stations that service switching terminals. The nonprofit Great American Train Foundation published its first "Guidebook on Train Station Revitalization" in 1999 to assist local governments and communities in transforming railroad stations into multimodal centers of transportation, commerce, and economic development.

CURRENT CONDITIONS

Interest in passenger rail continues to grow, with both intercity and rapid transit applications. The Congressional fiscal year 2000 budget for the federal transit program was \$5.8 billion, with the passenger railcar-building industry being a key beneficiary.

The Surface Transportation Board Reauthorization Act of 2003, introduced to Congress by the DOT on July 10 of that year, was intended to authorize appropriations for the Surface Transportation Board (which replaced the Interstate Commerce Commission) from \$20.5 million in 2004 to \$23.5 million in 2008. A key provision of the act, when it was reauthorized four years before as the Surface Transportation Board Reauthorization Act of 1999, was the mandate calling for reciprocal switching in railroad terminal areas, enhancing competition among terminal providers.

The remote control technology was not foolproof, however. In 2002, Atlanta experienced three collisions with remote controlled engines in only eight months. The third collision derailed five cars, three of them filled with cement. Those in the Brotherhood of Locomotive Engineers, a railway worker's union, claimed the collision would not have occurred under the oversight of a human engineer.

Although labor unions fought against radio remote control technology in the 2000s due to its impact on jobs, it was coming into widespread use by 2002. Engineers had begun to cease fighting a losing battle against the inevitable, and started training to work with the technology. While there were still documented cases of collisions due to equipment failures, the number caused by human error declined.

In addition, switching to remote control was expected to save the industry upwards of \$250 million annually. The technology was expected to completely pay for itself in a very short time. Rather than eventually become obsolete itself, radio remote control technology was able to be continually upgraded. In the 2000s, the government also was putting money into research and development of technologies, through such programs as IDEA.

INDUSTRY LEADERS

Indiana Harbor Belt Railroad Co. of Hammond, Indiana, led the industry with 2001 revenues of \$88 million and 800 employees. Belt Railway Company of Chicago, based in Bedford Park, Illinois, was second with \$78 million in revenues and 600 employees. In third place was Missouri-based Terminal Railroad Association of St. Louis, with \$36 million in revenues and 300 employees. Other industry leaders were Cuyahoga Valley Railway Company of Peninsula, Ohio, with \$19 million in revenues and 200 employees, and New York-based South Buffalo Railway Co., with \$13 million in revenues and 100 employees.

WORKFORCE

Railroad terminals use a hierarchical employment structure much like that found in the larger railroad industry, in which engineers, conductors, and brake operators

work together on operations. In the terminals, however, job descriptions are slightly different. Railyard engineers oversee the movement of cars within the freight yard or terminal and the assembly of trains. Yard conductors oversee all yard employees, instructing them in assembling and disassembling trains and switching cars between tracks. Yard brakemen (or “yard helpers”) assist the conductor and do much of the physical labor of coupling and uncoupling cars. In addition to the yard crew, railroad terminals employ clerks, maintenance workers, and signalers and signal maintainers. Passenger terminals also employ station agents and ticket agents, who deal directly with the public.

Because of continued automation, the industry was expected to lose employees, declining to 143,000 by 2006. This represents a drop of approximately 24 percent from 1995.

SIC 4111

LOCAL AND SUBURBAN TRANSIT

This industry consists of establishments primarily engaged in furnishing local and suburban mass passenger transportation over regular routes and on regular schedules, with operations confined principally to a municipality, contiguous municipalities, or a municipality and its suburban areas. Also included in this industry are establishments primarily engaged in furnishing passenger transportation by automobile, bus, or rail to, from, or between airports or rail terminals, over regular routes, and those providing bus and rail commuter services.

NAICS CODE(S)

- 485111 (Mixed Mode Transit Systems)
- 485112 (Commuter Rail Systems)
- 485113 (Bus and Motor Vehicle Transit Systems)
- 485119 (Other Urban Transit Systems)
- 485999 (All Other Transit and Ground Passenger Transportation)

INDUSTRY SNAPSHOT

Despite America's complaints of traffic congestion, pollution, gasoline prices, and lack of available parking, the truth is that Americans love their automobiles. However, as highway congestion continues to increase, improving and expanding mass transit systems remains on the agendas of most major metropolitan areas. By the beginning of the 2000s, Americans were spending three times as many hours idling in traffic as they did in 1982. Slowly, traffic is building on mass transit. In 2001, 9.5 million people rode on public transportation, setting a record for the sixth consecutive year. From 1996 to 2001 public transportation travel increased by 23 percent.

The sheer convenience of a personal automobile appears to be one of the biggest obstacles to the appeal of public transit. While most transit systems are intended to alleviate “rush hour” traffic associated with commutes to and from work, the truth is that almost 40 percent of morning traffic, and a clear 60 percent of afternoon rush hour traffic, is not even work related. Moreover, most transit systems were designed to serve urban metropolises and their suburbs, but only 19 percent of all commuters live in suburbs while working in the central cities.

For years, the mass transit industry had carried the stigma of the “1 percent argument,” the system would service only 1 percent of all trips made by persons. The argument has been close to reality: light-rail systems are used by only 5 percent of commuters. Public transit in general has historically served a captive clientele: persons without driver's licenses or without vehicles, comprising about 70 percent of all riders, according to the National Urban Transit Institute at the Center for Urban Transportation Research. Ultimately, government subsidies to maintain the failed systems were averaging almost \$10 dollars per one-way passenger and, in cities like Los Angeles, ran as high as \$40 dollars per commuter rail trip.

But all is not for naught. As the twenty-first century began, the statistical wake-up calls urged cities and policy-makers to shift focus. Instead of trying to increase ridership with billion-dollar subsidies, they needed to develop other innovative transportation solutions. As a result, the industry has been paving its way toward an effective and appealing solution to ease public transportation concerns.

ORGANIZATION AND STRUCTURE

Passenger transit is considered an essential public service in the United States. As such, large sums of government financial assistance are pumped into transit systems throughout the country every year. Since World War II, private transit companies have been converted into public enterprises on a huge scale. This trend was facilitated by the passage of the Urban Mass Transit Act of 1964. This act was created largely as a measure to save mass transit from disappearing, since the postwar rise in automobile use had pushed many transit companies into insolvency. By 1990, public transit systems accounted for 86 percent of the industry's vehicles, 94 percent of its vehicle miles operated, and 94 percent of its unlinked passenger trips.

Transit Modes. Local and suburban passenger transit includes several different transportation modes. The most common mode found in the United States is the motorbus, which sees heavy use throughout the country. In large cities, heavy rail systems, which generally means subways and elevated rails, are also common. Commuter trains, light rails, and trolleys are also part of the local transit network. This industry also includes vanpools, airport shuttles, and other transportation to transit terminals, provided they run over regular routes on fixed schedules.

Distribution. Obviously, the need for transit grows with population size. In general, smaller urban areas use more buses and vanpools, while rail systems are found primarily in only the largest cities and their metropolitan areas. More than half of the nation's road transit systems are located in urbanized areas with populations under 50,000. Of the 20 all-rail transit systems in the United States, 15 are in cities with populations in excess of two million. California and New York have the most transit systems in operation, with each state containing 362 systems. Texas, with 238, is the only other state with more than 200 transit operations.

Organizations. The American Public Transit Association (APTA) is an organization of mass transit operators in the United States and Canada. Based in Washington, the APTA has more than 1,000 members. The APTA is generally considered the definitive source of transit information in the United States. Its members include organizations involved in every facet of mass transit, including construction, design, financing, planning, and supplying. The APTA was created in 1974 upon the merger of the American Transit Association (ATA), founded in 1882 as the American Electric Railway Association, and the Institute for Rapid Transit (IRT). The federal agency that oversees the industry is the Urban Mass Transit Administration (UMTA), an arm of the U.S. Department of Transportation.

BACKGROUND AND DEVELOPMENT

Urban mass transit in the United States began to appear in the early part of the nineteenth century. In 1827, a horse-drawn stagecoach line began operating in Manhattan. Designed and planned by Abraham Brower, the line started out as a single 12-passenger vehicle, built by the coach-making company Wade & Leverich, running up and down Broadway. Two years later, Ephraim Dodge followed suit in Boston. Meanwhile, a more comfortable vehicle called an omnibus was gaining popularity on the streets of London and Paris. Brower took notice of the omnibus' success in Europe and, within four years of their New York introduction, over 100 omnibuses were rolling on New York's grid of streets. By 1844, omnibus service was also available in Philadelphia, Boston, and Baltimore.

Beginnings of Rail Service. At the same time that road transit was developing in the United States, street railway lines were making their debut. In 1832 John Mason, president of the Chemical Bank, founded the New York and Harlem Railroad, which initially ran along the Bowery from Prince Street to 14th Street, and eventually stretched all the way to Harlem. New Orleans launched a similar streetcar line in 1835, but this mode of transit did not really catch on until the 1850s, when Brooklyn, Cambridge, Philadelphia, Baltimore, Pittsburgh, Cincinnati, and Chicago all had horse-drawn rail lines built.

By 1882, more than 400 street railway companies were in business in the United States, with a total capital investment of \$150 million. Those companies operated 18,000 streetcars and owned 100,000 horses or mules. Approximately 1.2 billion passengers were riding in railcars annually. That year, the American Street Railway Association was formed in Boston as a nationwide trade organization.

The first successful cable-powered transit line began operating in San Francisco in 1873. Cable cars spread across the country more quickly than horse cars had, and by 1883, cable lines were operating in Chicago, Philadelphia, and New York. The New York line included a route across the newly built Brooklyn Bridge. Over nine million passengers rode cable cars across the bridge in the cable line's first year of operation. In 1888, the first successful electric-powered street railway line was launched in Richmond, Virginia. Powered by a small, stationary copper wire, this line quickly made cable cars—with their cumbersome systems of pulleys, wheels, and underground vaults—obsolete.

The next major development in urban transit was the elevated rail. Although elevated lines had popped up in New York throughout the second half of the nineteenth century, it was not until financier Jay Gould took them over and combined them into a single entity, the Manhat-

tan Railway, that the “els” became an important transit system. By 1893, the New York els carried 500,000 passengers a day. Steam powered elevated lines also appeared before the turn of the century in Kansas City, Missouri and Sioux City, Iowa, but these ventures were short lived. The Chicago “L” opened in 1892, and it was there that the first electric powered elevated rail was unveiled in 1895.

Ground was broken in 1900 for the nation’s first subway system, New York’s Interborough Rapid Transit (IRT). On the system’s first day of operation in October of 1904, 150,000 passengers paid five cents each to ride the new trains. The IRT quickly grew to resemble the sprawling system it is today.

The period between World War I and World War II was the golden age of the trolley. Trolleys were operating in virtually every city in the United States by 1917, covering 45,000 miles of track. By the mid-1920s, however, ridership had already begun to decline, largely due to competition from gasoline powered buses and the emerging automobile. The trolley industry was saved by the development of the PCC car, named for the Electric Railway Presidents’ Conference Committee that had spawned its design. The PCC car—lighter, more comfortable, and better performing than previous streetcars—was a major success, and revived streetcar business through the 1930s and early 1940s. After World War II, however, trolley ridership tailed off permanently.

Shift to Public Sector. The huge surge in the use of automobiles in the postwar era made it extremely difficult for transit companies to operate at a profit. In order for urban transit to survive, a shift from private to public ownership of many major systems became necessary. Under public control, transit systems were expected only to cover operating expenses, such as salaries and routine maintenance, through passenger fares. Capital expenses, such as facility construction, could be met through bond issues or taxation. New York’s subway companies and Cleveland’s transit were taken over by government agencies as early as 1940 and 1942. Chicago and Boston followed in 1947.

Rise of Buses. Another postwar trend was the shift from streetcars to buses as the main form of surface transit. By 1960, buses had an annual ridership of 6.5 billion, compared to 463 million streetcar passengers. This transition was assisted by the actions of companies like National City Lines, a transit holding company whose standard procedure was to absorb smaller street rail companies and quickly convert them into motorized bus operations. In 1964, Congress passed the Urban Mass Transit Act, creating a role for the federal government in ensuring the survival of local transit.

Ridership Decline. The decline in transit ridership eased a bit in the early 1970s, as concerns about energy consumption and environmental issues arose. One result of this modest resurgence was the development of light rail transit (LRT), which first appeared in the form of rehabilitation projects on old trolley lines. After successful LRT systems were launched in Canada in the late 1970s, LRT lines began operating in San Diego in 1981, Buffalo in 1984, and Portland, Oregon in 1986. Several other cities have built LRT systems since then.

In the United States in the mid-1990s, there were about 6,000 transit systems in operation. Those systems had active fleets containing 118,000 vehicles. Motorbuses made up the largest portion of transit vehicles, numbering 67,000. Ten thousand heavy rail cars and 4,500 commuter rail cars comprised another sizeable share. In 1995, the transit industry had operating funds of \$17.6 billion. Nearly half of this revenue was in the form of government assistance from local, state, or federal sources. Passenger fares accounted for about 40 percent of total revenue, just more than \$6 billion in 1995. Of the 8.4 billion trips taken on transit in 1994, 5.4 billion were made on buses and 2.7 were made by rail.

Despite the small rebound in the popularity of mass transit that took place in the 1970s, Americans were using it at a lower rate than ever before in the mid-1990s. Only about 5 percent of commuting was done via public transit systems, down from 9 percent in 1970. The exception to this trend was the increased use of vanpools, airport shuttles, and other smaller, nonpublic transit designed for special use.

Government Funding. Since 1974, nearly \$70 billion in federal funds have been pumped into the nation’s public transit systems. Although federal spending on local transit tailed off somewhat during the Reagan and Bush presidencies, this was offset by increases in local and state funding. In addition, the Intermodal Surface Transportation Efficiency Act of 1991 authorized \$31 billion in federal spending from 1993 through 1997.

Despite this huge outlay of money, there is little evidence to suggest that riders are choosing transit systems over their cars. In some cases, newly built rail systems are merely drawing passengers from existing bus routes. Several new systems, such as Miami’s \$1.2 billion, 21-mile rail system, are attracting fewer passengers than were projected at higher than predicted costs. In 1989, Miami’s system drew only 15 percent of its projected ridership and cost triple the forecast amount per car to run. A trolley system in Los Angeles cost \$700 million more to construct than was projected and ran slower than the bus routes it was designed to replace.

In 1998, almost 8.7 billion persons used public transit at least once, an increase of 4.6 percent from 1997.

Buses carried the largest number, approximately 5.2 billion in 1998. Heavy rail carried 2.6 billion riders, light rail had 278.8 million riders, and commuter rails carried 378.6 million. The trolley buses reported a loss, although they still carried 117.4 million passengers in 1998. All in all, 1998 was the third consecutive year that public transit ridership increased (by almost the same percent in 1997).

Light rail use increased in Portland, San Diego, Baltimore, Dallas, Denver, Boston, Los Angeles, St. Louis, and Sacramento in 1998. Philadelphia and Pittsburgh reported decreases, as did Buffalo, New York. During the same year, commuter rail systems increased their passenger numbers in Boston, Los Angeles, and North San Diego County in California. Tri-Rail suffered a 6.8 percent loss.

With an eye toward the future, public-private partnerships in the public transportation industry are increasingly common. For example, California's Route 91 express lanes in busy Orange County were converted to a fully automated toll road, complete with a toll-free "three + " lane for car-pools. The project represented a partnership between the California Department of Transportation (CALTRANS) and a consortium of private companies, including one French firm. CALTRANS saved the \$130 million construction cost, in return for a 30-year lease to the companies, to build and operate the toll road. The 10-mile, four-lane toll road opened in December 1995, but as of January 1998 was losing money. Even with \$3.20 tolls at peak hours, traffic congestion continued during rush hour, and the revenue loss was attributed to the car pool lanes.

CURRENT CONDITIONS

In 2001 public transportation received \$11.4 billion in capital from all funding sources. Of federal funds, 44 percent was designated for bus-related expenditures, 25 percent for fixed guideway modernization, 18 percent for new start transit projects, and 3 percent for planning. Operating expenses totaled \$23.5 billion in 2001: salaries, wages, and benefits, 69 percent; purchased transportation, 13 percent; fuel and supplies, 10 percent; and other expenses, 8 percent.

Just at a time when mass transit was receiving increased attention and use, the economic crunch of the early 2000s hit. The result of the sluggish economy was a cutback in revenues available for the transportation infrastructure. For example, although capital spending on rail transit is expected to hold steady at \$6.0 billion (\$2.85 billion for heavy rail, \$1.78 billion for commuter rail, and \$1.25 billion for light rail) in 2003, new projects could take a back seat to maintaining the current infrastructure.

Mass transit issues can be politically hot topics that revolve around funding allocations and how funding is spent. Ideas for the future of public transportation vary

widely with little agreement among public transit advocates, without even considering those who question the inherent value and viability of mass transit in general. Those who advocate better use of existing highway systems tout "bus rapid transit" as the inexpensive way to ease congestion. Bus rapid transit is described as bus service with rail service quality. Rail proponents argue that the only way to end congestion and its related problems is to take traffic off the road and put it on the rails. The debate between moving toward road or rail—and whether light or commuter—is so compelling that in 2003 the Port Authority of New York and New Jersey laid out \$300,000 to determine how best to replace a 5.5 mile stretch of tracks on Staten Island.

INDUSTRY LEADERS

The largest public transit system in the United States by far is New York's Metropolitan Transportation Authority (MTA), which accounts for about one-fourth of the nation's total trips. Its subway system makes 61 percent of the nation's heavy rail trips. Other large public transit systems include Chicago's Regional Transportation Authority, the Los Angeles-based Southern California Rapid Transit District, and the Washington Metropolitan Area Transit Authority.

In the private sector, the clear industry leader is New Jersey Transit Bus Operations Inc., a subsidiary of the huge New Jersey Transit Corporation. In addition to local buses, New Jersey Transit also operates intercity bus and commuter rail services. The Bus Operations subsidiary has annual revenue of \$194 million. Another large local bus line operator in the private sector is Liberty Lines Transit Inc., based in Yonkers, New York. Liberty Lines, founded in 1955, generates \$32 million in annual revenue.

WORKFORCE

There were more than 231,000 employees in the transit industry in 2001, according to the Department of Labor, Bureau of Labor Statistics. The country's inner city and transit bus drivers, totaling nearly 34,000, earned a mean annual income of \$26,740.

RESEARCH AND TECHNOLOGY

The technology of mass transit changes constantly. Many of the industry's developments have been in the area of communications. The Intelligent Mobile Data Network (IMDN) is a network of base stations and antennas scattered over a metropolitan area that can efficiently function as both a communications system and a vehicle locator. Wireless transmission systems, in conjunction with new camera technology, are also being developed for security use on rail platforms. Fare collection is another area that sees constant technological change. Many larger systems are incorporating fare

cards, which allow passengers to prepay for a variable number of trips. Some industry observers see fare cards as the first step toward the use of debit cards or a system similar to those used with automatic teller machines. In 1999, Motorola announced its contract with Nanjing, China, to provide public transit riders with custom smart cards for payments of ferry, subway, and bus fares. Motorola also services the Washington and San Francisco markets with smart cards. By 2002, Motorola will service 26 transit agencies.

As environmental concerns continue to trouble the transit industry, the search for efficient alternate fuels for buses remains an ongoing task. Sacramento has experimented with bus engines that run on natural gas, while Los Angeles is testing methanol and electric power. In Peoria, Illinois, ethanol made from corn, an abundant local resource, is being examined as a possible engine fuel for buses.

SIC 4119

LOCAL PASSENGER TRANSPORTATION, NOT ELSEWHERE CLASSIFIED

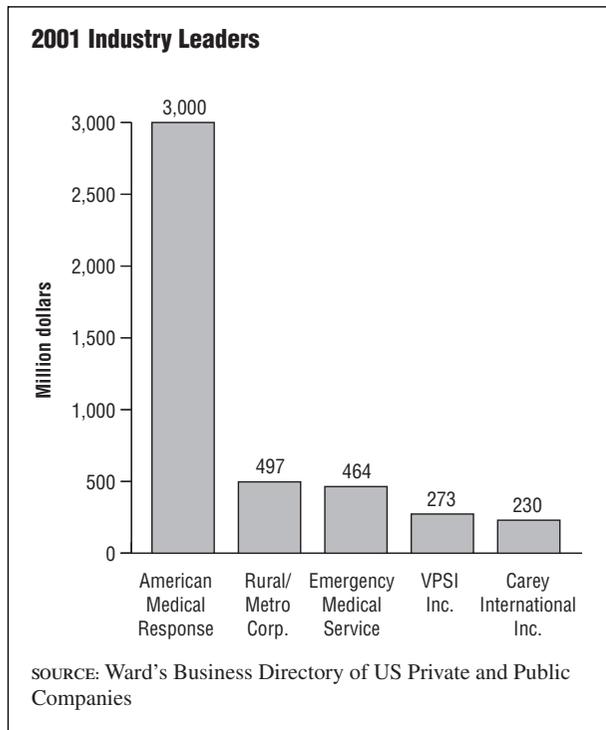

This industry classification includes establishments primarily engaged in furnishing miscellaneous passenger transportation, where such operations are principally within a municipality, contiguous municipalities, or a municipality and its suburban areas. Establishments primarily engaged in renting passenger automobiles without drivers are classified in services, Industry Group 751: Automobile Rental and Leasing, without Drivers. Establishments primarily operating ski lifts, tows, and other recreational lifts are classified as **SIC 7999: Amusement and Recreation Services, Not Elsewhere Classified**.

NAICS CODE(S)

621910 (Ambulance Service)
485410 (School and Employee Bus Industry)
487110 (Scenic and Sightseeing Transportation, Land)
485991 (Special Needs Transportation)
485999 (All Other Transit and Ground Passenger Transportation)
485320 (Limousine Service)

A diverse range of transportation modes makes up this industry classification. Among the types of companies in this group were ambulance services, limousine services (with drivers), and aerial tramways and cables cars that were not for amusement or scenic use. Sightseeing buses (non-charter), vanpool operations, and hearse rentals with drivers were also classified in this industry.

The overall industry leader in 2001 was American Medical Response of Aurora, Colorado, with \$3 billion in sales and nearly 21,000 employees. Rural/Metro Corp. of Scottsdale, Arizona, was second with \$497 million in sales and 10,500 employees. Emergency Medical Service of Maspeth, New York, had \$464 million in sales and 3,500 employees. Fourth was VPSI Inc. of Troy, Michigan, with \$273 million in sales and 300 employees. Rounding out the top five was Washington, D.C.-based Carey International Inc., with \$230 million in sales and 1,000 employees.

There were 7,915 establishments classified in this industry in the 1990s, according to *County Business Patterns*. This number decreased after the terrorist attacks of September 11, 2001 caused a general economic downturn. Many smaller companies did not survive. Almost 3,500 of them had been very small operations, with fewer than five employees. The industry employed 130,677 people, with a total annual payroll of \$2.2 billion.

Ambulance Services. The top companies in this catch-all industry were ambulance services. Collectively, ambulance services in the United States generated about \$7 billion a year in revenue. Following a wave of consolidation in the early and mid-1990s, two clear industry leaders emerged: American Medical Response (AMR), whose parent company, Laidlaw Inc. of Ontario, Canada, also merged in San Diego-based Med Trans; and Rural/Metro Corp. of Scottsdale, Arizona.

AMR operated more than 4,000 vehicles in 250 locations in 2004, serving 3.5 million patients annually. Rural/Metro was in 400 locations that year, and reported an increase to \$520.5 million in 2003 revenue.

The outlook for growth in the ambulance business was favorable, due to an aging population and health care reform measures, which resulted in patients being shifted between facilities more frequently. The industry faced increasing competition, however, for hospital and health maintenance organization contracts from public fire departments, whose personnel also were trained to respond

to medical emergencies. Nearly 60 percent of all calls to fire departments in 1995 were medical aid requests.

The Balanced Budget Act of 1997 had significant effects on the ambulance industry, tightening the criteria for Medicare reimbursement of emergency ambulance claims. By 1998, the Health Care Financing Administration had published its Medicare ambulance fee schedule and final rules for determining "medical necessity." The new rules required physician certification for non-emergency ambulance services. Most ambulance companies relied heavily on Medicare claims for business. In some states with large Medicare beneficiary populations, Medicare ambulance services could constitute as much as 60 percent of all transport revenues.

By 2002, ambulance services had to contend with increasing medical malpractice lawsuits. Unlike years ago, when ambulances were basically hospital-run vehicles, the privatization of the industry and the rising expectations for health care in general were contributing to the increase. Such lawsuits have no cap on the award amount a jury can make, and paramedics are sued under the same laws that apply to doctors. In addition, ambulance workers often have to perform their duties with the victims' families watching, a situation doctors are generally spared.

Limousine Services. Limousine services made up another significant share of the miscellaneous local passenger transportation industry. By 1999 there were more than 9,000 limousine companies in the United States, controlling a \$4.4 billion industry. However, as with many other industries, there was a general decline in limousine service companies in 2001 and 2002, following the September 11, 2001 terrorist attacks. Many smaller companies did not survive. When the economy began to rebound, the companies that had hung on saw their business increase as a result of less competition. At the close of 2001, there were 3,756 establishments employing 39,165 workers.

As the industry grew in size during the 1990s, and as the economy took a downturn during the 2000s, limousine services sought to widen their customer base by appealing to businesspeople in addition to their usual wedding and prom ridership. In particular, gains were made in the limousine industry's battle against taxicabs and shuttles for airport runs. Indeed, the cost of limousine service was not much higher than for a cab in some places. In New York and elsewhere, however, proposals to allow liveries and limousines to make on-street pickups (strongly opposed by taxicab associations) continued to be a controversial issue in the area of local passenger transportation.

Many of the companies that survived the economic downturn had an increase in international business. Clients, both corporate and private, were relying on U.S.

companies to arrange limousine travel on their behalf in other cities, both domestically and abroad. In addition, some companies were specializing in moving groups of people from place to place for corporate events. By 2002, there was a general trend toward luxury sedans, as opposed to the stretch vehicles typically thought of as limousines.

The limousine services industry was no stranger to innovation in services. In the 1990s vanpools also sprang up to fill the gaps left by ordinary forms of local transit. VPSI (formerly Van Pool Services Inc.) was founded in 1973 as an in-house ride-sharing program for Chrysler employees during the energy crunch of that year. It subsequently blossomed into a profitable company subsidiary. National Themes, Ltd. also created a niche in major cities such as New York and Chicago, transporting patrons between bars, restaurants, sports arenas, and other nightspots. Kids Kab, founded in 1991 in the Detroit area to take children to their various activities, was an immediate hit among suburban working mothers. By the mid-1990s there were more than 250 similar companies nationwide.

The largest luxury transportation companies in 2001, based on fleet size, were Carey New York with 524, Mears Transportation Group with 472, Empire International with 390, and Bell Transportation with 376.

SIC 4121

TAXICABS

This category covers establishments engaged primarily in furnishing passenger transportation by automobiles not operated on regular schedules or between fixed terminals. Taxicab fleet owners and organizations are included, regardless of whether drivers are hired or rent their cabs or are otherwise compensated. Establishments primarily engaged in furnishing passenger transportation by automobile or bus—to, from, or between airports or rail terminals—over regular routes, are classified under **SIC 4111: Local and Suburban Transit**. Taxi cab associations and similar organizations that supply maintenance and repair services to their members are classified under **SIC 4173: Bus Terminal and Service Facilities**.

NAICS CODE(S)

485310 (Taxi Service)

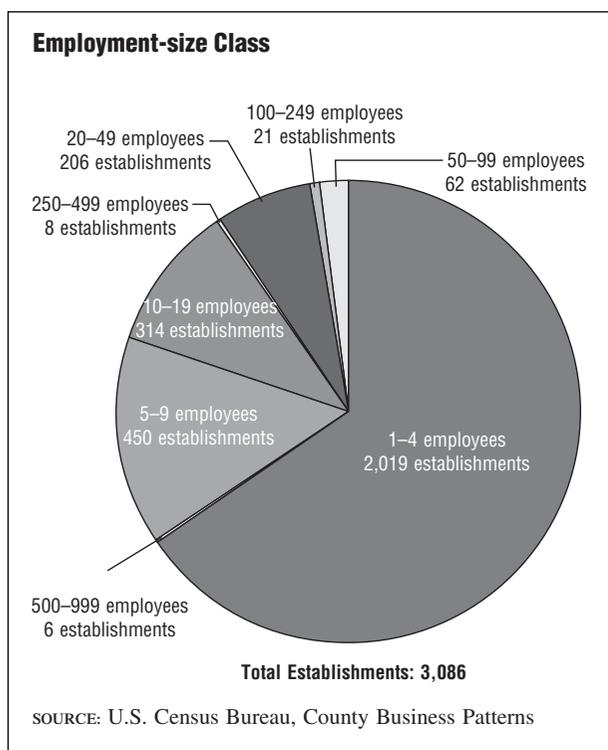

INDUSTRY SNAPSHOT

In the latter 1990s, U.S. consumers spent an estimated \$10.5 billion annually on taxis. By 2001, there were 3,086 taxi service establishments, employing a total of 30,281 workers with a payroll of \$489 million. Most of the companies were small; approximately 2,500 employed fewer than 10 workers. The majority of the drivers were either independent contractors licensed through and renting their vehicles from the taxi companies, or owner-operators affiliated with a taxi company or association. The industry continued to face competition from limousine services, executive sedans, and airport/hotel shuttle services. To compete, by 2003 taxi services were offering online bookings and vehicles equipped with televisions, as well as newer, more fuel-efficient vehicles.

ORGANIZATION AND STRUCTURE

Most taxi companies followed a similar organizational pattern. Managers—sometimes the company owners—ran the business, hired drivers, and performed other administrative duties. Dispatchers took calls and assigned cabs to passenger locations. In large companies, some dispatchers worked in two-person teams, one taking incoming calls and the other dispatching them. The position of dispatcher once represented a promotion awarded to experienced cab drivers, whose familiarity with the city best qualified them for the job. However, the increase in computer-based dispatching in the early 1990s prompted cab companies to favor computer skills over specialized knowledge of local geography when filling the dispatcher position.

Regulation of the U.S. taxi industry varied from city to city. While almost all cities had some form of licensing

requirements, larger urban areas had the strictest regulations. In New York, for example, the number of licenses or “medallions” allotted the industry remained at 11,787 from 1937 until 1996. In 1996, 133 additional medallions were auctioned at prices between \$172,000 and \$221,000. Applicants for a taxi driver’s license in New York were required to complete a 40-80 hour training course and pass an English exam, as well as a final exam. About 30 percent of applicants failed the English exam, and 33 percent failed the final exam. Boston’s regulations were similar to those of New York, with the number of available medallions frozen at 1,525 and selling for approximately \$90,000 in the 1990s.

In most cities, regulations focused on fares charged to customers, with rates assigned to designated zones of the city. Seattle and Phoenix experimented with deregulating their cab industry in 1979 and 1982, respectively. Fare limits were imposed only on trips to and from airports, to protect tourists from unscrupulous drivers. After some initial price wars, cab fares eventually stabilized in Phoenix, but Seattle re-regulated its industry in 1996, following years of declining service quality. The new regulations called for dress codes, standard per-mile fees, mandatory geography and language testing for drivers, and age limits on vehicles.

Government incentives for alternative fuels in the latter 1990s provided ample opportunity for city and county governments to convert their vehicles to energy-efficient fleets. In 1998, Ford Motor Company began

offering \$5,000 incentives to taxi operators who bought Ford’s compressed-natural-gas Crown Victoria taxi vehicles. The biggest market was New York City, where more than 105 vehicles were sold.

CURRENT CONDITIONS

With the trend toward energy efficiency, new products began to emerge. A joint venture between British, Belgian, and American companies built electric-powered taxis starting in 2000 for use in New York City. London’s Zevco (Zero Emissions Vehicle Company) was the world’s first company to launch the first fuel-cell powered taxi.

By 2002, Honda got in on the act, with natural gas-powered Civics joining fleets in Connecticut after a two year ban. By 2003, compressed natural gas was the clear winner in terms of passenger satisfaction, causing problems for cab companies that did not offer this option.

In an effort to compete with the rising popularity of other forms of transportation, taxi services in large markets began equipping their vehicles with televisions. Far more than providing entertainment for the passenger, the televisions were offering opportunities for advertising to an audience that can’t change the channel. Future plans included interactivity, allowing passengers to check show times and purchase tickets.

In 2003, *The Wall Street Journal* reported that New York City taxis may soon be the vehicles next in line for black boxes, due to their tendency to be involved in accidents.

INDUSTRY LEADERS

In 2001, Louisville Transportation Co. of Kentucky led the industry, with \$589 million in sales and 500 employees. Second was Whittlesea Blue Cab Co. of Las Vegas, with \$529 million in sales and 500 employees. Chicago-based Yellow Cab Co. was third with \$42 million in sales and 100 employees. Yellow Cab Delaware Inc. came next with \$25 million in sales, and SCSM Holdings Inc. of Stamford, Connecticut, rounded out the top five companies with \$18 million in sales.

WORKFORCE

There were 3,086 taxi service establishments in 2001, employing a total of 30,281 workers. Until the mid-1970s, drivers were usually employees of cab companies, with salaried jobs and standard benefits. However, in the late 1970s most companies began hiring drivers as independent contractors. Under this arrangement, drivers paid a flat per-day fee to the company and paid for all expenses out of their take from fares but did not receive employee benefits such as insurance. In another, similar arrangement, some drivers earned a percentage of total fares, plus tips, which averaged 15 per-

cent of a fare. Work hours varied, with full-time drivers often working as many as twelve hours a day, six days a week. Cab drivers' average salary was reported at \$20,000-\$40,000 a year in 1997.

Studies performed by the National Institute for Occupational Safety and Health in the 1990s indicated that in the U.S. workforce, cab drivers were at the greatest risk of being killed on the job. These studies reported that from 1990 to 1992, 22.7 out of every 100,000 cabbies were murdered while performing work-related duties. The national average rate of death at the workplace during this time was 0.70 per 100,000 workers. In 1998, 82 taxi drivers lost their lives on the job, roughly 60 percent from assault and violence and 40 percent from transportation accidents.

AMERICA AND THE WORLD

A self-drive taxi system, jointly developed by the French government and the car maker Renault, began testing in Paris in 1996. Under this system, drivers who registered for "smartcards" could access and drive 50 electric cars scattered around the city, then abandon the car when they reached their destination. French officials hoped this hybrid public-private form of transportation would ease traffic congestion by encouraging drivers to leave their own cars at home. New York City's 12,000-car taxicab fleet was poised for a makeover following the decision by General Motors to discontinue production of the Chevrolet Caprice, which, along with Ford Motor Company's Crown Victoria, made up the majority of the city's cabs. The mix of cars in the next generation fleet promised to strike a decidedly contemporary note with the addition of Ford Explorers and Honda Odyssey mini vans, approved for use by the Taxi and Limousine Commission (TLC) after withstanding six months of testing. The TLC also approved a number of sedans for experimental use, including the Lincoln Town Car and the Mercury Grand Marquis. In keeping with tradition, the new cabs were to be yellow.

RESEARCH AND TECHNOLOGY

In addition to the efforts to incorporate more alternative-fuel vehicles into taxi fleets, several other innovations were changing the way businesses operated. Early experiments with satellite dispatching systems—in which a satellite identified a cab's position to within 10 feet and sent computerized dispatch instructions to a terminal on the cab's dashboard—reportedly doubled ridership for some taxi companies. Satellite dispatching systems allowed more efficient assignment of cabs to passengers and offered customer service features such as a customer "call out" system, in which a computer called the customer and gives an estimated time of arrival, credit card payment systems, and computerized rate

quotation. By 2003, there were Internet companies springing up that allowed bookings to be made online.

SIC 4131

INTERCITY AND RURAL BUS TRANSPORTATION

This category includes establishments primarily engaged in furnishing bus transportation, over regular routes and on regular schedules. The transportation is principally outside a single municipality, outside one group of contiguous municipalities, and outside a single municipality and its suburban areas. Charter bus transportation services are classified in **SIC 4141: Local Bus Charter Service** and **SIC 4142: Bus Charter Service, Except Local**.

NAICS CODE(S)

485210 (Interurban and Rural Bus Lines)

INDUSTRY SNAPSHOT

Intercity and rural bus transportation appears to be a declining industry. According to the Department of

Transportation, only 15 companies were providing regular route intercity bus service, and only one carrier, Greyhound, maintained a national network in 2003, compared to 143 intercity bus companies in existence in 1960. The corresponding decrease in passenger miles was largely due to competition from private automobiles, Amtrak, and the airlines, which offered greater speed and convenience at a comparable price. The number of locations served by intercity bus lines also declined, totaling about 4,000 in 2002—fewer than half the number served in the early 1980s.

ORGANIZATION AND STRUCTURE

For years, Greyhound has dominated the intercity and rural bus transportation industry. The carrier's position was secured in 1987 when Greyhound acquired Trailways, the nation's second largest bus line. That purchase left Greyhound the only bus line in the United States with routes covering the entire country. In the early 2000s, a handful Class I bus companies (companies with average revenues of \$5.3 million over a three-year period) competed with Greyhound to provide regular route intercity bus service regionally. Greyhound accommodated about 58 percent of the industry's passengers in 1995, as compared to the next three largest carriers, which together carried only about 28 percent of intercity bus passengers.

Trade Associations. A number of trade associations served a variety of functions in the bus industry. The American Bus Association, in Washington, D.C., was founded in 1926. Of its 500 bus operator members, 75 provided intercity service on regularly scheduled routes. Another Washington, D.C. group, the National Bus Traffic Association, founded in 1933, served as a publisher of bus tariffs. The National Trailways Bus System was what remained of the Trailways system after the Greyhound merger. The system was an association of 32 independent, intercity bus companies, which coordinated schedules and promoted a unified approach to marketing and operating procedures.

BACKGROUND AND DEVELOPMENT

Intercity bus services sprang up independently in different regions across the United States in the early part of the twentieth century. Some of the earliest intercity bus lines began as extensions of urban jitney operations. Minnesota is often named as the birthplace of intercity bus transportation. The Mesaba Transportation Company, of Hibbing, Minnesota, transported miners between mining villages over regularly scheduled routes as early as 1913. Around the same time, the Pickwick Transportation Lines initiated intercity bus service in Southern California. By 1918, this company had expanded its service area to include Northern California and Oregon.

As road conditions improved, bus companies began to appear by the hundreds across the country. Over 4,000 intercity bus companies were in operation by 1926. Soon, the number of companies began to decrease as the industry consolidated. Mergers, acquisitions, and bankruptcies became commonplace, a trend that continued until the 1970s.

In December 1926, the Motor Transit Corporation, a \$10 million holding company, was organized by Eric Wickman, the founder of the early Hibbing bus operation. A few years later, the Motor Transit Corporation was restructured as the Greyhound Corporation. Greyhound acquired smaller bus companies and had routes covering most of the United States by the mid-1930s. In 1936, the National Trailways System was formed by an association of railroad-owned bus lines, including Missouri Pacific Trailways, Burlington Trailways, and Santa Fe Trailways. As the system grew through acquisitions, it evolved into the Continental Trailways System, a nationwide bus service. In 1943, the Continental Coach Company was launched. Continental, after changing its name to Transcontinental Bus System, was a nationwide line by 1953.

World War II brought about a dramatic increase in intercity bus ridership. Between 1940 and 1945, traffic grew from 10 billion to 27 billion passenger miles. After the war, the share of the intercity travel done by bus began to decline, although the number of bus travelers remained fairly steady. By 1960, only about 2.5 percent of intercity trips were made by bus, compared to a wartime peak of 10 percent.

As competition from air travel and improvements in automobiles increased, the industry's share of passengers eroded further. In the 1970s, the bus lines came under pressure from low fares offered by Amtrak. The deregulation of airlines also brought about the emergence of low-cost air operations. These events cut into the profitability of the bus lines significantly. Between 1975 and 1982, intercity bus service (measured by number of weekly bus departures) declined by nearly 5 percent a year. Greyhound lost about 30 million passengers, roughly half of its ridership, between the mid-1960s and the mid-1980s.

Greyhound spent the late 1980s and early 1990s in the throes of a drivers' strike and its consequences. The strike resulted in a number of violent confrontations and quite a bit of negative publicity for the company. Four months after the strike began, Greyhound declared bankruptcy. The company emerged from bankruptcy in 1992 under new ownership and management.

Role of Government. Federal agencies had no jurisdiction over bus companies that operated within one state. Bus lines whose routes crossed state borders fell under

the regulatory jurisdiction of the Surface Transportation Board (STB), formerly the Interstate Commerce Commission (ICC). Regulation was cut sharply, however, by the Bus Regulatory Reform Act of 1982. Following the 1982 Bus Act, entry into the industry was open, and applications for authority to operate rarely were challenged. Minimum insurance coverage and knowledge of safety regulations were the only requirements to prove a carrier's fitness to operate. Passenger carriers were required to file rate information with the STB, but these filings seldom were rejected since 1982. Only Class I companies were required to report financial statistics to the STB. Federal regulations pertaining to intercity bus drivers were somewhat stricter. Drivers had to be at least 21 years old and were required to pass a physical examination. Drivers operating vehicles designed to carry 16 or more passengers were also required to obtain a commercial driver's license from the state in which they lived. Additionally, most intercity bus companies required drivers to complete two to eight hours of classroom and behind-the-wheel training that included instruction in federal and state driving regulations and safe-driving practices.

Government Regulation. Regulation of intercity bus transportation arose during the industry's infancy. Pennsylvania became the first state to regulate the operation of passenger buses in 1914. By 1925, a majority of states had followed suit. That year, the industry's first national organization, the National Motor Bus Association, was formed. The U.S. Supreme Court determined, however, that state regulatory agencies had no jurisdiction over interstate bus lines. It was not until 10 years later, with the passage of the Motor Carrier Act of 1935, that the ICC was authorized to regulate fares, safety, routes, entry, exit, mergers, transfers of operating rights, and other service and financial matters of the interstate bus lines.

In the 1970s, Greyhound began to push for deregulation of the intercity bus industry in hopes of competing more effectively with the heavily subsidized Amtrak rail service. The ICC made entry regulations more liberal in 1977 and 1978. In 1980, the Motor Carrier Act was amended by Congress. The new version of the Act made the process of applying for operating authority easier and required quicker decisions on the applications.

The Bus Regulatory Reform Act of 1982 brought about major changes in the industry. Entry was liberalized to the point where any prospective carrier that was "fit, willing, and able" was granted authority, barring evidence that this authority was contrary to the public interest. The act also empowered the ICC for the first time to overrule state regulatory authorities on matters of intrastate rates if their rulings were harmful to interstate commerce. A 1992 report by the General Accounting

Office (GAO) suggested that the deregulation that took place in 1982 did not address the causes of the industry's decline, and a major result of the deregulation was the elimination of service to areas where there are fewer transportation alternatives, particularly rural areas and small towns.

Since deregulation in 1982, hundreds of routes in rural areas have been discontinued. Many of the areas that are no longer served are not accessible by air or rail systems, leaving residents without automobiles completely isolated. A 1992 study by the GAO recommended that the best way to address this problem was through more widespread use of a set-aside provision in the Intermodal Surface Transportation Efficiency Act of 1991. Section 18(i) of the act requires each state to set aside money to support intercity bus transportation. By 1992, 20 states had instituted such programs, which included subsidies to firms for continuing service on endangered routes, price breaks on vehicles, and financing for building and repairing terminals.

CURRENT CONDITIONS

By the beginning of the 2000s, there were between 5,000 and 8,000 intercity buses on the road. There were just 14 Class I carriers in the nation in 1999; they carried 42 million passengers in that year. Gross passenger revenues for regular-route intercity buses totaled over \$1 billion. Intercity bus service is provided to over 4,000 points, but this compares with over 16,000 points of service prior to deregulation. The industry continues to be dominated by Greyhound Lines and its subsidiaries.

INDUSTRY LEADERS

Greyhound Lines, Inc., a subsidiary of Laidlaw, Inc. since March 1999, boasted 25 million passenger boardings for 2002. Revenues that year were \$991.9 million, resulting in a net loss of \$111.6 million. The company operates a fleet of approximately 2,900 buses and employs 12,200 people nationwide.

Although Greyhound was the only bus line with a nationwide scope in 2003, several other companies had achieved solid positions in specific regions. With operating revenues of \$60 million at the beginning of 2002 from its intercity, charter, and other bus services, the 800-employee Peter Pan Bus Lines, Inc., of Springfield, Massachusetts, more than doubled its earnings from the early 1990s to become the second largest player in the intercity bus travel market. The company's growth came out of aggressive marketing efforts to increase ridership, including the addition of express services between major cities and advertisement on rock music radio stations to attract college students. In 1998, Peter Pan Bus Lines was voted the safest bus company in America by the National Safety Council.

Other prominent companies—all of which operated in the New York metropolitan area—included Connecticut Limousine; Hudson Transit Lines, Inc.; and New Jersey Transit Bus Operation, Inc.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, in 2001 the intercity and rural bus industry employed 25,640 workers. Bus drivers, which accounted for nearly 48 percent of all jobs, earned a mean annual income of \$30,510.

RESEARCH AND TECHNOLOGY

Advances in technology historically played a part in the rise and fall of the intercity bus industry. It was improvements in road conditions and the development of the interstate highway system that made a nationwide network of bus routes possible. Later, the increased availability of private automobiles and affordable air travel contributed to the bus lines' loss in ridership share.

Since fuel was a major cost in running a bus company, companies were always on the lookout for equipment that would improve fuel efficiency. Diesel engines were in regular use in buses since the 1950s, and steady advances were made in their engineering, leading to developments such as the turbocharged diesel engines introduced around 1980. In 1992, a new bus called the Neoplan Cityliner was unveiled in Colorado. Used mostly for organized tours in the early 1990s, the Cityliner featured a smoke-free diesel engine that polluted significantly less than traditional models. Bus manufacturers were also experimenting with fueling buses by way of pollution-free battery cells.

In the mid-1990s, technological innovations in intercity buses focused largely on reducing trouble-shooting and repair time. The newest motor coaches featured sophisticated systems monitoring and recording devices that allowed drivers and maintenance personnel to diagnose malfunctions in a fraction of the time previously required. Buses also were likely to sport electronic brake and steer-by-wire systems, similar to the fly-by-wire systems used in airplanes, which would offer drivers better feedback and control of the vehicle, as well as increased ease of maintenance.

SIC 4141

LOCAL BUS CHARTER SERVICE

This category includes establishments primarily engaged in furnishing local bus charter service where such operations are located principally within a single municipality, contiguous municipalities, or a municipality and its suburban areas.

NAICS CODE(S)

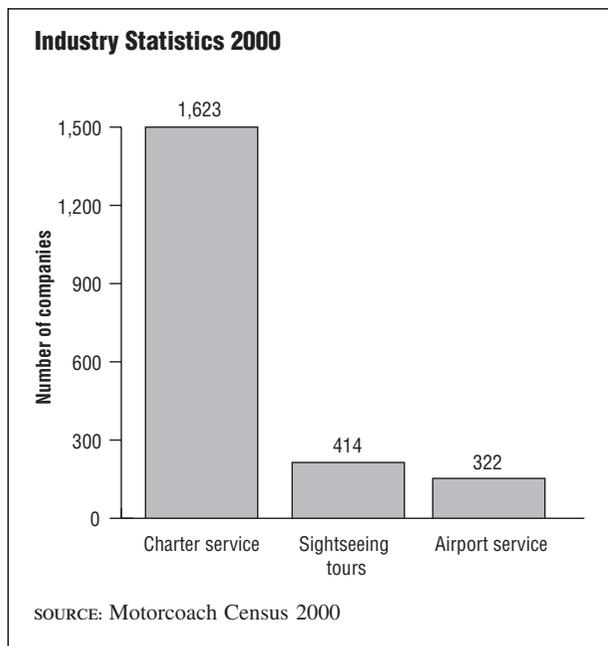

485510 (Charter Bus Industry)

The local bus charter service industry—whose primary business is in local sightseeing tours and airport shuttle service—grew rapidly after 1982. The number of employees increased from 3,781 in 1982 to 8,782 in 1997, and the number of establishments in the industry grew from 163 to 503 during those years. More than 40 percent of these establishments employed fewer than five people; fewer than nine establishments employed more than 100 people. The average salary for all employees in 1997 was \$16,094.

By 2000, the charter bus industry as a whole employed 38,380 workers, with a median hourly wage of \$10.31. In 2001, there were 1,395 establishments, with 33,406 employees and a payroll of \$660 million. The industry leader was Chesapeake Bus and Equipment Co. of Gaithersburg, Maryland, with \$228 million in revenue. Phoenix-based Super Shuttle International Inc. was second with \$75 million in revenue. Super Shuttle specialized in shared-ride door-to-door transportation.

According to the *Motorcoach Census 2000*, 1,623 companies offered charter service, 414 offered sightseeing tours, and 322 offered airport service.

Affiliates of the Dallas-based Gray Line Worldwide, a sightseeing and tour operator association with a global membership of 150 companies, provided charter services

and airport transfers across the country to accommodate local niches. Gray Line of San Francisco offered sightseeing expeditions around the city, as well as tours to nearby attractions such as the Napa Valley wine country. They also offered their tours in a number of foreign languages to accommodate the international tourist. Gray Line of Alaska maintained a fleet of more than 150 motorcoaches and offered more than a dozen different land tours of the state, some lasting as long as 10 days. In addition to its 21 daily sightseeing tours, Gray Line of Las Vegas did a high volume of business in airport shuttle service. With 65 coaches and 68 minibuses, its Airport Express service carried 2.4 million passengers to and from more than 70 hotels in the Las Vegas area in the mid-1990s. In 1996, Gray Line Worldwide announced plans to expand its membership and increase its electronic booking capacity.

According to the American Bus Association, only 8 percent of bus travel is due to sightseeing. The industry was expecting increases in passengers in 2004, as companies put more marketing effort into targeting the growing numbers of travelers.

SIC 4142

BUS CHARTER SERVICE, EXCEPT LOCAL

This category covers establishments engaged primarily in furnishing bus charter service, except local, where such operations are principally outside a single municipality, outside one group of contiguous municipalities, and outside a single municipality and its suburban areas.

NAICS CODE(S)

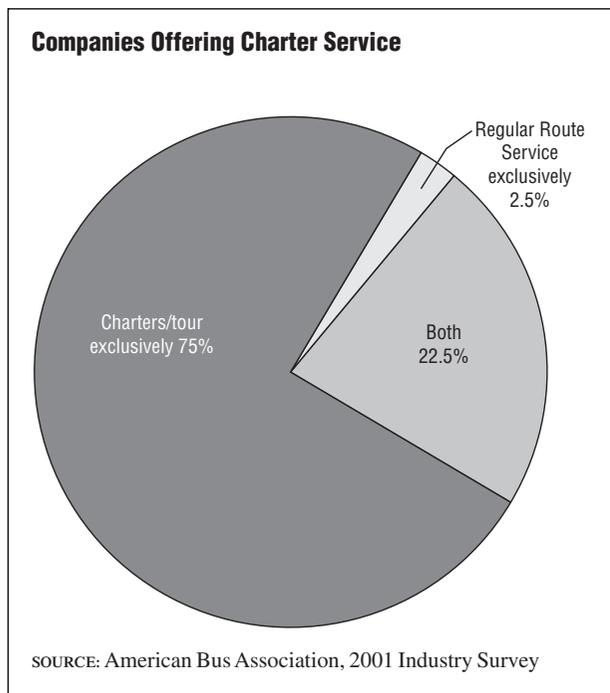

485510 (Charter Bus Industry)

INDUSTRY SNAPSHOT

According to the American Bus Association, 96 percent of bus companies provide charter service, with three-fourths providing only charter service. The *Motorcoach Census 2000* reported an industry-wide fleet of 44,000 that year. Of the 2,082 companies reporting, some 1,623 offered charter service.

The cost of a 40-foot motor coach was about \$350,000. There were more than 2,400 sold in 2002. To maintain a 40-foot charter bus, charter companies spent an average of \$12,000 per year in the early 1990s; the average operating cost for a 40-foot coach in 1996 was \$1.46 per mile, including driver's wages, fuel, and normal equipment usage. By 2001, that number had risen to \$1.90 per mile. Most charter bus companies charged customers—largely private groups paying for one-time trips—either by the mile or by the hour. The average per-mile rate in 1996 was \$2.09, which increased to \$2.51 in 2001. Drivers and mechanics were receiving higher wages as well. In 2001, 44 percent of companies paid drivers \$11 per hour or more, and 55 percent paid mechanics \$15 per hour and up.

According to American Bus Association (ABA) surveys, the top three events/activities used by groups for bus charters in 1998-1999 were theater shows, gaming/casinos, and sightseeing. On the down side, growth in

casino charter traffic has increased the number of accidents and fatalities involving interstate bus travel on a national basis.

Future growth in the charter bus industry was favorable in the latter 1990s, based on the growing population of affluent and active senior citizens. To accommodate a more comfort-conscious ridership, charter buses were increasingly incorporating ergonomic seat designs, user-friendly lavatories, and kitchen galleys for refreshments.

CURRENT CONDITIONS

In order to bring more business to the industry, marketing efforts were becoming more targeted. Specific interests were targeted in an effort to bring new travelers to charter buses. Motor Coach Industries and the ABA joined resources in 2003 to fund a commercial promoting motorcoach tourism during the 2003 Super Bowl.

Into the 2000s, insurance, salary, and marketing costs were going up, taking away from already slim profits. In addition to concerns about increasing costs coupled with decreasing revenue, charter bus companies in 2004 were concerned with the challenge of attracting willing and able drivers. The travel industry as a whole was improving in 2004, and the charter bus industry in particular was expecting increases in passengers. This was occurring as companies put more marketing effort into targeting the growing numbers of travelers. Travel to Washington, D.C. was expected to improve again as terrorist threats, the war overseas, and security issues were perceived as being less threatening. In 2003, the

Transportation Security Administration granted the industry \$20 million for motorcoach security measures.

INDUSTRY LEADERS

By 2000, the charter bus industry as a whole employed 38,380 workers, with a median hourly wage of \$10.31. In 2001, there were 1,395 establishments, with 33,406 employees and a payroll of \$660 million. Of these, some 1,873 employed fewer than 10 workers.

In 2004, two of the largest providers of charter bus service in the United States were Greyhound Lines Inc. and Coach USA Inc. Dallas-based Greyhound reported 2002 revenues of just under \$1 billion. The industry giant, Greyhound primarily offers scheduled bus services but also engages in charter bus services, shipping services, and food services. Only Greyhound had a regular intercity bus schedule nationwide, providing transportation for 25 million U.S. riders.

Coach, of Houston, Texas, reported revenues of more than \$961 million in 2003 from all operations. Formed as a company in 1995 with the intention of consolidating independent charter bus operators under a single corporation, Coach became an industry sensation after buying a dozen companies that operated more than 1,700 coaches in nine states. By 1998, Coach had spent \$500 million in acquisitions. Under a decentralized management strategy, the acquired companies maintained their individual operating practices and identity while turning finance and marketing functions over to Coach. Coach's chief executive, Richard Kristinik, said that lower financing costs, insurance premiums, and equipment costs were among the benefits of consolidation. Of Coach's 52 subsidiaries in 1998, 43 were motor coach operations. By 2004, in order to focus on the northeast and north central parts of the country, parent company Stagecoach Group was selling roughly two-thirds of Coach USA.

WORKFORCE

The charter bus industry workforce consisted primarily of owners or managers (in smaller companies, often the same person), dispatchers, maintenance workers, and drivers. The largest number of employees in the industry were drivers. Drivers transporting more than 16 passengers were required to have a commercial driver's license issued by their home state, and drivers conducting interstate travel were required to be at least 21 years of age. Many employers offered training for the requisite written and behind-the-wheel testing.

In most cases, charter bus drivers were assigned to a trip with the group chartering a bus, and remained with that group for the duration of the trip; in the case of intercity charters or tours, drivers remained with the group for several days. Drivers often were assigned on a

per-trip basis and available work hours varied greatly, with more work available in the summer months and around the winter holidays. Senior drivers were guaranteed more work than new hires, who might be “furloughed” when no work was available.

SIC 4151

SCHOOL BUSES

This category covers establishments engaged primarily in operating buses to transport pupils to and from school. School bus establishments operated by educational institutions are considered auxiliaries. This category does not include companies offering only bus manufacturing or maintenance.

NAICS CODE(S)

485410 (School and Employee Bus Industry)

There were 4,287 establishments in this industry in 2001, employing 168,940 total workers with a payroll of \$2.47 billion. About 43 percent were small organizations with fewer than 10 employees. In 2000, there were 1,960

school bus drivers earning a median hourly wage of \$8.82. As of 1999, nearly half of the nation’s children—24 million—rode buses to and from school. Sixty percent of all school buses were owned and operated by individual school districts, many maintaining as few as one or two buses; the remaining 40 percent of vehicles belonged to private companies that contracted their services with school districts.

Largely unregulated until the latter part of the twentieth century, the school bus industry began with the manufacture of vehicles owned by individual schools and districts and developed concurrently with the automobile industry. In the late 1960s, bus companies were exposed, peripherally, to the struggle for racial integration of American schools and, more directly in the early 1970s, to the automobile safety movement led by activist Ralph Nader. In the 1990s, bus companies continued to be subject to national and state safety legislation; during this time, a debate over the need for school bus seat belts was tabled, as advocates on either side of the issue failed to turn up conclusive information.

Safety issues have largely impelled innovations in the school bus industry. In August 1998, the National Highway Traffic Safety Administration (NHTSA) announced an extensive two-year research program to consider alternative methods for potentially improving federal school bus passenger crash protection requirements. Nevertheless, fatalities in school bus-related accidents continued to decline, with a 19 percent reduction in deaths from 1980 to 1990. In the 1990s, there was an average of 32 school-age children fatalities each year.

Since many fatalities occurred when buses hit riders passing through the bus driver’s blind spot, some buses were being equipped with automatic “crossing gates”

that swung out when the bus stopped, forcing children to walk 10 feet in front of the bus when crossing the street. To handle on-board safety issues, some school districts were equipping school buses with on-board video cameras as a deterrent to unruly or dangerous behavior among riders.

In 2003, the NHTSA introduced standards for a new, safer category of school bus as an alternative to the accident-prone 15-passenger van. The new category, called the “multifunction school activity bus,” would not transport children between school and home, but would be used for school activities and the like.

In the 2000s, along with concern about diesel emissions in other vehicles, there was great outcry over diesel emissions from school buses and their effect on children, prompting the Clean School Bus USA Program. In response, buses were being retrofitted to reduce emissions, or were replaced. In October of 2003, the Environmental Protection Agency (EPA) gave a \$500,000 grant to the National School Transportation Association to help subsidize the cost for some companies to comply. Later that same month, a \$5 million dollar grant was given to 17 school districts for compliance. As of 2004, the proposed federal budget included a \$60 million increase to the program for 2005.

Despite all the concerns regarding school bus safety, the National Association of State Directors of Pupil Transportation Services pointed out in 2003 that children were far more likely to be injured when they did not ride school buses than when they did.

In a more controversial development, some school districts were choosing to raise money by allowing advertisements to be painted on the sides of their school buses. New York City hoped to bring in \$53 million over nine years from contracts signed with commercial advertisers in 1996.

Because most school bus providers were school districts, management often was handled from within the district. Although there were jobs in management and maintenance, drivers were by far the largest employee category. In general, drivers worked an average of 20 hours or less per week during the school year. School bus drivers were required to get a commercial driver’s license from their state of residence, and in some cases were subject to a background investigation for criminal misconduct or a history of mental illness. Drivers generally received 1-4 weeks of driving instruction in addition to classroom training on state and local laws, safe driving practices, and first aid and emergency evacuation procedures. Aside from driving, they were responsible for checking their vehicles for safety and reliable operation, as well as issuing reports on fuel consumption, number of students and trips, and hours worked.

The industry leader in 2001 was Atlantic Express Transportation Group Inc. of Staten Island, New York. The company posted sales of \$353 million and had 7,500 employees. The following year, sales had jumped to \$427 million, and there were 8,500 employees. In 2004 the company had 6,500 buses in its fleet. In second place was Laidlaw Transit Services Inc. of Shawnee Mission, Kansas, with 2001 sales of \$212 million and 9,000 employees.

SIC 4173

TERMINAL AND SERVICE FACILITIES FOR MOTOR VEHICLE PASSENGER TRANSPORTATION

This industry includes establishments primarily engaged in the operation of motor vehicle passenger terminals and of maintenance and service facilities, not operated by companies that also furnish motor vehicle passenger transportation. Establishments that are owned by motor vehicle passenger transportation companies and are primarily engaged in operating terminals for use of such vehicles are classified in the same industry as establishments providing motor vehicle transportation. Separate maintenance and service facilities operated by companies furnishing motor vehicle passenger transportation are treated as auxiliaries. Establishments that provide motor vehicle maintenance or service for the general public are classified in various automotive repair industries, such as **SIC 7533: Automotive Exhaust System Repair Shops** and **SIC 7538: General Automotive Repair Shops**.

NAICS CODE(S)

488490 (Other Support Activities for Road Transportation)

In 2001, there were 1,031 establishments in the industry employing a total of 17,541 people. Combined, their annual payroll totaled \$452.5 million. Most of the firms were quite small, with only 42 percent employing more than 9 workers.

The majority of motor vehicle passenger terminals and maintenance facilities in the United States, whether their mode of transportation was bus, train, or some other method, were owned and operated by companies that were also directly involved in the transport of passengers. As a result, the terminal and service facility operations of those companies—from Greyhound to Amtrak—were treated as part of their overall transportation services and were classified with those services, rather than in this industrial classification. In 2004 Greyhound operated 2,400 buses and 112 terminals alone. In larger urban areas, a government-run, regional transportation authority usually maintained terminals.

The independent facilities in this industry suffered as a result of waning intercity bus ridership during the final decades of the century. In the 1920s, more than 4,000 intercity bus companies operated in the United States, and by the mid-1940s the bus transport industry registered 27 billion passenger miles annually. The popularity of this mode of transportation in turn spurred the success of terminal and service facilities of the time. Due to the increasing availability of personal-use vehicles, however, more and more Americans traveled between cities in their own vehicles. By 1998, nearly 80 percent of long distance trips were made by personal vehicle. According to the U.S. Department of Transportation’s *Transportation Statistics 1998 Annual Report*, the total intercity bus ridership accounted for only 2.1 percent of total highway miles traveled. But intercity buses were recognized as the safest form of transportation, and Greyhound reported that in 2003 it traveled 9 billion passenger miles.

The trend among publicly run regional transportation facilities moved toward intermodal transportation terminals that accommodated inter-city bus lines, passenger railroads, transit rail and buses, commuter rail, and subways all under one roof. In the mid-1990s, Boston; Newark, New Jersey; San Francisco; and Atlanta were all in various stages of designing intermodal facilities that made passenger travel more convenient. Acting as landlords, the transportation authorities leased space to their terminal tenants. In Boston’s new intermodal South Station, for example, prime bus bays were leasing for about \$35,000 a year in 1995.

Greyhound, in particular, was hoping to change the image of bus riding. In the 2000s, the company reported customer facts regarding levels of income and education, among other items, in an effort to de-stigmatize the industry and the image of what was generally perceived as its typical clientele.

Another trend in ground transportation terminals focused on establishing a more customer-friendly ambiance and providing both passengers and city residents with a greater diversity of services. By the late 1990s, the Port Authority of New York and New Jersey had transformed the Port Authority Bus Terminal in New York City, long associated with grime and criminal activity, into a shopping and entertainment center. Through aggressive marketing, the Port Authority attracted a host of upscale retailers, including drug stores, coffee and pastry vendors, and florists. It also installed a new 30-lane bowling alley, patronized primarily by corporate leagues and local families. In 1999, the George Washington Bridge Bus Station followed suit, upgrading its facilities with the same type of retailers and services.

Assurance of safety was a big concern for the industry, especially after the terrorist attacks of September 11, 2001, and the attack on a bus driver in Tennessee the

following moth. That year, Greyhound established security measures including metal detectors, searches, and frisking of passengers. In 2003, the city of Riverside, California, had uniformed officers on patrol in and around the bus station, and many bus stations across the country were doing the same.

SIC 4212

LOCAL TRUCKING WITHOUT STORAGE

This category covers establishments primarily engaged in furnishing trucking or transfer services without storage for freight generally weighing more than 100 pounds, in a single municipality, contiguous municipalities, or a municipality and its suburban areas. Establishments primarily engaged in furnishing local courier services for letters, parcels, and packages generally weighing less than 100 pounds are classified in **SIC 4215: Courier Services Except Air**; those engaged in collecting and disposing of refuse by processing and destruction of materials are classified in **SIC 4953: Refuse Systems**. Those establishments involved in removing overburden from mines or quarries are classified in various mining industries, while establishments such as construction contractors engaged in hauling dirt and rock as part of their construction activity are classified in various construction industries.

484110 (General Freight Trucking, Local)

484210 (Used Household and Office Goods Moving)

2001 Industry Leaders by Revenue

SOURCE: Ward's Business Directory of US Private and Public Companies

484220 (Specialized Freight (except Used Goods) Trucking, Local)

Trucks represent virtually the sole means of transporting freight in intracity and local markets—operating zones of 50 miles or less. Such diverse products as bakery goods, dry cleaning, auto products, fuel for service station pumps, and vending machine supplies are only a few of the enormous variety of goods delivered by local trucking firms.

Although over-the-road intercity truckers are the most visible segment of the industry as a whole, the trucking industry itself grew out of local, short-haul trucking in the early years of the twentieth century, when automobiles began to be converted into trucks to haul the freight traditionally transported by horse-drawn wagons.

The industry is divided into two types of establishments: private carriers who own or lease trucks to transport their products to customers, and for-hire carriers who contract with shippers to transport their goods for them. All companies in this industry are divided roughly in half between corporations and individual proprietorships or partnerships.

In 2001, the overall industry leader was Savage Industries Inc. of Salt Lake City, with revenues of \$12.9 billion and 1,000 employees. Savage handled a diverse

array of products, such as coal, chemicals, combustion byproducts, petroleum coke, and sulfur. In second place was Milwaukee-based Scherman Trucking Co., with \$8.4 billion in revenue and 700 employees. Next was GE Fleet Services of Eden Prairie, Minnesota, with \$4.5 billion in revenue and 1,700 employees. Rounding out the top five were Schneider National Inc. of Green Bay, Wisconsin, with more than \$3.0 billion in revenue and 16,000 employees, and J.B. Hunt Transport Services Inc. of Lowell, Arkansas, with \$2.3 billion in revenue and 16,300 employees.

For the industry segment involving mail, package, and freight delivery, the 2002 leader was United Parcel Service Inc., with revenues of \$31.3 billion. In 2003, the company reported sales of \$33.5 billion and 355,000 employees. Named the "World's Most Admired" company in the industry in 2004 for the sixth year in a row, UPS handled approximately 13 million packages each day. UPS joined the Environmental Protection Agency in 2004 in working to reduce harmful gas emissions from delivery vehicles. In second place was FedEx Corp., with \$20.6 billion in revenue.

For the industry segment involving trucking and truck leasing, Ryder System Inc. was the 2002 industry leader, with \$4.8 billion in revenue. With a fleet of 135,000, Ryder employed 26,700 workers in 2003. Other leaders in this segment were CNF Inc., Yellow Corp., and Roadway Express Inc.

The industry's largest segment, in terms of number of establishments, is comprised of local delivery firms transporting packages weighing more than 100 pounds. Almost one-third of these firms reported annual revenues of less than \$1 million. Although major intercity ground transport firms and air cargo companies also operated local large-package delivery establishments, by far the most common local large-package delivery establishments were smaller firms with names like Susie's Speedy Service or Lickety Split Couriers. The package delivery segment also included messenger services, grocery and food product transporters, newspaper distribution truckers, legal and medical delivery services, and the large-package delivery departments of taxicab companies.

Another important segment of the local non-storage trucking industry is comprised of light haulage and cartage truckers including warehouse goods transporters, freight forwarders (see **SIC 4731: Arrangement of Transportation of Freight and Cargo**), and distributors and goods transfer services. The industry also includes significant numbers of dump truck hauling firms, local log and timber transporters, bulk mail contract carriers, and "star route" carriers, which transport goods between transportation modes, such as from a port to a railhead.

In the late 1990s, a smaller segment of the local non-storage trucking industry consisted of highly specialized carriers such as hazardous materials transporters, like Enviroguard Technologies and Omega Environmental Control; local animal, livestock, and horse transporters, such as Ft. Worth Cattle Express and Hickory Hill Horse Transport; and local pet transporters, such as Pet' in on the Ritz and Happy Tails to You. The industry also included a variety of local household goods movers who did not offer storage services, ranging from the local divisions of large intercity movers like Bekins, to smaller firms like Starving Scholars Movers; Shleppers Movers; and Load, Lock, and Roll Moving.

By the late 1990s, many local non-storage-trucking firms were unionized. Overall, the local general freight trucking industry reported nearly \$15.0 billion in revenue in 2001, down from about \$15.2 billion in 2000. The local specialized freight trucking industry reported revenues of \$25.4 billion in 2001, a slight gain over \$25.3 billion in 2000. According to the *Occupational Outlook Handbook*, some drivers in this industry also have sales duties. There were 431,000 employed in this capacity in 2002. The overall employment expectation was for steady growth into 2012.

In 2004, the Transportation Security Administration was looking into the viability of requiring locks on all truck cargo areas. Companies were concerned about the cost of such a standard, and trucking companies that make frequent stops, such as UPS, were concerned about delivery delays such locks would create.

SIC 4213

TRUCKING EXCEPT LOCAL

This category covers establishments primarily engaged in furnishing “over-the-road” trucking services or storage services, including household goods either as common carriers or under special or individual contracts or agreements, for freight generally weighing more than 100 pounds. Such operations are principally outside a single municipality, outside one group of contiguous municipalities, or outside a single municipality and its suburban areas. Establishments primarily engaged in furnishing air courier services for individually addressed letters, parcels, and packages generally weighing less than 100 pounds are classified in **SIC 4513: Air Courier Services** and other courier services for individually addressed letters, parcels, and packages generally weighing less than 100 pounds are classified in **SIC 4215: Courier Services Except Air**.

NAICS CODE(S)

- 484121 (General Freight Trucking, Long-Distance, Truckload)
- 484122 (General Freight Trucking, Long-Distance, Less than Truckload)
- 484210 (Used Household and Office Goods Moving)
- 484230 (Specialized Freight (except Used Goods) Trucking, Long-Distance)

INDUSTRY SNAPSHOT

At the beginning of the twenty-first century, there were approximately 15.5 million trucks on U.S. roads, of which 1.9 million were tractor trailers. According to the Census Bureau’s *Statistical Abstract of the United States*, there were over 110,400 trucking establishments in the United States. Of that total, 55,800 firms were general freight trucking, and 54,600 were specialized freight trucking. Estimated annual revenue for the truck transportation industry in 2000 was \$171.7 billion, with \$109.3 billion generated by generalized freight transport and \$62.3 billion generated by specialized deliveries.

Highway miles traveled by trucks totaled 68.7 billion miles by fully or partially loaded trucks and an additional 17.9 billion miles by empty trucks.

A lack of demand during the early 2000s caused by a slowdown in consumer spending, combined with rising fuel costs and insurance premiums, led trucking companies to tighten their belts, suspend orders for new equipment, and pushed some into mergers and others into bankruptcy. Consolidated Freight, the nation’s third largest less-than-truckload (LTL) hauler, closed its doors abruptly in September 2002, leaving 15,000 workers suddenly unemployed and a gap in the LTL market. For those that survived the first years of the 2000s, better times are expected, if not immediately, then at least eventually. The trucking industry will be one of the first industries to respond to an upturn in the economy as manufacturers begin increasing shipments in tandem with heightened consumer spending.

ORGANIZATION AND STRUCTURE

The non-local trucking industry is divided into several segments that are based on the size of freight shipments (truckload, less-than-truckload), the type of goods hauled (household goods, general freight), the size of the trucker’s market (regional, national), and the nature of the availability of the trucker’s services to shippers (common, contract, or private carriage). Thus, an industry firm can be categorized as a regional contract carrier who hauls less-than-truckload shipments of general freight or as a national common carrier who hauls truckload shipments of bulk goods, and so on. National carriers have the equipment, facilities, and operating authority to transport freight cross-country while regional carriers primarily serve smaller multistate geographical areas such as the southern states or the West Coast. Long-haul transport is defined as shipments of 200 to 1,000 miles or more, and short-haul transport refers to shipments of 50 to 700 miles, depending on the carrier and other variables. “Off-the-road” transport refers to primarily agricultural and construction-related trucking involving minimal use of public roads.

Less-than-Truckload. LTL carriers haul shipments of 10,000 pounds or less in combined lots from more than one shipper. Although modern trucks can carry loads of 40,000 pounds or more, a “truck load” has traditionally been defined as 10,000 pounds. LTL carriers, then, are distinguished from truckload (TL) carriers not by the weight of individual trucks but by the number of individual shipments that comprise the truck’s load. Unlike TL shipments, which typically involve the direct hauling of one shipper’s freight from origin to destination, LTL shipments usually involve five phases: pick-up, sorting at a distribution terminal or transfer hub, line haul (the main, and longest, leg of the shipment), sorting at a

destination facility, and final delivery. The LTL market is divided evenly between general freight carriers and carriers of small packages (shipments weighing less than 500 pounds). The deregulation of the trucking industry in 1980 resulted in a flood of new TL firms, but the prohibitive costs of entry limited the number of new carriers in the LTL segment. A national LTL carrier must be able to finance a large sales force, expensive technology, and approximately 500 distribution terminals.

Shorter routes and increased use of information technology had the greatest impact on the for-hire trucking segment of the industry. Shippers continued to streamline product manufacturing cycles and required just-in-time delivery schedules. This, in turn, placed greater demand for shorter, more reliable truck supply routes. For-hire trucking firms were also faced with growing competition from doublestack rail. It forced many of them to surrender a number of long-haul routes to the railroads. Acknowledging the trend, a growing number of trucker-railroad alliances were formed. Under these partnerships, truckers handled pick-up and delivery.

Truckload. TL carriers haul shipments of 10,000 pounds or more from origin to destination. In 1992, roughly one-quarter of the non-local trucking industry's general freight tonnage was hauled by about 40,000 direct origin-to-destination TL carriers. With an onslaught of mergers, in 1995 there were some 20,000 truckload providers in the country. The TL segment hauls about 80 percent of all intercity freight and includes for-hire and private carriers. Because TL firms do not need to maintain intermediate freight consolidation facilities, the TL segment has historically been characterized by comparatively low start-up costs. When deregulation removed restrictions on new businesses entering the trucking industry, the TL segment experienced fierce competition among a large number of new, poorly capitalized firms. About two-thirds of the trucking industry consisted of such new, often high-debt, low-income firms. The largest TL carriers had low profit margins, market shares of only 1 percent to 3 percent, and revenues that ranged between \$30 million and \$40 million (compared with the several billion dollar revenues of the largest LTL carriers).

Common Carriers. Common carriers are "for-hire" public truckers whose operating authority is conditioned on the availability of their services to any shipper who buys them. Historically, common carriers have been categorized according to the cargo they carry and the routes they cover: "regular" (or specific, limited routes) and "irregular" (unrestricted routes).

Contract Carriers. Contract carriers provide trucks, equipment, and services (such as fleet maintenance or customer billing) on an exclusive, guaranteed basis for

shipping customers who prefer the convenience of leasing trucks to owning them. As dedicated contract carriers, truck leasing firms (such as Ryder Systems) may lease drivers in addition to trucks. Such firms may also provide fuel, safety training, insurance, maintenance and other services to their customers. Contract carriers are often common carriers with an additional operating authority that allows them to contract out their services and have historically transported TL shipments. The growth of just-in-time inventory management techniques, however, has created a niche for contract carriers to haul lighter LTL "time-sensitive" parts or materials from warehouse to plant for primarily large industrial firms.

For-hire. There were approximately 48,000 for-hire carriers in the 1990s. These carriers offer their services either impartially to all shippers (common carrier authority) or exclusively for specific shippers (contract carrier authority). In 1993, distribution of goods by the non-local for-hire trucking segment represented nearly 40 percent of the total industry. By 1994, that percentage had increased to 42.5 percent. Additionally, 60 percent of the freight hauled by for-hire truckers was categorized as general freight, and 25 percent of that freight tonnage was hauled by for-hire truckers and consisted of direct origin-to-destination TL shipments.

Private Carriers. The private carriage market consists primarily of manufacturers, builders, retailers, or other firms (such as Sears Roebuck and Wal-Mart Services) who own, lease, or control truck fleets for the exclusive transport of their own goods or products. Many older private trucking fleets were created as alternatives to the inflated shipping costs charged by truckers in the industry's preregulated, heavily unionized years. Private fleets were maintained by 33 percent of manufacturing firms, 55 percent of food processing companies, 65 percent of the wood and lumber industry, and 75 percent of the construction materials industry. Private carriage allows shippers to maintain greater control over scheduling and freight handling and to customize service for specialized equipment or products.

Types of Freight. Although the trucking industry hauled 55 percent of total U.S. freight tonnage in 1994, that tonnage represented nearly 75 percent of the total dollar value of U.S. freight, reflecting the dominance of the trucking industry in the transportation of high-value goods and commodities.

Traditionally, the types of freight truckers are authorized to transport have been classified in three ways: "specific" commodities (in which a trucker is authorized to carry only certain, specified goods); "specialized" commodities (in which the commodities truckers are authorized to carry are classified in broader but still limited terms, for example, "iron or steel articles"); and "gen-

eral” commodities (which includes all goods except “household goods, heavy and bulky articles, new automobiles, dangerous or explosive articles, livestock, articles of unusual value and articles injurious or contaminating to other commodities”). More narrowly classified, non-local trucking freight can be further divided into general freight or packaged merchandise; agricultural goods; hazardous materials; and miscellaneous goods. In the early 1990s, 70 percent of all steel, sheet metal, wire pipes, rods, semifinished metal products, and lumber and wood products were shipped by truck, as well as nearly 85 percent of all food, furniture, rubber products, fixtures, appliances, and plastics goods. The non-local trucking industry also hauls bulk commodities, automobiles, glass products, industrial water, heavy machinery, refrigerated liquids and solids, liquid petroleum products, building materials, synthetic fuels, and cargo requiring flatbed or specialized trailer transport.

Household Moving. The trucking industry includes 115,000 (local and non-local) household goods movers such as North American Van Lines, Mayflower Group, and Allied Van Lines. In the 1980s and 1990s, many household goods movers began to break out of the static, seasonal residential moving market by providing warehousing, logistics, LTL, and even intermodal service. In 1994 the household goods industry accounted for 4.6 percent of the industry’s distribution and 7.8 percent of its revenues.

Competitiveness. Industry firms distinguish themselves from their competitors through financial strength, quality of sales force, shipment tracking technology, breadth of route coverage, efficient claim settlement, delivery performance, proper billing, size and quality of fleet, insurance coverage, and superior safety records. Larger national carriers can also provide the benefits of economies of scale including lower equipment, advertising, and insurance costs as well as sophisticated management techniques, more efficient administrative procedures, and extensive financial resources. Many of the large national carriers have also entered into logistics services, whereby they offer customers the ability to track their shipments as they travel from point of departure to destination.

Rate Bureaus. Trucker’s rates are determined by nine regional rate bureaus that meet on a regular basis to determine rate increases for the carriers in their region based on those firms’ revenue needs. Rate bureaus also provide legal services, disseminate financial reports and market information, categorize shipments, and provide smaller carriers with rating software. Deregulation permitted carriers to publish rates independently of the Interstate Commerce Commission (ICC), and as a result the majority of large carriers withdrew from the rate bureaus between 1991 and 1992.

Rate bureaus continued to play a role in the non-local trucking industry, however, because international and intrastate rates could not be published independently and smaller carriers’ budgets prevented them from performing the kinds of services provided by the bureaus. In the early 1990s, 25 to 30 percent of all general freight was transported under rates published by rate bureaus. Historically, two or more general rate hikes (of between 3.5 percent and 4.8 percent in 1992, for example) are implemented per year, but truckers’ discounts (often ranging between 30 and 50 percent) reduce the de facto rates charged to shippers. Before industry deregulation in 1980, the ICC monitored rates more closely. However, because deregulation brought free market forces into play, new rates that did not reflect economic realities tended to regulate themselves down to natural levels by way of rollbacks and discounts.

Intermodal. From a manufacturer’s perspective, the biggest advancement in trucking industry came when truckers began entering into alliances with railroads in 1990. Among them were J.B. Hunt Transport Services Inc. and Schneider National, which formed alliances with Conrail, Norfolk Southern, Southern Pacific, Union Pacific, and Burlington Northern. Such alliances offered manufacturers the speed and flexibility of trucks and the low cost of rail service. As a result, trucking companies began to use equipment that accommodated intermodal containers rather than tractor trailers so that containerized cargo could be easily moved between both transportation modes. In intermodal arrangements, truckers team with rail or maritime freight carriers to haul goods in generic dual-use containers.

The trucker supplies the shorter origin-to-railhead and railhead-to-destination portions of the transport and splits the revenue from the haul with the railroad according to an agreed-upon formula. The percentage of general freight truckers’ vehicle-miles transported using intermodal rose from 1 percent in 1970 to as high as 15 percent for some TL carriers in 1991.

The advantages of container freighting—decreased theft, lower transport and handling damages, better driver retention through assignment of long hauls to railroads, and new markets for trucking companies—were virtually doubled with the introduction of “double stack” intermodal transport in 1984. In double stack arrangements, containers are “piggybacked” on top of each other on a rail car to increase hauling capacity.

BACKGROUND AND DEVELOPMENT

The invention of the combustion engine and the automobile in the nineteenth century and the development of the first public highways mark the origins of the modern trucking industry. The first transcontinental transport of freight by truck took place in 1912, and within five

years the U.S. Army's request for a vehicle capable of hauling troops and war materials led to the creation of a fleet of trucks and specially trained drivers that formed the core of a new civilian trucking industry after World War I. While the industry began to establish itself as a serious competitor to the railroads, the Federal Highway Act of 1921 laid the groundwork for a national highway system that by the early 1990s stretched 45,000 miles.

Several factors contributed to the rise of the trucking industry in the following half century: a shift of population and industry away from cities and railheads to suburban locations accessible only by truck; a continuing federal mandate for a network of national highways; the inherently superior cost efficiencies of trucks relative to railroads with respect to loading facilities and shipment packing and handling; and the greater flexibility of trucks in providing specialized routes and delivery schedules.

Regulation. Faced with increasing competition from the trucking industry, the rail industry pushed for legislation that resulted in The Motor Carrier Act (MCA) of 1935, which gave the Interstate Commerce Commission broad powers to approve acquisitions and mergers; classify commodities that are covered by and exempt from regulation; and govern the routes, services, and rates charged by the trucking industry. The 17,000 truckers in the industry during that period were granted perpetual "grandfather" operating authority, while potential new entrants had to meet restrictive requirements regarding the "public convenience and necessity" of proposed services. The MCA also guaranteed all communities route service regardless of the cost of such service to the trucking industry.

Over the years, federal regulation emerged as an artificial structure for maintaining wages and profits above natural market levels. Under ICC protection the trucking industry's share of total national intercity freight ton-miles (a measure of freight traffic expressed as one ton multiplied by one mile) grew from 9.7 percent to 22 percent between 1939 and 1974, and its share of the dollar value of U.S. freight began to surpass the railroads for the first time.

Deregulation. Although deregulation of the trucking industry had been contemplated as early as the Truman administration, it was not until the late 1970s that significant reform of the industry began to appear possible. When it passed, the Motor Carrier Act of 1980 radically altered the non-local trucking industry by eliminating ICC control over companies' abilities to enter the industry, determine their rates and routes, and enlarge their operations through acquisition, merger, or route extension.

The most immediate impact of the MCA of 1980 was seen in the number of failures of poorly capitalized new firms and noncompetitive existing firms, and the influx of

new carriers in the TL segment where start-up costs were less prohibitive. The number of trucking business failures jumped from about 400 in 1980 to over 1,561 in 1986; a total of 11,000 failures were recorded between 1980 and 1989. However, 19,000 new firms entered the industry between 1980 and 1982 alone, and the number of for-hire carriers with ICC-granted operating authority grew from less than 20,000 in 1980 to almost 50,000 in 1992.

Rate Undercharging. Since deregulation, industry firms began resorting to broad discounting programs to provide customers with rates more attractive than published tariffs. In the early 1990s, bankrupt truckers began suing brokers and their shipping customers for the difference (estimated at more than \$2 billion) between these unfiled discount rates and official published rates. In 1990, the U.S. Supreme Court ruled that shippers were obliged to pay the difference between filed tariff rates and rates negotiated with defunct truckers. Two years later, the ICC eliminated all regulations covering motor carrier contracts, making binding agreements between shippers and truckers easier to enforce and thus reducing the future likelihood of undercharge disputes.

Intermodal. Although some rail hauling of empty and loaded truck trailers existed in the 1950s and truckers subsequently began buying "piggyback" services from railroads, it was not until 1989 that the trucking and rail industries formally recognized the importance of intermodal transport with the signing of the first major intermodal agreement between a trucking firm (J.B. Hunt Transport) and a competing rail carrier (Atchison, Topeka and Santa Fe Railway). Between 1970 and 1991 alone, the percentage of vehicle-miles transported using intermodal by some TL carriers rose from 1 percent to 15 percent. In 1991, the Intermodal Surface Transportation Efficiency Act (ISTEA) was adopted, with the goal of reducing the amount of paperwork required by forcing states to adopt uniform measures, such as making fuel tax payments to a single state.

While the long-distance LTL segment experienced decreased revenues, regional LTL carriers experienced double digit growth by encroaching on the overnight delivery market once monopolized by small-package ground couriers, which are covered in **SIC 4215: Courier Services Except Air**. This trend was fueled by the widespread adoption of so-called "zero-inventory" production techniques by U.S. manufacturers, which entailed the creation of distribution centers or parts storage facilities within a delivery zone of two days or less in traveling distance from manufacturers' sites. The growing emphasis on regional markets was also enhanced by the industry's need to retain drivers by offering them shorter hauls, the rail industry's increasing competitiveness in long-distance freight, and growing emphasis by shippers on on-time delivery guarantees.

Legislation. Congress passed the International Registration Plan and International Fuel Tax Agreement, taking effect in 1996 and 1998, respectively, to allow truckers to avoid repetitive state-by-state vehicle registration requirements and fuel tax payments. The Clinton administration's gasoline and diesel fuel tax ratified in 1993 added 4.3 cents to per-gallon fuel costs, raising industry operating expenses by an estimated \$3 billion annually.

Additionally, several federal programs continued to affect the trucking industry's response to safety concerns. The Motor Carrier Safety Assistance Program, for example, gave the Federal Office of Motor Carrier Safety and relevant state agencies greater latitude in carrying out annual vehicle safety inspections. The resulting \$6,000 to \$9,000 per truck spent annually by the industry on maintenance and repair was expected to be offset by lower insurance premiums and cost savings derived from fleets maintained in optimal operating condition.

CURRENT CONDITIONS

During the early 2000s, trucking firms around the nation were negatively affected by lower freight demand—a result of a sluggish economy—as well as high fuel costs and increasing insurance costs. Freight levels fell an estimated 5 to 15 percent in 2001 and remained flat throughout 2002. Diesel fuel hit a two-year high in 2003, running \$1.542 a gallon in February 2003, while insurance rates increased as much as 15 percent. High driver turnover rates, which can run in excess of 100 percent annually, and driver shortages are also a consistent problem in the industry. The biggest hauler to stumble was Consolidated Freight, a long-standing leader in the industry, filing for bankruptcy in September 2002. Many other smaller companies also closed their doors or sold out to bigger firms.

Despite some tough years early in the decade, trucks continue to be a staple of the American economy. Trucks carry over two-thirds of all freight tonnage moved in the United States. For those who survived the downturn in the industry, there are positive signs for the future. For example, capacity has shrunk as weaker companies have been pushed from the playing field, leaving room for possible modest rate hikes as demand will pressure availability once the economy rebounds. Also, the decrease in trucks on the road has provided at least a temporary relief from the nagging problem of driver shortages. Some companies have taken the opportunity to restructure their driver compensation packages to save money. In December 2002, Jim Mele noted in *Fleet Owner*: "It's entirely possible such optimism is premature, but I think the fundamentals for trucking's recovery are all in place now, and whether it takes one month or six, you're going to reap the rewards of sticking to business when the times got tough."

INDUSTRY LEADERS

Two firms dominate the national LTL general freight market. Yellow Freight and Roadway Express, Inc. Consolidated Freight was the nation's third largest LTL hauler until closing its doors in 2002. Although no national TL carrier claimed a monopoly of the TL market, several firms, including Schneider National, J.B. Hunt Transport, and Werner Enterprises, Inc. have historically led that industry segment. The contract carrier/truck leasing sector is dominated by Ryder Systems, Inc., Penske Truck Leasing, and Rollins Truck Leasing Corp. Historical leaders in the non-local household goods moving segment include North American Van Lines, Mayflower Group, and United Van Lines.

WORKFORCE

According to the U.S. Department of Labor, Bureau of Labor Statistics, the trucking industry employed nearly 1.6 million people in 2001. Of that total, 765,000, or 48 percent, were drivers of heavy trucks or tractor trailers. Drivers' annual mean income was \$35,580. Truck driving is consistently ranked as one of the most hazardous jobs in the United States, due to highway crashes, loading/unloading injuries, and crimes against drivers. Long-haul drivers spend extended periods away from home, leading to a higher-than-average divorce rate among drivers. Finding, training, and retaining qualified drivers is one of the biggest challenges in the industry.

Fewer than 60 percent of new truck drivers lasted longer than four weeks on the job, and driver turnover rates (which rose as high as 100 percent for some firms) were considered to be among the most critical issues facing the industry. The president of American Trucking Association, Walter McCormick, Jr., in a 1998 interview for *Traffic World*, indicated that the lack of trained drivers was of top concern for the industry. Besides bonuses, benefits, and higher pay, methods used to retain drivers included expanded use of husband and wife teams, "relay" driving in which routes normally handled by one driver are divided up, increased scheduling of short hauls, and equipment amenities designed to make the driver's job less taxing.

Large LTL freight carriers with unionized employees often pay out 60 percent to 65 percent of their revenues in wages and benefits (including wages to independent drivers) compared with 40 percent to 45 percent in the mostly nonunion TL segment. Long-distance truckers are usually paid by the mile and receive increases based on seniority.

Teamsters. Although the International Brotherhood of Teamsters (IBT) has historically been the most effective and politically influential union in American industry, it has been plagued by a long tradition of scandal involving organized crime connections, racketeering, pension fund

dipping, insurance abuses, and federal investigation. In the 1970s, the IBT represented about 500,000 drivers, but by 1980 that number had declined to 300,000. After deregulation allowed scores of nonunionized carriers into the industry, the number of Teamster drivers continued to decline. Between 1981 and 1991, Teamster representation in the regulated for-hire sector alone fell 50 percent.

Nondriving Positions. Dispatchers are responsible for notifying drivers assigned to them (or traveling in their zone) where and when to pick up and deliver freight. They routinely juggle a continuously changing roster of drivers, destinations, routes, schedules, and freight categories to determine the most efficient distribution of the company's fleet resources.

Raters determine the minimum amounts a company can quote its customers for shipping freight based on such variables as the type of commodity to be shipped, current shipping rates and discounts, competitors' rates, and the relative profitability of the shipment.

While dispatchers focus on specific shipping zones and individual drivers, planners are responsible for the efficient distribution of drivers throughout whole regions and must take into consideration such factors as fluctuating seasonal shipping levels or mistaken sales of company services to unserved areas.

AMERICA AND THE WORLD

U.S. involvement in foreign trucking has historically centered primarily on the Canadian market. The degree of internationalization in the industry was expected to grow, however, as a result of the ratification of the North American Free Trade Agreement (NAFTA) in late 1993, the implementation of new phases of the General Agreement on Tariffs and Trade, the emergence of a formally unified European economy, and the openings to trade offered by the democratization of the former Soviet Union and Eastern Europe.

Canada. The United States and Canada trade more goods with each other than with any other economies, resulting in transportation costs—including trucking—of \$4 billion to \$7 billion a year. In 1989, Canada and the United States signed a trade agreement to promote cross-border commerce, which was expected to be further bolstered by the gradual implementation of NAFTA throughout the 1990s.

The NAFTA agreement called for opening cross-border traffic in the U.S. and Mexican border states by 1996. Other geographic and ownership access would be expanded by 2000, and virtually all access and investment restrictions on trucking companies would be lifted by 2003.

Before NAFTA, Mexican cross-border trucking was highly restricted. Mexico required foreign shippers to use

Mexican drivers and Mexican equipment to handle shipments there. This forced U.S. shippers and carriers to form alliances with Mexican carriers. In response to the restrictions, the United States established an embargo in 1982 that limited Mexican access to U.S. markets. U.S. certificates of registration restricted Mexican carriers' access to a border zone generally ranging 10 to 25 miles north of the U.S. border. But just before NAFTA's passage some 4,354 Mexican carriers held registration certificates. Only three Mexican motor freight carriers, however, held broader authority and none held 48-state authority.

U.S. trucking companies sending freight to Mexico were especially subjected to lengthy delays at border crossings since their trailers had to be unloaded from their tractors and re-loaded onto Mexican tractors. With NAFTA's passage, American truckers won access to all of Mexico in 1999, and Mexican truckers were granted full access to the United States.

NAFTA was regarded as bad news for U.S. trucking companies that faced difficulties retaining drivers for long hauls. Mexico lacked good roads, hotels, communications, and gas and repair stations—four requirements of most truckers. Meanwhile, the Mexican government began efforts to build a 7,240-mile network of superhighways that would crisscross the nation and connect most of Mexico's major ports with its principal commercial and industrial centers. As more American and Asian manufacturers began using Mexico for assembly of products, and trade increased with all of Latin America, many executives began seeing the traditional East-West, West-East trade routes replaced with an emphasis on North-South, South-North routes. The devaluation of the peso in 1995, however, had devastating effects on U.S. truckers operating there, causing many to rethink their involvement in Mexico.

Amendments to Mexico's federal weights and measures law in 1994 were met with enthusiasm by U.S. truckers. The new law lowered Mexico's weight limit for trucks to just under 90,000 pounds for an 18-wheel tractor-trailer, only 10,000 pounds shy of U.S. limits. Trucks from Mexico had been weighing in excess of 140,000 to 160,000 pounds, an amount considered unsafe in the United States. Prior to the amendment, many Mexican vehicles weighing high amounts came across the border into the United States since resources to monitor all vehicles at border crossings were lacking.

With the advent of the European Union in 1992, U.S. carriers quickly established a presence to control the European leg of their shipments. European operators like steamship line Nedlloyd began offering land-based transportation in Europe and employed the services of U.S. trucking companies to provide the U.S. leg of the shipment. Nedlloyd Road Cargo signed a contract with Con-

solidated Freightways' subsidiary Con-Way in 1992 to provide door-to-door LTL service between the United States and Europe, with Nedlloyd handling the European part of the venture. Carolina Freight opened an office in Rotterdam, the Netherlands, to provide faster service for its customers' European needs. Dutch motor carrier Bleckmann B.V. handled sales and marketing for Carolina's transportation services within the Dutch market, served as its general agent within the United Kingdom, and provided international trucking services within Europe. In 1993, Yellow Freight and The Royal Fran Maas group in Europe entered into an agreement to provide transatlantic LTL shipments.

The trend in the European trucking industry was toward increased concentration of business activities within the industry, decreased border restrictions, harmonization of excise duties and value-added taxes, and increased grants of operating authority for trucking firms.

New Markets. The number of trucking companies with international operations has grown, and American non-local truckers have been among the most active global firms. Expanding and potential markets included South America (arrangements by Consolidated Freightways and Carolina Freight, for example, with Argentina/Chile and Colombia, respectively), the Pacific Rim (direct service by Roadway Express to Australia, New Zealand, and 10 Asian countries), Russia (joint marketing agreement by Mayflower Transit with SovTransavto in 1990), and China (U.S.-China shipping accord signed in 1992).

RESEARCH AND TECHNOLOGY

The non-local trucking industry has not historically been associated with advanced technologies. Reliable braking and cab heating systems did not come into use until the 1940s, the diesel engine was not common until the 1950s, and as late as 1971 few trucking companies used computers for even basic office-related administrative applications. By the early 1990s, however, a typical heavy truck featured 3 to 20 forward gears, electronically controlled fuel-injection systems, aerodynamic airfoils, and roof-mounted satellite antennae linked to computers inside the cab and remote data storage centers.

The areas of technology with the greatest potential impact on the non-local trucking industry were vehicle and freight tracking systems and information storage and interchange systems. Because these technologies enabled industry firms to increase productivity, enhance responsiveness to customers, and distinguish themselves from competitors, they played increasingly critical roles in the industry's profitability in the early 1990s.

Tracking technologies use sophisticated computer systems to record the progress of freight from origin to destination and satellite technologies to provide precise

locations of fleet trucks. Bar code labels on freight packages and portable bar code scanners permitted industry firms to process extensive data on individual loads and monitor the movement of those loads during transport. Such electronic data interchange (EDI) systems allowed truckers to "capture" data automatically and permitted shippers to link up with a carrier's computer to access data on proof of delivery, invoices, shipment routing, and freight consolidation in "real time" with greater accuracy, and with reduced administrative paperwork and storage.

Handheld, laptop, and dashboard-mounted computers let truckers communicate with company computers, keep track of information on fuel taxes and fuel management performance, store navigational maps and information on truck stops and repair facilities, record departures and arrivals, send and receive messages, monitor vehicle speed and engine conditions, and register mileage or the results of trailer inspections.

Although satellite technology for vehicle tracking and navigation has been available since the early 1980s, active industry interest began only in 1987 when the first LT carriers began installing satellite tracking equipment. These systems enabled trucking firms to locate trucks to accuracies of 300 yards by linking on-board computers with company dispatchers via specialized satellites. Less expensive "meteor burst" systems bounced VHF radio waves off meteor trails to obtain the same positioning coordinates offered by satellite signals.

Using satellite tracking equipment, C. R. England and Sons achieved 98 percent on-time performance in the early 1990s. Although satellite tracking systems can add as much as 2 percent to operating costs, 2,000 U.S. trucking fleets had two-way satellite data links in 1992, and 30,000 trucks were equipped with position location systems. The number of trucks equipped with vehicle tracking equipment was expected to continue to grow.

Legislation. Several industry innovations have been direct responses to government regulations in the areas of vehicle emissions, radar evasion devices, and highway safety. Environmental Protection Agency pollution mandates and related clean air laws drove industry firms in the 1980s and 1990s to explore alternatives to diesel and gasoline fuels. In 1993, for example, all trucks were required to begin using low sulfur fuels. Although the practicality of other fuel sources such as compressed natural gas and liquid petroleum was unclear in the early 1990s, research breakthroughs in fuel modification, exhaust after-treatment, and engine redesign resulted in reductions in diesel engine emissions of 40 percent over preregulatory levels.

So-called "double-bottoms"—trucks hauling two trailers—were estimated to increase truckers' load capac-

ity by 35 percent, offering the industry improved ability to compete with rail carriers' stacked container methods. In the early 1990s, industry firms continued to push for legislative reforms permitting them to use double- and triple-trailers and other "longer combination vehicle" arrangements more widely.

Other Technologies. A wide range of technology applications were introduced or were under development, ranging from "early warning systems" that use radar technology to inform drivers when they are approaching a vehicle too quickly; cab-mounted computers that reduce accidents by enabling dispatchers to remotely monitor the status of the driver and vehicle; electronic systems for registering automatic payment of tolls without requiring trucks to stop; systems for automatically monitoring freight and engine temperatures and setting temperature levels in refrigerated vehicles; and diagnostic and prognostic software packages that allow engine computers to predict component failure based on engine performance trends.

Trucks themselves have been subject to technological research and advancement. German truck manufacturers Freightliner and Mercedes Benz tested a second generation of truck design that uses an interactive video computer system. Called Vector, the system videotapes the highway as the truck drives along, interprets data such as speed and traffic, and directs the truck as to what speed it should operate. Application of this technology was not expected to reach the marketplace until well into 2000.

Potentially important technologies outside of the truck cab included laser image-processing and optical character recognition devices for speeding up paperwork using electronic scanning techniques; driver training simulators based on aerospace industry designs; shipment planner software to allow truckers to reduce "deadhead" (or empty trailer) miles; and fax and voice response systems that provide shippers with constantly updated rate quotes, transit times, and locations of in-transit shipments.

SIC 4214

LOCAL TRUCKING WITH STORAGE

This category covers establishments primarily engaged in furnishing both trucking and storage services, including household goods, within a single municipality, contiguous municipalities, or a municipality and its suburban areas. Establishments primarily engaged in furnishing warehousing and storage of household goods when not combined with trucking are classified in **SIC 4226: Special Warehousing and Storage, Not Elsewhere Classified**. Establishments primarily engaged in furnishing local courier services for letters, parcels, and packages weighing less than 100 pounds are classified in **SIC 4215: Courier Services Except Air**.

NAICS CODE(S)

484110 (Local General Freight Trucking, Local)

484210 (Used Household and Office Goods Moving)

484220 (Specialized Freight (except Used Goods) Trucking, Local)

The local trucking and storage industry consists of firms that provide storage, warehousing, and other ser-

vices in addition to transport within an operating radius of 50 miles, which usually includes an urban area and its suburbs. The industry is divided between firms that transport and store furniture and household goods locally and firms that transport and store other goods locally.

In 1994, three-quarters of the industry's revenues were derived from motor carrier work (including the leasing of trucks with drivers). A total of 63 percent of these revenues came from local trucking and the remainder from long-distance trucking. The industry's non-motor carrier derived revenues from such activities as parking and storing vehicles, snow plowing, repair work and truck terminal leasing for other carriers, and the lease and rental of vehicles without drivers. Industry firms generally are classified as "specialty freight" carriers, because the materials they transport—typically household goods—require special equipment for loading, unloading, or transport.

Local firms that both moved and stored household goods comprised roughly 20 percent of the total U.S. household goods moving industry in 1987, with the remainder divided between non-local household goods movers and local truckers that did not offer storage. Typically, most residential moves occur in the summer, and industry revenues often drop by as much as 50 percent during the winter months. As a result of such revenue fluctuations, many local moving and storage firms have supplemented their core moving business with other services, including off-season commercial and business office relocation, less-than-truckload (i.e., less than 10,000 pounds of goods per truckload) freight transport, third-party logistics, and warehousing.

A growing trend in American industry in the 1980s and 1990s was the "just-in-time" production management system, in which manufacturers lowered their inventory costs by maintaining only a short-term stock of manufacturing materials. Shippers of manufacturing materials responded to this trend by warehousing goods in the same locality as their customers, enabling them to respond more quickly to continual changes in their customer's orders while also lowering shipping expenses. Local trucking and storage companies participated in this trend by providing transport, warehousing, and logistics services to shippers and their customers. In third-party logistics arrangements, local trucking and storage firms provided storage, inventory control services, packing or crating of goods, or pickup and delivery of shipments. Goods were stored in the customer's warehouse, the trucking firm's warehouse, or in "dedicated" warehouses owned by the trucking firm but maintained exclusively for the customer. Inventory management could be handled by the customer in the trucker's storage facility or by the local trucking firm itself. Some firms maintained small warehouses called "parts banks" where im-

portant components were kept ready for immediate (1-4 hour) delivery to customers.

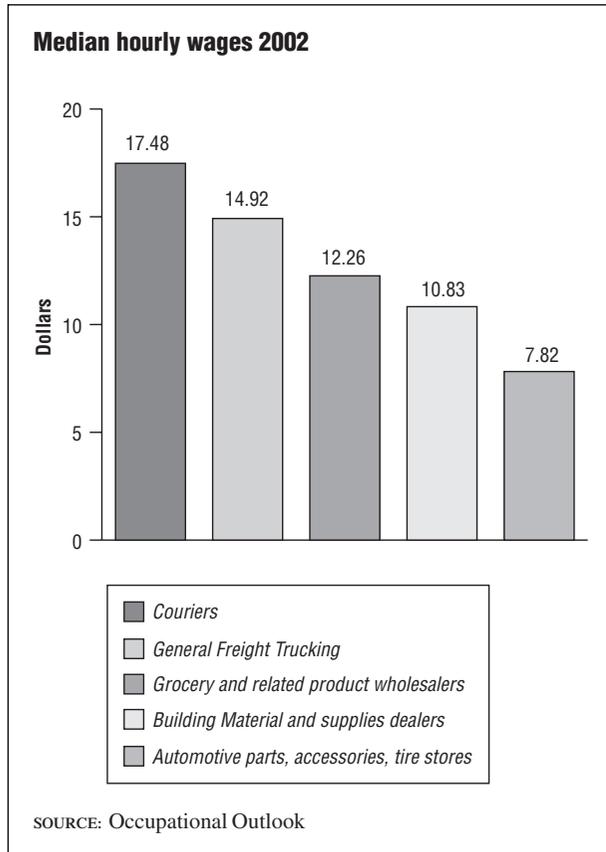

Many of the same firms that dominated the national intercity moving industry in the late 1990s—Bekins, Mayflower, Allied, North American, and U-Haul, for example—also operated in the local trucking and storage industry and were among the leaders in developing the nontraditional less-than-truckload and logistics services markets. Far more common, however, were smaller firms such as Kane Is Able Inc., Nice Jewish Boy Moving and Storage, Frozen Food Express, and Beverly Hills Transfer and Storage Inc.

In 2001, the industry leader was Bekins Van Lines LLC of Hillside, Illinois, with \$207 million in revenue and 400 employees. In second place was Paul Arpin Van Lines of East Greenwich, Rhode Island, with \$116 million in revenue and 500 employees. Next was Jacksonville, Florida-based Arnold Transportation Service Inc., with \$93 million in revenue and 700 employees. Rounding out the top five in the industry were Cord Moving and Storage Co., of Earth City, Missouri, with \$70 million in revenue and 300 employees, and McClendon Transportation Group of Lafayette, Alabama, with \$64 million in revenue and 300 employees.

In addition to national moving companies and smaller trucking and storage firms, the local trucking and storage industry includes a variety of specialized carriers, such as merchants' goods delivery services, refrigerated meat transporters, data transport and storage firms, liquid tank truckers, container and inter-modal companies, cement hauling firms, bus companies, farm goods transporters, crane and excavation companies, as well as the local trucking and storage divisions of such national rail carriers as CSX and Norfolk Southern.

In the mid-1990s, important trends in the local-trucking-with-storage industry included continued diversification into new areas of business: some companies, for example, would offer to pack up a company's computers, move them to a new office location, and reinstall them so employees could begin work immediately.

Overall, the local general freight trucking industry reported revenues of \$14.96 billion in 2001, down from \$15.15 billion in 2000, but up from \$14.27 billion in 1999. The local specialized freight trucking industry reported revenues of \$25.36 billion in 2001, a slight gain over \$25.33 billion in 2000 and \$24.09 billion in 1999. In general, employment in this industry is tied to the general health of the economy. According to the *Occupational Outlook Handbook*, there were a total of 3.2 million truck drivers employed in 2002. The overall employment expectation was for steady growth into 2012, with better opportunities for heavy and light truck drivers.

In 2002, the median salary for delivery and light duty truck drivers was \$11.48 per hour. Intense competition in the industry has driven up truckers' wages. At the same time, industry firms also concentrated on developing ways to retain drivers, such as only hiring drivers from within the company or offering generous benefits and profit-sharing plans. There was virtually no unemployment in the truck driving industry, and the labor shortage was expected to worsen into the mid-2000s.

The highest costs in the industry were labor-related. Other costs were associated with retrofitting trucks to meet new diesel emissions standards. Diesel emissions were to be cut by up to 90 percent by 2007. In the 2000s, the Transportation Security Administration was looking into the viability of requiring locks on all truck cargo areas.

SIC 4215

COURIER SERVICES EXCEPT AIR

This category covers establishments primarily engaged in the delivery of individually addressed letters, parcels, and packages (generally under 100 pounds), except by means of air transportation or by the United States Postal Service. Delivery is usually made by street or highway within a local area or between cities. Establishments primarily engaged in furnishing air delivery of individually addressed letters, parcels, and packages, except by the United States Postal Service, are classified in **SIC 4513: Air Courier Services**, and establishments of the United States Postal Service are classified in **SIC 4311: United States Postal Service**.

NAICS CODE(S)

492110 (Couriers)

492210 (Local Messengers and Local Delivery)

INDUSTRY SNAPSHOT

By the early 2000s, courier services were a multi-billion-dollar U.S. industry. In 2002 alone, industry leaders United Parcel Service (UPS) and FedEx earned some \$53 billion and employed approximately 578,000 workers. In the early 2000s, nearly 6,000 establishments operated within the industry. About three-fourths of these firms were local surface or ground-based couriers (those with an operating radius of 50 miles or less), and the remaining ones were non-local couriers. Despite the name recognition owned by UPS and its smaller competitors, local-market establishments with five or fewer employees and annual revenues between \$100,000 and \$250,000 have been the most common business types in the industry.

ORGANIZATION AND STRUCTURE

The diversity of business activities performed by industry firms was reflected in the number of establishments for which courier service was not their sole business. For example, industry firms included bus lines, messenger services, armored car services, temporary employment firms, business-only couriers, food product delivery companies, bicycle courier companies, newspaper publishers, specialized bank document couriers, couriers who provided “in-house” service for business clients within a single office building, and a wide variety of smaller firms. The vast majority of industry firms serviced local markets—for example, a single urban market and its environs—and offered no air delivery service.

The U.S. ground courier industry delivers packages and parcels generally weighing from 70 to 100 pounds for business and residential customers. (In 1994, however, UPS raised its weight limit to 150 pounds.) The types of delivery available range from overnight (or “next-day”) service to two-day and three-to-five-day service with a range of additional services such as international delivery, same-day intercity air delivery (packages picked up in the morning and delivered before 5:00 p.m. that day), and even express overnight service to Europe by 8:30 a.m. the next day. While overnight air service was increasingly the most dominant delivery service provided by air couriers, same-day, two-day, and three-day ground service remained a significant source of revenue for industry firms.

The industry continued to offer a wider range of services and rates to capture the many specialized niches of the package shipping market. For example, UPS introduced five new rate tiers based on commodity density, also later adding a tier for light and bulky parcels. One such service, accepting packages weighing 100 pounds or more, helped UPS and other carriers compete with the small-package niche of the less-than-truckload (LTL) segment of the trucking industry, which transported consolidated loads from different shippers that consisted of individual packages of 500 pounds or less. These traditionally general freight carriers began reacting to the ground couriers’ co-optation of their small package business by adopting the same operating strategies that helped the leading couriers dominate their industry: local pick-up and delivery of small packages and parcels, the creation of geographical distribution networks or hubs, and the use of tracking software and high-tech sorting facilities.

The leaders of the air and ground courier industries maintained extensive networks of drop-boxes and staffed drop-off centers in addition to providing on-site package pick up. For example, in addition to tens of thousands of unstaffed drop-boxes and other drop-off facilities, UPS operated the shipping center chain Mail Boxes Etc., Inc.

(MBE). By 2003, MBE consisted of some 4,500 worldwide locations, more than 75 percent of which were located in the United States. That same year, FedEx claimed to have more than 8,500 authorized ShipCenters in place, as well as more than 1,200 drop-off locations and more than 43,700 drop boxes. In 2003, the UPS delivery network consisted of more than 600 aircraft, 88,000 vehicles, and 1,748 facilities. The company serviced more than 200 countries and delivered 13.3 million parcels and documents each day in 2002. By comparison, in 2002 FedEx had 652 planes, 98,950 vehicles, serviced more than 210 countries, and had a daily volume of about 5.3 million shipments per day.

BACKGROUND AND DEVELOPMENT

UPS was formed in 1907 as American Messenger Company, a telephone message service in Seattle, Washington. In 1913, the company changed its name to Merchants Parcel Delivery when it began delivering small parcels for local department stores. When the company changed its name again to United Parcel Service in 1930, it had expanded its service areas to northern California, New York, New Jersey, and Connecticut. UPS began operating in Los Angeles in 1952 and in the years that followed gradually expanded its services throughout the nation.

As late as 1970, Federal Express was the only package courier in the United States specializing in express delivery, when the United States Postal Service (USPS) began to offer business customers priority mail delivery on an experimental basis. Within five years, the USPS was publicly acknowledging UPS as its principal competitor while Federal Express, aided by a 1974 UPS strike and its memorable slogan “When it absolutely, positively has to be there overnight,” began to emerge as the major force in the air segment of the courier market. UPS responded by offering air delivery services, though initially through the use of charter air services. In 1982 it offered guaranteed next-day air delivery to anywhere in the United States and began buying its own air fleet.

In 1986, UPS began automating its operational systems with a five-year \$2 billion technology upgrade program that was bolstered by an additional \$500 million technology investment each year thereafter. It also countered FedEx’s catchy corporate slogan with one of its own: “We run the tightest ship in the shipping business.” By 1987 UPS owned 90 planes; by 1988, it offered international service to 41 countries; and between 1987 and 1992 it acquired 16 firms. In 1990, UPS bought a 9.5 percent stake in Mail Boxes, Etc., a franchise neighborhood-oriented mailing and business service company that began offering UPS to its customers for their shipping needs. Between 1991 and 1992, UPS acquired three European courier firms, and by 1993, UPS

was delivering 11.5 million packages and documents a day and boasted over 1 million regular customers. In 1996 it paid \$110 million in sponsorship and marketing/advertising fees to be the official sponsor of the summer Olympic games in the company's hometown of Atlanta.

The major competitors in the ground courier industry continued to wage a fierce price war with each other and with the air courier industry. This battle resulted in lower rates for small package shippers but reduced earnings for firms in an industry already characterized by narrow profit margins.

The rapid spread of fax and e-mail technology in the 1980s and 1990s represented a significant source of competition for ground couriers (primarily in the same-day delivery niche) and was estimated to have cost the courier industry \$75 million in lost business in 1990 alone. At the same time, the adoption of cost-saving "just-in-time" or zero-inventory management policies by many American businesses in the same period created a demand for truckers capable of providing same-day warehouse-to-customer transport of time-sensitive parts and manufacturing materials. Because of the quick-delivery, short-haul nature of many courier firms, this growing market represented a natural niche for the ground courier industry.

Major industry events of the mid-1990s included the 1996 merger of U.S. Delivery Systems and Corporate Express in the same-day courier segment of the industry; the purchase of three smaller services by Consolidated Delivery and Logistics the same year; United TransNet Inc.'s acquisition of Eddy Messenger Service; and the merger of Quick International Courier and Specialty Mailing Inc. U.S. Delivery Systems, of Houston, Texas, continued its bid to become the leader of the U.S. same-day, point-to-point local courier industry by buying more than 33 smaller delivery services in 85 U.S. cities between 1994 and 1995. In 1996, UPS announced a joint venture with China's Sinotrans-Pekair transportation company to share its express delivery technology in the Chinese market and established a major new Asian-Pacific air express hub in Taiwan. In 1997, UPS also began selling passenger seats on its weekend airfreight flights to exploit the revenue potential of its fleet on Saturdays and Sundays.

Despite UPS' seemingly unassailable dominance of the U.S. ground courier industry, it was never very far away from bad press. In the early 1990s, for example, the carrier was accused of practicing anti-union employment policies, failing to ensure worker safety at package-sorting facilities, raising package weight limits without appropriately retraining employees, and refusing to pay workers overtime for extra hours and missed lunches (resulting in a class-action lawsuit settled out of court for \$14 million). Between 1993 and 1995, UPS spent about \$1 billion on safety

equipment and worker-training programs. However, UPS still had problems. It struggled with charges that it used predatory pricing tactics, and in 1996 the International Transport Workers' Federation launched a campaign to unionize the UPS non-U.S. workforce.

In the 1980s and 1990s, UPS, one of only three U.S. companies that competed nationally for small package delivery (Roadway Package system, Inc. and the USPS being the other two), and Federal Express—the air courier leader—increasingly encroached on each other's traditional markets, so much so that the differences between the two firms in services offered and size of fleet were almost negligible. Although UPS did not enter the air courier business until the 1980s, by 1995 double-digit growth in its air express operations allowed a UPS spokesperson to admit that airfreight delivery had completely changed the company's business approach. By late 1995, the UPS air express business was accounting for 25 percent of its annual revenues.

Despite the growth in electronic transmission of data and information, courier services maintained healthy markets into the millennium. For the 1999 Christmas holiday season, UPS expected to deliver 18 million expedited packages on Christmas Eve alone. Normal daily averages for UPS were about 12.5 million per day for 1999.

One of the biggest contributors to the continued success of courier services was the 1998 to 1999 rapid growth of e-commerce, including on-line shopping wherein on-line retailers delivered their parcels—as consumers often requested—by courier shippers. The convenience of the entire transaction outweighed hefty delivery charges for a generation of Web-users accustomed to near-instant gratification. In 1998, UPS shipped approximately 55 percent of all items bought on the Internet during the holiday season; the USPS delivered another 32 percent, followed by FedEx at 10 percent.

As competitors' prices remained parallel, the only real room for growth was overseas, and all three companies sought to secure these lucrative markets. However, higher fuel costs cut deeply into profits in 1998 and 1999, and UPS and FedEx announced increases in their charges of about 3 percent, starting in early 2000.

CURRENT CONDITIONS

The terrorist attacks against the United States on September 11, 2001 served to exacerbate an already faltering U.S. economy. In addition to reduced levels of consumer and corporate spending, concerns about the security of deliveries came to the forefront as mail tainted with deadly anthrax bacteria was circulated in the postal system, causing several deaths. Together, these conditions presented serious challenges to courier services. By early 2003, the economy was poised for recovery. How-

ever, military conflict in the Middle East served to complicate this upturn. The onset of war in Iraq resulted in a great deal of uncertainty over fuel prices—an important industry dynamic—and caused some carriers to levy fuel surcharges.

E-commerce continued to present ground couriers with great opportunities in the early 2000s. Consistent with earlier trends, e-commerce was slowly changing the dynamics of the business-to-consumer (B2C) retail sector, namely by eliminating layers from traditional retail distribution chains. As more transactions shifted to e-commerce, there was a movement toward higher volumes of smaller, individual shipments—many of which were handled by courier services—from manufacturers to consumers. In contrast, fewer numbers of large shipments were needed from manufacturers to so-called “middlemen” like wholesalers and distributors. According to Standard & Poor’s, Zona research revealed that UPS handled about 55 percent of all e-commerce transactions in the early 2000s, followed by the USPS (32 percent).

For the industry’s largest firms, foreign markets continued to represent the best growth prospects. By 2001, UPS was making greater inroads in Asia, where FedEx had already established a presence several years before. UPS first extended its reach to the Asia Pacific region in 1988 when it acquired Asian Courier System of Hong Kong. In 1997, UPS forged a joint venture with service agent Delbros, Inc. called UPS-Delbros International Express Ltd., Inc. However, it began direct service to China in March of 2001, after receiving approval from the U.S. Department of Transportation. According to UPS, the market expansion was expected to result in additional revenues of roughly \$100 million after one year. One month after it began offering service to China, UPS announced that it had signed a joint letter of intent with the Philippine government for the development of an intra-Asia hub. The company explained that the new hub would enable its planes to access every major city in Asia within four hours. Citing figures from MergeGlobal, in April 2002 *Business Week Online* reported that the new hub was in a strong position, given that annual growth of almost 17 percent was expected within Asia through 2005.

INDUSTRY LEADERS

The most successful couriers remained the large national companies such as UPS, FedEx, DHL Worldwide Express, Purolator Courier, Emery Forwarding, and Airborne Express, which offered air courier and ground operations and competed directly with the ground-only couriers for business. In fact, the largest air couriers maintained sophisticated and extended surface operations that dwarfed the scope of services offered by the majority of companies in the ground courier industry. Another

important provider of services closely related to the ground courier industry was USPS, which began to market itself as a direct competitor to UPS and FedEx in the delivery of two- to three-day parcels and documents.

In 2002, UPS earned \$3.2 billion on revenues of \$31.3 billion. The company has dealt with labor problems from the Teamsters, who filed a grievance in late 1999 claiming that UPS failed to meet its obligation under a settlement from the 1997 strike. By 2003, the UPS family of companies had grown to include UPS Air Cargo; UPS Aviation Technologies; UPS Capital Corporation; UPS Consulting; UPS Mail Innovations; Mail Boxes Etc., Inc.; UPS Professional Services; UPS Supply Chain Solutions; and UPS TeleServices.

FedEx Corp. earned \$710 million on revenues of \$20.6 billion in 2002. Although the company’s revenues were only five percent greater than 2001 levels, its net income jumped almost 22 percent. Like UPS, FedEx Corp. was organized into a suite of companies by 2003, including FedEx Express, FedEx Ground, FedEx Freight, FedEx Custom Critical, FedEx Trade Networks, and FedEx Services. FedEx retained its position as the world’s largest express-delivery company, with nearly 185,000 employees. In the early 2000s, FedEx was aggressively trying to wrest a larger percentage of the ground delivery market from competitor UPS with its FedEx Ground operations. This effort was aided by the acquisition of Caliber Systems (a former UPS competitor) in the late 1990s, as well as infrastructure and systems investments totaling some \$800 million.

RESEARCH AND TECHNOLOGY

In its operations centers, shipping points, and package pickup and delivery trucks, the U.S. ground courier industry was transformed by mobile communications technology and electronic scanning, tracking, and billing technology. Faced with increasing competition from Federal Express in the late 1970s and early 1980s, industry leader UPS inaugurated a technology modernization program in the mid-1980s that transformed it into a technology-driven enterprise with a management information systems (MIS) staff of 4,000. In 1990, UPS began installing a cellular phone system in 50,000 of its fleet trucks that enabled customers to determine the exact status of their packages in real time for a cost of 75 cents. The \$150 million system, called DIAD (Delivery Information Acquisition Device), used an electronic pen and clipboard device carried by the driver and was based on “image capture” software that recorded the customer’s signature and the package’s bar code data. When the driver attached the clipboard to an adapter in the truck, the data was sent via UPS’s UPSNet system to the company’s main data center for customer access. Among other advantages, the system largely eliminated the prob-

lem of verifying illegible signatures, thereby tripling the number of next-day air deliveries made without errors and enabling UPS to include an electronic “replica” of the recipient’s signature when providing the shipper with a proof of delivery. In 1992, UPS introduced GroundTrac for electronically tracking packages passing through the UPS system. It also began investing in coded package labels capable of containing more data than existing bar code labels.

UPS also established a toll-free hotline that shippers could call to get a faxed sheet displaying the time and location of their package’s delivery and the name of the person who signed for it. By 1996 this simple fax system had evolved into UPS’s interactive home page on the World Wide Web, through which customers could check the status of their shipments. Customers also could schedule pickups, get price estimates for shipping their packages, and make billing inquiries. By 1997, Federal Express’s online system claimed more than 400,000 customers who generated more than 60 percent of the company’s 2 million-plus daily transactions. In January 1997 alone, more than 800,000 packages were tracked via the Web, and its Internet transactions were growing at the rate 10 to 12 percent a month.

Other advanced technology applications that took place in the ground courier industry included parcel processing systems capable of sorting 20,000 packages per hour and satellite computer systems that could locate courier fleet trucks as precisely as 300 yards or better.

SIC 4221

FARM PRODUCT WAREHOUSING AND STORAGE

This category includes establishments primarily engaged in the warehousing and storage of farm products. Farm product warehouses provide temporary storage for non-perishable agricultural products such as grain. Establishments primarily engaged in refrigerated warehousing are classified in **SIC 4222: Refrigerated Warehousing and Storage**.

NAICS CODE(S)

493130 (Farm Product Storage Facilities)

INDUSTRY SNAPSHOT

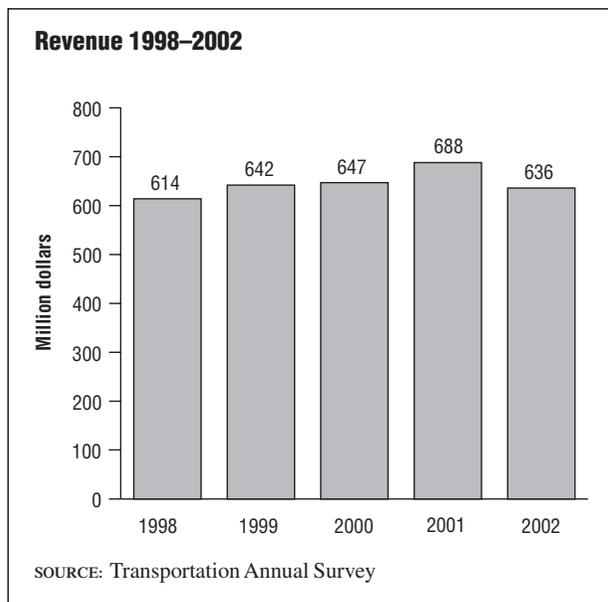

In 2001, there were 358 firms operating 552 establishments in this industry. Total employment was 5,459 with a payroll of more than \$147 million. The industry had combined revenues of \$636 million in 2002, down 7.6 percent from \$688 million in 2001 and \$647 million in 2000. The industry was served by the National Grain and Feed Association (NGFA), which worked to represent grain warehouse interests on the state and federal level, as well as conduct research to reduce industry costs and increase efficiency and reliability.

BACKGROUND AND DEVELOPMENT

Warehousing was established as a significant link between producers and consumers by 1783, particularly at port cities. Before elevator mechanization, grain was stored and shipped in sacks or barrels. A chain-bucket system to move grain from bins into elevators was invented in 1785 and improved in 1843, achieving widespread use by the 1860s. Before modern roads and rail transportation, country storekeepers doubled as warehousemen who traded commodities and offered credit. Transportation and storage improvements made it profitable to grow grains at greater distances from major markets, spurring the development of commodity exchanges.

The warehousing industry refined its basic function from simple storage and handling of bulk materials toward supplying the market with custom products; the baking industry launches 1,000 new products a year to satisfy demand for variety, quality, safety, convenience, price, and environmental compatibility. The shift demanded skillful management and specialized knowledge as warehousing evolved from high-volume processing to a transitional role in value-added product innovation.

Communication skills became more important as grain handlers linked producers and manufacturers. Computer-literate elevator personnel—fluent in crop va-

rieties, fertilizers, finance, marketing, and sales—offered a wider range of services to high-tech farmers and end-users. Growers delivered a variety of grains as raw materials for developing niche markets. In addition to cash crops such as corn, wheat, and soybeans, farmers produced barley, durum, rice, sunflowers, flax, edible beans, and other specialty crops. Advances in genetics and grain monitoring spurred demand for specialized end products. Crops were manipulated for food quality, protein yield, and mold resistance. Insects were detected by acoustic monitors. Nucleic acid probes discovered microbes, pesticides, and antibiotics.

Consumer demand is one of the most important factors that stimulates consolidation and vertical integration of the farm product warehousing industry. This development mirrors what occurred in other agriculture sectors such as pork, poultry, and vegetable processing. In the 1990s, per capita consumption of cereal and flour products was up 25 percent since 1968, while consumption of animal products expanded 1 percent. After four consecutive years of abundant harvests worldwide, the 1999 international demand for farm produce was weak, forcing farm prices to drop, domestically and on exports. Conversely, as demand waned, storage warehousing and insurance on agricultural products increased. Commercial storage of grain alone in 1999 was estimated at 8 billion bushels, with another 11 billion stored on farms. This was notwithstanding \$53 billion in U.S. farm exports in 1998.

More than 9,000 elevators were in operation in the United States in 1982, dropping to fewer than 8,000 by the mid-1990s. The top 44 U.S. firms primarily in the farm product warehousing and storage business posted total earnings between \$1 and \$3 billion in the 1990s. In 2003, Westeel grain storage systems, popular in Canada

and other countries overseas, were entering the U.S. market as a cost-effective alternative to on-ground grain storage.

In 2001, the industry leader was Federal Compress and Warehouse Company Inc., of Memphis, Tennessee, with \$1.3 billion in revenues and 1,600 employees. Impact Cooperative Inc. of Frankfort, Indiana, had \$413 in revenues and 200 employees. Richmond, Missouri-based Ray Carroll County Grain Growers Inc. had revenues of \$256 million and 100 employees. Other leaders were Farmers Cooperative Compress of Lubbock, Texas, with \$70 million in revenues and 300 employees, and Attlebury Grain Inc. of Amarillo, Texas, with \$82 million in revenues and 100 employees.

SIC 4222

REFRIGERATED WAREHOUSING AND STORAGE

This category includes establishments primarily engaged in the warehousing and storage of perishable goods under refrigeration. The establishments may also rent locker space for the storage of food products for individual households and provide incidental services for processing, preparing, or packaging such food for storage. Establishments primarily selling frozen foods for home freezers (freezer and locker meat provisioners) are classified in **SIC 5421: Meat and Fish (Seafood) Markets, Including Freezer Provisioners**.

NAICS CODE(S)

493120 (Refrigerated Storage Facilities)

In 2001, a total of 607 firms operated 942 refrigerated warehousing and storage establishments. There were 28,231 employees receiving a total payroll of \$853.7 million. Total revenue for the year was \$2.3 billion, which increased to nearly \$2.5 billion in 2002.

According to the International Association of Refrigerated Warehouses (IARW), there was a record total of 2.1 billion cubic feet of refrigerated/frozen storage in North America in 1999. The USDA estimated slightly more than 2.7 billion cubic feet, but this figure included both private and public storage space. The five states containing the largest gross general warehouse capacity were California, Florida, Washington, Texas, and Wisconsin. According to the USDA, there has been a 59 percent increase in capacity in the past 10 years. While refrigerated storage is generally used for food products, it also serves the pharmaceutical, chemical, medical, and scientific industries.

Cold storage operators have historically acted as middlemen between the manufacturers and the grocery or convenience store retailers. They provide storage and distribution services for domestic and international clients. These operators have been able to meet the needs of their clients by offering, through the latest technology, an efficient and inexpensive way to store their goods.

Many cold storage warehouses are at seaports where volumes of perishables are imported and exported. Berkshire Foods Inc. operates the cold storage facility at the Port of Savannah, Georgia, which is owned by the Georgia Ports Authority. Berkshire also operates four warehouse facilities, which include more than 4 million cubic feet of freezer space at -5 to -30 degrees Fahrenheit.

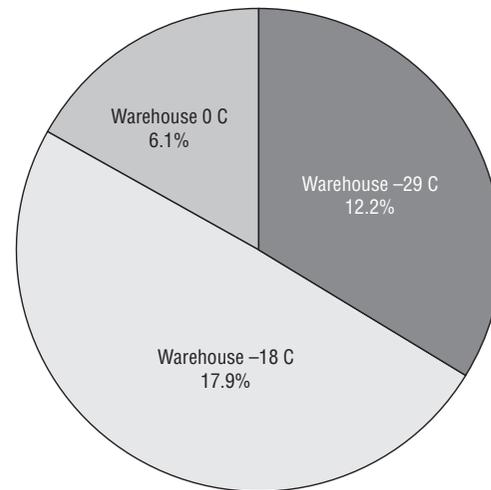

Companies, including seaports, that otherwise would have to operate large warehouses and spend considerable resources on computerized tracking systems are able to avail themselves of services from the cold storage operators. Throughout the second half of the twentieth century, cold storage operators developed expertise through experimentation and the application of new technology that food manufacturers were anxious to use. With the passage of time, the production of this expertise became costly and time-consuming for food manufacturers. Therefore, food manufacturers elected to outsource their food storage needs to refrigerated storage experts.

Since the 1970s, moreover, the use of artificial preservatives as a means of keeping food fresh has come under increasing scrutiny from health-conscious consumers. As a result, the demand for frozen foods, which do not contain as many preservatives, has increased. Cold storage providers were indirect beneficiaries of this evolving market trend.

As of 2003, the industry was growing slowly. Some 37.8 percent of warehouses reported increased turnover,

New Warehouse Construction Plans 2003, by Percentage of Regional Facilities

North America Total

SOURCE: Quick Frozen Foods International April 2003

down from 51.0 percent in 2002, and 57.1 percent reported steady inventories, up from 41.7 in 2002.

In terms of revenue, Americold Logistics LLC of Atlanta, Georgia, was the industry leader in 2001 with \$700 million in revenue and 6,200 employees. In 2004, the company had 541 million cubic feet of space and 100 locations. Burris Refrigerated Logistics of Milford, Delaware, had \$186 million in 2001 revenue and 1,000 employees. Cherry Hill, New Jersey-based United States Cold Storage Inc. was next, with \$144 million in revenue and 800 employees. Rounding out the top four was Hal's Warehouse Corp. of South Plainfield, New Jersey, with \$93 million in revenue and 200 employees.

In terms of storage space, Atlas Cold Storage was the industry leader with 277.8 million cubic feet of storage space throughout North America in 2003. Atlas was followed by P & O Cold Logistics, which had operations in Australia, New Zealand, and Argentina in addition to the United States. Other leaders included John Swire & Sons Ltd., which had operations in Australia and Vietnam, as well as the United States, and Versacold, which had operations throughout North America.

Along with the IARW, the industry also is promoted by an organization known as the World Group, which celebrated its twentieth anniversary in 1998. World Group is a consortium of eight public refrigerator warehouse companies in the United States and Canada. Their common interests are to promote state-of-the-art technology and to simplify manufacturers' distribution processes.

SIC 4225

GENERAL WAREHOUSING AND STORAGE

This category includes establishments primarily engaged in the warehousing and storage of a general line of goods. The warehousing of goods at foreign trade zones is discussed under **SIC 4226: Special Warehousing and Storage, Not Elsewhere Classified**. Field warehousing is found under **SIC 7389: Business Services, Not Elsewhere Classified**.

NAICS CODE(S)

493110 (General Warehousing and Storage Facilities)
531130 (Miniwarehouses and Self Storage Units)

INDUSTRY SNAPSHOT

At the turn of the century there were over 7,100 warehouse establishments operating in the United States, according to the U.S. Census Bureau's *Statistical Abstract of the United States*. The industry generated \$12.8 billion in revenues in 2000. Of that total, general warehousing accounted for \$7 billion; refrigerated warehousing and storage, \$2.5 billion; and all other warehousing and storage, \$3.3 billion.

Operating between shippers and carriers, companies engaged in the general warehousing business were third parties in the transportation industry. These businesses provide a variety of transportation and distribution services in addition to storage. As the industry entered the new millennium, large general warehousing companies offered value-added services ranging from customer bill-

ing to salvage and scrap disposal, and were marketing themselves as logistics services providers rather than as storage companies. Logistics, a term the transportation industry borrowed from the military, refers to all phases of the distribution process. Logistics-related services were provided by various industries including public warehouses, parcel express, and freight transport.

ORGANIZATION AND STRUCTURE

General warehousing companies received and shipped goods on behalf of their customers, serving as middlemen in the transportation process and a vital part of the logistics business. Although some of the large general warehousing companies, such as GATX Logistics, Inc. and DMSI, Inc., of Charlotte, North Carolina, operated their own trucking fleets, normally an independent carrier was used to transport the goods. The carrier was chosen either by the customer or by the warehouse operator who then acted as the customer's agent.

Like most transportation-related businesses, the general warehouse industry was well organized on a national level. Four trade associations, Affiliated Warehouse Companies, Allied Distribution, American Chain of Warehouses, and American Warehouse Association, founded in 1953, 1933, 1911, and 1891, respectively, maintained national networks for marketing, sales, and industry lobbying. Because this industry operated between the vast manufacturing industry and the powerful transport industry, national organization was critical to the preservation of its own interests.

Competitive Structure. Although eight multi-regional companies dominated the general warehousing business, dozens of medium and small companies operated throughout the country. Entry into this industry was relatively easy for businesses proposing to operate locally; expanding demand and low start-up costs encouraged new entrants. In fact, from 1988 to 1993 the number of firms in the industry nearly tripled. Entering the mid-1990s warehouse expenditures were declining due to lowered costs of data processing equipment, furniture, and overhead labor. Self-storage companies found the conditions particularly inviting. Public and contract warehouse operators involved in logistics, however, faced an increasingly competitive environment in which service and technology were critical to success.

Although expanding demand and relatively low barriers to entry encouraged new entrants, competition for national market share was strong. Once a shipper chose a warehouse operator, especially one that offered logistics support, a strong relationship developed, and the cost of switching to another warehouse operator was high. Expanding market share, therefore, was difficult. The largest firms faced competition from national trucking companies and specialized distribution services in the logistics sector.

In the warehouse sector, these companies competed with manufacturers' in-house storage operations. To gain market share, the national operators invested heavily in technology to differentiate their services.

BACKGROUND AND DEVELOPMENT

General warehouses have operated in the United States since colonial days. Located in major ports such as Boston, these early warehouses were used as repositories for goods being shipped to and from England. These warehouses served as temporary housing for the exports of raw materials, such as cotton, and imports such as finished goods like textiles.

It was not until the completion of the railroad trunk lines around 1860 that warehouses began to move from the port cities into the nation's interior. During this time, industry was developing in the northeastern states, and the western farmlands were producing corn and wheat for consumption in the east and for export.

General warehouses grew with the nation's economy. As production techniques became more efficient, finished goods were produced faster, allowing manufacturers to develop inventories that required storage. Manufacturers that could not afford to maintain a warehouse paid a public warehouse operator to store finished products and raw materials. Often, manufacturers would ship their products to and from warehouses at major railroad terminals.

From its inception, the primary function of the general warehouse industry was storage. During the twentieth century, however, the transportation industry became more complex. Manufacturers faced several regulations regarding interstate shipping and had to choose between hundreds of transport companies in the truck, rail, and airfreight transport business. Moreover, the deregulation of trucking in the early 1980s caused an explosion in the number of companies providing truck services. As the transportation landscape became more difficult to navigate, shippers turned to warehouse operators for more services including the arrangement of freight distribution.

The increased reliance on warehouse operators for services other than storage prompted some warehouses to diversify into different transportation areas. After deregulation of the truck business, for example, some warehouses operated private trucking fleets used for distribution. Others became involved in combining small shipments of freight from various shippers into truckload shipments. These types of services were more typical of freight forwarders or transport companies than of general warehouse operators. At the same time, however, freight forwarders and truckers were offering storage services in addition to their primary functions.

Such overlap in services resulted in the emergence of the logistics industry. In fact, the various industries al-

ready providing logistics-related services were involved in a cooperative marketing campaign called "Think Logistics." The marketing effort was developed in the wake of research indicating that, according to Michael Jenkins, president of the American Warehouse Association, the "traditional lines between freight transportation and warehousing, or brokerage and warehousing, or even manufacturing and warehousing were beginning to blur." By the mid-1990s, many warehouse operators had developed from temporary caretakers of raw materials and finished goods into logistics experts.

The precarious position of the general warehouse operator, between shippers and carriers, was illustrated in the legislative battle over "carrier undercharge." Carrier undercharge occurred when truck companies quoted shippers lower freight rates than were prescribed by the various rate bureaus throughout the country and then failed to file the discounted tariffs with the rate bureaus. An undercharge crisis occurred in the early 1990s when many truck companies went bankrupt. During the reorganization or failure of these truck companies, it became clear that some carriers had charged rates that did not match those on file at the Interstate Commerce Commission (ICC). In the wake of these discoveries, shippers were receiving bills for "carrier undercharge" from the trustees of the bankrupt truck companies. Often the undercharge bill arrived months or years after the freight was shipped.

By 1992, undercharge claims exceeded \$30 billion. In cases in which warehouse operators arranged the transportation of a manufacturer's goods, the warehouse operator received the undercharge bill. At this point, the warehouse operator had to either risk sabotaging a business relationship by trying to recover the undercharge costs from the true shipper, his client, or pay the bill himself.

The undercharge debate raged in Congress for years. In 1993, Congress passed the Negotiated Rates Act, legislation that set procedures for resolving claims involving unfiled, negotiated transportation rates. The legislation favored shipper interests and included a subsection allowing the public warehouse to settle for 5 percent of the claim, with any disputes settled by the ICC.

The fact that the public warehouse industry was mentioned specifically in this legislation attested to its lobbying skills and highlighted the industry's ability to defend its interests. Had this legislation not been passed, warehouses were in a position to lose millions of dollars in undercharge payments and court battles related to the payments.

In the mid-1990s, co-ops became the latest trend among suppliers and distributors, as companies combined their resources into one network to take advantage

of economies in transportation and warehousing. Most of their arrangements were made by suppliers or shippers through third parties. These types of arrangements benefited companies by reducing inventories, extending buying power, saving costs, improving service, and producing less paperwork.

The general warehousing industry was the beneficiary of corporate America's strategic responses to the 1989-90 recession. Corporate downsizing, inventory management, and increased customer service all became important competitive priorities as manufacturers struggled to turn a profit in a weak economy. General warehouse operators provided the services necessary for companies to employ these strategies.

Corporate Downsizing. Faced with an increasingly competitive business environment and a weak economy, many large corporations underwent major downsizing during the early 1990s. As a result, operations not related to the core business of the corporation were eliminated. Often, these operations were connected with in-house storage and distribution. Many large manufacturing companies such as Eveready Battery Corp. considered public warehousing to be a cheaper and more efficient alternative to operating company-owned warehouses. Eveready switched to 100 percent public warehousing in the early 1990s; as a result, in 1992 Eveready estimated that it saved \$2.1 million, at a cost of \$1.4 million.

Mothercare, a 200-store maternity retailer, also switched from private to public warehousing during the early 1990s. Mothercare hired DMSI to handle its logistics, from arranging transportation into DMSI warehouses to distributing merchandise by means of the DMSI fleet. In New Jersey, general warehouse storage was booming in 1999, with more than 60,000 people employed in the industry in that state. Volkswagen, Barnes & Noble, Tommy Hilfiger, and Howmedica all had built distribution centers in New Jersey in the latter 1990s.

Also affecting the evolution: increased competition from alternative formats, such as mass merchandisers and warehouse clubs, caused food distributors to rethink and reengineer their distribution strategies. For Fleming Companies, of Oklahoma City, Oklahoma, the nation's largest supermarket distributor, this meant fundamentally reinventing its business. For years, Fleming had served as the "middle man" between product manufacturers and grocery store retailers. By 1996, it operated as a major distributor and supplier of virtually every national brand and high-volume private label, as well as a variety of general merchandise and full lines of perishables, including meats, dairy and delicatessen products, frozen foods, and fresh produce. By incorporating "Efficient Consumer Response" (ECR), Fleming repositioned itself as a

value-added marketing and distribution company providing goods and services. ECR made it possible for customers to pick and choose which services they wanted and pay for only those used. In 1996, Fleming's sales topped \$17 billion. That same year, Fleming had 41 supply centers nationwide, and 44,000 employees servicing more than 3,500 supermarkets in 42 states, the District of Columbia, and several foreign countries. It operated approximately 370 company-owned stores.

Inventory Management. In addition to corporate downsizing, American businesses were eager to increase inventory turnover as a means of streamlining operations. As a result, Just-in-Time (JIT) inventory management was being used by more companies than ever before. In fact, logistics expert Robert V. Delaney of Cass Logistics estimated that by 2000 close to 40 percent of U.S. products would be shipped on a time-based standard, and that most deliveries from warehouses would be completed in 37 hours or less.

However, the successful execution of JIT required constant monitoring of inventory levels and flexibility on the part of shippers. JIT generally required more frequent, but smaller shipments of goods to and from warehouses. Public and contract warehouses were often better equipped than in-house warehouses to execute time-based inventory management. A critical advantage held by public warehouses was their ability to create economies of scale in distribution. In 1992, public contract warehouses shipped nearly two trillion pounds of product from their warehouses. With this volume, the warehouses often had more leverage than a small manufacturer with suppliers and carriers. The warehouse operator, therefore, could dictate the size and frequency of the shipment to meet JIT inventory requirements.

Furthermore, public warehouses could dedicate more resources to inventory management than would be efficient for some manufacturers. Expensive technology such as Electronic Data Interchange (EDI), bar coding, radio-frequency technology, scanners and specialized logistics software was critical to the successful implementation of JIT and prohibitively costly to some companies. Public warehouses, however, were able to spread the cost of this technology over many customers. By 1996, transport and logistics industries had become the world leaders in the use of advanced technologies such as EDI. USCO Distribution Services, of Naugatuck, Connecticut, for example, repaired personal computers, printers, and monitors for IBM. Some companies stated that they used public warehouses for service rather than storage.

The 1999 Annual Report published by *Logistics Management & Distribution* confirmed the shift to fewer but larger warehouse facilities. Warehousing costs, as a percentage of sales, rose 3.72 percent between 1997 and

1998. To compensate, warehouses began adding assembly, prepackaging and special labeling “value-added services” for their customers.

Respondents to a 1998 WERC member survey indicated that companies had decreased the number of warehouses in their networks by more than 2.5 percent for 1998 and expected to do the same in 1999. Manufacturing companies led the greatest decline, projecting a 23 percent decrease in the number of warehouses used (wholesalers predicted a slight increase).

New facilities in 1999 were estimated at 40 to 80 percent larger than existing warehouses. While this was expected to contain some of the rising costs, other factors could not be controlled. According to the 600-member International Warehouse Logistics Association (IWLA), labor, information technology, and ISO 9000 certification compliance remained key budget expenses at the end of the 1990s.

CURRENT CONDITIONS

Far from becoming obsolete as once predicted, warehousing has found its niche in the twenty-first century. By becoming more responsive and attune to customers’ needs, warehousing has remained an integral part of materials management. In fact, at the beginning of the twenty-first century warehouse construction was one of busiest segments of new construction in the United States. Warehouses are growing in size and their roles are changing. Cindy Dubin noted in *Food Logistics*, “As the supply chain evolves, so does the warehouse. With the new demands placed on warehousing, there’s one certainty: The warehouse won’t exist just to store inventory.” Companies are beginning to move such duties as light manufacturing and returns management to warehouse sites.

Trends that will likely dominate the way warehouses structure their businesses in the twenty-first century include compression of time and operations, increased automation, continuous flow, and customized warehousing. Compression of time and operations focuses on quick response and efficiency. As warehouses become bigger but fewer, more orders will be filled on a daily basis, requiring a flawless materials management and tracking system. Although widespread use of advanced automation, such as robotics, remains for the future, increased automation, including an effective conveyor belt system, will allow warehouses to better manage labor costs. Continuous flow offers customers smaller, more frequent shipments. What was once supplied quarterly or monthly will increasingly be shipped out weekly or even daily, allowing retailers to keep inventory costs low but also keep shelves stocked and rapidly restocked. Customized warehousing involves meeting specific and unique customer needs for such services as labeling and ticketing to process floor-ready merchandise.

INDUSTRY LEADERS

The top 2000 general warehouse contractors (by square foot of warehouse space) were: Exel plc (29.5 million square feet); GATX Logistics (22 million); Tibbet & Britten (15.1 million); the Kenco Group (13.1 million); and USCO Logistics (12 million); and DSC Logistics (11.8 million).

RESEARCH AND TECHNOLOGY

Employing the latest standards in shipping and warehouse technology was an industry standard for general warehouse operators. Because so many of the companies marketed themselves as logistics experts and as purveyors of value-added services, having the latest technological innovations was necessary to meet customer expectations. Within the warehouse industry itself, moreover, flexibility and efficiency were necessary to the survival of a firm. Technology enabled businesses to maintain levels of productivity.

One type of technology that saw rapid acceptance throughout the transportation industry was electronic data interchange (EDI). Allowing shipper and receivers to transmit invoices electronically, this mainframe computer system greatly reduced the routine paperwork associated with distribution. EDI was used by many large companies throughout the nation, putting pressure on general warehouse operators to install the system if they wanted to do business with these large companies.

In addition to EDI, general warehouses used electronic devices such as bar coding and radio frequency monitoring. These innovations enhanced the productivity and efficiency of warehouse operations and simplified inventory tracking. As customer expectations became more stringent and competition in the general warehouse industry increased, more warehouses were forced to invest in technology to remain contenders.

Improved technology appeared to contribute to the growth of the general warehousing industry. As traditional in-house storage and management facilities became obsolete, and the cost of upgrading outweighed the benefits of maintaining the facility, manufacturers looked to general warehouses to provide the high-tech warehousing facilities necessary for survival.

SIC 4226

SPECIAL WAREHOUSING AND STORAGE, NOT ELSEWHERE CLASSIFIED

This category includes establishments primarily engaged in the warehousing and storage of special products, not elsewhere classified, such as household goods, automobiles (dead storage only), furs (for the trade), textiles, oil, chemicals, lumber, whiskey, and goods at foreign trade zones. Warehouses primarily engaged in blending wines are classified in **SIC 5182: Wine and Distilled Alcoholic Beverages**.

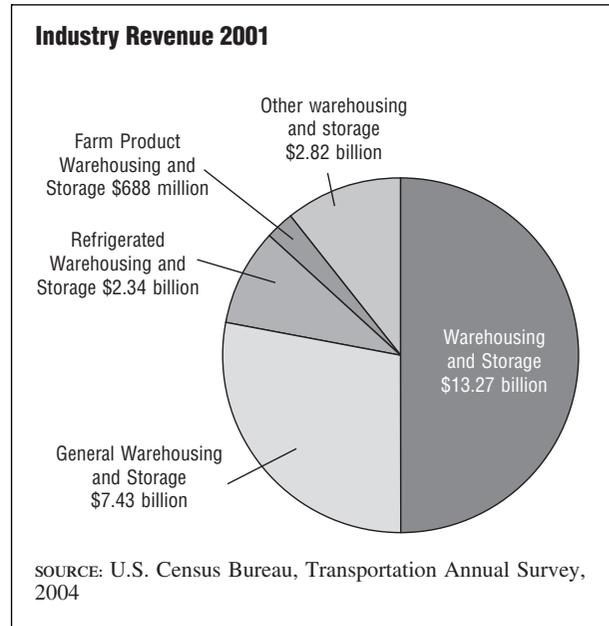

NAICS CODE(S)

493120 (Refrigerated Storage Facilities)

493110 (General Warehousing and Storage Facilities)

493190 (All Other Warehousing and Storage Facilities)

The special warehousing and storage industry is a heterogeneous group of companies serving a variety of niche-oriented markets. Businesses in this industry serve clients with both specific and unique storage needs. Be-

cause of this diversity, changes in the types of firms in operation occur frequently.

In 2001, the warehousing and storage industry as a whole had revenues of \$13.3 billion, up from \$12.8 billion in 2000. Of this amount, general warehousing and storage reported \$7.4 billion in revenue, followed by the refrigerated segment (\$2.3 billion) and the miscellaneous segment (\$2.8 billion). Only refrigerated warehousing and storage was down from the previous year. Employment for the industry as a whole was expected to increase steadily through 2012.

The majority of special warehousing and storage businesses in the 1990s were involved in petroleum bulk storage and oil and gasoline storage. Most of these warehouses were located in the vicinity of oil refineries in Texas and Oklahoma. A growing trend in the industry, however, was indicated by the steadily rising number of firms offering storage services at foreign trade zones. These facilities had expanded their services in response to increasing international trade. Frequently, these foreign trade zone warehouses are operated by companies whose primary business is custom house brokerage, classified in **SIC 4731: Arrangement of Transportation of Freight and Cargo**.

Companies engaged in petroleum-related storage benefited from the passage of the Clean Air Act and other environmental regulation requirements. Because states like California adopted stringent pollution control requirements in the mid-1990s, petroleum companies were forced to deliver the cleanest burning fuel available to certain markets. This clean burning fuel is shipped and stored separately from conventional gasoline and is often

blended with special additives, such as oxygenates, before final delivery to gas stations.

These storage and handling requirements were taxing for gasoline manufacturers with large, inflexible operations. The petroleum storage operators, however, were positioned to capitalize on the increased storage and processing demands. These specialty warehouse operators provided customers with safe, efficient, and reliable alternatives to storing and processing the fuel in-house.

While many companies provided petroleum storage, GATX Terminals Inc., the largest independent bulk terminal operation in the world, controlled the domestic industry. The company boasted 73 million barrels of storage worldwide, employed 6,000 workers in all operations, and generated approximately \$298 million in gross income for fiscal 1996. That year, GATX reported that 54 percent of its storage revenues came from petroleum, 25 percent from chemical storage, 20 percent from pipelines, and 1 percent from other products. GATX's bulk-liquid storage, distribution, and pipeline business rose sharply in 1999, with third quarter 1999 net earnings at \$6 million.

In 2002, due to the war in Iraq, oil supplies were dwindling and prices rose. But near the close of 2002, not only was there an increase in production from other sources, but Iraq began to pick up as well. In addition, demand was lower than it had been during the same time in 2001. The premium prices that the oil supply was expected to command did not materialize, and refiners were able to acquire the crude supplies at lower than expected cost.

As with petroleum storage, demand for foreign trade zone storage has increased. As companies expanded internationally, their traditional storage and distribution operations have, in some cases, fallen behind the competition. Rather than building large international transportation departments, some companies chose to hire outside companies to manage international storage and distribution. In an effort to better serve customers, some foreign trade zone warehouse operators introduced customs brokerage services and freight forwarding, in addition to warehousing. These comprehensive packages provide customers with one-stop shopping in the international logistics market.

In 2001, the industry leader was Boston-based Iron Mountain Inc., with \$1.3 billion in revenue and 11,300 employees. The company specialized in storage of records and other data or information products, such as microfilm, X-rays, computer disks, videotapes, and blueprints.

Baytank Houston Inc. of Seabrook, Texas, was a distant second, with 2001 revenues of \$433 million and 1,200 employees. Next was Auto Warehousing Co. of

Tacoma, Washington, with \$201 million in revenue and 600 employees. Rounding out the top five industry leaders were Houston-based VOPAK, with revenues of \$168 million and 500 employees, and Dallas-based Support Terminal Services, with revenues of \$122 million and 500 employees.

SIC 4231

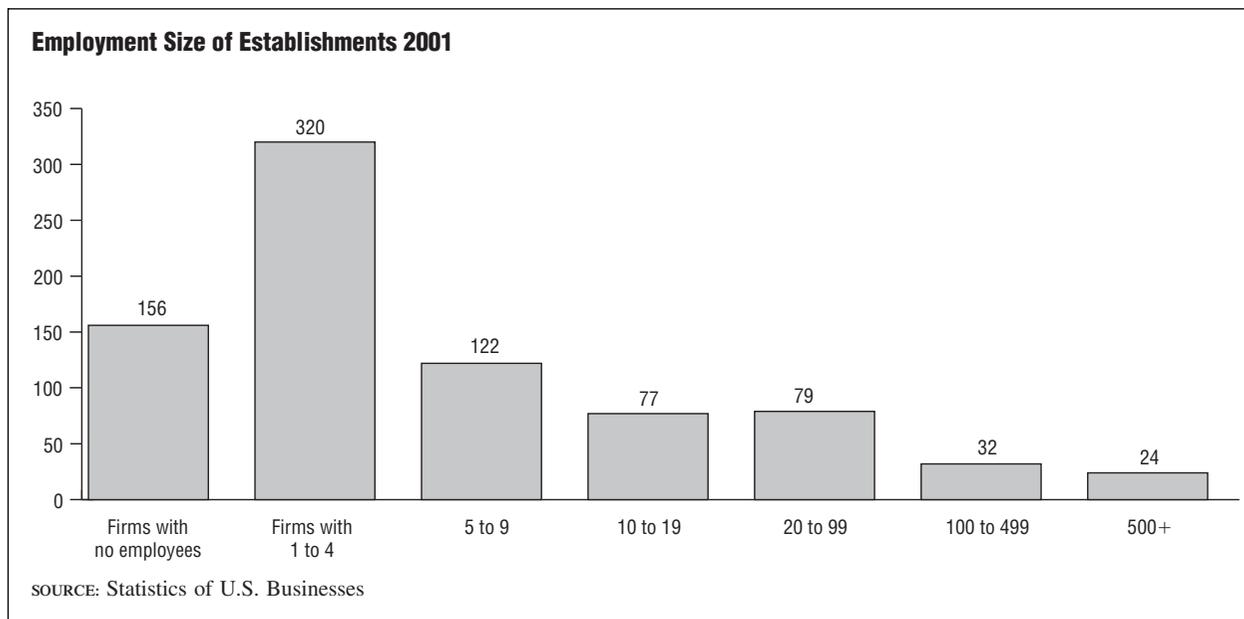

TERMINAL AND JOINT TERMINAL MAINTENANCE FACILITIES FOR MOTOR FREIGHT TRANSPORTATION

This category includes establishments primarily engaged in the operation of terminal facilities used by highway-type property carrying vehicles. Also included are terminals that provide maintenance and service for motor vehicles. Terminals operated by motor freight transportation companies for their own use are classified in **SIC 4212: Local Trucking Without Storage; SIC 4213: Trucking, Except Local; SIC 4214: Local Trucking With Storage; or SIC 4215: Courier Services, Except by Air**. Separate maintenance and service facilities operated by motor freight transportation companies are classified as auxiliary.

NAICS CODE(S)

488490 (Other Support Activities for Road Transportation)

Although trucking terminals provide a number of services, including showers for truckers and truck maintenance and repair, these establishments are primarily used for their storage and consolidation facilities. Freight is combined and redistributed at these terminals in an effort to reduce the distances and costs of transportation.

Terminals, therefore, are located in areas where the demand for transportation is high, and terminals are continually relocated according to shifting traffic patterns. While there are thousands of trucking terminals in the United States, most of these facilities are operated by trucking companies themselves and therefore are not included in this category.

The truck terminal industry boomed after the deregulation of the industry as a whole in 1980. Deregulation resulted in a 160 percent increase in the number of registered truckers between 1980 and 1991. These new truck companies were often small operations that could not afford to operate their own terminals. As the industry moved into the 1990s, however, shifts in both the economy and in distribution patterns reversed the truck terminal expansion. Although an increase in traffic in the southeastern United States fostered terminal growth in the south, many existing terminals were closed in the early 1990s.

A number of factors precipitated the terminal closings, such as the waning health of the trucking industry. By the late 1980s, many of the smaller operators who emerged after deregulation had been forced out of business. The post-deregulation boom was ended by the recession and an increase in competition from parcel carriers such as United Parcel Services. The remaining companies were large and generally operated their own terminal facilities. Even these large trucking companies were forced to streamline their terminal networks in the 1990s.

The focus on efficiency and quality in the 1990s further encouraged terminal closings. Shippers and truckers were committed to reducing cargo damage and handling costs. These reductions were often achieved by minimizing the number of times freight was handled. As

such, truck terminals were eliminated from the transportation equation if their use proved unnecessary according to freight handling standards, which emphasized efficiency over short-term cost savings.

One bright spot in the trucking terminal facility industry was the growth of the intermodal industry in the 1990s. Intermodalism, or piggybacking, is the use of two or more modes of transportation for freight movement. Often, railroads were unable to obtain right-of-way into ports because of the unavailability of land, creating an opportunity for intermodal truck terminals to be built in major ports.

Although the decline of the trucking industry had a negative impact on terminals, the growth in intermodal service presented opportunities for truck terminal facility expansion. Truck terminal owners continue to reevaluate location and access in search of new opportunities in a shrinking market. The transportation industry as a whole was expected to experience modest annual growth into 2012.

The industry leader in 2001 was Brake Systems Inc. of Portland, Oregon. The company posted revenues of 11 million that year. As its name implies, Brake Systems Inc. specialized in manufacturing and installing a variety of brake types, brake systems, and brake system designs.

According to the *Statistics of U.S. Businesses*, there were 810 firms operating 1,031 establishments in this industry in 2001, an increase from the 769 firms just the year before. There were 17,541 total employees earning a payroll in excess of \$452.5 million. About 17 percent of the firms employed 20 or fewer workers, and just 3 percent employed 500 or more.

SIC 4311**UNITED STATES POSTAL SERVICE**

This industry includes all establishments of the United States Postal Service.

NAICS CODE(S)

491110 (Postal Service)

INDUSTRY SNAPSHOT

The U.S. Postal Service is one of the largest organizations in the world. In fiscal 2002, it had nearly 753,000 employees and handled about 203 billion pieces of mail through an extremely complicated system of carefully coordinated activities. In addition to the national headquarters in Washington, D.C., the U.S. Postal Service consisted of regional and field division offices that together supervised 37,683 post offices, branches, stations, and community post offices throughout the United States. The U.S. Postal Service had a fleet of more than 215,000 vehicles and shipped millions of pounds of mail daily on various airlines, making it the nation's biggest shipper. It was the second-largest civilian employer in the United States during the early 2000s, behind Wal-Mart Stores, Inc.

The U.S. Postal Service was created as an independent establishment out of the old Post Office Department by the Postal Reorganization Act of 1970 and commenced operations on July 1, 1971. The industry was highly labor intensive, with employee wages and benefits accounting for 85 percent of the system's total costs. To cope with its soaring costs, the organization increased postal rates consistently, from 6 cents at the onset of the Postal Reorganization Act to 37 cents in 2002 for first-class letters. It also faced increasing competition from private mail and package delivery services, and new technologies such as facsimile services, and electronic mail and bill paying that reduced the need for postal services.

ORGANIZATION AND STRUCTURE

The purpose of the U.S. Postal Service was to process and deliver mail to individuals and businesses within the United States. This mission also entailed handling mail efficiently and protecting it from loss or theft. The Postal Service handled about 203 billion pieces of mail in 2002 through its interrelated system of 37,683 post office branches.

Organizational Hierarchy. At the top of the Postal Service's organizational hierarchy is a team of 39 officers. In charge of these officers is the postmaster general (PMG) and the deputy postmaster general, whose authority derived from the Postal Reorganization Act. The PMG is appointed by the nine governors of the Postal Service, who are, in turn, appointed by the president with the advice and permission of the Senate for overlapping nine-year terms. The governors and the PMG together appoint the deputy PMG, and these 11 people together form the board of governors. The remaining officers are appointed by the PMG, and the board of governors determines the nature and scope of activities of these officers. These officers consist of two associate postmasters general, five senior assistant postmasters general, 19 assistant postmasters general, six other headquarters functional heads, and five regional postmasters general. In addition to these officers, there are approximately 800 other persons in senior management positions in the country.

Geographical Distribution. The activities of the Postal Service are divided over five postal regions: central, eastern, northeastern, southern, and western. The reason for such field division is to reduce administrative layers and incorporate operating management expertise as near as possible to the locations where postal services are offered to the public. Each of the five regions has a number of “field divisions” that are regarded as the Postal Service's key organizational units, with all other local offices reporting to a division. Moreover, there are 74 field divisions located in key cities throughout the country, and there is a regional chief inspector at each of the five regions of the Postal Service. Any information or complaint with regard to postal violations is required to be presented to the closest postal inspector in authority. The five regional postmasters general are in charge of all the postal activities in a geographical region.

Economic Structure. The Postal Service is not considered a business, but rather a governmental institution designed to serve the U.S. public. When Congress created the Postal Service as an “independent establishment” of the federal government, however, one of the main objectives was to assure financial stability and self-sufficiency for the organization. In the 1970s this seemed a highly ambitious goal. At that time, not only did the Postal Service suffer from long-standing operating problems

and deficit-producing services, but it also faced a high inflation rate and rising cost of fuel. To cover its costs, the Postal Service received operating subsidies from the government, but these were discontinued in 1982, and the Postal Service has been self-supporting since that time.

The Postal Service is not supported by taxes or government appropriations. As a self-supporting organization, it must obtain its funds from its operating activities or through borrowing. Under this policy its debt reached nearly \$10 billion. From 1971 to 1994, prior years' losses accumulated to nearly \$9 billion. The Postal Service began to achieve positive net income in 1995, then reported four consecutive years of positive net income through 1998, when it had an operating surplus of \$550 million. From 1995 through 1998, the Postal Service had cumulative earnings of \$5.1 billion. Its debt was reduced from \$9.9 billion in 1992 to \$6.4 billion in 1998.

By the early 2000s, the Postal Service was losing money again and was saddled with more than \$11 billion in debt. In 2001, the organization recorded a net loss of \$1.7 billion, followed by a loss of \$676 million in 2002. Contributing to these poor financials were weak economic conditions and growing operational costs. The Postal Service also was trying to do more with less, adding some 1.7 million new addresses to its delivery base each year while scaling back its workforce by more than 34,500 career employees from 2000 to 2002.

Although postage rates held steady from 1995 to 1999, increases eventually were necessary to offset rising costs. New postage rates are reviewed and recommended by an independent body, the Postal Rate Commission, and then approved by the board of governors, a process that typically takes a year and a half.

Revenues come from different classes of mail. In 2002, almost 86 percent of all Postal Service revenue came from three classes of mail: first-class mail (54.8 percent), standard mail (23.8 percent), and priority mail (7.1 percent). Standard mail includes advertising mail, formerly known as third class or bulk-rate mail.

BACKGROUND AND DEVELOPMENT

The U.S. Postal Service has a long and rich history that began in the early days of the colonial period. This historical period gave birth to the first American post office. Following repeated failures to develop a postal system in colonial America in the seventeenth century, the British government delegated this critical responsibility to Thomas Neal in 1692. Neal's mail service was a dismal failure, and by 1707 the British government acquired the rights to the mail system. Although this new system was more successful than Neal's and broke even in the 1720s, it did not produce a profit until 1761. This newfound profitability was partly due to the management skills of Benjamin Franklin, who became co-deputy post-

master general in 1753, and partly due to a reciprocal agreement between the colonies and England.

Ironically, the successful postal service improved England's control over the American colonies at a time when the relationship between the two was deteriorating. The high postal rates were considered a prime example of "taxation without representation," and some Americans started to send mail via "alternative" mail distribution sources, such as postmen not associated with the British mail system who delivered mail for far less than what the colonial post office charged.

In 1774 Maryland newspaper publisher William Goddard initiated an independent postal system called the "Constitutional Post," which eliminated the need for alternative postmen. In 1775, the Second Continental Congress acquired the Constitutional Post and successfully ran the system throughout the Revolutionary War. In 1782 the Confederate Congress wrote an innovative, first-ever postal law allowing the Post Office a monopoly in the carrying and delivering of mail, establishing the office of postmaster general, setting postal rates, and carefully detailing the operating regulations of the postal service.

In 1792, the new Constitution gave Congress the right to establish post offices and roads. Therefore, Congress created a new postal law that established a new U.S. Post Office. This new law was more an addendum to the law of 1782 than a radical new legislation. The primary contribution was the establishment of the principles of the nation's postal policy, which stipulated that the Post Office was to be self-supporting (using any profits to expand the postal service), and that Congress (not the PMG) was to approve post offices and post roads. Therefore, Congress would completely control the post office and its growth. Moreover, the PMG was given the responsibility of managing the postal service, which included providing an annual budget to Congress that estimated the needs of the department.

In response to complaints by both rural and urban customers concerning high postal rates in 1851, Congress reduced the rates and stated that this would in no way reduce the postal service, even if postal deficits resulted from this action. Therefore, a customer-service policy, as opposed to a "self-supporting" policy drove the Post Office. This new policy eliminated distance as a factor in determining the price of a letter and led to greater use of the mail service through the modernization of the postal system, although it also produced annual postal deficits.

The next phase of the history of the U.S. Postal Service consisted of a series of significant events, including: initiation of mandatory prepayment of postage and the use of stamps in the 1850s; institution of a registered letter service in 1855 and a city free-delivery system in 1863; development of the first railroad post office in

1864, which revolutionized postal service by allowing employees to sort mail as they traveled on trains; introduction of mail delivery to farm homes in 1896 and parcel service to rural areas in 1913; use of automobiles to deliver the mail, replacing horses, in the early 1900s; and initiation of the first regular airmail service between Washington, D.C., and New York in 1918. In 1964, ZIP codes were introduced to identify each postal delivery area in the United States. “ZIP” is an acronym for “zone improvement plan.”

Postal Reorganization Act of 1970. The Postal Reorganization Act of 1970, which created the current structure of the U.S. Postal Service, was the most detailed and radical reorganization in two centuries. The postal department was removed from the president’s cabinet, and Congress was no longer able to set both postal employee wages and postal rates. The “new” Postal Service was able to run more like a business enterprise—for example, it could hire its own personnel.

Other specific changes resulting from the act included: establishment of the board of governors to oversee operations; creation of the independent Postal Rate Commission to provide advice to the board of governors on postal rates and classifications; establishment of provisions for an independent personnel system and direct collective bargaining between postal management and unions; authorization of a general “public service” subsidy in an amount equal to 10 percent (\$920 million) of the fiscal 1971 appropriations to the Post Office Department through the year 1979, and declining by 1 percent per year through 1984—by which time the Postal Service was expected to be self-sufficient; provision of a plan for gradually phasing out the preferential rates for various categories of mail, and assuring that rates covered only those costs directly applicable to the class plus some “reasonably assignable” portion of the system’s institutional costs; and authorization to modernize the postal system through borrowing money and issuing public bonds up to \$10 billion.

The 1990s, and most notably the years under Postmaster General Marvin Runyon (1992-98), marked a turning point for the Postal Service. From 1995 through 1998 the Postal Service had cumulative earnings of \$5.1 billion, compared to cumulative losses from 1971 to 1994 of \$9.9 billion. Under Runyon’s leadership, the Postal Service successfully set and communicated clear objectives, and improved automation, service, and customer satisfaction. It began using private sector tools, such as accepting credit cards and adopting longer hours, to better meet its customers’ needs.

Independent surveys confirmed that the Postal Service was achieving higher customer satisfaction. In 1998 the Pew Research Center for the People and the Press

reported that 89 percent of Americans rated the Postal Service the most favorably of any federal agency. According to a 1998 Roper Survey, 78 percent of all Americans had a highly or moderately favorable opinion of the Postal Service, the highest ranking of 15 federal agencies.

At the end of the twentieth century, the U.S. Congress was seeking ways to clarify the Postal Service’s role. As Postmaster General William J. Henderson noted in the 1998 Annual Report, “The potential exists for a redefinition or perhaps even a re-regulation of our services.”

CURRENT CONDITIONS

The Postal Service played a significant role in the development of the United States. Not only did it foster unity among the diverse individuals scattered over the nation, but it also contributed largely to the development of U.S. business. Over the years the U.S. Postal Service has received criticism about frequent rate increases, slow service, and lost mail. Proponents countered that the U.S. Postal Service actually improved the performance of the U.S. mail system in many dimensions, including finances, productivity, and service delivery. In 2002, President George W. Bush established a commission of nine individuals to evaluate the Postal Service and its future.

During the early 2000s, the Postal Service faced a number of significant challenges. In addition to a net loss of \$1.7 billion in 2001 and \$676 million in 2002, the organization was forced to operate in an environment of heightened security, characterized by mail-related terrorist acts that increased the cost and difficulty of operations.

In the wake of terrorist attacks against the United States on September 11, 2001, mail tainted with deadly anthrax bacteria was circulated in the postal system, causing several deaths. The Postal Service responded by implementing a number of security measures, including electron-beam irradiation for sanitizing mail in select locations. The organization also purchased nearly 90 million pairs of rubber gloves, as well as 5 million facemasks to safeguard its employee base. To protect postal customers, some 145 million postcards were sent to U.S. residents that provided explanations about what to do with suspicious items received via U.S. Mail.

Safety concerns did not stop with the anthrax scare, however. In 2002, the Postal Service was forced to contend with Luke Helder, a 21-year-old college student from Wisconsin who planted 18 pipe bombs in rural mailboxes. While no deaths resulted from the pipe bombs, a number of postal workers and residents were injured. During a time span of five days, the organization dedicated some 150 postal inspectors to the case—which covered five states including Colorado, Illinois, Iowa, Nebraska, and Texas—before it was finally resolved.

By the early 2000s, John E. Potter was serving as the Postal Service's postmaster general and CEO. At that time the organization faced stiff competition from competitors—although it had entered into limited partnerships with some of them, including an arrangement with FedEx to move first-class, express, and priority mail via air. Another source of competition came from the increasing use of e-mail. These factors were having an especially severe impact on first-class and standard mail, which dropped more than 4 billion pieces during 2002.

In late 2002, the Postal Service also was in the process of evaluating its arrangements with commercial airlines, which it had long relied upon for the transport of mail. In the wake of September 11, commercial airlines were not able to carry packages weighing more than 16 ounces. According to *Traffic World*, in order to achieve economies of scale, the Postal Service planned to cut back the number of airlines it used to move mail via commercial airlines. In addition, it was planning to eliminate the use of regional airlines. This led to protest among regional carriers, who appealed to Congress for intervention.

WORKFORCE

Nearly 753,000 people were career employees of the Postal Service in 2002, making it the second-leading civilian employer in the United States behind Wal-Mart Stores Inc. These individuals worked in facilities with contingents varying in size from one to more than 40,000 employees. The largest category of postal employees consisted of clerks and city delivery carriers, which constituted some 65 percent of the workforce, or about 490,295 individuals. The next largest categories were full-time rural delivery carriers and mail handlers, constituting 120,076 employees, or almost 16 percent of the total workforce. More than 37,800 people held supervisory and managerial positions, and more than 47,788 attended to building and vehicle maintenance. There were 25,771 postmasters in total, and the rest of the workforce filled a number of specialized jobs that ranged from nurses to the postmaster general.

The postal employees in the United States are unionized. The four major organizations that represent the postal workforce in collective bargaining with management over wages and other terms and conditions of employment are: the National Association of Letter Carriers (NALC); the American Postal Workers Union (APWU); the National Rural Letter Carriers' Association; and the National Post Office Mail Handlers, Watchmen, Messengers, and Group Leaders Division of Laborers' International Union of North America. The APWU and the NALC, representing clerks and carriers respectively, were the two largest of these organizations.

During the early 1990s, the U.S. Postal Service suffered a series of highly publicized, unfortunate incidents involving disgruntled or former employees. At post offices in several cities, such an employee brought a gun to work and shot fellow workers and managers. These incidents occurred far more frequently at post offices than in other businesses, raising concerns about the working environment. Some observers attributed the violence to the fact that relations between post office workers and management had grown increasingly tense, and claimed that some disturbed individuals were unable to handle the everyday stress of the job. Others blamed the strong employee unions for making it difficult for managers to discipline or terminate workers with behavioral or emotional problems. The Postal Service tried to address these concerns through reorganizations, offers of counseling, and training programs.

SIC 4412

DEEP SEA FOREIGN TRANSPORTATION OF FREIGHT

This category includes companies primarily engaged in operating vessels for the transportation of freight on the deep seas between the United States and foreign ports. Establishments operating vessels for the transportation of freight which travel to foreign ports and also to

noncontiguous territories are classified in this industry. A related industry group is **SIC 4424: Deep Sea Domestic Transportation of Freight**.

NAICS CODE(S)

483111 (Deep Sea Freight Transportation)

INDUSTRY SNAPSHOT

Deep sea foreign transportation of freight is greatly affected by the global economy and international competition. U.S. companies in this industry compete with each other and with foreign carriers. Competition in the industry is heightened in part because U.S. regulations have tended to make costs for U.S. ship owners higher than for ships bearing the flags of other nations. Many American-owned ships carry flags of nations with lower levels of expenses in order to stay competitive in the cargo transport business. By operating under the authority of other countries, U.S. shipping operations estimated they could cut labor costs by as much as 80 percent.

In the early 2000s, U.S. merchant ships engaging in the deep sea foreign transportation of freight carried more than 1 billion tons of cargo, according to The Transportation Institute. The United States remained the world's largest trading nation, with export and import trade equaling one-fourth, or more than \$500 billion of total world merchandise trade. By far, the majority of this trade cargo was transported by water. Nonetheless, in 2000 the U.S. ranked eighteenth in number of oceangoing vessels, and the U.S. flag merchant fleet ranked twelfth on a dead-weight tonnage basis. The U.S. fleet's share of oceanborne commercial foreign trade, by weight, was less than 5 percent.

Although tonnage of foreign merchandise trade increased over previous years, rising costs and price competition still meant declining profits for U.S. ship owners. Some shipping firms received subsidies from the U.S. government to compensate for high U.S. flag operating costs. These subsidies fell under the Maritime Security Program, in which steamships were made available to the U.S. Defense Department should the need arise.

By 2000, there were 454 active, privately owned U.S. vessels of 1,000 gross tons or more engaged in oceangoing transportation of freight, according to the U.S. Bureau of Transportation Statistics. The U.S. flag merchant marine's active oceangoing fleet consisted of 142 tankers, 136 general cargo ships, 90 container ships, 60 roll-on/roll-off vessels, 15 dry bulk ships, and 11 combination passenger/cargo ships.

The outlook for the U.S. flag fleet was predicated on several factors: foreign competitors; costs of labor, fuel, insurance, and other operating expenses; and volume of trade in relation to available cargo space. Overcapacity

has been a problem for U.S. and foreign merchant fleets for many years, resulting in lower freight rates.

In recent years, the top foreign-trade water gateways for freight cargo (ranked in descending order, based upon trade dollars) were: the Port of Long Beach, California; the Port of Detroit, Michigan; the Port of Los Angeles, California; the Port of New York, New York; and the Port of Buffalo-Niagara Falls, New York.

ORGANIZATION AND STRUCTURE

The U.S. merchant deep sea fleet is made up of three categories of service: liner, non-liner (or tramp), and tanker.

Liner service includes regular, scheduled stops at ports along a route. Vessels operating as liners may be owned or chartered by an operator. Operators must accept any legal cargo they are equipped to carry, unless it does not meet the minimum freight requirements of the operator. Liner service usually carries manufactured goods. Often, two or more carriers along a route form "conferences" in order to regulate rates and competition. All conference members must charge the same freight rates, although rates may fluctuate according to supply and demand for cargo space. Liner service vessels are designed to handle the cargo most often shipped along their routes. Trip frequency depends upon the demands for shipping along that route.

Non-liner, or tramp, shipping is scheduled individually by a customer who charters the ship to carry its cargo. Tramps usually carry only one type of bulk cargo, such as coal, ores, grain, lumber, or sugar. On occasion, two shippers of the same commodity may charter the ship jointly. Freight rates vary depending on the negotiations of the ship owner and shipper and the supply of and demand for cargo space. The tramp freight market peaked in 1995 and continued to decline except for a few peak rate periods.

Tanker service carries liquid cargoes, especially crude oil and petroleum products. Tankers may be operated by privately owned companies for charter or by the oil company or other company as part of its entire industrial organization. Oil companies also charter extra ships as needed. However, they are not the only ones to employ ships exclusively for their own trade. Other companies may have specialized ships for transport of their goods. For instance, produce growing and distributing concerns operate fleets of refrigerated vessels for transportation purposes.

Some companies chartered ships on a long-term basis. Doing so provided many of the same advantages of owning a fleet without the enormous investment. By owning a fleet or contracting for long-term charter, the shipper was able to maintain complete control over ship-

ping schedules. It could divert its ships to ports where demand for the product was high, and it could engage for service a fleet of ships with crews that had experience in handling a particular commodity.

Ships became increasingly more specialized during the twentieth century, and specialized ships were built to carry such diverse products as bulk cement, liquid chemicals, coal, iron ore, liquefied natural gas, newsprint and other paper products, petroleum and petroleum products, wood chips and wood pulp, refrigerated foods, and heavy equipment such as railroad locomotives or electric generator parts. Because many specialized ships were so expensive to build, a ship owner could agree to have a ship built for a company with the stipulation that the company agreed to lease the ship for most of its active life.

There were several federal agencies that administered laws and policies concerning the U.S. merchant fleet. The main agency was the Maritime Administration (MARAD), which was charged with coordinating the requirements of ship owners, shipbuilders, shippers, and labor unions for both domestic and foreign trade. In the late twentieth century, MARAD initiated and administered construction and operating subsidies, capital construction funds, and market development and maritime training.

BACKGROUND AND DEVELOPMENT

Since the earliest days in the United States, the federal government has considered the maintenance of a viable merchant fleet to be a priority for national security and the health of its foreign trade. During wars and other emergencies, the U.S. military chartered private ships to transport supplies.

Congressional legislation throughout U.S. history has helped to protect and promote the U.S. merchant fleet. Legislation in 1845 required the USPO to transport mail abroad on U.S. merchant ships. Mail contracts were offered as incentives to shipping companies to establish shipping lines with Cuba, Panama, and major European ports. The law also stipulated that merchant ships could be converted to warships if necessary. The Military Transportation Act, passed in 1904, directed the U.S. Army and Navy to give preference to U.S. flagships for the transportation of supplies for direct support of military operations abroad.

The Merchant Marine Act of 1928 offered incentives to the shipbuilding industry to build new ships so that U.S. fleets could compete more effectively in the world market. This legislation, however, failed to spur the construction of many new ships and U.S. foreign shipping continued to decline as it had for many years.

The Merchant Marine Act of 1936 has been called the Magna Charta for U.S. shipping. It called for the first

direct aid to merchant fleets for construction and operation. It also authorized the government to build ships and charter them to private companies for operation on foreign routes if private citizens did not provide that service. It required subsidized fleets to set up special funds to replace aging ships, provided loans and mortgage insurance, and authorized a training program for American crew members. That landmark piece of legislation was followed in 1954 by the "Fifty-Fifty Law," which required that at least half of the country's foreign aid or humanitarian aid cargoes be carried abroad by U.S. merchant ships.

A weak merchant marine was regarded as unacceptable to the U.S. Department of Defense, as the military has historically relied on private ships to carry military cargo during emergencies. Although all U.S. presidents since George Washington have recognized the importance of a strong merchant marine for the nation's security, the industry has not always received the support it needed to remain viable and to compete successfully with foreign ship operators. Presidents George Bush and Bill Clinton promised reform in order to maintain the shrinking U.S. merchant fleet, which carried only about 15 percent of U.S. exports in the early 1990s, according to *The Wall Street Journal*. The National Performance Review headed by former vice president Al Gore made several reform recommendations regarding the maritime industry, including striking down legislation that forced U.S. flag ships to carry military and aid cargoes; curtailing subsidies; repealing antitrust protection for carrier conferences established under the 1984 Shipping Act; and extending the U.S. flag to carrier lines that had foreign investors.

The Merchant Marine Act of 1970 was an attempt to counter several growing problems in the shipping industry. The U.S. fleet at that time carried only a small portion of the nation's foreign trade and a large portion of its ships were due to be scrapped because of age within the next few years. The 1970 legislation called for the construction of 300 merchant ships, deferred taxes for U.S. shipping companies if the money was put into funds to replace aging vessels, and operating and construction subsidies.

Despite the best intentions and stated policies of the U.S. government, American companies engaged in foreign deep sea transportation have been in trouble for many years. Operation Desert Shield and Operation Desert Storm, the 1990 to 1991 confrontation with Iraq over its invasion of Kuwait, called for a gigantic shipping effort to bring U.S. supplies and equipment to the Middle East. The military enlisted the services of the merchant marine for this task. It also used several dozen chartered transport ships it kept fully loaded and ready. However, even these privately owned ships could not handle the

demand of military shipments, and the U.S. was forced to turn to foreign transport to carry equipment and supplies. During the build-up of forces, almost half of the 200 ships carrying equipment to Saudi Arabia were foreign-owned. This dependence on foreign vessels was, in part, a consequence of the U.S. fleet's incompatibility with military needs. The U.S. military needed Ro/Ro (roll on/roll off) ships for ease of transport, but according to a *Fortune* magazine article, half the U.S. fleet consisted of oil tankers, and the rest were containerships or bulk carriers. *Fortune* also noted that although ships were much larger than in 1950, the U.S. shipping capacity had slipped by a third during that time.

Like the rest of the world's fleets, U.S. bulk carriers and supertankers were aged and worn. But replacing them was expensive, and the industry was likely to be unable to afford replacements because of its perennially shaky financial standing. After years of debate, the U.S. Congress finally passed the Maritime Security Act in 1996 by an overwhelming margin. This act reformed outdated maritime regulations and ensured that privately owned merchant ships would be available to meet national security sealift requirements. It also established a program to provide participating carriers with \$1 billion in operating assistance over 10 years.

Prior to passage of the act, the two largest U.S. shipping companies, American President Companies and CSX Corporation's Sea-Land Service, Inc., considered registering their fleets overseas and flying the flag of another nation unless the United States relaxed its rules and regulations, which ship owners regarded as prohibitively expensive. One of those restrictive rules stated that shipping lines must buy ships built in the United States in order to receive operating subsidies. John Lillie, president of the American President Lines Ltd. (APL), said that ship lines needed to have more freedom to buy vessels overseas because of the lower costs of those products.

Despite threats that even surpassed the passage of the Maritime Security Act, in January 1997, APL chose to remain a U.S. flag carrier, retaining at least a 51 percent U.S. ownership, by enrolling nine of its largest ships in the Maritime Security Program in return for \$2.1 million per ship in annual subsidies for a total \$18.9 million. Its other 38 vessels were enrolled in December of 1996. Nevertheless, APL Limited announced in April of 1997 that it was merging with Neptune Orient Lines LTD, a Singapore-owned and operated steamship line.

Sea-Land Services, Inc. also applied to the Maritime Security Program. The U.S. government accepted 15 of its ships. For this, Sea-Land received \$2.1 million per year for each ship participating in the program.

Legislation to deregulate the ocean shipping industry continued to be debated within the halls of Congress after

the National Industrial Transportation League proposed the issue in January 1995. Such reform would enable shippers to operate in a more certain regulatory environment and, according to steamship lines, would improve shipper-carrier relations and the efficiency of American exporters, plus reduce the federal government's involvement in unnecessary regulation.

In March of 1997, legislation to allow confidential contracting between individual ocean common carriers and shippers and other measures such as the making public of tariffs and the reduction of time required to post such a tariff rate increase were proposed to change the Shipping Act of 1984. Called the Ocean Shipping Reform Act, the bill, in essence, would eliminate the Federal Maritime Commission (FMC) and transfer remaining functions to an expanded and renamed Surface Transportation Board. If passed, the regulatory changes would take place in 1998 with the FMC eliminated in 1999.

Tankers and Oil Spill Legislation. Transport of oil in bulk began in the late 1880s. Tankers in the more than 100 years since then have changed dramatically, with ship work handled more by computers, thus cutting back on the size of the crew. The enormous size of the tankers of the modern era has also increased the risk of oil spills and the impact such spills have on the environment. The Alaskan oil spill in Prince William Sound by the *Exxon Valdez* in 1989, which caused significant ecological damage to the area, thus served as a catalyst in the institution of stricter environmental regulations for tankers and other vessels.

A U.S. law passed in 1990 required all tankers sailing in U.S. waters to be equipped with double hulls to prevent spills if the outer hull was damaged. The shipping industry claimed that another rule included in the act could shut down the shipping industry in U.S. waters. The rule required carriers to provide environmental-liability guarantees in the form of insurance, letters of credit, surety bonds, or Protection and Indemnity (P&I) clubs that insured more than 95 percent of the ships traveling in U.S. waters. However, the liability allowed was open-ended, making it impossible to find guarantors. This rule was not implemented pending resolution of the problem.

Although the number of oceangoing vessels dramatically decreased, fleet productivity, in terms of cargo-carrying capacity, improved by 42 percent since 1972. The last operating differential subsidy (ODS) contract expired in 2001. As of January 1999, three companies still held ODS contracts that covered seven vessels in the bulk trades: Ocean Chemical Carriers, Ocean Chemical Transport, and Liberty Maritime. Under 1996's Maritime Security Program (replacing ODS), 47 U.S. flag vessels remained as participants. Companies that were awarded

MSP agreements included: American Roll-On Roll-Off Carrier, American Ship Management, Central Gulf Lines, Farrell Lines, First American Bulk Carriers, and Waterman Steamship Lines.

The annual inflation rate for water transportation as of November 1999 was approximately 6.1 percent, a dramatic increase from 1997's 0.5 percent. Another 4 percent increase was expected for 2000. The biggest hike was for inbound deep-sea foreign transportation of freight.

The economic boom of the mid-1990s caused many ship owners to replace their aging vessels, the new vessels being delivered 18 to 24 months later, just when the market plummeted. The Baltic Freight index dropped and Japanese steel production dropped 13 million tons between 1998 and 1999. Seaborne trade in chemical products dropped 1 percent in 1998, and U.S. petrochemical shipments to the Far East dropped 18 percent. Although domestic business was booming, the Far East crisis left many owners of new vessels "all dressed up with nowhere to go." Consequently, in 1998, demolition of older vessels increased as owners attempted to avoid continued financial losses. The biggest demolition efforts in 1998 were in the Handy size (20/49,999 deadweight) of vessels in the 20 to 25 year age range.

CURRENT CONDITIONS

During the early 2000s, companies engaged in the deep sea foreign transportation of freight contended with a number of different challenges. While reduced levels of consumer and corporate spending, as well as lower production levels, affected shipment volumes, concerns over security and labor issues also plagued the industry. In the wake of a sluggish economic climate, made worse by the terrorist attacks of September 11, 2001, conditions were especially bleak for carriers operating routes in the North Atlantic. In 2001 and 2002, these companies struggled with dangerously low shipping rates that were taking a toll on carriers' financial health, leading to significant losses. According to *Country Views Wire*, member companies of the Trans Atlantic Conference Agreement saw their market share decrease significantly from 1994 to 2000, falling from 70 percent to 46 percent. The conference membership base also was on the decline, falling from 17 shipping lines in 1997 to a mere seven in 2001. Making matters worse was the fact that trans-Atlantic routes were stagnant in comparison to trans-Pacific routes that benefited from high-growth nations in regions such as Asia.

Shippers on the West Coast also had their share of challenges. In the fall of 2002, dockworkers at 29 coastal ports staged a lockout that lasted 10 days when the International Longshore and Warehouse Union failed to come to terms with the Pacific Maritime Association. The

lockout created a number of significant problems. Hundreds of ships were stranded, leading to congestion at area seaports. In addition to losses that some industry observers estimated would cost shipping companies anywhere from \$400 to \$600 million, the lockout had a more severe impact on the larger U.S. economy. For example, during the lockout *JoC Online* reported: "Analysts and business leaders have warned the shutdown will cause a noticeable increase in plant closings, job losses, and financial market turmoil. Already, storage facilities at beef, pork and poultry processing facilities across the country are crammed with produce that can't be exported." The publication revealed that the lockout's overall impact on the U.S. economy could range in the billions of dollars.

The terrorist attacks against the United States on September 11, 2001; a terrorist assault on the *USS Cole* in Aden, Yemen; and the U.S.-led war with Iraq in early 2003 were all factors that led to heightened concerns over security within the industry, as well as higher insurance rates for shipping companies. Faced with these threats, congressional leaders and industry experts were challenged with improving security levels without causing significant shipment delays. While it appeared that at least some standing delays were imminent, the industry was working to improve security by using new technology to insure the integrity of shipments. Among technologies being evaluated by the U.S. Department of Defense and the U.S. Department of Transportation were so-called "Eseals," which according to the September 2002 issue of *World Trade* were "metal bolts with radio transmission devices embedded. In the event of tampering, a radio frequency signal alert is sent to a central communication center." The publication also reported that global positioning satellite and cellular technologies were being employed in conjunction with Eseals in a program called CargoMate, which sought to monitor truck shipments en route from various ports to their final destinations.

RESEARCH AND TECHNOLOGY

Foreign shipping benefited from a revolutionary improvement first introduced in domestic transport in 1956—containerization of freight as part of an integrated transportation system. Prior to this new design, cargo was lifted aboard either in separate packing crates or bundled on pallets. However, container shipping involved large containers that fit the chassis of a tractor-trailer and that could be packed and sealed by the manufacturer, transported via truck to the ship terminal, removed from the truck chassis, and placed in the cargo hold of the ship with a large crane that was actually part of the ship. At its destination port, the container was lifted off the ship, placed on the truck chassis, and driven to its ultimate destination. The containers could also be hauled by train if necessary. This innovation eliminated much of the

handling that cargo once required. With this integrated system, it was handled once to pack it and once to unpack it, neither time by ship personnel, thus reducing the risk of damage and liability on the part of the ship owners.

Containerization also led the way to Ro/Ro (roll-on/roll-off) ships with their gigantic cargo doors on the sides and stern that allowed large vehicles or other large cargo to be driven or rolled on and off. Conversion to containerships was an expensive investment for ship owners, terminal operators, and port agencies. The adoption of containerships also led to the establishment of new companies that bought containers and leased them to the ship owners, thus removing from the ship owners the complex problem of keeping track of the whereabouts of empty containers.

In recent years, a number of shipping lines have installed sophisticated computers and information technology to provide shippers with access to information about their cargo, keep track of rates, and allow customs officers to screen cargo while the ship is still at sea.

The near future was expected to be marked by the introduction of significantly faster shipping vessels. David L. Giles, an aeronautical engineer, has invented a new craft dubbed FastShip. The new breed of freighter would be 863 feet in length and marry jet-ski technology to a novel hull design 100 feet shorter than the conventional super freighter. FastShip is estimated to cross the North Atlantic at speeds up to 40 knots in 3.5 days as compared to existing ocean service requiring seven to eight days. If the ship is successful, its biggest benefit will be delivering high-value time-sensitive (HVTS) cargo, such as automobiles and automotive parts, pharmaceuticals, apparel, and other consumer goods, on a door-to-door basis in five to seven days as opposed to the current 14 to 35 days that existing services require. Japanese researchers are experimenting with ships driven by superconducting electromagnets and ships propelled by water jets and powered by gas turbine engines. Further in the future, a Techno-Superliner might be capable of traveling between Japan and the United States in three days.

SIC 4424

DEEP SEA DOMESTIC TRANSPORTATION OF FREIGHT

This industry consists of establishments primarily engaged in operating vessels for the transportation of freight on the deep seas between ports of the United States, the Panama Canal Zone, Puerto Rico, and U.S. island possessions or protectorates. Also included are operations limited to the coasts of Alaska, Hawaii, or Puerto Rico. Establishments engaged in operation of vessels for transportation on the deep seas between the United States and foreign ports are included in the entry for **SIC 4412: Deep Sea Foreign Transportation of Freight**. Establishments primarily engaged in transportation of freight on the Great Lakes and St. Lawrence Seaway are included in **SIC 4432: Freight Transportation on the Great Lakes—St. Lawrence Seaway**. Establishments performing transportation of freight on the intracoastal waterways paralleling the Atlantic and Gulf coasts are classified in **SIC 4449: Water Transportation of Freight, Not Elsewhere Classified**.

NAICS CODE(S)

483113 (Coastal and Great Lakes Freight Transportation)

INDUSTRY SNAPSHOT

Deep sea domestic transportation of freight is part of a massive interrelated system of transport of manufactured and raw materials. According to the U.S. Army Corps of Engineers, there were more than 7,850 vessels operating on coastal and noncontiguous waters in 2000. Among them were 3,916 dry cargo barges; 1,612 towboats; 1,311 dry cargo and passenger/offshore sup-

port vehicles; 618 tanker barges; 240 vehicular ferries and railroad cars; 128 tankers; and 27 railroad car floats.

Although the health of the industry depends in large part on the health of the U.S. economy, domestic deep sea transportation plays an important role in the nation's private and public interests. Oceangoing domestic vessels facilitate business between various areas of the country by providing relatively low-priced shipping service and are part of the vast network of trains, trucks, and inland water carriers that keeps the nation's commerce moving. The industry also supports millions of other jobs at shipbuilding yards, seaports, and terminals. In addition, the domestic waterborne shipping industry is vital to national defense interests, as it has relieved rail congestion and provided transport of military equipment and supplies during periods of national emergency.

In 2000, the deep-sea sector of the U.S. domestic transport industry carried approximately 1.1 billion short tons (2,000-pound tons), according to the U.S. Army Corps of Engineers. Total coastal waterborne commerce for that year (by type of traffic) was 229 million metric tons.

Much of the success of the U.S. deep sea domestic industry over the years has been reliant upon oil drilling in Alaska. Since the 1989 oil spill disaster involving the *Exxon Valdez* in Alaska's Prince William Sound, new laws aimed to prevent oil spills in U.S. waters have become a serious concern for U.S. shipping companies. The Oil Pollution Act of 1990 required that all oil products be conveyed in double-hulled ships in order to prevent a repeat of the *Exxon Valdez* spill. The law also required each carrier to provide a guarantee of financial responsibility in the event of a spill. Ship owners claimed that the law, as written, threatened the survival of domestic shipping.

ORGANIZATION AND STRUCTURE

The U.S. deep sea fleet consists of three categories of service: liner, nonlinear (or tramp), and tanker service.

Liner service includes regular, scheduled stops at ports along a designated route. The operators either own or charter the ships and must accept any legal cargo they are equipped to carry, unless it does not meet the minimum freight requirements. Liner service usually carries manufactured goods. Often, two or more carriers form "conferences" in order to regulate rates and competition along a route. All conference members must charge the same freight rates, although the laws of supply and demand may affect rates from one sailing to the next. Frequency of trips depends upon the demands for shipping along the route.

Nonliner, or tramp, service is scheduled individually by a customer who, in essence, is chartering the ship to

carry its cargo. Tramps generally carry only one type of bulk cargo, usually a raw material such as coal, ores, grain, lumber, or sugar. On occasion, two shippers of the same commodity charter a ship jointly.

Merchant ships have become increasingly more specialized, especially during the last half of the twentieth century. Special ships were designed to carry bulk cement, coal, iron ore, liquefied natural gas, wood chips and pulp, refrigerated foods, and heavy equipment. These ships, operating as nonliner service, were often on long-term lease by one company. Because the ships were so expensive to build, the ship owner could require the company to sign a long-term lease for most of the life of the vessel before beginning construction.

Tankers carry shipments of liquid cargoes, especially crude oil and petroleum products. Oil companies could own and operate their own tanker fleets and charter privately owned ships as needed. The transport of oil in bulk began in the late 1880s. Tankers in the 100 years since then have changed dramatically, with ship work handled more by computers, thus cutting back on the size of the crew. The enormous size of the tankers of the modern era has also increased the risk of oil spills and the impact such spills can have on the environment. The infamous Alaskan oil spill in Prince William Sound by the *Exxon Valdez* in 1989, which caused significant ecological damage to the area, thus served as a catalyst in the institution of strict environmental regulations for tankers and other vessels.

One innovation in oil product shipment was the tug-barge. The bow of the tug fits into a notch in a barge weighing up to 20,000 tons and pushes the barge. This vessel was devised as a way to cut shipping costs on tanker routes from the Gulf of Mexico north along the eastern seaboard of the United States. The tug-barge requires only a fraction of the crew needed aboard a tanker.

Domestic shipping includes coastwise, intercoastal, and noncontiguous services. Coastwise shipping refers to movement of cargo along the coastlines of the 48 contiguous states, which includes shipment of goods between the Atlantic and Gulf coasts. For the most part, tankers and ocean tug-barge systems carry petroleum and tramps carry dry bulk cargoes along this route.

Intercoastal shipping includes movement of cargo between Gulf and Pacific ports and between Atlantic and Pacific ports. Most traffic of this type consists of oil tankers carrying their cargo from Alaska to Gulf ports. Noncontiguous shipping includes service to Alaska, Hawaii, and U.S. territories and possessions. Outbound Alaskan shipping consists largely of petroleum products and crude oil; inbound service carries consumer goods

for state residents. Hawaii and Puerto Rico rely on deep-sea freight to transport goods in and out of their islands.

Several federal agencies promoted and regulated the U.S. merchant ships before the Maritime Administration (MARAD), part of the Department of Commerce, was given jurisdiction in 1950. The Merchant Marine Act of 1970 strengthened and expanded the MARAD's function. It brought the many facets of the merchant marine together in order to ensure the strength of the industries involved, including shippers, shipbuilders, and ship owners, as well as the various unions in each of those industries. MARAD guarantees loans for shipbuilding as well as providing other subsidies and tax benefits for construction of new ships by fleet owners.

BACKGROUND AND DEVELOPMENT

Cargo ships showed little design improvement between 1850 and the late 1950s. Cargo of various shapes and sizes was stored in five different cargo holds. But in the late 1950s and the 1960s, ship design and the shipping industry were revolutionized.

In 1956, when the T-2 tanker *Ideal X* left Houston, Texas, a new era of deep-sea shipping was launched. Ship owner Malcolm P. McLean had initiated a new approach to shipping cargo by which the functions of both truck and ship were combined in an integrated transportation system. McLean had modified a 35-foot long tractor-trailer, so that the "container" holding the cargo could be lifted off the tractor-trailer chassis. These containers could then be loaded onto the ship by crane and stacked in rows. When the cargo reached its destination, each container was lifted off the ship and put back on a truck chassis. The cargo no longer had to be loaded and unloaded onto trucks at the ship terminal. The containers were packed and sealed by the shipper, then unpacked by the recipient of the goods at its ultimate destination rather than at the terminal. The containers could also be transported aboard freight trains. This new integrated transportation system saved time and drastically reduced the number of times a crate or pallet of packages was handled, thus eliminating instances when damage could occur.

Further development brought the addition of a ship-board crane so that the ships could unload at any port as long as there was a dockside apron large enough to accommodate a truck-tractor. The use of the container shipment method also cut down on the number of hours a ship had to be in port loading and unloading, thus resulting in less "down time." This improvement reduced the number of ships needed to maintain a specified frequency of service on a scheduled route. This revolutionary method of shipping quickly caught on among domestic and foreign carriers.

Roll-on/Roll-off (Ro-Ro) ships were a variation of the container ship: containers were placed on wheeled conveyors that are driven aboard the ship through huge cargo hold doors in the sides and stern of the ship. The containers were moved by ramps and elevators to their places in the cargo hold. The driver's cab was detached from the conveyor and driven back on shore. The container and conveyor remained on board to be unloaded at their destination. Roll-on/Roll-off ships were used to convey vehicles or other large cargo.

A speedier version of the container ship is the LASH (Lighter Aboard Ship) vessel. LASH ships are about 800 feet long. Barges (lighters) loaded with cargo are hoisted on board the LASH vessel by a crane on board the ship and stored in cargo holds.

The federal government has long held that a strong merchant marine was in the best interest of the country, both militarily and economically. Various laws and acts have been passed by Congress to protect and promote the merchant fleet operating in foreign and domestic trade. The Merchant Marine Act of 1920, which included the Jones Act, called for a merchant marine of "the best equipped and most suitable types of vessels sufficient to carry the greater portion of its commerce and serve as a naval or military auxiliary in time of war or national emergency." According to this law, ships carrying cargo between domestic ports must be U.S. flag ships, owned by U.S. citizens and built in U.S. shipyards, thus protecting domestic trade from foreign competition.

In March of 1997, legislation to allow confidential contracting between individual ocean common carriers and shippers was proposed by Congress to reform the Shipping Act of 1984. Called the Ocean Shipping Reform Act of 1998, the bill, in essence, eliminated the Federal Maritime Commission (FMC) and transferred remaining functions to an expanded and renamed Surface Transportation Board.

The domestic fleet was relatively old, but ship owners were reluctant to replace their aging ships very quickly because of low profit margins. In 1994, for example, one merchant vessel capable of carrying seven gross tons and one tanker capable of hauling 17 gross tons were constructed, according to figures available from the U.S. Maritime Administration. No new ships were constructed in 1993, and in 1992, three merchant vessels with a total of 44 gross tons hauling capability, one cargo vessel capable of carrying 32 gross tons, and two tankers with a hauling capability of 12 gross tons were constructed. According to the *U.S. Industrial Outlook*, published by the U.S. Department of Commerce, the ship owners were facing stricter laws governing hazardous materials, waste disposal, vapor recovery, crewing requirements, and inspections. Any new regulations would affect profits and expenses of fleet owners.

Presidential administrations have also supported proposals to help boost the U.S. shipping lines and make them more competitive. President Bill Clinton indicated support to revitalize U.S. shipping and a number of potential remedies were under consideration, including regulatory relief, tax credits, and bankruptcy law revisions. In the wake of the *Exxon Valdez* oil spill in Alaska, however, the Oil Pollution Act of 1990 called for stronger regulation of oil transport. A rule from that same act, designed to strengthen pollution controls and clean-up laws, was intended to insure that oil-shipping firms would be able to pay for damages from oil spills. The rule required ship operators to obtain a Certificate of Financial Security from the Coast Guard for each ship over 300 gross tons. This stipulation included not only oil tankers and barges but other ships as well because they carry oil as fuel.

The regulation called for operators to show proof of financial responsibility in the form of insurance, letters of credit, surety bonds, or other backing. However, the agency that provided the guarantee would also be liable for damages. Protection and Indemnity (P&I) clubs insured more than 95 percent of the ships traveling in U.S. waters or between U.S. and foreign ports. In this case, however, they refused to act as guarantors for environmental accidents because the regulation left the amount of liability open-ended and allowed any person, state, or local government to sue for the cost of cleanup, loss of natural resources, destruction of personal or real property, and loss of revenue or earning capacity. Insurance did not provide sufficient levels of coverage, so the law made ship owners responsible for paying the difference. Oil shipping firms insisted that this rule would shut them down. The rule was not implemented, pending further discussions on its potential ramifications for the industry.

Overall, the 1999 domestic deep sea industry appreciated about a 1.5 percent increase in rates over 1998. There was in 1999, no expected increase for 2000. The flat market was attributable to many factors, including a weak foreign market, high fuel costs, and excess cargo tonnage. In June of 1999, Peter Finnerty, vice president of Public Affairs for Sea-Land Service, Inc. and of Maritime Affairs for CSX Corporation, testified before the U.S. Congress on behalf of the proposed United States Flag Merchant Marine Act of 1999. The House bill proposed several tax rule changes that would possibly generate private investment capital for new U.S. flagships. In 1999, Sea-Land Service, Inc. operated a fleet of 100 container ships under both foreign and domestic flags. However, declining revenues forced its sale by CSX Corporation, its parent, to A.P. Moller-Maersk Line for \$800 million. CSX retained Sea Land's domestic shipping business, worth \$700 million. Despite the one-time

charge-off of \$315 million in profits as a result of the sale, CSX nonetheless reported third-quarter 1999 earnings of \$123 million. To help finance a cargo terminal to be used by the new Maersk-Sea-Land merger interests, the Port of Los Angeles announced in November of 1999 that it would sell \$300 million in bonds in 2000. The merger of the two shipping interests created the largest shipping company in the world.

CURRENT CONDITIONS

During the early 2000s, companies engaged in the deep sea domestic transportation of freight faced several challenges. On the economic front, reduced levels of consumer and corporate spending, as well as lower production levels, affected shipment volumes. Economic conditions worsened even more after the terrorist attacks of September 11, 2001. Popular tourist destinations like Hawaii and Puerto Rico—key industry shipping routes—saw tourism levels plummet.

In March 2003, the United States invaded Iraq on a scale that many considered to be greater than the first Gulf War during the early 1990s. According to the Transportation Institute, during the first conflict the United States' domestic fleet of oceangoing vessels played an important role in supporting the U.S. military under provisions of the Jones Act, federal legislation that allows U.S. ships, shipyards, and crews to be used for military purposes. On its Web site, the institute cited commentary from VADN Francis R. Donovan, USN Commander, Military Sealift Command, explaining that some 80 percent of sea cargo was carried by U.S. flagged ships during the first war. Donovan remarked that the military "tapped the U.S. maritime industry and thousands of merchant mariners to help augment the government's strategic sealift forces." In February of 2003 the U.S. Department of Transportation's Maritime Administration announced that, per the Military Sealift Command, 36 ships had been activated to support the nation's "war on terror," also known as Operation Enduring Freedom. As military action increased in Iraq, the likelihood of the U.S. domestic fleet being used for military or security purposes also increased.

The Jones Act also affected the industry in another way during the early 2000s. As the Transportation Institute explains, the Jones Act "specifies that domestic waterborne commerce between two points within the United States and subject to coastwise laws must be transported in vessels built in the United States, documented under the laws of the United States, and owned by the citizens of the United States." In the fall of 2002, dock workers at 29 coastal ports staged a lockout that lasted 10 days when the International Longshore and Warehouse Union failed to come to terms with the Pacific Maritime Association. The lockout created a number of

significant problems, including stranded ships, financial losses for shipping companies, and a negative impact on the larger U.S. economy. After the lockout ended, a backlog of inbound shipments remained. In order to expedite the movement of these shipments to their intended destinations, the National Industrial Transportation League petitioned the U.S. Customs Service for a 90-day Jones Act waiver so that foreign vessels could provide assistance. However, this led to protests from groups like the Sailors' Union of the Pacific, which argued the move would jeopardize national security.

INDUSTRY LEADERS

Among the industry's leading firms in the early 2000s was Charlotte, North Carolina-based CSX Lines, a subsidiary of CSX Corp. that claimed more than 35 percent of the market for ocean-liner routes between the U.S. mainland and Alaska, Guam, Hawaii, and Puerto Rico, according to *Loan Market Week*. Other leaders in the industry included Alexander and Baldwin, Inc. The company's subsidiary, San Francisco-based Matson Navigation Co., was a market leader in the shipment of automobiles to Hawaii and Guam. Crowley Maritime Corp. offered triple-deck barges and container ships (roll-on/roll-off and lift-on/lift-off) service to and from U.S. ports to Puerto Rico. Finally, APL Limited of Oakland, California, was an established player in the container ship segment.

RESEARCH AND TECHNOLOGY

Shipping lines have invested in more sophisticated computer equipment to help track cargo and display information about the size, weight, origin, or destination of specific containers. Computers were increasingly used to perform many of the tasks that crew members once performed on board. Technology has also allowed shippers to access information about the progress of their own cargo.

SIC 4432

FREIGHT TRANSPORTATION ON THE GREAT LAKES-ST. LAWRENCE SEAWAY

This category covers establishments primarily engaged in the transportation of freight on the Great Lakes and the St. Lawrence Seaway, either between U.S. ports or between U.S. and Canadian ports.

NAICS CODE(S)

483113 (Coastal and Great Lakes Freight Transportation)

INDUSTRY SNAPSHOT

In late 2002, the U.S. Flag Great Lakes Fleet consisted of 67 vessels, 58 of which were in active service. According to the Lake Carriers' Association, the active fleet included 48 dry-bulk carriers, six tankers, and four cement carriers. In addition to engaging in the transportation of domestic freight on the Great Lakes and upper St. Lawrence River, these ships also carried freight between U.S. and Canadian ports. Federal cabotage laws required that cargo shipped between U.S. ports be carried in ships built and registered in the United States and owned and crewed by U.S. citizens. Ships of other maritime nations also sailed the Great Lakes-St. Lawrence Seaway. Any U.S. flagged ships involved in international trade other than to Canadian ports would be classified elsewhere. According to the U.S. Coast Guard, in recent years an estimated 500,000 private sector jobs were dependent on Great Lakes commercial shipping. The Maritime Association placed actual shipboard jobs in the Great Lakes at about 1,300.

The principal cargoes shipped on the Great Lakes-St. Lawrence Seaway are iron ore and coal. Freighters carry iron ore mined in Minnesota and Michigan to steel mills in Illinois, Indiana, Michigan, and Ohio. A single Great Lakes freighter can carry enough iron ore to produce the steel needed to build 87,000 automobiles. The second-largest cargo is coal, mined primarily in West Virginia, Kentucky, Pennsylvania, Ohio, and Illinois, and shipped to utilities and factories in the upper Great Lakes states and Canada. Great Lakes freighters also carry low-sulfur Western coal shipped initially by rail to Superior, Wisconsin. The U.S. fleet typically hauls millions of tons of cargo annually during a nine-month navigation season. The principal cargoes of foreign transporters are wheat, barley, corn, and other grains from the Midwest and Canada that are destined primarily for European markets. In 2002, dry-bulk cargo shipments via the Great Lakes amounted to 162.3 million net tons, down from 164.6 million in 2001 and 176.3 million in 2000.

Nearly all of the U.S. flag ships engaged in freight transportation on the Great Lakes are members of the Lake Carriers' Association, founded in 1880 and one of the oldest active trade organizations in the United States. The Cleveland-based organization lists 14 members who owned 63 vessels. This includes two steel companies that operate ore carriers. The fleet includes 60 dry-bulk carriers and three double-hulled tankers. Their collective cargo capacity is more than 1.8 million tons.

BACKGROUND AND DEVELOPMENT

The Great Lakes constitute the single largest body of fresh water in the world, covering more than 95,000 square miles. Lake Superior alone covers 31,700 square miles, making it the world's largest freshwater lake. With their connecting waterways, the five Great Lakes—Superior, Michigan, Huron, Erie, and Ontario—also constitute the world's largest inland water transportation system. Eleven hundred miles separate Duluth, Minnesota, the westernmost point of Lake Superior, from the St. Lawrence River, which stretches another 800 miles to Quebec, where it empties into the long, narrow Gulf of St. Lawrence. This waterway provides access for the transport of goods from the heart of the Midwest directly to the Atlantic Ocean.

This massive, interconnected waterway has been an important trade route for more than three centuries. As early as 1660, French explorers were transporting furs by canoe from the upper reaches of Lake Superior to Quebec on the St. Lawrence River. In 1679, the explorer Sieur de La Salle built the *Griffin*, the first commercial vessel on the Great Lakes. Built and launched above the falls on the Niagara River, which connects Lake Ontario and Lake Erie, the *Griffin* was also the first ship to sail on the upper Great Lakes.

La Salle sailed the *Griffin* to Green Bay, then a French outpost on the western shores of Lake Michigan, where it was loaded with furs. The five-man crew of the *Griffin* then set out on the return trip, while La Salle headed south to explore the Illinois River. The *Griffin* never survived its maiden voyage, however, as it was apparently lost during a violent storm. Father Louis Hennepin, who sailed with La Salle, later wrote an account that suggested the *Griffin* foundered on Lake Dauphin, the French name for Lake Michigan. In 1890, a lighthouse keeper discovered seventeenth-century artifacts and four skeletons in a cave on Manitoulin Island in Lake Huron, but the *Griffin* and the chest of gold coins it reportedly carried were never found.

Struggle for Control. The next ships to sail the Great Lakes after the ill-fated *Griffin* were warships built on Lake Ontario in the years leading up to the French and Indian War, in which France and England struggled for control of the profitable North American fur trade. The first naval battle fought on the Great Lakes took place in 1756, and the English commander fled without firing a shot. However, British forces eventually captured Quebec and Montreal, the two most important French settlements. In 1763, France ceded Canada and most of its possessions east of the Mississippi River to Great Britain. The English established a shipyard at Navy Island on the Niagara River and built the first commercial ships to sail the upper Great Lakes since the *Griffin*.
