Evacuation of transportation stations in the event of a fire or other emergency must also be addressed during the design phase. For example, the U.S. National Fire Protection Association (NFPA) has developed the NFPA 130 Standard for Fixed Guideway Transit Systems, which specifies exit capacities, minimum widths for exit passageways, maximum evacuation times, and maximum distances for travel to an exit. Although the NFPA standards are widely accepted, local building codes may take precedence. Consequently, designers of intermodal passenger facilities must have extensive knowledge of applicable codes and standards for the jurisdiction in which each facility is located.

## B. Bus Stations/Stops

Planning for bus stops, stations, and terminals depends on the different bus technologies using the facility and should consider new bus developments that might become increasingly important in coming years. Such developments include tube stations, which are used as a key element of the surface bus transit system in Curitiba, Brazil; guided

and/or dual-powered buses operating in urban transit systems in several countries; the introduction of low-floor buses, which facilitate step-less boarding; and alternate fuel propulsion systems.

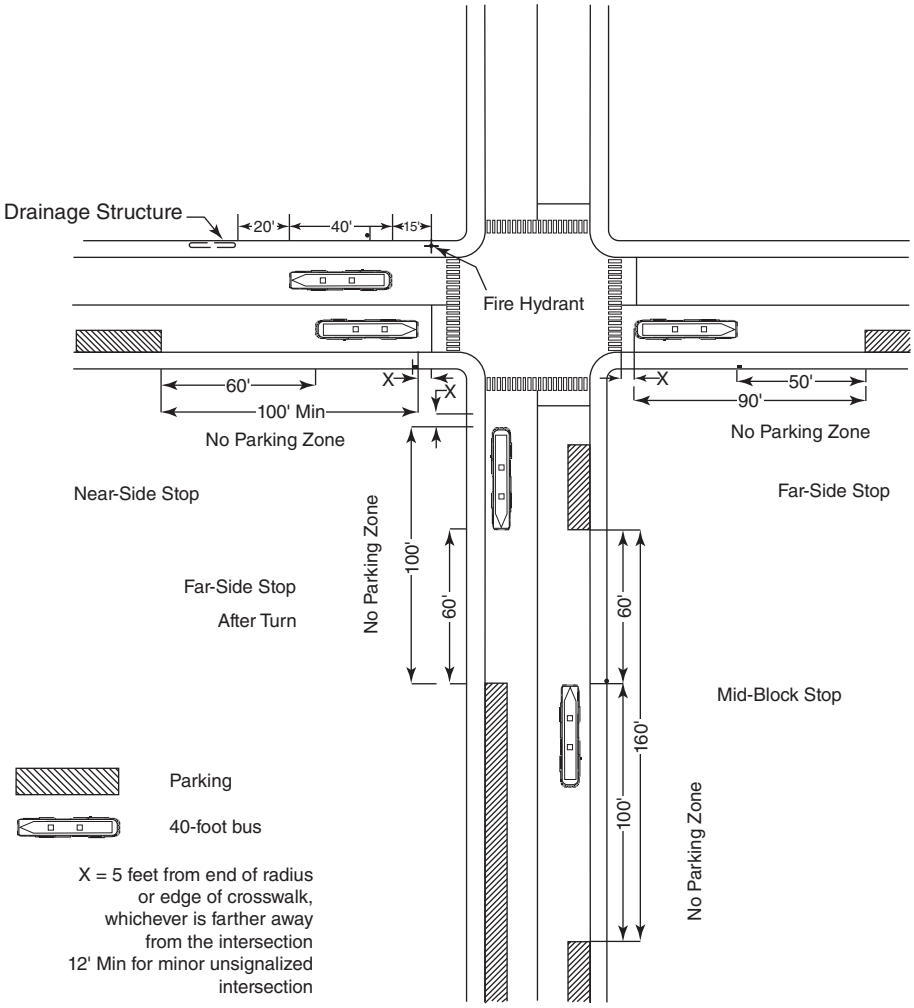
### *1. Bus Stops on Streets*

The planning for bus stops primarily involves decisions on bus stop spacing and location. In particular, the compromise decision is between shorter access times (thus stops close together) and higher operating speeds (thus stops farther apart). Bus stop spacing should reflect the location of expected passenger origins and destinations. Stop spacing should be such that, on average, buses might stop at distances of 1,320 to 1,968 ft (400 to 600 m) and in exceptional cases, somewhat closer. In a number of U.S. cities, shorter spacing, as little as approximately 500 ft (150 m), is used in downtowns and other densely developed areas. This short spacing is not efficient and can degrade service quality, including speed and comfort. The choice of stop spacing in many cases represents a blending of economic and technical factors, local policies, and experiences.

Three types of locations for bus stops occur along streets: the nearside of an intersection before crossing the cross street, the far-side of an intersection after crossing the cross street, and midblock, away from intersections. Because several different factors influence the choice of locations, variations among stop locations along a street, particularly nearside and far side, can often bring considerable advantages in terms of higher bus speeds and passenger comfort. Major factors influencing the choice of stop locations are traffic signal coordination, passenger access including transfers from other routes, vehicular and pedestrian traffic conditions at intersections, and the geometry of bus turning and stopping.

Each of the three bus stop location types has associated desired dimensions. Figure 12-26 shows each type of location and the associated dimensions. [Florida Planning and Development Lab. 2008] Where bus signal priority is deployed,

**Figure 12-26. Bus Stop Locations and Dimensions**



Source: Florida Planning and Development Lab. 2008

nearside bus stops may reduce or even cancel the benefit of this priority. Far-side stops are preferable in this situation. In general, transit planners and traffic engineers prefer far-side stops for safety and efficiency reasons.

In some locations, it may be appropriate to configure bus stops so they extend out from or are indented into the existing curb lines. Bus stops that are indented from the curb line are called *turn-outs*. Bus stops that are extended out from the curb are called *bulb-outs.*

The *Transit Capacity and Quality of Service Manual* is a good source of information on bus stops. [Kittelson & Assocs. et al., 2013]

***2. Bus Stops/Stations on Freeways***

Express buses often require intermediate stops on freeways to serve the demand in the corridor. Although these stops may reduce bus operating speeds, they are essential to provide desired service levels and increase bus patronage. Stops within interchange areas can be provided more easily and at lower cost if they are included in the original freeway design.

The location of freeway bus stops will be influenced by: (1) the density of population in the adjacent tributary area; (2) pedestrian, car, and bus access for potential transit users; (3) potential development growth and future demand possibilities; (4) nearby generators such as hospitals and universities; (5) major intersecting transfer routes; and (6) major outlying parking areas. The stops can be located at either the street or freeway level. Street-level stops are generally more convenient for bus passengers because they do not have to change levels to access the bus. Freeway-level stops are generally preferred by bus operators because there is minimal time lost for exiting and reentering the freeway. Street-level stops are usually preferable in urban areas because they provide the most convenient access for passengers and require no special geometric designs at the freeway level.

***3. Off-Street Bus Stations***

Bus terminal and park-and-ride facilities serve at least two important functions. They provide off-street downtown distribution for radial express bus operations, and they help intercept motorists and local buses in outlying areas and facilitate passenger transfer to express transit lines. Stations and park-and-ride facilities can also be used to facilitate an interchange between suburban-oriented bus and rail services and to encourage the use of ridesharing modes (for example, carpools, and vanpools).

Off-street terminal planning, location, and design embody basic traffic circulation, transit operations, and site planning principles. Relevant factors include line-haul transit routes (for example, rail, and bus); passenger interchange needs; passenger arrival and departure patterns; bus distribution opportunities and constraints within the city center; and land requirements, availability, impacts, and costs. Stations in medium-sized communities will usually be part of transportation centers in which intercity bus services and parking facilities are principal components. They could also be strategically located at outlying parking lots serving express bus lines. Central area stations consolidate bus operations at a single location, facilitate passenger interchange among bus lines, reduce bus journey times, and improve general traffic flow.

Stations are essential to express bus operations where other bus priority measures are not feasible. They make it possible to achieve high bus volumes on expressways, across bridges, and in tunnels by providing off-street loading for large concentrations of buses. In conjunction with special bus ramps and bus roadways, they attain grade-separated bus operations in congested centers, and they provide an option to downtown busway development. One-point delivery in the downtown area usually requires secondary distribution by local bus or rapid transit.

Stations range from single-level facilities serving intercity buses and offering minimum passenger amenities, to large multilevel transportation centers serving several modes and containing supporting land uses. Downtown off-street bus stations should be considered wherever the complementary services and development potential exceed the costs involved. They are appropriate where downtown curb loading capacity is limited, where large volumes of express buses are expected, and where on-street bus routing is slow, unattractive, unreliable, and cannot be improved through bus priority measures.

Central business district (CBD) bus stations should provide direct connections to expressways, be located between the expressways and the CBD core, be removed from points of peak land value, and be within a few blocks of major employment centers. These stations may incorporate air rights developments, depending on the commercial potential

of the location. Bus terminal type, size, and design should reflect specific passenger, bus service and traffic access requirements. Relevant factors include passenger traffic volumes, arrival modes and peaking patterns; bus volumes and operating practices including fare collection, service frequency, loading patterns, layover times, and driver rest requirements; and access linkages to surrounding roads and streets. Desirable functional objectives include:

- Grade-separated bus entry and exit.
- Direct pedestrian connections to other modes.
- Separate commuter and intercity bus levels.
- Separate commuter bus loading and unloading areas.
- Parallel unloading areas with passing lanes for commuter buses.
- Commuter bus loading areas in shallow sawtooth platforms.
- Sawtooth loading-unloading platforms with passing lanes for intercity service.
- Platform size adequate for accommodating the projected number of waiting passengers.
- Air-rights development of commercial uses (including accessory parking), if commercially feasible.
- Accessibility and universal design features.

Bus dimensions and maneuverability influence several design aspects, including:

- *Bus Lane Widths*: Buses require additional clearance for mirrors, which can typically add 1.5 ft (0.46 m) to the total width required for the vehicle. Consequently, an 8.5-ft (2.6-m)-wide bus can require a minimum 10.0 ft (3.1 m) of horizontal space (note: many transit agencies will not operate vehicles on lanes that are 10 ft or less). Eleven-foot lanes are preferable where ample terminal space is available and therefore are the minimum width for 8.5-ft-wide buses.
- *Roadway Width:* Double-width or two-lane roadways should be provided wherever possible. They allow passing and overtaking of buses and provide temporary storage. Unloading bus roadways should be two lanes wide to enable empty or lightly loaded buses to proceed past a loaded bus. This is essential where the unloading roadway is also the only terminal entrance road. Double-lane roadways should be at least 22 ft (6.7 m) wide for overtaking buses parked close to the curb; a 24-ft (7.3-m) width is preferable, especially where bus maneuvering distances are limited.
- *Additional Clearances and Widths:* The width and radii of driveway entrances and exits to roadways should permit equipment to operate without sharp turns.
- *Ramping*: Ramp grades to and from street roadways (or busway connections) should be set to avoid rough treatment of equipment and passengers, particularly when buses are heavily loaded.
- *Headroom and Side Clearance:* Adequate headroom and side clearance must be provided where buses enter terminal buildings and other structures. Minimum side clearance to all structures along the roadway should be at least 1 ft (0.31 m). Vertical clearance should be at least 12 ft for typical equipment. Special allowance should be made for use of stations by deck-and-a-half or double-deck buses.

The design and arrangement of bus loading platforms should be scaled to specific capacity and operational requirements for different types of services using the platforms. The following are suggested guidelines for the types of services noted.

*Separate Intercity and Commuter Services*. These two types of bus operations have different service characteristics and platform design requirements. Intercity buses have long layover times to allow for passenger loading, unloading, and the handling of baggage and parcels. Closely stacked sawtooth platforms should be provided. They allow greater passenger amenity because they can be readily enclosed and climate controlled. Commuter buses need higher peak-hour capacities. Passenger unloading and loading areas should be clearly separated to minimize passenger conflicts and reduce dwell times. Accordingly, stations should use linear or shallow sawtooth loading platforms that

allow several buses to queue at the same platform and also allow pull-through bus movements. Some of the design requirements include:

- *Berth Requirements:* Queuing theory or simulation analysis, taking into account projected passenger volumes and loading times, should be used to determine the berth requirements.
- *Loading Platforms:* Loading platform space and arrangement is generally the most critical feature in terminal operation. Separate loading spaces for different main routes or destinations should be provided. Where several bus routes are involved, the number of routes or different-type services assigned to one platform should be held to the lowest possible minimum—preferably not more than two or three. Loading platform widths for simple operations may be as narrow as 8 ft (2.4 m); however, platforms requiring substantial queuing of accumulated passengers and involving considerable circulation should be at least 12 ft (3.7 m) wide. For sawtooth positions, loading platforms parallel to the bus door should be at least 5 ft (1.5 m) wide. In layouts where passengers for different routes must circulate past each other, the platform space may need to be increased.
- *Loading Queues:* Queuing is necessary for most rush-hour conditions to avoid crowding and minimize the use of available space.
- *Passenger Platforms:* Loading and unloading spaces and bus lanes may form one continuous flat surface for low-cost or temporary terminal layouts. For permanent installations, passenger-loading platforms should be raised. Passengers should be protected from buses in multi-lane stations with a guardrail along the back edge adjacent to the next vehicle lane.
- *Platform Shelters:* Canopy-type shelters over loading areas on open lots are important for patron convenience and protection. Canopies should extend over the roof of buses for increased weather protection.
- *Unloading Platforms:* Unloading platform length should reflect the number of berths required to accommodate peak unloading passenger volume, and bus pull-in, pull-out, and tail-out characteristics. Where a considerable number of empty buses enter a terminal with need to stop at the unloading platform, a separate lane protected from the unloading runway by a physical divider should be provided. Another important factor is whether buses are allowed to stand or layover empty at the unloading platform as a holding area in lieu of proceeding to the loading platform, a separate holding area, or out of the terminal. Such layovers generally should not be permitted except for small-scale operations.
- *Vertical Access:* Access should be provided by stairways, ramps, and escalators in multilevel stations. Elevator access should also be provided to accommodate wheel chair users. Location at one end of a platform usually minimizes obstruction, particularly if the platform is relatively narrow. Expanded circulation areas are needed at such access points to maintain passenger throughput.
- *Other Facilities:* Intercity bus stations and large commuter terminals should provide ancillary passenger and bus service facilities. Passenger concourses should be enclosed, well-lit and climate-controlled. Restaurants, newsstands, stores, dispatchers' offices, and restrooms should be provided. Revenue from consumer services can be quite significant in helping to cover the capital and operating costs of the terminal.

Outlying mode transfer stations form the interface between line-haul transit and local transit serving neighborhoods. They are usually found along outlying rapid transit stations, at the ends of rapid transit lines, at interchange points between major highway and rail lines and along express bus lines. They recognize the need for auto and local bus connection to express transit from areas where population densities are too low to rely on walk-in patronage. Parking at outlying express transit stations allows automobiles to serve areas in which it is not economical to operate local bus service. The proportions of park-and-ride and kiss-and-ride passengers usually increase with distance from the city center.

Outlying transfer facilities are developed at a smaller scale than downtown stations. Designs should be simple, ancillary facilities should be kept to a minimum, and relatively few bus bays should serve heavy peak-hour loads. Direct pedestrian access should be provided to major nearby generators such as office buildings, shops and apartments. The application of appropriate transportation planning and engineering principles will produce the designs most suitable for a particular situation. The three designs described below illustrate the application of these principles in several *outlying* transfer combinations.

*Arterial Street Bus-Rail Interchange*. The most common type of modal interchange involves bus turn-outs on arterial streets that cross express transit lines. Turn-outs are located adjacent to station entrance and exit points. A median island with a fence may be desirable to preclude midblock pedestrian crossings.

*Busway-Local Bus Interchange.* Local buses circulate in a clockwise pattern crossing the busway at a signalized intersection. Direct platform access is provided to and from the major travel direction. The at-grade bus intersection provides opportunity for entry into the busway and direct expressway service to downtown.

*Typical Bus Terminal within Freeway Interchange*. A single bus bridge in conjunction with a pair of new bus runways adjacent to frontage roads alongside a depressed freeway provide direct access for arterial and freeway buses. Buses circulate clockwise around a central express transit station. Special bus-actuated traffic signals allow bus entry and exit from adjacent arterial streets. Where a secondary street bridge across the freeway is located within 500 ft (152 m) of the arterial overcrossing, it may be used in lieu of the special bus bridge.

### *4. Park-and-Ride Facilities*

Park-and-ride facilities are designed to intercept automobiles at outlying locations along express transit lines and are also used as key elements of programs to encourage ridesharing. They permit principal portions of downtown trips to be made by public transport without reducing passenger convenience or increasing walking distances. Outlying parking facilities are provided in major cities with rail transit and along express bus routes. Individual facilities can range upward to 3,000 spaces, with lots in the 100- to 300-space range common. The optimum distance of intercept parking points from the city center depends on locations of major topographic barriers as they relate to the center city, street convergence patterns, line-haul express transit system configuration, land development intensities, land availability and costs, and parking costs. Common locations for park-and-ride lots are at the stations near the end of the line haul lines. Other factors to be considered include:

- *Bus Service*—Express bus travel from the park-and-ride station to the CBD or activity center should be quick and reliable, either in mixed traffic, in an exclusive lane, or on an exclusive bus roadway. The last stop of an express bus route inbound toward the CBD or activity center is usually a desirable location for a park-and-ride station. Efficiency in bus operations is obtained by filling buses at the parking facility and running them nonstop to the terminal. At the same time, commuter travel times are minimized by eliminating intermediate stops.
- *Intermodal Integration*—While the focus of park-and-rides is on the car, sites should also include bicycle parking and good pedestrian and cycling connections.
- *Land Availability and Use*—Sites should be compatible with adjacent land uses, should not adversely affect nearby environments, and should achieve a reasonable level of use relative to development costs. Development costs and environmental effects can sometimes be minimized by shared use, that is, by leasing existing parking facilities in shopping or recreation centers. This shared use also has advantages in terms of passenger access to other amenities and the perception of safety. Peak parking use at these centers normally does not coincide with commuter peaks.
- *Road Access*—Park-and-ride facilities should have good highway access, intercepting motorists prior to points of major route convergence and congestion. Facilities should be located as far from downtown as practical to reduce VMT as much as possible during the peak traffic period. It may be necessary, however, to locate the lots closer in where there can be more frequent transit service.

Outlying park-and-ride potential should clearly recognize growth patterns in the metropolitan area, constraints to increasing CBD or activity center parking supply, and proposed extensions of express transit services into auto-oriented areas. Important factors include:

- *Demand Estimates*—Multimodal choice models can be used to estimate parking demands as one of the access modes to express transit service (see chapter 6 on travel demand modeling). Importantly, the parking prices will have a strong effect on likely demand for parking spaces.
- *Facility Size*—Parking capacity should be scaled to forecasted parking demand and bus service potentials.
- *Parking Availability*—The design load factor at each park-and-ride facility (that is, the number of autos simultaneously parked divided by the number of spaces) should not exceed 90 to 95 percent, if supported with

real time occupancy signage. This will assure commuters a reasonable chance of finding a parking space. If there is no available community-acceptable backup space on nearby local streets, the design load factor should not exceed 70 to 80 percent. However, for lots or spaces designated for monthly or yearly permit holders, parking authorities often sell permits for more than 100 percent of the spaces, under the assumption that not all permit holders will try to use the lot at the same time.

### *5. On-Street Bus Stations*

Bus streets represent a major commitment to downtown transit operations. They fully separate bus and car traffic, increase bus service reliability, enhance bus identity, and provide downtown distribution for regional express routes. For certain ranges of passenger volume, they can be an alternative to off-street stations, and in some cases as noted below, they can be combined with off-street stations. They enhance pedestrian access and, through the use of supporting amenities, can improve the downtown environment.

Bus streets as part of auto-free zones incorporate bus flow requirements with urban design considerations. Examples in the United States include the Nicollet Mall in downtown Minneapolis, Minnesota; the 16th Street Mall in Denver, Colorado; and the Fulton Street Mall in Brooklyn, New York. Short sections of bus streets are also found in several European cities. Bus streets provide an early-action, cost-effective downtown option for eventual development of busways, BRT services, and transportation centers. Some design characteristics include:

- *Auto-Free Zone*—The elimination of automobiles from major portions of downtown areas is common in European cities with narrow, discontinuous, and highly convergent street patterns. Buses are allowed to traverse the auto-free precincts to maintain route continuity and serve major activities.
- *Bus Loop*—A series of bus-only streets forming a loop may be appropriate where streets terminate and extended bus layovers are required.
- *Bus-Pedestrian Mall*—Downtown bus streets (or bus malls)—as incorporated in urban redevelopment projects—provide direct bus access to major generators. They are designed to simultaneously improve pedestrian amenity and bus access. Bus malls could operate throughout the day or be limited to peak hours. Taxis and service vehicles (during off-peak periods) can use bus streets.
- *Short Connector Links*—Short sections of bus-only roadways may be desirable to achieve direct service where street continuity is limited and bus service over arterial streets is circuitous and slow.
- *Terminal Approach*—Exclusive bus access can be provided adjacent to a downtown bus terminal and on links connecting the terminal to express highways or busways.

Additional considerations include:

- The nature, extent, and operating periods of bus streets should be adjusted to allow for essential services. One variant might be to allow local car access in bus lanes but prohibit through-traffic. Alternatively, mid-block access bays could be provided for off-peak goods delivery.
- Traffic capacities of parallel streets should also be increased to accommodate displaced traffic. This may entail additional one-way routings as well as further restriction of curb parking.
- Turns off the bus street by buses, taxis, and service vehicles should be prohibited in the core area. This will permit conflict-free pedestrian crossings at intersections and two-phase signal operations.
- Kiosks, bus shelters, and waiting areas should be located along the bus street. Consideration should be given to eliminating surface parking lots, especially where they can be served from other streets.

Providing convenient transfer facilities at the destination is one of the major challenges for BRT or other express bus services. There is no one right solution, even when anticipated passenger and vehicular volumes are relatively high. There are usually several potentially feasible on- or off-street schemes or combinations (see [APTA, 2010]). Such a planning process is well illustrated by studies for a major express bus terminal in Phoenix. [Grote et al., 1987] The Phoenix study involved the planning of an interface between express buses on a proposed depressed I-10 freeway and shuttle buses on an intersecting major arterial road. The two routes were to cross within a proposed 30-acre freeway deck park. This park would allow uninterrupted pedestrian movement from one side of the freeway to the other.

This would place the shuttle buses on the bridge two levels above the express buses on the freeway, with an urban park in between. Several alternatives were considered.

- *Bus Mall on the Freeway Deck*—The first alternative was to build a busway across the top of the deck. However, bus operations through the park were deemed inconsistent with the purpose of the park. This alternative was rejected.
- *A Bus Street North or South of the Park*—A second option was to build a bus street north or south of the park. However, no feasible location was found for a bus street.
- *Bus on Existing Streets*—A bus loop could be established with buses exiting the freeway on HOV ramps and traveling along local streets. Flexibility in operating buses would be attained, but buses would lose the time advantage gained from high occupancy vehicle (HOV) lanes on the freeway by operating on congested surface streets.
- *Median Bus Station*—A bus station could be placed in the median of I-10 under the park as shown in Figure 12-27. Riders could walk to nearby offices, or transfer to local buses. Buses would enter and leave the station from separate bus-only ramps to the I-10 HOV lanes. However, the narrowness of the area posed a significant design challenge. Ventilation, noise and security concerns would have to be overcome. On the other hand, the median bus transfer had a greater bus capacity than the other alternatives, avoided significant express bus operations on congested local streets, and avoided negative impact on the park. Consequently, this alternative was advanced into more detailed project planning.

The Phoenix planning process resulted in the development of an innovative, unique design (see Figure 12-28) adapted to the technical, social, environmental, and community characteristics of that particular situation.

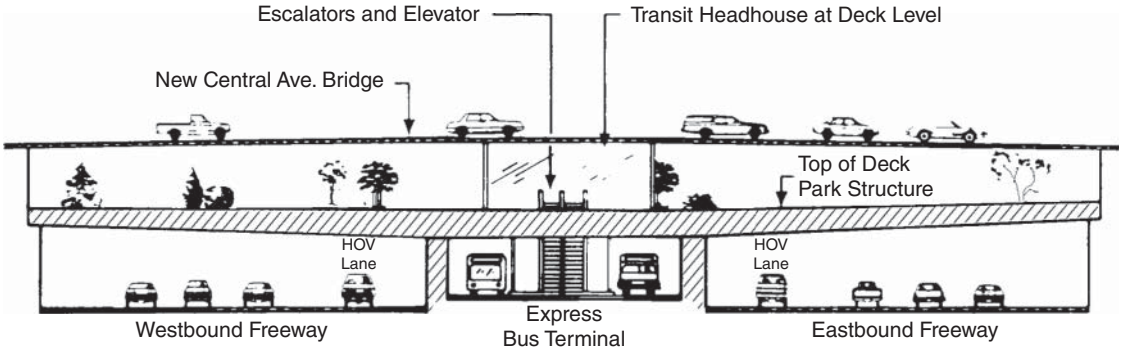

**Figure 12-28. I-10/Central Avenue Express Bus Terminal, BRT, Phoenix, Arizona**

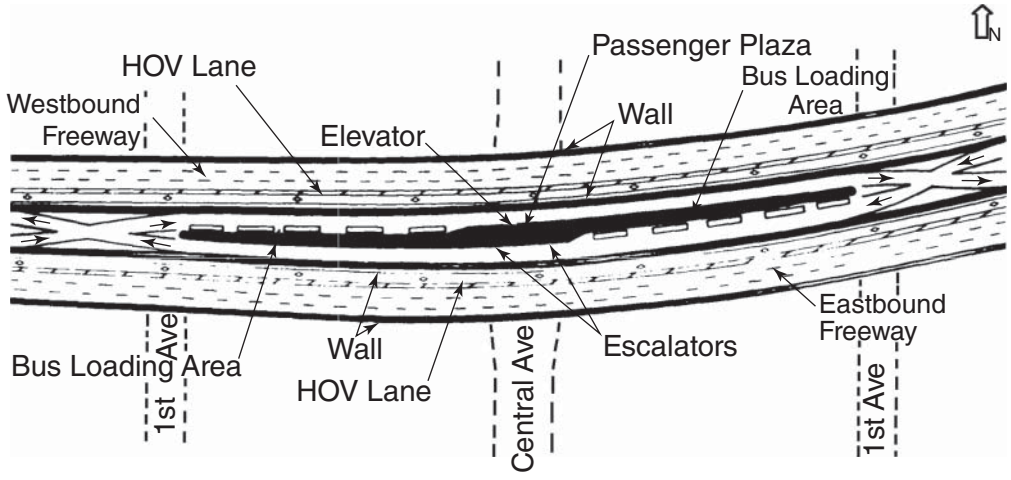


## C. Rail Stations/Stops

Stops, stations, and terminals are important components of rail systems because they represent the major contact points between rail service and the surrounding areas, and with other modes, such as walking, auto, or other transit services. Terminal operations strongly affect passenger convenience, comfort, and safety on one hand, and service reliability, operating speed, and line capacity on the other. Large stations often require considerable investment. Careful design and planning of station operations are, therefore, very important for optimal use of investment and efficient system operation. Stations are discussed in the following sections first for light rail, then for rail rapid transit, commuter rail, and multimodal and ferry stations.

### *1. Light Rail Stations*

*Operational Considerations.* LRT operations provide some unique challenges with respect to station location and design. Because light rail stations often have few obstacles to pedestrian circulation and most often have low-level platforms, vehicle operators must have a clear view of pedestrians and waiting passengers as they approach stations. Sharp curves with limited visibility, steep grades, and sharp vertical curve crests should thus be avoided for station locations.

Station platforms should be as close to level as possible, preferably with track vertical grades limited to 1 or 2 percent. For new stations constructed in accordance with guidelines established pursuant to the ADA, the gap between the rail vehicle floor and the platform can be no more than 3 inches (76 mm) horizontally and five-eighths of 1 inch (16 mm) vertically. Essentially, ADA requirements dictate that platform edges be tangent and parallel to the vehicle and have no vertical curvature.

*Platform Access.* Light rail platforms can be either center platforms with a track on each side or side platforms with a track along one side only (see Figure 12-29). Pedestrian access to light rail platforms is often provided at-grade. For side platforms with few obstructions, access may be provided at any appropriate location along the side of the platform opposite the track. For center platforms, at-grade access is typically limited to the ends of the platform. Such end-loaded platforms require all passengers to walk to the end of the platform when exiting, and exit flow capacity is limited by the width of the platform. Consequently, exit flow capacity must be calculated to permit platforms to be cleared of passenger crowding within the interval between arriving trains.

**Figure 12-29. Suburban Office Park Light Rail Station, Side Platform**

Photo courtesy of Michael Meyer

*Waiting and Boarding Areas.* Most stations have canopies covering a portion of the platform, and most have some vertical surfaces that are usually transparent to maintain visibility and to provide limited protection from wind and wind-driven precipitation. On exposed platforms, especially in colder climates, more extensive passenger shelters are often used, with enclosures on all sides and in some instances heating provided. Limited seating and leaning areas are usually provided on platforms.

*Fare Vending and Collection.* Almost all North American LRT systems use a self-service, proof-of-payment (POP) fare system. To facilitate POP fare inspection, some LRT stations have free areas and paid areas. All persons entering a paid area must possess and display upon request a valid ticket. This permits fare inspectors to check tickets in stations prior to passengers boarding vehicles. Ticket vending machines (TVMs) must be located in free areas. Free areas must have adequate space for TVMs and queuing, and good signage is needed to ensure passengers are aware of the limits and access requirements of paid areas. Most POP systems require the use of validators. These are devices into which passengers insert their tickets to have the time and date stamped prior to use. Validators should be located at the entrances to paid areas. For POP systems in which peak-hour vehicle design loads exceed 0.25 passengers per square ft (2 passengers per square meter), onboard fare inspection becomes less effective, because fare inspectors will have difficulty moving through the cars. For these systems, off-vehicle fare inspection becomes a more important consideration, if the agencies place a priority on reducing fare evasion.

*Platform and Vehicle Access.* LRT stations must be designed to accommodate the needs of individuals with disabilities. TVMs and validators must be usable by individuals with vision and mobility impairments. Accessible paths of travel must be provided that are comparable with paths of travel provided for unimpaired riders. A 24-in.

(61 cm) wide ADA-compliant detectable (tactile) warning surface is required along platform edges or other drop-offs not protected with railings or other barriers. Vertical level changes will require ramps or elevators.

To accommodate the needs of mobility-impaired passengers, all light-rail systems include boarding and alighting provisions that accommodate wheelchairs. These accommodations depend on the height difference between the vehicle floor and the platform. Conventional light rail vehicles have floors approximately 40 in. (1 m) above the top of the rail. Most of these vehicles require passengers to climb three to four steps to enter the vehicle. Mobility-impaired passengers are accommodated by on-vehicle or wayside lifts or by short platform sections constructed at the level of the vehicle floor. Such short high-level or mini-high level platforms are generally reached via ramps from the low-level sections of the platforms, and they require deployment of portable or vehicle-mounted bridge plates to span the gap between the vehicle and the platform. Some LRT systems have stations with all high-level platforms, allowing all vehicle doors to be used by wheelchair users.

New low-floor light rail vehicles are now found in many systems. Low-floor light rail vehicles have all or portions of the vehicle's floor at a level approximately 14 in. (350 mm) above the top of the rail. Doors in the low-floor portions of the vehicles may be boarded directly from platforms at floor height, or from platforms at a nominal 6- to 7-in. (150- to 140-mm) curb height using short bridge plates deployed automatically from the vehicle.

*Platform Dimensions.* Platform lengths should be designed to accommodate the longest train normally used. Typically, LRT trains are from one to four cars long. Platform lengths will be dimensioned to accommodate a fixed number of car lengths, plus additional length at the ends of platforms to accommodate queuing at end doors, fare collection areas, and variations in stopping distances for vehicles. In many instances, LRT systems are constructed in stages. In such instances it is possible to reduce initial construction costs by constructing station platforms to accommodate train lengths required to support initial operations while designing a station footprint that will allow future platform extensions to accommodate projected ridership.

Platform widths must be dimensioned to accommodate dynamic loads of waiting passengers and passengers exiting the trains, and in particular emergency evacuations. Such loads are usually determined by simulations of peak period conditions. End-loaded center platforms, because of the obvious design constraints, require careful attention to peak-loading conditions. Minimum platform widths must accommodate the detectable warning strip and unobstructed passage for wheelchairs and pedestrians of 6 ft (1.8 m) adjacent to the warning strip. Consequently, side platforms must be no less than 8 ft (2.44 m) between platform edge and any obstruction, including structural members and platform furniture. However, the actual minimum platform width should be determined individually for each station according to local codes and standards for queuing and evacuation of passengers.

*Station Types.* At-grade LRT stations generally include four types: in-street right-of-way, in reserved street median, side of street, and exclusive right-of-way. With the introduction of pedestrian areas with transit services in many cities in recent years, numerous LRT stops have been placed in areas such as pedestrian malls, shopping streets, large pedestrian squares, and so on. In most cases, crossing the tracks is allowed everywhere because LRT vehicles operate only at moderate speeds. The track consists of rails embedded in pavement with the tops of the rails either flush or slightly depressed and separated by low curbs. In addition to warning pedestrians, the curbs assist vehicle boarding at stops. An effective way of designating stop areas is the use of textured pavement, usually squares of two different colors.

*At-Grade Transfer Stations.* Major transfer stations for surface transit should be located in large pedestrian areas, separated from automobile traffic. Short walking distances between vehicles of different routes should be provided. Crossing tracks and roadways are usually unrestricted; controlled pedestrian crossings and overpasses or underpasses should be used only if vehicle speeds are high or pedestrian volumes are very heavy.

### *2. Rail Rapid Transit (Controlled-Access) Stations*

All rapid rail transit, some commuter rail, some LRT and most major intercity rail systems use stations that are grade-separated from other facilities and have full control of passenger access. Typically, fares are collected or checked at the entrances to the boarding areas so that this process does not delay the vehicle boarding. This permits simultaneous loading on all doors along the train. In addition, fully controlled stations allow use of high-level platforms that make getting into and out of vehicles extremely easy and fast. Consequently, controlled-access stations represent by far the highest transit terminal capacity.

With long trains and many doors, it is possible to achieve boarding and alighting rates of 40 to 80 persons per second. LRT vehicles with simultaneous loading of two, six-axle cars can achieve rates of 6 to 20 persons per second, while LRT trains of three, eight-axle cars, and high-level platforms can reach rates of 15 to 30 persons per second. These rates are one to two orders of magnitude greater than rates of passenger boarding of surface transit vehicles that involve fare collection at the entrance, require riders to step up into the vehicle, and have only one or two doors.

Controlled-access stations have a durable effect on both the operation of the transit system and its interaction with the surrounding environment. Their design must be based on a very careful analysis of the requirements of the three major affected parties: passengers, the operating agency, and the community.

Passengers using the stations require:

- Comfort, including aesthetically pleasing design, weather protection, small vertical climbs, and the like.
- Linkages to the community, such as wayfinding signage, surrounding area maps, and good pedestrian connections.
- Minimum time and distance to the platform or between platforms for transferring between lines.
- Safety and security, maximum protection from accidents through safe surfaces and good visibility and illumination, which deter vandalism and prevent crime.

The operating agency requires:

- Minimum operating costs.
- Adequate capacity of the transit system and pedestrian areas.
- Flexibility of operation, such as adaptability to different peaking conditions and changes in fare-collection methods.
- Good visibility of platforms, fare collection and other areas to enable supervision of operations and ensure efficiency, safety, and prevention of vandalism.
- Good integration with surrounding areas and utilization of station space for various shops, displays, information booths, and so on.

The *community* is interested in having a well-used and efficiently operated transit system. It is therefore also concerned that the requirements of passengers and the operator be satisfied. The community considers these requirements, together with investment costs that are in many cases its obligation. In addition, however, the community is also interested in both the immediate and the long-range effects of the station on its surroundings. The immediate effects include environmental impact, visual aspects, noise, and possible traffic congestion. Long-range effects include the type of development in the vicinity, which may be stimulated or discouraged by the station's presence.

*Station Platforms.* Rapid rail stations can have either lateral platforms or a center platform (see Figure 12-30). Because cars have doors on both sides, either of the two types can be used at a station along the line. Several older rapid rail systems used mostly center platforms to reduce right-of-way width and operating personnel needs. However, with increasing and sometimes total automation and centralized supervision of stations, this difference has disappeared on some systems. The choice between the two types thus depends on many factors, such as fare collection, train departure procedure, entrance locations, and available right-of-way width.

**Figure 12-30. Side and Center Platforms for Atlanta's MARTA System**

Photo courtesy of Phillip Cherry

Stations with multiple tracks and multiple platforms are provided in three different cases. First, when passenger interchange is heavy and the line operates at capacity, three platforms can be provided so that each track has platforms on both sides. This design permits simultaneous boarding and alighting of passengers on the opposite sides of the trains, considerably reducing passenger standing times. This type of station exists in Barcelona, Spain, and on the Munich S-Bahn system. The second case is on lines with local and express service, common in the New York subway system.

A third type of platform arrangement is used for stations where lines intersect and transfers are permitted. This type of station is seen in several locations on the Washington, DC, Metro, on the Atlanta, Georgia, MARTA system and in Montreal, Canada. This type of station has rail lines crossing at different levels. Levels are connected by stairs, elevators, and escalators. Where possible, one level has side platforms and the other has a center platform. This configuration permits stairs and escalators to be parallel to the track on the center platform and perpendicular to the track on the side platforms. Where side platforms are not feasible, escalators and stairs from both track levels must connect with a third-level mezzanine.

Platform length is usually determined as the length of the longest train plus a distance of 16 to 32 ft (5 to 10 m). Although it requires additional construction cost, this extra distance actually reduces travel time because it requires a lower precision of braking. Platform width can also be an issue, especially for older systems that were built to different standards. The most important factor in platform width is the safe handling of passengers, both those waiting to enter the train and those exiting. In some older systems like London and Mexico City, the demand at some stations is so great during peak periods that the transit agency has to prohibit passengers from entering the platform after a threshold has been reached. Once the platform has emptied into a train, the next group of passengers is allowed to enter. Platform heights have a major influence on station construction costs and space requirements, as well as on their operations. There are two categories of platform heights:

- *Low-level platforms* are at a ground level or one curb height above it. Used by all streetcars, most light rail, some commuter rail, and some intercity rail, these platforms require simple, low-cost arrangements, but they may involve slower boarding and alighting if passengers must use steps inside the vehicles.
- *High-level platforms* are even with or slightly lower than the car's floor, 2.8 to 3.3 ft (0.85 to 1.00 m) above the top of the rails. Used on all rapid rail, most commuter rail, some light rail, and most major intercity rail systems, these platforms involve considerably higher construction costs and take more space, but they provide faster, safer, and easier boarding and alighting. Most controlled stations (with access through fare-collection areas only) and some open stations have high-level platforms.

*Station Levels.* Controlled-access stations usually consist of three levels. Entrances and stairways are at the street level. The intermediate, mezzanine levels contain the fare-collection system, which divides it into a free area (part of a public street) and a paid area (the transit station proper). The third level has platforms and tracks where train boarding takes place.

A variety of designs of the three station levels is possible, but the most typical ones can be classified by their three basic characteristics: subway versus aerial stations, two versus three levels, and center versus side platforms. The differences between these designs can be seen from their schematic cross sections in Figure 12-31.

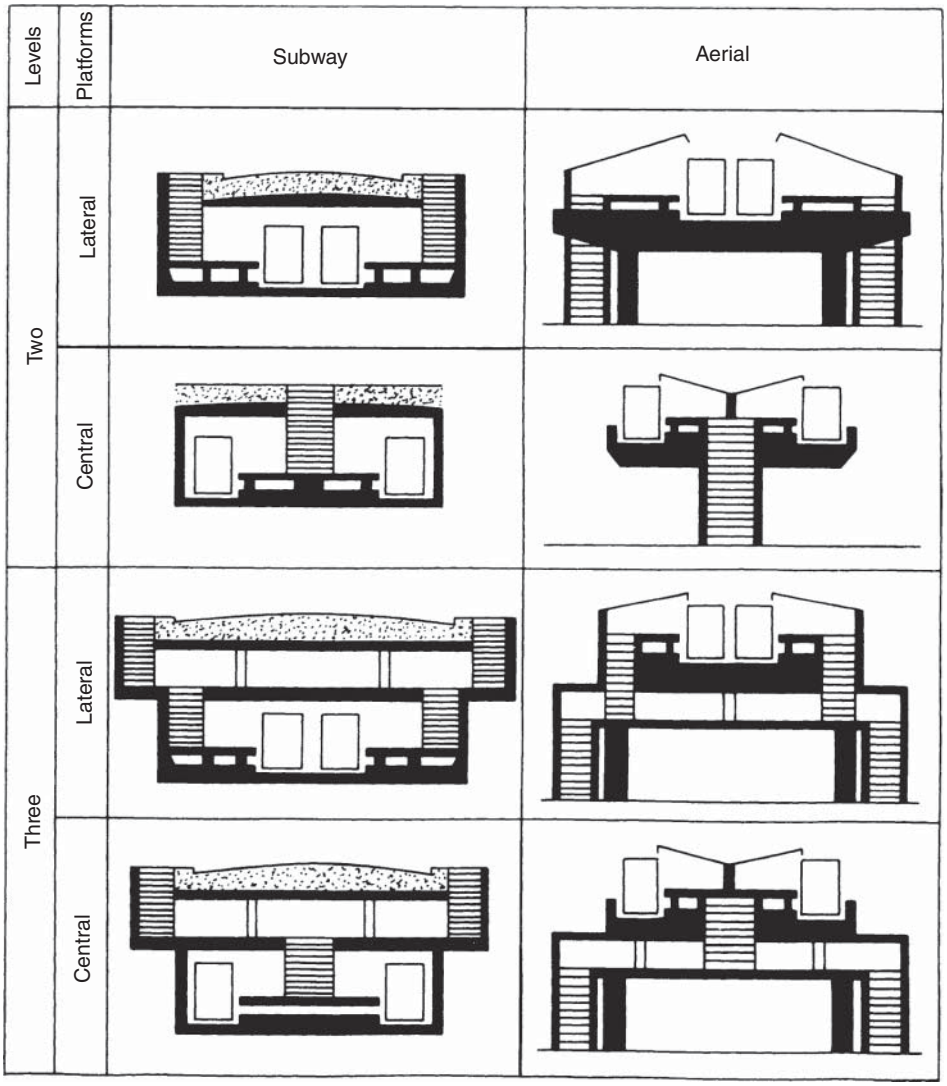
*Fare Collection.* Virtually all rapid rail systems require passengers to pass through a barrier or turnstile where fares are collected. Gates or turnstiles are usually provided in a bank or several banks of parallel devices to accommodate anticipated peak passenger volumes and provide adequate queuing space. Older transit systems use magnetic stripe tickets (with stored value) have become typical fare media for new systems and some older systems. To accommodate wheelchair-bound passengers, some gates have wider openings or are equipped with special release devices. On some systems, magnetic stripe cards must be inserted in turnstiles on both entry and exit, allowing the use of specific distance-based, station-to-station fares. Common technology is using contactless or proximity cards for fare payment. These smart cards are not inserted in readers, but they can be placed on or near a designated area on the barrier and activate the gate using wireless communications. Emerging technologies include payment directly with contactless credit/debit cards and using Near Field Communications (NFC) technology on smartphones.

In most systems, ticket vending machines are located in free areas near station entrances to permit passengers to purchase fare media. Some systems with distance-based fares also locate add-fare machines in the paid areas near exits. For some rail rapid transit systems that use a proof-of-payment (POP) fare system, validators may need to be placed at the entrance to paid areas as in many light-rail systems.

*Entrances and Integration with Surroundings.* The number and location of station entrances directly influences passenger convenience and transit system integration with adjacent areas and buildings. Because passengers feel that they have reached the transit system when they come to the station entrance, station layout should provide stairways at both ends of the platform. Such a layout effectively results in an increased area coverage compared with single-entrance layout. For transit stations that are located in the middle of a freeway, often extensive overhead pedestrian bridges will be necessary to connect to the surrounding community (see Figure 12-32).

Direct connections between the station mezzanines and the basements of major stores or other buildings are also common. Well-designed and extensively used large underground plazas and malls with stores, restaurants, and connections

**Figure 12-31. Rapid Transit Station Types**



Source: Vuchic, 2005

with hotels, office buildings, rapid rail and railroad stations exist in Frankfurt and Hamburg, Germany; London; Montreal (Place de la Marie complex); São Paolo, Brazil; and many other cities.

*Highway and Rail Transit Interface (Bus Service and Parking).* To achieve an interface between automobile travel in suburban areas and the transit network, stations must accommodate automobile access in two forms—kiss-and-ride (the drop-off and pick-up of passengers) and park-and-ride (transit passengers park their cars at the station). These access modes usually create high peak-hour volumes, such that the station design must extensively utilize traffic engineering techniques. Because of traffic volumes and parking facilities, these stations require a very large area per passenger.

The basic principles governing the design are:

- Priority in convenience of access should be given to modes that are identified as part of the station planning process. For example, some agencies might choose a sequence of: pedestrians, feeder transit, bicyclists, taxis, kiss-and-ride, and park-and-ride. Others, for example, might place bicyclists higher in the priority.
- Maximum possible separation of all access modes is desirable.
- The pedestrian walk between access modes and the station platform should be safe, convenient, and as short as possible.
- Adequate capacity, easy orientation, and smooth traffic flow should be provided for each mode.

**Figure 12-32. Pedestrian Access to Center Freeway Rapid Transit Station, Atlanta**

Photo courtesy of Metropolitan Atlanta Rapid Transit Authority

Typically, the station building is located in the middle of the station area. Feeder routes (usually buses) have stops close to station doors along curbs that may be straight or have a sawtooth pattern. Where conditions allow, bus ramps are built to provide direct, across-the-platform transfer to trains, eliminating the need for passengers to climb stairs. Pedestrian access from all streets and parking areas requires walkways that should be at least 4.9 ft (1.50 m) or two pedestrian lanes wide. Lowered curbs, mild gradients, and convenient doors should allow access to stations by people in wheelchairs. Bicycle racks and, if bicycle volume is heavy (for example, near schools and campuses), bicycle lanes should be provided.

The kiss-and-ride area should be easily reachable from all access streets. It should have a sheltered drop-off area and a parking area for waiting with good visibility of the station entrance. The remaining station area is used for parking. Circulation roads should be remote from the station building to minimize auto and pedestrian conflicts. Aisles directed toward the building and right-angle parking usually provide the best circulation and space utilization.

Commuter parking facilities can use a variety of payment systems. Because of the regularity with which they are used, some facilities can use prepaid permits that eliminate daily payment transactions and reduce operating costs. Such permit-payment lots can be designed with many access points and no barriers.

Alternatively, as transportation systems become more seamless, there is often a desire to use a single fare instrument for all modes of transportation, such as an electronic smart card. Access to such lots may require channeling all cars past a reading device linked to a moveable gate or barrier to accept the smart card or electronic transponders (tags mounted on the vehicles).

Commuter parking facilities may require special treatment from designers. Facilities that are served by rail transit systems may have surge loads of afternoon peak commuters alighting from trains at frequent intervals. Such loads may place large numbers of pedestrians in the lot coincident with large exiting volumes of vehicles. In addition, parking facility flows may conflict with kiss-and-ride pick-up, queues, and flows. Coupled with the fact that in many

locations, for most of the year, either one or both peak periods occur in darkness, surge loads of commuters rushing to and from trains require the designer to consider carefully the safe movement of pedestrians through the facility. The horizontal and vertical distances between parking facilities and the station platform experienced by riders are also an important consideration in facility design. Requiring park and ride patrons to walk long distances or to use stairs to access platforms can serve as an obstacle to many in their decision to use a park-and-ride facility.

### *3. Regional Rail Stations*

Commuter rail is an attractive alternative in areas where existing freight rail lines parallel congested freeways. Most commuter rail stations have major termini in downtown business districts, often areas that were initially developed as commercial districts because of the presence of passenger railroads and terminals. Consequently, access to most of these termini will be on foot or by local transit service. Most commuter rail stations in suburban areas are accessed primarily by auto and have correspondingly sized park-and-ride lots.

Where new stations are developed along existing freight railroads, additional passing tracks may be required to permit simultaneous operation of freight and passenger service. Because freight railroads may need to accommodate tall and wide loads, it is not desirable to operate freight on tracks adjacent to high-level passenger platforms. Freight clearance dimensions might create a wide gap between the platform edge and typical commuter rail cars, which is undesirable. Some commuter rail stations are equipped with movable platform edge strips that can be retracted to allow wider clearances for freight cars and extended to provide smaller gaps for passenger boarding. Retractable platform edge strips require integration with the train control and signal system to ensure safe operation. An option for providing additional clearance for freight cars at passenger stations is use of a gauntlet track, which adds a second set of rails that are parallel to the passenger track, but are offset from the platform by an additional distance.

If freight and passenger trains are permitted to operate simultaneously, grade-separated pedestrian access must be provided to commuter rail platforms. Similarly, grade-separated access is required for stations on lines that feature frequent, high-speed operations, have express trains bypassing stations, or have an electrified third rail. In areas where commuter trains are relatively short and operate at relatively low speeds, it is usually possible to permit pedestrians to cross commuter rail tracks at designated and suitably protected at-grade crossings, similar to light rail operations.

Most commuter rail stations have platforms at car-floor level, which is approximately 4 ft (1.2 m) above the top of the rail. Standard railroad passenger cars are 85 ft (26 m) long and are seldom operated in trains less than two cars long. Typical trains include four to eight cars (10 to 12 cars in major metropolitan areas) and a locomotive. Some new passenger cars, particularly with multiple levels, are low-floor, permitting level boarding from platforms only 25 in. (64 cm) above the top of rail.

Commuter rail systems generally feature on-board fare collection in which conductors walk through the vehicle and validate tickets. High-volume stations may have ticket offices and automated TVMs. Some commuter rail systems use POP fare systems similar to light rail.

### *4. Intercity Rail Stations*

Intercity passenger rail travel in the United States, after a long period of declining traffic, is showing some growth. This is particularly true in the Northeast Corridor between Washington, DC, and Boston, Massachusetts, which is the highest density intercity rail corridor in the United States. During the 1990s, electrified operation on the Northeast Corridor was extended from New Haven, Connecticut, to Boston and new high-speed train sets were acquired. In several states, including California, Illinois, and Texas, corridors have been considered as candidates for high-speed rail operations. Some general principles for intercity rail stations are presented here along with examples of some major existing rail stations of this type.

A rail station complex will include platforms and platform tracks, concourse and other access ways, ticket sales, baggage and checkroom facilities, waiting rooms, restrooms and other amenities, such as restaurants and sales booths, parking areas and access through covered walks or tunnels to streets and to local modes of transport. Stations for rail transport are of two general types—stub and through. The through-station is, in effect, a way station with arriving trains continuing through to the stations beyond. The stub station is found primarily where the trains terminate their runs. Some stations have both stub and through-tracks. At the stub end, the train is stopped, loaded or unloaded and backed out; with electrified and diesel push-pull multipower unit equipment, the engineer shifts operations to the opposite end of the train. Stub-end terminal operations usually consume more time for this changeover and, therefore, usually require more tracks to accommodate the same hourly number of trains processed at the line stations.

At stations with light traffic, the platforms are usually adjacent to the main tracks. Where traffic is heavy, especially where many commuter trains operate, the main line tracks will be augmented by platform tracks diverging from main tracks or terminal lead tracks. The tracks that connect the platform tracks to the principal leads or to the mains are termed *throat tracks*. A general rule is to have a 2.5:1 to 3:1 ratio between a throat track and the number of platform tracks it serves. There must be enough platform tracks to serve all trains scheduled to arrive or depart at a particular time, plus a few additional to take care of off-schedule and extra trains. A track may also be reserved to park special equipment.

Minimum length of platform is based on the longest train anticipated (car length times the number of cars plus locomotive), plus two or three additional car lengths for emergency situations and to provide a factor of safety in stopping the train. Additional length may be added to anticipate longer trains of the future. Platform widths vary from 20 ft (6.1 m) if baggage trucks also use the platform to 13 ft (3.96 m) for passengers only. Wider platforms than these minimums are found in practice, especially if pedestrian flow studies indicate they are needed. Access to the platform gates is through a concourse from the street or through walkways from the station service area. When the waiting and service areas are on different levels, then ramps, stairways, escalators, and elevators are needed adjuncts. Pedestrian flow studies should also be done to size these facilities.

The usual intercity traveler moves slowly through the station area. The passenger may not be familiar with the routine, have baggage to handle and check or retrieve, have a long wait for connections or delayed trains, and may require information, food, and a comfortable place to sit. Commuters, on the other hand, are familiar with the route through the station, have little or no luggage, and are usually in a hurry. They want direct access to or from local streets and transport. These two types of traffic should be kept separate to avoid conflict and confusion. In some large stations such as Grand Central Terminal in New York City, commuter and intercity trains arrive and depart on different levels. In smaller stations, separate platforms should be used and traffic routed so that the two lines of movement do not cross. In some instances, separate stations are in use. Clear and concise direction and routing signs and other means of channelization are desirable.

## D. Waterborne Stations

Rivers, lakes, bays, and other bodies of water are often major obstacles to transportation. However, in some cases, they can also be used as transportation routes, offering more convenient and even faster travel than land-based systems. The boat types used for different across-the-water connections can be classified in three basic technologies: ferryboats or ferries, jetfoils or hydrofoils, and hovercraft. This section deals with ferries, the most widely applied mode, particularly for high-volume movement of passengers on-foot or in vehicles.

### *1. Ferry Stations (Passengers Only)*

Ferries are by far the most common vessel for passenger transportation on water. Although they are rather slow, ferries offer low-cost, reliable, comfortable, and sometimes even faster service than any competing mode can offer among the locations served. Ferry systems can be planned for passengers only, passengers and vehicles (for example, autos, buses, and trucks), and special train-carrying ferries (lighterage).

Passenger-carrying ferries are in wide application around the world using conventional ferry vessels of various sizes and configurations. Notable examples include the Staten Island Ferry, Hudson River, and New York Waterway ferries in New York City; the Water Emergency Transportation Authority (WETA) and Golden Gate Ferry services in the San Francisco area; Washington State Ferries in the bays around Seattle; and the Star Ferry service in Hong Kong.

The Vancouver, British Columbia Sea-bus is one of the more innovative examples of ferry service in North America. Ferry stations at both terminals are served by several bus routes. The south (Vancouver) terminal is also connected by direct pedestrian passageway to an automated LRT system and to commuter rail serving downtown Vancouver and some of the easterly suburbs. Bus schedules and fares are integrated with those of the ferries. Each terminal has a floating structure with two docks to provide easy docking regardless of the tides, which fluctuate as much as 20 ft (6 m). The ferries fit precisely in each dock and open six double doors on each side. Passengers embark from the center portion of the terminal, while those leaving the ferry disembark into its outer corridors. This one-way passenger flow allows a complete exchange of 400 passengers (seating capacity of the boat) in 90 seconds.

### *2. Ferry Stations (Passengers and Vehicles)*

Ferries that serve both passengers and vehicles are found in geographic situations where highway transportation via fixed roadways and bridges is not feasible. Examples include Delaware Bay, Puget Sound, and the Great Lakes in the United States; coastal British Columbia; and Scandinavia. The design of these types of ferry stations consider several functional elements: marshaling yards and approach lanes, passenger facilities, and ferry berths and ramps. The baseline for the design is the forecasted traffic and pedestrian volume, with vehicle capacity also being a key factor. Both the total traffic volume and its distribution over time are important parameters, as well as the mode share. Establishing such parameters is challenging in that once a new terminal is established it will itself influence the traffic pattern in ways that are difficult to predict. Fortunately, ferry routes are usually flexible systems, which within a year or two may be modified relatively quickly to cope with changes in traffic volumes and patterns.

Given annual passenger and cargo vehicle peak traffic forecasts, traffic volumes can be projected as direct design parameters for the functional elements of the ferry terminal. The forecasted traffic is often expressed in equivalent passenger car units (PCUs). One PCU may be considered to occupy 32.8 ft (10 m) of deck. Trucks are equivalent to 4 to 7 PCUs, depending on their size, and buses about 4 PCUs. This is used to estimate transfer capacity in terms of car deck area, as well as for marshaling yard requirements.

The turnaround time at the terminal depends mainly on the distance between the ferry landings, the cruising speed, and the loading and unloading time. Analysis of ferry operations will establish whether a few large ferries or more, smaller ferries should be preferred, what cruising speed is desired, and the number of ferry berths.

To speed up operations, reduce bottlenecks, and avoid accidents, it is essential to prepare the layout of marshaling areas to avoid conflicts in vehicle and passenger flows. The departing traffic should not interfere with the arriving traffic. The latter should be separated into passenger cars, trucks and trailers, buses, and other vehicles, with special waiting areas provided for pedestrians, bicycles, and motorcycles. Further, lanes for waiting vehicles with and without reservation should be separated. Reservation possibilities will increase the required number of lanes for waiting vehicles, but they will reduce the required total length of the lanes because vehicles with reservations spend a shorter time waiting. A rough idea of the size of the marshaling area can be obtained under the assumption that waiting time during peak traffic of more than two to three hours would not be accepted. With trip frequencies of about one hour, this would indicate a marshaling area corresponding to two or three ferry departures.

Ramps are designed to sustain the traffic load and to be able to transfer vehicles safely during extreme water levels. The length of the ramp may be determined on the basis of information on high- and low-water statistics and the maximum allowable steepness of the ramp (normally a 10-percent grade), together with specifications of the vehicles to be transported. The ramps must be able to allow small roll movements of the ferry at berth.

## E. Multimodal Stations

Stations and interfaces often serve more than one mode. The stations described below are designed to incorporate more than one mode (for example, a major rail station that incorporates a bus terminal within the facility, or vice versa).

Current thinking on the effectiveness of multimodal passenger transportation stations revolves around the concept of seamless transportation. Truly seamless transportation is a one-seat, one-fare ride from origin to destination, with minimal delay and discomfort associated with transfers. However, virtually all journeys include an access trip to the boarding terminal, a line-haul trip on the major mode of travel, possible transfers to other line-haul modes and an egress trip from the terminal to the final destination. To accommodate seamless travel, the terminal designer should maximize passenger convenience for transfers between modes by reducing distances between boarding and alighting points, providing clearly marked routes for transfers, minimizing level changes, and providing real-time information on boarding locations, schedules, and delays.

Terminal planners should examine market forecasts for travel demands and identify the demand for transfers. By studying the relative volumes of passengers transferring between modes, the planner can prioritize the importance of transfers between each mode and develop plans accordingly.

The most recent example of a multimodal terminal is Denver's new Union Station (see Figure 12-33). This station serves light rail, a new 22-gate bus concourse, Amtrak, and commuter rail services in one location. The station was

**Figure 12-33. Denver's Union Station**

Source: Courtesy of the Denver Regional Transportation District

initiated in 2001 when the Denver transit agency, Denver RTD, purchased the site in accordance with a jointly funded Intergovernmental Agreement among RTD, the City and County of Denver, the Colorado Department of Transportation (CDOT) and the Denver Regional Council of Governments (DRCOG). A master plan for the area was developed and rezoning for transit-oriented development was approved by the city council. Besides serving at a major intermodal hub in downtown Denver, the station has become the focal point for major developments in the downtown as well.

Although not specifically developed for multimodal stations as in the Denver Union Station example, the following guidelines from San Diego on the design of intermodal transit stations and/or stops provide a good framework of the principles that should be followed. [SANDAG, 2009]

**Station Location.** Transit stations are likely to draw more riders if they are located in areas that attract many visitors and workers, and if they provide nearby amenities that benefit commuters. Locate transit stations at or near major trip generators such as sports venues, concert halls, schools, offices, and shopping areas. Provide frequently used services near transit stations, such as dry cleaners, coffee shops, restaurants, and childcare facilities. To encourage patronage of these businesses, place them between vehicle parking areas and the transit stop.

**Intermodal Connections.** Many transit trips require people to transfer between buses, trains, and shuttles. Transit stations should be designed to make these transfers as simple and convenient as possible.

- Minimize walking distances between different modes of transportation.
- Allow pedestrians to transfer between modes without crossing major thoroughfares or walking through large parking lots.
- Group bus stops together into one part of the transit station.
- Where passengers often transfer between two bus routes, locate the stops for each route close to one another.
- At transit stations that are near large employers, provide space for commuter shuttles.
- Incorporate space for taxi queueing where demand warrants.
- Post clear, easy-to-read signs that provide direction for how to transfer between different transportation modes and transit operators.
- Provide fare information and timetables at points of transfer, along with maps showing transit routes and connections to other transit services.

**Pedestrian and Bicycle Access.** Many people arrive at transit stations by walking and biking, and most transit riders will have a short walk to their destination at the end of their trip.

- Design stations to provide for pedestrian and bicycle access, and plan for improved facilities where needed to support pedestrians and bicyclists.
- Provide direct, logical paths from the street to passenger waiting areas.
- Include pedestrian and bicycle connections that link the station to nearby homes, businesses, offices, and civic buildings.
- Post "bike parking" directional signs at entrances to the transit station.

**Vehicle and Bicycle Parking.** Adequate bicycle parking must be available as well as vehicle parking, with appropriate policies that encourage people to use transit, walk, or bike to reach the station.

- Locate bicycle parking in places with high foot traffic, so that it receives natural surveillance from passersby.
- Provide secure bicycle parking in the form of bike lockers or "bike stations" with valet parking. Use bike lockers that clearly indicate when they are occupied, so station patrons can see they are being used.
- Design transit stations to provide for increased bicycle parking in the future as mode share increases.
- Incorporate an appropriate amount of vehicle parking, using parking structures wherever possible. Manage demand by charging a fee for parking where appropriate.
- Place surface parking lots in clusters that are large enough to be developed in the future with mixed-use buildings, offices, townhouses, multifamily dwellings, or parking structures.

**Passenger Waiting Areas.** Thoughtfully designed waiting areas create a more welcoming environment for passengers.

- Provide aesthetically pleasing bus shelters that offer protection from sun, wind, and rain.
- Post transit schedules and route maps at all waiting areas.
- Display real-time arrival information for buses and trains if available, and ensure that it can easily be viewed from all waiting areas.
- Provide adequate, well-lit seating at all waiting areas. For safety, design the waiting area so that passengers can see what is around them at all times.

**Universal Design.** The Americans with Disabilities Act requires transit stations to be designed so that anyone can access and use them, regardless of physical abilities. This requirement ensures that public transit is available to all.

- Provide wide, level, and smooth paved surfaces in boarding areas. Avoid changes in grade or obstacles that could pose a tripping hazard or interfere with the movement of baby strollers and bicycles.
- Connect different parts of the station to one another and to the adjacent street with low-slope ramps and wide, flat paths.
- Where escalators must be used to provide access to part of the transit station, provide an elevator as close to the escalators as possible.
- Ensure that all seating areas also provide adequate space for people in wheelchairs.

**Signage.** All passengers must be able to find information about how to use the transit station and connect to surrounding areas. Signage must meet the needs of frequent transit riders who need to find schedule or route information quickly, as well as new riders who may not be familiar with the station or its surroundings. Some guidelines include:

- Design signs with typefaces that are easy to read even in dim lighting.
- Display maps that show the transit system as a whole, as well as local maps of the station that indicate connections between different routes and modes of travel.

- At bus stops, display schedules that use a clear symbol to indicate when the bus connects to another mode of travel, such as a commuter train.
- Integrate accessibility features such as Braille signs and audible announcements of upcoming train or bus arrivals.
- Place signage where it is highly visible and easy to locate for people entering the station, as well as new riders who may not be familiar with the station or its surroundings (wayfinding signage).
- Provide schedule information and route maps for all routes that use the transit station.

## X. LINES AND NETWORKS

Designing a transit network that promotes efficient and cost effective trips is one of the ways of providing transit service that meets customer and owner expectations. [Chatman et al., 2014] Line alignments and station locations comprise the basic infrastructure of transit systems. Together, the layout and design of lines and stations create transit networks, the nature of which has profound influence on the quality of transit service offered and the function of the system. Investments in lines and stations vary greatly among modes, from minimal facilities for bus lines operating on streets, to very complex, permanent structures of rail systems that are fully grade separated. Although the ranges and scopes of planning vary greatly among modes, the objectives in transit network planning and design are common for all modes. Networks should be designed to achieve the following three basic goals:

- *Maximize transit ridership, as measured in either unlinked trips or passenger-miles served*. This objective requires providing attractive service to passengers, including good area coverage, short access to stations, high-frequency services, and high-speed and reliable services between major trip generators.
- *Achieve maximum operating and economic efficiency.* This objective focuses on operating efficiently, that is, achieve high output per unit costs, labor, and other resources. It should also ensure integration and convenient transfers with other modes of transport, as well as balance the system's investment and operating costs.
- *Achieve maximum positive impacts on the city and region.* These impacts might include short-term increases in transit's modal split and, in the long term, support for desirable urban form and livability, while reducing traffic congestion and ensuring low air pollution and noise.

These service planning principles apply to all types of transit lines. They vary by two basic types of network design and vehicle type. Street transit, generally buses, involves many lines with a dense network that can be established and modified easily, without major investment or construction efforts. Semi-rapid transit, consisting mainly of rail lines, requires longer range planning, and utilizes a separate network of high-performance services. Finally, rapid transit systems, having reserved rights-of-way (category A) only, require large investment and long-range planning, which includes an analysis of the relationship and impact of these systems on ridership and urban form. For example, well-designed, dense transit networks can support and enhance the pedestrian-orientation of urban areas.

Small and many medium-sized cities usually rely on bus services. Large- and some medium-sized cities have rail transit networks, which must be carefully planned and coordinated with bus and other area-wide, lower-performance modes operating supplementary and feeder services.

The following discussion of lines and networks covers mainly rail systems, with some attention given to bus services and various feeders, such as private cars (kiss-and-ride and park-and-ride), taxis, and pedestrians.

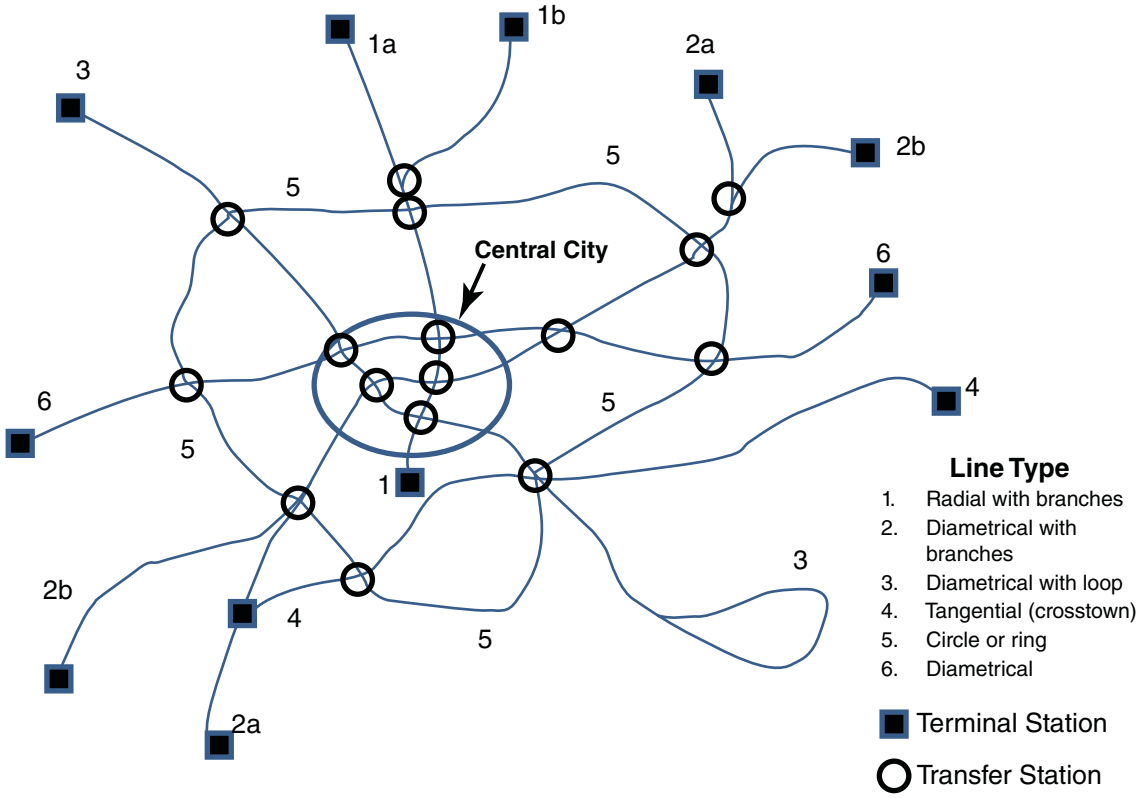
### A. Types and Characteristics of Lines

Transit lines are defined and categorized by their alignments and stations, and further identified by scheduling and the efficiency of operation. The basic types of lines are shown in Figure 12-34, with their characteristics described below.

#### *1. Line Alignment Types*

*Radial lines* (also often known as a "hub-and-spoke" network) are the oldest and most common form of transit lines. They originate in a region's CBD and serve radial alignment corridors toward outer suburban areas. These lines are

**Figure 12-34. Types of Lines in a Transit Network**



typically used by residents commuting inbound to urban employment, commercial, and entertainment locations. Their cumulative loading steadily decreases line utilization in the outbound direction.

*Diametrical lines* have both route end stations in suburban areas with alignments that pass through the city center. Like radial lines, diametrical lines provide radial access to the CBD from the suburban areas, but also serve suburb-to-suburb connections. Diametrical lines may have generally straight alignment through the downtown or may follow an L-shaped form, common for several subway lines in Manhattan, New York. Such lines generally have more transfer points with other lines than straight lines. One major concern in the design of diametrical lines is the balancing of passenger volumes on the two radial sections. Uneven passenger volumes usually result in low utilization on one side of the diametrical line.

Diametrical lines have several advantages over radial lines: better coverage of the central area, more transfer points in the network, and direct service for many suburb-to-suburb trips. U-shaped lines, such as the Red Line of the Washington, DC, Metro, experience well-balanced ridership, but they may not attract as many trips through the CBD because of their circuitous nature.

*Tangential lines* serve major corridors perpendicular to radial lines in close suburbs, and do not enter the CBD. Circumferential lines serve portions of circles in close-in suburbs, similar to tangential lines.

*Circle or ring lines* follow an alignment forming a full circle around the city center, but with a limited number of stations. These lines provide connecting services between radial lines originating in the city center. They also allow for suburb-to-suburb travel without having to pass through the downtown. Operationally, circle lines are more complex because no terminal time can be scheduled to recover delays, and they often need large interchange stations with the radial lines.

### *2. Line Relationships in a Network*

Generally, lines may be operated independently or be integrated with other lines.

*Independent lines* operate by themselves on their alignment; no other line operations occur on the track. This type of operation is the simplest and most reliable so that minimum headways and maximum line capacity can be achieved. Such lines require passengers traveling to other routes to transfer at stations. These lines usually offer the same capacity along their entire lengths, so that they are used in areas with similar population densities. Examples of this type of lines are found on many metro systems with large, high-density central cities, such as Moscow, Paris, Toronto, Boston, Philadelphia, and Tokyo.

*Integrated lines* have sections where lines merge, diverge, and overlap, providing line connectivity with fewer transfers. This type of operation results in longer headways in the branch lines than with independent lines, and provides more single-seat trips where shared line operations occur. Scheduling of integrated lines is more complicated and irregular headways may be unavoidable on some joint or separate sections of integrated networks. On the other hand, the combined operations may result in more precise scheduling according to demands on individual sections, resulting in higher load factors and operating efficiency. Examples include Atlanta, Chicago, and New York City.

Figure 12-35 shows the Washington, DC, Metro system, which uses a combination of independent and integrated lines. The Red Line (the U-shaped line) is operated independently between its terminals. The Blue, Orange, and Silver Lines operate on common track and share stations between Rosslyn station and Stadium Armory. The Yellow Line is integrated with both the Blue Line (between National Airport and Pentagon) and the Green Line (between L'Enfant Plaza and Fort Totten).

The most common types of integrated lines are trunks with branches, typically used on radial and diametrical lines (examples include Chicago and San Francisco). As a major common corridor, referred to as the trunk line, goes from center city toward the suburbs, its ridership decreases, while the service area increases. The most used service strategy is to operate a trunk line by a high-capacity mode, usually metro or LRT, which then splits into two or more branches to increase area coverage. This may be done by allocating subsequent trains to different branches beyond the trunk. In the case where, for example, three branches are served, capacity on each branch is one-third the capacity of the trunk.

An alternative approach is to terminate the high-capacity trunk mode at approximately the limit of the city and the suburb. The trunk is then fed by several independent feeders, typically lower-capacity modes operating at higher frequency (the Skokie Swift in Chicago). Passengers are required to transfer from the feeder mode to the trunk mode.

Branches, compared to feeders, have the following advantages:

- They provide direct service without transfers between the trunk and branches.
- Being longer than feeders, branch lines have shorter terminal times, reducing operating costs.
- No transfer stations are required.

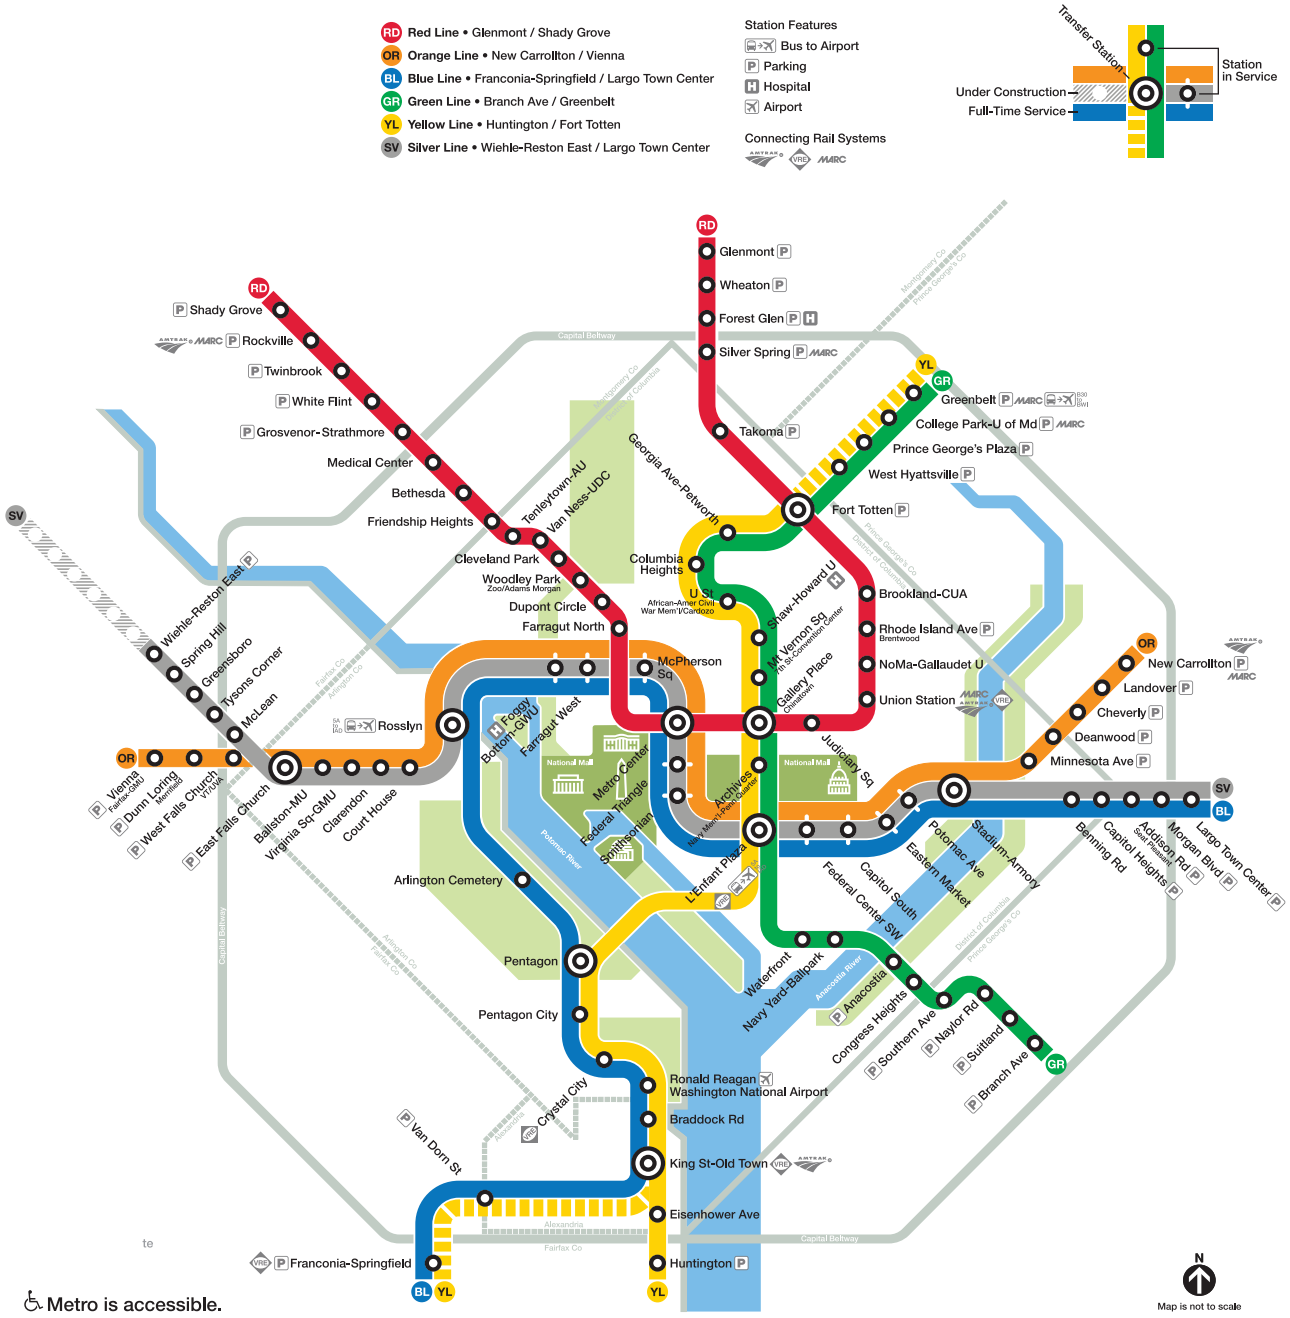
Feeders have the following advantages over branches:

- Each feeder can be optimized with respect to mode, type of vehicle, and schedule. Regular headways can be operated on the trunk and on each feeder.
- Delays are not transferred between the trunk and feeders.

As this description shows, branches and feeders each have certain advantages. In most cases, rail lines with higher performance operating on a major radial corridor have several branches serving major directions, and a greater number of feeder lines served by different types of buses and different headways, depending on their volumes. Branch line operations entering the trunk section must be carefully controlled for reliability.

The choice between trunk line with branches and trunk line with feeders depends heavily on the passenger demand for the trunk line relative to demand in outlying areas. Passenger demand on the trunk determines the cost and reliability of providing service with different modes and rights-of-way. Where demand suggests that high-capacity modes and exclusive rights-of-way may be necessary,, outlying areas may be served with feeder services consisting of lower-capacity modes or smaller vehicles. If demand is more balanced and the trunk headways can be consistent over peak periods

**Figure 12-35. Washington Metro with Independent and Integrated Lines**



Source: Reprinted with permission of the Washington Metropolitan Area Transit Authority

(for example, consistently 10 minutes during the peak), then branches are more appropriate (in this case operating at 20-minute headways).

The appropriateness of independent versus integrated lines also depends on the mode operated on the line. Regional rail systems usually operate with large numbers of branches. The issue of uneven demand on branch lines resulting in irregular headways on the trunk section is less problematic in regional rail systems because they typically have very short trunk sections. The merging of lines with different headways is, therefore, operationally acceptable. Irregular headways remain a problem when the trunk approaches capacity, such as in Tokyo, Paris RER (which has two branches), and New York City, where Pennsylvania Station serves two trunks of regional rail systems as well as Amtrak.

For metro systems, where system reliability is paramount, some transit operators prefer to have independent lines due to their simplicity. However, integrated networks have significant advantages in reducing the need for passengers to transfer and exhibiting higher load factors on lines. Most metro systems, therefore, have either two to three

(exceptionally up to five) branch lines on major corridors, as well as other types of integrated line topologies. San Francisco's BART has four branches in the East Bay, as well as a line connecting two of the branches. This network results in very high frequency on the trunk line.

The New York subway has a highly integrated network, which despite its complexity has a significant advantage in its ability to adjust services under special conditions or emergencies and even to reorganize lines as the travel demand in the city changes. Such changes cannot be done on networks with independent lines, such as in Moscow, Mexico City, or Boston.

LRT systems are operationally more conducive to integrated networks than metro lines, because they usually operate with visual control, which permits short and irregular headways. Therefore, most LRT networks have overlapping lines offering direct services among different parts of the city. Even on trunk-branch lines, LRT trains can merge from four or five branches with satisfactory performance, as is the case in Boston (four lines), Philadelphia, and San Francisco (five lines).

Buses have few restrictions on line integration because they usually operate without any control of headways. On integrated lines, given sufficient lanes and road width, buses can be allowed to overtake each other at stops, achieving headways of less than one minute. In Portland, Oregon, the bus trunk line operates on an exclusive bus street using four sets of stops with leapfrogging of buses. This complex operation achieves an average headway of about 20 seconds or a frequency of 180 buses per hr. Madison Avenue in New York City has similar throughput along its dual bus lanes.

The ability of buses to operate on complex networks is, however, often incorrectly used by transit network designers. Many bus systems have been designed with the goal of providing no-transfer travel throughout city centers. This design can result in many overlapping lines with long headways, unreliable service, and a very poor service image. In some cities, there are even several bus routes designated by the same number using different terminal points. The weak attraction of excessively extensive networks has led to the reorganization of bus networks in many cities into fewer lines with higher service frequencies and capacity. This has been the experience in Los Angeles where this design has been the key to BRT success.

## B. Network Design

Designing the alignments for transit lines requires two major considerations. First, transit lines should follow major directions of travel demand in the city. Second, the relationship of each line to other lines must be evaluated. This should include each line's contribution to the system's area coverage, the lines' geometric relationships (merging, diverging, or crossing), and the locations of their transfer and terminal stations.

Rail systems may consist of a few lines serving major corridors or the network may be designed to provide service to a larger central area as is common in several very large cities. While there is a trade-off between network extensiveness and frequency of services on individual lines, in central areas of large cities such as Berlin, Mexico City, and Washington, DC, the metro network should be designed to provide large or total area coverage.

Street transit—bus, trolleybus, and tramway—generally forms a network that provides nearly ubiquitous coverage in the central city area, even when its coverage is defined as one-quarter mile (400-m) circles around stations and stops. Street transit serves short- to medium-length trips dispersed throughout the street network. Rapid transit and LRT networks provide services for large volumes of medium to long trips along major corridors or throughout dense areas of large cities where surface transit serves as feeders to this line-haul service.

Although no metro network is geometrically regular, many can be classified into several geometric forms, which give them certain operating and service characteristics. They can be grouped into several types.

*Radial networks* consist mainly of radial and diametrical lines, sometimes supplemented by circumferential, circular, or tangential lines. Examples are the Moscow Metro, Philadelphia, and San Francisco rapid transit and LRT networks, and regional rail networks in New York and Chicago. These networks provide excellent access to the center city from many sections of the city and region, but may be limited in the coverage of central city sections.

*Grid networks* consist of rectangular lines, which provide good area coverage throughout a large city area, but for diagonal trips, numerous transfers are necessary. Such networks are often a result of rectangular street networks, which

are common in many North American cities. Good examples are Toronto's rapid transit, streetcar, and bus lines, and the Mexico City Metro.

*Ubiquitous coverage networks* represent full coverage of an entire city within its boundaries (as well as some radial lines outside of it) using diametrical, tangential, circumferential, and other types of lines. The Paris Metro provides excellent service in a network consisting of 14 lines. The more recently designed Munich U-Bahn network employs diametrical lines intersecting at different points in the central city, each having two branches at one or both ends. For passengers, the Munich system provides excellent area coverage, multiple points of connectivity among U-Bahn lines as well as intermodal transfers with regional rail (S-Bahn). Operationally, passenger loads are well balanced on the lines; both tramway and bus feeders are efficiently achieved. The third example is the Tokyo Rapid Transit network, consisting mostly of L-shaped diametrical lines, which provide a greater number of direct transfers among lines than more traditional diametrical lines would have.

Polycentric networks have been developed in many North American cities in recent decades as a result of the emergence of suburban downtowns or major activity centers (MACs). This urban form poses challenges for transit providers. Multi-centered, radial networks with localized feeder services may be most effective in providing competitive transportation in this type of urban form. [Casello, 2007] This type of transit network is most effective when organized as timed transfer systems (TTS), such as numerous rail/bus TTS centers in Portland, Oregon; Sacramento, California; and Vancouver, British Columbia. The same polycentric form of rapid and regional rail transit networks is also found in large older metropolitan areas, such as New York City and the San Francisco Bay Area, where some diametrical lines connecting suburban towns and MACs have lengths of up to 62 miles (100 kms) (all three regional rail networks in New York and the line from Bay Point to San Francisco Airport in the Bay Area).

## C. The Role of Transfers in Transit Networks

Transferring is an important element in network design (see Table 12-21). Well-designed and convenient transfers with coordinated schedules can involve very little physical inconvenience, financial costs, or time delays while providing passengers faster and more attractive trip paths. They can help minimize the adverse effects of changing modes or vehicles between the main trunk line and feeder services. Many large systems such as Toronto, Chicago, and New York City provide extensive intramodal and intermodal transfers.

Transfers should be as direct and physically convenient as possible. The most desirable transfer is directly across a platform where two lines (or a local and express service on a single line) share the station. This design requires the meeting of two track alignments at shallow angles to allow parallel routing of tracks for some time. Hong Kong's metro uses two stations and differing grades to accommodate four transfer movements directly across platforms. Singapore, New York City, Chicago, and Philadelphia also provide transfers across platforms.

Financially, transfers can require that passengers pay a second, full fare, a reduced transfer fare, or no additional fare. Free transfers, the most desirable for both the passenger and the operator, can be accomplished by planning and designing interline (and intra-modal) connections that remain within a station's paid area or through the use of automated fare collection systems.

The duration of transfer times depends on the length and level of coordination of the headways of the arriving and departing lines. In the case where the departing line operates with high frequency (less than 10-minute headways), transfer times will always be short, regardless of the arriving line's headway. If the departing line's headway is long,

**Table 12-21. Relationship of Headways and Schedule Coordination to Transfer Times**

| Headway Arriving Line | Headway Departing Line | Level of Coordination | Transfer Time |
|---|---|---|---|
| Short | Short | Any | Short |
| Long | Short | Any | Short |
| Short | Long | None | Variable |
| Long | Long | None | Variable–Long |
| Long | Long | Full (TTS) | Short |

then, in the absence of schedule coordination, the transfer times are variable, but are likely to be less with short arriving headways (because passengers can choose an arriving service that precedes the departing service). In the case where both lines have long headways, full coordination, or a timed-transfer system (TTS) can be used to ensure short transfer times.

The simplest form of a TTS is a unifocal network (also known as a *pulse system*), a transit network with one transit center at which vehicles from several transit lines meet at regular headways. These are called *clock face headways,* that is, headways that are divisible in 60, so that they repeat themselves every hour. There are two possible sets of clock headways: one with the basic headway of 15 minutes, which also accommodates lines operating at 7.5, 30, and 60 minutes. The other is a set based on 20-minute headway, which can also accommodate lines with 10, 40, and 60-minutes headways. Thus, the lines meeting at the center can have different lengths if their operating speeds are different, so that the cycle times are equal. Differences between operating times can be adjusted by using terminal times at outer terminals to compensate for variations in travel time. Scheduling timed transfers at multiple locations, however, is a challenge.

The cycle time for a TTS center is actually the basic module for the schedule of the lines that radiate from the center, and it can be used not only for the design of radial lines, but also for diametrical lines going through the center with the cycle time *2 T*. Some lines can also have cycle times that are multiples of *T*, with a correspondingly greater number of trains or vehicles in service. Thus, a line that has cycle time *2 T* operated with two consists, (*N*, the number of cars in the consist is thus $N = 2$), will have the same headway at the transit center as the lines operating with *T* and $N = 1$. Finally, if some lines do not justify the same headway, they can operate at twice the longer headway, so that its vehicle meets every other pulse at the center. For instance, if a series of routes pulse from the center every half hour (with one bus allocated to each route and a round trip time on those routes of a half-hour) then an additional diametrical route that passes through the center will need to take an hour in each direction and will require two buses.

TTS can be superior in service and performance to conventional transit services in low-density areas. Independent scheduling of individual lines in such areas creates services that require long and inconvenient transfers, so they are avoided by all except captive riders. When a TTS is organized, transit offers a coordinated network that provides short and easy transfers among lines and captures a much greater number of passengers. Thus, the quality and role of transit services can be drastically changed and elevated by the introduction of TTS.

A number of cities, such as Edmonton, Alberta; Vancouver, British Columbia; Portland, Oregon; and Denver, Colorado have introduced TTS for large portions of their service areas and have achieved significant increases in transit ridership. Use of TTS has been particularly successful in increasing ridership when a new LRT system was introduced (Portland, Sacramento, and Dallas). For a more detailed explanation of the scheduling procedure for TTS, see [Vuchic, 2005, Sec. 4.5]. For general references on transit scheduling see [Pine et al., 1998; Boyle et al., 2012].

## XI. TRANSIT ROUTE PLANNING

The transit planning process evaluates the impacts of new or modified transit facilities, services, or policies. The evaluation procedure includes an assessment of a plan's effects on passenger attraction (as a function of quality of service offered), the operating agency (in terms of operational efficiency) and on the region served. Proposals may be assessed both quantitatively and qualitatively, and may be evaluated over various timeframes—short-term, medium-term, or long-term—depending on the magnitude of the planned system or service expansions. This section discusses the planning at the individual route level.

Transit service planning occurs all the time in transit agencies. In most cases, transit agencies make changes to their schedules and often route structure on a periodic basis to reflect the ongoing changes in the transit market, for example, every quarter for route schedules and perhaps every three to five years for a comprehensive examination of route structure. Most importantly, planning must consider transit vehicle movements, line schedule, route cycle time, and necessary transport capacity in relation to the market area served. An understanding of these elements is important for comparing and selecting transit rights-of-way and modes, evaluating their level of service (speed, service, frequency), and assessing system operating costs and efficiencies. The following sections provide an overview of key principles of vehicle motion and travel times as they apply to transit route planning and scheduling, factors that influence the locations of transit stops and stations, as well as vehicle design. It is not the intent of this section to delve deeply into

the physics of vehicle motion that dictate the guidelines and standards used by planners for transit planning. Those interested are referred to [Vuchic, 2007].

## A. Vehicle Motion and Travel Times

The performance of transit vehicles depends very much on the right-of-way on which a line operates. In mixed traffic, transit vehicles travel at speeds that are largely dependent upon the general traffic flow. Transit vehicle speeds are further reduced by stop dwell times. To achieve speed increases for transit vehicles, several strategies are available. Transit signal priority (TSP) allows a traffic signal controller to detect the presence of a transit vehicle and adjust the cycle times such that the transit vehicle is less likely to encounter a red signal. Intersections may be designed to include queue-jumpers, or dedicated lanes that allow transit vehicles to bypass waiting private autos.

On transit lines with separated right-of-way, particularly for electrically powered guided systems on fully controlled right-of-way, travel times can be predicted and programmed much more precisely because they depend on known elements: alignment geometry and vehicle dynamic performance characteristics (acceleration, maximum speed, braking rate, and passenger dwell times at stops). Travel along a line consists of a series of station-to-station travel modules. Analysis of this travel between two stations, that is, analysis of interstation spacing, includes four motion variables as functions of time as shown in Table 12-22.

A typical station-to-station travel module consists of five travel regime intervals: accelerating, operating at maximum (or constant) speed, coasting, braking, and standing. Figure 12-36 simplifies this movement in showing only the operating speed and standing times between two stations. The distance and speed variables are commonly used in computations of travel times and distances; the acceleration/deceleration are mainly used to evaluate vehicle dynamic capabilities and performance; and the jerk is analyzed for measuring passenger comfort.

A fundamental relationship between service frequency and headway serves as the basis for much of the analysis underlying route service planning. Equation 12.3 shows this fundamental relationship.

$$N = \frac{60}{h_{min}} = \frac{3600}{h_{sec}} \tag{12.3}$$

Where:

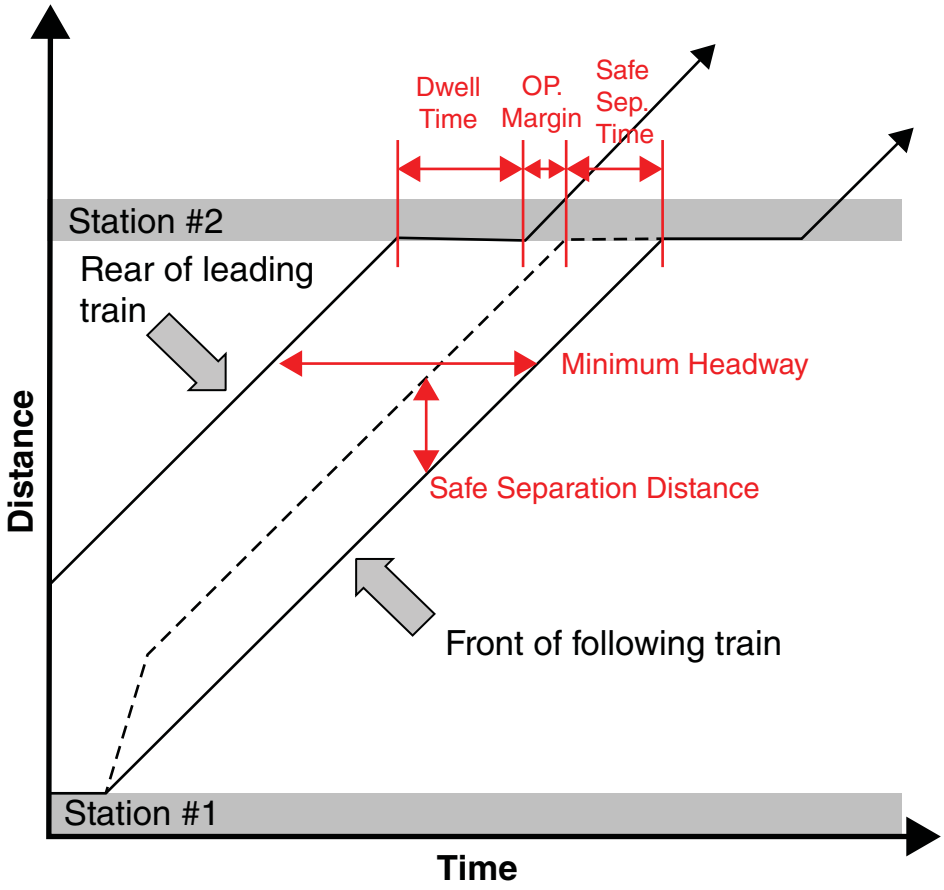
$N$ = Number of transit units per hour (frequency)
$h_{\text{min}}$ = Time in minutes between departures (headway)
$h_{\text{sec}}$ = Time in seconds in seconds between departures (headway)

Thus, if an agency has established 10 minute headways for a particular bus route, the service frequency is 60/10 or 6 departures per hour. From this fundamental relationship one can determine the capacity of a line by the physics of vehicle motion (acceleration, deceleration, cruise speed, and so forth) and the amount of time it takes for passengers to get on and off the vehicle or rail car. Using Figure 12-36 as an illustration and assuming a consist can enter a station as soon as it safely can do so, the headway variable, $h$, in equation 12.3 can be replaced with the mathematical relationships dictating how much time it takes for a consist to pass through a particular movement. For example, if an agency has established a minimum distance between trains due to the ability of the control center to safely dispatch

**Table 12-22. Motion Variables Necessary in Computing Interstation Travel Times**

| Motion Variable | Symbol | Relationship to Time |
|---|---|---|
| Distance | $s$ | $s = v \times t$; $s = {}^1/_2\, a \times t^2$ |
| Speed | $v$ | $v = dx/dt$ |
| Acceleration | $a$ | $a = d^2s/dt^2$ |
| Jerk | $z$ | $z = d^3s/dt^3$ |

**Figure 12-36. Distance-Time Diagram of the Movement of a Transit Unit**



Note: Acceleration and braking curves omitted for clarity.

Source: Kittelson et al., 2013, Reproduced with permission of the Transportation Research Board.

trains, called minimum control time separation, and as well has established an operating margin time for the time between trains, the maximum number of transit units per hour can be given by equation 12.4.

$$N = \frac{3600}{h_{gs}} = \frac{3600}{t_{cs} + t_d + t_{om}} \tag{12.4}$$

Where:

$N$ = Number of transit consists per hour
3600 = Conversion of seconds to hour
$h_{gs}$ = Sum of the controlling time requirements
$t_{cs}$ = Minimum train control separation (secs)
$t_d$ = Dwell or stopped time at station (secs)
$t_{om}$ = Time for operating margin (specified by agency) (secs)

The maximum person capacity of the line can be estimated by applying a person per space factor in equation 12.4, as shown in equation 12.5.

$$P = (N)LP_m\,(PHF) = \frac{3600\ L\ P_m\ (PHF)}{t_{cs} + t_d + t_{om}} \tag{12.5}$$

Where the variables are defined as before except with the following:

$P$ = Person capacity (passengers/hour)
$L$ = Train length (feet or meters)
$P_m$ = Linear passenger loading level (passenger/ft length or per m length)
$PHF$ = Peak hour factor relating peak 15 minute period to total hour

One can derive other sorts of relationships that might be useful in defining transit performance. For example, the time it takes to traverse a rail segment between two stations, assuming that the consist will reach maximum cruise speed, is shown in equation 12.6.

$$t_{ij} = \frac{V_{max}}{2}\left[\frac{1}{a} + \frac{1}{d}\right] + \frac{S}{V_{max}} + t_d \tag{12.6}$$

Where:

$t_{ij}$ = Travel time between station $i$ and $j$ (secs)
$V_{max}$ = Maximum cruise speed (ft/sec)
$a, d$ = Acceleration and deceleration rates (ft/sec$^2$)
$S$ = Distance between stations (ft)
$t_d$ = Dwell time at the destination station (secs)

The number of consists that are needed to provide service on a route given a headway and route length is estimated by equation 12.7.

$$N = \frac{120 \text{ x } L}{V_c \text{ x } h} \tag{12.7}$$

Where:

$N$ = Number of transit consists per hour
120 = Conversion of minutes to hour
$L$ = Length of route (miles)
$V_c$ = Average speed on route (mph)
$h$ = Headway (mins)

Equations 12.3 to 12.7 estimate various variables for fixed guideway transit, that is, where there is no external influence that can affect the movement of a consist, such as traffic congestion. For those cases where there is such an influence, Kittelson et al. [2013] provide other mathematical relationships that can be used to estimate important variables as travel time and vehicle or person capacity. Equation 12.8, for example, can be used to estimate the capacity of a transit line (whether bus or light rail) that runs on a road with traffic signals (assuming no signal preferential treatment for the vehicle or consist). In this case, the capacity is defined at a boarding location, usually the one that takes the longest for riders to get on and off the vehicle or consist.

$$B_l = \frac{3600 \ (g/c)}{t_c + t_d \ (g/c) + Z \ C_v \ t_d} \tag{12.8}$$

Where:

$B_i$ = Loading area capacity (consist or vehicles per hour)
$g/c$ = Ratio of signal green time to total signal cycle length
$t_d$ = Station dwell time (secs)
$Z$ = Standard normal variable relating to a desired failure rate of vehicle arrivals
$C_v$ = Coefficient of variation of dwell times

Note in equation 12.8 that not only is the influence of traffic signals considered in the capacity analysis, but that the uncertainty associated with dwell times is incorporated through the $Z$ variable and the coefficient of variation. Equation 12.8 can be used as well for light rail and streetcar operations in mixed traffic.

It is beyond the scope of this chapter to provide the reader with all of the analysis approaches and tools that can be used to conduct route-level service planning. The reader is referred to [Kittelson et al., 2013 and Vuchic, 2007] for excellent material on all aspects of transit route analysis.

## B. Planning Considerations Influencing Scheduling and Operations

A number of decisions are made in the planning of new lines that directly affect travel time, which in turn influences operations, particularly fleet and driver requirements. First, selecting the line's alignment and degree of right-of-way separation influences operating speed. A second critical component is the selection of station spacing, which requires an analysis of the trade-off between shortened passenger access time and longer in-vehicle time. Vehicle dynamics, such as acceleration rates, braking rates, and maximum speeds, are specified in the planning stages as part of vehicle procurement and also help determine operating speeds.

A critical but often overlooked operational component is standing (or dwell) time, represented as $t_d$ in the travel time equations. Reducing standing time at stations shortens travel times, which may result in higher frequency of service or decreased driver and fleet requirements. Dwell time at a station is a function of the number of passengers boarding and alighting, as well as the number, width, location, access height of a transit vehicle's doors, and method of fare collection. Dwell times increase substantially for crush load conditions. Many of these characteristics are specified during the planning process.

The width and number of doors on a transit vehicle are specified by transit agencies during the vehicle procurement process. The two attributes are often combined and expressed as the number of channels or entry and exit paths. A transit vehicle with three sets of doors, each of which is sufficiently wide to accommodate two passengers simultaneously, is said to have six channels. As the number of channels increases, dwell times decrease. The location of a transit vehicle's doors influences the access time for passengers from within the vehicle. Doors located at the end of vehicles require passengers, on average, to walk a distance equal to one-half of the vehicle's length. By specifying so-called quarter point doors, doors located at one-quarter and three-quarters the length of vehicles, the average passenger walks only three- sixteenths of the vehicle's length to access the doorway. This helps speed the alighting process and reduces total dwell time.

Transit vehicles that require steps to enter and exit have slower boarding and alighting rates, and thus, longer dwell times. High-platform and low-floor vehicles eliminate or reduce the vertical difference in accessing transit vehicles and, therefore, speed boarding and alighting rates and decrease dwell times. High-platform vehicles are most often used when the line is operating on an exclusive right-of-way. Standing times are also greatly influenced by the way passengers' fares are collected.

# XII. FUTURE TRANSIT ISSUES

In both developed and developing countries, the primary growth in population is in cities, and in some cases combinations of cities called megaregions. Mobility in urban areas will become increasingly more difficult as population growth spurs new demands for transportation. Public transportation will play an increasingly important role in the function of cities. Several issues in particular will likely present challenges to transit agencies as they attempt to meet this demand.

## A. Transit Financing

Obtaining the level of funding that will be necessary to provide transit infrastructure and services will be the most important challenge facing the transit industry in coming years. This is especially the case where megaprojects costing in the billions of dollars will be needed to provide transit with successful performance characteristics. Historically, in the United States, much of this funding has come from the federal government, but this level of contribution has been steadily declining over time. Increasingly, communities have been relying on their own sources of funding through a variety of financing strategies (see chapter 5 on transportation finance and funding). In many cases, the sources of

funds for these strategies have been local referenda where voters have approved the imposition of some form of tax (usually sales tax) over some period of time to fund transit. Many of these referenda have been successful and have resulted in important improvements to the local transit system (for example, Denver). Others, however, have been defeated, leaving the transit agency with little opportunity to provide the services that are needed today, no less in the future.

## B. Service Branding

Transit agencies need to aggressively market their services if they hope to compete with today's motor vehicle-oriented transportation system, and even more so if connected vehicle technologies make automobile travel more convenient and safer. Part of this marketing effort will be branding their services. Such branding can be done through advertising campaigns, outreach efforts, and vehicle/infrastructure design (see Figure 12-37). In essence, transit service needs to be viewed as a product that needs to be "sold" in the public marketplace.

## C. Role of the Private Sector

Given the scarcity of public resources, transit agencies have been looking at innovative financing methods for network construction (or expansion) and greater efficiencies in their operations. These two goals may be achieved by greater involvement of various tiers of government and private sector enterprises. These arrangements are broadly known as public-private partnerships (PPP) (see chapter 5 on transportation finance and funding). The primary goals of engaging the private sector in infrastructure projects are to reduce costs and shift the risk of cost overruns from taxpayers.

Private sector involvement in infrastructure investments ranges from designing and building facilities to the financing, owning and operating of systems. An example of planned and constructed systems with private sector involvement includes Los Angeles's LRT Gold Line, a so-called design build project where the project team simultaneously designed and oversaw the construction of a transit system. This design-build concept helped expedite system construction and reduce the need for communication between designers and contractors.

**Figure 12-37. Bus Branded for Downtown Circulator Service, Denver Regional Transportation District**

Photo courtesy of Russ Chisholm, Transportation Management & Design, Inc.

In design-build-operate-maintain contracts, like that used on New Jersey's Hudson Bergen LRT Line, the same consortium that designs and constructs the system operates and maintains the system for some prescribed period of time. This method gives the contract team incentive to produce a high-quality, low-operating cost system. In Vancouver, the Richmond-Airport-Vancouver line (the Canada Line) was advanced as a design-build-finance-operate project. A private contractor (InTransitBC) teamed with Translink, the Province of British Columbia, and the Vancouver International Airport Authority to partially finance, construct and operate the $1.9-billion (CDN), 11.4-mile (19 km) automated rail transit line. In other cases, public/private partnerships and value capture techniques are being used to fund rail stations.

It seems likely that in large metropolitan areas in particular the future of transit system expansion will be tied to innovative finance strategies.

## D. Taxation and Pricing Changes

In addition to land use management, North American government agencies often implement other policies that can affect transit system performance. One example is the policy dealing with the tax implications of employer-sponsored parking. Briefly, employers receive a tax benefit for providing employee parking, but until 1987 no commensurate benefit was available to promote transit use. Since the mid-1980s, employees and employers may derive taxation benefits for costs associated with transit commuting. In Ontario, the provincial government has made the cost of transit passes fully exempt from provincial tax. Similar tax exemptions are available in U.S. cities for employees of companies who participate in such federally sponsored programs.

A reallocation of gas taxes to fund public transportation can provide a secure revenue source for transit agencies and an overall improvement in the quality of services offered. In Canada, municipalities in provinces have reached gas tax agreements by which the federal and provincial governments transfer a substantial portion of gas tax revenues to municipalities for the promotion of sustainable initiatives. Modern road pricing is a technique that sets and automatically collects tolls on roadway sections. Often, prices vary as a function of the time of day or real-time monitoring of traffic conditions. Road pricing can also act as an auto disincentive. In addition, the revenues generated from highway tolls may be used to finance public transportation systems construction and operation.

This practice has become common in Europe with such programs in place in London, Rome, and other cities. In the United States, the concept has been adopted in California, where San Diego's I-15 is priced with revenues dedicated to supporting the Inland Breeze bus service in the corridor. In New York City, revenues generated from bridge tolls help support public transportation. Litman [2004] identified many other fiscal methods that heighten drivers' awareness of auto costs and present opportunities to generate revenue for public transportation.

## E. Advancements in Technology

The rapid development of communications technology has had positive impacts on passenger attraction and operating efficiency. Control centers are now able to monitor and broadcast (by smart phone or Internet) the location of all transit vehicles. This allows users to access real-time information on system performance from home or work using mobile applications (or "apps") or at stations on LED/LCD displays. Real-time passenger information helps reduce uncertainty in waiting times and can increase transit ridership. [Brakewood et al., 2015] For the operator, real-time vehicle location information helps maintain schedule adherence and dispatching of vehicles in response to disruptions in service.

In stations, many transit agencies are installing closed-circuit video surveillance. These systems can be monitored in a control center to expedite responses in emergency situations. Alternatively, the systems may only be recorded and viewed only as necessary in response to a security issue. Closed-circuit TV systems have acted as a deterrent to crime in transit stations and have improved passengers' sense of security. In addition, as noted earlier, automated transit systems have become more common. Improvements in computer control technologies allow automation to play a larger role in the planning and design of medium- and high-capacity transit systems.

Transit agencies will be applying technology to both passenger information and system operations much more in the future. Not only will such technologies make the system more efficient, but they will also provide incentives for people to ride transit.

The other aspect of transportation technology, and one not controlled by transit agencies, is the technological advancements that are occurring in automobiles. New technologies relating to autonomous and connected vehicles are likely going to make automobile travel more convenient, safer, and efficient. One of the first applications of such technologies as the automobile fleet takes time to turn over will likely be dedicated lanes on major freeways where similarly outfitted vehicles can be mixed together. Of course, such freeway corridors are usually prime markets for transit services. Thus, transit agencies need to plan ahead in envisioning their role in transportation system that is more technologically advanced (see discussion above on branding).

## XIII. SUMMARY

Public transportation is a key component of comprehensive and coordinated regional transportation system. This chapter has examined this role from the perspective of the magnitude of trip-making and the impacts that transit has on a community's economic and quality of life. Because of the interconnected nature of transit service, that is, the need for riders to access the network and often transfer from one mode or line to another, transit planners must carefully plan the type of service and the service characteristics to appeal to transit riders. This includes attention to route structure, operational characteristics such as headway, station and stop placement and design, trip costs, and the relationship to surrounding land uses. The most successful transit systems are those that provide trips to where people want to go, and that do so in manner that is comfortable, reliable, and efficient.

Transit planners also have access to many planning guides and manuals that serve as excellent sources of information on planning methodology and tools. Some of the more important references include:

# Planning for Pedestrians and Bicyclists[1]

## I. INTRODUCTION

The transportation system provides travel opportunities for many different types of travelers. From the end of World War II to the 1980s, statewide and metropolitan transportation planning—and even planning at the municipal level—focused almost exclusively on motor vehicles, with only limited attention given to transit and even less to bicycle and pedestrian transportation. However, almost every trip taken either by car or by some form of transit begins with a traveler walking to a vehicle. And in many cities, bicycling is no longer just for recreational trips, but has become an important mode of transportation for other trip purposes as well.

Although transportation engineers and planners are gaining a better understanding of the role and characteristics of bicycle and pedestrian movements, there is still much to learn about pedestrian and bicyclist behavior. One issue, in particular, the safety of pedestrians and bicyclists as they use the transportation system, merits much more attention. Efforts such as the Institute of Transportation Engineers' (ITE) pedestrian and bicycle count database (http://bikepeddocumentation.org/) represent important steps in assembling information about the number of nonmotorized travelers, their characteristics, and the trip purposes/land uses most frequently served by such travel. The transportation planning field has a long way to go, however, to develop tools and methods for analyzing walking and bicycling that are as sophisticated as those associated with motor vehicle network modeling. Some of the exciting developments in pedestrian and bicyclist planning include:

- New technologies, such as remote detection and speed control, as well as new design options, such as split pedestrian crossovers and curb extensions for shorter crossings, are enhancing the visibility and safety of pedestrians.
- In some instances, increased emphasis on land-use interrelationships with nonauto trips is resulting in community designs that are more conducive to pedestrian and bicycle use.
- New transportation design practices such as context-sensitive solutions and Complete Streets can produce roadway designs that incorporate walking and bicycling opportunities in more meaningful ways (see chapter 9 on road and highway planning).
- A rising concern about the relationship between public health and transportation has led to greater emphasis on active transportation, whereby walking and bicycling not only serve a transportation purpose, but also lead to health and safety benefits.

The next section describes typical policy goals that have often served as the foundation for pedestrian and bicycle planning. The following section presents a historical perspective on the evolution of pedestrian and bicycle planning in the United States. This is followed with a description of the planning process used to identify strategies and actions to enhance the walking and bicycling experience. The next section examines design issues specific to both pedestrian and bicycle transportation often discussed during the planning process; the final section presents information on the pedestrian and bicycle experience in Europe and Asia.

## II. GOALS AND BENCHMARKS FOR PEDESTRIAN AND BICYCLE PLANNING

Walking and bicycling are poised to play a greater role in the transportation system. There are many reasons for this. From concerns about increasing levels of motor vehicle congestion to improving public health through increased physical activity to including a more "humanist" perspective in local community design, walking, and bicycling are now commonly part of many transportation plans. Typical goals for pedestrian and bicycle programs usually include: (1) increase the number of bicycling and walking trips as an alternative to motorized transportation, (2) promote bicycling and walking as part of a healthy lifestyle as well as improving the safety of all users of the right-of-way, (3) promote bicycling and walking as a less costly travel mode, and (4) reduce environmental impacts by replacing motor vehicle trips with bicycling or walking trips.

### A. Pedestrian and Bicycle Trips as Alternative Modes of Transportation

Table 13-1 summarizes U.S. walking and bicycling trips as a percentage of all trips for 1990, 1995, 2001, and 2009. To put these numbers in context, a National Bicycling and Walking Study (NBWS) authorized by Congress in 1990 established a goal of doubling the percentage of walking and bicycling trips from 7.9 percent to 15.8 percent. [FHWA, 1994] As shown in the table, walking trips as a percentage of total trips decreased between 1990 and 1995 and increased between 1995 and 2009. These changes are likely attributable to both changes in data collection methods and an actual increase in the percentage of walking trips. The 2001 survey specifically asked respondents to report walking trips, whereas previous surveys did not. In addition, the National Household Travel Survey (NHTS) did not record bicycle trips independently, but included them in an "other" category. Table 13-1 indicates that more people walk or use bicycles than use public transit in the U.S. In fact, these numbers might be underestimated, as many advocates of pedestrian and bicycle transportation argue that these modes are underrepresented in national surveys.

A benchmark report from the Alliance for Biking and Walking, sponsored by the Centers for Disease Control and Prevention's Healthy Community Design Initiative, provides another indication of the changing use of walking and bicycling. [Alliance for Biking and Walking, 2014] The report made the following observations about changes in walking and bicycling from 2005 to 2012:

- There was a small but steady increase in the number of people biking and walking to work.
- There are lower bicyclist and pedestrian fatality rates where there are more people biking and walking.
- More people tend to bike or walk to work when a city has strong biking and walking advocacy.
- People are healthier in states where more people bike and walk.
- Biking and walking fatality rates have been decreasing for decades—but are seeing a recent uptick.
- Few federal dollars go toward bicycling and walking, when considering the total number of trips taken and fatality rates.
- More and more cities are setting goals to increase biking and walking and improve safety. [Alliance for Biking and Walking, 2014]

**Table 13-1. Walking and Bicycle Trips, National Household Travel Survey Results, 1990, 1995, 2001, and 2009**

| | Walking Trips (billion) | Walking Trips % | Bicycling Trips (billion) | Bicycling Trips % | Combined Trips (billion) | Combined Trips % |
|---|---|---|---|---|---|---|
| 1990 NPTS | 21.9 | 7.2% | 1.7 | 0.7% | 19.7 | 7.9% |
| 1995 NPTS | 20.3 | 5.4 | 3.3 | 0.9 | 23.6 | 6.2 |
| 2001 NHTS | 33.1 | 8.6 | 3.3 | 0.8 | 36.4 | 9.5 |
| 2009 NHTS | 41.0 | 10.4 | 4.1 | 1.5 | 42.5 | 11.9 |

NPTS = National Personal Travel Survey

NHTS = National Household Travel Survey

## B. Walking and Bicycling for Healthy Lifestyles

From 1900 to 2010, average life expectancy in the United States increased by 30 years, mainly reflecting improvements in public health services. [Arias, 2014] However, in the past several decades, the average weight of the U.S. population has steadily increased. By the mid-2000s, as much as 60 percent of the U.S. adult population was overweight or obese. [Glendening et al., 2005; Sallis, et al., 2004] This increase in weight and obesity has been attributed by many studies to a lack of physical activity, which has a pronounced aggravating effect on several chronic diseases. See, for example, [Department of Health and Human Services (DHHS), 1996; Frank et al., 2006; Bodea et al., 2008].

According to the U.S. Surgeon General's report on physical activity and health, 70 percent of adults in the United States today do not get the daily recommended amount of physical activity, and approximately 25 percent report being completely inactive when not at work. [DHSS, 1996] Not surprisingly, using motor vehicles for all types of trips reduces the amount of walking and physical movement associated with accomplishing many tasks. Couple the availability of motor vehicles with suburban land-use patterns that have tended to spread activities far apart, and the result is more reliance on motor vehicle travel. [Marshall and Garrick, 2010] For instance, a U.S. Environmental Protection Agency (EPA) study, *Travel and Environmental Implications of School Siting Policies*, showed that between 1969 and 1998, the number of children walking to school dropped by 33 percent. [EPA, 2003] Lifestyle choices, heavily influenced by transportation and urban development patterns, have removed physical activity for nonexercise purposes from many American's lives. [Ewing et al., 2006; Humphrey, 2005]

Physical inactivity also contributes to other health risks. An estimated 32 to 35 percent of all deaths in the United States are attributed to coronary heart disease, colon cancer, and diabetes. These deaths could be reduced if the population were more physically active. Physical inactivity is estimated to account for about 2.4 percent of U.S. health-care costs, or approximately $24 billion per year. [Task Force on Community Preventive Services, 2002] Chronic diseases exacerbated by inactivity account for seven out of every 10 deaths in the United States and more than 60 percent of all medical expenditures. Active transportation—that is, transportation requiring some form of human physical power—is a simple way that physical activity can be included in people's daily lives. [Safe Routes to School, 2012] Approximately 25 percent of all trips in the United States are less than 1 mile (1.6 km) in distance, but almost 75 percent of these trips are made by automobile. [Transportation Research Board (TRB), 2005] In many cases, these short auto trips could be replaced by an active mode such as walking or biking.

## C. Less Costly Travel

Not only has the private automobile been a fixture of American culture for most of the last century, but the cost of owning and operating motor vehicles has also been a major part of an average household's budget. According to the 2009 National Highway Travel Survey, the average U.S. household with a median per-household income of $51,939 per year spends 16.4 percent of its household's expenditures on vehicle ownership (including car payments, fuel, maintenance, insurance, and registration). [U.S. Census, 2012; Oak Ridge National Laboratories (ORNL), 2012] In contrast, the cost of bicycle use is minimal, and the cost of walking is even less. In addition, the cost of providing infrastructure for cycling and walking is significantly less than that for motorized transportation.

## D. Environmentally-Friendly Travel Modes

Bicycling and walking offer an environmentally-friendly alternative to motor vehicle use. Motor vehicle use impacts air quality, water quality, noise, and other community functions (see chapter 4 on environmental consequences in transportation planning). For example, approximately 2,300 pounds of equivalent carbon per person are released into the atmosphere each year from motor vehicle use. Vehicle fluid leakage and tire decomposition contribute to water pollution. See the Federal Highway Administration website [FHWA, 2014c] on the health and environmental benefits of walking, and for an overview of the environmental benefits associated with active transportation. See also Litman et al. [2002].

# III. PEDESTRIAN AND BICYCLIST SAFETY

Given the difference in mass and speed (fatality risk increases sharply at vehicle speeds of 25 mph or greater) between a motor vehicle and a pedestrian or bicyclist, a crash between the two will likely be more deadly to the nonmotorist. National crash records support this. However, crash records that report bicyclist and pedestrian involvement in a

motor vehicle crash represent only a portion of the injuries to bicyclists and pedestrians. In many cases, only collisions that result in an injury or fatality are formally reported and documented in a state's crash database. Many injuries can occur to walkers or bicyclists without a motor vehicle being involved. For example, an analysis of hospital emergency admissions data in 1998 showed that 70 percent of reported bicycle injury events and 64 percent of reported pedestrian injury events did not involve a motor vehicle. [Stutts and Hunter, 1999]

As reported in 2013, 66,000 pedestrians were injured and 4,735 pedestrians killed in traffic crashes. [National Highway Traffic Safety Administration (NHTSA), 2015a] This averages to one crash-related pedestrian death every 2 hours, and a pedestrian injury every 8 minutes. Although a staggering statistic, this actually represents an 18 percent decrease from the number of pedestrian fatalities reported in 1991, consistent with a decreasing trend in all road-related fatalities during the last 15 years. This also exceeds the goal of a 10 percent reduction set in the National Bicycling and Walking Study. [FHWA, 1994]

As shown in crash statistics, pedestrian crashes represent a greater risk for young children and seniors. Nearly one-fifth of children 14 years and younger killed in 2013 traffic crashes were pedestrians, and pedestrians from ages 5 to 15 and 65 and older accounted for 23 percent of all 2013 pedestrian fatalities in traffic crashes. [NHTSA, 2014] Of the estimated 66,000 injured pedestrians in traffic crashes in 2013, 10,000 (15%) were children.

Time-of-day statistics suggest that for young pedestrians (under 16), the afternoon and early evening hours between 3:00 p.m. and 9:00 p.m. are high-risk times, with 61 percent of all fatal young pedestrian crashes occurring during these hours. Nearly half of all pedestrian fatalities involved alcohol, for either the driver or the pedestrian. The number of pedestrian fatalities from distracted drivers rose from 344 in 2005 to 500 in 2010. [Stimpson et al., 2013]

Reported bicycle fatalities have historically represented a smaller percentage of traffic fatalities than pedestrians. Some sobering facts:

- Traffic crashes killed 743 pedalcyclists (bicycles and tricycles) in 2013, and 48,000 were injured, of which 7 percent were children. [NHTSA, 2015b]
- Hospital emergency rooms recorded 515,000 bicycle-related visits in 2012. [DHHS, 2013]
- Over a 10-year period (2004 to 2013), the average age of pedalcyclists killed in motor vehicle crashes has steadily increased from 39 to 44.
- Bicyclists aged 45 to 54 represented 22 percent of those killed and 15 percent of those injured in 2013.
- Alcohol involvement for either the driver or bicyclist was reported in 34 percent of the fatal pedalcycle crashes. [NHTSA, 2015b]
- The number of pedalcyclist fatalities from distracted drivers rose from 56 in 2005 to 73 in 2010. [Stimpson et al., 2013]

See Table 13-2 for the top reasons associated with pedestrian and pedalcyclist fatal crashes in 2013.

Analysis of 2013 crash types and locations indicates that 20 percent of pedestrian fatal crashes (45 percent of those injured) and 33 percent of pedalcyclist fatal crashes (56 percent of those injured) occurred in or near an intersection. [NHTSA, 2014] Of these, almost one-third involved a turning vehicle, and approximately one in five involved a pedestrian running across the intersection or darting out in front of a driver whose view was blocked prior to the event. Sixteen percent of the crashes were related to a driver violation. Midblock locations account for another 26.5 percent of all crashes, with the "dart-out" crash type being the most common.

Several reports illustrate the types of strategies that can reduce pedestrian and bicycle-related crashes, for example:

- *Reducing Collisions Involving Bicycles*, http://safety.transportation.org/htmlguides/bicycles/description_of_strat.htm.
- *Improve Pedestrian and Bicycle Facilities to Reduce Conflicts between Motorists and Non-motorists*, http://safety.transportation.org/htmlguides/UnsigInter/description_of_strat.htm#S17.1_B18.

| Table 13-2. Top Reasons for Pedestrian and Pedalcyclist Fatalities, Representing over 1 Percent of Fatalities, U.S., 2013 | | |
|---|---|---|
| **Contributing Crash Factor** | | |
| **Pedestrian** | **Number** | **Percent of Fatalities** |
| Failure to yield right of way | 1,181 | 24.9 |
| In roadway improperly (standing, lying, working, playing) | 744 | 15.7 |
| Not visible (dark clothing, no lighting, etc.) | 733 | 15.5 |
| Improper crossing of roadway or intersection | 686 | 14.5 |
| Under the influence of alcohol, drugs, or medication | 658 | 13.9 |
| Darting or running into road | 618 | 13.1 |
| Failure to obey traffic signs, signals, or officer | 175 | 3.7 |
| Physical impairment | 103 | 2.2 |
| Inattentive (talking, eating, etc.) | 99 | 2.1 |
| Wrong-way walking | 81 | 1.7 |
| **Pedalcyclist** | **Number** | **Percent of Fatalities** |
| Failure to yield right of way | 233 | 31.4 |
| Failure to obey traffic signs, signals, or officer | 79 | 10.6 |
| Not visible (dark clothing, no lighting, etc.) | 78 | 10.5 |
| Under the influence of alcohol, drugs, or medication | 55 | 7.4 |
| Darting or running into road | 40 | 5.4 |
| Making improper turn | 38 | 5.1 |
| Wrong-way riding | 34 | 4.6 |
| Improper crossing of roadway or intersection | 32 | 4.3 |
| Operating without required equipment | 28 | 3.8 |
| Inattentive (talking, eating, etc.) | 16 | 2.2 |
| Riding on wrong side of the road | 14 | 1.9 |
| Failing to have lights on when required | 19 | 1.5 |
| Improper or erratic lane changing | 9 | 1.2 |
| In roadway improperly (standing, lying, working, playing) | 9 | 1.2 |

See chapter 23 on integrating safety into the transportation planning process, for further discussion on pedestrian and pedalcyclist safety. (Note: The term *pedacyclist* was used in this section because of the way safety statistics are reported. The following sections will use the more common term *bicyclist.*)

## IV. EVOLUTION OF PEDESTRIAN AND BICYCLE PLANNING IN THE UNITED STATES

### A. Early History

Walking is the oldest and most basic form of transportation, whereas the use of bicycles is more recent, dating from the mid- to late 1800s. The ability to walk from place to place directly contributed to the size and shape of cities before the Industrial Revolution. Only the very largest cites could not be crossed on foot in less than 1 hour. Accordingly,

planning for pedestrians prior to the last 50 years typically consisted of providing the ability to walk safely from one part of the community to another (for example, sidewalks). This was particularly true in downtowns and city centers. In most cases, in the late 1800s and early 1900s, sidewalks were paved before roadway surfaces.

Bicycling became immensely popular in the late 1800s. The League of American Wheelmen was formed during this period to lobby for better roads for bicycles, which led directly to the paving of some roadways even in advance of the automobile. The first officially designated bicycle path in the United States was built in 1894 along Ocean Parkway in Brooklyn, New York, and other roads were designated as bicycle routes. Dedicated bicycle facilities, such as bicycle lanes and multi-use paths, did not become widespread until the latter half of the twentieth century, when more formal planning efforts for bicyclists and pedestrians were initiated.

## B. Beginning of Formal Planning Efforts

The bicycling boom of the late 1800s was followed by a period of declining bicycle use in the early 1900s as the motor vehicle became the most popular means of transportation. As the demand for paved roads increased due to rising auto ownership, many urban road designs relegated bicycle use to a secondary or even a nonexistent concern. Outside of downtown areas, pedestrian accommodations such as sidewalks were hardly ever part of the road design. When the U.S. federal-aid highway program was established in the late 1950s, federal aid was targeted toward highway projects, with transit investments becoming eligible in the mid-1960s. Sidewalks and bike paths were considered a local responsibility.

By the 1970s, several states and cities had initiated studies on pedestrian and bicycle transportation. In 1971, for example, Oregon passed legislation requiring the Oregon DOT as well as cities and counties to spend at least 1 percent of their highway funds on bicycle and pedestrian facilities. This resulted in new planning efforts to identify the highest-priority projects for these funds. States such as California, Florida, and New Jersey also began active bicycle programs in the 1970s and 1980s.

At the national level, several initiatives reflected the increasing interest in pedestrian and bicycle transportation. The U.S. DOT *Policy on Major Urban Mass Transportation Investments*, published in August 1975, included a provision for pedestrians and bicycles. The Surface Transportation Assistance Act of 1978 included federal funding support for bicycle projects at about $20 million annually. The Transportation Research Board's *Highway Capacity Manual* first included chapters on pedestrians and bicycles in its 1985 edition, presenting methods to analyze the operations of pedestrian and bicycle facilities.

## C. Recent Interest

Additional support for formal bicycle and pedestrian planning efforts came from the Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991. ISTEA represented a significant shift in U.S. transportation policy because it allowed states and local agencies to develop programs and plans to meet their unique needs. Under ISTEA, all states and metropolitan planning organizations (MPOs) were required to consider facilities for bicyclists and pedestrians as part of their transportation plans. Federal annual spending on bicyclist and pedestrian improvements increased from $4 million to an average of $160 million. And in 2010, the U.S. DOT issued a policy statement on bicycles and pedestrians that stated, "every transportation agency, including DOT, has the responsibility to improve conditions and opportunities for walking and bicycling and to integrate walking and bicycling into their transportation systems. Because of the numerous individual and community benefits that walking and bicycling provide—including health, safety, environmental, transportation, and quality of life—transportation agencies are encouraged to go beyond minimum standards to provide safe and convenient facilities for these modes." [U.S. DOT, 2010]

With the passage of ISTEA, many states and local agencies prepared bicycle master plans, whereas some combined both bicycling and walking in a bicycle and pedestrian master plan. Some states, such as California, required local agencies to have an approved bicycle master plan to qualify for certain state funds. Elements of such plans typically included designating routes and design guidance for new facilities. More sophisticated planning techniques occurred in the 1990s with the advent of geographic information systems (GIS) and aerial imaging to designate bicycle routes and close network gaps.

Through much of the 1990s, pedestrian planning efforts were typically combined with bicycle plans and often were not treated as a distinct mode of travel (and in some cases were grouped with transit in the form of "alternative transportation"). Even today, many state and local agencies combine bicyclist and pedestrian planning under the umbrella of *nonmotorized planning*. However, pedestrian needs are different from those of other travelers. Pedestrian plans typically include policies for pedestrian planning and a discussion of the relationships between transportation and land use. Improvements are typically prioritized and, as with bicycle plans, design guidance for new facilities is frequently suggested. In this text, pedestrians and bicyclists are treated similarly in each section, and differences noted where appropriate. The reason for this is that much of the research and literature on pedestrian and bicyclist transportation can be found together in most reports.

Providing mobility for those with disabilities is a major concern in pedestrian planning. The U.S. Americans with Disabilities Act (ADA) of 1990 is the primary law directing such consideration. Under Title II of the act, all state and local governments "must ensure that individuals with disabilities are not excluded from services, programs (pedestrian facilities such as sidewalks and curb ramps fall under the definition of government programs), and activities because facilities are inaccessible." A U.S. Access Board is responsible for developing minimum standards for accessible design. The ADA Access Guidelines (ADAAG) provide guidance for the design of accessible bicyclist and pedestrian facilities. [U.S. Access Board, 2007] The Board has also adopted Public Rights-of-Way Accessibility Guidelines (PROWAG) that include accessibility provisions for pedestrian access routes (including width, grade, and cross slope) and alternate routes; curb ramps and blended transitions; street crossings; transit stops and shelters; street furniture; and on-street parking.

To assist with designing accessible facilities and ensuring access for all users, FHWA produced *Designing Sidewalks and Trails for Access*, a two-part design guide for designing bicyclist and pedestrian projects. [FHWA, 2001] In addition, the FHWA provides a reference library on bicyclist and pedestrian planning and design at the following website: http://www.fhwa.dot.gov/environment/bicycle_pedestrian/publications/.

## D. State, Regional, and Local Programs

Much of the bicyclist and pedestrian planning efforts in the United States occur at the state and local levels. The federally required statewide bicyclist and pedestrian programs were intended to establish goals and policies for state agencies and to summarize design guidance for local jurisdictions. Some state DOTs have created policies supporting or requiring the integration of bicyclist and pedestrian considerations into the transportation planning and design process [Biton et al., 2014] as well as manuals and guides for design, construction, maintenance, and operation of such facilities. [FHWA, 2014a] Importantly, in some states, dollars have been set aside to support investment programs. For example, statewide programs in Michigan and Oregon allocate 1 percent of gas tax revenues to bicycle and active transportation programs.

Education and safety issues can also be coordinated at the state level. For example, from 2005 to 2012, a federal program called Safe Routes to School provided more than $1 billion to states to support walking and bicycle school access improvements (later legislation combined this with other programs to create a Transportation Alternatives program). Many states have programs to provide off-street trails for bicyclists and pedestrians. National organizations such as the Rails to Trails Conservancy also actively campaign for increased trail facilities.

At the regional level, metropolitan planning organizations (MPOs) are required to develop long-range (20 to 25 years) transportation plans (LRTPs) and multiyear transportation improvement programs (TIPs) to qualify for federal transportation funds (see chapter 16 on metropolitan transportation planning). These plans are required to consider such factors as safety for pedestrian and bicyclist travel, accessibility, environmental quality, and community quality of life impacts, each of which relates to pedestrian and bicyclist transportation.

Given that much of the physical environment for walking and bicycling is the result of local government decisions, local policies and actions are an important context for bicyclist and pedestrian planning. [Meyer and Dumbaugh, 2005] Policies establish long-term directions for jurisdictions and guide staff in the everyday decisions that affect bicyclists and pedestrians, with a goal of creating safe environments for all roadway users. The mechanisms for implementing local policies typically include general or comprehensive plans, modal plans, redevelopment plans, bicyclist and pedestrian plans, ordinances, codes, and standards (see chapter 3 on land use and urban design). Zoning ordinances and development review procedures, for example, can ensure the inclusion of bicycle or pedestrian facilities in new development and redevelopment projects.

Standards describe the types, dimensions, and other design specifications of transportation improvements. In addition to typical roadway cross sections, standards can also include guidelines for traffic control and the requirements for all road users, especially for accommodating pedestrians and bicyclists. Street design that safely accommodates bicyclists and pedestrians and that is sensitive to the surrounding context is one of the most important factors in creating safe travel ways for bicyclist and pedestrian trip-making. For an excellent example of how street designs can do this, see the National Association of City Transportation Officials (NACTO), *Urban Street Design Guide*. [NACTO, 2013]

## E. Important Considerations in Today's Planning Environment

Given the large number of topics and issues considered in the transportation planning process, it is not surprising to find walking and bicycling a consideration in many of them. Some of the more important concepts relating to walking and bicycling include:

### *1. Balance among Transportation Modes and Complete Streets*

The underlying principle of bicyclist and pedestrian planning is that a *balanced* transportation system recognizes the important role that walking and bicycling can play in giving travelers a choice for certain types of trips. For this to happen, bicycling and walking must become more attractive as modal options. In many cases, creating a reasonable balance means more than simply installing sidewalks or designating bicycle facilities. For the pedestrian, it means increased attention to factors that have in the past been beyond the domain of engineers. For example, it could mean making streetscape improvements, which requires collaborative efforts among transportation engineers, planners, landscape architects, and urban designers.

The concept of Complete Streets has become an important framework for considering pedestrians and bicyclists (and other modes) in roadway design. The National Complete Streets Coalition defines a complete street policy as "routinely designing and operating the entire right of way to enable safe access for all users, regardless of age, ability, or mode of transportation." [National Complete Streets Coalition, 2014] Many states and cities have developed planning and design manuals that emphasize design flexibility and balance in developing road space. Some notable examples include:

- Boston—*Boston Complete Streets*, http://bostoncompletestreets.org/.
- Chicago—*Complete Streets Chicago: Design Guidelines*, http://www.cityofchicago.org/content/dam/city/depts/cdot/Complete%20Streets/CompleteStreetsGuidelines.pdf.
- New York City—*Street Design Manual*, http://www.nyc.gov/html/dot/downloads/pdf/nycdot-streetdesign manual-interior-lores.pdf.
- Institute of Transportation Engineers—*Designing Walkable Urban Thoroughfares: A Context Sensitive Approach*.
- National Association of City Transportation Officials (NACTO)—http://nacto.org/usdg/.
- Seattle—Complete Streets Checklist, http://www.seattle.gov/transportation/docs/UPDATED_Complete%20Streets%20Checklist_%2011%2021%2014.pdf.
- Washington State Department of Transportation—*Washington's Complete Streets and Main Street Highways Program*, http://www.wsdot.wa.gov/research/reports/fullreports/780.1.pdf.

See also chapter 9 on road and highway planning.

### *2. Context-Sensitive Design/Solutions*

The quality and character of bicycle and pedestrian facilities have a strong relationship to the *livability* of surrounding communities. Context-sensitive solutions (CSS) is a collaborative, interdisciplinary approach to roadway design that encourages stakeholders to consider the many different aspects of how a roadway "fits" into its environment (see chapter 3 on land use and urban design). The CSS approach seeks designs and solutions that fit the physical

setting and that preserve scenic, aesthetic, historic, and environmental resources while at the same time improving safety, access, and mobility. CSS calls on transportation professionals to consider the needs of all roadway users and the special design features and elements for each group. For bicyclists and pedestrians, these efforts can result in more flexible designs responding to a broader range of community interests. See also chapter 9 on road and highway planning.

### *3. Land Use*

Bicyclist and pedestrian trips are typically characterized by short trip distances, approximately up to one-quarter to 1 mile (1.6 km) for pedestrian trips and up to one-quarter to 3 miles (4.8 km) for bicycle trips. Land-use patterns, therefore, have a critical influence on bicyclist and pedestrian trips. Suburban sprawl and decentralization do not provide effective linkages between residential areas and shopping/employment centers; they instead create a distance barrier for bicycling and walking. Opportunities to provide accessible, safe, convenient, and inviting environments for walking and bicycling need effective land-use planning and design standards. As discussed in chapter 3 on land use and urban design, there is a clear link between urban form and travel characteristics. Some have estimated that land-use strategies involving the 4 Ds—diversity (mixed-use development), density, destinations, and design—have the potential to reduce auto trips by more than 20 percent when compared to sprawling development patterns. [McCormack et al., 2001]

### *4. Education, Encouragement, and Enforcement*

Training and educating bicyclists, pedestrians, and motorists, as well as enforcing laws and regulations, are critical elements of a successful program to enhance walking and bicycling. Children, older adults, recreational bicyclists, walkers, and commuters all have different skill levels, experience, and perceptions of risks when it comes to active transportation. It is important to understand these varying types of users and their needs, to provide both the infrastructure and services that best meet active transportation demand. Every state has a Governor's Highway Safety Representative (with an accompanying office) who is responsible for coordinating the federally supported safety programs in the state. This office is an important participant in planning efforts to enhance the safety environment for those who walk or ride bicycles.

An example of an education and encouragement campaign comes from Pasadena, California, where the city has targeted commuter bicyclists. As of 2015, the city has installed 450 bicycle headlights and tail lights and has distributed bicycle helmets to bicyclists throughout the city. The police department has also focused enforcement efforts on motorist violations that are most dangerous to bicyclists in areas of the city having the most bicycling. [City of Pasadena, 2015]

Perhaps one of the most comprehensive education programs in the country is found in New York City, where the city's transportation and police departments have been working together to provide a safer environment for walking and bicycling. Some of the strategies as targeted on particular groups include:

**School Programs**

- Continue to provide Safety City and in-school presentations for children ages 5–14 focused on navigating streets safely with an increased emphasis on arterial streets and high-risk corridors.
- Develop intensive traffic safety workshop, theater, and art programs (after-school and summer) for students aged 11–17 that reside near the highest-risk corridors in each borough.
- Expand sign and mural artist-in-residence programs for students to engage local communities in traffic safety issues through the creative arts.
- Expand the use of web-based social media resources such as YouTube, Facebook, and Twitter for teens to share their involvement in traffic safety programs with peers.
- Provide Train-the-Trainer programs to Substance Abuse Prevention and Intervention Specialists (SAPIS) at the City's Department of Education to help incorporate traffic safety education into classroom curricula.

**Parents**

- Host parent workshops and "Safety from the Start" program for new parents, targeting low educational attainment populations.

- Focus new effort on pedestrian, passenger, and bicycle safety through Safe Kids Coalition injury prevention outreach to new immigrant groups.
- Expand non-English outreach programs and education efforts, targeting neighborhoods that face a higher risk for pedestrian fatalities.

**Older Adults**

- Provide Safe Streets for Seniors presentations at senior centers located near high-risk corridors and major arterial streets.
- Expand multilanguage pedestrian safety programs, particularly to Asian residents ages 65+ who face higher risk for pedestrian fatalities.
- Develop comprehensive active transportation programs for older adults including information on pedestrian safety, biking, fall prevention, nutrition, medicine, and fitness.

**Materials**

- Update and create new printed educational materials highlighting dangerous behaviors, including failure to yield, speeding, aggressive driving, and inattention.
- Translate additional materials for high-risk, non–English speaking populations. [City of New York, 2010]

***5. Design Flexibility to Enhance Safety***

The 2010 U.S. DOT *Policy Statement on Bicycle and Pedestrian Accommodation Regulations and Recommendations* "encourages transportation agencies to go beyond the minimum requirements, and proactively provide convenient, safe, and context-sensitive facilities that foster increased use by bicyclists and pedestrians of all ages and abilities, and utilize universal design characteristics when appropriate." [USDOT, 2010] All of the design manuals referenced in this chapter provide such flexibility in their guidance and recommended design concepts.

The City of New York has considered a range of design strategies to enhance the walking and bicycling environment, including turning downtown streets into pedestrian zones. Other actions have included:

- Improvements near schools such as signs, high visibility school crosswalks, speed reducers, traffic signal improvements, and bike lanes.
- Removal of curbside parking spaces at the approach to an intersection, to increase pedestrian visibility and reduce turning-vehicle pedestrian crashes.
- Reduction in speed limits in selected neighborhoods and near schools.
- Installation of around 75 speed reducers per year. Before/after studies found an average of 19 percent reduction in speeds where speed reducers are in place, and a city DOT study has found that speed reducers reduce injury crashes by approximately 40 percent.
- Installation of pedestrian countdown signals at the majority of intersections in the city, with priority given to intersections with high pedestrian crashes.
- Added pedestrian crossing time at over 400 traffic signals, installation of 25 pedestrian refuge islands and numerous curb extensions, median extensions, and pedestrian ramps at locations with higher-than-normal elderly populations. [City of New York, 2010]

As will be discussed in the next section, one of the recent perspectives on the design of bicycle networks is the desire to create comfortable and low-stress conditions for use of the lanes and paths. The intent is to provide a design (for example, separated and/or buffered lanes) such that users will perceive the use of the lane as being comfortable and safe.

The best approach for dealing with these considerations is to develop a comprehensive strategy for the community. Pedestrian and bicyclist crashes and injuries, hazardous traffic conditions, lack of enforcement of traffic laws, poor maintenance of walkways and bicycle routes, inadequate lighting and security, and inadequate bicyclist and pedestrian training programs contribute to a challenging environment for walking and bicycling.

## V. PEDESTRIAN AND BICYCLIST PLANNING

Enhancing the pedestrian and bicyclist experience can occur through urban design, facility design, traffic calming, traffic engineering, landscaping, and bicyclist and pedestrian behavior strategies. Notwithstanding the distinct nature of several aspects of both bicycling and walking, this chapter follows the same basic structure described in chapter 1 for transportation planning and shown in Figure 1-1. Each step will be presented from the perspective of how both bicycling and walking transportation planning can be considered. Where specific characteristics of each warrant separate discussion, it is presented in that section.

### A. Understanding the Context and Problem

Most planning studies begin with a preliminary analysis of the problem(s) or challenges being faced. In the case of pedestrian and bicyclist planning, this might reflect such questions as, What are the safety challenges facing pedestrians and bicyclists? Where are the demands for such travel now and in the future? How do demographic characteristics influence walking and bicycling, and thus the characteristics of the facilities and services to meet this demand? What are the characteristics of current walkways and bike lanes, and how do they provide safe and low-stress travel experiences? Is the "network" truly connected to the community, to the transportation system, and to other pedestrian and bicycle facilities?

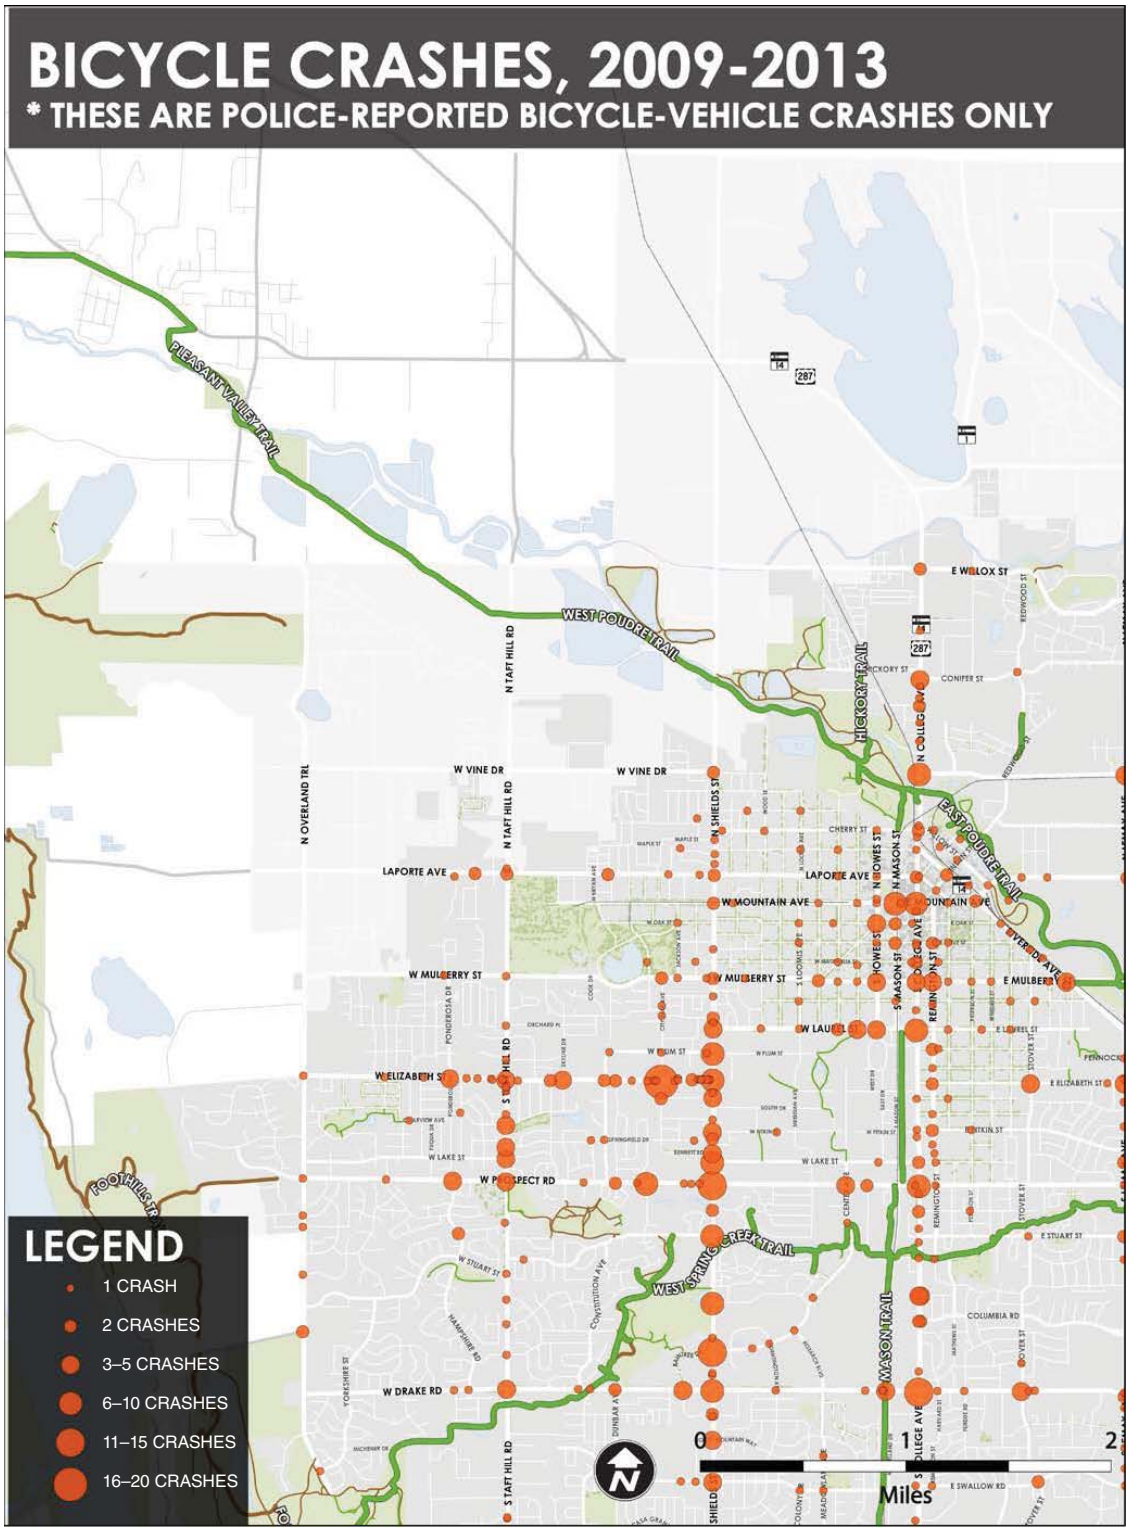
This early analysis is intended to present a comprehensive picture of the existing pedestrian and bicycle system, and the way that addressing its challenges can help guide policy making and the selection and prioritization of future improvements. According to the FHWA, an assessment of current conditions and needs should include the consideration of:

- Current levels of use for walking and bicycling trips, and current numbers of injuries and fatalities involving pedestrians and bicyclists.
- Existing transportation infrastructure (including on- and off-road facilities) to determine current conditions and capacities, and to identify gaps or deficiencies in accommodating potential and existing pedestrian and bicyclist travel.
- Capacities and the type and security level of bicycle parking offered at intermodal connections such as transit facilities and major destination points.
- Desired travel corridors for pedestrian and bicyclist trips.
- Existing land use and zoning, and the patterns of land use in the community.
- Planning, design standards, and agency policies, and the extent to which they affect the accessibility of the transportation system for pedestrians and bicyclists; for example, do they meet policies and design guidance issued by national organizations such as the American Association of State Highway and Transportation Officials (AASHTO) for bicycle and pedestrian facilities?
- State and local laws and regulations affecting a community's vision and goals, for example, growth management and trip reduction laws, or constitutional restraints on expending highway funds on walking and bicycle facilities.
- Availability of bike-on-bus or bike-on-rail access, including hours of service, routes where available, and incentives and barriers to using the service (that is, training, permit, or additional charges). [FHWA, 2014b]

Existing condition data can come from surveys of existing street conditions, journey-to-work data from the most recent U.S. Census, pedestrian and bicycle collision data, and community input. As an example, Figure 13-1 shows the location of bicycle crashes in Ft. Collins, Colorado. By using such information, planners and engineers can better understand the types of issues facing a community, and as illustrated by Figure 13-1, show where serious problems exist.

Gaps in the current network are another common problem/need. In many cases, the pedestrian and bicyclist "network" has developed incrementally over time and often in different geographic locations. Thus, some neighborhoods might have an excellent sidewalk network, while adjacent neighborhoods suffer from a very limited one. Conducting

**Figure 13-1. GIS Depiction of Bicycle Crashes, Ft. Collins, Colorado**

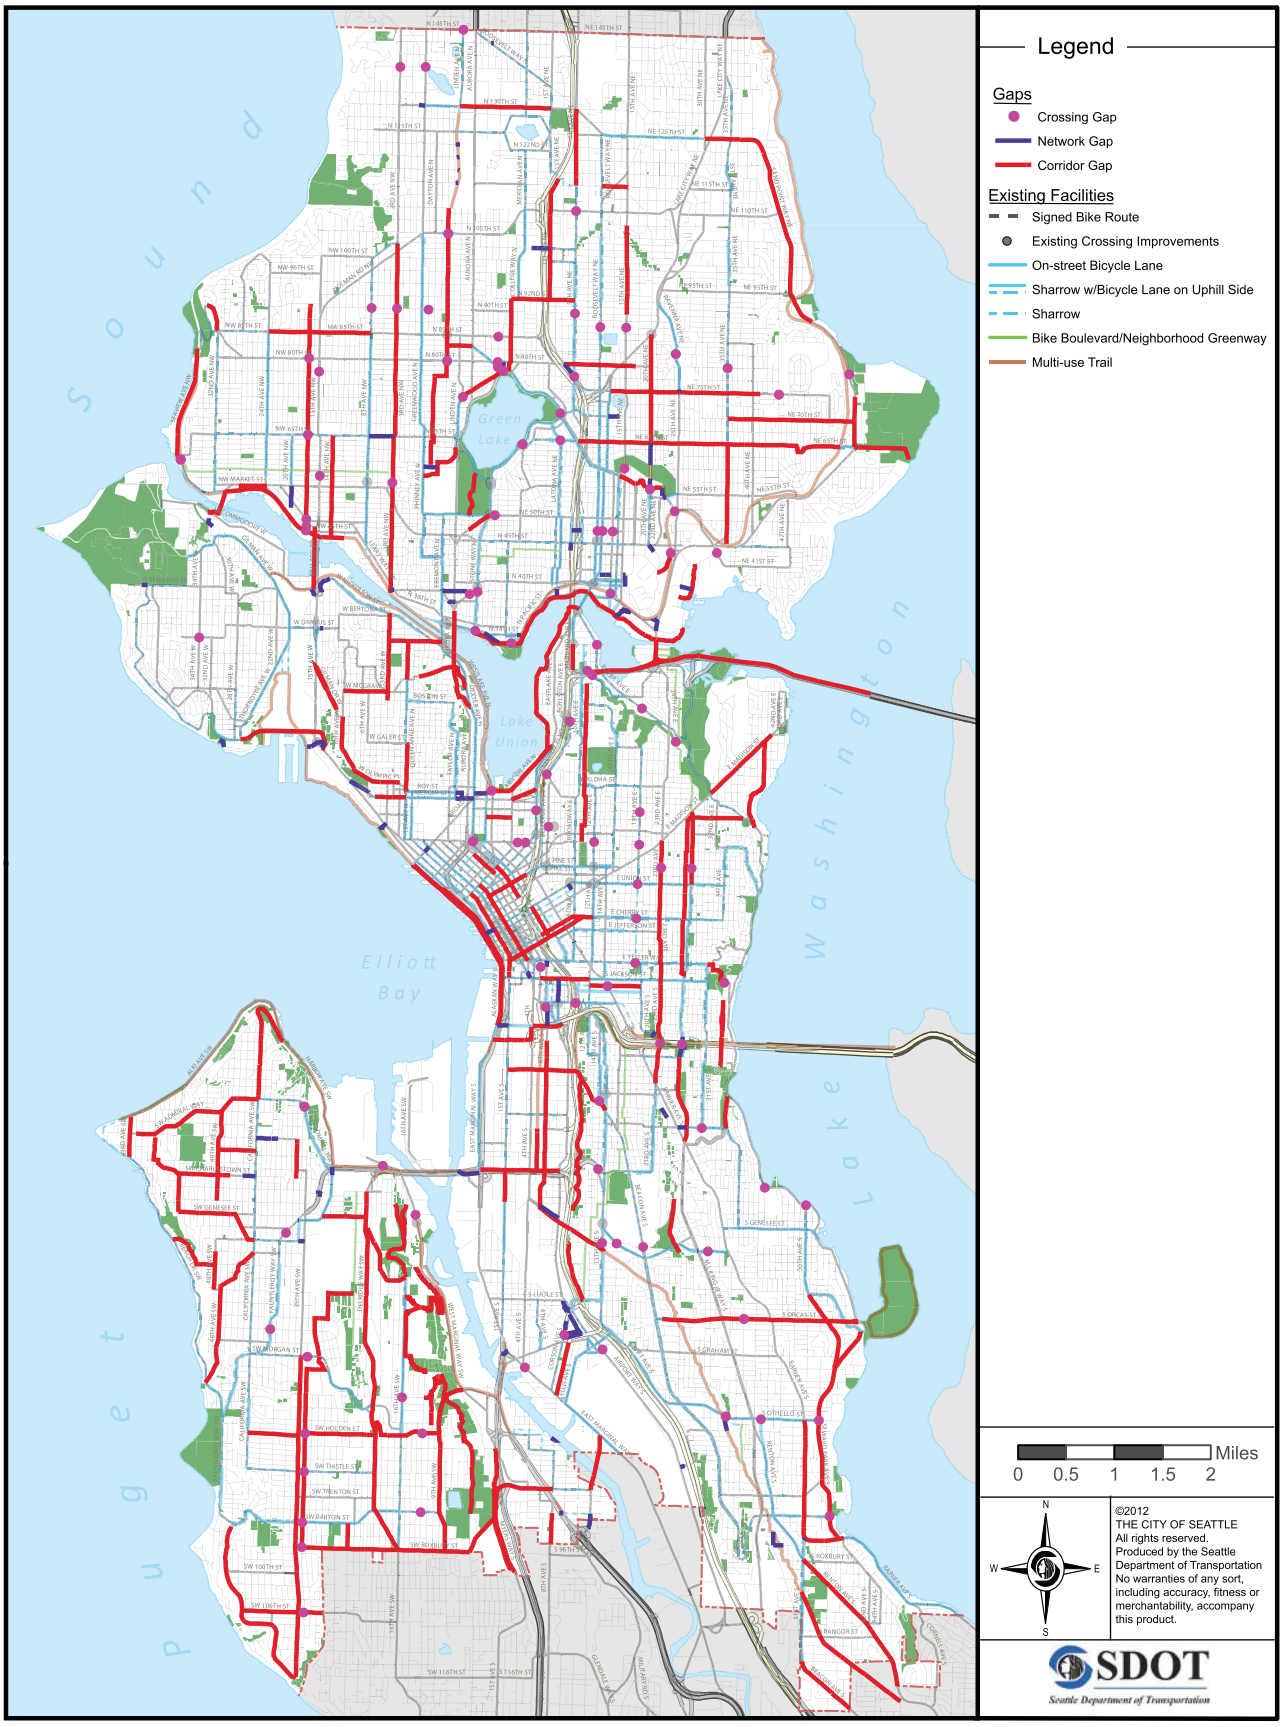


Source: http://www.fcgov.com/bicycling/pdf/appendix_b_state_of_bicycling_in_fort_collins.pdf

a network gaps analysis is one of the first steps in understanding the challenges facing pedestrians and bicyclists. Figure 13-2 shows a typical gaps analysis from Seattle, Washington. Three types of gaps were defined as:

- Crossing gaps are bicycle-related intersection improvements recommended in the 2007 Bicycle Master Plan (BMP), which have not been implemented.

**Figure 13-2. Bicycle Network Gaps Analysis, Seattle, Washington**



Source: City of Seattle, 2012

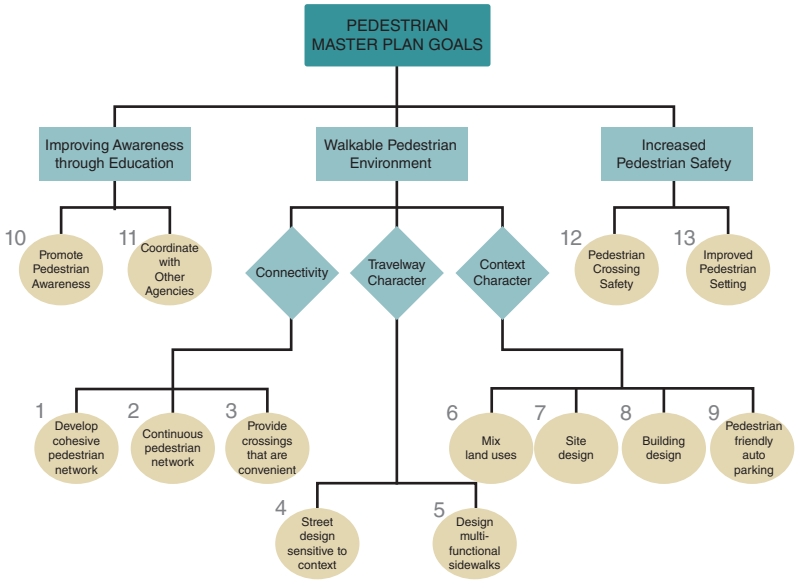
- Network gaps are "missing links" in the network recommended in the 2007 BMP that are less than 1/4 mile (0.4 km) in length and were recommended as either bike lanes, climbing lanes, bicycle boulevards, or multi-use trails, which have not been implemented.
- Corridor gaps are larger voids in the network (greater than 1/4 mile in length). These gaps are most often corridors needed to connect neighborhoods to destinations, giving bicycle riders a variety of travel route options. [City of Seattle, 2012]

## B. Developing Vision/Goals/Objectives/Performance Measures

Planning for pedestrians and bicyclists should be based on a vision of what a community desires with respect to pedestrian and bicycle movement, and a clear statement of a study effort's goals and objectives. As with any planning document, it is important to delineate existing and proposed policies and objectives. These help guide subsequent planning and other future planning activities. The vision/goals/objectives also clearly communicate to citizens, government agencies, and developers the desired role of pedestrian and bicyclist transportation in the state, region, or city. Good plans also evaluate broader jurisdictional goals, such as those contained in general or comprehensive plans, to determine their influence on bicycling and walking. Land use, level of service, and level of stress or comfort policies are particularly relevant.

The vision should inform the development of the goals, which are subsequently used to determine program objectives and policies. Objectives, in turn, determine the evaluation criteria for assessing actions, programs, projects and tasks. Figure 13-3 shows the concept of a hierarchy as seen in the Sacramento Pedestrian Plan, and Table 13-3 shows a similar hierarchy with performance measures from the 2015 Chicago Bike Plan. Note in Table 13-3 that examples of strategies and performance measures are provided for only one objective, to illustrate the concept. The remainder of the table presents the objectives and corresponding strategies. For a more complete presentation of the Chicago material, see [City of Chicago, 2015].

**Figure 13-3. Goals and Objectives for Sacramento Pedestrian Plan**



Source: City of Sacramento, 2006

The City of Pasadena's Bike Plan provides another example of a goals statement. [City of Pasadena, 2015] Six goals were identified to guide the process of bike planning:

1) Create an environment where people can circulate without a car.
2) Increase the number of bicyclists in Pasadena by encouraging people to use their bicycles instead of driving.
3) Increase the safety of bicycling in Pasadena.
4) Increase opportunities for traffic safety education for all travel modes and age groups in Pasadena.
5) Promote the health of Pasadena residents by providing opportunities to bicycle for commuting, recreating, shopping, and visiting.
6) Facilitate the economic viability of Pasadena by making Pasadena an attractive place to live, shop, and operate a business.

| Table 13-3. Vision, Objectives, Strategies, and Performance Measures, City of Chicago Bike Plan |
|---|
| **Vision: Establish a 500-mile bikeway network in Chicago that is the equal of the best in the world** |
| **Objective 1: Add new bike lanes and signed bike routes** |
| *Strategy 1:* Establish the bike lanes recommended in the *Streets for Cycling Plan*. |
| Performance Measure: Establish 10 miles (16.1 km) of bike lanes by 2007; an additional 10 miles by 2010. |
| *Strategy 2:* Establish bike lanes at locations that are not identified in the *Streets for Cycling Plan*. |
| Performance Measure: Determine locations by 2007. Establish 26 miles (41.8 km) of bike lanes by 2015. |
| *Strategy 3:* Establish shared bus/bike lanes. |
| Performance Measure: Establish 2–3 bus/bike lanes by 2008. |
| *Strategy 4:* Continue signing the bike routes identified in the *Streets for Cycling Plan*. |
| Performance Measure: Sign an additional 85 miles (136.8 km) of bike routes by 2009. |
| **Objective 2: Establish new trails, improve existing trails, and improve access to trails** |
| **Strategies**<br>• Construct grade-separated connections at appropriate locations to connect trails and provide safe crossings of busy roadways.<br>• Regularly update trail planning, design, and construction standards.<br>• Ensure that trails built as a condition of development approval are designed and built to appropriate standards.<br>• Establish a trail circuit to permit a long recreational or fitness bike ride in Chicago.<br>• Establish the trails recommended in the *Chicago Trails Plan*.<br>• Establish the new trails, trail improvements, and new trail access points recommended in the South Lakefront Access Study and Chicago Park District Framework Plans.<br>• Upgrade and extend existing trails. |
| **Objective 3: Use innovative designs to expand and enhance the bikeway network.** |
| **Strategies**<br>• Color the pavement at selected bikeway locations to alert motorists and bicyclists of conflict areas and assign the right-of-way to bicyclists.<br>• Install special pavement markings on streets too narrow for bike lanes.<br>• Install signs advising motorists and bicyclists that bicycle traffic may move to the center of the travel lane.<br>• Consider establishing bikeways on streets with rush hour parking controls.<br>• Establish dedicated right and left turn lanes for bicycles.<br>• Determine the appropriateness of advanced stop bars at intersections with high volumes of bicycle traffic.<br>• Install raised bike lanes at appropriate locations.<br>• Establish bike boulevards to prioritize bicycling on streets with low traffic volumes and slow speeds.<br>• Implement measures on selected streets with bikeways to reduce speeding and encourage bicycling. |
| **Objective 4: Establish bikeways to priority destinations.** |
| **Strategies**<br>• Establish bikeways to elementary schools, high schools, colleges, and universities.<br>• Connect bikeways to adjoining municipalities.<br>• Establish or enhance existing bikeways to transit stations. |

(*continued*)

| Table 13-3. (*Continued*) |
|---|
| **Vision: Establish a 500-mile bikeway network in Chicago that is the equal of the best in the world** |
| • Identify the locations for new crossings over the Chicago River, Calumet River, North Shore Channel, and Sanitary and Ship Canal.<br>• Establish bikeways to and within the loop.<br>• Improve access to the Lakefront Trail and other popular trails. |
| **Objective 5: Help current and potential bicyclists choose safe, convenient routes.** |
| **Strategies**<br>• Develop and widely distribute a new Lakefront Trail map.<br>• Collect data to identify popular bikeways and the impact of Bike 2015 Plan strategies.<br>• Provide detour routes and signage.<br>• Provide interactive online mapping to enable bicyclists to develop personalized maps.<br>• Install bicycle information boards at critical junctures in the bikeway network to provide bicyclists detailed route information. |
| **Objective 6: Prioritize ongoing maintenance and repair of the bikeway network.** |
| **Strategies**<br>• Maintain bike lanes in excellent condition.<br>• Ensure prompt repair of pavement cuts on streets with bikeways.<br>• Upgrade the on-street bikeway network on a regular basis.<br>• Identify and immediately replace grates that trap bicycle wheels.<br>• Retrofit metal grate bridges to make them safer for bicycling. |

Source: City of Chicago, 2015

Each of these goals had related objectives, and each objective had recommended actions to achieve the objective. For example, one of the objectives and associated actions for the first goal above included:

Objective: Increase the proportion of bicycle commute trips in Pasadena by 5 percent.

Actions

1. Implement planned citywide network of bikeways.
2. Recognize that bicyclists ride on all streets and that all streets need to accommodate bicycles.
3. Improve technology to ensure that bicyclists can activate traffic signals at vehicle-actuated intersections.
4. Maintain bikeway and roadway system.
5. Conduct periodic bicycle counts at various locations and upgrade the bikeway network.
6. Assist employers with promotional campaigns to encourage bicycle commuting.
7. Coordinate with the Pasadena Trip Reduction Ordinance enforcement and monitoring to ensure that employers and land owners of commercial property carry out bicycle commuter incentive programs.

Performance measures monitor the performance of the transportation system with respect to identified goals. This is a relatively recent concept in transportation planning and is intended to provide accountability for the investments made to improve system performance. Examples of performance measures for pedestrian and bicyclist planning might

be the number and rate of pedestrian- and bicycle-related crashes, the number of established pedestrian and bicycle routes to schools and transit stops, the level of investment in pedestrian and bicyclist amenities, the number of outreach meetings or website hits, and the number of projects that incorporate pedestrian and bicyclist considerations into their design.

The bicycle plan for the City of Ft. Collins, Colorado, [City of Ft. Collins, 2014] provided some sense of what a bicycle future in the city might look like:

- A target 20 percent of people will commute by bicycle.
- A balance of genders will bicycle.
- There will be zero bicycle fatalities.
- The number and severity of bicycle-related crashes will be lower than today.
- There will be a 162-mile (260.7 km) low-stress bicycle network.
- A target 80 percent of residents will live within one-quarter mile (0.4 km) of a low-stress bicycle route.
- All neighborhoods will have access to a low-stress bicycle route.
- The City will have implemented a protected bike lane demonstration program.
- A target 8,000 K–12 students will receive bicycle education annually.
- Participation in the City's bicycle education and outreach programs will reflect the demographic and socioeconomic breakdown of the Fort Collins population.
- The number of residents participating in the City's education and outreach programs will have doubled.
- A target 55 percent of residents will find it very easy to travel by bicycle.
- Childhood and adult obesity rates will be lower.
- Greenhouse gas emissions will be 20 percent lower than 2005 levels.

An effective pedestrian and bicyclist planning process should involve the public and various stakeholders, especially in helping define the community vision and related goals/objectives. This participation may include staff from related agencies, potential users of the system, citizen's advisory committees, and other groups that the plan may affect. Bicyclists, in particular, have formed advocacy groups that are very active in the transportation planning process. Partnerships, including intra-agency partnerships, public-private partnerships, and community involvement strategies, can be useful for implementing local bicyclist and pedestrian policies and helping secure necessary funding. Because an entire chapter is dedicated to public engagement techniques and strategies, the reader is referred to chapter 24 on public participation and engagement for further information.

## C. Analyzing Walking and Bicycling Alternatives

Several techniques and tools can be used to analyze the conditions faced by pedestrians and bicyclists, and to identify improvement strategies. The first section focuses on the types of data that these techniques and tools rely on.

### *1. Data*

As with data collected for motor vehicle and transit trips, planners will want to collect data on the characteristics of walking and bicycle trips. This includes such things as the overall number of trips, trips by time of day, distance traveled, number of repeat trips, and characteristics of the travelers themselves. However, walking and bicycle trips exhibit very different characteristics than trip-making by car or transit. According to Ryus et al. [2014], the main differences include:

> *Pedestrian and bicycle volumes are more variable than motor vehicle volumes. While both motorized and nonmotorized volumes vary over time (e.g., by time of day, by season of year), nonmotorized volumes on a given day are much more sensitive to the weather that day than are motorized volumes. In addition, hourly pedestrian and bicycle volumes at*

*most locations tend to be relatively low compared to the volumes observed at typical motorized vehicle count sites; these lower volumes also contribute to higher day-to-day variability.*

*Pedestrian and bicycle trips tend to be shorter than automobile trips and are often made for different purposes. As a result, pedestrian and bicycle volumes tend to be more sensitive to adjacent land uses (automobiles may be just passing through an area, rather than beginning or ending a trip there), and peak periods for pedestrian and bicycle trips may not necessarily coincide with the peak periods for automobile traffic.*

*Motor vehicles tend to be easier to detect than pedestrians and bicycles. Pedestrians and bicyclists are smaller than motor vehicles, often travel together in close groups, and may travel outside designated walkways and bikeways. In contrast, motor vehicles are large, metal objects that move in lanes and travel with relatively sizable gaps between each vehicle.*

*Experience with pedestrian and bicycle counting technology is more limited than for motor vehicles. The technologies commonly used to count motor vehicles are well established, counting errors associated with particular technologies are understood, and methods for addressing errors are fairly well developed [FHWA 2013]. In contrast, some of the counting technologies used for nonmotorized counting are different than those commonly used for motorized vehicle counting, and new technologies are emerging.*

The type of data collected will depend on the type of study being undertaken, and the evaluation criteria that will be used later to assess the relative effectiveness of different strategies and alternatives. For example, if the data are intended for an area-wide pedestrian and bicycle study, then it is likely that data collected would relate to existing conditions, trip-making characteristics, factors affecting future demand, and socioeconomic characteristics of those walking or bicycling. However, if the study is a before-and-after study of the implementation of a particular strategy or action, then the data collection would be much more targeted on the specific changes that were expected once the project was in place.

An example of the influence of evaluation criteria on data collection comes from the City of Pasadena Bike Plan. The major evaluation criterion in determining need and network gaps was the level of stress associated with traveling the current bicycle network. Table 13-4 shows how four levels of stress were defined in the study.

It was noted in the study that vehicle speed was the most important factor in defining the level of traffic stress, and that lower levels of stress could be achieved only on streets with a speed limit of 30 mph or lower. Figure 13-4 shows how the collected data on traffic stress were portrayed on a network map. Those segments with bolder colors are identified as routes with extremely low comfort levels for many bicyclists.

It is beyond the scope of this chapter to present all of the information and data that would likely be collected as part of a study on pedestrians and bicyclists. However, Tables 13-5 to 13-8 illustrate the types of data that are often collected. These tables come from NCHRP Report 803, *Pedestrian and Bicycle Transportation Along Existing Roads—ActiveTrans Priority Tool Guidebook*. [Lagerwey et al., 2015] This report is discussed in more detail in the section on prioritization.

In addition, cell phone–based probe data can be used to obtain bicycle and pedestrian speeds. Detailed information on the data collection process and typical data collection technologies is found in [Ryus et al., 2014].

**Table 13-4. Level of Traffic Stress Criteria, Pasadena, California**

| Level of Traffic Stress (LTS) | Level of Comfort | Description |
|---|---|---|
| LTS 1 | High | Comfortable for most children |
| LTS 2 | Medium | Comfortable for mainstream adult population—generally considered to be 60% of the U.S. population who are interested in bicycling, but only comfortable, generally, on off-street bikeways or quiet residential streets |
| LTS 3 | Low | Comfortable for "enthusiastic and confident" adult bicyclists generally considered to be +/− 6 percent of the population and who prefer dedicated bicycling space |
| LTS 4 | Extremely low | Comfortable for only "strong and fearless" adult bicyclists generally considered to be ≤ 1 percent of the population and who will generally bicycle regardless of the facility type |

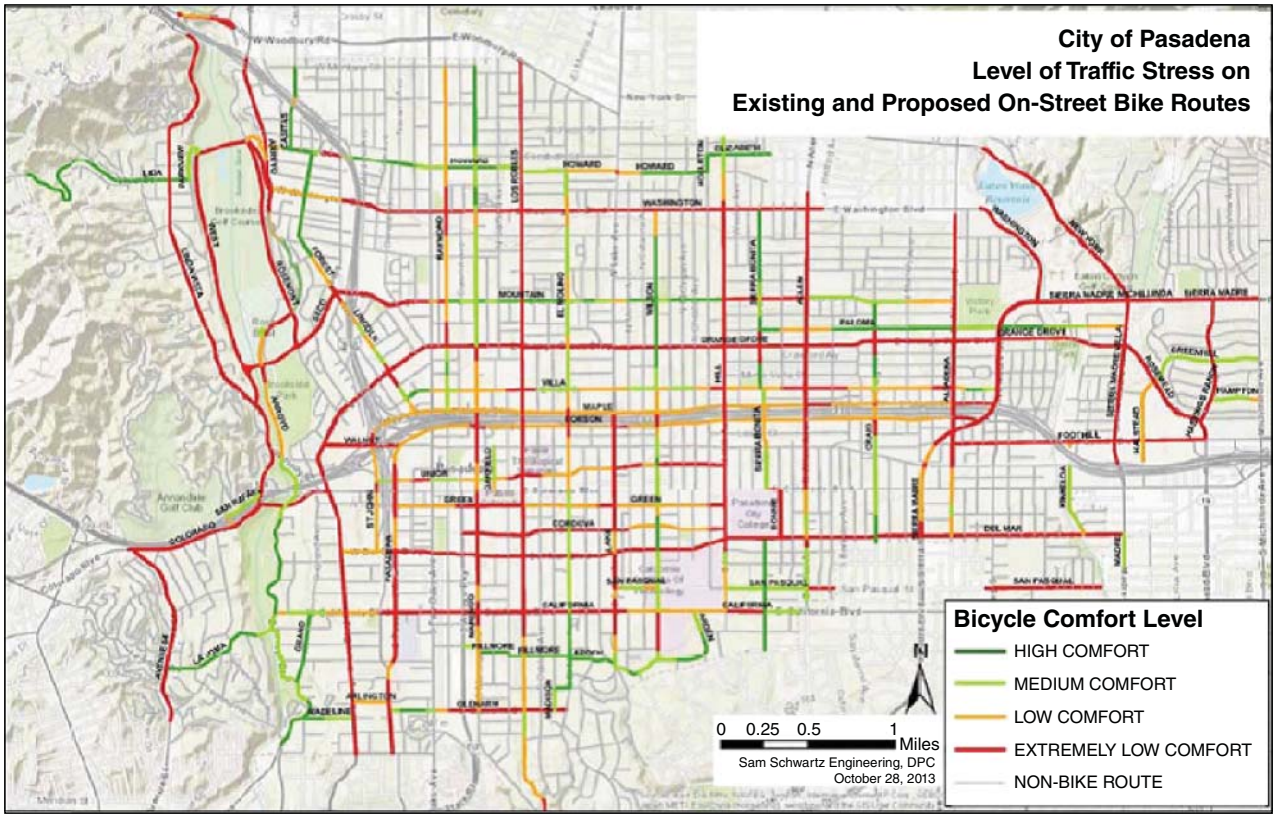
**Figure 13-4. Application Traffic Stress Level Data in Defining Bicyclist Comfort Level, Pasadena, California**



Source: City of Pasadena, 2015

### *2. Surveys*

One of the most common approaches for identifying current problems and defining the characteristics of walking and bicycling demand is to survey likely travelers. For survey results to be representative, they should be statistically valid (that is, sample sizes and population distributions should reflect the community's population), although many informal surveys are done simply to assess people's attitudes about walking and bicycling (see chapter 2 on travel characteristics and data). For example, a telephone survey conducted by The Gallop Organization for the National Highway Traffic and Safety Administration (NHTSA) in 2008 included a nationally representative sample of 9,616 respondents 16 or older. [Royal and Miller-Steiger, 2008] The results were then weighted to reflect the national population of 208 million aged 16 or older at that time in the United States. These survey results were not only useful in understanding some of the key factors that influenced pedestrian and bicyclist trip-making, but they could readily be related to the types of variables used in travel demand models. Some of the interesting results from this survey included:

- Nearly half of people 16 or older (46 percent) had bicycles available for their use on a regular basis. Those under 21 were the most likely to have access (62 percent), while less than one-quarter (23 percent) of those 65 or older reported access.
- While males are only somewhat more likely to have access to a bicycle than females (51 percent versus 42 percent), they are nearly twice as likely as females (24 percent versus 13 percent) to say they ride their bicycle at least once a week in the summer months.
- Reasons for not bicycling include lack of access to a bicycle (28 percent) and lack of need or desire to ride a bicycle (25 percent). Physical difficulty (11 percent) or weather conditions (10 percent) were mentioned by 1 in 10. Bicyclists 65 and older were most likely to cite physical difficulty (21 percent) as their primary reason for not bicycling recently.
- Nearly 9 in 10 (89 percent) trips began at a residence either belonging to the bicyclist or someone else. An additional 7 percent of trips began at a leisure or recreational site such as a park. Just 1 percent began at work, and 3 percent began in some other location.

| Table 13-5. Data Sources/Tools for Inventorying Data and Related Existing Conditions Variables for Nonmotorized Transportation | |
|---|---|
| **Inventory Data Source/Tool** | **Can Be Used to Inventory Data for These Variables** |
| Aerial imagery | • Sidewalk and buffer presence and width<br>• Marked crosswalk presence and type<br>• Median island presence and width<br>• Bicycle facility presence and width<br>• Lane width/shoulder width<br>• Pedestrian crossing distance |
| Street-level imagery (e.g., video log, street view) | • Curb ramp presence<br>• Tactile warning strips<br>• Pedestrian/bicycle-related signage<br>• Major sidewalk obstructions<br>• Pedestrian signal heads<br>• Pedestrian push buttons |
| Direct field observation (using technological data collection tools or manual observations) | • Precise lane width/shoulder width<br>• Traffic volume<br>• Traffic speed<br>• Sidewalk condition<br>• Crosswalk condition<br>• Pavement condition<br>• Curb ramp slope<br>• On-street parking presence and occupancy |

Source: Lagerwey et al., 2015, Reproduced with permission of the Transportation Research Board.

- The most common purposes of trips were for recreation or leisure (29 percent) and for exercise or health reasons (24 percent). Fewer trips were made to run personal errands (14 percent), to go home (14 percent), or to visit a friend or relative (10 percent). Just 5 percent said they used their bicycles for commuting to work or school.
- Nearly 3 in 4 (72 percent) people 16 or older reported that they walked on average at least once a week during the summer months.
- While about one half (51 percent) of all pedestrians reported no change in their walking behavior compared to a year ago, 3 in 10 (30 percent) reported walking more often, while 19 percent reported walking less often. Females (32 percent) were slightly more likely to report an increase in walking behavior from a year ago than were males (28 percent).
- The top reasons given for not walking included lack of desire or need (27 percent), disabilities and other health impairments (25 percent), and weather conditions (23 percent). Females were more likely to cite disability (31 percent) and weather conditions (28 percent) as a reason for not walking than were males (18 percent and 19 percent, respectively). Males were more likely to report a lack of desire or need (32 percent) than females (23 percent). One-half (50 percent) of those 65 and older who did not walk reported the main reason was because of a disability.

| Table 13-6. Data Considerations/Sources for Demand Proxy Variable for Nonmotorized Transportation | |
|---|---|
| **Example Demand Proxy** | **Data Considerations/Sources** |
| Population density | • Population of given geography divided by its area |
| Employment density | • Employment is often compiled at the regional level and made available to local agencies by request from the Census for traffic analysis zones. Density is calculated by dividing the number of employees by a measure of area. |
| Commercial retail property density/proximity/accessibility | • Parcel data |
| Transit station or stop density/proximity/accessibility | • Point data typically maintained by the transit agency |
| Density/accessibility/proximity of key attractors (schools, parks, community centers) | • Parcel data, point data layers for specific land use attractor types |
| Proximity to college/university campus | • Parcel data |
| Bicycle facility density/accessibility | • Facility inventory |
| Presence of sidewalk | • Sidewalk inventory |
| Roadway density/connectivity | • Street centerline data |
| Roadway slope | • May be calculated using topographical data and length of segment, may also be part of street centerline data |
| Number of boardings at transit stop | • Daily, monthly, or annual boardings may be available from the transit agency, or may be an attribute of stop location point data or transit route data; may include patrons with bicycles. |
| Socioeconomic characteristics | • U.S. Census data |
| Proximity to or number of bike share docking stations | • Point data layer (GIS) of bike share stations |

| Table 13-7. Data Considerations/Sources for Safety Variable for Nonmotorized Transportation | |
|---|---|
| **Example Safety Variable** | **Data Sources** |
| Total number of pedestrian/bicycle crashes | Police crash database, often available at the state or local level |
| Fatal and severe injury pedestrian/bicycle crashes | Police crash database, often available at the state or local level |
| Pedestrian/bicycle crash rate | Police crash database combined with measure of exposure (e.g., pedestrian/bicycle counts, pedestrian/bicycle demand proxy variables) |
| Proportion of pedestrians walking in the roadway | Pedestrian counts (generally manual counts in the field, with instruction to note pedestrians in roadway) |
| Proportion of pedestrians complying with "Don't Walk" signals | Pedestrian counts (generally manual counts in the field, with instruction to note "Don't Walk" compliance) |
| Proportion of bicyclists complying with red lights | Bicycle counts (generally manual counts in the field, with instruction to note red light compliance) |
| Proportion of motorists complying with right turn on red restrictions | Vehicle counts (generally manual counts in the field, with instruction to note right turn on red movements) |
| Proportion of motorists yielding to pedestrians in crosswalks | Vehicle counts (generally manual counts in the field, with instruction to note yielding rates) |
| Number of "near misses" involving pedestrians/bicyclists | Multimodal counts (generally manual counts in the field, or based on video footage of a location) |

Source: Lagerwey et al., 2015, Reproduced with permission of the Transportation Research Board.

| Proportion of population that is overweight or obese | • Public health agency community surveys or health profiles |

Source: Lagerwey et al., 2015, Reproduced with permission of the Transportation Research Board.

Because this was a representative sample of the U.S. population, the results can be understood to explain bicyclist and pedestrian behavior in the United States during the mid-2000s.

An example of a nonrepresentative survey comes from Baltimore, Maryland, where planners distributed surveys over a multiyear period at public meetings, libraries, universities, and on the Internet to find out more about bicyclist behavior and desires. [City of Baltimore, 2006] Just over 300 surveys were completed and, although from a statistical sense the results cannot be considered representative of the entire community, they did provide useful information concerning bicycle use and bicyclists' desires. Some results included:

**Preferred facilities for bicycling:**

- 43 percent—bike lanes
- 31 percent—street with no facilities
- 19 percent—bike paths
- 7 percent—sidewalks

**Factors for choosing to bike:**

- Safety of travel route
- Weather
- Traffic levels
- Need for exercise

Respondent profile: 58 percent men; 42 percent women; average age 36; used a bike on average 3 days per week; and 30 percent had been involved in a crash.

### *3. Travel Demand Models*

Current bicycle and pedestrian volumes are not a complete indication of the potential demand for walking or bicycling. Inadequate facilities for safe travel as well as dispersed land-use patterns that create a perception of long trip distances can dampen the desire to walk or bicycle. While bicyclist and pedestrian travel demand models have not reached the level of sophistication of road network demand modeling, some techniques can provide reasonable estimates of the demand for such travel (see, for example, [Krizek et al., 2006]). Characteristics of the land uses adjacent to bicycle and pedestrian networks and how they can influence the decision to bicycle or walk are an important consideration

in these models. NCHRP 770, *Estimating Bicycling and Walking for Planning and Project Development: A Guidebook* [Kuzmyak et al., 2014], is one of the best references for estimating pedestrian and bicycle demand. Some lessons learned from this research included:

- Recognize an obvious but critical difference between biking and walking; although both are nonmotorized modes and often combined as such in regional models, the distance range (0.7 mile [1.1 km] average trip length for walk, 2.3 miles [3.7 km] for bike), network needs, user characteristics, and trip purpose types are substantially different between the two modes.
- The relationship between the built environment (land use) and travel network are extremely important, particularly for walking and biking. Walking and biking demand levels are heavily predicated on the number and variety of opportunities accessible within comfortable travel distance/time envelopes.
- Acceptable trip distances vary by trip purpose: travelers seem more willing to travel longer distances for trips to work (about 1 mile for pedestrians, 4 miles for cyclists) than for personal business, shopping, or socializing (0.5 to 0.7 miles [0.8 km to 1.1 km] for pedestrians, 1.0 to 1.5 miles [1.6 to 2.4 km] for cyclists).
- Persons living in more compact, mixed-use settings tend to make more trips as simple tours (single-purpose, one-stop journeys), while those in automobile-oriented settings make more multi-stop complex tours; the choice of walk, bike, and transit as modes was found to be much more likely with simple tours.
- The natural environment is of much greater consequence to nonmotorized travelers than those traveling by automobile or transit: steep hills and topography that cause circuitous travel paths are barriers. Extremes in temperature, precipitation, and hours of daylight affect proclivity to walk or bike.
- Personal safety is a major concern to nonmotorized travelers, particularly in relation to exposure to motor vehicle traffic. In areas with higher traffic volumes or higher speeds, as in commercial areas, sidewalks and separated paths become more important considerations in the decision to walk or bike.
- Sociodemographic differences are observed between motorized and nonmotorized travelers, and between pedestrians and cyclists. In general, walking and biking rates peak in the youngest years, and then tail off with advancing age, although this is a trend more common in the United States than in other peer (Western) countries. Although women over 25 years of age have a higher percentage of walking than men, male cyclists outnumber females by almost four to one (again a trend highly indigenous to the United States).

The report identifies several analysis methods and tools that can be used to estimate the travel demand for walking and bicycling. The authors divide them into three major categories:

- *Tour-Generation and Mode-Split Models*. Pedestrian and bicyclist models can be used for generating trip tours as well as predict mode choice as part of activity-based models (see chapter 6 on travel demand modeling for a more detailed description of tour-based and activity-based modeling).
- *GIS-Based Walk-Accessibility Model*. Estimates of walk trip generation and mode split can come from geographic information system (GIS) tools and data. Similar types of analyses have been conducted in several U.S. cities. The approach estimates measures of accessibility to or from any point by any mode and by type of attraction. By comparing modal accessibilities, the model can then estimate mode split and create walk trip tables by trip purpose.
- *Enhancements to Trip-Based Models*. The conventional four-step modeling process can be modified by introducing a "pre-mode split" step, which first divides trips into intra- versus interzonal groups, and then performs a mode-split step specific to those groups. This allows the analysis to take into account zone-specific characteristics that could influence pedestrian and bicyclist demand. Some of these variables could include: number of local intersections within one-half mile (0.8 km) of each zone, households within one-half mile of each zone, retail employment within one-half mile of each zone, total employment within one-half mile of each zone, door-to-door travel time, zone-to-zone travel time, and auto ownership. See chapter 6 on travel demand modeling for a discussion of the four-step model.

| Table 13-9. Different Tools for Estimating Pedestrian and Bicyclist Demand |
|---|
| **Application Category/Approach** |
| **Regional Planning** |
| Trip generation: trip generation augmented by special models that estimate nonmotorized productions based on density, land-use mix, accessibility, and/or urban design. |
| Auto ownership: context-enhanced auto ownership as input to nonmotorized trip production. |
| Destination choice: separate models to forecast trip generation for inter- and intrazonal trips based on land-use/accessibility context factors. |
| Mode choice: Special context-sensitive models to estimate nonmotorized mode split for intrazonal trips. |
| Activity/tour-based models: projected replacement to trip-based models, spatial resolution reduced to parcel level and individual travelers—remove traffic analysis zone (TAZ) aggregation bias in clarifying nonmotorized mode use; travel treated as simple versus complex tours which impact mode choice. |
| **Corridor, Subarea, and Transit Oriented Development Planning** |
| Scenario planning tools: Estimation of nonmotorized travel and vehicle miles traveled reduction in relation to alternative land-use and transportation investment scenarios. |
| Walk trip models: Models that resemble four-step regional approach, but employ "pedestrian" zones instead of TAZs; create trip tables and assign to facilities. |
| **Facility Planning** |
| Factoring and sketch-planning methods: attempt to predict facility-demand levels based on peer comparisons, application of trip generation rates to sociodemographic data, association with other related data/trends, proximity rules, etc. |
| Direct demand: Project bicyclist or pedestrian volumes based on counts related to various context and facility factors through regression models. |
| Aggregate demand: Seek to quantify relationship between overall demand (e.g., annual regional bike trips) and underlying factors, often as a way of gauging importance of infrastructure types and extents. |
| Route or path choice: Methods that try to account for the characteristics of a transportation network or its users in determining route choice, and for identifying network improvement priorities. |

Source: Kuzmyak et al., 2014 Reproduced with permission of the Transportation Research Board.

Table 13-9 summarizes the different types of models that can be used for walking and bicycling analysis. The NCHRP report also described several other tools, such as walk trip generation and flow models, the Portland Pedestrian Model, and facility demand models. The reader is referred to NCHRP 770 for more detailed information on these analysis tools. In addition, Alisar et al. [2015] provide a good overview of how travel demand models can be used in pedestrian and bicycling analysis.

The U.S. Environmental Protection Agency's (EPA's) Smart Growth Index was one of the earliest efforts to analyze a community for walking and bicycling use. [EPA, 2003] This is a GIS-based sketch tool for comparing alternative land-use and transportation scenarios, and evaluating the outcomes using indicators of community and environmental performance. Transportation inputs to the index include such things as sidewalk completeness, pedestrian route directness, street network density, street connectivity, bicycle network, transit stop coverage, regional accessibility, parking demand, parking supply, transit service density, and rail transit boardings. The following factors are among those recommended by the U.S. EPA in developing its Smart Growth Index for identifying locations that have the greatest potential to serve a large number of cyclists or pedestrians: population density, employment density, mix of land uses, zero-vehicle households, proximity to transit, and proximity to a university. Figure 13-5 shows the application of this Index approach to Sacramento.

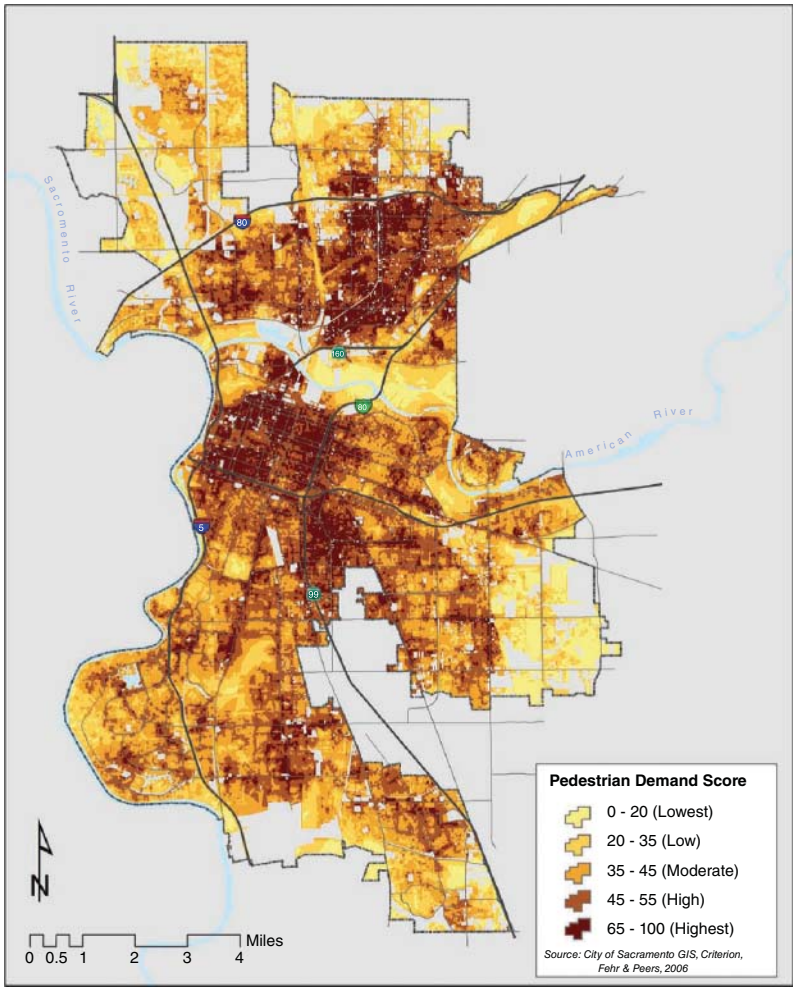
#### *4. Pedestrian and Bicyclist Suitability, Level of Service, and Level of Traffic Stress Analysis*

Suitability and level of service (LOS) analysis for bicycling and walking is used by many transportation planning agencies to identify network deficiencies and to determine what type of improvements are needed. [Landis et al., 2005; Sisiopiku et al., 2007] Some analysis methods determine the relative comfort of a bicyclist given the conditions of a particular street segment, such as FHWA's Bicycle Compatibility Index [FHWA, 1998] and the Bicycle Level of Service (BLOS) model. [Baltimore Metropolitan Council, 2004] These methods use variables such as the amount of motor vehicle traffic, traffic speed, degree of separation between the bicyclist and moving traffic, percentage of heavy

vehicles, presence of on-street parking, and the condition of the pavement surface to determine bicycle compatibility. Figure 13-6 shows a bicycle level of service analysis for Baltimore.

Pedestrian suitability (or walkability) models are in a more formative stage. Pedestrian suitability refers to the ease, comfort, and safety of walking, and is influenced by network connectivity, accessibility, the sense of safety (real and perceived), and the quality of the pedestrian environment. A suitability analysis can account for physical deficiencies in the pedestrian environment to determine where walkability is low and improvements may be needed. GIS applications are particularly useful for performing suitability analyses. Early research focused primarily on quantifying walkway space, flow characteristics, and pedestrian capacity analysis. Today more advanced simulation models (as discussed in the next section) can be used to conduct this analysis.

**Figure 13-5. Application of a Smart Growth Index for Pedestrian Demand, Sacramento, California**



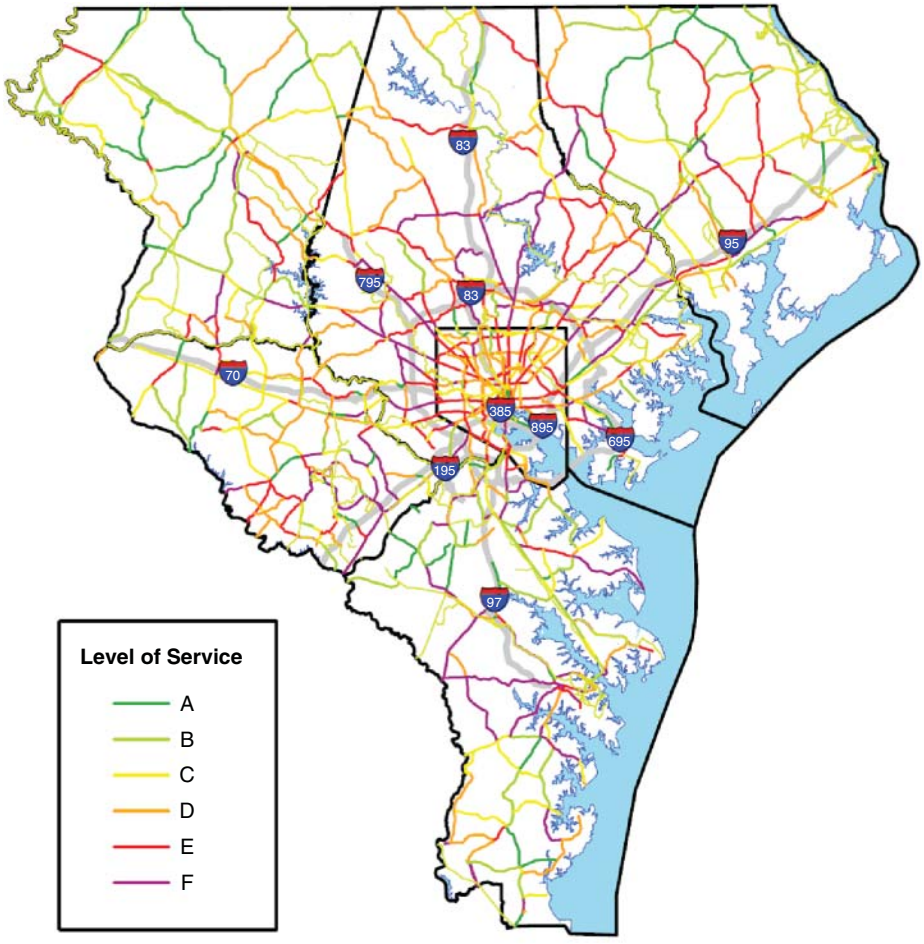
Source: City of Sacramento, 2006

As noted earlier, many bicycle studies are now using the concept of level of traffic stress as a means of understanding bicycle networks from a user perspective. This measure is intended to account for limitations in the BLOS approach, which include the need for traffic volume and lane width data (often not available networkwide), and an unclear correspondence between the BLOS level and user tolerance. The basis for the analysis is the identification of criteria that can be used to classify road segments by level of traffic stress depending on "traffic characteristics (for example, road width, traffic speed, the presence of a parking lane) and whether bikes are in mixed traffic, in bike lanes, or on segregated paths. A low level of stress can be achieved in mixed traffic on local streets with low traffic speeds. As the number of lanes, traffic speed, and traffic volume increase, providing a low level of stress requires progressively more protective measures such as dedicated bike lanes and ultimately physically segregated bikeways." [Mekuria, Furth, and Nixon, 2012] This concept can also be used to evaluate network connectivity for a specified level of traffic stress by using "percent trips connected" (the percentage of trips in the regional trip table that are connected without exceeding the specified level of stress and without undue detour) and the "percent nodes connected" (the percentage of node-to-node pairs in the street network that are connected without exceeding the specified level of stress and without undue detour) as evaluation criteria.

The Transportation Research Board's *Highway Capacity Manual* includes analysis procedures to evaluate both bicyclist and pedestrian delay at signalized intersections. [TRB, 2010] In both cases the measure for quality of service is related to the amount of delay experienced when traveling through the intersection; specific time thresholds have been established to correspond with the familiar LOS A to F scale. Each measure is directly related to the signal timing and green time allocated to the particular crossing movement. More recent pedestrian analyses have also investigated factors affecting a pedestrian's level of comfort in a given road corridor. These models examine quality-related comfort, convenience, and safety factors of the pedestrian environment through a mix of qualitative and quantitative analysis elements.

For example, Fort Collins, Colorado, includes categories of "visual interest and amenity" and "security" in its evaluation of pedestrian LOS. It has also developed its own local multimodal LOS guidelines that address bicyclist and

**Figure 13-6. Bicycle Level of Service, Baltimore, Maryland**



Source: Baltimore Metropolitan Council, 2004

pedestrian operations. Another approach taken in Charlotte, North Carolina, is to consider the pedestrian and bicyclist impacts of roadway capacity improvements as they occur.

The Pedestrian and Bicycle Information Center is an excellent source for analysis, audit, and data tools that can be used for pedestrian and bicyclist planning (see http://www.pedbikeinfo.org/planning/tools_audits.cfm).

### *5. Pedestrian and Bicyclist Safety Analysis*

Safety is the most important goal in transportation planning and design. Many analysis tools are available for identifying crash "hot spots" and determining the most appropriate countermeasures. Some of the tools include:

- Pedestrian and Bicycle Crash Analysis Tool (PBCAT)
- Pedestrian Safety Guide and Countermeasure Selection System (PEDSAFE)
- Bicycle Countermeasure Selection System (BIKESAFE)

These tools are described at the FHWA website for transportation safety (see http://safety.fhwa.dot.gov/tools/data_tools/fhwasa09002/). Chapter 23 on integrating safety into the transportation planning process provides more detail on transportation safety analysis.

### *6. Simulation and Network Models*

Traffic operations modeling and microsimulation tools also provide new methods to quantify and evaluate interactions among motor vehicles, bicyclists, and pedestrians, primarily at intersections. These models specify the behavior and

desired paths through a network for each individual, allowing the analyst to quantify delay for each mode due to interactions such as right-turning conflicts. In addition, pedestrian flow models simulate pedestrian interactions and design requirements in settings such as transit platforms, shopping malls, evacuation routes, and sports stadiums. Figure 13-7 shows a simulated intersection crossing for both pedestrians and bicyclists.

**Figure 13-7. Multimodal Intersection Simulation Using VISSIM™**

Source: Courtesy of WSP | Parsons Brinckerhoff. Vissim 7.00 -15

Space Syntax™ is another suite of modeling tools and simulation techniques for analyzing pedestrian movements and predicting pedestrian volumes. Space Syntax™ uses the layout and connectivity of urban street grids to generate movement potentials, which it then compares to sampled pedestrian counts at key locations and land-use indicators, such as population density. The resulting correlations are used to predict pedestrian volumes on a street-by-street level for an entire city. Space Syntax™ was created at the University College of London in the mid-1980s and is widely used throughout Europe and Asia.

### *7. Transportation Impact Studies*

Although not an analysis tool by themselves, transportation impact studies, whether as stand-alone documents or as chapters in an environmental document, are intended to assist decision makers and the public in the project review process. As such, they serve as an important platform for the analysis of pedestrian and bicyclist transportation needs. The National Environmental Policy Act (NEPA), the federal law governing environmental analysis, as well as many state environmental laws, requires a full disclosure of transportation impacts, including those on pedestrians and bicyclists, not just vehicular traffic impacts (see chapter 19 for more discussion on site-impact analysis).

Transportation impact analyses should evaluate the effects of new developments on vehicle movements, transit ridership, and bicycle and pedestrian trips. This evaluation should examine not transportation access to a site, but on-site circulation as well. The analysis scope might be even broader in jurisdictions that define neighborhood livability, land-use compatibility, transportation demand management, and/or quality of life objectives. The significance criteria that follow represent a minimum standard for assessing a broad set of transportation impacts. They are generally organized around the themes of identifying impacts that disrupt existing operations, interfere with plans for the future, conflict with adopted policies, and/or create new demand beyond that anticipated in existing planning documents.

Pedestrian and bicyclist impacts are considered significant if any of the following apply:

- A project disrupts existing pedestrian and bicycle facilities. This can include adding new vehicular, pedestrian, or bicycle traffic to an area experiencing safety concerns (such as on a crosswalk adjacent to a school), particularly if the added traffic reduces the number of opportunities for pedestrians to cross at unsignalized locations or causes queues to spill back through pedestrian crossings. (Note: Particular attention should be paid to on-street bicycle facilities on roadways with proposed driveways.)

- A project interferes with planned pedestrian or bicycle facilities. In existing and/or planned urbanized areas, main streets, or pedestrian districts, this can include impacts to the quality of the walking and bicycling environment, such as reduced sidewalk widths. This includes failure to dedicate right-of-way for planned on- and off-street bicycle facilities included in an adopted bicycle master plan, or to contribute to construction of planned bicycle facilities along the project's frontage.

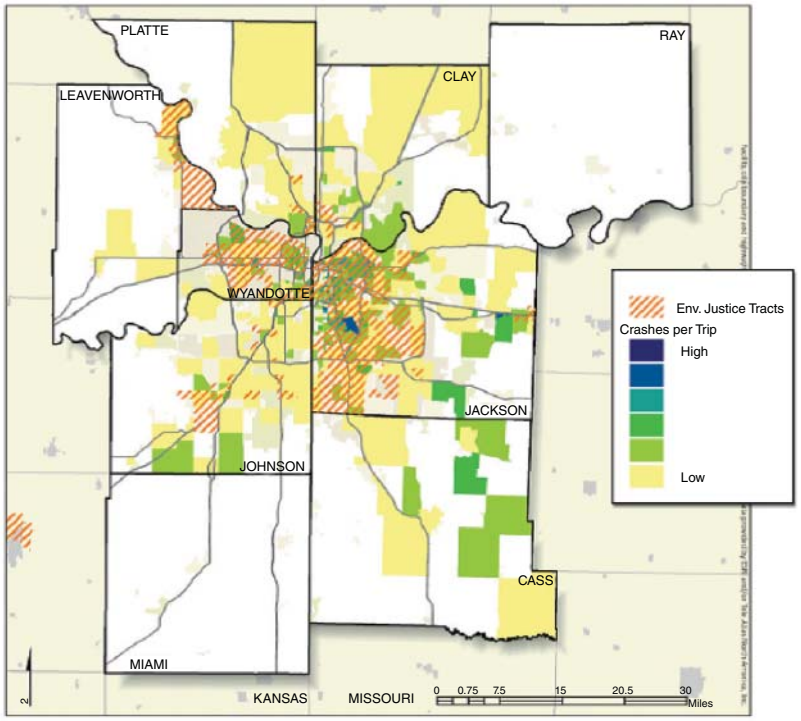
- A project conflicts or creates inconsistencies with adopted pedestrian and bicyclist system plans, guidelines, policies, or standards. This can include project designs that are in conflict with policy language, such as pedestrian and bicyclist directness, connectivity, and network completeness.

### *8. Environmental Justice Analysis*

Transportation planning should consider the disproportionate impacts of transportation benefits and costs on different population groups. Environmental justice analysis examines such impacts on a study area's low-income and minority populations, defined as: [Mid-America Regional Council (MARC), 2013]

- *Minority Population*—Any identifiable group(s) of minority persons who live in geographic proximity. This includes persons who are Black/African-American, Hispanic or Latino, Asian American, American Indian and Alaskan Native, and native Hawaiian and other Pacific Islander.
- *Low Income*—A person whose median household income is at or below the U.S. Department of Health and Human Services poverty guidelines.

**Figure 13-8. Environmental Justice Analysis of Pedestrian Crashes, Kansas City, Kansas**



Source: MARC, 2013

A typical environmental justice analysis from the Mid-America Regional Council (MARC) is shown in Figure 13-8. The analysis used GIS to identify the locations of environmental justice census tracts as compared to pedestrian crashes. The accompanying statistical analysis in Table 13-10 shows that a disproportionate number of pedestrian crashes occur in the environmental justice tracts. This would suggest that investment priorities should focus on reducing the number of crashes occurring in low-income and minority neighborhoods. See City of Seattle [2012] for another good example of an environmental justice analysis.

**Table 13-10. Environmental Justice Analysis of High-Severity Pedestrian Crashes, Kansas City, Kansas, 2009–2012**

| | EJ Areas | Non-EJ Areas | Total |
|---|---|---|---|
| **Total number of high-severity pedestrian crashes** | 183 | 209 | 392 |
| **Total Percentage** | 46.7% | 53.3% | 100% |
| **Total Population** | 620,937 | 1.347,932 | 1,968,869 |
| **Population Percentage** | 31.5% | 68.5% | 100% |

Source: MARC, 2013

## D. Prioritizing Projects/Strategies

States, metropolitan areas, and municipalities do not have enough funds to meet all of the needs identified by the planning process. Thus, an important step in the planning process is to prioritize the many different projects and strategies that can improve the bicycling and walking experience. [Swords et al., 2004] One of the challenges facing such a process for pedestrian and bicyclist planning (especially if the process is based on benefit/cost analysis) is that, when compared to large-scale road improvements, pedestrian and bicycle projects usually do not have the same aggregate level of time or cost savings as road projects. For metropolitan areas, in particular, pedestrian and bicycle projects could be competing with thousands of projects. In response, many states and MPOs have set aside funds only for pedestrian and bicycle projects. Choosing which projects to fund in these programs requires a process for establishing a priority ranking among the eligible projects.

One of the ways to prioritize projects is by ranking them according to the score each receives in a suitability analysis. Table 13-11 shows how this approach was used in the San Diego region. In this approach for active transportation projects (including pedestrian and bicycle projects), the ratings compared the degree to which each capital project satisfied 16 criteria. [San Diego Association of Governments (SANDAG), 2014] Another set of criteria was used for noncapital projects. Note that the criteria are applied to projects once 25 percent of the funds have been spent on disadvantaged communities, a policy decision of the SANDAG Board of Directors. Geographic equity is thus an important consideration in the prioritization process.

Another key aspect of prioritizing projects is the phasing of implementation. With limited resources, it is often good practice to consider the likelihood that projects will be ready for implementation if funds are assigned to them in the regional program. This is especially true where local governments are expected to provide a match to federal or state funds.

**Table 13-11. Capital Project Prioritization Points for Active Transportation Projects, San Diego Region**

| No. | Category | Criteria | MPO Points Possible | % |
|---|---|---|---|---|
| **Project Readiness** | | | | |
| 1 | Completion of Major Milestones | Projects are eligible for points following the completion of each phase:<br>• Community active transportation strategy/neighborhood-level plan/corridor study<br>• Environmental clearance<br>• Right-of-way<br>• Final design | Up to 12<br>2<br>4<br>4<br>10 | 13% |
| 2 | Connection of Regional Bicycle Network | Project directly connects to regional bikeway network or<br>Project is a part of the regional network | Up to 8<br>6<br>8 | 5% |
| 3 | Completes Connection/Linkage in Local Bike Network | Closes gap between existing bicycle facilities (guidance will include definition of gap and will include situations where there exists an undesirable change in facility type) | 8 | 5% |
| 4 | Completes Connection/Linkage in Existing Pedestrian Network | Closes gap in the existing network | 8 | 5% |
| 5 | Connection to Transit | *Bike improvements proximity:*<br>Within 1.5 miles (2.4 km) of regional transit station<br>*Pedestrian improvements proximity:*<br>• Within 1/4 mile (0.4 km) of a local transit stop<br>• Directly connects to a local transit stop<br>• Within 1/2 mile (0.8 km) of a regional transit station<br>• Directly connects to a regional transit station | Up to 12<br>6<br><br>2<br>4<br>4<br>6 | 8% |
| 6 | Safety Improvements and Overcoming Barriers | Completes connection in existing network at location with documented safety hazard or accident history.<br>1–2 correctable crashes involving non-motorized users within the last 7 years<br>3–4 correctable crashes involving non-motorized users within the last 7 years<br>5 or more correctable crashes involving non-motorized users within the last 7 years<br>and/or creates access or overcomes barriers in area where hazardous conditions prohibited safe access for bicyclists and pedestrians | Up to 12<br>2<br>4<br>6<br>6 | 8% |

(*continued*)

Table 13-11. (*Continued*)

| No. | Category | Criteria | MPO Points Possible | % |
|---|---|---|---|---|
| | | **Quality of Project** | | |
| 7 | Effectiveness and Comprehensiveness of Proposed Bicycle, Pedestrian, and/or Traffic Calming Measure | How well will the proposed traffic calming address the identified need in the project area?<br>How well will the proposed pedestrian improvements address the identified need in the project area?<br>How well will the proposed bicycle improvements address the identified need in the project area? | Up to 15<br>Up to 5<br>Up to 5<br>Up to 5 | 9% |
| 8 | Relationship to Program Objectives | How well does the project meet the program objectives? | Up to 18 | 11% |
| 9 | Innovation | Is the project an FHWA or state experimentation effort?<br>Does the project propose solutions that are new to the region, and have the potential to serve as a replicable model for other cities in the region? Does the project utilize innovation solutions such as those listed in the NACTO Urban Bikeway Guide? | Up to 8<br>4<br>Up to 4 | 5% |
| | | **Supporting Policies and Programs** | | |
| 10 | Complementary Programs | Is the project accompanied by programs that complement the capital improvements, such as an awareness campaign, education efforts, and increased enforcement? | Up to 3 | 2% |
| 11 | Supportive Policies and Plans | Demonstrated policy language in approved plan, or a completed community active transportation strategy/plan | Up to 3 | 2% |
| | | **Formula Scores** | | |
| 12 | Demand (GIS Analysis) | Factors not contributing to score: population and employment, population and employment densities, intersection density, vehicle ownership, and activity centers | Up to 15 | 9% |
| 13 | Matching Funds | Matching funds can be from any of the following sources:<br>Identified and approved capital funding from identified source<br>Approved match grant<br>In-kind services | Up to 10 | 6% |
| 14 | Cost/Benefit | Subtotal score (not counting matching points)/Grant application amount | Up to 10 | 6% |
| 15 | Public Health | Does the project improve public health by targeting populations with high-risk factors for obesity, physical inactivity, asthma, or other health issues? | Up to 10 | 6% |
| 16 | California Conservation Corps | Has the applicant sought California Conservation Corps or qualified Corps participation on the project? | 0 to −5 | −3% |
| | | **Total Points** | **160** | |
| | | **Total Score After Reaching 25% for Disadvantaged Communities** | | |

Source: SANDAG, 2014

NCHRP Report 803, *Pedestrian and Bicycle Transportation Along Existing Roads—ActiveTrans Priority Tool Guidebook*, is a step-by-step methodology for prioritizing improvements to pedestrian and bicycle facilities, either separately or together as part of a Complete Streets evaluation approach (see chapter 9). The methodology identifies nine factors that are commonly considered in prioritization and that can reflect a range of community/agency values. They include:

- *Stakeholder Input*—The amount of public feedback in support of (or against) a pedestrian or bicycle facility improvement at a particular location.
- *Constraints*—The relative level of difficulty in implementing a pedestrian or bicycle project.

- *Opportunities*—The ability of an agency to take advantage of resources that can support project implementation.
- *Safety*—The risk of a pedestrian or bicyclist being involved in a traffic collision (or crash).
- *Existing Conditions*—Physical conditions that have an impact on pedestrian or bicyclist safety, comfort, or demand, such as whether or not a sidewalk exists, the number of travel lanes, or the presence of a buffer.
- *Demand*—Existing or potential pedestrian and bicyclist activity levels.
- *Connectivity*—The degree to which a project allows pedestrians or bicyclists to travel comfortably and continuously throughout their community.
- *Equity*—The degree to which opportunities for safe and convenient pedestrian and bicyclist travel are distributed evenly to all groups within a community.
- *Compliance*—Whether or not existing infrastructure is compliant with current pedestrian and bicycle standards and guidelines.

Table 13-12 shows how important some of these factors can be given different types of prioritization contexts. Tables 13-13 and 13-14 provide more information on two of the prioritization factors to illustrate the types of data and data sources necessary for this tool, but also the type of information that could be used in any prioritization scheme.

Note in Table 13-14 the use of variables that represent total crashes. Another way of representing such information that accounts for different segment characteristics is to normalize, in this case by unit length, so that all projects compete on the same basis.

## E. Producing Planning Products

A planning process can result in many different products, ranging from recommended projects to changes in regulations and policies. For pedestrian and bicyclist transportation, in particular, many different outcomes are possible. Strategies and programs for bicyclists and pedestrians require a comprehensive strategy, encompassing the five E's defined by the League of American Bicyclists and commonly used in safety programs:

- *Engineering*—Physical measures constructed to create safer conditions for cyclists and pedestrians.
- *Education*—Raising awareness and sharing information with drivers, pedestrians, and cyclists on best ways to share the road.
- *Encouragement*—Promotion and advocacy of bicycling and pedestrian amenities.
- *Enforcement*—Targeted police enforcement supports neighborhood and community goals for improving safety.
- *Evaluation and Planning*—Level to which walking and bicycles are used as a transportation mode and ways to increase this usage.

Readers are referred to the Fredericksburg, Virginia, Bicycle and Pedestrian Plan [Fredericksburg Area MPO, 2013] and [Walsh, 2012] for good examples of the types of actions that can be taken in each category.

The following sections describe possible products resulting from a pedestrian and bicyclist planning process.

### *1. Master Plans*

Walking and bicycling master plans typically include the following topics:

- *Introduction*. The introduction usually provides background on the pedestrian and/or bicyclist planning process in the community. A description of the extent of citizen and community involvement in development of the plan, including but not limited to letters of support, could be included in this section.

**Table 13-12. Illustrative Prioritization Contexts and Relevance of Criteria**

| | Stakeholder Input | Constraints | Opportunities | Safety | Existing Conditions | Demand | Connectivity | Equity | Compliance |
|---|---|---|---|---|---|---|---|---|---|
| **Corridor** | | | | | | | | | |
| Given 20 high pedestrian-crash corridors in a region, identify four to receive grant funding for safety enhancements. | Ø | Ø | Ø | • | • | • | o | • | Ø |
| Given 10 candidate corridors for side path construction, identify the top three for implementation. | • | Ø | • | • | • | • | • | Ø | o |
| **Segment** | | | | | | | | | |
| Given a planned bicycle network consisting of approximately 500 miles (804.7 km) of recommended facilities (bike lanes, cycle tracks, shared lane markings, etc.), select 50 miles (80.7 km) for implementation in the next five years. | • | • | • | Ø | • | • | • | • | o |
| Given a neighborhood where sidewalks are absent, select 30 segments to construct sidewalks over the next three years. | • | Ø | Ø | • | • | • | Ø | • | o |
| **Intersection/Crossing** | | | | | | | | | |
| Given a regional trail with 50 unsignalized roadway crossings, identify 12 to implement safety enhancements. | • | o | Ø | • | • | Ø | o | Ø | • |
| Given 500 locations where curb ramps are missing in a municipality, identify an initial 50 locations for ramp installation using available grant funding. | • | Ø | Ø | Ø | o | • | Ø | • | o |
| Given a city with more than 500 signalized intersections, identify the 30 priority traffic signals to be converted to accessible pedestrian signals when they are upgraded or replaced. | • | o | Ø | • | • | • | Ø | • | • |
| **Area** | | | | | | | | | |
| Given a county with 30 elementary schools, rank the designated school zones to determine which ones should be further evaluated for future pedestrian improvements. | • | o | Ø | • | • | Ø | o | • | • |
| Given a city that consists of 15 defined neighborhoods, prioritize two for the initial focus of a Complete Streets evaluation. | Ø | o | o | • | • | • | • | • | • |
| Given a city of 20 neighborhood commercial centers, rank all 20 centers in terms of their need for additional bicycle parking. | • | o | Ø | o | • | • | o | Ø | o |

• = Very Relevant  Ø = Less Relevant  o = Not Likely Relevant

- *Vision, Goals and Policies*. This section includes a definition of the community's vision for pedestrian and/or bicyclist transportation and desired outcomes.
- *Existing Conditions*. This section paints a comprehensive picture of existing facilities, including an inventory of the facilities and assets existing in the study area, the condition of these assets (data usually coming from surveys of existing street conditions, collision data, and community outreach), and an assessment of current performance levels. This section also describes current land uses and characteristics that will influence the propensity to use pedestrian or bicycle facilities.
- *Future Problems and Challenges*. This section identifies future locations where, because of development growth or increases in traffic volumes, the pedestrian and bicyclist environment will deteriorate. This usually includes

estimated performance measures and the results of suitability metrics. GIS techniques may be particularly useful for mapping and identifying areas where the need for improvements exists. A description of the methodology used to estimate future performance could be presented here or in an appendix.

- *Recommended Network*. This section defines the desired network based on the policies and objectives established in the beginning of the plan and opportunities for improvement in the network identified in the future problems section. In contrast to a bicyclist plan, a pedestrian plan sometimes does not have recommended pedestrian routes. It should be possible, however, to identify areas where pedestrian activities will be the most concentrated, such as the central business districts, transit stations, civic centers, commercial centers, schools, universities, and the like.
- *Support Facilities and Intermodal Connections*. Support facilities at or near the destination of a trip, including on transit vehicles or at transit stations, can play a large role in making walking and/or bicycling an attractive transportation alternative. Pedestrian master plans can also contain other elements, such as pedestrian-friendly site design guidelines and recommendations for development review.
- *Design Guidelines*. Design guidelines (sometimes created as a separate document or included in the appendix) are intended to identify and communicate the design elements necessary to improve pedestrian and bicyclist comfort levels.
- *Education and Enforcement*. One of the main goals of a plan is to provide facilities that help improve bicyclist safety. Safer facilities alone, however, will not ensure that no crashes will occur. As with motor vehicles, a combination of education and enforcement plays a large role in making pedestrian and/or bicyclist transportation safer.
- *Implementation: Capital Improvement Program*. The capital improvement program is one of the most important elements of a plan, in that it helps guide implementation. The content can include: (1) a consolidated list of all proposed improvement projects, (2) the priority or phasing for the implementation of each improvement, (3) the cost of each project, and (4) the anticipated source(s) of funding for each project.

### *2. Development Plans*

Project site plans and proposed offsite improvements, including mitigation strategies, should be reviewed for consistency with local design standards, parking codes, and other adopted guidelines. Where local policies do not identify significance criteria for project impacts, the impacts should be considered significant if a project fails to provide accessible and safe pedestrian connections between buildings and to adjacent streets and transit facilities. Developers should be encouraged to coordinate with future capital investments by others, such as government agencies or other developers.

### *3. Trail and Greenway Plans*

Trail and greenway plans concentrate on an offroad system of pathways that supplement sidewalks and bikeways. Accessibility for all should be part of the planning process (for example, considering the hard surfacing of trails). The paths or trails included should be planned and designed to meet the needs of various users, including bicyclists and pedestrians. Individual greenway and trail projects are typically addressed through a feasibility study and/or in a pre-engineering phase of a road project. Atlanta's Beltline project is an excellent example of an urban multiuse trail that has had a significant impact on development and neighborhood quality of life (see Figure 13-9).

### *4. Traffic Calming*

Traffic calming programs are often a critical component of pedestrian and bicyclist planning. Many traffic calming measures enhance the pedestrian environment by reducing traffic speeds and volumes. Traffic calming can also be used to create a network of streets that encourages bicycling. Best practice examples can be found in U.S. cities such as Boulder, Colorado; Boston, Seattle; and Portland, Oregon. Good practice is well documented in *Traffic Calming: State of the Practice*, published by FHWA and ITE [Ewing, 1999], as well as the websites http://trafficcalming.org/ and http://www.pps.org/reference/livememtraffic/. See also chapter 9 on road and highway planning.

### *5. Streetscape Plans*

Streetscape plans typically focus more on physical planning issues. Such issues could include traffic calming; streetscape and urban design improvements; improvements to pedestrian, bicycle, and motor vehicle flow; and removing barriers to improve accessibility, among others.

**Figure 13-9. Example of an Urban Multiuse Trail, Atlanta's Beltline**

Photo courtesy of Adam Rosbury

### *6. Safe Routes to School*

*Safe Routes to School* (SRTS) was a federally funded program designed to increase the number of children walking and biking to school. The program was intended to integrate health, fitness, traffic relief, environmental awareness, and safety under one program. Many local and regional agencies have developed programs in recent years primarily in response to the federal program. Although it is no longer a stand-alone program, many states and local communities have continued with similar types of strategies.

### *7. Safe Routes to Transit*

*Safe Routes to Transit* is similar in concept to the SRTS programs. Studies have shown that easy and safe access to transit services is one of the most important considerations in a traveler's decision to ride transit. Travel- demand models usually consider a distance of one-quarter mile (0.4 km) as the potential walk-to-bus-transit market area (one-half mile [0.8 km] for rail transit). The time to walk this distance is about 6 minutes, given an average walking speed of 3 to 4 feet per second (0.9 to 1.2 meters per second) or 2 to 2.7 miles per hour (3.2 to 4.3 kilometers per hour). Distances and travel times for different trip purposes are shown in Table 13-15.

Safe Routes to Transit programs are designed to promote bicycling and walking to transit stations by making walking and bicycling feeder trips easier, faster, and safer. Safe Routes to Transit projects usually focus on areas adjacent to or surrounding transit stations or stops. They may also address onsite pedestrian and bicycle accommodations.

**Table 13-15. Assumed Distances for Modeling Pedestrian Trips by Trip Purpose**

| Type of Trip | Example Distance | Travel Time |
|---|---|---|
| Commute trip to work | 3/4 mile (1.2 km) | 20 minutes |
| Errands trip to bank | 1/4 mile (0.4 km) | 6 minutes |
| Incidental trip from parking | 1/8 mile (0.2 km) | 3 minutes |

Source: City of Sacramento, 2006

### *8. Americans with Disabilities Act (ADA) Transition Plans*

The ADA and subsequent interpretations by the Department of Justice require municipalities to prepare a plan detailing how they will make their streets and roads accessible to disabled individuals. These so-called *ADA transition plans* identify and prioritize access projects, estimate project costs, note the implementation schedule and funding strategies, and establish grievance and monitoring programs.

The ADA transition plan should be coordinated with pedestrian master plans to provide consistency in all forms of pedestrian planning. Recent litigation has concluded that jurisdictions are responsible not only for curb ramps at intersections—typically included in transition plans—but also for the area between the intersections. In *Barden v. Sacramento*, the U.S. Supreme Court ruled that cities and other public entities must make all public sidewalks accessible, which includes addressing barriers such as missing or unsafe curb cuts on the public sidewalk system, as well as barriers that block access along the length of sidewalks.

## F. Monitoring Plan Progress

The final step in the pedestrian and bicyclist planning process is to monitor the progress occurring with respect to goals and objectives. This monitoring is usually tied to the performance measures identified early in the process. An example of such monitoring is shown in Table13-16, which shows the report card prepared periodically in Seattle to monitor the degree to which goals are being achieved.

# VI. PEDESTRIAN AND BICYCLIST PLANNING/DESIGN ISSUES

Although transportation planning can recommend actions appropriate for both pedestrians and bicyclists, some issues are specific to each mode. This section discusses some of the mode-specific issues that engineers and planners often face when planning for pedestrian and bicyclist transportation.

## A. Bicycle Network/Facility Design

When designing for bicycle facilities, it is important to, (1) know the travel-related characteristics of the bicyclist, (2) follow design guidelines and standards established for different bikeway types, (3) make certain that transition areas (where facilities begin and end) are safe for both bicyclists and motorists, and (4) address not only the need for additional operating space, but also any existing spot hazards as well as ongoing maintenance of the facility.

### *1. What type of bicyclist is most likely to use a facility?*

Bicycles are legally classified as vehicles in most states and are therefore subject to the same rules and responsibilities as all other vehicles. One of the first steps in determining appropriate design for bicycle facilities is to determine the characteristics of the users, because it is the bicyclist who determines how the bike facility will be used. In a 1994 document, *Selecting Roadway Design Treatments to Accommodate Bicyclists*, FHWA stated, "any roadway treatments intended to accommodate bicycle use must address the needs of both experienced and less experienced riders."

| Table 13-16. Performance Monitoring of Bicycle Program in Seattle | | | | |
|---|---|---|---|---|
| **Goal** | **Performance Measure** | **Baseline Measurement** | **Performance Target** | **2011 Evaluation** |
| Goal 1: Increase use of bicycling in Seattle for all trip purposes. Triple the amount of bicycling in Seattle between 2007 and 2017. | Number of bicyclists observed at counting locations throughout Seattle | 2007 counts | Triple number of bicyclists between 2007 & 2017 | 2007 downtown counts = 2,273<br>2011 downtown counts = 3,330 |
| Goal 2: Improve the safety of bicycling throughout Seattle. Reduce the rate of bicycle crashes by one third between 2007 and 2017. | Number of reported bicycle crashes per total number of bicyclists counted and annual traffic volumes | 2007 collision rate | Reduce the bicycle crash rate by one third between 2007 & 2017 | 2007 collision rate = 0.158<br>2011 collision rate = 0.105 |
| Objective 1: Develop and maintain a safe, connected, and attractive network of bicycle facilities throughout the city. | Percentage of Bicycle Facility Network completed | 67.6 miles (108.8 km) of existing facilities (in 2007) | Implement 450 miles (724 km) of recommended facilities by 2017 (includes existing) | 67.75 miles (109 km) with 67.6 miles of existing facilities prior to the adoption of the 2007 BMP (52.8% not including the facilities that were existing prior to 2007) |
| Objective 2: Provide supporting facilities to make bicycle transportation more convenient. | Number of bicycle racks installed through the SDOT Bicycle Parking Program | | Provide 6,000 racks by 2017 (includes existing) | 806 bicycle racks installed between 2007 & 2011 + 3,000 existing bicycle racks = 3,806 |
| Objective 3: Identify partners to provide bicycle education, enforcement, and encouragement programs. | Number of Seattle Bicycling Guide Maps distributed | 23,338 maps distributed in 2005 | 150,000 bicycle maps to be distributed between 2007 & 2017 | Approximately 292,780 maps distributed between 2007 & 2011 |
| Objective 4: Secure funding and implement bicycle improvements. | Percentage of targeted SDOT staff who participate in training on bicycle issues | Counted in 2007 | 100% of targeted staff participating in training every year | SDOT has not tracked this metric |
| | Number of bicycle project grant applications applied for and obtained for bicycle programs | Tracked in 2007 | At least one grant application for every available funding opportunity | 2008 applied for 3 grants & received 2 – 2009 applied for 4 grants & received 3 – 2010 applied for 4 grants & received 4 – 2011 applied for none – 2012 applied for 7, all pending |
| | Number of Bicycle Spot Improvements completed | Counted in 2007 | Depends on needs & priorities set for each year | 33 on-street spot improvements |

Source: City of Seattle, 2012

[Wilkinson et al., 1994] Whereas in the 1990s and early 2000s this was defined by level of service calculations, as described earlier, many studies have now adopted a "level of traffic stress" estimation that relates directly to the type of bicyclist using a facility.

The concept of providing a user-oriented metric for planning and designing bicycle facilities has taken several forms. AASHTO, in its bicycle design guide, adopted the skill level of bicycle users as an important factor in designing bicycle facilities. [AASHTO, 2012] More experienced cyclists are confident riding on high-speed roads with or without designated bicycle facilities. At the other end of the skill spectrum, children often lack the experience of many older riders. AASHTO defined three types of bicycle users:

*Group A* — Advanced or experienced riders generally use their bicycles as they would a motor vehicle. Their primary purpose for riding is to reach a destination with minimum delay. They are comfortable riding with motor vehicle traffic.

*Group B* — Less confident adult riders use their bicycles for transportation but avoid roads with fast traffic unless there is ample room for safe motor vehicle passing. They are comfortable riding on neighborhood streets and shared-use paths.

*Group C* — Children will not likely ride very fast, but will still need access to such destinations as schools and parks. Streets with low motor vehicle speeds and well-defined separation between vehicles and the child bicyclist are preferred.

The city of Portland, Oregon, one of the leading municipal governments in the United States with regard to bicycle planning, has identified four categories of bicyclists: "The Strong and the Fearless," "The Enthused and the Confident," "The Interested but Concerned," and nonriders, called the "No Way, No How" group. [Geller, 2015] As noted by Geller, "The Strong and the Fearless" are the people who will bicycle regardless of roadway conditions. They are "bicyclists;" riding is a strong part of their identity, and they are generally undeterred by roadway conditions. "The Enthused and Confident" are those who are comfortable sharing the roadway with automobiles, but they prefer to do so operating on their own facilities. "The Interested but Concerned" group are curious about bicycling and like riding a bicycle, but they are afraid of sharing the road with automobiles. The "No Way, No How" group is not interested in bicycling at all.

Separated bike lanes have great potential to fill needs in creating low-stress bicycle networks (generally separated from heavy vehicular traffic or sharing the road with motorists only on very low-volume residential streets). To encourage the "Interested but Concerned" group to use cycling as a transportation option for short- to moderate-length trips, many municipalities are focusing on creating a connected bicycle network that these riders will confidently use.

This enhanced network pays particular attention to higher-quality, lower-stress connections, even if this results in some backtracking or extra distance requirements for cyclists using it. An example of a planning effort in Montgomery County, Maryland focused on low-stress bicycle networks is shown in Table 13-17. The goal of a low-stress network is to create connections within a municipality while emphasizing the *quality* of bicycle facilities over the number of miles available.

### *2. What guidelines exist for bicycle facilities?*

Several national design guidelines and standards apply to bicycle facilities. The AASHTO *Guide for the Development of Bicycle Facilities* is a comprehensive guideline to bicycle facility planning and design. [AASHTO, 2012] The *Manual on Uniform Traffic Control Devices* (MUTCD) addresses bicycle facility signage and striping, both for onroad and offroad bicycle facilities. [FHWA, 2009] The 2010 ADA *Access Guidelines* should be consulted if a particular bicycle facility is also expected to accommodate pedestrians, as is the case with most trails. [U.S Department of Justice, 2012] Other useful guidelines include:

- ChooseHealth Utah [undated]
- CROW (the Netherlands) [2007]
- FHWA [2015b]

| Table 13-17. Montgomery County, Maryland Bicycle Stress Map | |
|---|---|
| **Level of Stress** | **Bicyclist Response** |
| Very High | Very few adults will bicycle. |
| High | Few adults will bicycle. |
| Moderate High | Some adults will bicycle. |
| Moderate Low | Many adults will bicycle. |
| Low | Most adults will bicycle. |
| Very Low | All adults and some children will bicycle. |
| None | Everyone will bicycle. |

- National Association of City Transportation Officials (NACTO) [2013, 2014]
- Torbic et al. [2014]
- Vermont Agency of Transportation [2002]
- Ryan Snyder and Associates and Transportation Planning for Livable Communities [2011]

Instead of relying on national design guidelines, however, one of the common recommendations of planning studies for both bicyclist and pedestrian transportation is to develop local design guidance. Such guidelines are defined in ways that are more appropriate to the context in which a bicycle facility is being constructed or implemented. As a general guide, most communities choose to design their bicycle network to meet the needs of basic adult riders and youth bicyclists. In this context, the most important question is: What type of improvement would work best to increase the comfort level of bicyclists on each segment? If a bicycle suitability analysis has been performed, it is possible to show different design scenarios and their effect on the bicycle level of service for the given roadway segment.

### *3. What treatments are appropriate for different facilities?*

A variety of facility types or roadway treatments can be used to accommodate bicyclists. They can include signed routes, shared lane markings, onstreet bike lanes, onstreet buffered bike lanes, separated bike lanes, and offstreet paths/side trails. [FHWA, 2015b] The following discussion divides the treatments by whether the road space is shared.

**Shared Roadways.** All streets where bicyclists are permitted to ride and share the same travel lanes with motor vehicles are technically classified as shared roadways. In most cases, a motorist will usually have to cross into the adjacent travel lane to pass a bicyclist. However, there are several treatments that can enhance shared roadways for cyclists—bike routes, bike lanes, paved shoulders, bike boulevards, and road diets.

*Bike routes* are shared roadways that meet a set of minimum design and operational criteria for bicycle compatibility and that have been designated with bicycle route signs as connector routes within a bicycle network. Suggested criteria for bike routes include:

- Obstacles and barriers to bicycle travel should be addressed, including hazardous drainage grates, potholes, uneven manhole covers, angled railroad crossings, and narrow bridges. Where certain obstacles cannot be improved but do not pose an undue risk to bicyclists, advance-warning signs (as recommended by the MUTCD) should be used to alert bicyclists of their presence.
- The proposed bike route should be part of an interconnected system of bicycle facilities. Bicycle routes should not abruptly end at barriers.
- Pavement markings should be provided and well maintained that clearly indicate where bicyclists should be riding (see Figure 13-10).
- Future street maintenance and construction activities should consider and plan for safe transport along this route. This normally means more frequent street clearing and paving.

*Bike lanes* are a portion of the roadway designated for preferential use by bicyclists, typically with a minimum width of 5 ft (1.5 m). Many communities have begun installing bike lanes not only for the additional operating space they provide for bicyclists, but also as a method to encourage more bicycle travel. The needs of cyclists can be accommodated by retrofitting bike lanes onto existing urban streets. In many cases this can be accomplished by re-striping the existing cross section to add bike lanes. Figure 13-11 presents a typical road cross section including a bike lane. Figure 13-12 shows another cross section with a shared use path.

*Paved shoulders* can also be used in some cases on streets with no curb and gutter, particularly in rural areas. While any additional space is beneficial, a 4- to 6-ft (1.2-m to 1.8-m) shoulder is preferred. Paved shoulders should be included on both sides of the roadway. In addition to the benefits to bicyclists, paved shoulders can also serve the needs of motorists. As with bike lanes, paved shoulders should be constructed to withstand heavy loadings (since trucks and service vehicles will occasionally use them) and should be free of surface irregularities. Regular maintenance is essential if paved shoulders are to be useful to bicyclists. The use of edge-of-road rumble strips could create a dangerous situation for bicyclists; therefore, sufficient warning should be provided via signs.

A *bicycle boulevard* is a roadway that motorists may use, but that gives priority to bicycle traffic through the use of various treatments. Through motor vehicle traffic is discouraged on the street. Local traffic is slowed to approximately the same speed as bicyclists. Stop signs and signals

on the bicycle boulevard are limited to the greatest extent possible, except where they aid bicyclists in crossing busy streets. The bicycling environment may be further enhanced through the use of directional signage and other amenities. The development of a bicycle boulevard may include changing intersection controls and installing signage, stencils, or other treatments that facilitate bicycling. Bicycle boulevards are most effective when several treatments are used in combination. Cities that have implemented bike boulevards include, not surprisingly, many university communities, including the cities of Palo Alto, Berkeley, and San Luis Obispo, California; Portland, Oregon; Cambridge, Massachusetts; and Denver. Vancouver, British Columbia, has an extensive system of bike boulevards.

*Road diets*, or a reduction in the number of roadway lanes to improve safety and reduce traffic volumes, may also provide opportunities for new bike lanes. In many cases, road lanes can be converted to a dedicated bike lane along with increased median or pedestrian space for those crossing the road. Figure 13-13 shows the concept of a road diet and the incorporation of a bike lane into a reconfigured cross section.

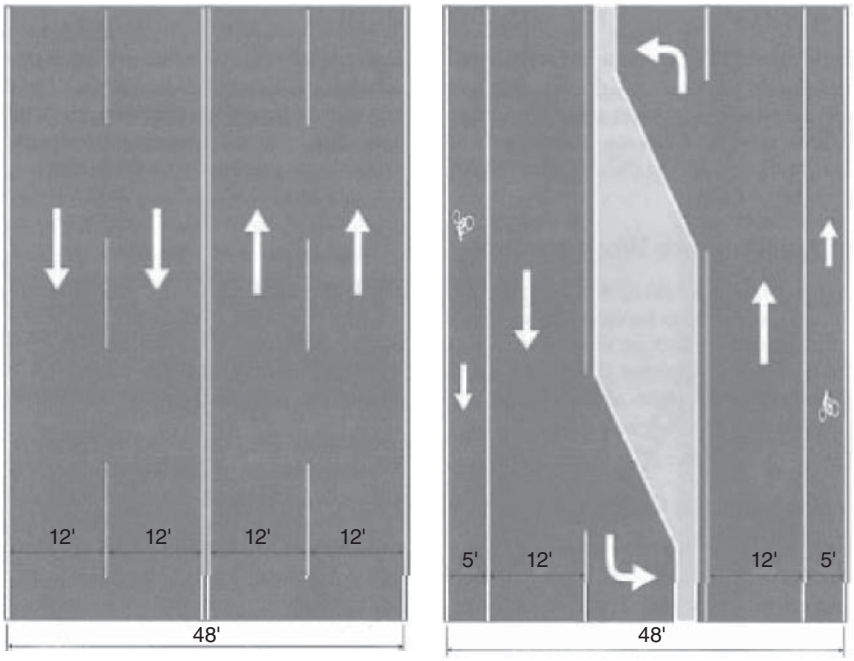
A number of innovative, onroad bicycle treatments not included in the MUTCD are used throughout the United States. Examples of these include left-side bike lanes on one-way streets and contra-flow bike lanes. ITE's *Informational Report on Innovative Bicycle Treatments* describes these innovative applications. [Nabti, 2002]

**Separated Bike Lanes.** A separated bike lane is an exclusive facility for bicyclists located within or directly adjacent to the roadway and is physically separated from motor vehicle traffic. Research has shown that most Americans are reluctant to ride bicycles in the absence of physical separation from motor vehicles. Those willing to face a higher stress factor in traveling without some physical separation represent a very small minority of those who are willing to bike. As part of a connected bicycle network, separated bike lanes can:

- Provide a more comfortable experience for less-skilled riders.
- Improve access to destinations such as schools, jobs, health-care facilities, and essential services.
- Enhance access to public transportation, for example by helping to solve the first/last mile challenge.
- Improve access to employment opportunities, especially for those without access to a private automobile.
- Provide a linkage between regional trail systems. [FHWA, 2015b]

*Cycle tracks* are physically separated from motor traffic and distinct from the sidewalk. Common elements include: (1) space intended to be exclusively or primarily used for bicyclists, and (2) separation from motor vehicle travel lanes, parking lanes, and sidewalks. Where on-street parking is allowed, cycle tracks are located to the curb side of the parking (in contrast to bike lanes). [NACTO, 2014]

**Figure 13-13. (a) and (b): Road Diet and the Incorporation of a Bike Lane into a Reconfigured Cross Section**



(a) 4-Lane Undivided Before
ADT = 13,500
Motor Vehicle LOS = C V/C
Ratio = 0.40
Bicycle LOS = D

(b) 4-Lane Undivided After
ADT = 13,500
Motor Vehicle LOS = D V/C
Ratio = 0.83
New Bicycle LOS = B

*Offroad Multiuse Trail*. Offroad and multiuse trails are the highest-order bicycle treatment, involving the complete separation of bicycle and motor vehicle traffic, and are appropriate for all skill levels. Multiuse trails are physically separated from motor vehicle traffic (except at crossings with streets) by an open space or barrier. They are usually built within an independent right-of-way, such as a utility or railroad right-of-way, or along easements across private lands (see Figure 13-14). Trails can accommodate a variety of users for both recreation and transportation purposes, including pedestrians, joggers, skaters, bicyclists, horseback riders, and people in wheelchairs. A shared-use level of service calculation is a great tool for determining the width of the trail. The minimum width for two-directional trails is 10 ft (3 m); however, 12- to 14-ft (3.7- to 4.3-m) widths are preferred where heavy or mixed traffic is expected. Due to the popularity of offroad trails, centerline stripes should be considered for paths that generate substantial amounts of pedestrian traffic.

Multiuse trails can provide connectivity in corridors not well-served by the street system, and they are particularly helpful to bicyclists if they provide a direct, traffic-free route linking origin and destination points. National guidelines for the design of multiuse trails are provided in AASHTO's *Guide for the Development of Bicycle Facilities*. [AASHTO, 2012]

Trail and roadway intersections can become areas of conflict if not carefully designed. In some cases, these intersections could be signalized (in California, such an intersection is one of three instances where a warrant exists for bicycle traffic signals). For high-speed, multilane arterials and freeways, the only viable solution may be a grade-separated crossing. Overpasses can be extremely expensive and marginally successful if users are expected to climb long entrance ramps. Underpasses should be of adequate width and should be well lit with vandal-resistant fixtures. Crime Prevention Through Environmental Design (CPTED) principles should be followed when designing underpasses (see [U.S. Department of Justice, 1996]).

Approach ramps for grade-separated crossings must meet ADA or American National Standards Institute (ANSI) standards.

**Figure 13-14. Off-Road Bike Trail, Cape Cod, Massachusetts**

Photo Courtesy of Toole Design Group

As the demand for trails increases, planners and user groups are increasingly considering putting trails into corridors alongside active rail lines. Many railroad corridors are more than 100 feet wide and have just one or two active lines still in operation; other corridors are bounded by open space and appear to be good candidates for trail development. Many rail lines have low service levels, with one or two trains per day. Examples of successful rails-with-trails programs and of "user separation" issues such as grade separation, vegetation, ditches, and fencing can be found at http://www.fhwa.dot.gov/environment/recreational_trails/publications/rwt/page08.cfm.

**Bicycle Route Signage.** Signing should always include directional information, such as an arrow and the name of the destination served, and, if appropriate, the distance to the destination. Signage is also helpful for wayfinding (see Figure 13-15). Signage on state highways will need to meet the standards of the *Manual of Uniform Traffic Control*

**Figure 13-15. Example of Wayfinding Signs**

Photo courtesy of Toole Design Group

*Devices* (MUTCD), which should be considered when planning a wayfinding program for a city or community. Some communities have developed unique bike route signs, which is acceptable provided the design is simple so that cyclists do not have to stop to read the sign.

**Bicycle Storage and Parking.** Bicycle parking is an important part of improving and encouraging bicycle travel in urban areas, especially as it interfaces with transit stations and major attractors. Transit stations and schools are examples of locations typically needing bicycle parking facilities (see Figure 13-16). Parking can be addressed through city ordinances or zoning codes and can refer to the bicycle master plan for policies and guidelines on the type and location of parking.

Appropriate locations for bicycle parking facilities should be considered on a case-by-case basis with an analysis of the specific design constraints at each location. The following general location criteria are recommended:

- Parking facilities should be located immediately adjacent to the building entrance they serve (where bicyclists would naturally transition into pedestrian mode).
- Parking facilities should be installed in a public area within easy viewing distance from a main pedestrian walkway, usually on a wide sidewalk with 5 or more feet of clear sidewalk space remaining. In general, sidewalks that are narrower than 12 ft (3.7 m) cannot accommodate bike racks.

**Figure 13-16. Example Bike Parking at Transit Station, Boston. (a) Storage Cage, Alewife Transit Station, and (b) Covered Bike Racks, Maverick Transit Station**

(a)

(b)

Photos courtesy of Toole Design Group

- For bike parking facilities placed near walls or buildings, a minimum of 2 ft (0.6 m) clear space is needed between the bicycle rack and a parallel wall, and 2.5 ft (0.8 m) from a perpendicular wall.
- Bike racks should be placed on hard surfaces rather than in grassy medians or unpaved areas.
- Racks should be placed to avoid conflicts with pedestrians. They are often installed near the curb and at a reasonable distance from building entrances. They should not be placed in a manner that interferes with pedestrian traffic exiting crosswalks.
- Bicycle rack placement within the right-of-way should not block access or obstruct movement. In general, bike racks should not be placed in front of doors (including cellar doors in urban downtowns) or in close proximity to fire hydrants, bus stop shelters, telephones, mailboxes, benches, newsstands, or subway exits. On streets with metered parking, racks placed between meter poles should be as close to midway as possible. [Association of Pedestrian and Bicycle Professionals, 2002]

Bike parking has become an even more important issue with the popularity of bike-sharing programs. Bike-sharing programs have been created in over 600 cities worldwide, including many in major U.S. cities. The concept of renting a bicycle, using it, and depositing it when finished, implies that there need to be many locations where bicycles can be stored. Parking is often located at major trip origins and destinations in cities, and in particular at major intermodal transportation terminals. Often in cities catering to tourists, one will find parking for bike sharing programs at parks, major tourist sites and attractions, and at convenient locations where space is available near streets or bike paths.

***4. What spot hazards need to be identified and rectified?***

Sudden changes in the bicycle facility alignment or pavement conditions can have a very detrimental effect on bicyclists, particularly when they occur with no forewarning. Unless quick evasive actions are taken, such obstacles and irregularities can cause bicycle crashes. It can also be a problem when bicyclists suddenly swerve to avoid a hazardous condition, since unpredictable movement can result in a crash with a motor vehicle. The following are some examples of bicycle hazards and special design considerations (consult AASHTO's *Guide for the Development of Bicycle Facilities* for further detailed solutions).

Maintenance on an urban street network occurs frequently, causing problems for bicyclists who must maneuver across milled pavement, over sudden pavement changes and steel plate covers (which are slippery when wet), and through narrowed lanes. In general, bicycles are far more susceptible to sudden pavement changes in construction areas than motor vehicles are. Warning signs can help give bicyclists advanced notice of upcoming pavement changes. When at all possible, a clear path should be maintained through construction areas for bicycle travel.

Rough railroad crossings set at an acute angle to the roadway are particular obstacles to bicyclists. Streets with inlaid rails (trolley streets) can also be difficult to negotiate if the rail is in the normal operating area for bicyclists, or if pavement adjacent to the rail has deteriorated and left open cracks.

Adequate space for bicyclists and pedestrians should be a standard element for all new bridges where bicycles are permitted to operate. These guidelines should apply regardless of whether bicycle lanes or sidewalks connect to the bridge at the time it is built. Minimum accommodations for bicyclists should include bike lanes and sidewalks on each side. It is also important to provide bike lanes where roadways pass beneath bridges, so that these areas do not present a barrier.

Manholes that are lower or higher than the surrounding pavement create an obstacle to cyclists. This sometimes occurs during roadway resurfacing when a manhole is not raised to the new surface level. Local roadway engineers should develop specific design solutions to address the need for a level pavement surface, including raising manholes to meet the same grade as newly laid pavement. In addition, avoid placing utility covers in bike lanes, where possible.

Some types of drainage grates can trap a bicycle wheel and cause a crash, particularly those with a wide opening between bars or with bars parallel to the direction of travel. Bicycle-safe drainage grate designs have been developed and should be used wherever bicyclists are expected to ride. It is also important that drainage grates be placed on an even grade with the surrounding pavement.

Acceleration and deceleration lanes can create difficult and continuous conflicts between bicyclists and motorists. Conflicts occur when the vehicle is accelerating or decelerating and making a merge or turning maneuver. At intersections and driveways where adequate width is available, the bike lane should be transitioned to the left of the acceleration or deceleration lane. In addition, the mixing zone should be as short as possible and designated with green paint.

At merge locations, the acute angle of approach creates visibility problems, and the speed differential is often high. In this situation the bike lane can be transitioned to cross the merge lane at close to a right angle, improving sight distance and moving the crossing point away from the vehicular merge point.

## B. Pedestrian Network/Facility Design

An individual's decision to walk is as much influenced by the perceived quality of the experience as it is by security, safety, and convenience. Thus, whereas traditional pedestrian planning has focused on the physical characteristics of the pedestrian and of pedestrian movement, more recent studies have looked at a much broader context. This perspective not only includes what is needed to physically walk from one location to another, but also how urban design and the interaction between road network structure and land-use patterns can enhance or degrade this experience.

| Table 13-18. Pedestrian Crash Survival Versus Speed on Road | |
|---|---|
| | **Pedestrians vs Speed** |
| **Speed** | **Survival %** |
| 20 mph | 95% |
| 30 mph | 55% |
| 40 mph | 15% |
| **80% of pedestrians struck at 35 mph will be killed** | |

Source: City of Sacramento, 2003

For example, one study found that streets without sidewalks had 2.6 times more pedestrian and automobile collisions than expected based on exposure, while streets with sidewalks on only one side had 1.2 times more pedestrian crashes. [Knoblauch, 1988] Design and control speeds for adjacent roadways also affect pedestrians; higher travel speeds result in more severe injuries for pedestrians in the event of a collision (see Table 13-18). It is both clearly preferable and good practice to have some type of safe walking facility out of the traveled roadway. A separate walkway is the best option, but a roadway shoulder will also provide a safer pedestrian accommodation than walking in the travel lane.

Direct and convenient pedestrian connections should be provided between residences and activity areas. It is usually not difficult to determine where connections between residential areas and activity centers will be required during the early stages of development. Development density can be used as a surrogate for pedestrian usage in determining the need for sidewalks. Local residential streets, especially cul-de-sacs, can accommodate extensive pedestrian activity on the street because there is little vehicular activity (although cul-de-sacs also discourage connectivity among neighborhoods). Collector streets are normally used by pedestrians to access bus stops and commercial developments on major arterial roads.

Sidewalks are particularly important for those desiring to use transit. Sidewalks should be provided on all streets within one-quarter mile to one-half mile (400 to 800 m) of a transit station, depending on agency policy. Sidewalks should also be provided along developed frontages of arterial streets in commercial areas. Collector and arterial streets near schools should be provided with sidewalks to increase school trip safety.

***1. What are the characteristics of pedestrians that need to be considered in the planning process?***

Basic definitions and the characteristics of pedestrian movement, their relationship to various land-use contexts, quality of space, proximity to nearby active uses, and common pedestrian crash types should be considered when planning for pedestrian movement. Pedestrian characteristics, described in AASHTO's *A Policy on Geometric Design of Highways and Streets* (known as the "Green Book") and the Transportation Research Board's *Highway Capacity Manual*, include information on, (1) average pedestrian space needs (the average pedestrian occupies a space of 18 in. by 24 in. [45 cm by 60 cm]), (2) walking speeds, and (3) capacities for pedestrian-related facilities. Where pedestrian movement is very dense, such as on pedestrian bridges or tunnels, intermodal connections, outside stadiums, or in the middle of a central business district, pedestrian capacity analysis may be needed. As with road capacity, level of service concepts have been developed for pedestrians that relate flow rate to spacing and walking speed.

An average walking speed of 4 ft/second (sec) (1.2 m/sec) has been used as a standard walking speed for many years. This speed has been shown to be closer to the $50^{th}$ percentile of pedestrians crossing an intersection; the $15^{th}$ percentile is roughly 3.5 ft/sec (1.1 m/sec), and the $5^{th}$ percentile is roughly 3.0 ft/sec (1.0 m/sec), which is appropriate near senior housing, hospitals, and schools. Many pedestrian studies are now using 3.5 ft/sec (0.9 m/sec).

Facility design must also take into account pedestrians with physical, visual, or mental disabilities, for example, providing increases in average pedestrian space requirements for individuals using canes, walkers, wheelchairs, shopping carts, or baby carriages. Pedestrians with ambulatory difficulties are sensitive to walking surfaces. Persons with hearing or visual impairments or learning disabilities may be less able to process typical sensory information, such as colors or signage.

***2. What are typical design considerations for pedestrian facilities?***

With limited funding and varying demands for pedestrian facilities in most jurisdictions, the type of pedestrian improvements should be compatible with the characteristics of the area. This concept is described in the City of

Sacramento's *Pedestrian Master Plan* [City of Sacramento, 2006]. The most fundamental level of improvement is referred to as "basic." This is the baseline that should apply to all parts of the jurisdiction. The "upgraded" level of improvement includes everything in the basic level plus added features such as wider sidewalks, more intense lighting and landscaping, and higher-quality street crossing treatments. These improvements are targeted for commercial streets with medium to high levels of automobile traffic. "Premium" improvements include all of the basic and upgraded-level improvements plus additional elements that make the pedestrian setting an active urban place. Items such as extra-wide sidewalks, special lighting, signage, and seating are some of the features included. Upgraded improvements are recommended for all pedestrian corridors, and premium improvements are appropriate for pedestrian activity nodes.

Pedestrian facilities should be designed with the following factors in mind:

- *Sufficient Width*. Sidewalks should accommodate anticipated volumes based on adjacent land uses, and they should at a minimum allow for two adults to walk abreast. Greater detail on sidewalk dimensions is provided later in this chapter.
- *Protection from Traffic*. High-volume or high-speed (greater than 25 miles per hour, or 40 kilometers per hour) motor vehicle traffic creates dangerous and uncomfortable conditions for pedestrians. Above 25 mph, the chance of death increases by 50 percent for pedestrian/motor vehicle crashes. Physical (and perceptual) separation can be achieved through a combination of methods: a grassy planting strip with street trees, a raised planter, bicycle lanes, on-street parallel parking, and others.
- *Intersection Design*. Intersection design should facilitate both vehicular and pedestrian movement with geometric dimensions that reduce pedestrian crossing distances and provide median refuge islands.
- *Street Trees*. Street trees are an essential element in a high-quality pedestrian environment. Not only do they provide shade, they also give a sense of enclosure to the sidewalk environment, which enhances the pedestrian's sense of walking in a protected environment. Concerns about trees limiting pedestrian visibility, particularly at intersections, can be mitigated by use of proper street trees with mature trunk diameters of 12 in. (30.5 cm) or less and canopies higher than 8 ft (2.4 m). Such trees should be considered from the perspective of approach sight distance for motor vehicles.
- *Pedestrian-Scale Design*. Large highway-scale signage reinforces the general notion that pedestrians are out of place. Signage should be designed to be seen by the pedestrian. Street lighting should likewise be scaled to the level of the pedestrian rather than provided by light poles that are more appropriate on high-speed freeways. Components such as street furniture, vistas, and landmarks should be incorporated into designs to help make walking routes interesting.
- *Continuity*. Pedestrian facilities are often discontinuous, particularly when private developers are not encouraged to link on-site pedestrian facilities to adjacent developments and nearby sidewalks or street corners. New developments should be designed to encourage pedestrian access from nearby streets. Existing gaps in the system should be placed on a prioritized list for new sidewalk construction.
- *Clearances*. Vertical clearance above sidewalks for landscaping, trees, signs, and similar obstructions should be at least 8 ft (2.4 m). In commercial areas and central business districts, the vertical clearance for awnings should be 9 ft (2.7 m). The vertical clearance for building overhangs that cover the majority of the sidewalk should be 12 ft (3.6 m).
- *Conformance with National Standards*. All pedestrian facilities should be consistent with ADA requirements. Specific guidance is provided by the Architectural and Transportation Barriers Compliance Board's *ADA Access Guidelines*, and "Proposed Guidelines for Pedestrian Facilities in the Public Right-of-Way (PROWAG)."

A number of guidelines are available for pedestrian facility design, including:

- AASHTO, *Guide for the Planning, Design, and Operation of Pedestrian Facilities* [2004]
- City of Chicago, *Complete Streets Chicago* [2013]
- City and County of San Francisco, *Designing Complete Streets* [2015]
- City of New York City, *Street Design Manual* [2013]

- Department of Transport, Main Roads Western Australia, *Planning and Designing for Pedestrians: Guidelines* [2012]
- Institute of Transportation Engineers (ITE), *Designing Walkable Urban Thoroughfares: A Context Sensitive Approach* [2010]
- MetroAnalytics, *Utah Bicycle and Pedestrian Master Plan Design Guide* [undated]
- NACTO, *Urban Street Design Guide* [2013]
- New Zealand Transport Agency, *Pedestrian Planning and Design Guide* [2016]

The MUTCD and ADA *Access Guidelines* also address a range of pedestrian facility design standards. Many of these resources, however, deal primarily with roadway design for motor vehicles and contain limited pedestrian-related material. At the local level, when pedestrian planning has occurred, it is often common to find examples of comprehensive design practices that recognize locality-specific pedestrian needs.

***3. What design treatments are appropriate for different pedestrian environments?***

How planners provide for pedestrian transportation varies from one context to another. The following sections present some of the factors that should be considered when designing facilities in specific contexts.

*Sidewalk width and setbacks* will vary, depending on the community. The following recommendations provide guidelines for sidewalk width and setbacks. It is important to note that some area contexts warrant wider sidewalks than the minimum width. For example, sidewalks in and around universities and colleges must accommodate a much higher volume of pedestrians and, therefore, warrant additional width. The following recommendations are based on FHWA and ADA guidelines and common practices used by pedestrian-friendly communities in the United States.

*Sidewalks in Community Benefit Districts (CBDs)*. Sidewalk widths in CBDs are, for the most part, already determined by building setback and street widths, although in some cities such as New York City sidewalks are being made wider by taking road space. Should a reconstruction project warrant further study of sidewalk width in a CBD, service standards are found in AASHTO's *Green Book* [2011].

*Arterial and Collector Streets in Commercial and Residential Areas*. Sidewalks on arterial and collector streets in commercial and residential areas should be a minimum of 5 ft (1.5 m) wide. A minimum of a 2-ft (0.6-m) wide planting strip should be provided. If no planting strip is possible, the minimum width of the sidewalk should be 6 ft (1.8 m).

*Sidewalks on Local Streets in Residential Areas*. On local streets in residential areas, sidewalk width may be based on the number of dwelling units per acre. For multifamily developments and single-family homes with residential densities that exceed four units per acre, the sidewalk should be a minimum of 5 ft (1.5 m) wide with a minimum setback of 2 ft (0.6 m). For densities up to four dwelling units per acre, the sidewalk should be a minimum of 4 ft (1.2 m) wide with a 2-ft (0.6-m) setback.

*Curb Extensions or Bulb-Outs* are extensions of the sidewalk into the street on one or both sides of a crosswalk. The primary benefits are shorter crossing distances at intersections for pedestrians, increased visibility for the pedestrian, reduced traffic speeds, and less exposure to vehicle conflicts in the roadway. Curb extensions are normally only used where onstreet parking is present. The design typically extends into the street by the same or lesser dimension as the on-street parking. To avoid bike conflicts, the curb extension should not extend into bike lanes or wide outside lanes for bikes.

*Sidewalks on Streets with No Curb and Gutter*. The setback requirement is based on roadway cross sections that include curb and gutter. Sidewalks located adjacent to "ribbon pavement" (pavement with no curb and gutter) are not recommended. However, if no other solution is possible, sidewalks adjacent to ribbon pavement should have a much greater setback requirement, depending on roadway conditions. More specific guidelines can be found in the AASHTO *Green Book*.

*Sidewalks in Rural Areas*. In most rural areas, the low volume of pedestrians does not warrant sidewalk construction. In most cases, 4-ft (1.2-m) wide paved shoulders can provide an adequate area for pedestrians to walk on rural roadways. Exceptions should be made in areas where isolated developments such as schools, ballparks, or housing communities create more pedestrian use. For example, motorists might regularly park along a rural road to access a nearby ballpark. A sidewalk may be warranted in this circumstance so pedestrians can be separated from traffic. Sidewalks in rural areas should be provided at a width based on the anticipated or real volume of pedestrians, with 5 ft (1.5 m) being the minimum width.

*Crosswalks* serve to channel pedestrian traffic through an intersection, as well as heighten the awareness of motorists to possible pedestrian crossing movements. It is important to note that although crosswalks are an important element in intersection design, a crosswalk alone does not ensure the safety of a pedestrian. Too often, crosswalks are the sole provision for pedestrians at intersections, when other safety measures are also needed.

The recommended width of crosswalks is 10-ft (3-m) wide, with a minimum width (as set by MUTCD) of 6 ft (1.8 m). Wider crosswalks should be installed at locations with higher pedestrian volumes. At signaled intersections with stop bars, a minimum separation of 4 ft (1.2 m) is necessary between the stop bar and edge of the crosswalk. At midblock locations, stop or yield bars should be placed to allow motorists adequate stopping time, particularly on multilane sections.

*Curb Ramps* should always be placed to lead the pedestrian directly into a striped crosswalk area. Intersection corners should include two curb ramps or at least one broad ramp that serves both crosswalks. Curb ramps should always be provided with a matching ramp on the opposite side of the road, as well as ramps at pedestrian refuge islands. ADA provides federal guidance for curb ramp installation.

Pedestrian safety at intersections depends in part on minimizing the length of time that the pedestrian is exposed in the street. One way of minimizing conflict and exposure at intersections is to improve *traffic signalization* and improved intersection geometric design. Traffic signal improvements for pedestrians may include:

- Improvements to timing options and turn phasing.
- Elimination of right-turn-on-red movements.
- Elimination of free-right turning movements (with yield signs).
- Addition of pedestrian signals (WALK and DON'T WALK).
- Pushbutton signals that can be actuated by pedestrians.
- Reduced corner radii and curb extensions to shorten the distance the pedestrian must cross, therefore also shortening the signal intervals.

Guidelines for traffic signalization to accommodate pedestrian crossings are provided in the MUTCD. Traffic engineering analysis is necessary on a case-by-case basis in order to determine the best signal option. Signaled intersection design and audible signals should be given special consideration in areas with higher numbers of senior citizens, school-age children, and disabled persons, including longer pedestrian clearance intervals.

Characteristics of good pedestrian signaled intersections include:

- Compact intersections with short cycle lengths.
- Short pedestrian crossings.
- Medians for multilane streets.
- Crosswalks with pedestrian indicators on all approaches.
- Signal heads (pedestrian and vehicle indicators) located for optimum visibility.
- Heads on the intersection side of the crosswalk so they are not obstructed by large vehicles stopped at the stop bar, and concurrent pedestrian and vehicle phase heads co-located on one pole (this is especially important where permitted left-turn phasing is concurrent with the crosswalk being crossed by the left-turning vehicle).
- Advanced stop bars to enhance pedestrian visibility and reduce incidence of motorists stopping in the crosswalk.
- Signal controller located outside of walking areas.
- Pedestrian pushbuttons located at or near the top of curb ramps.
- Audible signals for all new installations and significant signal modifications.
- No right turns on red where conflicts with pedestrians are likely.
- Good intersection lighting, including pedestrian-scale lighting.

Curb Extensions or Bulb-Outs, as previously discussed, are extensions of the sidewalk and curb into the street on both sides of a pedestrian crosswalk. Curb extensions have several advantages for the pedestrian. The primary benefit is a shorter crossing distance at an intersection. Shortening this distance decreases the amount of time the pedestrian is exposed to traffic. By narrowing the traffic lane and creating a smaller corner radius, curb extensions also reduce traffic speeds at the intersection. Curb extensions increase visibility for the pedestrian in areas with on-street parking by offering an unimpeded view of oncoming traffic (and allowing oncoming traffic to see approaching pedestrians).

*Pedestrian Refuge Areas* can be essential for large, multilane, urban, and suburban intersections. These areas serve several purposes. They allow a resting place for slower pedestrians who cannot make it across the intersection within the time allotted. In wider urban intersections, refuge areas allow pedestrians to cross one direction of traffic at a time and provide a place to wait for the next pedestrian cycle. In this case, they also reduce the overall delay to motor vehicles that would otherwise have to stop to allow a pedestrian to cross the entire length of the intersection.

Medians and refuge areas can be particularly important for urban intersections with center turn lanes and left turn signals. Traffic signals that serve these intersections often do not allow adequate time for the pedestrian to traverse the length of the intersection. The center median, therefore, provides a refuge for pedestrians who must wait through several cycles to complete a crossing.

*Split Pedestrian Crossings (SPXOs)* represent a variation on a median refuge where pedestrians are encouraged to cross one half of the street, enter the refuge, walk toward traffic, and then exit across the second half of the street. The benefit of this design is that pedestrians face on-coming traffic as they maneuver through the crosswalk. This treatment is typically used at midblock locations or near transit connections.

*MidBlock Crossings* are most appropriate in locations where a high pedestrian traffic attractor is located directly across the street from a significant source of pedestrians. Examples include a commercial area with fast food restaurants across the street from a university, or a shopping center across from a high school. However, due to the increased safety risk of a pedestrian crossing in midstream traffic, midblock crossings should be generally discouraged unless one or more of the following conditions apply:

- The location is already a source of a substantial number of midblock crossings, or it is anticipated to generate midblock crossings (for a new development).
- The land use is such that a pedestrian is highly unlikely to cross the street at an adjacent intersection and midblock crossings are frequent.
- The safety and capacity of adjacent intersections create a situation where it is dangerous to cross the street, except at a designated midblock location.
- Spacing between adjacent signals exceeds 600 ft.
- Other lesser measures to encourage pedestrians to cross at adjacent intersections have been unsuccessful.

Other treatments such as flashing beacons and high-intensity activated crosswalk (HAWK) signals can improve pedestrian safety at midblock crossings. HAWK signals are a combination of beacon flashers and traffic signals (see Figure 13-17). Bulb-out designs might also be appropriate at such locations.

Grade-separated crossings are considered when the volumes of pedestrians and motor vehicles on the crossing road are very high. Pedestrians can rarely be convinced to use a poorly located crossing, and will almost never use an overpass if it takes 50 percent longer to cross than an at-grade crossing. Grade-separated crossings should thus be provided within the normal path of pedestrians wherever possible.

Topography should be a major consideration in determining whether an underpass or overpass is more appropriate. These facilities are regulated by ADA standards; therefore, extensive ramping is usually necessary to meet the ADA grade requirements.

*Sidewalk Pavement Design* is important not only from a safety perspective but also because it adds to the walking experience of the pedestrian. Sidewalks and roadside pathways should be constructed of a solid, debris-free, and slip-resistant surface. Special paving, stamped concrete, and colored concrete can enhance the pedestrian environment and are popular for more decorative sidewalks. The use of stylized surfaces is encouraged; however, they must be designed with surface uniformity and slip resistance characteristics that meet applicable standards.

*Sidewalk Obstacles* can create safety and pedestrian flow problems. Street furniture and utility poles create obstacles to pedestrian travel when located directly on the sidewalk. At a minimum, there should be 4 ft (1.2 m) of sidewalk width to allow a wheelchair to pass. Where possible, utilities should be relocated so as not to block the sidewalk.

**Figure 13-17. Midblock Crossing with HAWK Signals**

Photo courtesy of Adam Rosbury

Benches should not be sited directly on the sidewalk, but set back at least 3 ft (0.9 m). Curb design can also result in obstacles related to on-street parking. Use of vertical curbs is preferred to rolled curbs.

*On-Street Parking*, especially parked cars near intersections, has been cited as a contributing factor in many pedestrian crashes in urban areas. Parked cars block visual access to oncoming traffic, so that neither pedestrians nor motor vehicles can see each other. Parked cars also provide a buffer between the sidewalk and the travel lane, however, increasing the space between pedestrians and vehicles traveling at high speeds. Consideration should be given to removing parking in the immediate vicinity of crosswalks for adequate sight distance and visibility. Curb extensions at intersections can also mitigate visibility problems with less loss of parking.

*Construction Zones* can disrupt pedestrian and bicycle circulation and often create barriers for pedestrian movement. Just as traffic is rerouted during roadway construction, pedestrians and bicyclists should be provided a safe alternative through the work zone. Factors to consider include extent of the construction zone, duration of construction, convenience and safety of alternate routes, and cost of accommodation.

Pedestrians and bicyclists should be rerouted well in advance of the construction barriers because most are unlikely to retrace their steps to get around the work zone. Construction sites are particularly difficult to traverse for disabled pedestrians. An alternate accessible route should always be provided when the main route is interrupted by construction activities.

Pedestrian facility maintenance is an important aspect of creating adequate and comfortable facilities for pedestrians. A crumbling sidewalk is not only an eyesore, but also a hazard to the pedestrian and a barrier to the disabled. Most sidewalk maintenance is the responsibility of the fronting property, but in some cases, jurisdictions have assumed this responsibility. A periodic inspection schedule for pedestrian facilities should be adopted by local jurisdictions. Crosswalks will need restriping. A general maintenance budget should be allocated by each local government for use on a yearly basis, perhaps combined with a maintenance budget for bicycle facilities.

Pedestrian safety is often jeopardized in areas where freeway and expressway ramps intersect with arterial, collector, and local streets. For new roadways and roadway-widening projects, a pedestrian circulation plan should be developed for interchange exit and entrance ramp locations, particularly for areas with the following characteristics:

- Areas having substantial pedestrian volume or nearby pedestrian attractors.
- Where existing sidewalks are located in the vicinity of expressway exits and entrances.
- Where new sidewalks are planned for the vicinity of expressway exits and entrances.

Several measures can increase the awareness of motorists and improve conditions for pedestrians at interchanges. Ramp width should be minimized to reduce the crossing distance for pedestrians. Warning signs should be posted on exit ramps to warn motorists of upcoming pedestrian crossings. Motorists should be encouraged to quickly reduce their vehicle speed after exiting the highway, both through signage and traffic calming methods. Extra care should be taken to improve these areas for pedestrians wherever possible.

Modern *roundabouts* reduce traffic speeds at junctions and reduce severe vehicular crashes. Their design also minimizes the number of pedestrian conflicts when compared to traditional intersections. This is accomplished in part by removing some of the conflict points, such as left turns, that cause crashes at traditional intersections. Roundabouts can also reduce delay for vehicles in many cases, replacing stop control with the yield-at-entry rule.

Roundabouts should be designed to accommodate pedestrians and bicyclists safely. [Harkey and Carter, 2007; Rodegerdts et al., 2007] It is important that automobile traffic yield to pedestrians crossing the roundabout. Splitter islands at the approaches slow vehicles and allow pedestrians to cross one direction of travel at a time. Single-lane approaches can be designed to keep speeds down to safe levels and allow pedestrians to cross.

Finally, it is important for all of the facilities described to have good drainage such that walk areas do not flood or experience ice accumulation (such as at corner street ramp locations). Street drains should not be located in crosswalks.

## VII. PEDESTRIAN AND BICYCLE TRANSPORTATION IN ASIA AND EUROPE

Notable efforts to enhance bicyclist and pedestrian travel in Asian, Australian, and European cities include bike-share systems, transportation pricing, safety, and traffic calming treatments. The lessons learned from these experiences are presented in a FHWA study on case studies from around the world. [FHWA, 2015a] The report notes that following practices from overseas that might by appropriate for the United States:

- Various types of bicycle priority streets (superhighways, shared bicycle priority streets, wider separated lanes, and "green waves") for longer cycle trips and improving connections to employment and urban centers. Some communities have planned extensive networks of connected facilities linking important origins (outlying areas and cities) to important destinations. Overpasses, underpasses, and grade separated junctions are frequently used to bypass major roads and other barriers such as rivers and canals.
- Lower-speed, experimental designs for multi-lane, at-grade roundabouts and their approaches to help bicyclists safely travel through.
- Path or lane lighting (energy-efficient) for nighttime use, using technologies to detect users and raise the lighting and then dim the lighting as the user moves away.
- Bicycle signals and various measures for bicycle priority at intersections, including:
  - "Green waves" traffic signal progression.
  - More green time for bicyclists.
  - More split phasing to separate conflicting motor vehicle and bicycle movements.
  - Allowing nonconflicting bicycle through movements (bicycle green) when signal is red for parallel motorized traffic.
  - Leading bicycle interval/head start.
- Path or two-way bicycle facility priority at junctions with low-volume streets.
- Traffic restricted, pedestrian priority zones.

The case studies from Asian and Australian cities, in particular, indicate that nonmotorized transportation use varies primarily on how the safety of bicyclists and pedestrians is perceived by the general public, bicyclists, and pedestrians; and the degree to which the street character is considered inviting for walking or bicycling. These findings suggest that perhaps household income and weather—two factors often pointed to in the United States as reasons for minimal bicycle and pedestrian use—are not always the most appropriate factors in explaining the propensity to walk or bike.

Japanese and European examples show the importance of bike-share systems for the efficient operation of an intermodal transportation system. Guarded bicycle parking, bicycle rental services, and bicycle accommodations on transit vehicles enhance the efficiency and effectiveness of transit. In China and India, bicyclists use transit to travel long distances for work, which reduces congestion on city streets (although in both countries, automobile ownership is rapidly overwhelming the road networks). Comprehensive bicycle networks, effective pedestrian facilities, and traffic calming efforts further reinforce nonmotorized transportation access to transit stations in Asia and Europe (see Figure 13-18).

An FHWA synthesis of international pedestrian safety research included a review of pedestrian amenities such as crossing signs, marked versus unmarked crosswalks, countdown pedestrian signals, illuminated pushbuttons, automatic pedestrian detectors, and traffic calming efforts. The synthesis found that European cities are particularly innovative in the application of pedestrian-only zones to encourage walking, with limited late night and early morning delivery truck access. [FHWA, 2003] Australia was a leader in combining education, promotion of designated routes, and individual pedestrian design treatments. The United Kingdom was the key developer of the midblock Puffin crossing in high pedestrian activity areas (the Puffin crossing controls pedestrian clearance intervals with crosswalk detectors, which minimizes motor vehicle delay and improves pedestrian safety).

An ITE bicycle tour of The Netherlands provided important insights on how and why bicycling has become such a major form of transportation in that country. [Miller et al., 2013] Most importantly, the Dutch have been systematically planning bicycle networks for many decades. National and local policies have been put in place to encourage bicycle transportation, often with a trade-off of less capacity for motor vehicles. Most cities have cycle tracks, bike lanes, bike paths, bike signals, bike-share programs, and indoor/outdoor bike parking. The facilities try to separate bicyclists from motor vehicles as much as possible, but where this is not possible, vehicle speed limits are reduced.

One of the important strategies to complement pedestrian and bicyclist treatments is a reduction in vehicle speeding. In 1988, for example, the United Kingdom implemented a remote speed enforcement policy that allowed automatic speeding citations without the need for a police officer. The results of the 3-year evaluation period (2000–2003) of 24 new camera areas in the United Kingdom showed a 7 percent reduction in average speed and a 30 percent reduction in vehicles over the speed limit. Adjusting for long-term trends, there were 33 percent fewer personal injury collisions and 40 percent fewer persons injured or killed during this same period.

In London, England, the implementation of a downtown congestion pricing program shifted commuters primarily to transit, while others shifted their route, walked, or used a taxi, motorcycle, or bicycle (30 percent increase in cycling following implementation). Japan and Singapore have implemented transportation policies with pricing elements related to parking, vehicle registration, gasoline tax, and tolls, which have contributed to higher use of nonmotorized travel.

Colored bike lanes and advanced stop lines are other innovative bicycle treatments being used in Asia and Europe to enhance the safety and attractiveness of a bicycle network. A cycle track increases the separation between motor vehicles and bicycles and minimizes encroachment of motor vehicles into the bicycle lane. Colored bicycle lanes define the right-of-way at locations with a high conflict potential between motor vehicles and bicycles. Finally, an advanced stop line or bicycle box improves the visibility of bicyclists and allows them to correctly position themselves at intersections with high motor vehicle and bicycle volume. The ITE publication *Innovative Bicycle Treatments: An Informational Report* includes other applications with a discussion of sample sites, a description of each treatment, and the costs, advantages, and disadvantages of each. In addition, readers are referred to the following FHWA website for the latest information on pedestrian and bicyclist transportation, http://www.fhwa.dot.gov/environment/bicycle_pedestrian/resources/.

## VIII. SUMMARY

This chapter has presented an overview of planning for pedestrians and bicyclists. In urban areas, in particular, such transportation can be an important component of the transportation system. Enhancing the ability of travelers to walk or bike involves not only providing the infrastructure and safe strategies for using the facilities but also linking urban design and streetscapes to those factors that encourage walking and bicycling. Of great concern, pedestrians represent a disproportionate percentage of road-related fatalities, and thus, special focus should be given to addressing safety issues.

The planning process for pedestrians and bicyclists can range from master plans to recommendations for spot improvements. As zoning codes and infrastructure standards evolve in a community to reflect changing values and desires as to community character, serious attention should be given to how these tools can be used to foster development patterns more conducive to nonmotorized transportation. Most importantly, pedestrian and bicyclist transportation needs to be considered as a serious component of a state, region, or city/town transportation plan.

## Acknowledgments

This original chapter was prepared through a collaborative effort including a number of individuals. Maria Vyas with input from Shaunna Burbidge, Daniel Rubins, and Matt Haynes wrote sections of the chapter in the third edition. Many sections of the report were also retained from the second edition prepared by Jennifer Toole.

# Travel Demand Management[1]

## I. INTRODUCTION

Beginning in the 1970s and 1980s, transportation planners became increasingly interested in ways of providing mobility and accessibility without necessarily expanding the physical capacity of the transportation network. There were many reasons for this. The oil embargoes against the United States of the late 1970s caused federal, state, and local governments to encourage more efficient use of the transportation system. Air quality legislation around the same time sought to lower motor vehicle–related emissions, which led to initiatives to encourage auto drivers to seek other means of travel, such as ridesharing. In addition, federal investment in transportation was being strained by numerous requests for federally supported projects, and federal officials soon realized that there would not be enough federal dollars to support all of the requests. Their response was to encourage alternative mobility strategies that did not need massive levels of federal investment.

At the state and local levels, governments and employers became interested in ways of reducing congestion on the highway network, especially at major activity centers. This often led to interest in flexible work hours, rideshare programs, subsidies for transit services, and parking management.

Thus, by the mid-1980s, many transportation professionals were involved with a variety of strategies to influence travel demand, an effort known as travel (or transportation) demand management (TDM) (or mobility management in Europe). The Center for Urban Transportation Research (CUTR), the Federal Highway Administration (FHWA), and Litman [2014] define TDM in the following ways:

> *CUTR: "TDM is helping people change their travel behavior to meet their travel needs by using different modes, travelling at different times, making fewer or shorter trips, or taking different routes."*
>
> *[CUTR, 2005]*

> *FHWA: "Managing demand is about providing travelers, regardless of whether they drive alone, with travel choices, such as work location, route, time of travel and mode. In the broadest sense, demand management is defined as providing travelers with effective choices to improve travel reliability."*
>
> *[Gopalakrishna et al., 2012]*

> *Litman: "Various strategies that change travel behavior (how, when and where people travel) in order to increase transport system efficiency and achieve specific planning objectives."*
>
> *[Litman, 2014]*

As can be seen in these definitions, providing travelers with a trip choice is a key TDM concept. This choice can include: (1) determining whether travel is necessary, given changes in communications technology and lifestyles, (2) shifting demand from single-occupancy vehicles to other modes of transportation such as transit, carpools or vanpools, bicycling, or walking, (3) shifting travel times to reduce peak-period congestion, (4) reducing the distance of required travel through land-use planning and urban design strategies, and (5) helping travelers to choose less congested facilities by providing real-time information. For transportation planners, TDM strategies represent another tool that can be used to enhance mobility and accessibility in support of state, regional, or community goals.

Today, TDM has evolved into a means of achieving multiple community goals. Litman [2014], for example, suggests numerous TDM benefits that reflect a range of goals (see Table 14-1). According to Black and Schreffler, TDM also promotes the following sustainability benefits, which broadens the role of TDM in community planning:

- *TDM reduces the need for new or wider roads.* By persuading people to drive less often, to closer destinations, outside of rush hours or using less busy routes, TDM can reduce the demand for new road infrastructure.

[1] This chapter was written by Michael D. Meyer, WSP/Parsons Brinckerhoff.

| Table 14-1. Benefits of Travel Demand Management Strategies | |
|---|---|
| **Benefit** | **Description** |
| Congestion Reduction | Reduces traffic congestion delays and associated costs. |
| Road & Parking Savings | Reduces road and parking facility costs. |
| Consumer Savings | Helps consumers save money by reducing their need to own and operate motor vehicles. |
| Transport Choice | Improved travel options, particularly for non-drivers. |
| Road Safety | Reduced crash risk. |
| Environmental Protection | Reduced air, noise, and water pollution, wildlife crashes, and other types of environmental damages. |
| Efficient Land Use | Supports strategic land-use planning objectives, such as reduced sprawl, urban redevelopment, and reduced habitat fragmentation. |
| Community Livability | Improved local environmental quality and community cohesion. |
| Economic Development | Supports a community's economic objectives, such as increased productivity, employment, wealth, property values, and tax revenues. |
| Physical Fitness and Health | Improved public fitness and health due to more physical activity, usually through increased daily walking and cycling. |

Source: Litman, 2014

- *TDM makes personal travel decisions more efficient.* Many drivers make travel decisions based on poor information and a lack of experience with non-automobile options. TDM improves their awareness and understanding of options, and their willingness to try them.

- *TDM maximizes return on infrastructure spending.* Studies have shown that good information can significantly increase ridership on new transit infrastructure and services. Likewise, reducing overall travel demand on highways adds to the effective lifespan of strategic capacity improvements.

- *TDM makes the most of our current assets.* It saves people money and time by helping them make efficient travel decisions. It improves health by promoting physical activity and less-polluting modes. It benefits employers by increasing productivity, reducing parking costs, and helping to attract and retain workers. It promotes economic development by reducing congestion and enhancing worker mobility.

- *TDM is a versatile and dynamic management tool.* TDM measures can be customized for specific audiences (e.g., business park commuters), destinations (e.g., major hospitals), travel modes (e.g., cyclists), travel corridors (e.g., a busy highway), trip purposes (e.g., school), or specific timeframes (e.g., major events). TDM strategies can be delivered in months, rather than years.

- *TDM initiatives have multimodal benefits.* It recognizes that people see alternatives to driving as a "suite" of options. Nondrivers tend to be public transport users, carpoolers, pedestrians, or cyclists at different times, for different reasons. TDM expands travel choices within this suite of options.

- *TDM works at the scale of individuals, but has huge power across a community.* If every person who drives to work in a community decided to leave his or her car at home just one day a month, the 5 percent reduction in commuter traffic could significantly ease daily congestion.

- *TDM strategies are relatively low cost for meeting mobility solutions.* In general, the budgeted amounts allocated for TDM are considerably less than those for more capital-intensive and operational projects.

- *TDM strategies are comparatively cost-effective in meeting policy objectives.* Similarly, TDM strategies have been shown to be a cost-effective means of meeting key policy objectives. One study of projects funded by the federal Congestion Mitigation and Air Quality (CMAQ) program concluded that TDM measures were among the most cost-effective of those implemented as part of the program.

- *TDM strategies generate good benefit/cost ratios.* Several research projects have developed methodologies to calculate the costs and benefits of TDM in order to allow for objective project selection and evaluation. [Black and Schreffler, 2010]

Although this chapter uses the transportation planning process outlined in chapter 1, and in particular Figure 1-1, to provide a foundation for the discussion of transportation planning, another conceptual planning framework, called least-cost planning, is particularly relevant to TDM. The Oregon DOT defines least-cost planning in the following manner:

> *"Least-cost planning means a process of comparing direct and indirect costs of demand and supply options to meet transportation goals, policies or both, where the intent of the process is to identify the most cost-effective mix of options."*
> *[Oregon DOT, undated]*

Similar in concept to the planning process shown in Figure 1-1, least-cost planning includes the following steps:

1) Identify goals (general things that you want to achieve), objectives (ways to achieve those goals), and targets (measurable outcomes that you want to achieve).
2) Identify various strategies that can help achieve the objectives and targets. These can include both projects that increase capacity and demand management strategies.
3) Evaluate the costs and benefits of each strategy (including indirect impacts, if any), and rank them according to cost-effectiveness or benefit/cost ratios.
4) Implement the most cost-effective strategies as needed to achieve the stated targets.
5) After they are implemented, evaluate the programs and strategies with regard to various performance measures, to insure that they are effective.
6) Evaluate overall results with regard to targets to determine if and when additional strategies should be implemented. [Litman, 2010]

As can be seen, the major steps in least-cost planning include the same steps as found in Figure 1-1. Least-cost planning, however, explicitly recognizes that demand management is equivalent to capacity expansion and considers indirect costs and cobenefits of implementing TDM actions. The justification for encouraging mode shift is that, compared to automobile travel, alternative modes (for example, walking, cycling, ridesharing, public transit, telework, and delivery services) tend to be much more resource-efficient. The assessment of transportation projects and actions in a least-cost evaluation framework includes road and parking space total costs, user financial costs, fuel consumption, pollutant emissions, and other societal costs such as public health impacts. TDM programs tend to broaden the assessment criteria used in the decision-making process.

This chapter focuses primarily on the different types of strategies and actions to influence the demand for transportation. It is important first, however, to place the use of these strategies in the institutional and planning contexts most often found in the United States and Canada. Three major contexts are of most interest to planners: (1) statewide or regional TDM programs, including medium to small urban areas (for example, see Fraser Basin Council [2009]), (2) activity center programs aimed at subareas with multiple employment sites, and (3) site-specific programs primarily created in response to local development ordinances such as trip reduction ordinances. The first two will be addressed together given their similarities in program structure; the site-specific programs, although discussed briefly, are presented in greater detail in chapter 18 on local/municipal and activity center planning.

The next section presents examples of TDM goals, objectives, and performance measures. The following section examines different TDM strategies that can be used by both government-sponsored programs and private companies interested in enhancing mobility for their employees. Typically, a TDM program will consist of a number of complementary strategies, which are described in the following section. The impacts of TDM strategies are presented next, followed by a section on data analysis and models.

TDM programs use many different strategies in their efforts to influence travel behavior. Readers might find the following chapters in this handbook of particular interest: chapter 3 on land use and urban design, chapter 11 on parking, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, chapter 18 on local/municipal and activity center planning, chapter 19 on site planning and impact analysis, and chapter 24 on public participation and engagement.

## II. TDM GOALS, OBJECTIVES, AND PERFORMANCE MEASURES

TDM plans or programs focus on enhancing traveler mobility. In some cases, such as in California and the state of Washington, the goals relate to state legislation requiring demand management considerations in the planning process. In others, an areawide TDM plan is viewed as just another part of the transportation planning process, usually found as a chapter in the long-range transportation plan, thus reflecting the normal steps in planning whereby goals and objectives represent an important starting point.

Traditionally, TDM programs focused on employer-based strategies, utilizing such strategies as ridesharing, vanpools, and telework programs. As noted earlier, TDM today has much broader interests and focus. In Atlanta, Georgia, for example, a recent TDM plan "expanded the view of traditional TDM strategies by making the connection between traditional TDM (employer-based rideshare, vanpools, and telework programs) with livability, sustainability, transit, walking and biking, systems operations, transportation planning, economic development, climate change, healthy communities, and active aging." [Atlanta Regional Council (ARC), 2013] The goals and key strategies in this plan were (note: those indicated in bold were identified as having the highest priority):

**Improve customer convenience and user experience.**

- **Build on Georgia Commute Options rebranding to promote seamless customer experience.**
- **Improve connection of TDM to regional information systems.**
- Develop more targeted messaging for specific modes, locations, audiences, and customers.

**Increase transportation connectivity, mode choice, and access.**

- **Improve regional coordination of transportation planning, land use, and travel choice.**
- Incorporate TDM into local development policies and review processes.
- Improve and invest in bicycle and pedestrian infrastructure, access, and safety.
- Restructure parking policies to encourage non-single-occupant vehicle (SOV) travel.
- **Strategically link express bus service, local transit, vanpools, managed lanes, and park-and-ride lots.**

**Streamline regional coordination of policies, programs, services, and investments.**

- Determine a lead agency to oversee management and funding for regional TDM programs.
- Coordinate regional and local marketing and outreach through a marketing manager.
- Create a TDM Advisory Committee aligned with the regional planning committee structure.
- **Enhance integrated operations, branding, and marketing of the regional vanpool program.**
- Align TDM planning and decision making with the regional planning process and programs.

**Leverage and diversify funding sources for program sustainability.**

- Better educate policymakers, local governments, and the public on TDM benefits and funding.
- Better leverage public and private infrastructure investments.
- Incorporate TDM into strategic funding allocations through the regional planning process.
- **Leverage and diversify existing and potential funding sources to support creative, long-term, and innovative strategies.**

**Pursue continuous performance and operations improvements.**

- Establish a single portal for collection and reporting of TDM and other transportation data.
- **Develop performance metrics and evaluation criteria for all programs and services.**
- **Use data to improve programs and services.** [ARC, undated]

Another example of TDM goals and objectives comes from Arlington, Virginia, where the following goals were adopted for the countywide TDM program. (Note: Only objectives for the first goals are shown to illustrate how more specific objectives are associated with individual goals. For the complete goals and objectives, see [Arlington County Department of Environmental Services. 2012].

GOAL 1: Influence Growth in the Use of Transportation Options. Offer programs and services to get Arlington residents, employees, businesses, and visitors to use transportation options for travel to, from, and within Arlington County.

Objectives

- Maintain and improve current mode splits for Arlington, contributing to the County's overall objective of one-half percent single occupant vehicle (SOV) reduction per year for all types of trips the next 20 years.
- Encourage efficient, cost-effective modes of transportation that focus on moving people, not vehicles.
- Maximize use of transportation options while minimizing SOV travel.
- Minimize perceived barriers to using transportation options.
- Maximize the use of transportation options for trips generated by new development.

GOAL 2: Provide Quality TDM Service to Arlington Residents, Employees, Businesses, and Visitors.

GOAL 3: Encourage a Culture in Arlington in which there is Increased Awareness and Appreciation of Transportation Options and Their Benefits.

GOAL 4: Increase Transportation System Sustainability through TDM.

GOAL 5: Provide Transparency and Ensure Return on TDM Investment through Program Monitoring and Evaluation.

The goals for TDM programs at development sites are much more targeted on desired mobility outcomes. Such outcomes are often defined in the zoning ordinances that require developers to provide mitigation strategies for expected development-related trip generation. For example, the trip reduction requirements in the City of Pasadena, California, zoning code is intended, "to reduce the demand for vehicle commute trips by ensuring that the design of major residential and nonresidential development projects accommodates facilities for alternative modes of transportation." [City of Pasadena, undated]

Performance measures are used to monitor the outcomes of a TDM program (see chapters 7 on evaluation and 16 on metropolitan planning). Performance measures thus relate to the goals that a program is trying to achieve. The Arizona DOT notes that the most important primary measures for TDM programs are mode split and vehicle trips. [Arizona DOT, 2012] Thus, reductions in vehicle trips and vehicle miles traveled are two measures that could be used to assess the effectiveness of a TDM program or of individual strategies. However, as noted in the DOT report, decision makers often want to know more about the impact of a TDM program, and thus measures such as energy and emissions reductions, cost-effectiveness, number of parking spaces reduced, potential user awareness of the program, and participation levels are sometimes added to the performance report.

The TDM program in Halifax, Nova Scotia, Canada, is very similar in terms of measuring two primary indicators—mode split and individual TDM measure metrics. Mode split (or mode share) is the percentage of person-trips made by one travel mode relative to the total number of person-trips made by all modes. The individual TDM measure assessment was simply the number of users associated with each TDM strategy. [Halifax Regional Municipality, 2010]

Most of these measures are quantitative in that specific numbers or amounts can be attached to the metric. Some planning agencies augment the performance measurement with qualitative performance measures. This is usually done through surveys of those using the TDM program services, as well of the general population to determine why these services are not being used. For example, the San Diego Association of Governments (SANDAG), the metropolitan planning organization (MPO) for the San Diego metropolitan area, measures the number of trips and vehicle miles of travel avoided in the region due to the SANDAG iCommute program (part of its TDM effort),

as well as the associated environmental and monetary savings. The data are collected on a monthly basis and reported on quarterly. Qualitative measurement is obtained from yearly customer surveys. [SANDAG, 2012]

Table 14-2, from Arlington County, Virginia, shows the metrics that are used to monitor the progress of the county's TDM program. As shown, each performance measure is linked to a particular goal and includes both quantitative and qualitative measurements. [Arlington County Department of Environmental Services, 2012]

Other good examples of performance measures for TDM programs are found in Loudoun County, Virginia [Loudoun County, 2010] and Hampton Roads, Virginia. [Hampton Roads Transit, 2014]

## III. TDM STRATEGIES

TDM programs can lead to many different outcomes. First and foremost, the primary impact will be on travel demand, the major focus of almost all TDM programs. Second, over the long term, TDM measures can influence land use in terms of density and urban design considerations. Third, in combination with other supply-side strategies, TDM programs can affect the performance of the transportation system and services. For example, flex time and variable work hour programs can have a very positive effect on freeway and transit facility performance by "flattening" peak-period demands.

TDM strategies have been classified in many different ways. Table 14-3 shows one way of portraying different types of TDM strategies. In this case, the classification identifies two major focus areas—transportation options and land-use management—along with the incentives that encourage travelers to shift behavior and the implementation programs that institutionalize TDM strategies in existing standard operating procedures.

The classification scheme in Table 14-3 is used in the online *TDM Encyclopedia* as the organizing concept for a large amount of information on TDM strategies and program structure (see http://www.vtpi.org/tdm/tdm12.htm). The same encyclopedia presents TDM strategies from the perspective of how they help achieve equity objectives (see Table 14-4).

A common way of representing TDM strategies is to identify the most appropriate strategies by scale of application. Table 14-5, for example, shows SANDAG's approach to its comprehensive TDM strategy categorized by site, city, and regional/state applications. The table also shows performance measures that can be used to measure the effectiveness of individual TDM actions. Many of these strategies are specific to San Diego, such as the state's Sustainable Communities Strategies (SCS) requirement. However, in general, the strategies shown in the table are illustrative of the many strategies that can be considered by a metropolitan area.

The following sections adopt the classification scheme presented in Table 14-3, primarily because it is the approach used by the *Online TDM Encyclopedia* (http://www.vtpi.org/tdm/tdm12.htm). The encyclopedia provides extensive descriptions of the individual TDM actions in each category, which will thus not be repeated here. However, some of the more important TDM actions in each category are described below.

### A. Improve Transportation Options

TDM strategies aimed at improving transportation options (and thus reducing single-occupant vehicle (SOV) use) were some of the first TDM strategies implemented in the 1970s. [Meyer, 1999] They are today considered some of the more traditional TDM strategies, those needed in your program because they provide travelers with important alternatives to SOV use. The effectiveness of strategies aimed at reducing SOV use relates to the reasons that travelers would be willing to use an alternative mode. Figure 14-1 shows the results of a survey from northern Virginia that solicited reasons for commuters to use modes other than single-occupant vehicles. As shown, reducing stress, helping the environment, and reducing costs were the major reasons for reducing SOV use. The "Inner Beltway" and "Outer Beltway" labels reflect the residential address of those responding to the survey, inside and outside of the Washington, DC beltway freeway.

The following types of TDM actions are commonly found in the "Improve Transportation Options" category.

**Table 14-2. Performance Measures for a TDM Program, Arlington, Virginia**

| Goal | Performance Measure | Metrics Used |
|---|---|---|
| Goal 1: Influence Growth in the Use of Transportation Options | Mode split data from surveys | • SOV usage as compared to previous survey.<br>• Non-SOV usage (i.e., mode splits between alternative modes of transportation) as compared to previous survey.<br>• Mode use at Arlington worksites offering TDM services. |
| | Growth of TDM conditions in site plans | • Percent of new development/redevelopment with TDM conditions implemented in site plan vs percent of total new development/redevelopment. |
| | Service enhancements/growth of transit corridors | • Growth in increased transit options.<br>• Removal/decrease in transit corridors/gaps in service. |
| | Environmental impact measures attributed to TDM plan | • Use Environmental Protection Agency (EPA) approved models to measure vehicle trip reduction changes per year.<br>• Use EPA approved models to measure Green House Gas Emission increases/reductions as a result of annual changes in SOV use. |
| Goal 2: Provide Quality TDM Service to Arlington Residents, Employees, Businesses, and Visitors | Customer approval and satisfaction ratings for measured programs | • Number of employer clients participating in employee commute programs (i.e., transit subsidies, on-site pass sales, etc.). |
| | Program use | • Number of commuter store/commuter direct customers.<br>• Fare-media sales by commuter stores and commuter direct.<br>• Website hits/unique visitors. |
| Goal 3: Encourage a Culture in Arlington in Which there is Increased Awareness and Appreciation of Transportation Options and Their Benefits | Number of new and continuing transportation options awareness events | • Event attendance and participation figures.<br>• Post-event awareness satisfaction ratings (from surveys administered after a county event.<br>• Number of sponsorships of transportation-themed events (i.e., bike to work sponsors, rideshare fairs, sports arena advertisements for transit).<br>• Dollar amounts of non-in-kind sponsorships of transportation-related causes. |
| | Employer-based TDM program awareness | • Survey employees in regards to whether they were aware if their employer has a commuter program (yes or no). |
| | Membership-based program growth | • Car share membership. |
| | Transit-oriented development growth | • Increase in square footage of development surrounding transit stations/hubs (commercial, retail, residential). |
| | Vehicle ownership | • Number of vehicles registered as a percentage of the population. |
| Goal 4: Increase Transportation System Sustainability through TDM | Greenhouse gas emission and vehicle miles traveled reductions | • Peak-period VMT on Arlington street network (5% of 2005 levels).<br>• Peak-period vehicle trips on Arlington street network (5% of 2005 levels).<br>• Peak-period to nonpeak trip shift (10% of 2008 peak-period trips to nonpeak trips by 2020). |
| | Transit sales | • SmartBenefits sales, pass sales. |
| | Policy growth | • Number of new buildings with compliant TDM site plans.<br>• Number of existing buildings with compliant TDM site plans. |
| Goal 5: Provide Transparency and Ensure Return on TDM Investment through Program Monitoring and Evaluation | No performance measures other than to conduct monitoring and evaluation. | |

### *1. Rideshare Services*

Ridesharing occurs when two or more people share a single vehicle. In most metropolitan areas, a public agency or private firm provides ride-matching services, acting in essence as a facilitator for matching potential rideshare users. In Denver, the program is called RideArrangers; in Atlanta, it is called Georgia Commute Options; and in Boston it is called NuRide (although there is a website called Carpool Massachusetts that provides similar matching services). The regional ride matching database in the Washington, DC, metropolitan area is administered through Commuter Connections. Using Commuter Connections' online tool for regional carpool ride matching, residents, and employees can receive ride-matching information almost instantaneously.

With respect to vanpools, many metropolitan areas have companies and/or subsidized programs to provide vans and to recruit vanpool participants. The Commuter Connections online tool can also be used for regional vanpool ride-matching. A VanStart/VanSave program is available that provides financial assistance to pay for vacant seats when starting a new vanpool or to keep an existing vanpool in service until vacant seats can be filled by regular riders.

In Denver, RideArrangers also targets families who need to transport their children to school, either by carpool, walking, biking, or riding transit. The program, which operates through the schools, is the largest school pool program in the United States.

### *2. Transit Services and Amenities*

Efforts to reduce SOV use depend on there being desirable and convenient alternatives to SOV travel. Transit services and amenities are often the most common of such potential alternatives. In London, for example, site of one of the world's largest congestion pricing programs, the implementation of a significant increase in the price for automobile travel in central London was preceded by extensive upgrades in transit services in the area, so that those leaving their cars had a reasonable mobility alternative. Depending on the size of the metropolitan area, transit could include bus, light rail, heavy rail, and paratransit services (see chapter 12 on transit planning).

Although transit service is an important alternative to SOV use, research has shown that other incentives and support programs can often make the difference in choosing transit over auto use. For example, discounted transit passes, other transit subsidies, and targeted marketing are important services for informing and encouraging travelers to use transit. [Boyle, 2010] Most transit systems have different transit passes that can be subsidized by employers, local governments, or some other organization. For example, in Denver, many employers offer their employees the EcoPass, which allows unlimited rides on the bus or light rail anywhere within the transit agency's fixed-route system. A program called Flex Pass is designed to offer employers an annual pass program that can be customized to meet the needs of the company and its employees. Similar types of passes are available for college campuses and neighborhoods. The use of transit passes as an encouragement to ride transit has been made easier through the use of "smart cards," which not only expedite the traveler's trip through a station or boarding a transit vehicle, but that also allow easy reloading of cash values.

Other transit-related actions that can make a transit trip easier and more comfortable include: bus shelters, informative and visible signs and maps, car- and/or bike-sharing services at stations, accommodations for bicycles on transit vehicles, and wireless capabilities on vehicles.

### *3. Active Transportation: Programs and Infrastructure*

The Denver Regional Council of Governments (DRCOG) estimates that more than 1.5 million car trips each day in the Denver region are less than 5 minutes in length. Many of these trips could be made on foot. Many opportunities to ride bicycles for some types of trips exist as well. Companies can encourage employees to bike to work by offering amenities such as secure bicycle parking and shower and changing facilities. Others sponsor bike-to-work day events. Many cities are increasingly seeing bike-sharing programs whereby members can pick up a bike at any bike station and return it to that same station or any other station when they are done. In Denver, in addition to individual memberships, corporate memberships in such a program are offered through the B-Cycle Program, which allows companies to purchase various levels of membership for employees.

An important component of a TDM program that encourages bicycle and pedestrian transportation is providing the facilities needed to safely accommodate such travel. This could mean the construction of new pedestrian/bicycle facilities, the improvement of existing facilities, enhanced safety features, and better accessibility/linkages to the existing system (see chapter 13 on pedestrian and bicycle planning).

### *4. Teleworking*

In a company teleworking program, employees are allowed to work from home for one or more days each week, and in some cases remote telework sites are set up so employees can drive a short distance to their work site. Teleworking only makes sense for those types of jobs where an on-site presence is not necessary. Not only does it reduce the amount of work-related travel, research has shown that for high-tech companies in particular it is becoming an important recruiting advantage. Some examples include:

- Telework Arizona is a telework program operated by the Arizona Department of Administration. An evaluation of the program revealed that more than 75 percent of supervisors approved of the program and appreciated the resulting increases in employee productivity and morale. By 2007, state agencies, boards,

and commissions reported that more than 20 percent of state employees in Maricopa County (Phoenix) teleworked.

- U.S. Patent and Trademark Office's Trademark Work-at-Home Program has 46 percent of its more than 9000 nationwide employees teleworking at least weekly.
- Georgia Power's Telework Program (Atlanta, Georgia) has shown that prior to teleworking, 70 percent of the participants drove alone; after teleworking, the drive-alone rate dropped to 44 percent, with 28 percent of the change attributed to teleworking. Eighty percent of teleworkers reported that productivity increased an average of 27 percent while teleworking. Forty percent of managers believed productivity had increased by 5 percent as a direct result of teleworking, while 60 percent of managers thought that productivity had stayed the same. [Arizona DOT, 2012]

Telework can be a strong component of an overall congestion management strategy given that it is an effective method of fully removing commute trips from the roadway system while simultaneously reducing parking demand.

### *5. Compressed and Flexible Work Schedules*

Next to rideshare programs, encouraging employers and employees to adopt more flexible work hours or locations has been one of the mainstays of TDM programs. To a large extent, these programs surfaced in the 1970s in response to oil embargoes and a growing concern for energy conservation. Compressed work schedules include different work hour arrangements.

- *Flexible Work Hours*. Flexible work hours are programs allowing employees a degree of freedom in choosing their starting and quitting times. Employees must be at work during core periods (typically 9:30 to 11:30 a.m. and 1:30 to 3:30 p.m.) and must observe earliest allowed starting time and latest allowed quitting time limitations.
- *Staggered Work Hours*. Staggered work hours are a fixed scheduling of work that normally spreads the employee starting and quitting times over a 1- to 3-hour period, with individual groups of employees designated to report and leave at 15- to 30-minute intervals.
- *Compressed Work Week.* A compressed work week allows employees to work a greater-than-standard number of hours each day so as to reduce the total number of days worked, and hence, the number of times it is necessary to commute to the work site. A popular arrangement is the 9/80 schedule in which employees work 9 hours per day versus the standard 8 hours, and then get the 10th day off. [Kuzmyak et al., 2010]

A major new development in northern Virginia proposed the following steps to implement a flex work week as part of its TDM commitments to the local jurisdiction. A designated transportation coordinator(s) will:

- Coordinate with tenant organization points of contact to educate them on the importance of Flex Work Week (FWW) schedules and encourage making most employees eligible for FWW.
- Advertise FWW in the orientation handbook, and encourage employees who have not taken advantage of FWW to do so as they relocate to the new site.
- Develop new-hire orientation packets to inform employees about their FWW eligibility and encourage employees to travel during the early or later part of the peak period.
- Coordinate with traffic engineers to conduct biannual traffic counts at key intersections and parking garage entrances to determine actual peak-hour congestion levels. The Transportation Coordinator will issue a report to tenant organization points of contact detailing peak hours of congestion. If it is determined that at a certain peak hour, intersections are operating at consistently failing levels of service, the report will encourage supervisors within each tenant organization to inform employees to avoid traveling to work during the peak hour of congestion and encourage being flexible with their arrival time to work, within reason and when possible.
- Develop and/or acquire brochures, pamphlets, web-content, and posters advertising the FWW program. [City of Alexandria, undated]

### *6. Guaranteed Ride Home (GRH)*

Studies in the 1980s that examined the effectiveness of ridesharing programs determined that one of the greatest barriers for many who might be interested in using such services was "getting caught" at work without a means to leave the workplace. This was a particularly big concern for those who felt they needed the ability to leave if necessary to pick up a sick child, handle emergency situations with elderly parents, or deal with similar situations. Starting in the 1980s, several ridesharing programs offered a guaranteed ride home program that did exactly as the name implies—provided rides either through a company car or by taxis to those in ridesharing programs who needed to leave unexpectedly. This program became a mainstay of many ridesharing (and today, bike) programs and has been successful in reducing the level of anxiety in participating in ridesharing programs. For more information on GRH, see University of South Florida, [2010].

## B. Incentives

Regional and employer-based TDM programs are more successful when incentives (usually monetary) reinforce the desired change in travel behavior. The most common form of TDM incentive increases the cost of SOV use.

### *1. Road Pricing*

For many years, economists who have studied road congestion have argued that marginal pricing of road use would go a long way toward reducing congestion by encouraging travelers to seek alternative modes of travel or to encourage trip-making outside of the peak period. One of the best ways of influencing travel demand is thus by pricing the use of automobiles. [Saleh and Sammer, 2009] Several strategies have been suggested for doing this. (Note that chapter 5 on transportation finance and funding provides more in-depth discussion of most strategies, viewed primarily as the source of funds for investment purposes. Thus, for example, motor fuel taxes are not discussed in this chapter.)

**VMT Fees or Mileage-based User Fees.** Charging a per-mile fee for using the road network is a suggestion that has received increasing attention in recent years. This is very close to the economic concept of a "user fee" in that the amount paid is directly related to how much one uses the road network. Although conceptually appealing, proposals to adopt such a fee structure have run into opposition from those who, on average, travel many miles per year. In addition, some of the strategies for collecting vehicle mileage have been viewed by some as infringing upon personal privacy.

**Tolling.** Toll roads are another variant of road pricing. Tolls have been used for many years to pay for the construction and maintenance of critical road facilities (for example, the New Jersey Turnpike, Pennsylvania Turnpike, and the like). Over the past two decades, with the emergence of public/private financing of new roads, tolls have again become an important part of highway finance. Many metropolitan areas have also implemented managed lanes where a fee is charged that varies by time of day or by the level of congestion in the lane itself (see chapter 10 on transportation system management). Although tolls have been used primarily as a financial strategy, the pricing of road use does influence travel demand on that facility.

**Cordon Pricing.** Cordon pricing charges road users for entry into a defined cordon area. Singapore was one of the first cities in the world to implement such a program in the 1970s. In 2003, Central London introduced cordon pricing (the "London Congestion Charge"), using license number plate recognition technology. Cordon pricing strategies have been proposed in many European cities and in New York City.

**Pay-As-You-Drive (PAYD) Insurance.** Pay-as-you-drive (PAYD) insurance links insurance premiums to vehicle miles of travel. The more one travels, the higher the risk of accidents and thus the higher the premium. Alternatively—and thus the influence on travel demand—the lower the mileage, the smaller the premiums.

### *2. Parking Pricing and Cash Out*

Managing the price and availability of parking is widely recognized as one of the most effective TDM strategies. [Shoup, 2005; Marsden, 2006] Strategies include parking regulations; parking space maximums; priority parking for carpools, vanpools, and short-term parkers; remote parking with shuttle service; and parking pricing. According to a City of Seattle report, "the most effective parking strategies are cost-based or pricing measures that link parking rates more directly to demand or provide financial incentives and/or prime parking spaces to preferred markets such as carpools, vanpools, and short-term parkers." [City of Seattle, 2007] Parking cash-out policies are an example of this.

These are used in some cities where the employer subsidy for the cost of parking is assumed as a monthly subsidy to the driver, and that amount is provided to the company's employees to use for parking, transit passes, or for walking and bicycling. [Shoup and A. P. Association, 2005] Using the subsidy for transit, walking, or bicycling (which would cost must less than the subsidy itself) provides extra dollars to each traveler that can be used at his/her discretion.

Unbundling parking costs from the leasing cost of property is another parking strategy identified in the Seattle report. Unbundling the costs means that parking spaces would be leased or sold separately from the property itself. The evidence suggests that this strategy can reduce parking demand and increase nonSOV mode share. As noted in the report, it was estimated that including the price of parking in an overall lease can increase costs by as much as 25 percent—whether or not the tenant has a car—and can be perceived by the customer as an "invisible" cost. [City of Seattle, 2007]

See chapter 11 for further discussion on parking strategies.

### *3. Commute Benefits*

In keeping with the important role that financial incentives can play in influencing traveler behavior, the federal government changed the tax code in 2001, allowing employers to provide tax-free transit, vanpool, or parking benefits to employees (Section 132 (f) of the tax code). Qualified benefits included:

- *Transit Passes* — Transit passes include any vouchers, passes, fare cards, tokens, or related items that employees can use to pay for transportation on mass transit facilities or on transportation provided by a person in the business of transporting persons for compensation or hire, if such transportation has a seating capacity of at least six adults (not including the driver).
- *Transportation in a Commuter Highway Vehicle* — Better known as a vanpool, the tax code defines a "commuter highway vehicle" as a vehicle that has a seating capacity of at least six adults, not including the driver; at least 80 percent of the vehicle's mileage results from trips between work and employees' homes, and during these trips at least one-half of the vehicle's capacity must be filled (not including the driver).
- *Qualified Parking* — Qualified parking is defined as parking near or at the employers' place of business or parking located near or at a place where employees commute to work by mass transit, commuter highway vehicles, or carpools (for example, parking at a transit station, park-and-ride lot, or vanpool staging area). [ICF Consulting et al., 2003]
- *Qualified Bicycling* — Qualified commuting expenses include the purchase of a bicycle and bicycle improvements, repair, and storage.

As of 2015, employers can subsidize parking at $250 per month, offer $130 per month for transit/vanpool, and reimburse up to $20 per month for regular commuting by bicycle. Commuters can receive both the transit and parking benefits (that is, up to $380 per month). Depending on the individual's income tax bracket, the savings could add up to hundreds of dollars annually for employees.

In some cities, nonprofit organizations have been created to motivate employers and employees to use alternative modes of transportation. For example, in Atlanta, Georgia, a group called Georgia Commute Options provides consulting advice to metropolitan Atlanta employers on implementing telework programs, compressed work weeks, and flextime. Staff members speak at events about commute options and the resources available to employees at the worksite, as well as the monetary incentives to motivate commuters to switch from driving alone. Expert consultants are available to start or expand telework, compressed work week, or flexible work hour programs. Surveys are provided to employers to help them better understand the mobility needs of their employees. Consultants provide assistance to employees in finding carpool or vanpool partners who live and work near each other. Up to five free rides home each year are provided via a guaranteed ride home program for registered employees who use commute alternatives. The organization promotes employers in local media, provides annual awards that spotlight an organization's positive impact on commute options, and provides assistance to employees moving into the region by showcasing the best commute options.

Another commute benefit program, also from Georgia, is called "cash for commuters." [Georgia DOT, 2009] This program provided $3 per day to commuters for each day they used a clean commute (defined as an alternative to single-occupant motor vehicle use), up to $100, over an assigned 90-day period. The program also adopted a systematic

monitoring program that followed the cash for commuters program participants, primarily to determine the extent to which the program provided lasting changes in travel behavior. Table 14-6 shows the results of the surveys for two waves of participants in 2007 and 2008.

Remarkably, 57 percent of the first program participants were still using alternative modes of transportation 18 to 21 months after the cash subsidy ended. Table 14-7 shows the reasons that participants gave for starting the use of alternative modes (note: 2008 was the start of an economic recession and gas prices rose dramatically).

Alternatively, Table 14-8 shows the primary reasons why participants stopped using an alternative mode. Notice the importance of losing a rideshare partner. This has been shown in other studies to be an important factor in the ending of car pools.

**Table 14-6. Short- and Long-Term Impact of Cash for Commuters Program, Atlanta, Georgia**

| Alternative Mode Status | Cash for Commuters (CFC) Wave 1 | | | CFC Wave 2 | 2007 CFC Program Year | 2008 CFC Program Year |
|---|---|---|---|---|---|---|
| | 3–6 Months After Program Completion (n = 302) | 9–12 Months After Program Completion (n = 300) | 18–21 Months After Program Completion (n = 308) | 3–6 Months After Program Completion (n = 300) | 18–24 Months After Program Completion (n = 237) | 3–6 Months After Program Completion (n = 400) |
| Continued use of alt. mode | 71% | 64% | 57% | 74% | 74% | 69% |
| Stopped use of alt. mode | 29% | 36% | 43% | 26% | 26% | 31% |

## C. Land-Use Management

Many of the TDM strategies presented in the previous sections are focused on what can be done in the short term to influence travel behavior. Over the long term, this means influencing land-use and development decisions. Some TDM programs thus consider strategies such as transit-oriented development (TOD) as part of their TDM strategy. Others consider TDM site plan review requirements—for example, reviews of developments of regional impacts (DRIs) or trip reduction ordinances—as part of a regional TDM strategy (see chapter 12 on transit planning for further discussion of TOD strategies).

Table 14-9 shows some of the TDM strategies that can be considered in the land development process. As shown, such strategies aim to, (1) influence trip length, choice of mode, and route, (2) link to regulation, and (3) use travel costs, trip frequency, and time of day/week of trip-making as key focal points. Table 14-10 shows different types of TDM strategies recommended in Arizona as they relate to different land uses.

Many examples exist of how TDM strategies are linked to land-use decisions. For example, a British Columbia, Canada, planning district allows developers a reduced parking requirement in exchange for providing new residents with a transit pass for one year, a car-share vehicle with membership for each unit, and secure underground bicycle storage. [SANDAG, 2012] The city of New York has adopted Active Design Guidelines that encourage active transportation (walking and biking to transit or work) and recreation for neighborhoods, streets, and outdoor spaces. Key strategies include:

- Mixed land uses in city neighborhoods.
- Improved access to transit and transit facilities.
- Improved access to recreational facilities such as parks, plazas, and open spaces.
- Improved access to full-service grocery stores.
- Accessible, pedestrian-friendly streets with high connectivity, traffic calming, landscaping, and public amenities.
- Facilitate biking for transportation and recreation through bicycle networks and infrastructure. [SANDAG, 2012]

In Seattle, Washington, Growing Transit Communities (GTC) is an initiative to encourage housing, jobs, and services to locate close enough to transit to make it a viable option for most people. Ultimately, the goal is to "provide all people the choice to live in affordable, vibrant, healthy, and safe communities where they can conveniently walk or take a train or bus to work, and have good access to services, shopping, and other activities." [PSRC, 2013]

In Loudoun County, Virginia, developer proffers are often part of the development negotiations. Proffers are frequently used for the construction of sidewalks, trails, bike paths, bus stops, and other transit and TDM-supportive elements on development sites in addition to the purchase of transit vehicles.

See chapter 3 on land use and urban design for more detail on land-use strategies and smart growth. For a review of TDM programs in Canada and in many other parts of the world, see Halifax Regional Municipality [2010].

## D. Implementation Programs

Although the TDM strategies presented in the previous sections were described individually, in reality, many are often packaged into a program. At the metropolitan or subarea levels, this means that governments or TDM providers operate at an areawide level.

### *1. Government-Sponsored TDM Programs*

TDM programs sponsored by government agencies often tie their TDM policy to other planning efforts. Thus, for example, Arlington County, Virginia, has incorporated TDM into its master transportation plan policies, as seen in Table 14-11. As shown, TDM is tied into the comprehensive transportation master plans for all new development sites as well as existing public buildings and facilities.

| Table 14-9. Range of TDM Strategies Potentially Addressed in the Land Development Process, Arlington County, Virginia | | |
|---|---|---|
| **Means of Influencing Travel Behavior** | **TDM Strategy (Examples)** | **Supporting Action (Land Development Process)** |
| **Trip Length** | | |
| Reduce Quantity of Vehicle Miles | • Transit-oriented development.<br>• Proximate commuting by allowing employees to relocate job to the branch office nearest their homes. | • Clustering related land uses and providing more direct access (comprehensive plans and land development regulations).<br>• Providing incentives to employers. |
| **Mode** | | |
| Increase Efficiency of System to Carry More People in the Same Number of Vehicles | • Developing land support of alternative modes, such as transit-oriented development.<br>• Limited parking supply.<br>• Offering alternative modes, such as transit, vanpooling, carpooling, bicycling, walking. | • Locating land development to take advantage of existing underutilized transportation services such as transit routes.<br>• Providing on-site amenities, such as lockers, showers, bicycle parking, and preferential carpool parking (land development regulations).<br>• Providing support services such as marketing, ride matching, and guaranteed ride home.<br>• Providing transportation services and physical transportation facilities off-site.<br>• Shared parking. |
| **Route** | | |
| Bypass Congestion | • Transit-oriented development.<br>• Providing route alternatives.<br>• High-occupancy vehicle lanes with queue jumps. | • Providing a grid system, street connectivity, and destinations within easy walking distance (comprehensive plans and land development regulations).<br>• Implementing Advanced Traveler Information Systems. |
| **Regulation** | | |
| Mandate Specific Traffic Management Actions or Outcomes by Local Ordinance | • State growth management provisions.<br>• Concurrency.<br>• Trip reduction ordinances.<br>• Zoning ordinances.<br>• Subdivision ordinances.<br>• Parking ordinances.<br>• High-occupancy vehicle lanes. | • Carried out primarily by land developers, property managers, employers, neighborhood associations. |
| **Cost** | | |
| Establish Incentives and Disincentives | • Parking pricing.<br>• Transit subsidies.<br>• Parking cash-out.<br>• High-occupancy toll lanes.<br>• Commuter tax benefits. | • Tax benefit program assistance. |
| **Frequency** | | |
| Reduce Number of Trips over Given Time Period | • Providing on-site amenities.<br>• Compressed work week.<br>• Telework. | • Providing physical facilities, such as employee cafeteria, fitness center, bank.<br>• Providing technical support to employers. |
| **Time of Day/Day of Week** | | |
| Move Trips to Less Congested Periods or Avoid Vehicle Trip Completely | • Compressed work week.<br>• Staggered work hours.<br>• Telework.<br>• Flex time. | • Unbundling parking from employment site leases.<br>• Providing technical support to employers. |

| Table 14-11. Incorporating TDM into Transportation Master Plan Policies, Arlington County, Virginia |
|---|
| Incorporate comprehensive TDM plans for all site plans and use-permit developments to minimize vehicular trips and maximize the use of other travel options. |
| Incorporate TDM measures with respect to all existing public buildings and facilities, irrespective of redevelopment status. Explore strategies and incentives to achieve TDM measures in existing private buildings. |
| Require regular travel surveys of new development with TDM plans and link to performance measures to enable follow-up actions. Undertake biennial evaluations of the effectiveness of the County's TDM policies and private-sector compliance with TDM commitments, and implement revisions as warranted. |
| Conduct County-wide resident and worker transportation surveys every 3 years, in conjunction with the Virginia and Metropolitan Washington Council of Governments (MWCOG) State of Commute surveys, to monitor travel behavior and system performance, and guide future efforts. |
| Apply TDM programs to non-work travel, as well as commuting, for resident, visitor, and employee trips through informational displays, website, promotional campaigns, and mailings of materials. |
| Coordinate TDM efforts with other jurisdictions and agencies across the region, and actively promote the expansion of the TDM program. |

Source: Arlington County Department of Environmental Services. 2012

In Kitchener, Ontario, Canada, the city adopted a parking control strategy to implement a policy of shifting mode share to non-SOV travel, but subsequently realized that the control of parking was not sufficient to achieve the total shift desired. The city therefore relied on the bicycle master plan and a new TDM plan to augment the expected shifts from the parking program. These plans included the following strategies: [City of Kitchener, 2011]

**Cycling Master Plan**

- Implement the cycling network over time.
- Develop and implement a cycling wayfinding signage strategy.
- Update zoning bylaws to include bicycle parking.
- Develop program to assist property owners in retrofitting for bike parking.
- Develop and communicate design guidelines and review of site plans.
- Integrate cycling infrastructure in every new road and road reconstruction.

- Consider needs of cyclists in transportation projects and services.
- Work with Region to integrate cycling with bus services and rapid transit.
- Provide staff training on cycling needs and infrastructure.
- Partner with Region, School Boards, and Public Health to provide education and cycling programs.
- Develop marketing program to promote cycling.
- Provide support to events that promote cycling.
- Provide support to the Cycling Advisory Committee.

**Transportation Demand Management**

- Subsidize corporate transit passes.
- Carpool matching.
- Guaranteed ride home program.
- Conduct promotional events.
- Develop and distribute promotional materials.
- Pilot telework program.
- Carbon tracking tools.
- Employer stakeholder support.
- TDM-friendly site design.
- Outreach to large employers citywide.
- Outreach to downtown residents and employers.
- Individualized marketing campaigns.

A more aggressive approach to publicly sponsored TDM programs commonly occurs in community policies and regulations for the review of large development projects. In Cambridge, Massachusetts, for example, a combination of TDM incentives to walk, bike, take transit, and rideshare, along with disincentives to drive alone, are required for larger projects and projects that expand parking. These incentives include, but are not limited to:

- Transit subsidy.
- Free shuttle bus.
- Bus shelter.
- Market-rate parking fee charged directly to employees or patrons.
- Daily parking charge available for occasional drivers instead of monthly parking pass.
- Bicycle parking above minimum zoning requirement.
- Shower/locker.
- Financial incentive for walking or biking.
- Emergency ride home.
- Car/vanpool matching.
- Priority/discounted HOV parking.

| Table 14-12. State DOT Participation in TDM Activities | | |
|---|---|---|
| **Activity** | **Percent** | **Number** |
| Bicycling | 95% | 39 |
| Carpooling | 88% | 36 |
| Promotion of transit use | 83% | 34 |
| Walking | 80% | 33 |
| Vanpooling | 80% | 33 |

- Transportation information.
- Hiring of Cambridge residents.
- On-site TDM coordinator.
- Transportation Management Association (TMA) membership.

Government-sponsored TDM programs also occur at the state level. Many state DOTs aggressively pursue strategies for reducing travel demand, and in fact were at the forefront of some TDM strategies such as ridesharing and van pools starting in the 1970s. The impetus for this involvement was primarily an increasing concern about energy conservation and mitigation efforts associated with major freeway reconstruction projects. A survey of state DOTs in 2010 showed that many state DOTs are still involved in a range of TDM strategies (see Table 14-12). "Bicycling" at the top of this list is not surprising given the federal requirement to have a state bicycle coordinator; "parking management" near the bottom of the list is also not surprising, given that most responsibility for parking management rests with local municipalities.

One of the important roles for government-sponsored TDM activities is that they can be part of a much larger mobility strategy. For example, sponsoring an area-wide ridesharing or van pooling program can be an important supporting strategy for a managed lane or high-occupancy vehicle lane program. Supporting flextime programs can help dampen the peak demand on publicly supported and operated transportation facilities. Table 14-13 from ITE's *Traffic Engineering Handbook* shows the many different strategies that can be considered for traffic management and TDM. The TDM strategies are shown in the shaded areas. Again, as noted, it is often the combination of many of these strategies that leads to notable changes in travel behavior.

### *2. Private Company-Sponsored TDM Programs*

The types of TDM strategies considered by private companies at large employment sites are very similar to those described above, and thus will not be repeated. In most cases, however, the program is not as expansive as might be found in a government agency–sponsored TDM initiative. In many metropolitan areas, transportation management organizations (TMOs) or associations (TMAs) have taken the lead in TDM implementation. TMOs are usually nonprofit organizations formed by employers and other major stakeholders in an area to provide (primarily) transportation services to the area. They serve as a focal point for TDM implementation for their members, and in some cases, such as in Atlanta, Georgia, they are combined with community investment districts (CIDs) having a dedicated

| Table 14-13. Traffic Management and TDM Strategies Influencing Choice | |
|---|---|
| **Technique** | **Traveler Choices Affected** |
| *Arterial Management* – The management of traffic signals, dynamic and fixed lane management along surface streets including speed management, pedestrian and bicycle interaction with vehicles, vehicle priority coordination, and coordination with other techniques such as traveler information, electronic payment, or incident management. | R, M, L |
| *Freeway Management* – The management of lanes along freeway and associated ramps interfacing with the arterials including speed management, and coordination with other techniques such as traveler information, electronic payment, or incident management. | R, M, L |
| *Transit Management* – Transit service available to a site, personal security, route and scheduling information, and coordination with traveler information services. | R, M, T, OD |
| *Incident Management* – The detection, response, and recovery from events that are non-recurring, providing information to response personnel and the public, minimizing the impacts on traffic flow, and optimizing the safety of the public and responders. | R, L, T, OD |
| *Emergency Management* – Hazardous material routing and security management, routing, coordination of emergency response service providers, and information dissemination and coordination. | R, M |
| *Road Pricing and Electronic Payment* – Payment services and systems associated with toll facility operations, variable pricing, VMT fees, parking facilities, and transit services. | R, M, L, T, OD |
| *Traveler Information* – Pre-trip, near pre-trip, and en-route information provided to the traveler via roadside, in-vehicle or personal communication devices on the current travel conditions, trip planning services, tourism, special events, and parking information. | R, M, L, T, OD |
| *Roadway Operations and Maintenance* – The management of work zones and route closures through the use of traveler information, lane and speed management systems, and enforcement and response service providers. | R, L, T, OD |
| *Road Weather Management* – Planning for and responding to weather events impacting traffic operations and roadway conditions, information distribution to travelers and response personnel, and operations of facility under inclement conditions. | R, M, L, T, OD |
| *Commercial Vehicle Operations* – Clearance and screening of commercial carriers to optimize flow of goods and services while optimizing safety and efficiency through the use of roadside and in-vehicle technology. | R, L, T |
| *Intermodal Freight* – Integrated operations of freight transported by multiple modes both internationally and domestically. | R, M, L, T, OD |
| *Parking Management* – Parking information, variable pricing, routing to available parking. | M, T, OD |
| *Quality Pedestrian Movement* – Availability of pedestrian facilities that are integrated within the overall transportation network and accommodate or even promote non-motorized travel. | R, M, T, OD |
| *Amenities On-Site* – Bicycle locks, showers, automated teller machines, vanpool or carpool parking, local shuttle service, infrastructure for teleworking. | M, T, OD |
| *Ridematching Program* – Carpools, vanpool programs, preferred parking, transit, or parking subsidies. | R, M, L, T, OD |
| *Alternative Work Schedules* – Four 10-hour days per week, staggered hours, flexible hours. | R, M, L, T, OD |
| *Telecommuting Options* – Work environment that supports employer-employee relationship from remote sites with consideration of accessibility, accountability, and productivity. | R, M, T, OD |
| *Travel Plans* – Worksite, school, or event plans that incorporate travel demand and traffic management strategies to reduce the negative impacts of car use to the site. | M, T, L, OD |
| *On-Site Travel Coordinator* – Staff and services focused on travel services and demand management strategies. | R, M, T, OD |

Key travel choices: Route (R), Mode (M), Location (L), Time (T), or origin/destination (OD)

Shaded areas indicate TDM strategies.

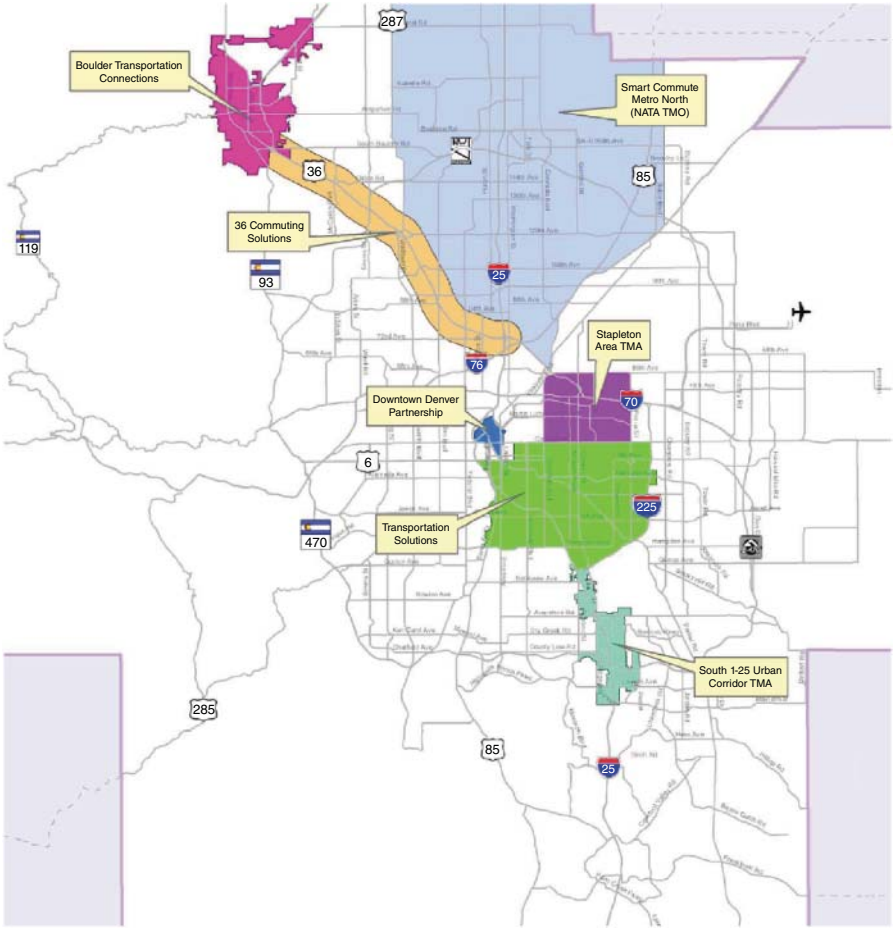
**Figure 14-2. Transportation Management Associations in Denver, Colorado**



Source: DRCOG, undated

funding source (for example, receiving a percentage of the commercial property tax millage rate). The TMO/CID combination is particularly useful for TDM strategy implementation because the financial resources are available to implement many different strategies. Figure 14-2 shows the TMAs that have been formed in Denver, Colorado. They tend to focus around major employment sites, such as the Stapleton Area TMA, or along interstate corridors, such as the 36 Commuting Solutions TMA.

For further information on employer-sponsored TDM programs, see Luten et al. [2004], ICF Consulting and Center for Urban Transportation Research [2005], and Kuzmyak et al. [2010].

### *3. Marketing and Employer Support*

Marketing includes both general efforts to promote the use of alternative modes of transportation and efforts that are more targeted on specific marketing objectives, such as promoting transit passes. As noted in the Denver, Colorado, TDM plan, there are several scales of marketing efforts:

- *Regional campaigns* require participation and collaborative efforts among all TDM service providers and the media in order to be successful and cost-effective.
- *Subarea campaigns* are often led by individual employer associations or local governments with specialized messaging for their localized audience.
- *Site-based marketing* efforts are usually led by individual employers or property managers.

In many public agencies, a TDM coordinator has been hired to provide assistance to employers interested in implementing a TDM program. For example, in Loudoun County, Virginia, a full-time staff member provides outreach and assistance to employers to promote transit and high-occupancy commute modes and encourage and assist employers with employee commute benefits and incentives. Other examples might include conducting SOV trip reduction challenges, sponsoring an employer vanpool, or the providing transit passes or discounts. [DRCOG, 2012]

Beginning in the mid-1990s, many marketing scholars proposed the adoption of marketing theory to bring about social change, called social marketing. Social marketing (sometimes called individualized marketing) was defined as:

> *"The application of commercial marketing technologies to the analysis, planning, execution, and evaluation of programs designed to influence the voluntary behavior of target audiences in order to improve their personal welfare and that of their society."*
>
> *[Andreasson, 1995]*

First applied in transportation applications in Germany, the concept was soon transferred to Australia (where it was called TravelSmart), and first used in the United States in Portland, Oregon, in the early 2000s. The concept is to provide marketing materials and other information concerning mobility options to individuals, households, or targeted neighborhoods. [McGovern, 2005; Cooper, 2006; Taylor, 2007; Thogerson, 2013] In Portland, residents in the targeted neighborhoods received personalized information from city officials about different travel options (walking, cycling, transit, and car sharing) and were made aware of guided walks, rides, and other events. [Dill and Mohr, 2010] Most evaluations of the impacts of such marketing are based on before-and-after surveys, usually one year after the start of the marketing campaign. The results have been impressive. Table 14-14, for example, shows such before-and-after evaluations in different cities in the United States. The reduction in drive-alone trips ranges from 4 percent to 12.8 percent.

One of the limiting factors of the trip reduction results shown in Table 14-14 is that most of the before-and-after studies have occurred after a relatively short period of time. Dill and Mohr [2010] examined the longer-term impacts of such marketing in the Portland neighborhoods that had been targeted by the city. The findings of this study varied by neighborhood. In one neighborhood, there was a notable drop in the share of weekday trips made by single drivers, but much of this change could have been attributed to a significant increase in gas prices between surveys. The increase in walking was not statistically significant, and the share of people who had biked in the previous month saw a significant increase.

In another neighborhood, the share of drive-alone walking, and bicycling daily trips were comparable to the results of the short-term surveys; that is, there was a significant decrease in drive-alone trips and a significant increase in walking and bicycling. As noted by the authors, "The findings indicate that the benefits of the programs may extend beyond one year and up to at least two years. However, the findings from the Southwest target area indicate that the programs may not be as effective in all environments. The programs may be more effective in neighborhoods with a physical environment more conducive to walking, bicycling, and transit." Perhaps most importantly, the authors

**Table 14-14. Estimated Short-Term Trip Reduction from Individualized Marketing Campaigns, United States**

| Location | Date | Results |
|---|---|---|
| Portland, OR—Hillsdale | 2003 | 9% reduction in drive-alone trips |
| Portland, OR—Interstate | 2004 | 9% reduction in drive-alone trips |
| Portland, OR—East | 2005 | 8.6% reduction in drive-alone trips |
| Portland, OR—Northeast | 2006 | 12.8% reduction in drive-alone trips |
| Portland, OR—Southeast | 2007 | 9.4% reduction in drive-alone trips |
| Cleveland, OH | 2005 | 4% reduction in drive-alone trips |
| Durham, NC | 2005 | 7% reduction in drive-alone trips |
| Sacramento, CA | 2005 | 2% reduction in drive-alone trips |
| Bellingham, WA | 2004 | 8% reduction in drive-alone trips |

Source: As reported in Dill and Mohr, 2010

noted that "the research also found that attitudes, norms, and perceptions play a large role in travel decisions. To be most effective, individualized marketing programs need to influence these factors." [Dill and Mohr, 2010]

## IV. POTENTIAL IMPACTS OF TDM STRATEGIES

The impacts of TDM strategies on the number of trips, trip rates, vehicle emissions, and mode split are often difficult to determine, especially when a comprehensive TDM program is being evaluated. In such cases, given that many different strategies are being utilized, it is challenging to distinguish which strategy is contributing what impact to the overall outcome. Accordingly, many of the studies that have assessed the effectiveness of TDM strategies have resorted to qualitative assessments to indicate the level of impact for different types of policy goals. Tables 14-15 and 14-16 are examples of such an assessment.

However, some studies have been conducted to determine the actual impact of TDM actions on a variety of performance measures. Many of these studies were conducted in the 1990s, such as the Transit Cooperative Research Program (TCRP) Report 95 series on traveler response to transportation system changes. This series of reports was one of the first major efforts to understand systematically the potential consequences of implementing TDM strategies. Gopalakrishna et al. [2012] also present a good overview of the likely impacts as identified in other reports. Tables 14-17 to 14-19 provide some of the latest information on the impacts of different TDM strategies. As shown, the tables reinforce many of the factors described in this chapter that influence the choice to change travel behavior, such as the importance of having alternatives available when providing disincentives to automobile use, or the significant impact of pricing on travel behavior. Other useful information on the impacts of TDM strategies can be found in City of Seattle [2007], ICF Consulting and Center for Urban Transportation Research [2005], and Ison and Rye [2008]. See also the *Transportation Demand Management Encyclopedia*, http://www.vtpi.org/tdm/.

## V. DATA, MODEL USE, AND RESULTS

The data used for TDM analysis relates directly to the goals established for the program. Table 14-20, for example, shows the data collection plan for the Arlington County, Virginia, TDM program. In this case, the data collection plan relies on the level of participation of county employees and residents in the different TDM strategies. In addition, the data shown in the table is augmented by more traditional data collection efforts that measure traffic counts, transit ridership, and pedestrian/bicycle counts. These data are used to estimate mode share and levels of service for network performance (see chapter 2 on travel characteristics and data). Much of this data collection is undertaken to establish a baseline for monitoring program effectiveness.

| Table 14-18. Washington State DOT Assessment of TDM Impacts | | |
|---|---|---|
| **Strategy** | **Details** | **Employee Vehicle Trip Reduction Impact** |
| Parking charges[1] | Previously free parking | 20%–30% |
| Information alone[2] | Information on available single-occupant vehicle alternatives | 1.4% |
| Services alone[3] | Ride matching, shuttles, guaranteed ride home | 8.5% |
| Monetary incentives alone[4] | Subsidies for carpool, vanpool, and transit | 8–18% |
| Services plus monetary incentives[5] | For example, transit vouchers and guaranteed ride home | 24.5% |
| Parking cash-out[6] | Cash benefit offered in lieu of accepted free parking | 17% |

Source: As reported in Smart Growth America, 2013

Several methods and approaches have been developed to forecast the impacts of TDM programs. The simplest is an elasticity analysis that relates the change in demand to a change in network characteristic, such as cost of travel or frequency of transit service (see chapter 6 on travel demand). In some applications, elasticity-like ratios are applied to reflect the types of urban design characteristics found in a study area. [Ewing and Cervero, 2010] More complicated approaches utilize components of the four-step travel or activity-based models. For example, trip generation is a component of both modeling approaches, and the number of trips generated could be modified (that is, reduced) by the application of TDM strategies. The reduced number of trips generated would then be carried throughout the rest of the model application.

As reported in Gopalakrishna et al. [2012], four primary models are used for TDM analysis:

- *COMMUTER Model*—The EPA COMMUTER Model used a logit model that provides a pivot point tool to predict mode shift changes resulting from measures that change the time and/or cost of travel for a given mode choice. The employer support program component is based on the professional judgment of the model developers, and is in the form of average modal share changes from supportive activities for those modes.
- *TDM Effectiveness Evaluation Model (TEEM)*—This model is a spreadsheet-based model that uses elasticities of demand to estimate potential changes in vehicle trips.
- *Worksite Trip Reduction Model (WTRM)*—This model, developed by the Florida DOT, includes over 100 TDM measures with the ability to group the measures into comprehensive packages.
- *Trip Reduction Impacts of Mobility Management Strategies (TRIMMS)*—TRIMMS combines the features of both the WTRM and TEEM models. TRIMMS uses a constant elasticity of substitution trip demand functions to evaluate measures that can be expressed in cost or time and benchmarking results for "softer" support and informational measures. TRIMMS was developed for a single worksite or a subarea with a predefined travel market.

Gopalakrishna et al. [2012] suggest that TRIMMS is likely the most appropriate model for application in transportation planning efforts. See also Winters et al. [2007] and Bay Area Air Quality Management District [2012] for additional examples of TDM analysis tools.

## VI. SUMMARY

Travel demand management (TDM) strategies focus on providing travelers with options for trip-making that do not rely on single-occupant vehicles. With rising travel demands in many metropolitan areas, and with limited abilities to expand the transportation network, transportation planners are considering ways of affecting the demand for travel. This might include reducing the overall demand for travel (e.g., trip reduction ordinances), or influencing when and where this demand occurs on the transportation system (e.g., flextime programs). TDM planning includes articulating goals and objectives, identifying performance measures, and analyzing the likely impacts of TDM strategies. In addition, comprehensive TDM programs include a wide variety of strategies that can be implemented by government agencies or by private organizations. TDM analysis relies on a range of data, from traditional data collection methods, such as traffic and ridership counts, to subjective information such as that obtained from surveys.

Travel demand management is a very important part of a state's or metropolitan area's transportation planning process. Successful implementation often requires careful analysis of the travel desires of those in the travel market, as well as strong coordination and collaboration with a diverse set of agencies and organizations. Given the constraints that many metropolitan areas have with respect to adding additional capacity to the region's highway network, TDM serves as one of the major options available to transportation planners to provide the mobility and accessibility upon which the economic health of the region depends.

In addition, Gopalakrishna et al. [2012] identify some key lessons from the literature on the impact of TDM strategies.

*One Size Does Not Fit All*—TDM effectiveness is highly dependent on the application setting, complementary strategies, nature of the travel market segment being targeted, and even the 'vigor' with which TDM is implemented and promoted. Unlike many physical improvements, TDM strategies require some amount of education and outreach. This is all to say that the transferability of TDM strategy effectiveness is highly dependent on local conditions.

*TDM Impacts Are Largely Localized*—TDM effectiveness is most readily measured at a localized level, and this appears to be where the greatest impacts can be found. TDM is applied to specific worksites, developments, employment centers, venues, or activity centers. Localities with well-defined travel markets tend to produce the most readily available and significant impacts.

*Travelers Respond to Their Wallets*—Most evaluation studies point to the overwhelming effectiveness of financial incentives and disincentives to manage demand. At one level, this makes sense as price influences demand in a classic microeconomic analysis.

*Parking Influences Travel Choices*—Parking management is another widely accepted strategy to effectively change travel behavior, especially mode shift, time shift, and location shift . . . . Parking supply management can be effective as well. If parking is tight, meaning that all cars cannot be accommodated if everyone drives alone, commuters will adapt by sharing rides, shifting to transit, or even bicycling or walking if the distance allows.

*Packaging Is Key*—TDM strategies are most effective when packaged into logical, complementary packages to realize synergistic effects. On the other hand, some strategies do not complement one another. One example of an unintended consequence from traditional TDM is flex-time and carpooling. Some employers who implement flex-time strategies as an employee perk or to address congestion at parking entrances have found that this can also serve to discourage ridesharing arrangements, which tend to do better with set work hours.

*TDM Is Not a Solution to All Transportation Problems*—TDM can be highly effective at a relatively low cost (as compared to capacity enhancements) when applied in the right place, at the right time for the right travel market. However, TDM, in and of itself, is not adequate to solve congestion, air quality, energy, and other urban woes.

Although many planning processes have developed stand-alone TDM plans, the really successful TDM programs are those that have integrated TDM policies and strategies into the mainstream transportation planning efforts in the state or region. Tables 14-21 to 14-24 show how this can be done.

| Table 14-21. TDM in Statewide Planning | |
|---|---|
| **Type of Plan** | **How to Integrate TDM/Role of TDM** |
| **Statewide Long-Range Transportation Plans (SLRTP)** | • Adopt a "capacity-last" policy setting limits on the amount of highway capacity a state will provide in certain corridors or subareas.<br>• Set vehicle miles traveled (VMT) growth limits or targets for an absolute reduction in VMT, relative to current levels (in support of energy conservation policies). |
| **Land-Use Policies and Plans** | • Work with regional and local governments to assess the need for TDM to mitigate the impacts of large-scale developments (Developments of Regional Impacts [DRIs]) on adjacent highways.<br>• Initiate "smart growth" programs to provide technical and policy guidance in local land-use and zoning decisions that align a state's ability and intention to provide state system highway capacity with a locality's need and desire for land development or redevelopment. |
| **Tolling, Pricing, and Taxing Policy** | • Implement variably priced high-occupancy toll (HOT) facilities that allocate capacity based on market demand. These pricing strategies help state DOTs better manage demand and achieve better performance of their system.<br>• Note: Some states feel that equity issues and other consequences associated with such pricing measures require additional study and understanding prior to committing to their implementation. |
| **Freight Plans** | • Identify, sign, and map key truck routes on roadway segments and corridors that have the appropriate functional and alignment characteristics (e.g., turning radii, adequate shoulders) to accommodate single- and multiple-unit vehicles in the traffic stream.<br>• Identify locations at which low-cost improvements can improve traffic flow and throughput significantly with little or no additions to capacity. |
| **Operations and Intelligent Transportation System (ITS) Plans** | • Operate variable signing and other infrastructure control mechanisms to permit flexible system management in peak and off-peak periods of demand by, for example, changing hours of operation, permitting one- or two-way operation, changing vehicle occupancy requirements, etc. |
| **Construction and Development Plans** | • Employ variable message signing, flexible signal timing, and public relations campaigns for high-impact capital projects to alert motorists of construction activities, allowing them the opportunity to reroute their trip or to change their travel times.<br>• Form partnerships (highway and transit providers) to increase transit service opportunities, and to mitigate congestion in construction zones. |
| **Multimodal Plans (various state DOT plans that deal with multimodal issues including new infrastructure projects)** | • Operate statewide TDM programs and perform planning that includes the means to integrate TDM activities with other state functions.<br>• Incorporate telecommunication technologies that have the potential to improve the efficiency of the transportation system, relieve congestion, decrease energy consumption, and improve air quality by reducing the need to travel. |

Source: Gopalakrishna et al., 2012

**Table 14-22. TDM in Metropolitan Planning**

| Plan | How to Integrate TDM/Role of TDM |
|---|---|
| **Metropolitan Transportation Plans** | • Large Metropolitan Planning Organizations (MPOs): Make TDM a cornerstone of their long-range plans.<br>• Medium-sized MPOs: Set aside funding for TDM initiatives.<br>• Small MPOs: Explore TDM-based approaches and gauge the interest of member jurisdictions.<br>• Envision that TDM projects can reduce, or at least postpone, the need for capital-intensive projects that increase roadway capacity. |
| **Congestion Management Processes** | • MPOs designated as TMAs can demonstrate, as part of their CMP process, that demand management programs have been given due consideration prior to recommending projects that add general-purpose capacity to a given roadway corridor.<br>• Provide a way to analyze TDM and operational strategies for construction projects in non-attainment zones that result in an increase of SOV travel. Travel demand reduction and operational management strategies should be incorporated into the SOV project or committed to by the State and MPO for implementation.<br>• Define specific TDM and Transportation System Management (TSM) strategies for a region's most congested facilities, and prioritize potential TDM and TSM strategies for each facility. |
| **TDM-Specific Plans** | • Develop TDM-specific strategic plans to help guide (1) long-range pursuit of TDM initiatives or (2) shorter-term operation of in-house TDM operations.<br>• TDM-focused Task Forces/Working Groups—To further refine TDM-related initiatives, organize specific TDM committees, task forces, or advisory boards to help guide the overall planning process related to TDM.<br>• Articulate regional TDM goals by, (1) recommending TDM activities to meet these goals, (2) guiding investments in TDM activities, (3) defining an administrative structure to oversee the regional TDM program, and (4) establishing evaluation measures. |

| Table 14-23. TDM in Corridor Planning | |
|---|---|
| **Plan** | **How to Integrate TDM/Role of TDM** |
| **Major Investment Studies** | • States and regions looking at significant improvements that might add capacity in a given corridor can integrate TDM into planning activities through efforts such as MIS.<br>• Plans include a TDM or Transit/TDM scenario aimed at assessing the effectiveness of mode choice measures in meeting growing travel demands via trip reduction strategies. |
| **New Smart Capacity Project Plans** | • Integrate demand management in a holistic manner, to create "smarter" capacity improvements, such as managed lanes. |
| **Reconstruction Plans** | • Add enhanced travel options (such as vanpooling and special bus service) and incentives to use them (special discounts or financial rewards).<br>• Expand the nature and number of travel options provided through enhanced travel information services.<br>• Implement temporary demand management infrastructure, such as HOV lanes, during construction. |
| **Congestion Management Process (CMP)** | • Address system deficiencies that might be addressed with relatively short-term, low-cost solutions, including TDM.<br>• Convene TDM/CMP Task Force to formulate TDM strategies that can address key bottlenecks on congested facilities. |
| **Integrated Corridor Management Plans** | • Inform travelers of approaching congestion and the availability of parallel transit service with parking availability to instigate in-route mode shift. |
| **HOV/HOT System Plans** | • Plans, such as HOT corridor studies in Virginia, have integrated TDM and transit supportive measures into the plans in order to maximize the efficiency and person throughput of the enhanced facility. |
| **Interregional Corridor Plans** | • Incorporate discussions on interregional travel which crosses state lines and requires special planning activities through special collaboration. |
| **Corridor TDM Program Plans** | • Develop plan for relieving congestion in corridors to make travel easier for commuters.<br>• Identify better travel choices that help to foster responsible economic growth. |

| Table 14-24. TDM in Local Planning | |
|---|---|
| **Plan** | **How to Integrate TDM/Role of TDM** |
| **General Plan Circulation Elements** | • Include recommendations on TDM in the circulation element of the general plan as a strategy to make local arterials operate more efficiently.<br>• Include TDM as a complement to parking management activities.<br>• Include TDM mitigation requirements for new developments when outlining land-use and zoning policies. |
| **Site Development Review Process** | • Codify the role of TDM in the site plan review process via trip reduction ordinances or more informal, negotiated processes. |
| **TMA or TDM Plans** | • Elicit TDM planning under the auspices of localized TDM implementing agents, such as Transportation Management Associations (TMAs) or Transportation Management Districts (TMDs). |
| **Municipal TDM Plans** | • Develop citywide TDM plans to focus the TDM-specific activities of the municipality. May include a description of current city activities, how these fit into state and regional plans and efforts, and a set of specific implementation objectives for the next several years. |
| **Climate Action Plans** | • Develop action plans to address climate change; since the reduction of car use is often a key strategy in climate action plans; TDM often plays a central role.<br>• Include ways that cities and citizenry can operate greener and cleaner (low energy solutions, clean municipal fleets). |
| **Sustainable Urban Transport Plans** | • Make TDM the centerpiece by developing transportation solutions that are grounded in sustainability. Plan places travel choices, environmental mitigation, and social inclusion at the top of the plan's goals and objectives. |
| **Future Applications** | • Elevate the importance of TDM to a stand-alone planning activity in order to coordinate all related activities at the municipal level. Municipal TDM plans should seek to go beyond traditional TDM (often the focus of site-level mitigation strategies) to include the broad spectrum of travel demand influencing efforts, including parking pricing, neighborhood marketing, special event planning, cordon pricing, and preferential treatments on arterials. |

# Statewide Transportation Planning[1]

## I. INTRODUCTION

State departments of transportation (DOTs) are responsible for the planning, design, construction, operation, and maintenance of a state's highway system. In addition, most states also have some responsibility for other modes of transportation, such as transit, ferries, and airports. State DOTs provide a critical state-level context to both analyzing transportation needs and resolving transportation problems at an interstate, state, and regional level. The overall connectivity of the individual modes serving a state is an important characteristic of an effective transportation system, and the state DOT sits in a unique position to evaluate the interrelationships among the state's highway, airport, transit, rail, and harbor systems. This is becoming increasingly important as individual state economies become more dependent on national and international economic transactions (for example, as jobs are moved across borders and goods are traded on a worldwide basis).

With many states now experiencing a trend toward more localized control over transportation planning and project implementation, state-level plans provide a necessary context to regional/county/municipal/local transportation plans. An increasing reliance on local, metropolitan, and public-private transportation financing arrangements to replace decreasing state and federal support also suggests the need for such a context. Promoting a systems perspective on transportation needs and solutions creates a need for more, not less, intergovernmental planning and cooperation at the state and metropolitan levels.

Statewide transportation planning includes a wide range of activities and products. Many states, for example, develop statewide plans for individual modes of transportation, such as statewide rail, pedestrian/bicycle, aviation, and transit plans. Other states produce one statewide multimodal transportation plan that outlines the policies and investment strategies to improve overall transportation system performance. Many states undertake planning efforts on issues that could affect the future effectiveness of the transportation system, including but not limited to statewide freight flows, the aging population, and/or declining revenues dedicated to transportation system investment. Still others spend considerable resources on corridor-level studies that identify infrastructure and operations strategies for improving transportation in these critical components of the transportation system.

The 2025 California Statewide Transportation Plan provides a good description of the role of statewide transportation planning (emphasis added by the editor as underlined text):

> *The California Transportation Plan 2025 (CTP) is a policy plan designed to* guide transportation investments and decisions *at all levels of government and by the private sector . . . .*
>
> *It is* consistent with and supports the findings *of the California Commission on Building for the 21st Century's report Invest for California, Strategic Planning for California's Future Prosperity and Quality of Life, the Speaker of the Assembly's Commission on Regionalism's report . . . .*
>
> *This document* provides a vision *for California's transportation system and explores major trends that will likely influence travel behavior and transportation decisions . . . . it then* provides goals, policies, and strategies *to reach the vision . . . .*
>
> *Most notably, the CTP* reflects the shift in transportation planning and project selection responsibilities *resulting from Senate Bill 45 . . . .*

[1]The original chapter in Volume 3 of this handbook was written by Sandra K. Beaupre, AICP, Director, Planning & Economic Development, Wisconsin Department of Transportation, retired. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

*The CTP is developed in consultation with the State's 44 Regional Transportation Planning Agencies and* provides guidance for developing future regional transportation plans . . . .

*Additionally, the CTP* considers the findings and recommendations of numerous other focused transportation plans *such as the California Aviation System Plan, Interregional Transportation Strategic Plan, Intelligent Transportation System strategic deployment plans, California State Rail Plan, High-Speed Rail Plan, Amtrak's California Passenger Rail System 20-Year Improvement Plan, California Blueprint for Bicycling and Walking, and the Ten-Year State Highway Operation and Protection Plan. [Caltrans, 2006]*

As generalized from this list, statewide transportation planning, (1) provides information to the investment decision-making processes in the state, (2) reflects policy guidance from other state agencies, (3) provides a vision, goals, objectives, and strategies for improving the state's transportation system, (4) responds to legal requirements, (5) acts as guidance for the planning of other agencies in the state, and (6) incorporates the findings of other state planning efforts. Another reason for statewide transportation planning in the United States is that the federal government requires such a process be undertaken on a periodic basis. The federal requirements for such planning and a brief history of the federal role in fostering statewide transportation planning are discussed in the next section.

It is also important to note that statewide transportation planning can examine a wide range of investment options and strategies aimed at making the transportation system more effective and efficient. [Meyer, 1999] In some cases, these strategies are the responsibility of the state DOT (for example, construction or reconstruction of roads on the state highway system), while others, such as smart land-use policies, are the responsibility of other organizations often at different levels of government. This mix of mobility and land-use strategies suggests that not only will state DOT staff need a range of professional expertise, but it is also likely that state transportation planners will devote considerable energy interacting with many different groups and organizations. This interaction will occur not only among the state DOTs and other organizations, but also within the state DOT itself. Thus, for example, those most capable of developing operations strategies will likely be in the DOT traffic operations or traffic engineering groups. To the extent that such strategies are part of a statewide or regional transportation plan, state transportation planners will likely interact closely with these other units within their agency.

State officials are generally most concerned with the facilities and services they manage, that is, those that primarily carry intercity travel. These include many state highways in metropolitan areas that serve intracity and intraregional travel, and in fact often represent the most-used highways in the state. The role each level of government plays in transportation planning and decision making is often defined by the functional classification of the road network (see chapter 2 and chapter 9). State DOTs tend to focus on the interstate highway system and major intercity and interregional routes. Local governments tend to focus on minor arterials, collectors, and local roads. This is not true for some states such as North Carolina where the state DOT has responsibility for most of the roads in the state.

State DOTs also often participate in multistate corridor studies. These studies usually cross the boundaries of many states, following the market boundaries of freight and intercity passenger movement. Many of the earliest multistate studies were conducted in conjunction with international trade routes, specifically the Mexico-United States-Canada trade flows. Today, many corridor studies focus on the interstate movement of people and goods where multistate cooperation will be necessary, not just for international trade. A state DOT's transportation planning program has an important role to play in such studies, ranging from the provision of state-specific data to the consideration of innovative forms of multistate transportation finance.

This chapter next discusses the legislative foundation for statewide transportation planning, with emphasis on the evolution of relevant federal legislation. The following section presents the major steps in statewide transportation planning with examples provided from state planning efforts. This discussion is primarily focused on multimodal transportation planning. The final section then discusses efforts on the part of states to undertake modal planning, that is, planning focused on particular modes, for example, state rail plans, bike and pedestrian plans, and aviation plans.

## II. THE ROLE OF THE FEDERAL GOVERNMENT

The history of statewide transportation planning in the United States is closely linked to federal legislation and to the provision of federal dollars for developing a national road system. It is beyond the scope of this chapter to examine such influence in detail; however, it is important to examine some of the benchmark federal laws that have influenced

statewide transportation planning in the United States because of the legacy they have left to current practice (see chapter 1 for a more detailed description of the role of the federal government in transportation planning).

The 1921 Federal Highway Act was the first federal law that provided funding to the states to construct a "federal-aid highway network." In 1934, Congress authorized states to use 1.5 percent of a state's annual federal highway apportionment for surveys, plans, and engineering and economic analyses, which was the first time federal funds could be used for such purposes at a programmatic level. This level of federally funded planning support became even stronger with the Federal-Aid Highway and Revenue Acts of 1956, which both authorized the construction of an Interstate Highway and Defense System and provided the means of funding this system through a federal gas tax. With the passage of these acts, states initiated a massive highway building program that dominated statewide transportation planning activities until the 1990s. Given the decades of emphasis on interstate highway planning, as well as the development of a state's own road network, it is not surprising that state DOTs have often had difficulty focusing on new multimodal forms of transportation and their associated program directions.

Perhaps the most important piece of legislation to define the post-Interstate statewide transportation planning context was the Intermodal Surface Transportation Efficiency Act (ISTEA) of 1991. Even though many states had been conducting statewide transportation planning for many years, this act for the first time required every state to have a statewide transportation planning process and a statewide transportation plan (STP). ISTEA required that the planning process be multimodal in scope, closely linked to transportation planning conducted in metropolitan areas, and reflect goals other than just transportation system performance. The resulting transportation plan was to address, at a minimum, a 20-year planning horizon. In some cases, states reinforced these federal requirements with their own state laws, mandating the inclusion of bicycle, pedestrian, and transit investments in the planning process. ISTEA also required increased attention to the provision of transportation for traditionally underrepresented groups, with specific attention to the environmental impacts of transportation projects on these groups.

Significantly, ISTEA emphasized the shared nature of the transportation investment decision-making process in metropolitan areas. Metropolitan planning organizations (MPOs) were in a unique regional planning position, often actively involved in both resource and land-use planning at the local level. By expanding the role of MPOs in deciding transportation priorities in their regions, it was anticipated that they would provide a broader context—looking beyond purely transportation impacts—when investment priorities were made. ISTEA also required metropolitan transportation plans to be "fiscally constrained," that is, the plan should include only those projects for which expected investment dollars were available. This requirement was an effort to inject a sense of realism to transportation plans and, in the process, encourage the trade-offs needed to provide a realistic program of multimodal transportation projects and services.

In 1998, Congress passed the Transportation Equity Act for the 21st Century (TEA-21), which reaffirmed the basic framework for state DOT and MPO transportation planning as defined by ISTEA. New funding programs were created to support community preservation, transportation enhancement, and environmental mitigation goals. With respect to planning, TEA-21 consolidated the planning factors that had been previously required for statewide and metropolitan transportation planning into seven major categories:

1) Support overall economic vitality of the United States, the states, and metropolitan areas, especially by enabling global competitiveness, productivity and efficiency.
2) Increase the safety and security of the transportation system for motorized and nonmotorized users.
3) Increase the accessibility and mobility options available to people and for freight.
4) Protect and enhance the environment, promote energy conservation, and improve quality of life.
5) Enhance the integration and connectivity of the transportation system across and between modes throughout the state for people and freight.
6) Promote efficient system management and operation.
7) Emphasize the preservation of the existing transportation system [23USC135(h)(1)].

The Safe, Accountable, Flexible, Efficient Transportation Equity Act—A Legacy for Users (SAFETEA-LU) of 2005, continued the requirement that state DOTs prepare STPs. Each state was required to, (1) carry out a continuing,

comprehensive, and intermodal statewide planning process, including the development of an STP having at least a 20-year planning horizon, and (2) develop a statewide transportation improvement program (STIP). The STIP was a list of all significant statewide projects to be constructed or implemented using federal dollars over a four-year period. Any MPO-prepared list of projects for its region in the state had to be incorporated into the STIP without modification. SAFETEA-LU further required that the statewide planning process be coordinated with the MPO planning process and include consultation with affected local government officials involved in transportation planning in non-metropolitan areas of the state. Although the MPO transportation plan was to be fiscally constrained, the STP did not have the same stipulation.

Other significant provisions in SAFETEA-LU relating to statewide transportation planning included:

1) State long-range plans had to discuss "potential environmental activities and potential areas to carry out these activities, including activities that may have the greatest potential to restore and maintain the environmental functions affected by the plan." This discussion was to be developed in consultation with federal, state, tribal, wildlife, land management, and regulatory agencies. This consultation involved comparing STPs with appropriate state and tribal conservation plans, maps, and inventories of natural or historic resources.

2) State long-range plans had to be developed in consultation with MPOs, affected nonmetropolitan government officials, and tribal governments. The development of an annual list of transportation projects "shall be a cooperative effort" between the state, the appropriate transit operator, and the MPO.

3) State DOTs were required to enhance their public participation processes by publishing plans and improvement programs, holding public meetings at convenient and accessible times and locations, and employing enhanced visualization techniques when describing plans and programs.

4) States were required to develop a strategic highway safety plan that outlined the road safety issues facing the state. Although this responsibility did not fall to statewide transportation planners, it was clear that the safety plan and the STP were to be consistent and linked together (see chapter 23 on safety planning).

One of the most significant changes in the new law was the requirement that state-level planning promote consistency between transportation projects and locally planned land-use and development activities. SAFETEA-LU modified the fourth TEA-21 planning factor (see above) in the following way:

> *"… protect and enhance the environment, promote energy conservation, improve the quality of life and promote consistency between transportation improvements and state and local planned growth and economic development patterns."*

This provision was consistent with a growing focus of many state-level plans on the relationship between the state long-range planning and local land-use plans. Some states already had laws that required them to conduct their planning processes in a manner consistent with local planning; in other states there was a more direct and explicit requirement for how they interrelated with local plans.

The Moving Ahead for Progress in the 21st Century (MAP-21) law, passed in 2012, introduced a significant new component into statewide and metropolitan transportation planning…. the use of performance measures to monitor progress toward achieving plan goals. MAP-21 incorporated performance goals, measures, and targets into the process of identifying needed transportation improvements and in the project selection process. The long-range plan was to describe the performance measures and targets used in assessing system performance and progress in achieving the performance targets. The law established the following national performance goals for federally supported highway programs:

- *Safety:* Achieve a significant reduction in traffic fatalities and serious injuries on all public roads.
- *Infrastructure Condition:* Maintain the highway infrastructure asset system in a state of good repair.
- *Congestion Reduction:* Achieve a significant reduction in congestion on the National Highway System (NHS).
- *System Reliability:* Improve the efficiency of the surface transportation system.

- *Freight Movement and Economic Vitality:* Improve the national freight network, strengthen the ability of rural communities to access national and international trade markets, and support regional economic development.
- *Environmental Sustainability:* Enhance the performance of the transportation system while protecting and enhancing the natural environment.
- *Reduced Project Delivery Delays:* Reduce project costs, promote jobs and the economy, and expedite the movement of people and goods by accelerating project completion through eliminating delays in the project development and delivery process, including reducing regulatory burdens and improving agencies' work practices.

States were responsible for setting performance targets in support of these goals, with the statewide plans describing how program and project selection would help achieve the targets. In addition, MAP-21 required that a national freight network be identified, with incentives for priority projects that advanced the freight performance goal. Although not required, states were encouraged to develop their own freight plan and establish a freight advisory committee, if one already did not exist. The law also stipulated that projects identified in a FHWA-approved freight plan would be eligible for supplemental federal funding. The major impact of MAP-21 on statewide transportation planning was that most state transportation plans were now to focus on the performance goals established by the law, with attention given to how the state was achieving these performance targets.

The Fixing America's Surface Transportation (FAST) Act, passed in 2015, continued the planning requirements established in MAP-21. In addition, it stipulated the following requirements:

- Required the state to submit a report describing the actions to be taken to achieve performance targets if a state DOT did not achieve or make significant progress toward achieving the targets in any performance measurement area after one reporting cycle.
- Expanded the scope of the planning process to include addressing resiliency and reliability as well as enhancing travel and tourism of the transportation system.
- Required state DOTs to incorporate the performance measures of a transit agency not represented by a metropolitan planning organization (MPO) into its long-range transportation plan regardless if it is in an urban or rural area.
- Added language that the long-range transportation plan shall consider public ports and freight shippers.
- Encourages consideration of intermodal facilities that support intercity buses as part of the metropolitan and statewide planning process.

Perhaps most importantly, the act reinforced the requirement for a state DOT to include a description of adopted performance measures and the system performance report in a state's long-range transportation plan. This step is an important component of what chapter 1 called performance-based planning.

## III. STATEWIDE TRANSPORTATION PLANNING

Statewide transportation planning identifies the most cost-effective and appropriate transportation strategies to achieve a desired level of system performance for a state's transportation system. The generic transportation planning process described in chapter 1 can be used to illustrate how statewide transportation planning occurs in most states.

Most statewide planning processes begin with a basic identification of the nature of the current system (past trends and current system condition), followed by an analysis of how well that system addresses existing and future travel needs. The next step involves a description of future issues usually identified through public outreach efforts and data analysis, followed by the identification of potential solutions. Alternatives are evaluated against predetermined criteria to identify the most cost-effective investment strategy for the state. Finally, a capital program is developed. This planning process is continuous, that is, plans are developed, financed, and implemented, then evaluated and reconsidered again in the next planning cycle, all done in a publicly transparent manner.

Although the planning process varies by state according to tradition, state law, and the capabilities of the state DOT, several aspects of statewide planning are common from one state to another. The basic steps in statewide transportation

planning processes are not that different from any other public planning process. The biggest difference is primarily the scope of a state planning effort, either encompassing a large geographic area such as an intercity corridor or the entire state itself. Following the planning framework presented in chapter 1, the basic steps in a statewide transportation planning process include:

1) Define the focus and boundaries of the planning effort.
2) Identify issues and opportunities.
3) Define vision and goals.
4) Identify and using system performance measures.
5) Collect and analyzing system performance and condition data, leading to a needs assessment.
6) Analyze individual transportation system alternatives for targeted performance characteristics.
7) Evaluate transportation system alternatives to compare relative benefits and costs.
8) Prioritize programs and projects.
9) Monitor system and program performance.

Each of these steps will be described in more detail in the following sections. In some cases, other chapters in this handbook describe in greater detail the approaches that could be used to accomplish a particular task. These chapters are referenced in the text; the material is not repeated here.

It is important to note that statewide transportation planning is conducted in a very "open" way. Over time, state DOTs have moved toward more ongoing public engagement, and as recent federal laws have emphasized, more attention is being given to public input and potential impacts on underrepresented groups. This input also includes interaction with the state's MPOs, as well as with state natural resource agencies, in particular, the agency responsible for the state air quality implementation plan. Air quality management plans are required under federal law for those areas that have not attained national ambient air quality standards. These plans can have considerable influence on the development of future transportation facilities and services. Although primarily affecting projects in air quality nonattainment areas (as defined by the U.S. Environmental Protection Agency), the Clean Air Act Amendments of 1990 required that transportation plans, programs, and projects must conform with air quality implementation plans developed by state environmental agencies. Many states now have DOT representation on interagency conformity workgroups and MPO/state resource planning groups that direct air quality policy.

## A. Defining the Study Focus and Boundary

The purpose of the planning process, its focus, and study boundaries need to be defined early in the process. For example, will a planning effort address all transportation systems and modes in the study area, or does it focus simply on those systems that are the responsibility of the state DOT? Will it provide specific project recommendations as an outcome, or is it intended simply to establish overall policy directions? In some cases, state law is very specific about the responsibilities of the state DOT, as well as the products and timing of the statewide transportation planning process. In addition, federal law defines the general characteristics of a state's transportation planning process, and often influences which major state systems receive priority given the availability of federal funds.

Statewide transportation plans can take many forms. This is not surprising given the changing context of statewide transportation planning and the different perspectives that states have on what an STP should accomplish. Some examples include:

- *Policy Plans*—These plans usually include broad goal statements to establish the general direction of the DOT, but often they do not include specific implementation activities, maps, or projects. Policy plans are considered flexible enough to direct departmental activities as well as promote more general societal goals and objectives. However, state-level policy plans are often criticized for not identifying specific actions (and thus the funding that follows such actions) or not providing specific timeframes for achieving planning goals.

- *Strategic Plans*—Sometimes called business plans, these plans address the internal operations of the state agency. Such plans are often prepared after an overall policy plan has been developed and tend to direct agency resources toward shorter-term, targeted priorities.
- *Investment or Financial Plans*—These plans can be tailored to fit the agency's budget process or can be used to detail longer-term, project-specific expenditure plans. They are often tied to specific program performance goals.
- *Medium-Range Transportation Project Plans*—These programs provide a 6- to 10-year project programming schedule, where the first 3 to 4 years include the projects that the DOT will actually design and construct, and the latter years provide those projects that will likely move into construction during the planning period. The project descriptions for these latter projects are often fairly general with no more than a project location, stage of completion, and total budget allocation.
- *Systemwide or Corridor-Level Plans*—System-level plans are usually based on a statewide or regional perspective. Corridor plans are defined by major transportation routes and often include a "beyond the pavement" view of such issues as access, intensity of development, and land uses.

In general, each of these plans can be used by the state DOT or other state-level planning organizations to develop and communicate the strategic direction for the agency. They can also serve as a vehicle to illustrate and justify future needs; guide program and project development activities in the agency; communicate with political leaders and the general public about transportation issues; and monitor overall system and investment performance goals.

The following examples illustrate different approaches for defining the transportation plan and planning process and the study boundaries established for state DOT responsibility.

***1. California***

California statutes require the California DOT to develop a California Transportation Plan (CTP) that includes:

a) Policy statements describing the state's transportation policies and system performance objectives.

b) Strategic elements that incorporate broad system concepts and strategies synthesized from adopted regional plans . . . . that is, the state plan will not be project-specific.

c) Economic forecasts and recommendations to achieve concepts, strategies, and performance objectives.

California law also directs designated regional transportation agencies to adopt 20-year regional transportation plans. Under the guidance of the California Transportation Commission, these regional plans, the CTP, and all other transportation plans developed by local units of government must be consistent. The Commission cannot program projects that are inconsistent with these adopted regional transportation plans. In addition to these requirements, California state law also directs a large portion of its state funding to the regions for investment decisions.

***2. Indiana***

The Indiana Department of Transportation (INDOT) through the 2030 Long-Range Plan defines the state's transportation system by the level of system management responsibility—state, MPO, and small urban and rural areas. The state system focuses on those routes that move people and goods between the major activity centers considered important to the state's economy.

The Indiana long-range plan is based on a corridor classification system that includes: (1) statewide mobility corridors, which are defined as corridors that provide "safe, free-flowing, high-speed corridors" serving major metropolitan areas and surrounding states, (2) regional corridors, designed to provide mobility within regions of the state, and (3) local access corridors, which include the remainder of the highway system.

Highway corridors are evaluated on the basis of the following elements:

- Accessibility measures between major urban areas.
- Designation as a principal arterial on the Federal Highway Administration (FHWA) functional classification system.

- Designation as part of the National Highway System.
- High volumes of commercial traffic and commodity movements.
- Concentrations of high passenger vehicle traffic volumes.

The Indiana statewide planning emphasizes the networks that serve major metropolitan areas, have higher design standards and higher speeds, serve longer-distance trips, exhibit large through-traffic volumes (both commercial and commuter), and do not allow nonmotorized vehicle access. The Indiana state highway system focuses on directly connecting metropolitan areas with a population of 25,000 or more.

### *3. Minnesota*

Minnesota is another example of how states define their responsibilities for a state's transportation system. As noted in the plan, the transportation policy framework "focuses on multimodal solutions that ensure a high return-on-investment while considering the context of place, and how land use and transportation systems should be better integrated." [MnDOT, 2012] The plan is organized by six major questions:

- Where are we going?
- Where are we now?
- What is directing this plan?
- How will we guide ourselves moving forward?
- What comes next for MnDOT?
- How do I get more information?

The plan adopts a multimodal perspective on the state's transportation system, even though the state DOT only has responsibility for a portion of it. Table 15-1 shows the extent of the state's transportation system.

Figure 15-1 shows the key elements of the state's transportation system, that is, those elements that the state DOT focuses on. The state's role in modal areas where it does not have primary responsibility is to support and encourage that mode's use. For example, MnDOT's role in rail and waterways includes developing plans that guide funding allocation, administer highway/railroad construction projects, and develop freight-related data sources. In aviation, the state serves as a promoter of both general and commercial aviation through technical and financial assistance, educational activities, and statewide planning and research. Note in the figure that the DOT has designated a system of interregional and regional travel corridors as part of the state highway network. These corridors were designed to connect key trade centers in the state based on population and business density, and receive priority investment consideration from the DOT.

The Minnesota statewide transportation plan also illustrates another characteristic of statewide transportation planning as it relates to study boundaries. The plan relies on and references other DOT plans that have focused on more specific modal issues. For example, the plan is linked to the state aviation system plan, statewide bicycle system plan, statewide freight system plan, 20-year state highway investment plan, statewide ports and waterways plan, statewide pedestrian system plan, state rail plan, and the greater Minnesota transit investment plan. In some ways, the statewide plan serves as a means of integrating the key concepts and recommendations from each of these plans. [MnDOT, 2015]

### *4. Virginia*

The Virginia Department of Transportation (VDOT) uses Corridors of Statewide Significance (CoSS) as a way of identifying potential multimodal transportation strategies and to guide local land-use planning and transportation investments. The characteristics of a CoSS include:

- *Multimodal*—Must involve multiple modes of travel or must be an extended freight corridor.
- *Connectivity*—Must connect regions, states, and/or major activity centers.
- *High Volume*—Must involve a high volume of travel.
- *Function*—Must provide a unique statewide function and/or address statewide goals. [VDOT, 2015a]

| Table 15-1. Minnesota's Transportation System, 2012 | |
|---|---|
| **Streets, Roads, and Highways** | **141,482 miles** |
| State trunk highways | 11,896 miles |
| County state, aid highways | 30,548 miles |
| Other county roads | 14,348 miles |
| Municipal state-aid streets | 3,321 miles |
| Other city streets | 18,837 miles |
| Township roads | 58,101 miles |
| Other public roads | 4,431 miles |
| **Bicycles and Trails** | |
| Designated trails | More than 3,800 miles including 22 state trails. |
| Bike sharing | 1,328 bicycles and 146 stations (as of July 2012). |
| **Bus and Light Rail Transit** | |
| Twin Cities area (7 counties) | 218 bus routes and one light rail transit corridor with another under construction. |
| Greater Minnesota | 70 of 80 (non-Twin Cities metro) counties with countywide transit service, 8 counties with municipal service only, 2 counties with no service. |
| Intercity bus | 87 destinations served in the state as well as every metropolitan area in the Midwest. |
| **Rail** | |
| Freight | 4,458 track miles (19 railroad companies). |
| Commuter | Northstar commuter rail line. |
| **Air** | |
| Passenger and Cargo | 135 airports, 8 with airline service. |
| **Waterways** | |
| Great Lakes | 4 ports on Lake Superior. |
| Rivers | 5 ports on 222 miles of the Mississippi River system (including the Minnesota and St. Croix rivers). |
| **Miscellaneous** | |
| Carsharing | 2 systems (HOURCAR and Zipcar). |

Source: MnDOT, 2012

Unique statewide corridor functions include: (1) evacuation routes or providing critical network redundancy, (2) security and national defense routes (military access, Strategic Highway Network (STRAHNET), Strategic Rail Corridor Network (STRACNET)), (3) tourism routes, (4) truck routes, (5) state bicycle routes or interregional trails, and (6) support for economic development. Figure 15-2 shows Virginia's corridors of statewide significance.

As noted in the guidance for identifying these corridors, "the perspective of the state may differ from that of regional planning bodies in that the state is concerned with transportation throughout the Commonwealth, whereas MPOs and regional planning commissions appropriately focus on more regional interests. The state must also ensure that regions are connected and that interstate needs are addressed." As further noted, the intent of the statewide multimodal network was not to replace regional plans, but to "connect the dots" among regional and modal agency plans. Further explanation of Virginia DOT's corridor-based planning process can be found at: http://vtrans.org/vtrans_multimodal_transportation_plan_2025_needs_assessment.asp.

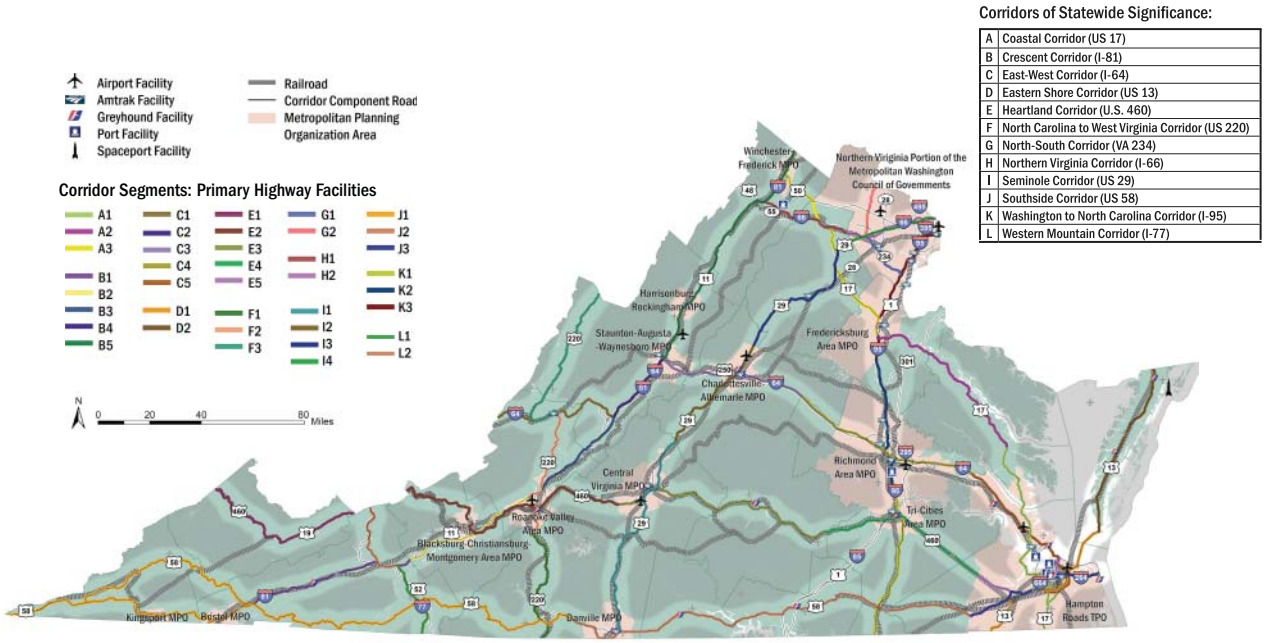
### *5. Michigan*

In its 2030 STP, the Michigan Department of Transportation (MDOT) examined travel flows in the state and how these flows related to and affected economic development. Major corridors were identified that connected the state's most important economic centers and that served the majority of the state's population. Figure 15-3 shows how MDOT used a geographic information system (GIS) to illustrate how much of the state's population was within 20 miles, centered on the state-identified corridors. Thirty-five percent of the state highway miles are located in the corridors, carrying 72 percent of annual vehicle miles and 96 percent of the truck ton-miles on the state highway system. Ninety-seven percent of the rail ton-miles, 94 percent of the state's commercial airports, and 95 percent of the state's intercity bus terminals are also in the corridors. [Michigan DOT, 2012a]

**Figure 15-1. Key Elements of Minnesota's Transportation System**

Source: MnDOT, 2012

**Figure 15-2. Virginia's Corridors of Statewide Significance**

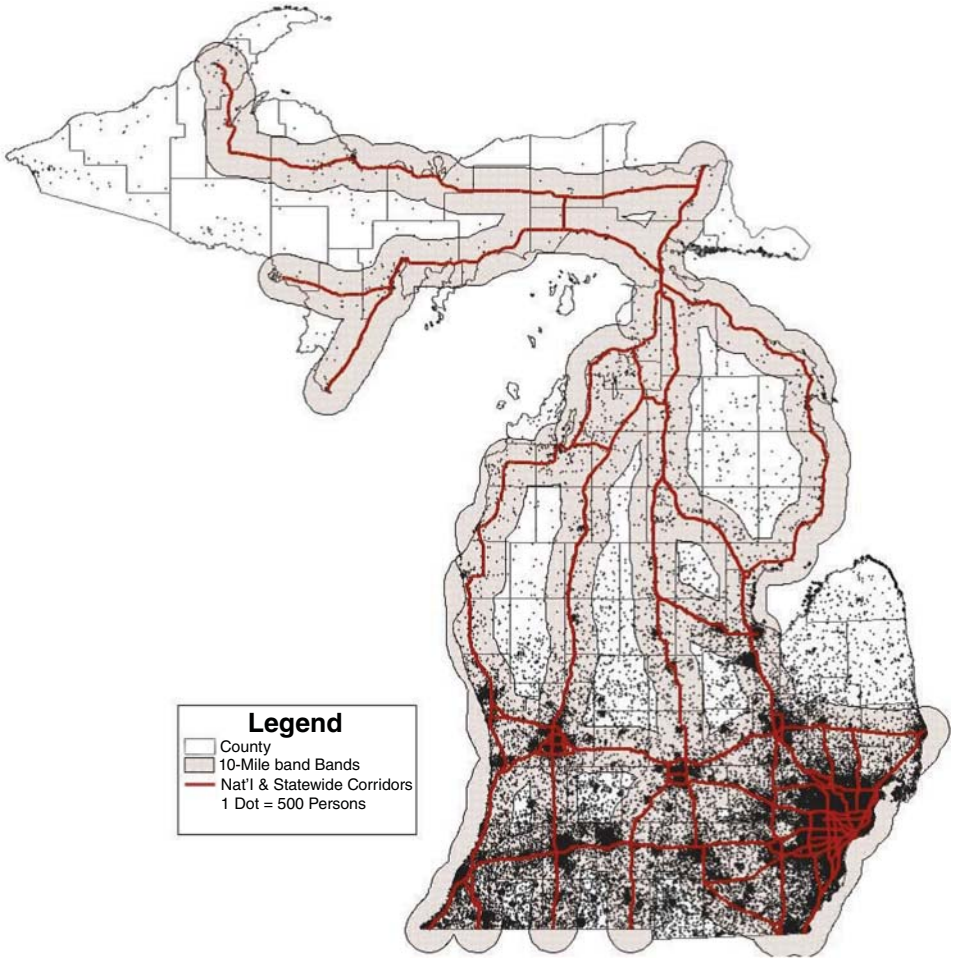


Corridors of Statewide Significance:

| | |
|---|---|
| A | Coastal Corridor (US 17) |
| B | Crescent Corridor (I-81) |
| C | East-West Corridor (I-64) |
| D | Eastern Shore Corridor (US 13) |
| E | Heartland Corridor (U.S. 460) |
| F | North Carolina to West Virginia Corridor (US 220) |
| G | North-South Corridor (VA 234) |
| H | Northern Virginia Corridor (I-66) |
| I | Seminole Corridor (US 29) |
| J | Southside Corridor (US 58) |
| K | Washington to North Carolina Corridor (I-95) |
| L | Western Mountain Corridor (I-77) |

Source: Virginia DOT, 2015a

**Figure 15-3. Corridors of Highest Significance (COHS) and Population Location, Michigan**



Source: Michigan DOT, 2012a

The 19 corridors have a major impact on supporting both the state's population and economy. Approximately 93 percent of Michigan's population and approximately 99 percent of Michigan's employment base resides within the geographic area centered on the corridors.

The update to the plan, the 2035 statewide plan, reaffirmed these corridors as a major focus of statewide transportation planning. As noted in the update:

- Both the rail track miles and the rail ton-miles increased their percent usage of national/international and statewide corridors by 1 percent. Rail value by mile held steady at 97 percent.
- The percent of usage of national/international and statewide inclusive airports increased 7 percent.
- Overall, water cargo tonnage decreased almost 25 percent from 2003 to 2009. The percentage of the overall statewide total, within the COHS, increased from 85 to 94 percent.
- The economic recession of 2008–2009 had a negative impact on both cross-border passenger car traffic (commuters and recreational trips) and commercial (truck) traffic. However, since January of 2009, combined passenger car traffic at Michigan's border crossings has been increasing at the rate of 0.66% per month, or 7.89% per year, and combined truck traffic has been increasing at the rate of 0.70% per month (8.5% per year) while the value of trade carried by those trucks has been increasing at an average rate of 1.5% per month (18% per year).

- Overall, U.S./Canada trade moved by truck was up $16 billion (5 percent) from 2006 to 2011. Current forecasts indicate a continued slow improvement in passenger car traffic over the next 20 years. Commercial traffic over the next 20 years is expected to reach volumes double that observed in the pre-recession period. [Michigan DOT, 2012b]

The Michigan example aptly illustrates the concept of targeting investment priorities on key elements of the transportation system, and of monitoring what happens over time.

## B. Identifying Transportation Issues and Opportunities

Most states begin a transportation planning process with a "scan" of the key issues facing the state's transportation system, sometimes even before the vision and goals are defined. Key stakeholder and public input is then used to redefine the vision and goals of the planning process. In fact, many states continue to redefine their vision and goal statements throughout the planning process. This process can be a key framing element for the overall planning process, and should be tied closely to the early engagement of public and private stakeholders.

### *1. Florida*

Florida is one of the few states that has adopted a very long-range perspective for its statewide transportation plan. The 2060 Florida Transportation Plan (FTP) was the first statewide transportation plan for Florida to cover a 50-year period. [FDOT, 2010] Per the plan, "This longer horizon enables all transportation partners to work toward a future transportation vision addressing both today's challenges and tomorrow's opportunities." The 50-year time horizon also focuses attention on some of the key issues that will influence the transportation system of the future. For example, some of the issues identified in the FTP included:

*Diverse Population:* Florida is leading the nation in two important demographic changes—the aging and increasing diversity of the population. By 2030, 26 percent of Floridians will be over the age of 65, compared with about 20 percent nationally. The number of students, visitors, disabled persons, and others with specific mobility needs will continue to grow.

*Innovation Economy:* Florida's economy is increasingly driven by innovation. While traditional strengths in agriculture and tourism remain, Florida's future economy will rely on emerging industries such as aerospace, clean energy, life sciences, and creative industries. These industries tend to develop in clusters around vibrant communities, universities, and research laboratories, where they can gain access to skilled workers.

*Global Markets:* Market reach for Florida businesses is shifting from local and regional to global. Global trade patterns will shift following the widening of the Panama Canal and anticipated increases in trade from Asia, Latin America, and other markets. This could position Florida as a crossroads for both north-south and east-west trade. Florida's ability to connect to global markets and tap into this trade flow will be a critical driver of future prosperity, yet Florida must compete with other states aggressively pursuing this opportunity.

*Emerging Megaregions:* The key unit of economic competition is shifting from metropolitan areas to megaregion networks of urban and rural areas connected through economic relationships and infrastructure. The Florida peninsula may be one of about 10 megaregions driving U.S. growth in the global economy. The connections between Miami and Jacksonville or Orlando and Tampa, for example, may become more important than differences between them. Northwest Florida could become part of this megaregion or may become more integrated with the western Gulf Coast from Alabama to Texas.

*Shifting Development Patterns:* The sprawling development pattern of the past 50 years may give way to higher density development focused in urban centers. Florida's diverse population desires a range of choices for where to live—vibrant cities, quiet suburbs, small towns, and rural places—but with distinctive characteristics and easy access from homes to jobs, schools, shopping, and services.

*Higher-Density, Mixed-Use Urban Development and Rural Employment Centers:* These land-use patterns connected with multimodal transportation corridors and separated by open spaces will be a key emphasis of development over the next 50 years.

*Technological Revolution:* Rapidly changing technologies will reshape the way Floridians live, work, and travel. Communication technologies will reduce the need for some trips to work, meetings, shopping, and schools—but at the same time, they may increase the number of small packages moving throughout the state on a daily basis.

*New Vehicle Technologies:* Small electric vehicles, smart cars, trucks, new large aircraft, high-speed railways, enhanced transit systems, mega-containerships, and next generation launch vehicles and spacecraft will reshape existing travel options and provide new options for moving people and freight.

*Environmental Stewardship:* Florida's environment will be under increasing pressure if urban development fragments, encroaches on, or replaces important natural lands, agricultural lands, and open spaces. In addition, population growth will strain water supplies, and growth in travel and industrial development will impact air and water quality. A changing global climate may impact Florida more than any other state due to its many miles of coastline and its low elevation. How Florida responds to these environmental challenges will be a key determinant of its future quality of life and economic competitiveness.

*Changing Role of the Public and Private Sectors:* Florida's public agencies will redefine their roles to meet the challenges of the next 50 years, while also trying to meet public requirements and expectations with increasingly constrained revenue sources. The private sector will continue to expand its role as a leader or partner with the public sector in accomplishing specific priorities. [FDOT, 2010]

#### *2. Hawaii*

One of the common approaches for identifying key trends and issues affecting a state transportation system is to develop issue papers that examine how key aspects of the future will influence future transportation system performance. Hawaii DOT's update of its statewide transportation plan is an example of this approach. As part of the update, 10 emerging issue papers were developed on the following topics:

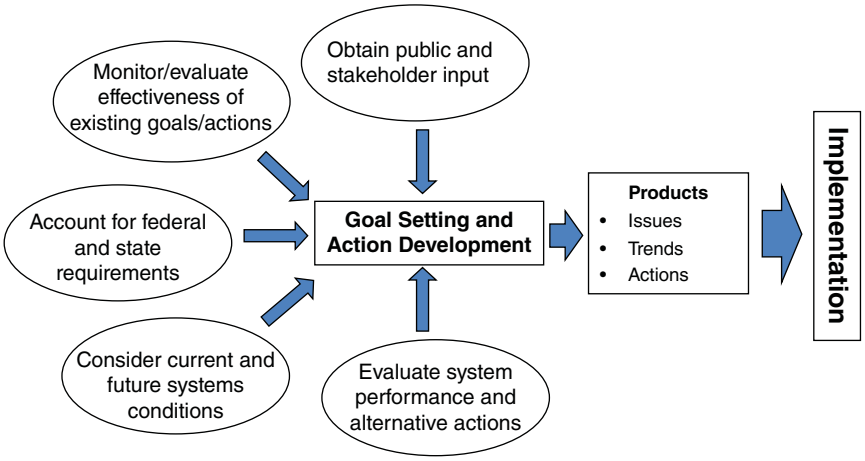
- Federal planning factors
- Climate change and sea level rise
- Aging population and transportation
- Fuel and energy scenarios for Hawaii
- Land-use planning
- Integration of planning and design: context sensitive solutions, Complete Streets, smart growth, and transit-oriented development
- Transportation security
- System preservation and asset management
- Financial scenarios
- Environmental coordination: Linking planning and environmental review

## C. Formulating a Vision, Goals, and Objectives

Vision, goals, and objectives can be developed from a variety of sources. For example, Figure 15-4 shows the sources of information used by the Montana DOT in defining the goals and objectives (called actions) for its transportation plan update. As shown, the process of setting goals and developing actions relies on system performance and alternative actions, current and future system conditions, the relationship to federal and state program requirements, the effectiveness of existing goals and actions, and input from the public and other stakeholders.

Many DOT mission and vision statements are defined in state statute. An example is the Wisconsin Department of Transportation, whose statutory mission is to manage state and federal aid for "planning, promotion and protection activities in highways, motor vehicles, traffic enforcement, aeronautics, railroads, waterways, specialized transportation services, mass transit systems, and any other transportation mode." [Wisconsin Statutes] This very broad mission was

**Figure 15-4. Information Sources for Goals and Actions, Montana DOT**



Source: Montana DOT, 2008

created in 1973, yet each state plan update has reexamined and retained the vision for the state's transportation program. Most states reevaluate and redefine vision statements each time a plan is updated to reflect the planning challenges and opportunities for the time horizon addressed by the planning study.

Transportation planning goals and objectives do not address just transportation system performance but also reflect the values and objectives of society at large, including the overall quality of life in the state, economic development, land-use planning, and social justice goals. As a result of these broader social goals, transportation planners at the state level often redesign their outreach to target groups representing interests that often do not participate in the plan development process. The increasing use of the Internet and websites is not only the result of enhanced technology, but also addresses the need to reach a growing transportation stakeholder base. However, state DOT outreach efforts and public engagement programs need to recognize that not all population groups have access to the Internet and websites.

The following examples illustrate the type of vision statement and goals found in statewide transportation planning today:

### *1. Minnesota*

The Minnesota 2012 STP developed a vision statement that was the result of extensive public outreach as well as an examination of the factors and trends likely to affect future system performance. The vision statement reads:

> ***Minnesota's Multimodal Transportation System Maximizes the Health of People, the Environment, and Our Economy***
>
> The system:
>
> - Connects Minnesota's primary assets—the people, natural resources, and businesses within the state—to each other and to markets and resources outside the state and country.
> - Provides safe, convenient, efficient, and effective movement of people and goods.
> - Is flexible and nimble enough to adapt to changes in society, technology, the environment, and the economy.
>
> ***Quality of Life***
>
> The system:
>
> - Recognizes and respects the importance, significance and context of place—not just as destinations, but also where people live, work, learn, play, and access services.
> - Is accessible regardless of socioeconomic status or individual ability.

***Environmental Health***

The system:

- Is designed in such a way that it enhances the community around it and is compatible with natural systems.
- Minimizes resource use and pollution.

***Economic Competitiveness***

The system:

- Enhances and supports Minnesota's role in a globally competitive economy as well as the international significance and connections of Minnesota's trade centers.
- Attracts human and financial capital to the state. [MnDOT, 2012]

The plan identified specific strategies to realize the vision.

### *2. Hawaii*

The Hawaii DOT identified eight goals that formed the overall direction for the plan.

*Goal 1: Mobility and Accessibility*—Create and manage integrated multimodal transportation systems that provide mobility and accessibility for people and goods.

*Goal 2: Safety*—Enhance the safety of the air, land, and water transportation systems.

*Goal 3: Security*—Ensure the secure operation and use of the air, land, and water transportation systems.

*Goal 4: Environment*—Protect Hawaii's unique environment and quality of life and mitigate any negative impacts.

*Goal 5: Economy*—Ensure that the air, land, and water transportation facility systems support Hawaii's economy and future growth objectives.

*Goal 6: Energy*—Support the state's energy goal of 70% clean energy, which includes 40% produced by renewable energy and 30% from increased energy efficiency, enhancing the reliability and security of energy sources.

*Goal 7: Funding*—Create secure, flexible, and sustainable revenues for funding sources for transportation needs.

*Goal 8: Planning*—Implement a statewide planning process that correlates land use and transportation while supporting decision making and programming for Hawaii's integrated, comprehensive, multimodal transportation systems.

Each goal was followed by several objectives (too numerous to repeat here). As an example, one of the objectives for the "environment" goal was to "Implement sustainability and livability practices in existing and new facilities," with "sustainability" defined as: "Respect the culture, character, beauty, and history of the state's island communities; strike a balance among economic, social, community, and environmental priorities; and meet the needs of the present without compromising the ability of future generations to meet their own needs." See HDOT [2013] for a complete list of the objectives.

### *3. Maryland*

Maryland DOT defined the vision and mission of the state DOT and of the transportation plan as being:

Provide a well-maintained, sustainable, and multimodal transportation system that facilitates the safe, convenient, affordable, and efficient movement of people, goods, and services within and between population and business centers. [MdDOT, 2014]

The Maryland Transportation Plan identified the following goals as directing future transportation investments:

*Safety & Security:* Enhance the safety of transportation system users and provide a transportation system that is resilient to natural or man-made hazards.

*System Preservation:* Preserve and maintain the state's existing transportation infrastructure and assets.

*Quality of Service:* Maintain and enhance the quality of service experienced by users of Maryland's transportation system.

*Environmental Stewardship:* Ensure that the delivery of the state's transportation infrastructure program conserves and enhances Maryland's natural, historic, and cultural resources.

*Community Vitality:* Provide options for the movement of people and goods that support communities and quality of life.

*Economic Prosperity:* Support a healthy and competitive Maryland economy.

The nature of state government today—short-term programming and funding, annual fiscal constraints, and the like—provides great challenges to the visioning and goal-setting process of long-term planning. However, because it can now take up to 10 years or more to plan, design, and build major transportation facilities, this long-term perspective has become critical to state-level planning.

## D. Identifying and Using System Performance Measures

The next step in the planning process is identifying and using system performance measures. In some instances, such measures have already been established through other planning efforts, and thus the task is simply to apply them to the current study. In other cases, planning-specific performance measures will need to be developed to focus on the most important system performance characteristics identified by key stakeholders. This step could occur in a different sequence depending on the specifics of the study.

Since the enactment of ISTEA and certainly with the passage of MAP-21, many transportation agencies have become interested in developing system and policy performance measures for STPs. Performance measures are different from goals, objectives, and evaluation criteria in that they represent a small number of selected indicators monitored over time to determine changes in system performance (see chapter 7 for more discussion on performance measures). The intent in using performance measures is to provide agency decision makers, key stakeholders (such as the legislature), and the general public with some notion of how system performance is changing over time and to relate this change to state investment in the transportation system. The types of performance measures can vary widely, primarily depending on the type of information desired by key decision makers (see [South Carolina DOT, 2013] for a good example).

### *1. Maryland*

A good example of using performance measures for the monitoring of a state's entire transportation system is found in the Maryland DOT, which produces an annual report on transportation system performance. [Maryland DOT, 2014a] The measures cover a wide range of issue areas. In addition, Figure 15-5 shows an interesting feature of this annual report. For those performance measures that show appreciable change over time, the Maryland DOT provides an explanation. Thus, the report indicates not only what is happening to system performance, but also provides explanations as to why.

### *2. Michigan*

Performance measures can serve different purposes. However, to be effective, performance measures should be chosen with certain characteristics in mind. The following list from the Michigan DOT (MDOT) provides a good point of departure for the issues that need to be considered when selecting performance measures:

- *Currently used?* Is the measure currently being used in any form in the agency?
- *Data availability.* Does the agency have the capacity to collect and provide the data to support the measure?
- *Analytical capability.* Does the agency have the capacity to analyze the data supporting a specific measure?
- *Clarity.* Does the measure provide meaningful and easy-to-understand outputs?

**Figure 15-5. Performance Measurement in Maryland**

Source: Maryland DOT, 2014a

- *Public interest.* To what extent is the public interested in the performance measure area?
- *Control/causality.* To what extent does the agency control affect changes in performance results through decisions and actions?
- *Reporting value.* To what extent is the measure valuable in communicating what is important and a priority to the public, stakeholders, and/or internal staff?
- *Decision value.* Can the measure be used in a predictive fashion to inform decision-making processes, such as serving as an early warning system?
- *Management value.* Can the measure be used to support agency accountability?
- *System measure.* Can the measure be applied statewide or to the overall transportation system?
- *Corridor measure.* Can the measure be applied to corridor-level system performance, such as characterizing differences among corridors? [MDOT, 2006]

Table 15-2 shows the performance measures for monitoring the goals and objectives of the Michigan STP.

### *3. Colorado*

The STP for Colorado has four major goals: improve safety, preserve infrastructure condition, improve system performance, and maintain roadways and facilities. The adopted performance measures relating to these four goals include: [CDOT, 2015a]

**Safety**

Highways

Number of fatalities

Fatality rate

| Table 15-2. Performance Measures Linked to Plan Objectives, Michigan |
|---|
| **Stewardship** |
| • Improve and sustain 95% of all freeway bridges in good or fair condition. |
| • Sustain 85% of all non-freeway bridges on the trunkline system in good or fair condition. |
| • Reduce the number of trunkline bridges that are structurally deficient. |
| • Improve or sustain 90% of trunkline pavements in fair or better condition based on sufficiency. |
| • Improve or sustain 90% of trunkline pavements in fair or better condition based on International Roughness Index. |
| • Improve or sustain 90% of trunkline pavements with a remaining service life value of 3 years or higher. |
| • Increase the percentage of trunkline railroad crossings that are related in fair or better condition. |
| • Maintain 100% of all tier 1 airport primary runway pavements in good or better condition. |
| • Minimize the portion of the rural transit and the specialized transit fleet that is operating past its useful life. |
| • Preserve existing intercity passenger rail transportation services. |
| • Preserve existing rural intercity bus service. |
| • Preserve existing local bus services including specialized transit service. |
| • Maintain 90% of all trunkline carpool parking lot pavements in good or fair condition. |
| **Safety and Security** |
| • Reduce crash severity on all roadways, statewide. |
| • Reduce crash severity on the state trunklines. |
| • Reduce crash severity on the local roadways. |
| • Ensure that safety projects provide the maximum return for funding dollars. |
| • Enhance and increase protective measures and implement effective border continuity. |
| **System Improvement** |
| • Increase percent of route miles along corridors of national/international significance having acceptable level of service. |
| • Expand MichVan access. |
| **Efficient and Effective Operations** |
| • Reduce delays: Minimize disruption to mobility resulting from incidents. |

Number of serious injuries

Serious injury rate

Bikes and Pedestrians

Number of bicyclist and pedestrian fatalities involving motorized vehicles

Number of bicyclist and pedestrian serious injuries involving motorized vehicles

**Infrastructure Condition**

Bridges

Condition of National Highway System (NHS) bridges

Condition of state highway bridges

Risk-Based Asset Management Plan measures for bridges

Highways

Pavement condition of the interstate system

Pavement condition of the NHS, excluding interstates

Pavement condition of the state highway system

Other Assets

Risk-Based Asset Management Plan measures for other assets (measures for buildings, intelligent transportation systems (ITS) equipment, roadway fleet, culverts, geohazards, tunnels, traffic signals, and walls)

Transit

Transit Asset Condition

**System Performance**

Interstates, National Highway System, and State Highway system

Interstate Performance—Planning Time Index (PTI)

NHS Performance excluding Interstates—PTI

Colorado Freight Corridors Performance—PTI

Transit

Transit Utilization—Ridership statewide for small urban and rural "transit grantees"

Transit Connectivity—Revenue service miles provided

**Maintenance**

Level of service (LOS) for snow and ice removal

Overall Maintenance Level of Service (MLOS) for the state highway system

The plan also provided aspirational targets for each of the measures.

Given the importance of performance measures for identifying system performance and providing important input into the decision-making process, the selection of which measures to monitor is often part of a state DOT's public and stakeholder outreach effort. This is especially true if the performance report is directed at a particular audience, such as the state legislature.

## E. Needs Assessment

Most state DOTs want to develop a data-driven plan. Traditionally, this has meant focusing on and evaluating transportation system performance, including standard condition deficiencies and network operations performance. State DOTs have been collecting these types of data for many years, and thus have good databases to determine overall trends as well as identify specific locations where deficiencies exist. However, even with this history of data collection, the statewide transportation planning process is often subject to the following five types of data-related challenges: data accessibility, data quality and timeliness, data interoperability, data redundancy, and staff delegation and cooperation. [Guo and Gandavarapu, 2009]

Adequate data for other modes that interact with the state highway system are often lacking, including transit performance data, commuter or intercity rail data, movement of freight on the state highway, and other modal data. In part, this is due to different governmental agencies or private-sector organizations that collect, analyze, and control the performance data, thus making these data difficult to obtain by the DOT.

A typical transportation system database for a state DOT is extensive and contains data for both the condition and operational performance of the state's transportation infrastructure. Of growing interest is the development and use of system maintenance and operations data in transportation planning. Many states generate such data, but because the data are used for so many different types of activities, they are often collected, stored, and analyzed by different units within the DOT. As noted in chapter 8, the growing interest in asset management approaches to investment decision making also leads to a focus on effective database management, and therefore a potential strong linkage between asset management and statewide transportation planning.

For transportation planning purposes, data are used to identify transportation needs (for example, poor pavement quality or congested road segments), as well as provide input into the analysis and evaluation of different investment strategies. It is beyond the scope of this chapter to inventory the range of data that might be used for transportation planning purposes (see chapter 2). However, some examples provide an indication of what types of data are useful for state transportation planners.

### *1. Hawaii*

Hawaii DOT's STP illustrates a common characteristic of statewide transportation planning. As shown in Figure 15-6, the STP uses data and recommended actions from other plans undertaken in the state, in this case plans for water, air, and land transportation systems. Each of these plans has its own planning process and data sources, and therefore there is no need to replicate the analysis results in the statewide planning process.

### *2. Oregon*

The Oregon DOT has developed a coordinated set of data management systems designed to provide information to those setting investment priorities. The Oregon Transportation Management System (OTMS) is the overarching program responsible for managing highway pavement, bridges, highway safety, traffic congestion, public transportation facilities and equipment, intermodal transportation facilities, and systems and traffic monitoring for highways. The vision of OTMS is to "integrate information, analyses and analysis tools to help decision makers prioritize Oregon's transportation needs." [Oregon DOT, 2015] The individual management systems that are part of the OTMS include:

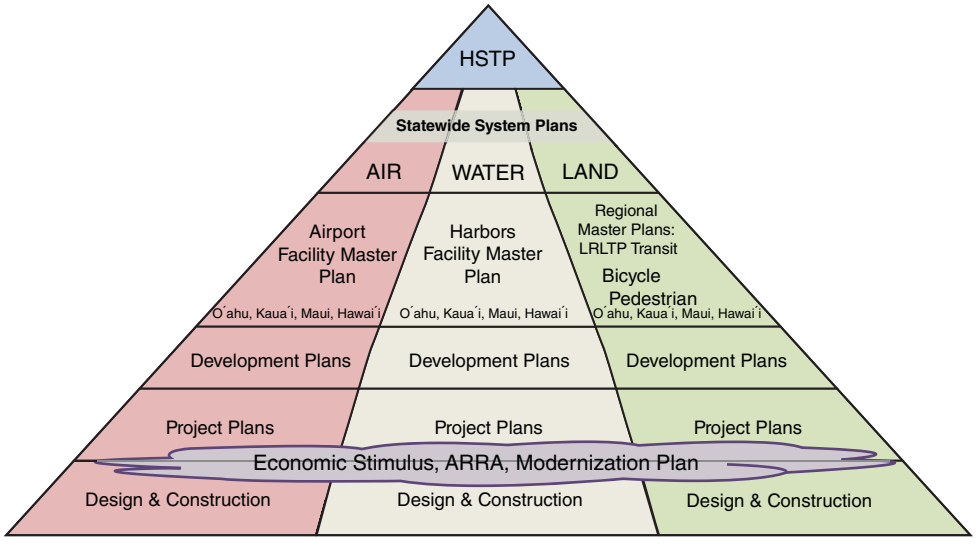
Integrated Transportation Information System

Bridge Management System

Pavement Management System

Congestion Management System

**Figure 15-6. Using Other Plans as Input into the Statewide Transportation Plan, Hawaii**



Source: Hawaii DOT, 2013

Intermodal Management System

Safety Management System

Traffic Systems Monitoring System

Combined, these management systems provide roadway inventory data and data on other transportation infrastructure features, analyze and summarize these data, identify and track performance measures, identify needs, help determine strategies and actions to address those needs, and monitor and evaluate the effectiveness of strategies and actions that are implemented.

### *3. Utah*

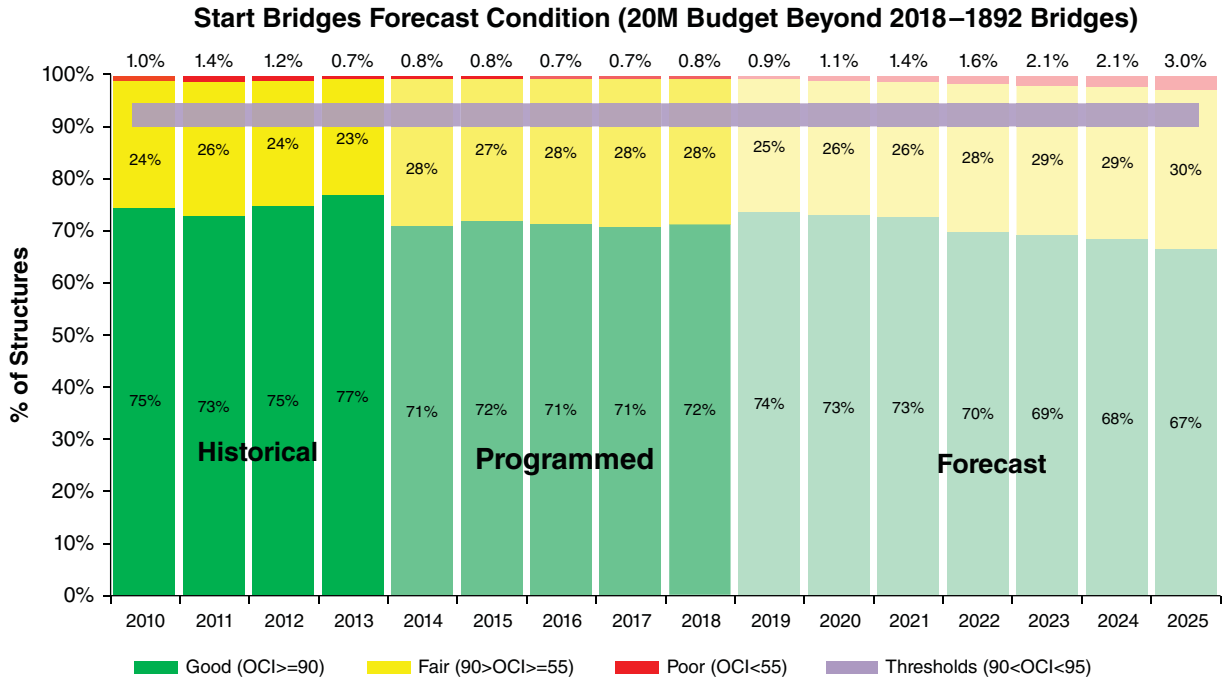
The Utah DOT has been a national leader in developing an asset management system that feeds directly into investment decision making. The DOT data portal provides data and trend information on 57 different assets and system performance characteristics that might be of use to transportation planners. [Utah DOT, 2015] Access to this data allows state DOT planners and asset managers to quickly obtain trend data such as those shown in Figure 15-7, and by using deterioration functions, estimate future condition as well.

### *4. Colorado*

The Colorado STP illustrates the concept of a needs assessment. Transportation investment needs are generally defined as the dollars required to meet the performance goals of the STP. The following categories of needs and the data sources used are from CDOT's needs and gaps technical memorandum:

- *Asset management and maintenance:* Asset management includes replacing and rehabilitating existing and future transportation facilities on a long-term basis, including preventative maintenance. Maintenance includes the everyday and annual maintenance of the transportation system; for example: snow plowing, equipment maintenance, and minor road and bridge repairs. The CDOT Program Distribution, the results of the most recent CDOT Asset Management Delphi process (budget setting), and the CDOT Transportation Deficit Report were used to determine the needs.
- *Expansion:* Investments that add capacity to the multimodal transportation system by enhancing existing facilities or creating/building new infrastructure and services. The needs were determined through

**Figure 15-7. Bridge Condition Trends and Extrapolation, Utah DOT**



Source: [Utah DOT, 2015b]

Metropolitan Planning Organization (MPO) (2035 or 2040) and Regional Transportation Plan (2040) documents, lists developed by the Transportation Planning Regions (TPRs), CDOT Region project lists and data, and other existing lists of projects. The team also used safety data from CDOT (known as level of service for safety, or LOSS), travel time data and speed data (for the National Highway System (NHS) only) from the Federal Highway Administration, and information from environmental documents and MPO plans. Projects were screened and validated as potential needs based on criteria that included safety, low travel speeds, congestion levels, environmental document completion, and regional input. The input received from regional planners assisted in providing context for long-term economic vitality and development needs.

- *Safety:* Safety is generally enhanced with every project. The safety category includes education and targeted safety focused projects such as rail crossings and safety hot spots. CDOT created maps and a database showing the severity and locations of crashes and congestion, and evaluated the potential of projects to address these issues.
- *Bicycle/Pedestrian:* CDOT is conducting an inventory of bicycle/pedestrian facilities on and along the state highway system that will include a route system that serves recreational and commuter markets and that provides connectivity between attractions, work locations, and population centers. The route system will require bicycle/pedestrian compatible features such as wider shoulders and lanes, signs, new bridges, and sidewalks. These needs will be developed and analyzed once the inventory is complete.
- *Rural, Small Urban, and Interregional Public Transportation:* A preliminary analysis of rural and interregional transit needs was prepared for the plan. This includes costs for operations such as driver salaries, vehicle maintenance and fuel, as well as capital costs for regular fleet replacement and rehabilitation. Transportation Planning Regions plan for services that reach a variety of travel markets, including commuting, low-income, elderly, and disabled populations in low population density areas. In addition, expansion investments were also considered to address unmet current needs or meet anticipated future needs, based on demographic or socioeconomic growth projections. CDOT is conducting a more detailed transit needs analysis that will be completed in the future. The needs as identified represent the current level of funding going to rural and small urban transit through CDOT and existing funding for interregional transit. The current analysis does not include MPO interregional or high speed rail needs. [CDOT, 2015b]

This information is then compared to expected revenues, and the revenue shortfall is estimated for satisfying all of the DOT's needs. Table 15-3 shows such a table for the Colorado needs assessment.

### *5. North Carolina*

The North Carolina DOT (NCDOT) conducted a similar needs assessment as Colorado's. It too listed the methods and data used to develop the needs estimates, shown in Table 15-4. However, one of the unique aspects of the NCDOT needs assessment was its recognition in its analysis that "needs" can often be related to the level of service (LOS) desired for state-owned facilities. For example, if a current facility is operating at LOS E and the desired LOS is B, this implies a certain level of investment to reach the desired target LOS B. However, if LOS C is acceptable, not as much investment is likely needed. Table 15-5 shows this impact of different assumed levels of service for the definition

**Table 15-3. Gap Analysis 2016–2025, Colorado DOT**

| Category | Needs | Revenue | Gap | Annual |
|---|---|---|---|---|
| Highway Asset Management | $5,840,780,000 | $3,761,544,700 | ($2,079,235,300 | ($207,923,530) |
| Highway Maintenance | $2,745,610,000 | $2,544,000,000 | ($201,610,000) | ($20,161,000) |
| Highway Expansion | $8,620,080,000 | $661,517,754 | ($7,958,562,246) | ($795,856,225) |
| Highway Operations | $321,640,000 | $257,978,544 | ($63,661,456) | ($6,366,146) |
| Highway Safety | $1,203,000,000 | $1,013,710,723 | ($189,289,277) | ($18,928,928) |
| Transit | $384,177,826 | $384,177,826 | - | - |
| Flexible | - | $1,720,616,554 | $1,720,616,554 | 172,061,655 |
| Total | $19,115,287,826 | $10,343,546,100 | ($8,771,741,726) | ($877,174,173) |

Source: CDOT, 2015b

| Table 15-4. Needs Estimation Methods, North Carolina DOT | |
|---|---|
| **Mode/Mode Element** | **Estimation Method** |
| Highways-Pavement | 10-year estimate developed with pavement management system software and pavement inventory database. |
| Highways-Bridges | Estimate developed with bridge management system software and bridge database. |
| Highways-Maintenance | Developed from maintenance needs estimate for biannual maintenance condition assessment report. |
| Highways-Expansion, Metropolitan | MPOs provided listing of highway needs per most recent long range plan for metro areas. Coordinated with listing of costs to complete for loops and intrastate road improvements. |
| Highways-Expansion, Non-Metropolitan | Developed from analysis of roadway characteristics database in GIS format, applying traffic growth rates and segment capacities developed by the SPOT, and applying cost improvement matrix. Coordinated with listing of costs to complete for loops and intrastate road improvements. |
| Highways-Modernization | Developed from analysis of roadway characteristics database in GIS format, screened against minimum tolerable standards and applying cost improvement matrix. |
| Highways-Safety | Developed through estimates formulated for safety prioritization program, extended to 30-year period. |
| Highways-ITS | Developed from updated ITS program requirements, including both capital and operating costs. |
| Public Transportation | Developed from review and analysis of historic department funding role and review of programmatic needs; coordinated with program prioritization estimates. |
| Bicycle/Pedestrian | Developed from review of nearly 100 planning reports and review of programmatic needs; coordinated with program prioritization estimates. |
| Rail | Developed from listing of freight and passenger projects identified in new Rail System Plan, with costing of capital and operating requirements. |
| Ferries | Developed from listing of infrastructure assets and operating costs estimated for each facility/service. |
| Ports | Developed from 10-year capital needs estimate and historical operating budget, allocated to goals, and extrapolated to 30 years, excludes any major new strategic investments to ports. |
| Aviation | Developed from current listing of project needs and state funding participation. |

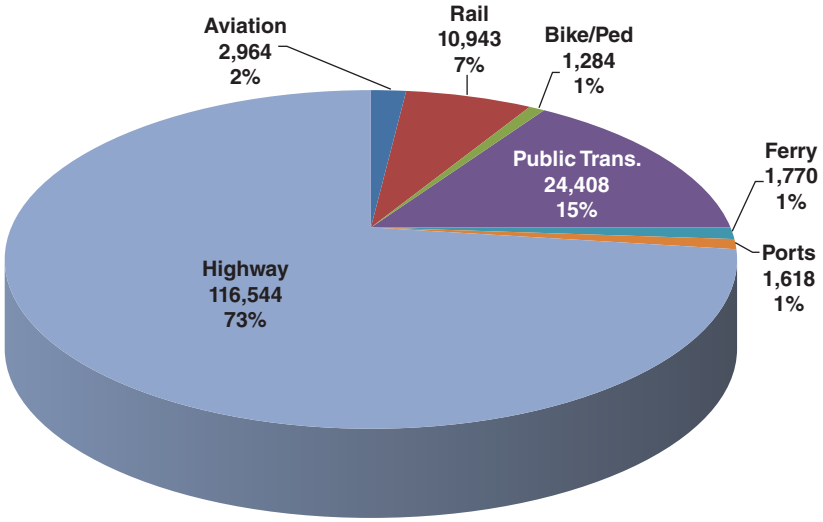
| Highways-Safety | $2,499 | $1,999 | $941 | $1,000 | $1,999 |
| Highways-Modernization | $4,028 | $3,222 | $2,417 | $1,611 | $2,244 |
| Highways-Expansion, Non-Metro | $10,412 | $8,330 | $6,247 | $4,165 | $8,582 |
| Highways-Expansion, Metro | $45,311 | $36,249 | $27,187 | $18,124 | $40,564 |
| Highways Total | $116,543 | $94,192 | $68,519 | $46,617 | $93,030 |
| | | | | | |
| Grand Total | $159,532 | $130,386 | $94,128 | $66,172 | $122,833 |

Source: NCDOT, 2012

**Figure 15-8. Distribution of Investment Needs by Mode, North Carolina**



Source: NCDOT, 2012

of need. As can be seen, there is a significant difference in the needs estimate depending on which LOS one assumed. Figure 15-8 is another common presentation of data in a needs assessment.

## F. Analyzing Transportation System Alternatives

The development and analysis of different investment alternatives and/or scenarios is the core of the technical approach for statewide transportation planning. Analyzing different plan alternatives allows the DOT and the public to assess the implications of different policies, programs, and funding approaches. This part of the process is critical to the overall success of the plan, as it allows members of the public to play an important role in identifying, analyzing, and selecting alternative plans. The level of sophistication of the analysis tools used to analyze alternative system alternatives varies by state. In some cases, state DOTs have developed a statewide traffic demand model and/or a statewide freight model that can be used to forecast performance outcomes. Chapter 6 on demand modeling and chapter 22 on freight transportation provide an overview of the structure and use of such models. The following example from Ohio provides an overview of some of the key aspects of statewide travel demand forecasting.

### *1. Ohio*

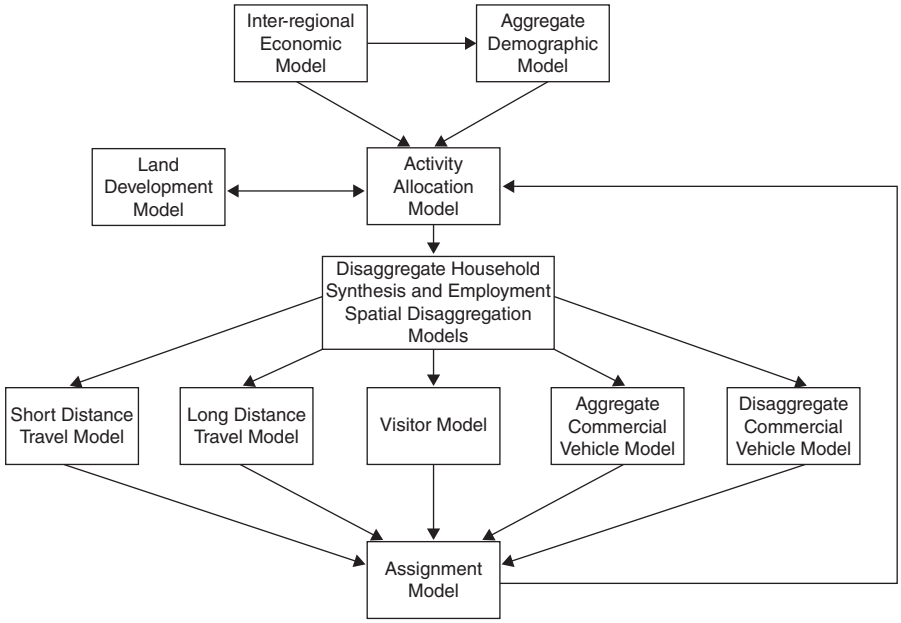
The Ohio DOT began the development of a statewide travel demand model in the late 1990s to "provide the ability to analyze large multi-region corridors, to conduct consistent system-wide analysis and to provide a traffic forecasting tool in the rural areas of the state not covered by the urban MPO models." [Ohio DOT, undated] Interestingly, the Ohio DOT first surveyed key decision makers who would be relying on the results of demand modeling to determine the most desired outputs of the model. The three priority issues were:

- Reducing/minimizing/avoiding roadway congestion and delay.
- Sustaining and improving the state economy.
- Including freight planning, particularly with regard to the management of truck traffic and the potential for shifting it to other routes and modes.

The following factors were considered desirable, if they were cost-effective to provide:

- Support multimodal/intermodal options for travel, passenger, and freight.
- Improve conditions for non-auto (and non-single-occupant auto) mode services.
- Maintain/improve safety.

**Figure 15-9. Ohio Integrated Economic, Land Use, Transport Model**



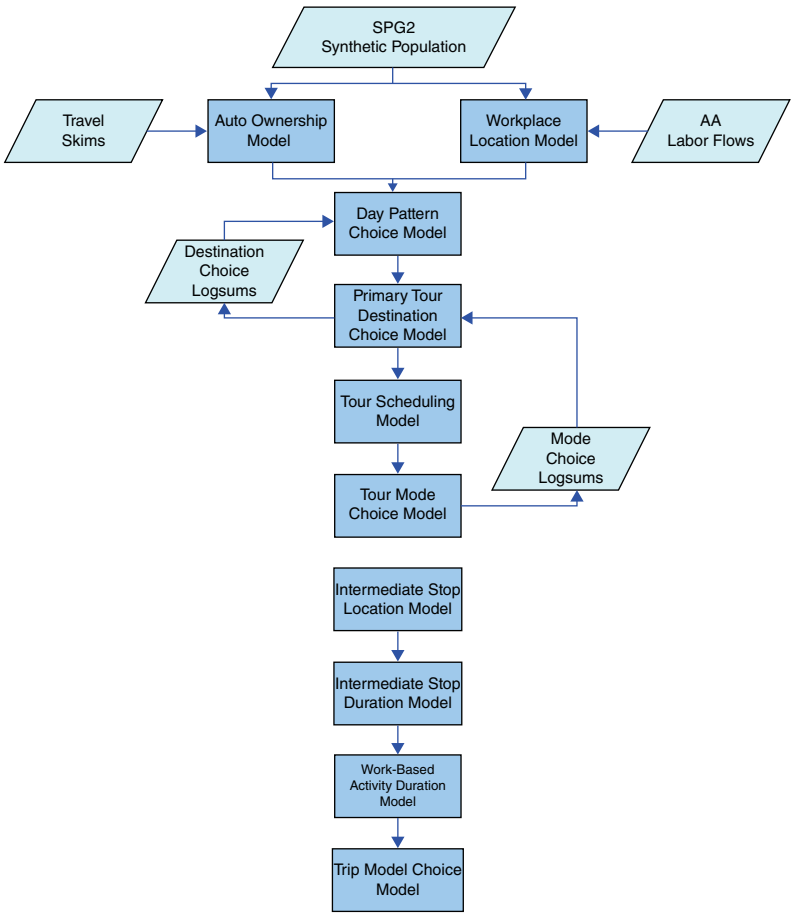
Source: Courtesy of the Ohio DOT [Ohio DOT, undated]

- Mitigate the impacts of new development and related access management.
- Maintain/improve air quality.
- Reduce conflicts between modes

The model structure chosen to provide these capabilities is shown in Figure 15-9. As indicated, the model includes the typical traffic forecasting element of such models, but it also links to a state economic model and a demographic model. The basic modeling approach uses trip tours or more generally an activity-based model (see chapter 6 on travel demand) as seen in Figure 15-10. The types of output from the model include estimates on: vehicle miles traveled; vehicle hours traveled; crashes; level of service; delay; growth rates; air pollution emissions; volume to capacity ratios; duration, extent and location of congestion; vehicle operating costs; value of time; cost of travel time for both persons and transported goods; and origin-destination flows.

One of the implications of using a statewide travel demand model is that the zone structure for the analysis will be large. In addition, the zones representing origins or destinations outside of the state will be even larger. Figure 15-11 shows the traffic analysis zone structure used in the Ohio model. As can be seen, the farther away from Ohio one gets, the larger the zones, eventually resulting in entire states being

**Figure 15-10. Ohio Short Travel Distance Demand Model**

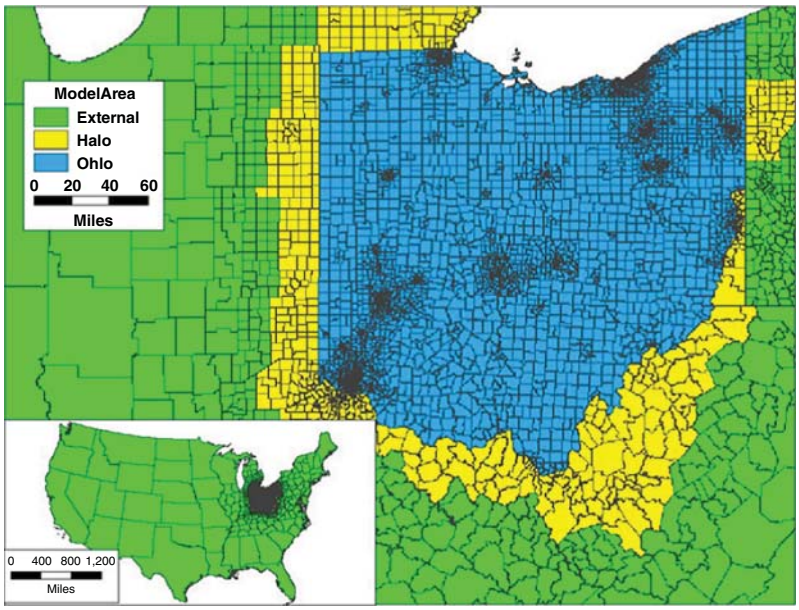


Source: Parsons Brinckerhoff, 2010

a zone. For freight models, an even larger zonal system is often used to represent freight flows going outside the country.

There are very few states with models at the level of sophistication as found in Ohio. However, many states are developing models that are similar, and that can be used to support agency planning and decision making.

**Figure 15-11. Ohio Demand Model Analysis Zones**



Source: Parsons Brinckerhoff, 2010

### *2. Rhode Island*

Scenario analysis is becoming another tool that states are using to analyze future investment options. Scenarios are often viewed as being slightly different than alternatives. A scenario reflects a specific context for transportation investment—for example, focusing transportation investment in existing communities, emphasizing bottleneck removal, or examining the implications of limited availability of petroleum-based fuel in the future. Given each scenario, specific alternatives can be developed that best reflect the characteristics of that scenario.

The Rhode Island Department of Administration (on behalf of the Rhode Island Department of Transportation) developed an STP that used two different types of scenarios—one relating to alternative patterns of development (and the consequent impact on system performance), and another on different levels of investment in the transportation system. [RIDOA, 2012] With respect to the land-use scenarios, three different assumptions were examined.

- *Current Trend:* Assume current population and employment projections as assigned to the traffic analysis zones (TAZs) for use in forecasting VMT and emissions. The trend at the time showed 55 percent of the growth going to TAZ's inside the urban area and 45 percent outside (55/45 split).
- *Sprawl Scenario:* Assume the rural area absorbs more of the population and employment growth (20 percentage points more of the 2000–2030 growth than in the Current Trend scenario for a 35/65 split).
- *Compact Scenario:* In this scenario, the urban area absorbs more of the population and employment growth (30 percentage points more of the 2000–2030 growth than in the Current Trend scenario for an 85/15 split).

Table 15-6 shows the results of incorporating these different scenario assumptions into the statewide travel demand model.

### *3. South Carolina*

The South Carolina Department of Transportation (SCDOT) developed five investment scenarios as part of its statewide transportation plan. These scenarios were:

- *Baseline:* Allocate resources to focus on the core highway system. Baseline resembles the current program distributions.
- *Multimodal System:* Allocate resources to maintain and expand highway, transit, rail, and nonmotorized systems linking cities and towns.
- *Serve the Economic Drivers:* Investment to support business attraction and retention, with resources focused on ports, distribution facilities, airports, and leisure destinations.

| Table 15-6. Scenario Analysis for Land Development Patterns, Rhode Island | | | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Growth Scenarios | Population 2030 | | Employment 2030 | | Daily Vehicle Miles Traveled 2030 | | | Transit Ridership 2030 | | |
| | Urban | Rural | Urban | Rural | Urban | Rural | Total | Urban | Rural | Total |
| Current Trend (55/45) | 855,947 | 284,596 | 438,084 | 77,964 | 16,390,489 | 10,355,817 | 26,746,306 | 108,475 | 835 | 108,310 |
| Sprawl Scenario (35/65) | 836,433 | 304,110 | 417,482 | 98,566 | 15,810,783 | 11,345,517 | 27,156,300 | 104,789 | 998 | 105,787 |

| Percent | 3.1% | −9.3% | 0.9% | −4.8% | 0.7% | −3.7% | −1.0% | 2.1% | −6.8% | 2.0% |

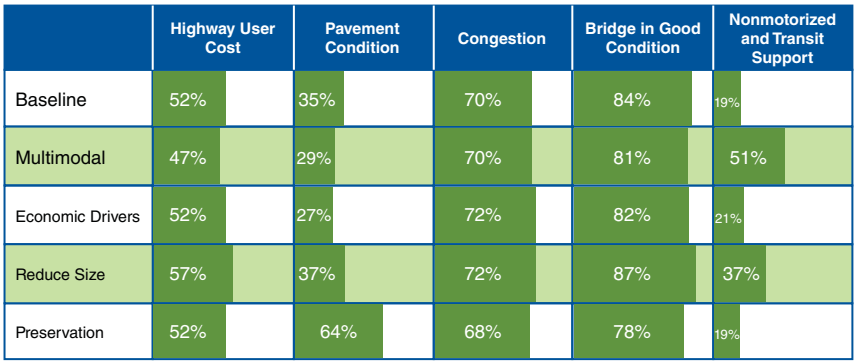
Source: Rhode Island Department of Administration, 2012

- *Reduce System Size:* Transfer ownership of roughly 50 percent of the nonfederal-aid highway system to counties and municipalities over the lifetime of the plan. There are approximately 10,000 nonfederal-aid roadways miles that carry less than 200 vehicles per day.
- *Preservation:* Focus on maintaining highways and bridges at a high level of preservation and reliability. Less focus on congestion and multimodal expansion.

Figure 15-12 shows the results of the scenario analysis. The percentages indicate the degree to which each scenario achieved the goals of minimizing highway user costs, improving pavement condition, reducing congestion, keeping bridges in good condition, and supporting nonmotorized and transit options. As noted in the plan,

> *No one individual investment scenario optimally addresses the future performance of the state's transportation system. Allocating limited resources to efficiently address a multitude of transportation needs throughout South Carolina is a top priority of SCDOT. While SCDOT cannot address all the transportation needs alone, it is clear that a narrower focus will be necessary to achieve measureable gains in any of the Plan goal areas. A more strategic focus can include shifting a greater share of funding to system preservation while relying on non-federal funding sources to address mobility needs, as well as targeting investment to priority networks that support state mobility needs and economic competitiveness, such as the Interstate system and the Statewide Strategic Corridor Network.*

**Figure 15-12. Alternative Investment Scenario Analysis, South Carolina**



Source: South Carolina DOT, 2014

### *4. Virginia*

The Virginia DOT example is typical of the alternative investment plan analysis approach toward transportation planning. As noted earlier, VDOT adopted a strategic corridors approach for statewide transportation planning. Guidelines were developed that provided a template for analyzing these corridors, including the following information:

**Analysis of Existing Corridor**

Purpose: *To compile information on the current state of the facility/corridor.*

Items discussed include:

- Existing facility type(s)/cross-section(s).
- Current travel demand along the facility. This includes the traffic volumes of passengers, vehicles, and trucks; and depending on the level of analysis, bikes, and/or pedestrians.
- Degree and type of freight movement (if applicable).
- Level of service (LOS) and capacity analysis along the existing corridor.
- Safety/crash analysis.
- Manner by which the facility fits within and connects to the rest of the transportation system.
- Other existing non-highway modes of transportation (such as a nearby rail facility).

**Needs Assessment**

Purpose: *To develop the purpose and need for improvements along the corridor.*

Items discussed include:

- Specific goals of the study.
- Selection of the facility as a Strategic Highway Corridor.
- Need for improvements along the facility as they relate to the corridor's function as a Strategic Highway Corridor.
- Future travel demand along the corridor (autos, trucks, and/or freight movement, and depending on the level of analysis, bikes, and/or pedestrians).
- LOS and capacity analysis of the future travel demand.

**Alternatives Development and Analysis**

*Purpose: To develop and analyze alternatives that meet the goals, intent and purpose and need of the corridor study.*

This task is performed in coordination and collaboration with key stakeholders and the general public. Depending on the purpose and need and the intent of the study, the level of effort will vary. For example, if the primary focus of the study is determining the appropriate access management techniques that should be implemented along a corridor, alternatives may be developed solely for accomplishing this goal. Likewise, if the corridor study is a tiered environmental impact statement (tiered EIS), alternatives developed might be approximately 100-miles long and 2,000-feet wide. Alternatives include a no-build alternative along with several potential build alternatives. In addition, other modes of transportation may be examined as necessary, depending on the intent of the corridor study, such as a tiered EIS.

An analysis of each of the alternatives developed will occur to determine the best solution(s) that meet(s) the purpose and need and goals of the study. The analysis may include items such as:

- Mobility benefits
- Economic benefits
- Environmental impacts

- Indirect and cumulative impacts
- Cost-effectiveness benefits
- Effects on other components in the transportation system
- Travel forecast (if applicable)

### *5. Arizona*

The Arizona DOT's transportation plan, *What Moves You Arizona*, is a good example of a plan that provides a strategic, performance-based perspective on transportation needs as well as in the identification of project priorities. The planning process established a set of performance measures to identify transportation needs and to serve as evaluation criteria for individual projects. Through outreach to key stakeholders, this process identified the differing weights assigned to individual performance measure categories by important decision makers. The different weights were then used for the individual performance measure categories.

Needs were determined by examining the consequences of three different investment strategies:

- *Preservation:* Activities that protect transportation infrastructure by sustaining asset condition or extending asset service life; preservation includes regular maintenance and resurfacing of pavements, replacing aged transit vehicles, upgrading rail track, and airport runway rehabilitation.
- *Modernization:* Highway improvements that upgrade efficiency, functionality, and safety without adding capacity; examples of modernization activities include widening of narrow lanes, access control, bridge replacement, hazard elimination, lane reconstruction, aviation upgrades, and bus system upgrades.
- *Expansion:* Improvements that add transportation capacity through the addition of new facilities and or services; expansion activities include adding new highway lanes, expanding bus service, construction of new highway facilities, and adding rail passenger service or facilities. [ADOT, 2011]

*Highways*

Three major analysis methods were used to determine needs.

*HERS-ST :* The Highway Economic Requirements System—State Version (HERS-ST) model, developed by FHWA, was used to determine 25-year State Highway System needs. A roadway condition database known as the Highway Performance Monitoring System (HPMS) provides the input information for this analysis (see chapter 2).

*NBIAS:* Bridge needs were analyzed with the National Bridge Investment Analysis System (NBIAS) model. The NBIAS model forecasts bridge performance and identifies improvements based on economic indicators.

*New Facilities and Other Capital State Highway System Needs:* New capital needs built on new rights of way cannot be determined from HERS-ST or the NBIAS. ADOT identified proposed new projects from existing state DOT plans, from the regional long-range transportation plans from the state's MPOs, and other planning sources. The new location highway needs totaled $15.8 billion over the life of the plan.

In addition, the above tools do not estimate noncapital needs such as routine maintenance. These were estimated separately.

*Transit*

For public transportation needs, the following analysis approaches were used:

*Urban Preservation Needs (or "State-of-Good-Repair" Needs):* These needs focused on bus and light rail vehicle replacement and rehabilitation, as well as the maintenance and rehabilitation of supporting infrastructure. Needs were estimated by comparing Arizona's share of transit assets in relationship to the 2010 Federal Transit Administration's (FTA) National State-of-Good-Repair Study and the needs-based report from the American Association of State Highway and Transportation Officials.

*Urban Transit Expansion:* Metropolitan-area transportation plans, along with the most recent 2008 Arizona Statewide Transportation Investment Strategy, was used to estimate expansion needs.

*Rural Preservation and Expansion:* These needs had already been estimated in a recent ADOT Rural Transit Needs Study.

*Freight Rail*

Several sources were used to estimate long-term freight rail investment needs in the state, including recent state transportation plans, the Arizona State Rail Plan, ADOT's 2009 Railroad Inventory and Assessment, a Multimodal Freight Analysis Study, and interviews with railroad officials.

*Passenger Rail*

The passenger rail needs focused on state-of-good-repair, modernization, and expansion requirements that were obtained from the Federal Railroad Administration's High Speed Rail Strategic Plan, ADOT's Statewide Rail Framework Study, Maricopa Association of Governments' (the MPO for Phoenix) Commuter Rail Strategic Plan, an Amtrak Report on Accessibility and Compliance with the Americans with Disabilities Act of 1990 and internal route performance reports conducted by ADOT staff.

*Aviation*

The Arizona State Airports System Plan (SASP) was used to identify costs to improve the state's airport system. In addition to the projects identified in the SASP, airport-specific capital projects and costs were identified by examining each airport's master plan

*Operating Costs*

Cost estimates for operating the highway and bridge network, and providing transit services were based on prior work conducted by the DOT. In addition, the operating costs associated with matching federal aid programs were also included in the overall needs assessment.

Once the needs were identified, ADOT compared different investment scenarios:

- *Alternative Investment Choice (AIC) A, Highway Focus:* AIC A focuses on preserving the state's highway system with limited system expansion. Preserving the system had surfaced from extensive public outreach efforts as the more important goal of the transportation plan.
- *Alternative Investment Choice (AIC) B, Expanded Travel Choices:* This scenario shifts funding from preservation to expansion and provides some non-highway funding to non-highway investments such as transit, rail, aviation, and other modes. Highway investments are focused on the interstate system, and approximately 10 percent of all state funding is allocated to other transportation choices, such as transit and passenger rail.
- *Recommended Investment Choice (RIC), Combination of Investment Choices:* The RIC combines elements from AIC A and AIC B. For example, like AIC A, the RIC emphasizes state highway system preservation and modernization. Like AIC B, funding is shifted from highway expansion to non-highway modes (that is, rail and transit) to provide mobility options. [ADOT, 2011]

Table 15-7 shows the percent allocation of state dollars for each scenario.

**Table 15-7. Distribution of Funding by Scenario, Arizona DOT**

| Improvement Category | AIC A Funding | AIC B Funding | RIC Funding |
|---|---|---|---|
| Highway Preservation | 34% | 17% | 34% |
| Highway Modernization | 22% | 10% | 29% |
| Highway Expansion | 41% | 52% | 27% |
| Non-highway Improvements | 3% | 21% | 10% |
| Total | 100% | 100% | 100% |

Source: ADOT, 2011

ADOT examined the impacts of each scenario on different condition and performance measures. Figures 15-13 to 15-15 show some of the forecasted impacts. In each of these figures, the "full state needs" scenario is also shown. This scenario is the base case for comparison purposes and represents meeting as many needs as possible with expected revenues.

ADOT also assigned a "grade" for each scenario with respect to its ability to achieve plan goals. Identifying the grades for each goal area included significant interaction with ADOT staff, individual stakeholders, a technical advisory committee members, and the steering team. Table 15-8 shows the grades that were assigned. One of the major purposes of assigning grades was to explain the impacts of different investment scenarios in terms that the public could understand. It is interesting to note that even the highest level of investment was generally rated as being just above average in meeting the needs.

Each of the examples above—and almost every statewide transportation planning effort—relies on computer models for producing the analysis that feeds into the evaluation process. It is beyond the scope of this chapter to discuss the different types of analysis models that can be used for forecasting both person and freight flows (see chapters 6 and 20, respectively). Forecasted traffic-flow information, however, is used in a variety of ways by a state DOT. Customers include not only the planning unit, but also other groups concerned with design, performance monitoring, and traffic engineering. Table 15-9 shows the types of data that are the products of traffic forecasting and how these products are used as noted by the Vermont Agency of Transportation.

One of the challenges facing DOTs in developing long-range plans is the relationship between statewide travel demand models and those models developed by MPOs. Assumptions made by the state about growth and traffic into and out of urban areas should match those of MPOs. In some states, this coordination has not always occurred. The primary application of the regional models is to provide a tool to update long-range transportation plans and develop project-level forecasts for highway design purposes. However, MPO models often do not consider the systemwide growth in traffic generated from statewide forecasts. The Wisconsin DOT used an expert panel review process involving planners and technicians from both the DOT and the state's MPOs to reach a consensus on traffic growth rates for both the urban areas and the statewide model.

|---|---|---|---|---|
| **Goal Area** | **ADOT Existing Investment Strategy** | **Alternative Investment Choice A** | **Alternative Investment Choice B** | **Recommended Investment Choice** |
| Improve mobility/accessibility | B | D | C+ | C– |
| Preserve and maintain system | B+ | A | D | A– |
| Support economic development | C+ | D | B– | C– |
| Link transportation and land use | C– | C– | B | C+ |
| Consider the environment and natural resources | B– | B– | B+ | B+ |
| Enhance safety and security | C+ | C– | B– | B– |
| Investment in non-highway modes | D | D | C+ | C |

Source: ADOT, 2011

Transportation interest groups and the public continue to have an interest in the models used by state DOTs, the assumptions that drive the modeling process and the use of model results. In many cases, the technical capabilities of forecasting models available for use in long-range planning at the state level have not kept up with these expectations—particularly in the areas of modeling of land-use decisions, modeling transportation trade-offs and incorporating freight data. As more and more data are generated for state-level forecasting purposes, DOTs are challenged to maintain the quality and integrity of their basic database and to provide resources to update system data continually—all within the context of reduced resources.

The following state DOT websites provide good examples of the web-based resources that are now available to planners in obtaining data that can be used in transportation planning studies.

Florida DOT, Geographic Information Systems Roadway Characteristics Inventory, http://www.dot.state.fl.us/planning/statistics/gis.

Massachusetts DOT, Data, http://www.massdot.state.ma.us/planning/Main/MapsDataandReports/Data.aspx.

Michigan DOT, Intermodal Data, http://mdotcf.state.mi.us/public/tms/idm.cfm.

Minnesota DOT, Traffic Forecasting & Analysis, http://www.dot.state.mn.us/traffic/data/coll-methods.html#WIM.

Washington State DOT, Maps and Data, http://www.wsdot.wa.gov/mapsdata.htm.

## G. Evaluating Transportation System Alternatives

In evaluating different state transportation system alternatives, planners synthesize the information associated with each alternative and compare their impacts. Because of the aggregate nature of the alternatives and scenarios investigated, state DOTs very seldom conduct detailed evaluation as is done in metropolitan plans or for that matter in state DOT-sponsored corridor studies. This is the case primarily because the scale of the transportation system and the many different kinds of modal strategies being considered makes a quantified evaluation process very difficult. Often the most information provided is similar to that described earlier from the Arizona statewide plan example, which included both quantitative estimates for such things as pavement and bridge condition, as well as a subjective assessment (that is, letter grades).

However, when state DOTs focus on one mode as they do in state modal plans (discussed later) or when they focus on a particular region of the state, one often sees evaluation results as shown in Figure 15-16. This figure comes from the Georgia DOT where a key state initiative developed a portfolio for strategic transportation investment in the state. Given that the Atlanta metropolitan area was the most complex from a transportation perspective, and given the Atlanta MPO had a travel demand model capable of estimating travel demands, the DOT produced the evaluation results shown in the figure.

Different methods and approaches for evaluating alternatives can be found in chapter 7.

| Table 15-9. Traffic Forecasting Products and Customers: Vermont | | | | | |
|---|---|---|---|---|---|
| **Type of Forecast** | **Available Methods** | **Applicability** | **Key Data Requirements** | **Advantages** | **Disadvantages** |
| Future year population and employment in the corridor study area | Statewide travel demand model | Appropriate "baseline" forecast | Existing data | Existing, consistent statewide forecast of population and employment by town | Assumptions underlying forecast may not fully reflect local conditions |
| | Trend analysis | Appropriate in absence of other data<br>Can be tempered with judgment on expected future trends | Historical trends in study area population, employment, development permits | Reflects past/current trends | Assumes past/current trends will remain consistent in the future |
| | Build-out analysis | Appropriate for towns with rapid growth/approaching build-out in analysis period, or for studies taking long-term (>20 years) perspective | Study area zoning (allowable densities, types of uses)<br>Locations of existing development<br>Locations with environmental constraints to development | Reflects current local plans and policies<br>Supports a "worst- case" scenario of growth | Not possible in towns without zoning; difficult without electronic zoning map<br>Forecast year development may be much less than build-out. |
| | Estimate future development based on known plans | Best for short term studies, or area with slow change<br>Can be combined with longer-term estimation methods | Permitted or planned developments (industrial park expansion, subdivision applications) | Realistic pictures of near-term future development | Likely to underestimate 20-year development |
| | Expert judgment (e.g., Delphi/expert panel method) | | Past trends<br>Permitted/planned developments<br>Knowledge of corridor economic and planning environment | Can combine other methods and data to arrive at a consensus | Subjective—Different "experts" are likely to disagree |
| | Scenario planning | Best for regions that want to conduct proactive and long- term planning for future growth | Varies; may utilize other planning and forecasting tools | Involves public and stakeholders in discussing alternate futures and their potential impacts | Process involving significant effort |

(*continued*)

Table 15-9. (*Continued*)

| Type of Forecast | Available Methods | Applicability | Key Data Requirements | Advantages | Disadvantages |
|---|---|---|---|---|---|
| Specific locations of future year development | Know plans methods | (see above) | | | |
| | Build-out analysis | (see above) | | | |
| | GIS-based forecasting tools | Examine changes in development patterns based on major trans. Investments and land use policies<br>Provides inputs to detailed trans. model, GIS-based environment analysis | Areawide population and employment control forecasts<br>Planned land use/zoning<br>Developmental constraints<br>Transportation accessibility measures | Rational/consistent method for allocating development | Data and resource-intensive to develop and apply |
| Future traffic volumes on study area roadways | VTrans statewide travel demand model | Baseline traffic growth projections on major roads | Existing data | Accounts for forecast statewide development patterns and transportation network improvements | Not available for roads not included in statewide model |
| | VTrans growth factors | Baseline traffic growth projections | Existing data | Based on historic trends on roadway | Assumes historic growth trends will continue in future |
| | Traffic impact study | Assess impacts of growth policies regarding specific major developments, or general locations of development in corridor | Locations, type, and size of new high-trip generators<br>Trip generators rates (ITE manual or other source) | Accounts for traffic impacts specifically from study area development<br>Can account for seasonal trip generation, e.g., from recreational sources | Needs to be added to background traffic levels<br>Caution required to avoid double-counting |
| | Rural Traffic Shed Model | Forecast traffic volumes from development in a "traffic shed" area served by a single major road | Future land use and development by "traffic shed"<br>Trip generation rates associated with various land uses | Similar to an areawide trip generation study | Not tested in Vermont |
| Intersection performance (delay, LOS) given future traffic volumes | *Highway Capacity Manual* (HCM) Chapters 16 and 17 | Estimates delay, LOS, V/C, queue lengths at controlled intersections | Traffic volumes (including turning movements)<br>Control type through and turn lanes | Standard, widely applied methodology | Requires detailed traffic and geometric data for each intersection analyzed |
| Road segment performance (speed, LOS) given future traffic volumes | HCM Chapter 20 | Estimates speeds, LOS for roadway segments | Traffic volumes, lane and shoulder widths, trucks, directional split, passing zones, free flow speed | Standard, widely applied methodology | Requires traffic and geometric data for each road segment analyzed<br>LOS is subjective depending upon expectations for road |

| | | | | | |
|---|---|---|---|---|---|
| Corridor performance and delay | HCM Chapter 29 | Combines intersection and segment level techniques; most applicable for urban, multimodal corridors | See above | Can account for demand-shifting between modes (e.g., highway and transit) and parallel facilities | Analysis procedures can estimate under severely congested conditions |
| Overall corridor travel time given future traffic volumes | Ski corridor travel time model (combines intersection and road segment methods) | Best analyzing inter-sections improvement, roadway segment improvements, changes in study area trip generation | Same data requirements as for HCM analysis<br>Requires corridor travel time data for validation | Proven overall corridor-level measure of travel time performance<br>Sensitive to development traffic and mitigation measure | Does not provide reliable estimates under severely congested conditions |
| | Statewide travel demand model | Primary use is forecasting traffic volumes statewide-Not roadway-specific travel times | Change in capacity for roadway corridor | Reflects statewide travel patterns | Not sensitive to intersection or small-scale improvements<br>Limited accuracy of speed estimation<br>May require calibration for corridor-specific application |
| | Statewide travel demand model—Enhanced for corridor studies | Best for analyzing: shifting growth within study area locations, adding links to roadway network, major capacity upgrades | Refined level of detail on road network, study area population and employ-ment | Can account for shifting of growth or trip generation within study area, traffic diversion to alternate facilities | May involve considerable effort<br>Not sensitive to intersection or small-scale movements |
| Crash reductions from safety and operational improvements | NCHRP Report 500 – information on effectiveness of strategies | Analyze potential safety benefits of various roadway and operational improvements | Existing conditions Improvement being proposed<br>Traffic volumes | Low cost/easy to apply | Results reported from other studies—actual benefits may vary widely depending upon context |
| Traffic reductions from alternative mode strategies | Sketch-plan assessment of mode shifts | Analyze vehicle traffic reduction or nonmotorized traffic increases from transit service, bicycle/pedestrian facilities, TDM strategies, pedestrian friendly development | Observed or modeled travel behavior changes from similar strategies in other areas | Can provide quantitative estimate for this factor | May be difficult to find research for comparable situations |
| | Stated-preference surveys | Ask people to state choices for alternative modes under different scenarios | Survey—original data collection | Can reflect specific facility/service improvement being proposed | Can be expensive to administer<br>Survey must be carefully designed, otherwise people may overstate choices |

(*continued*)

Table 15-9. (*Continued*)

| Type of Forecast | Available Methods | Applicability | Key Data Requirements | Advantages | Disadvantages |
|---|---|---|---|---|---|
| Congestion and safety benefits of access management strategies | NCHRP Report 420 | Predict changes in crash rates based on addition of driveways, intersection spacing, median treatments | Number of unsignalized and signalized intersection per mile<br>Type of median | Estimates based on empirical data | Crash rates and strategy impacts likely to vary depending upon context |
| | HCM Chapters 16 and 17 | Analyze delay at new/ improved controlled intersections | (see above) | | |
| Environmental and community impacts of transportation and development patterns | Qualitative assessment | Conduct sketch-level assessment of impacts of corridor strategies, based on professional and stakeholder knowledge | Various background data on existing conditions<br>Proposed transportation and land-use strategies | Low cost/easy to apply | Subjective—will vary by person; nonquantifiable |
| | GIS-based community impact assessment tools | Scenario analysis of alternative transportation and development patterns producing indicators such as land developed, impermeable surface area, transit access, walkability, energy consumption | Existing and future land use/development patterns (GIS-based)<br>Transportation network data<br>Other land use, environmental data | Can assess a wide range of community impacts related to future development patterns | Data and resource-intensive<br>Have primarily been applied in metropolitan area applications, not for rural areas |
| | Detailed analysis methods | Most appropriate for specific projects, typically conducted as part of the NEPA process | Varies depending upon impact and method | Provides in-depth information on impact | Often data/resource intensive |
| Visual/aesthetic impacts | Visual preference surveys | Assess visual/aesthetic preferences | Images of different types of development or roadway design alternatives | Low cost—can use existing images/examples from other areas | Does not show what actual project of development would look like |
| | Computer visualization techniques-land use | Develop computerized representations of alternative development scenarios | Planned land use, including location of development, density, other physical design parameters | Powerful tool to communicate visual/aesthetic impacts related to development scenarios/alternatives | Requires detailed data<br>Building design/architecture may not resemble actual development |
| | Computer visualization techniques-transportation facilities | Development computerized representations of alternative transportation facility designs | Landscape/background<br>Transportation facility design | Powerful tool to communicate visual/aesthetic impacts related to development scenarios/alternatives | Requires detailed data<br>Most appropriate for detailed project analysis, not corridor planning |

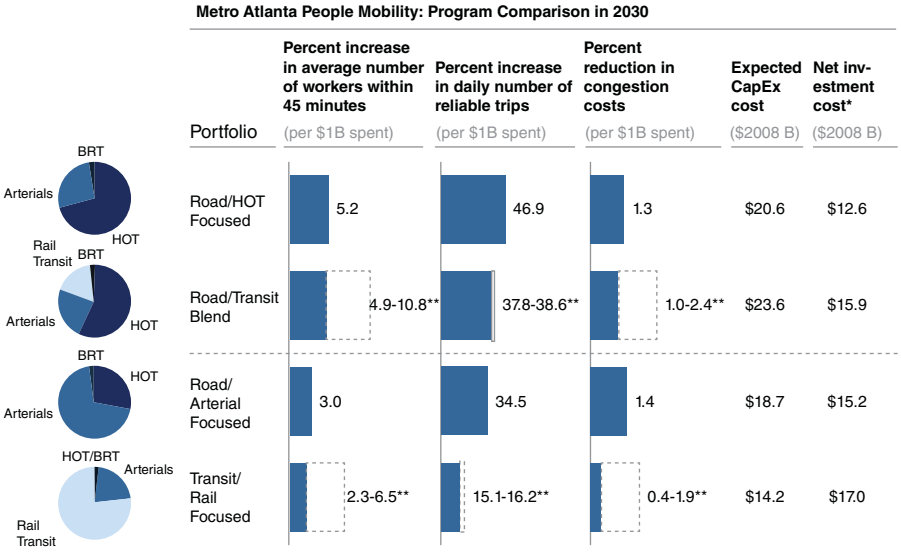
**Figure 15-16. Example Evaluation of Different Investment Portfolios, Georgia DOT**



* Includes CapEx and 20-year O&M costs, less expected revenue (e.g., tolls, fare recovery)

** Upper end of range reflects benefit of aggressive coordinated development in employment centers and enhanced demand management programs, which is more likely to occur with transit investments

Source: Georgia DOT, 2010

## H. Prioritizing Programs and Projects

The most sophisticated models, the best public involvement process, and the most comprehensive view of statewide transportation planning cannot ensure that programs and projects will be implemented. As a result, the link between system planning and the state DOT project programming process is one of the most important relationships in investment decision making. As noted earlier, the development of a statewide transportation improvement program (STIP) is a requirement of the federal government. The following examples illustrate typical approaches for prioritizing projects.

### *1. Minnesota*

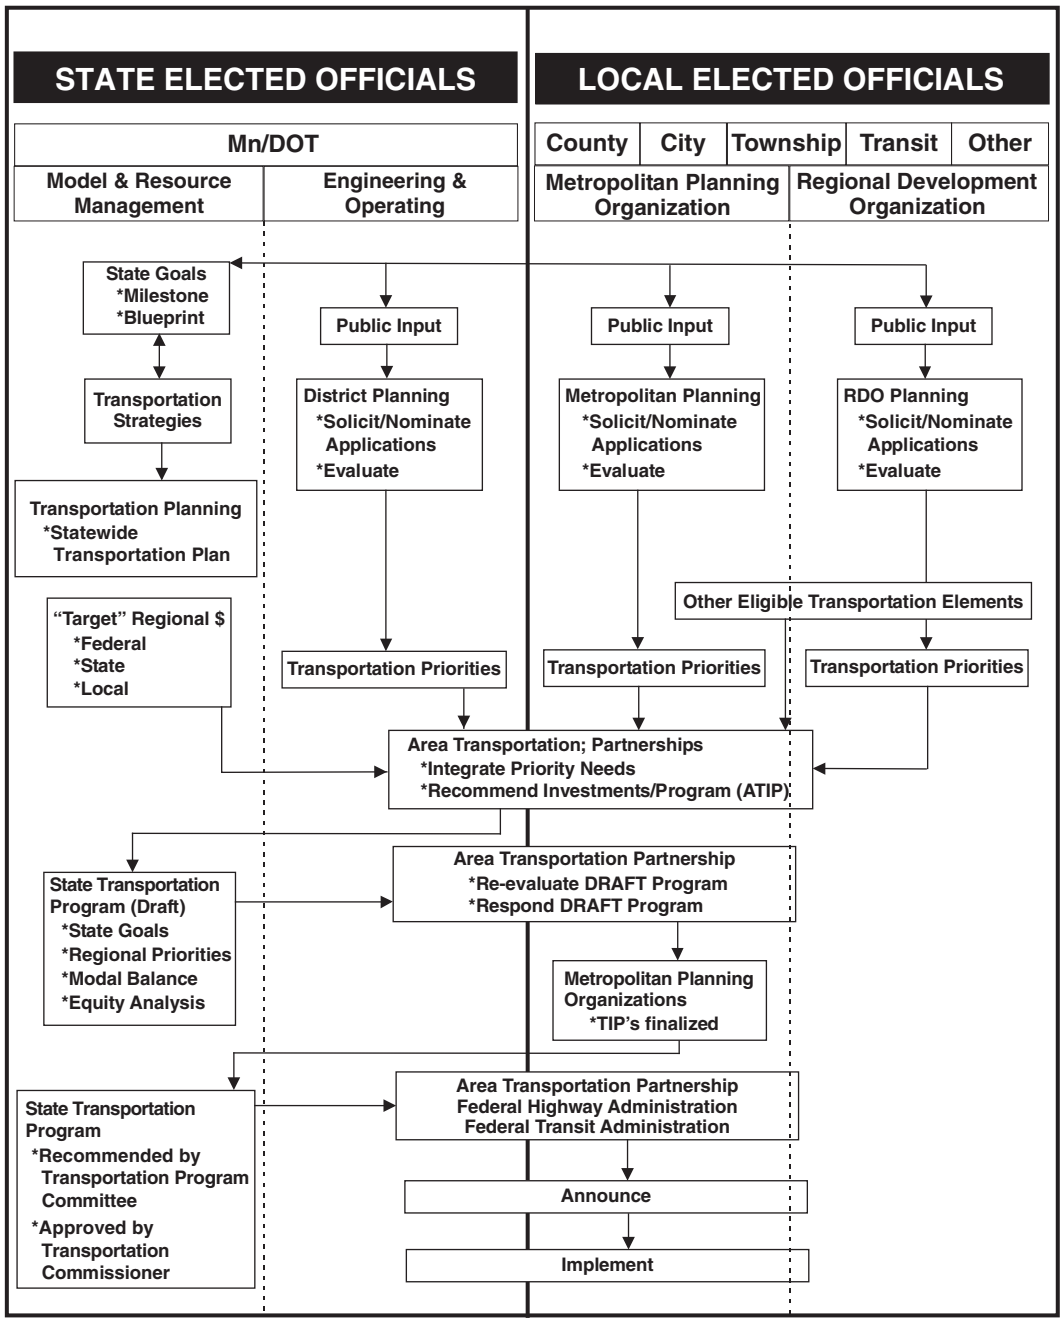
In many cases, identifying project priorities involves many different agencies and levels of government. Figure 15-17 presents Minnesota's decision-making process for transportation investment, which includes units within the DOT, as well as metropolitan planning and regional development organizations. [MnDOT, 2014] The STIP, the product of this process, is not finalized until all of the input from these many different sources is incorporated. The Area Transportation Partnerships (ATPs) shown in the figure are subregional groups enabled by MnDOT to develop a regional transportation improvement program for their area of the state. Participants include representatives from MnDOT, MPOs, Regional Development Commissions (RDCs), counties, cities, tribal governments, special interests, and the public.

One of the main purposes of the STP is to identify projects for STIP programming. The process of moving a project from the plan to the program, that is, identifying the priorities associated with individual projects and overall programs, varies from state to state. In some cases, and for specific programs, measures of effectiveness or impact indicators are used to identify projects of greatest benefit to the state. For example, the priorities for projects funded with federal safety dollars must be established using benefit-cost analysis. The performance measures and evaluation criteria established earlier in the process can also be used as input. In other cases, decision-making bodies, such as state transportation commissions, establish overall priority category priorities and choose projects that best meet these priorities.

### *2. Colorado*

The Colorado STIP is a rolling four-year plan, that is, each year a new year's worth of projects is added to the STIP as the initial year is put into construction. The Colorado Transportation Commission ultimately approves the STIP, but the process that precedes the Commission includes many other agencies and groups. Each CDOT region holds county meetings to review transportation needs and funding availability developed as part of the regional plans. After the county meetings, the CDOT region holds at least one meeting, open to the public, to discuss prioritizing projects

**Figure 15-17. Minnesota's Transportation Investment Process**



Source: MnDOT, 2014

within that region. [CDOT, 2015c] Although the process is very much a "bottom-up" process for identifying projects, the Commission still has the responsibility for deciding project priorities, and it does so by considering the following four criteria:

- *System Quality:* Maintaining the functionality and aesthetics of the existing transportation infrastructure.
- *Mobility:* Providing for the efficient movement of people, goods, and information.
- *Safety:* Reducing fatalities, injuries, and property damage for all users of the system through services and programs.
- *Program Delivery:* Providing for the successful delivery of Colorado DOT projects and services.

As noted in the plan, these specific categories and associated performance measures allow the Transportation Commission and Colorado DOT to make trade-offs to best allocate limited financial resources. In addition, Colorado relies to a large extent on substate and corridor studies (350 corridors have been identified in the state) to define transportation needs.

### *3. Vermont*

In response to state legislation, the Vermont Agency of Transportation developed a quantitative prioritization process for choosing projects in the STIP. The scoring methodology differed by project type. [VTrans, undated]

Paving Projects

- *Pavement condition index (20 points):* Weighted based on condition; more points are assigned for higher levels of deterioration.
- *Benefit/cost (60 points):* The B/C is provided by the pavement management system. Factors include optimal treatment, traffic volume, and type of traffic (trucks).
- *Regional priority (20 points):* Does the regional planning commission support the project from a local land-use and economic development perspective?

Bridges

- *Bridge condition (30 points):* Weighted based on condition of major inspected components (deck, superstructure, substructure, and culvert); more points assessed for higher levels of deterioration. The condition is determined by the most recent inspection.
- *Remaining life (10 points):* Correlates the accelerated decline in remaining life to condition.
- *Functionality (5 points):* Compares roadway alignment and existing structure width, based on roadway classification, to accepted state standards. Too narrow or poorly aligned bridges are safety hazards and can impede traffic flow.
- *Load capacity and use (15 points):* Is the structure posted or restricted? What is the inconvenience to the traveling public if the bridge is out of service? What is the average traffic use on the structure?
- *Waterway adequacy and scour susceptibility (10 points):* Are there known scour issues or concerns? Is the structure restricting the natural channel? Are channel banks well protected or vegetated?
- *Project momentum (5 points):* Points are assigned if the project has a clear right-of-way (ROW), has all environmental permits, and the design is ready and waiting for funds to become available.
- *Regional input and priority (15 points):* Does the regional planning commission support the project from a local land-use and economic development perceptive?
- *Asset benefit/cost factor (10 points):* This compares the benefit of keeping a bridge in service to the cost of construction. The "benefit" considers the traveling public by examining the traffic volume and the length of a detour if the bridge were posted.

Roadway

- *Highway system (40 points):* This factor looks at the Highway Sufficiency Rating and network designation. Interstates are held to the highest standard, followed by non-interstate primary and then off-primary roads. The Highway Sufficiency Rating considers traffic, safety, width, subsurface road structure, and more.
- *Cost per vehicle mile (20 points):* This is the project cost divided by the estimated number of miles vehicles will travel on the project. This is a relatively easy method to generate a benefit/cost ratio for comparing similar projects.

- *Regional priority (20 points):* The top regional planning commission (RPC) roadway project is assigned 20 points. The score is reduced for lower RPC priorities. Projects listed as priority #10 and lower get two points.
- *Project momentum (20 points):* This factor considers where the project is in the development process and anticipated problems such as right of way or environmental permitting.
- *Designated downtown project:* Per state law, VTrans awards 10 bonus points to the base score for projects within a designated downtown development district.

Traffic Operations (Intersection Design)

- *Intersection capacity (40 points maximum):* This factor is based on Level of Service (LOS) for the intersection and the number of intersections in the coordinated system. Projects with a lower LOS and that are part of a larger coordinated system receive higher scores for this category.
- *Accident rate (20 points maximum):* This factor is based on the critical-accident ratio for the intersection. Projects with higher critical-accident ratios receive higher scores.
- *Cost per intersection volume (20 points maximum):* This factor uses the estimated construction cost and average-annual-daily traffic through the intersection. VTrans calculates the construction cost of the project for each anticipated user through the intersection. Projects with lower costs per intersection volume receive higher scores for this category.
- *Regional input and priority (20 points maximum):* This factor is based on the ranking of projects from the RPCs/MPO. The RPCs/MPO rank the projects based on criteria they develop. Projects with higher regional rankings receive higher scores for this factor.
- *Project momentum (10 points maximum):* This factor considers: (1) where the project is in the development process, (2) anticipated problems such as right of way or environmental permitting, and (3) funding.

Transportation Alternatives

Points are awarded for transportation alternatives based on the proposal submitted by applicants.

Public Transit

Proposals are rated based on the following measures: mobility improvements, environmental benefits, operating efficiencies, project coordination, regional connectivity, local financial commitment, and sustainability of funding continuation.

Aviation

Projects for publicly owned airports are scored with the following possible points.

- Airport activity (number of operations and based aircraft) (0 to 100 points)
- Population served & local government support (0 to 24 points)
- Economic development (0 to 40 points)
- Project type (runway type, paving, navigation, etc.) (0 to 120 points)
- FAA priority & standards ranking (0 to 120 points)
- Previous federal/state funding (0 to 200 points)
- Cost/benefit for projects less than $75,000 (100 points)
- Resource impacts (0 to 40 points)
- Local interest/support (0 to 20 points)

Rail

Projects use the following criteria for scoring freight rail projects.

- *General Safety*—Safety of the rail system is critical to evaluating projects. Safety can involve bridge condition based on inspection, rail crossings, ROW, security, etc.
- *Railroad Freight Operations*—This measures the increase in ton-miles or car-miles and economic impact.
- *Railroad Passenger Operation*—Does the project increase the efficiency of the passenger rail service or expand passenger rail service and will the improvement have the potential to increase ridership?
- *Line Conditions*—Consideration is given if the project increases the Federal Railroad Administration track condition. Does the proposed project address clearance and/or weight limitations?
- *Priority Route*—Consideration is given if the project is on the of the rail priority routes based on the Statewide Rail Plan.
- *Vermont-Based Activity*—Consideration is given for carloads and passengers in Vermont and/or rail jobs created in Vermont.
- *Economic Development*—Consideration is given to projects that fit into regional economic development plans.
- *Documented Nonstate Funding Opportunities*—Does the project have a source of funding that does not require a state match?
- *Resource Impacts*—Does the project require environmental mitigation or mitigate environmental issues?
- *Regional Scope*—Consideration is given if the project increases competition, partners with other states, or improves intermodal connections.
- *Utilization of Resources*—Consideration is given if the project schedule is one year or less.

Safety

The DOT uses the Highway Safety Improvement Program (HSIP), which prioritizes safety projects in the state (see chapter 23 on transportation safety). Agency staff reviews the top 50 crash locations, and determines possible improvements. A cost/benefit analysis is conducted to determine the maximum safety improvement for limited dollars.

It is important to remember that the development of the STIP, as well as many other planning documents, must satisfy the federal and state laws and regulations that guide such development. In the United States, state DOTs can self-certify that the STIP satisfies such laws.

Chapter 7 provides an overview of methods that can be used to prioritize projects.

## I. Monitoring System and Program Performance

The political process now demands greater accountability for the use of state funds. Providing measurable and understandable performance metrics is now a critical piece of the overall plan development process. Many states are providing these metrics through quarterly report cards, dashboard measurements and program compasses designed to be outcome-oriented, customer-service focused, and legislatively responsive. The following three states have developed performance-based statewide transportation plans and are reporting on the status of the system as it relates to defined performance measures.

### *1. Michigan*

Figure 15-18 shows a very typical format for monitoring system condition and performance. The Michigan DOT has been producing such information for many years, and has found that its dissemination has been very effective at explaining to the public and key stakeholders the challenges facing the state's transportation system.

**Figure 15-18. System Performance Monitoring by the Michigan DOT**

| Measure *(Click on a measure to get more information.)* | Status | Change frorn Last Report | Change over Last 5 Year |
|---|---|---|---|
| Freeway Bridge Condition | Green | ⇔ | ↑ |
| Non-freeway Trunkline Bridge Condition | Green | ↑ | ↑ |
| Reduction of Structurally eficient Trunkline Bridges | Green | ⇔ | ↑ |
| Trunkfine Pavement Condition Based on Sufficiency | Yellow | ↓ | ⇔ |
| Trunkline Pavement Condition Based on International Roughness Index | Green | ↓ | ↑ |
| Trunkline Pavement Condition Based on Remaining Service Life | Yellow | ↓ | ↓ |
| Trunkline Railroad Crossings | Green | ⇔ | ↑ |
| Tier 1 Airport Primary Runway Pavements | Yellow | ↓ | ⇔ |
| Rural and Specialized Transit Fleet Condition | Green | ↑ | ↑ |
| Level of Intercity Passenger Rail Services | Green | ⇔ | ↑ |
| Rural Intercity Bus Access | Green | ⇔ | ⇔ |
| Level of Local Bus Transit Services | Green | ⇔ | ⇔ |
| Carpool Lot Condition | Green | ⇔ | ↑ |
| Statewide Crash Severity Reduction | Green | ↑ | ↑ |
| Trunkline Crash Severity Reduction | Yellow | ⇔ | ↑ |
| Local Roadway Crash Severity Reduction | No Standard | ↑ | ↑ |
| Safety-funded Project Return on Investment | Green | ↑ | ↑ |
| Road Agencies Serviced with Interoperable Communication Equipment | No Standard | ↑ | Not Available |
| Percentage of Program Dollars Spent on Protective Efforts | Green | ↑ | ⇔ |
| Acceptable Level of Service on (Inter-)Nationally Significant Corridors | No Standard | ⇔ | ⇔ |
| Michivan Access Expansion | Green | ⇔ | ↑ |
| Manage Traffic Incidents Timely | Green | ⇔ | Not Available |

| | |
|---|---|
| GREEN | Current status is at 90% or greater of target |
| YELLOW | Current status it between 75% and 90% of target |
| RED | Current status is less than 75% of target |

| | |
|---|---|
| ↑ | Condition Improving |
| ↓ | Condition Declining |
| ⇔ | Condition Staying About the Same |

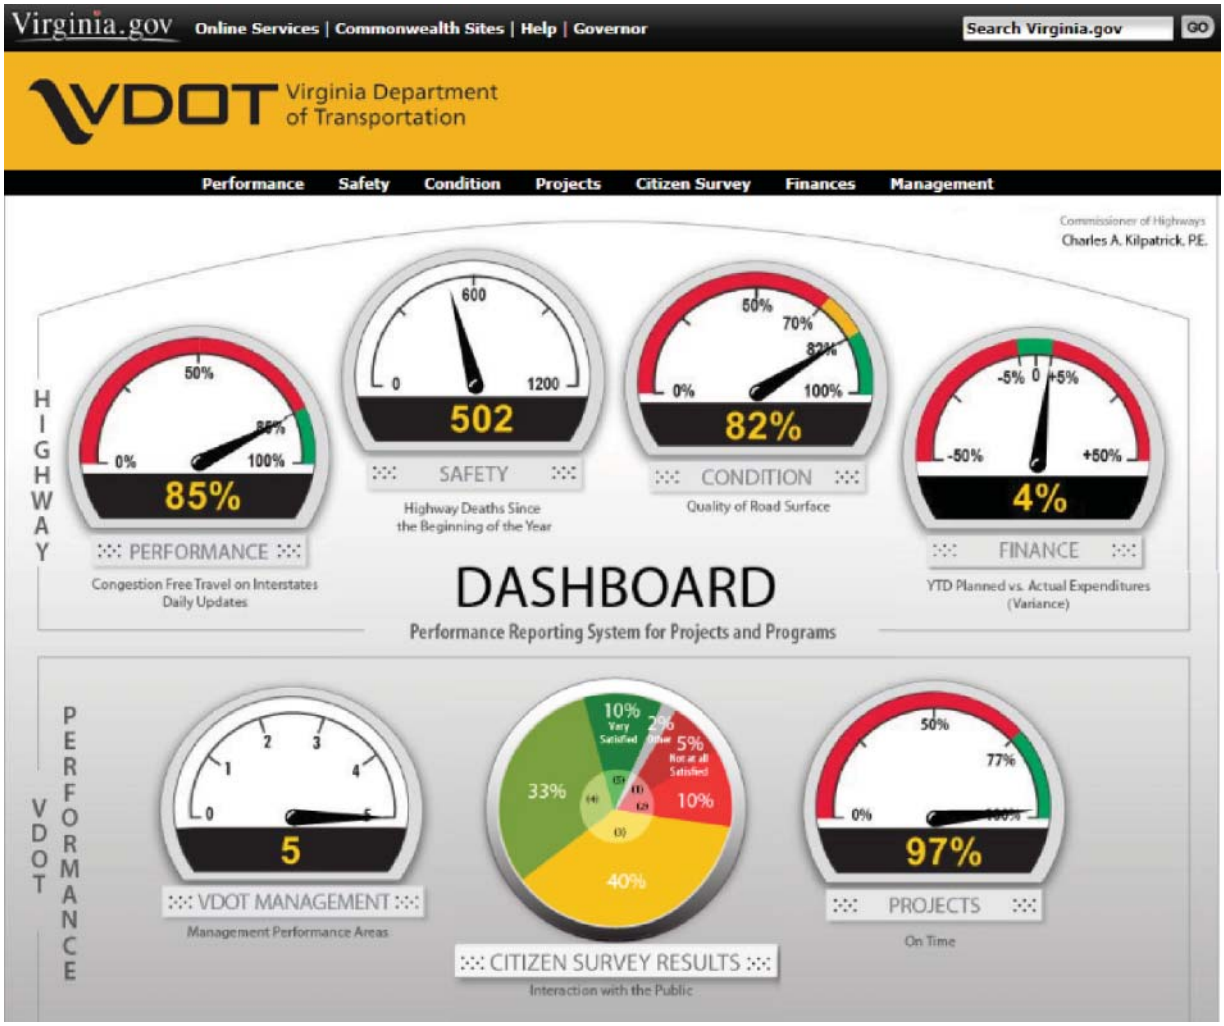
### *2. Virginia*

In response to a state government financial crisis in 2002, VDOT was charged with restoring the overall financial accountability of its programs and services. VDOT responded by providing performance data in an understandable, user-friendly way available to both the legislature and the public. Through the development of reporting documents such as a quarterly report card and a project dashboard (a simple graphical presentation of data that can be used to drill down to underlying information), and as part of the goals and recommendations in Virginia's long-range transportation plan, VDOT developed a mechanism to link financial accountability and performance goals.

The VDOT Project Dashboard is a web-based tool that provides an overview of projects and contracts for the public (see Figure 15-19). The measures included on this website are:

- Environmental compliance measures, including compliance on construction/maintenance projects and number of complaints reported by month.
- Finance measures, including forecast versus actual revenues, planned vs. actual cash balances, labor expense, and contract balances.
- Safety measures, including crash and fatality data for the past 12 months compared to the five-year average.
- Engineering measures, including performance on time for project design and advertising, and accurate estimation of project costs.
- Construction measures, including measures for on-time, on-budget performance for both active and completed construction projects.
- Maintenance measures, including percent of years' pavement resurfacing plan complete, bridge conditions, and progress toward annual maintenance spending plan goals.
- Operation measures, including access to roadway information or incidents, construction work zones, weather conditions, and traffic cameras.

**Figure 15-19. Virginia DOT's Dashboard Monitoring System**



Source: Virginia DOT, 2015b

These measures were designed to address concerns raised by the legislature and public on the accountability of VDOT in delivering programs efficiently and effectively. These measures are not multimodal, but they do address the fundamental mission of the DOT—emphasizing core values of on-time project delivery, public safety, and environmental compliance. The experience of VDOT in providing specific actions in its state-level policy plan linked to performance measures and financial accountability is not unique and reflects a new environment and focus for state DOTs.

### *3. Washington State*

One of the earliest and most extensive reporting of a state's transportation and program performance is found in the state of Washington with the DOT's *Gray Notebook*. The Gray Notebook provides annual overviews on bicycle and pedestrian safety, pavement conditions, highway maintenance, environmental compliance, tolling, and construction cost trends. Semi-annual overviews of travel time trends and freight rail, and quarterly reports on such topics as incident response, and ferries and passenger rail usage are also provided. Reports are provided on targeted projects. Figure 15-20 shows a typical page from the Gray Notebook.

## IV. STATEWIDE MODAL PLANS

The previous discussion presented statewide transportation planning primarily from the perspective of the steps necessary to prepare a statewide multimodal transportation plan. Often, however, states undertake planning that focuses on specific modes of transportation, such as rail, freight, bicycle/pedestrian, aviation, and state transit plans. In almost

**Figure 15-20. The Gray Notebook Performance Report, Washington State DOT**

| Policy goal/Performance measure | Previous period | Current period | Goal | Goal met | Five-year trend *(unless noted)* | Desired trend |
|---|---|---|---|---|---|---|
| **Safety** | | | | | | |
| Rate of **traffic fatalities** per 100 million vehicle miles traveled (VMT) statewide (Annual measure: calendar years 2012 & 2013, data for 2013 considered preliminary) | 0.77 | 0.77 | 1.00 | ✓ |  | ↓ |
| Rate of **recordable incidents** for every 100 full time WSDOT workers (Annual measure: calendar years 2013 & 2014) | 5.7 | 5.4 | 5.3 | — |  | ↓ |
| **Preservation** | | | | | | |
| Percentage of state **highway pavement** in fair or better condition by vehicle miles traveled (Annual measure: calendar years 2012 & 2013) | 91.9% | 92.6% | 90.0% | ✓ |  | ↑ |
| Percentage of **state bridges** in fair or better condition by bridge deck area (Annual measure: fiscal years 2013 & 2014) | 91.7% | 91.8% | 90.0% | ✓ | | ↑ |
| **Mobility (Congestion Relief)** | | | | | | |
| **Highways:** Average (Weekday) vehicle **hours of delay** statewide at **maximum throughput speeds**[1] (Annual measure: calendar years 2012 & 2013) | 30.9 million | 32.4 million | N/A | N/A |  | ↓ |
| **Highways:** Average **incident clearance times** for all Incident Response program responses (Calendar quarterly measure: Q3 2014 & Q4 2014) | 12.2 minutes | 13.2 minutes | N/A | N/A |  (Five-quarter trend) | ↓ |
| **Ferries:** Percentage of trips departing on time[2] (Fiscal quarterly measure: year to year Q2 FY2014 & Q2 FY2015) | 96.6% | 96.4% | 95% | ✓ | | ↑ |
| **Rail:** Amtrak Cascades on time performance[3] (Annual measure: calendar years 2012 & 2013) | 72.6% | 76.9% | 80% | — |  (Three-year trend) | ↑ |
| **Environment** | | | | | | |
| Number of WSDOT **stormwater management facilities** constructed (Annual measure: fiscal years 2013 & 2014) | 169 | 189 | N/A | N/A |  | Not applicable |
| Cumulative number of WSDOT **fish passage barrier improvements** constructed (Annual measure: calendar years 2012 & 2013) | 270 | 285 | N/A | N/A |  | ↑ |
| **Stewardship** | | | | | | |
| Cumulative number of Nickel and TPA **projects completed,** and **Percentage on time**[4] (Calendar quarterly measure: Q3 2014 & Q4 2014) | 361/ 87% | 364/ 87% | 90% on time | — |  (Five-Quarter trend) | ↑ |
| Cumulative number of Nickel and TPA **projects completed,** and **Percentage on time**[4] (Calendar quarterly measure: Q3 2014 & Q4 2014) | 361/ 91% | 364/ 91% | 90% on budget | ✓ |  (Five-Quarter trend) | ↑ |
| Variance of total project costs compared to **budget expectations**[4] (Calendar quarterly measure: Q3 2014 & Q4 2014) | under budget by 1.7% | under budget by 1.9% | on budget | ✓ |  (Five-Quarter trend) | Not applicable |

Source: Washington State DOT, 2015

every case, the steps described above are similar to those used for developing a modal plan. The modal planning process starts with some sense of what the problems and issues are. This then leads to a set of goals and objectives, the identification of performance measures, analysis and evaluation of different alternatives and options, and eventually the selection of a preferred investment strategy and/or the identification of other state actions to address the problems identified. Table 15-10 shows the type of information that is needed in a statewide rail plan, in response to a federal law requiring states to develop such a plan, the Passenger Rail Investment and Improvement Act of 2008 (PRIIA).

| Table 15-10. State Rail Plan Elements Outlined in PRIIA | |
|---|---|
| **Planning Step** | **Elements to Include** |
| Inventory | Role of rail in state's surface transportation system<br>Proposed high-speed rail corridors |
| Review of rail lines | Significant rail line segments not currently in service |
| Passenger rail service objectives | Minimum service levels for all routes |
| Transportation, economic, and environmental impacts of rail | Congestion mitigation<br>Trade and economic development<br>Air quality<br>Land use<br>Energy use<br>Community impacts |
| Long-range rail investment program | Freight capital projects with public and private benefits and correlation between the two<br>Consideration of funding |
| Public financing issues | Current capital and operating funding sources<br>Prospective capital and operating funding sources |
| Rail infrastructure issues | Reflecting consultation with all relevant stakeholders |
| Review of intermodal connections and facilities | Freight intermodal<br>Freight facilities<br>Seaports<br>Prioritized options to maximize integration of modes |
| Review of publicly funded safety and security projects | Safety, including projects funded under 23 U.S.C. Section 130 (grade-crossing protection) |
| Performance evaluation of passenger rail | Evaluation of performance<br>Possible improvements<br>Strategies to achieve improvements |
| High-speed rail plan | Compilation of high-speed rail studies<br>Funding plan for recommended corridors |
| Compliance with Section 22102 | Demonstrate qualifications under 49 U.S.C. Section 22102<br>(State has organized itself to support rail planning) |

Source: Texas DOT, 2010

Similar to statewide multimodal transportation planning, modal planning relies on the involvement of many different stakeholders in the process. Not only can stakeholders provide feedback on the different strategies that are being considered, but also much of the data needed for analysis often come from sources outside of the public domain. Private companies can often provide some of this information for planning efforts that directly affect their industry.

One of the reasons state DOTs conduct mode-specific planning is that funding categories are often mode-specific. Thus, for example, an illustration from Texas for statewide rail planning relates to the rail-specific funding sources that can be used to make improvements in the state's rail system. The same is often true for aviation, pedestrian and bicycle, and state transit planning. Even though modal plans establish funding priorities for specific types of projects, it is important that these plans be integrated into the state's multimodal transportation plan. Given the interconnectivity of a typical state's transportation system, what happens on the rail system can directly affect the highway network, such as the shifting of freight to trucks. Thus, even though a state develops plans for the major modes, the STP needs to be the point where policies and investment strategies are connected.

## V. SUMMARY—CONTINUING STATE PLANNING CHALLENGES

State transportation departments and the long-range plans they develop will continue to evolve to meet society's changing expectations. Gone are the days when the transportation engineers used their expertise to recommend solutions to mobility problems. Calls for accountability and transparency in both decision making and project implementation will only grow greater as public resources decline. As transportation planning and decision making involves more

interest groups and greater societal expectations, DOTs are being challenged to develop the necessary technology and skills to meet the demands. Some of these challenges include:

*Improving the connection between state-level transportation plans and local land-use decisions*. Traffic and economic activity at the local level drive the demand for transportation services at the regional and state level, yet land-use decisions are often made in a strictly local level. There is a growing expectation among major transportation stakeholders that transportation investments reflect more than mobility and economic development goals, but state DOTs are often ill-equipped to use their planning and programming decisions effectively to guide development, direct mode choice, or meet the needs of the disabled or walking public. By better connecting state- with regional- and local-level planning decisions, especially MPO planning activities such as data and analysis sharing, consensus on goals, and joint funding, DOTs may begin to improve this connection.

*Better links between planning and implementation.* Most states are beginning to address the need to improve plan implementation, but new techniques and analysis tools are needed. Plans must be designed from the beginning with projects that can be implemented and outcomes measured; however, some plan outcomes cannot be effectively measured because the data are not available or the DOT does not control the service. One way to better link plan recommendations and projects at the state and regional level is to use corridor plans (see chapter 17). These plans usually generate locally acceptable priorities, and focus on fairly well-defined projects.

*The freight planning challenge.* As reflected in federal legislation, freight planning is receiving increased national interest. States have a unique system planning perspective given freight movements across urban boundaries, interregional boundaries and interstate boundaries. However, the challenges of quality and timely freight data, inadequate communication between the state and freight shippers, the lack of control over intermodal/port investment decisions, and the lack of designated funding for freight planning and implementation still characterize much of the statewide freight planning activities in the United States (see chapter 22).

*Financial planning and accountability.* There continues to be a gap between the public's expectations for transportation and the willingness to financially support those expectations. States consider many interests when conducting statewide transportation planning. States often struggle with the development of a 20- or 25-year plan that must be constrained by existing resources, particularly when it can take a decade or more to actually build new facilities. In addition, states must adopt the projects developed through the MPO planning process, even when additional resources are assumed in a financially constrained MPO plan to be coming from state and federal funding programs.

In a similar fashion, the political process has required more accountability for taxpayer dollars, often demanding that measures be developed for programs that are not easily measured. Many of the performance measures required by state legislatures are driven by budgetary data and press releases rather than by meaningful measures of the service provided by the state system. As resources continue to be constrained, there is more pressure to develop alternative funding mechanisms—including public/private partnerships, joint state/local government funding agreements, and tolling options (see chapter 5). Some states continue to have issues with who controls and maintains these facilities? How are revenues collected at the local level? How are basic transportation services for the most needy being adequately and fairly provided under these arrangements?

*What does it mean to be multimodal?* For many state DOTs, a multimodal, state-level policy plan addresses overall transportation system goals for the state. The development of individual modal plans can then carry out these overall goals. The vision is multimodal, but the implementation is modal. In part, this is due to the nature of the funding available for transportation. Each modal program comes with separate modal funding, with little ability to move dollars to meet priorities. Even with comprehensively planned corridor plans at the regional level, funding is often available for the highway recommendations, but not for nonhighway recommendations. These funding arrangements are also reflected in the organization of DOTs, with each mode in a separate organizational structure managing a separate program and allocating separate funds. Many DOTs have not organized themselves to respond to a multimodal agenda.

For state department of transportation (DOT) planners, the transportation planning process has changed dramatically during the last 20 years. However, to those viewing the state transportation planning process from outside a DOT, change seems slow. No matter the perspective, both would agree that transportation planning has an important role in guiding state-level transportation investment, which in turn helps shape how people live and work. Statewide transportation planning, along with the transportation planning that occurs in metropolitan areas, will likely play an even greater role in shaping the form and function of society in the future.

# Metropolitan Transportation Planning[1]

## I. INTRODUCTION

Urbanized areas in the United States with populations of 50,000 or more are required to participate in a federally mandated transportation planning process. In many other countries and in U.S. nonmetropolitan areas, regional planning agencies (RPAs) have similar responsibilities as their urban counterparts. In the United States, the planning agency responsible for carrying out the transportation planning process in urbanized areas is called the metropolitan planning organization (MPO), which is designated by the governor of the state. The 1973 U.S. federal law that required MPOs defined them as a "forum for cooperative transportation decision making for the metropolitan area." The MPOs (and RPAs) thus provide an institutional mechanism for regional collaboration, coordination, and decision making in the provision of transportation infrastructure and services.

This chapter will focus on metropolitan transportation planning, which encompasses the communities included in an urbanized area. Urbanized areas can be quite small, such as Pascagoula, Mississippi, the smallest urbanized area in the United States with a 2010 population of 50,428 (ranked 497$^{th}$). Or they can be very large, such as the New York City region with a 2010 population of 18.4 million (ranked 1$^{st}$). Given that each urbanized area and community is unique, it is not surprising that transportation plans vary from one region to another. Most transportation plans, however, share common challenges on issues such as transportation mobility, accessibility, environmental quality, system preservation, maintenance, safety, security, and management and operations. The transportation planning process provides much-needed information and knowledge for regional and local decision makers in dealing with these issues.

Although federal law and regulations require the MPO planning process to consider topics of national interest, the process must also be responsive to community interests and local laws. The regional transportation planning process is valuable because it integrates and links the planning efforts of communities in a region, such as local land-use plans, economic development strategies, and environmental/natural resource plans. Transportation planning must also take into account other laws such as state and local land-use laws, the Clean Air Act, the Americans with Disabilities Act (ADA), and Title VI of the Civil Rights Act of 1964 (see chapter 1).

This chapter presents an overview of the metropolitan transportation planning process and associated requirements. The next section provides an historical overview of how metropolitan transportation planning has evolved. Various aspects of this planning process are discussed, including organization and institutional aspects, essential elements of the planning process, and the technical tools required for successful planning. The key concepts presented provide a better understanding of the complexities of the planning environment. The chapter also describes how metropolitan areas create transportation plans as well as the role that planners play in the process. The reader should note that much of this chapter will focus on medium to large metropolitan areas, defined as urbanized areas over 250,000 population. Those interested in transportation planning for smaller urbanized areas are referred to chapter 18 on local and activity center planning.

## II. LEGISLATIVE CONTEXT FOR U.S. METROPOLITAN TRANSPORTATION PLANNING

The form and substance of transportation planning in a typical metropolitan area has been influenced by many factors, including the history of planning, the relative roles of state and local government agencies, the planning culture

[1]The original chapter in Volume 3 of this handbook was written by Jane Hayse, Director for Livable Communities, Atlanta Regional Commission, retired. Changes made to this updated chapter are solely the responsibility of the editor.

of the region, and the types and perceived magnitudes of the transportation problems being faced. It is thus difficult to present a generalized transportation planning process describing all such efforts in every metropolitan area. One influence in particular, however, has provided a strong impetus for transportation planning in the United States—at least over the past 50 years—and has resulted in some commonality among metropolitan and regional planning processes. Perhaps more than any other influence, the federal government has had the greatest impact on the structure and policy context for transportation planning as practiced in the United States. The national governments of other countries have varying influences over transportation planning in their countries as well—in France, for example, the national government plays a strong role, whereas in Canada the major influence is at the metropolitan and provincial levels.

It is beyond the scope of this chapter to provide an exhaustive listing of all federal laws and regulations that have influenced metropolitan transportation planning (see Weiner [2010], chapter 1 and chapter 4). However, several federal laws stand out with respect to their impact on the substance and style of today's transportation planning process in U.S. metropolitan areas. Some terminology and language embodied in 1960s legislation, for example, is still commonly used today. Thus, it is important to begin this chapter with an understanding of the key themes and contributions of these benchmark laws in transportation planning history.

## A. The Early Years

The motor vehicle and its need for reliable roads has had a profound impact on the transportation policy landscape of the United States and most other nations. With the rapid motorization of society in the early 1900s, Congress recognized the need to support the creation of roads that served a "federal purpose." In most cases, this federal purpose focused on rural roads (postal routes, for example) and highways connecting cities. City roads or highways that served primarily urban areas were considered the responsibility of city governments.

In anticipation of post-World War II population growth and needed support for national economic recovery, Congress passed the Federal-Aid Highway Act of 1944, which authorized the construction of a national highway system. This act together with the Federal Highway Revenue Act of 1956 was the beginning of the National System of Interstate and Defense Highways (the interstate highway network) and the use of federal gas taxes to pay for it. This era of interstate highway construction fostered a growing interest in transportation planning (especially statewide transportation planning), and particularly on the need to plan and design major intercity highways to meet future demand.

Of significance to metropolitan transportation planning, the state highway departments' early focus in constructing the interstate system was primarily on rural connections between major cities. Most of the urban portions of this system were not designed and constructed until the late 1950s and early 1960s. For many cities, the move toward constructing urban interstate highways caused growing concern about the corresponding impact on the city and its residents. One response to this concern was to provide more support for metropolitan-level transportation planning.

## B. Toward a Balanced Transportation System

Almost all of the federal interest in transportation during the 1950s and 1960s was on highways; very little policy interest was given to public transit or other modes such as walking or bicycling, which were viewed strictly as a local issue. Beginning with the Housing Act of 1961, however, small-interest federal loans were made available to city transit systems that were on the verge of disappearing given low ridership and competition from the automobile. It was not until the Federal-Aid Highway Act of 1962 that the concept of a multimodal transportation system, and thus the need for multimodal transportation planning (then called a balanced transportation system), was first established. This 1962 act contained significant provisions still in effect today. Federal aid was provided to those areas with a population of 50,000 or more to establish "a continuing and comprehensive transportation planning process carried out cooperatively by state and local communities." This 3C (continuing, cooperative, and comprehensive) process still underpins metropolitan transportation planning in the United States today. [FHWA and FTA, 2007]

The act defined *comprehensive* to include the following factors:

- Economic factors affecting development
- Population

- Land use
- Transportation facilities including those for mass transportation
- Travel patterns
- Terminal and transfer facilities
- Traffic control features
- Zoning ordinances, subdivision regulations, building codes, etc.
- Financial resources
- Social and community-value factors, such as preservation of open space, parks, and recreational facilities; preservation of historical sites and buildings; environmental amenities; and aesthetics

*Cooperative* was defined as cooperation among federal, state, and local government agencies and among units within each level of government. *Continuing* was defined as requiring periodic reevaluation and updating of transportation plans.

The 1962 act was followed by the Urban Mass Transportation Act of 1964, which established the first formal program for federal assistance to transit agencies with matching funds provided on a two-third federal/one-third local share basis. Through this act, transit planning was further integrated into metropolitan transportation planning and decision making, and represented a first step to make multimodal planning truly consider more than the just the automobile mode in the planning process. The Federal-Aid Highway Act of 1970 continued to reinforce the need for metropolitan transportation planning by stating that "no highway project was to be constructed in any urban area of 50,000 population or more unless the responsible local officials of such urban area … have been consulted and their views considered with respect to the corridor, the location, and the design of the project." This act began an evolution in transportation planning in which metropolitan and local officials have increasingly received more authority over transportation priorities, requiring state transportation agencies to share what once was their sole responsibility over highway construction.

By the mid-1970s the need for metropolitan transportation planning had been clearly articulated in federal and many state laws. The Federal Highway Act of 1973 formally created MPOs in urbanized areas with populations of 50,000 or more to be funded through the federal-aid transportation program. The act increased the role of local officials in the transportation decision-making process, allowing them to choose projects with concurrence from the state transportation agencies. Transportation projects funded with federal funds now had to come from the 3C planning process as defined in the 1962 act. The 1973 act also allowed transit projects to be funded from the Highway Trust Fund and increased the federal share of such projects to 80 percent.

In 1975, the Federal Highway Administration (FHWA) and the Urban Mass Transit Administration (UMTA), now the Federal Transit Administration (FTA), created joint transportation planning regulations for metropolitan areas. A long-range transportation plan and a transportation improvement program (TIP) were now a regulatory requirement as was the development of a unified plan work program (UPWP) for areas with populations of 200,000 or more. Transportation planning based on the 3C process continued to be reinforced.

## C. The Modern Era

Significant changes in the focus and substance of metropolitan transportation planning occurred during the 1990s. This occurred for many reasons. The interstate highway system, begun in 1956, was nearing completion and federal attention turned to what type of program should replace it. In particular, federal interest began to focus on how to better improve existing transportation system performance, rather than expand capacity. More emphasis was placed on multimodal solutions. In addition, policy interest continued to link transportation decision making to issues such as economic development and air quality. The Clean Air Act Amendments (CAAA) of 1990, for example, greatly strengthened the relationship between metropolitan transportation planning and Clean Air Act requirements. States were required to develop state implementation plans (SIPs) reflecting the severity of an urbanized area's nonattainment of the National Ambient Air Quality Standards (NAAQS). MPOs had to demonstrate that their long-range transportation plans and TIPs conformed to the SIPs. This conformity was determined by forecasting mobile source emissions

over the life of the plan and the TIP, and showing that the planned projects did not worsen air quality. Significant financial sanctions were included in the legislation if a metropolitan area was unable to create a conforming plan.

From a transportation perspective, the landmark transportation legislation of the 1990s was undoubtedly the Intermodal Surface Transportation Efficiency Act of 1991 (ISTEA). The legislation stated that it was in the "national interest to encourage and promote the development of transportation systems embracing various modes of transportation in a manner which will efficiently maximize mobility of people and goods within and through urbanized areas and minimize transportation-related fuel consumption and air pollution." ISTEA's vision was for an integrated planning process, taking into account local plans, financial resources, and expectations. The requirements of ISTEA provided a closer linkage between the 3C process, the Clean Air Act, and statewide planning.

For metropolitan transportation planning, ISTEA called for:

- A proactive and inclusive public involvement process.
- Consideration of specific planning factors to ensure that the transportation planning process reflected a variety of issues and concerns, such as land-use planning, energy conservation, environmental management, and major investment studies to address significant transportation problems in a corridor or subarea that might involve the use of federal funds (the requirement for a major investment study was later rescinded in the Transportation Equity Act for the 21st Century (TEA-21)).
- Development and implementation of management systems including: congestion management, intermodal management, pavement management, bridge management, safety management, public transportation facilities and operations management systems (some later rescinded or made optional).
- Development of financial plans for implementing the transportation plan and TIP.
- Assurance that the transportation plan and TIP conform to the SIP pursuant to the standards of the CAAA.

ISTEA emphasized multimodal solutions, which included both people and goods movement along with an ability to "flex" federal funds from one program category to another based on the particular metropolitan area's needs. For the first time, MPOs were required to financially constrain their long-range plans and TIPs; that is, the number of projects in a plan was limited to those for which funds were reasonably expected to be available from federal, state, and local sources. Other requirements included: The long-range plan had to be at least 20 years in duration, the TIP had to be updated at least every two years, and it had to cover a minimum three-year timeframe. See [Lane and Waldheim, 2011] for an overview of the practices MPOs use in updating the TIP.

As noted above, ISTEA identified specific factors that were to be considered as part of the transportation planning process. The factors, arrayed in three general groupings, were:

**Mobility and access for people and goods**

- International border crossings and the promotion of access to critical areas and activities.
- Road connectivity from inside to outside of metropolitan areas.
- Enhancement of efficient freight movement.
- Expansion and enhancement of transit services and use.

**System performance and preservation**

- Congestion relief and prevention.
- Preservation and efficient use of existing transportation facilities.
- Transportation needs identified through the implementation of management systems.
- Preservation of rights-of-way.
- The use of life-cycle costs in the design and engineering of bridges.

**Environment and quality of life**

- Overall social, economic, energy, and environmental effects of transportation decisions.
- Consistency of planning with energy conservation measures.
- Relationships between transportation and short- and long-term land-use planning.
- Programming of expenditures on transportation enhancement activities.
- Capital investments that increase transit system security.

The actual process of how MPOs considered these factors varied from one locale to another and required an integration of different issues at all levels of planning. Long-range plans, for example, had to be developed with significant input from the public and be coordinated with transportation providers, such as regional airport managers, ports, freight carriers, and others. Input into the planning process could occur through formal public hearings, access to public records, a proactive and open process of public engagement, and interagency consultation for air quality and conformity issues.

MPOs with populations greater than 200,000, designated as *transportation management areas (TMAs),* had additional requirements. These MPOs were required to develop a congestion management system (CMS) to provide ongoing "information on the performance of the transportation system and on alternative strategies to alleviate congestion and enhance mobility." [USDOT, 1995] Most importantly, the CMS was to emphasize the management of existing facilities through the use of non-single-occupant vehicle capacity-adding improvements. Solutions such as regional traffic management using traffic management centers and travel demand reduction programs were to be considered. The CMS was to provide for a continuous program of data collection and system monitoring.

The next major federal law affecting transportation planning was the Transportation Equity Act for the 21st Century (TEA-21) passed in 1998. TEA-21 reduced the ISTEA planning factors to seven:

1) Support the economic vitality of the metropolitan area, particularly by enhancing global competitiveness, productivity, and efficiency.
2) Increase the safety and security of the transportation system for motorized and nonmotorized users.
3) Increase the accessibility and mobility options available to people and freight.
4) Protect and enhance the environment, promote energy conservation and improve the quality of life.
5) Enhance the integration and connectivity of the transportation system, across and between modes, for people and freight.
6) Promote efficient system management and operation.
7) Emphasize the preservation of the existing system.

The Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU), signed into law in 2005, changed the timelines for producing long-range plans and TIPs. In air quality nonattainment and maintenance areas, the long-range transportation plan was to be adopted every 4 years, while in attainment areas the time period remained 5 years. The plan still had to have at least a 20-year time horizon. For TIPs, the timeline changed to an adoption of at least every 4 years, with the TIP having at least 4 years of projects and strategies included.

Several TEA-21 planning factors were revised. The most significant difference between TEA-21 and SAFETEA-LU planning factors was the separation of safety and security into two distinct factors. This change reflected the concerns for security due to natural disasters and terrorist threats. In addition, the environmental factor was modified to include greater consistency between transportation plans and economic growth. SAFETEA-LU further emphasized the importance of public engagement in the planning process by requiring MPOs to produce a public participation plan, use visualization techniques as part of the outreach efforts, and make plans readily available electronically to the general public.

## D. Era of Performance-Oriented Decision Making

The Moving Ahead for Progress in the 21st Century (MAP-21) law, passed in 2012, introduced a significant new component into metropolitan transportation planning. The federal government required each MPO (and state transportation agency, see chapter 15) to develop and use a performance-based planning process. Specifically, each MPO was required to:

- Establish and use a performance-based approach to transportation decision making and the development of transportation plans.
- Establish performance targets that are consistent with national goals and performance management measures, and coordinated with state and local public transportation providers.
- Integrate into the metropolitan transportation planning process other performance-based transportation plans or processes.
- Include officials of public agencies that administer or operate public transportation systems in the structure of the MPO.
- Include in the long-range transportation plan a description of the performance measures and performance targets used in assessing the performance of the transportation system.
- Include in the plan a system performance report and subsequent updates evaluating the condition and performance of the transportation system with respect to the established performance targets.
- Use multiple scenarios during the development of the plan if so desired.
- Include in the TIP a description of the anticipated effect of the TIP toward achieving the performance targets established in the plan, linking investment priorities to the performance targets.

Performance-based planning had been an important trend in transportation planning since the early 1990s when ISTEA mandated the creation of management systems to support investment decisions. Today, updating transportation plans partially means integrating performance measures into the planning process and the document itself. In the future, the plans will be reporting on the progress made in achieving the performance targets.

The Fixing America's Surface Transportation (FAST) Act of 2015 reinforced the focus on performance-based planning for MPOs. Other notable requirements from this law included:

- Metropolitan transportation plans and TIPs should provide for facilities that enable an intermodal transportation system, including pedestrian and bicycle facilities, facilities that support intercity transportation (including intercity buses, intercity bus facilities, and commuter vanpool providers), and the identification of public transportation facilities.
- The plan must include consideration of the role that intercity buses may play in reducing congestion, pollution, and energy consumption in a cost-effective manner; and strategies and investments that preserve and enhance intercity bus systems (including those that are privately owned and operated).
- Representatives of a transit provider are provided equal authority as other MPO officials in official MPO business.
- Tourism and the reduction of risk of natural disasters should be considered as part of the transportation planning process. The scope of the planning process should include improving transportation system resiliency and reliability, reducing (or mitigating) the stormwater impacts of surface transportation, and enhancing travel and tourism.
- Public ports and certain private providers of transportation, including intercity bus operators and employer-based commuting programs must be a "reasonable" opportunity to comment on the transportation plan.
- MPOs that serve a transportation management area (TMA as defined by the Environmental Protection Agency) are allowed to prepare a congestion management plan (distinct from the congestion management process) that will be considered in the MPO's transportation improvement program. Any such plan must

include *regional goals* for reducing peak hour vehicle miles traveled and improving transportation connections, must identify *existing services and programs* that support access to jobs in the region, and must identify *proposed projects and programs* to reduce congestion and increase job access opportunities (emphasis added).

## III. INSTITUTIONAL STRUCTURE FOR METROPOLITAN TRANSPORTATION PLANNING

Transportation plans represent a blueprint for effective transportation investment in study areas. Because future development patterns and the characteristics of an area's transportation system are the result of numerous decisions by public officials, private companies, and individuals, it is important to provide a forum for discussion and debate on the appropriate future for the area (see chapter 3 on land use and urban design). The process of developing a transportation plan provides better information for decision makers, as well as opportunities for input from numerous groups and individuals who have a stake in the future of their community.

Because the transportation plan is the result of a collaborative process, many contribute to its development through the MPO structure. Key contributors include regional agencies, local government(s), advocacy groups, private sector representatives, transit operators, federal agencies, tribal nations, state agencies, professional associations, and the public. The role of the transportation planner in this institutional environment is particularly important. The planner must not only be able to conduct technical analysis, but also understand the needs of the stakeholders and how to convey key concepts to those not well-versed in technical problem-solving approaches.

### A. Core Characteristics of an MPO

Although the characteristics of MPOs reflect the varying requirements and circumstances of individual states, there are some common responsibilities. According to federal guidance, each MPO should:

- Establish and manage a fair and impartial setting for effective regional decision making in the metropolitan area.
- Evaluate transportation alternatives, scaled to the size and complexity of the region, to the nature of its transportation issues, and to the realistically available options.
- Develop and update a long-range transportation plan for the metropolitan area covering a planning horizon of at least 20 years that fosters: (1) mobility and access for people and goods, (2) efficient system performance and preservation, and (3) quality of life.
- Develop a TIP based on the long-range transportation plan designed to serve the area's goals using budget, regulations, operations, management, and financing tools.
- Involve the public and all significantly affected subgroups. [FHWA, 1999]

Federal regulations spell out the basic requirements for MPOs, and several key characteristics are important to note. The MPO is a metropolitan area's transportation policy-making and planning body and must include representatives of local, state, and federal government agencies and of other transportation authorities. The MPO must ensure that federal spending on a transportation program occurs through the 3C process. The MPO is initially designated by the state's governor and the local units of government through a formal agreement. Although different organizational arrangements can be made to host this process, at a minimum, the basic structure should include a policy board and a defined planning area boundary.

#### *1. MPO Policy Boards*

The MPO can be a stand-alone organization, a council of governments, a unit within a city or county government, or a separately elected body. The following examples show the often complex nature of MPO decision making.

**Stand-Alone Agency, Members Appointed.** The Metropolitan Transportation Commission (MTC), the MPO for the San Francisco, California, metropolitan area is a stand-alone organization. Of the 21-member policy board, 16 commissioners are appointed directly by local elected officials. The two most populous counties, Alameda and Santa Clara Counties, each have three representatives on the commission. The county board of supervisors selects one member; the mayors of the cities within the county collectively appoint another; and the mayors of the biggest

cities in these two counties—Oakland in Alameda County and San Jose in Santa Clara County—each appoint a representative. The city and county of San Francisco are represented by two members, one appointed by the county board of supervisors and the other by the mayor. San Mateo County and Contra Costa County each have two representatives on the commission, with the county's board of supervisors selecting one representative, and the mayors of the cities within that county appointing another. The four northern counties of Marin, Napa, Solano, and Sonoma Counties each appoint one commissioner; and two voting members represent regional agencies—the Association of Bay Area Governments (ABAG) and the Bay Conservation and Development Commission (BCDC). Finally, three nonvoting members represent federal and state transportation agencies and the U.S. Department of Housing and Urban Development. [MTC, 2015]

Another stand-alone agency example is the Metropolitan Council ("council") for the Minneapolis-Saint Paul, Minnesota, metropolitan region. Created in 1967, the council, in conjunction with its Transportation Advisory Board as further detailed below, is the designated MPO for the seven-county Twin Cities area, which covers seven counties and 180+ communities. The council has 17 members, all appointed by the governor and confirmed by the state senate. The 17 consist of the chairperson (serving at large) and 16 members each representing individual geographic districts.

Because the council is an appointed body and not elected, a Transportation Advisory Board (TAB) was considered necessary to meet the requirements of the federal law requiring the governing bodies of all MPOs to include local elected officials as part of the decision-making process. The TAB consists of 33 members: ten elected city officials, one member from each county board in the metropolitan area (for a total of 17 [51%] elected officials), the commissioner of the Minnesota Department of Transportation, the commissioner of the Pollution Control Agency, one member of the Metropolitan Airports Commission, one person appointed by the council to represent nonmotorized transportation, one member representing the freight transportation industry, two members representing public transit, one citizen representative from each council district (for a total of eight), and one council member. The TAB chair is appointed by the council from among the 33 members (more information can be found at http://metrocouncil.org/Transportation/Publications-And-Resources/Transportation-Planning-and-Programming-Guide-2013.aspx).

The council fills a regional planning role, developing a long-range comprehensive development guide for the metropolitan area along with system plans for transportation, aviation, wastewater and water resources, and regional parks. Beyond its planning functions, the council also fills an operational role. It owns and operates much of the transit system, operating over 900 buses across almost 140 routes (95% of the bus trips in the region), plus two light rail lines, and a commuter rail line. It operates eight regional wastewater treatment plants, serving 108 of the region's communities, processing 250 million gallons of wastewater daily. It coordinates and helps fund 53 regional parks and park reserves covering 54,000 acres and 340 miles of regional trails.

**Stand-Alone Agency, Members Elected.** The MPO can also be a stand-alone elected body. The MPO in Portland, Oregon, is such an example. Known as Metro, the organization is governed by a council president elected regionwide and six councilors elected by district. The Metro council president and council members focus on matters of regional concern. The Metro council establishes policies for, and oversees the operation of, Metro's programs and functions. It develops long-range plans and ensures the financial integrity of Metro by adopting an annual budget and establishing fees and other revenue measures. Importantly, because of state enabling legislation, Metro has more powers on land-use management than a typical MPO in other parts of the country. [Portland Metro, 2015]

**Council of Government.** Many MPOs are part of a council of governments (COG) or a regional development organization, such as the Atlanta Regional Commission (ARC) in Atlanta, Georgia, or the North Central Texas Council of Governments (NCTCOG) in Dallas-Ft. Worth, Texas. ARC's Policy Board includes:

- Each county commission chairman in the region.
- One mayor from each county (except Fulton County) chosen by a caucus of mayors from each county.
- A mayor from the northern half of Fulton County elected by a majority vote of the mayors of all municipalities located within the northern half of Fulton County, and the mayor of a municipality within the southern half of Fulton County elected by a majority of the mayors of all municipalities located within the southern half of Fulton County.
- The mayor of the city of Atlanta.

- The president, presiding officer, or a member of the City Council from the city of Atlanta, elected by a majority vote of the members of the City Council.
- A resident from each of the ARC districts, elected by the public members of the Board. Members at large may hold no elective or appointed public office nor be employed by any of the political subdivisions of the area. The total number of members at large is fifteen (15).
- If the commissioner of the Georgia Department of Community Affairs determines that an additional member or members of the ARC board are necessary to comply with applicable laws or regulations, the board may elect such additional member(s), who shall be nonvoting. [ARC, 2015]

In the Dallas-Ft. Worth region, the MPO is housed in the region's Council of Governments. However, the policy committee, known as the Regional Transportation Council, is an independent transportation policy body for the MPO. As of March, 2016, NCTCOG had 238 member governments including 16 counties, numerous cities, school districts, and special districts. Each member government appoints a COG voting representative from its governing body. These voting representatives make up the General Assembly, which annually elects the Executive Board. The Executive Board, composed of 13 locally elected officials, is the policy-making body for all activities undertaken by the Council of Governments, including program activities and decisions, regional plans, and fiscal and budgetary policies. [NCTCOG, 2015]

**Existing Government Agency.** The MPO can be hosted within an existing city or county government, such as the Metropolitan Planning Commission (MPC) in Savannah, Georgia. The MPC is a joint planning agency for the city of Savannah and Chatham County. Each governmental body appoints seven members to the policy board. Two of these members are the city and county managers. These 14 members serve without pay and represent government, private enterprise, and citizens' interest groups. [MPC, 2015]

As illustrated by the above examples, MPO policy board membership varies based on the type of organization. MPOs strive for balanced representation on their decision-making body because it provides the greatest level of support for transportation investment decisions. This balance often is represented geographically, governmentally, and by sector (public and private sector representatives).

### *2. MPO Committees*

Most MPOs have an established committee structure for their decision-making processes. Committees often develop and comment on proposed policies and plans. Typically, an MPO will have a technical committee made up of local public works or planning staffs, transit agency staff, and state DOT staff. In addition, many MPOs have a citizen advisory committee(s) to obtain public review and comment on MPO products. Most MPOs, and particularly large agencies, also rely on advisory committees of interested citizens, local experts, and academicians for a variety of technical and policy issues. Examples include committees that focus on environmental justice, bicycle and pedestrian movement, freight, and/or a travel demand modeling user group.

The ARC, for example, heavily relies on its planning team structure to provide input into policies and strategies for its long-range plan development. Besides the Executive Committee, the ARC has the following technical committees: Aging Advisory Committee, Aging and Health Resources Committee, Budget Audit Review, Strategic Relations Committee, Community Resources Committee, Land Use Coordinating Committee, Transportation and Air Quality Committee, Transportation Coordinating Committee, and the Regional Transit Committee.

### *3. MPO Professional Staff and Planning Partners*

Just as the MPO boards differ in composition, MPO staffs vary as well in that they may be county or city staff or employed by a council of governments. Most importantly, the MPO staff is responsible for providing information and technical support to board members and advisory committees. They are responsible for preparing documents and managing the planning process. This includes fostering interagency consultation and facilitating public input and feedback.

Managing the planning process is a critical function of the MPO staff because the process is designed to foster the involvement of many stakeholders. Because most MPOs are not implementing agencies, it is important that they build strong relationships with the state DOT, regional transit agencies, and toll authorities, as well as with other transportation organizations responsible for constructing capital projects and operating the transportation system.

No single agency has the responsibility for constructing, operating, and maintaining the entire transportation system. The MPO must work with all responsible agencies and the public to maintain an effective 3C planning process.

Two professional organizations provide good information on the latest activities of MPOs in the United States—the Association of Metropolitan Planning Organizations (AMPO) (http://www.ampo.org) and the National Association of Regional Councils (NARC) (http://narc.org).

## B. MPO Planning Products

The metropolitan transportation planning process produces information in many different forms. For example, MPOs often undertake subarea or corridor studies focusing on the transportation needs in a particular part of the metropolitan area. They might undertake studies on topical issues, for example, studies on freight movement, pedestrian and bicycle flows, the aging of the population, and growth management policies. In many cases, MPOs participate in environmental studies for individual projects. Most MPOs also have extensive public outreach efforts that disseminate information on the region's transportation system and possible improvement strategies. There are, however, several work products that must be produced by the MPO to satisfy federal guidelines and which are, therefore, common across all MPOs in the United States. These include the unified planning work program (UPWP), long-range transportation plan (LRTP), the TIP, and the annual listing of obligated projects. In addition, there are several other mandatory requirements that are discussed in this section.

### *1. Unified Planning Work Program (UPWP)*

The MPO is required to develop a UPWP every year. This work program not only details the annual work activities of the MPO, but also captures the planning work conducted by the metropolitan area's transportation planning partners, such as transit authorities, local governments, and the state DOT. The UPWP is meant to be a compilation of all transportation planning work conducted under the 3C planning process.

Metropolitan areas designated as transportation management areas (TMAs) are required to have more detail in their UPWPs than non-TMA agencies. Typical UPWPs include:

- Planning tasks and studies to be conducted during the year.
- All federally funded studies and other relevant studies being carried out by state and local governments, regardless of funding source.
- Identification of funding sources for each work task.
- A schedule of activities.
- Agency responsibility for each task or study.

The UPWP is approved by the MPO policy board each year. State DOTs may submit a simplified version in their required statewide planning work program. Most MPOs post the UPWP on their website, which thus becomes a good source of information of the MPO's program of work for the near future.

### *2. Long-Range Transportation Plan (LRTP)*

As noted earlier, the LRTP forms the basis for transportation investment decisions in a metropolitan area. It must have a planning horizon of at least 20 years and be updated at least every 5 years (every 4 years for air quality nonattainment areas). An important aspect of the plan is to articulate the vision for the region through policies and objectives. This vision denotes the link between transportation and regional land use, economic development, housing, and employment patterns. The plan should identify the performance measures used to assess system performance and the evaluation criteria used to determine the effectiveness of individual projects and strategies. The plan must also be "financially feasible" meaning that there are sufficient funds for a project to be planned, built, operated, and maintained throughout the life of the plan.

The development of the LRTP should provide many opportunities for public comment and outreach. More detail on the elements of the long-range plan will be presented later in this chapter.

### *3. Transportation Improvement Program (TIP)*

While the LRTP articulates the region's vision and identifies possible improvement strategies, the TIP details how the highest priority projects will advance over the next four years. It also programs federal funds over the short-range to reflect the priorities of the plan. Projects cannot receive federal funds unless they appear in the TIP because the TIP is the instrument for matching strategies or projects with available funds.

In addition, the TIP must also be financially constrained by year. For air quality nonattainment areas, only projects with available or committed funding can appear in the first two years of the TIP. Thus, it is important that the TIP represent a staged, multi-year multimodal program of projects for the metropolitan area. It must also reflect public comment. The TIP also differs from the long-range plan because it must be approved by the governor and be incorporated into the statewide transportation improvement program (STIP) developed by the state department of transportation (DOT). The development of the TIP will be described in more detail later in this chapter.

### *4. Annual Listing of Obligated Projects*

MPOs produce an annual listing of projects "for which federal funds have been obligated in the preceding year." [FHWA and FTA, 2007] This list "shall be published or otherwise made available by the metropolitan planning organization for public review. The listing shall be consistent with the categories identified in the transportation improvement program." Federal law clarified and reinforced this requirement by stating that the annual listing "shall be a cooperative effort of the state, transit operator, and MPO" and "shall include investments in pedestrian walkways and bicycle transportation facilities for which federal funds have been obligated in the preceding year."

### *5. Transportation Management Area (TMA) Requirements*

Transportation management areas receive a guaranteed suballocation of federal funding. The MPO rather than the state DOT selects projects for the TIP. TMAs, however, must also meet several additional requirements. As described in later sections, these requirements further enhance and add to the complexity of the planning process in these areas.

## IV. THE TRANSPORTATION PLANNING PROCESS

As noted earlier, a typical transportation planning program includes a variety of planning activities that could result in many different products. The LRTP, however, is one of the most important products of this program. Given typical differences in metropolitan areas, the regional transportation plan becomes a unique document oriented to the needs and aspirations of a particular metropolitan area. A successful plan provides an important foundation for future planning activities, such as problem identification and study boundary definition for corridor studies and major modal system plans. The long-range plan should also address broader regional issues that influence transportation, such as land use and economic development.

The framework for the transportation planning process described in chapter 1 and shown in Figure 1-1 presented the major steps in metropolitan transportation planning. The following sections are organized by the major planning steps outlined in this figure.

## A. Basic Principles

At the outset of any transportation planning activity, the planner must be sensitive to the following issues:

*Uncertainty in predicting the future*. Many factors, often outside the control of transportation agencies, affect the demand for transportation and the performance of the transportation system. This is especially true when looking 20 to 25 years into the future (and more so with longer time horizons). Uncertainty is inherent in such questions as: What vehicle and/or fuel technology changes could significantly influence travel behavior during the next several decades? What will be the cost of fuel in 20 years? Are population and employment forecasts reasonable? The plan must acknowledge and incorporate uncertainty into its analyses and recommendations.

*Limitations of the analysis process*. Travel demand and land-use models are important tools for transportation planning. Although these models continue to improve, the ability to forecast travel behavior is often beholden to the assumptions made on those factors influencing travel decisions. Travel behavior is complex and difficult to explain fully with

mathematical tools. Transit use, carpooling, and nonmotorized travel are particularly difficult for models to handle. Models are usually calibrated on past travel patterns that may not be continued into the future, thus adding another challenge to the analysis process. However, even with these limitations, a travel demand model is essential for analyzing transportation solutions (see chapter 6 for a discussion of travel demand models).

*Influence of the political process.* The MPO is, in essence, a political forum where local officials and transportation agency representatives strive to reach consensus. Elected officials often have political agendas that might predispose them toward one transportation solution, such as a new highway or a light rail line. In addition, elected officials tend to focus on issues with more immediate effect and often find it difficult to relate to discussions on issues that will occur 25 years into the future. The planner must understand the characteristics of political decision making in presenting plan information. Effective communication and political skills are just as necessary to the planner as technical skills.

The preceding considerations can be applied to any type of transportation planning. For long-range transportation planning, in particular, the following factors become important.

*A plan needs to recognize and provide an understanding of the interconnectivity of the different modal networks in the region's transportation system*. For example, most metropolitan areas have a road network also used by bus services. Thus, achieving a reasonable level of service on the highway system becomes an issue as much for transit mobility as for highway congestion reduction. These same roads may be designated as part of a strategic road network because they connect to important economic activities. In addition, bicycle and pedestrian systems are important in an urban environment in part because they provide important connections to transit systems. Such intermodal connectivity should be an important concern for the transportation planning process.

*A long-range plan must have a time horizon of at least 20 years.* Major capital investments, such as new highways or transit lines, may take upwards of 10 years or longer to complete. Land-use patterns also tend to develop over long timeframes. A 20-year time horizon provides a sufficient timeframe to consider longer-term effects. Most MPOs use a 25-year time horizon, and more recently some MPOs have been developing 40- and 50-year plans. Some issues, such as climate change and the corresponding impacts on transportation system performance, are even extending this timeframe out to 2100 (although no MPOs have yet adopted such a long time horizon for its plan).

*A plan should be both multimodal and intermodal.* All modes must be considered (thus the term *multimodal*) as part of the planning analysis—auto travel, transit services, freight movement, bicycle and pedestrian travel, and others that are important to the metropolitan area. Modal connections, that is, where transfers are made (thus the term *intermodal*), also become an important focus of attention.

*The link to land-use planning is critical*. As noted in chapter 6, transportation demand is a derived demand, meaning that travel occurs because travelers are trying to accomplish an activity at a trip's destination. Thus, a transportation plan needs to be linked to expected land-use patterns in the study area. This becomes an important challenge for a long-range, metropolitan-level plan because a regional land-use plan or context must be provided to conduct the analysis. How MPOs do this varies across the country (see chapter 3 on land use and urban design).

*Federal law requires that the long-range plan be financially constrained.* The plan must include a financial element that describes the assumptions made to forecast future revenues. The cost of the projects in the plan must not exceed the expected revenues available to provide the planned improvements.

*Given the uncertainty about future funding sources, many MPOs have created a vision plan in addition to a financially constrained plan.* The vision plan, often called an aspirations plan, can take many forms, often part policy and part project-specific. A vision plan allows a region to determine what additional financial resources are required to meet all the needs for this vision beyond what is forecast to be available. In many cases, the projects that are listed in this vision plan are considered illustrative of what can be done if additional resources are made available (and often become the focus of public referenda to obtain the funds to support the plan).

*The plan must have broad input from all interested and key stakeholders.* Opportunities for public participation in the planning process must be provided throughout the process, and MPO planners must be responsive to the input provided.

*All planning factors in federal legislation must be addressed.* As noted earlier, the federal government plays an important role in establishing the approach and substance of metropolitan transportation plans. Many of the sections found in a typical transportation plan are there to satisfy federal requirements.

*The plan should address environmental justice issues.* The Environmental Justice Executive Order 12898 of 1994 states that federally funded plans should not unduly burden low-income and minority populations. Coupled with Title VI Civil Rights laws, this executive order leads to an analysis of transportation plans and TIPs on disadvantaged communities. This analysis is part of the long-range transportation planning process, and often accompanies the plan as an appendix or as a section in the plan itself.

*The plan must take into account all planning studies* conducted by the MPO and other planning partners since the last plan update. The results of these studies should be analyzed from a regional perspective and be incorporated into the plan as appropriate. Subarea, corridor, and modal studies provide important sources of projects and strategies to be considered when developing a long-range transportation plan.

## B. Defining Study Boundaries

Federal law requires that the state and local decision makers agree on MPO planning boundaries, and that defining the boundary should be a cooperative process among the representatives of the local governments contained within the urbanized area, the state's governor, and any adjacent MPOs. The MPO planning boundary must include the entire urbanized area boundary as identified in the latest decennial census and the contiguous geographic area likely to become urbanized within 20 years. In many instances, MPO planning efforts will have different study boundaries depending on the study purpose. For example, in Atlanta, the ARC, (1) develops the LRTP based on the census-defined urbanized area, (2) conducts planning as the state-designated regional commission in 10 counties (whose boundaries are not contiguous with the urbanized area), (3) has 19 counties in the agreed-upon MPO structure, (4) does transportation planning in a 15-county planning boundary for ozone analysis, and (5) conducts planning in a 20-county planning boundary to satisfy air quality requirements for particulate matter.

For planning efforts that are not at a regional scale, MPOs often define the focus of a planning effort based on a variety of factors. For example, a recent review of the congestion management process (CMP) in 10 MPOs showed how differently the targeted network is defined (see Table 16-1). [ARC, 2015a]

## C. Identifying Transportation Issues and Opportunities

The planning framework offered in chapter 1 began with an effort to understand the problem(s) facing a particular community or region. In special planning cases, such as those relating to safety or air quality, analysis often precedes the identification of specific issues in order to understand the transportation component of the problems being faced. For example, for safety, many states conduct preliminary data analysis to identify what types of crashes should be of greatest concern to the planning study. Because of the continuing nature of metropolitan transportation planning, this step in the planning process occurs through the normal planning activities of the MPO. Information on critical issues affecting transportation system performance is constantly being fed back into the planning program.

Some typical issues/threats/challenges/opportunities that have been identified by MPOs as part of the transportation planning process include:

**Metropolitan Council, Minneapolis–St. Paul, Minnesota**

***Challenges and Opportunities***

- Land use and development patterns affect the stewardship of the transportation system.
- Transportation investments can help sustain and strengthen the region's economic competitiveness.
- The region's population and employment are going to grow, leading to more travel.
- Highway congestion is a reality of economic growth and can be managed and eased.

| Table 16-1. Targeted Road Networks for Congestion Management Processes, Various Metropolitan Areas | |
|---|---|
| **Agency** | **System Coverage** |
| Metroplan Orlando, Florida | • Systemwide evaluation is performed (Level 1), leading to the identification of potentially congested roadways/intersections (Level 2), from which evolve detailed corridor or intersection studies (Level 3). |
| Maricopa Association of Governments, Phoenix, Arizona | • Freeway corridors identified in the Performance Measurement Framework report.<br>• Transit facilities and services.<br>• Bicycle and pedestrian facilities.<br>• Arterial streets that either currently experience significant congestion or are projected to experience significant congestion in the future or make up part of a corridor or activity area that is subject to current or future congestion. |
| North Central Texas Council of Governments, Dallas-Ft. Worth, Texas | • A corridor inventory of 25 regional limited access facilities. |
| Mid-America Regional Council, Kansas City, Missouri | • All National Highway System routes.<br>• All other routes with average daily mid-block traffic volumes of 25,000 or more for segments of 2 miles or more in length.<br>• All routes with high levels of transit service. |
| Delaware Valley Regional Planning Commission, Philadelphia, Pennsylvania | • Congested corridors segmented into subcorridors.<br>• Sketch corridors likely to become congested in the future that serve key regional roles.<br>• Corridors based on CMP Analysis Points, Transportation Refinement Layers, and Community Refinement Layers. |
| Genesee Transportation Council, Rochester, New York | • All interstate highways, principal, and minor arterials.<br>• Collector roads in the vicinity of special event venues. |
| Chicago Metropolitan Agency for Planning, Illinois | • Expressways and tollways.<br>• Regionally important roads.<br>• Regionally important transit systems. |
| Puget Sound Regional Council, Seattle, Washington | • Based on the Metropolitan Transportation System (regionally significant multimodal transportation facilities that provide access to activities crucial to the social or economic health of the region).<br>• Additional layers added to the CMP to reflect multimodal or freight considerations, including:<br>  ◦ Core freeway and HOV network.<br>  ◦ Washington State Department of Transportation (WSDOT)-identified bottlenecks.<br>  ◦ Top 25 regional "key" arterials identified by Regional Traffic Operators Committee.<br>  ◦ Key transit corridors identified by transit stakeholders.<br>  ◦ T1 and T2 truck freight routes identified in regional Freight and Goods Transportation System.<br>  ◦ Critical infrastructure and significant emergency management routes. |
| Regional Transportation Commission, Las Vegas, Nevada | • Major interregional corridors and major arterial corridors connecting cities to the base congestion management network.<br>• Only regionally significant corridors considered as candidates for the network.<br>• The initial network was refined from the list of candidate corridors to include facilities with "existing or potential recurring congestion;" professional judgment was used to identify corridors with existing congestion and those likely to become congested. |
| Hampton Roads Transportation Planning Organization, Virginia | • Principal arterials (interstates, freeways, or other expressways).<br>• Minor arterials.<br>• Roadways classified as collectors based on network connectivity, access to major activity centers, and input from jurisdictions.<br>• Major roadways expected to be constructed in the future. |

Source: ARC, 2015a

- People and businesses are demanding more and better travel options.
- Transportation decisions impact communities and the environment, and thus should be made responsibly.
- Access to jobs and opportunity is an issue of equity.
- Traditional transportation needs are greater than the resources available.
- There is a need to innovate and make strategic decisions. [Metropolitan Council, 2015]

**Denver Regional Council of Governments (DRCOG), Colorado.** DRCOG identified the following factors that the transportation system will respond to, influence, and be impacted by:

- *Economic and population growth.* The population of the Denver region is expected to increase from about 2.9 million in 2010 to more than 4.3 million in 2035, an increase of about 50 percent.
- *Location of growth.* Most of the expected increase in the region's population and employment will occur within the urban growth boundary/area. In addition, much of it will be concentrated in urban centers. However, the majority of this growth will occur in locations far from the Denver Central Business District (CBD).
- *Less efficient development patterns*. Developments with circuitous streets and poor pedestrian connections, and those with separated residential and commercial areas can result in an increased reliance on the automobile.
- *Lower development densities.* Many residential areas are developed at lower housing unit densities and cannot be served cost-effectively with conventional public transit.
- *Development near airports.* Several residential subdivisions have developed within the influence area of the region's airports. This may give rise to future noise impact issues that could hinder the regional airport system's ability to grow or respond to changes in the service market.
- *Automobile dominance.* The automobile (including cars, vans, pick-ups, and sport utility vehicles) is the region's dominant form of household transportation. And for most trips, the automobile contains only a single occupant, the driver.
- *Increased travel*. The rate of annual VMT growth was not as high between 2000 and 2010 as it was in previous decades, but is currently forecast to steadily increase through 2035.
- *Jobs/housing balance.* In areas that lack a good balance of jobs and housing, there are fewer opportunities to live close to work.
- *Difficult to institute change.* Changing personal travel habits is difficult, particularly when people are not aware of options, viable options do not exist, and benefits are not clearly understood.
- *Growth of elderly and disabled population*. Both the elderly and disabled populations are growing at rates faster than the general population.
- *Limited existing transportation system capacity*. Without improvements and expansion, the region's existing transportation system cannot provide a desirable level of mobility to meet expected demand.
- *Increased congestion.* The number of congested miles is expected to more than double between 2006 and 2035.
- *Impacts of expansion and construction*. The ability to widen a roadway or provide a rapid transit corridor is more costly and politically difficult when additional right-of-way is needed. Often this requires residential and business acquisitions that may cause community and economic impacts.
- *Increase in traffic crashes.* The number of crashes on the roadway system increased by about 3 percent annually between 1990 and 2005.
- *Mobility options for persons without a car.* According to the 2000 Census, about 67,000 households in the Denver region did not have an automobile available.
- *Recreational traffic*. Thousands of people travel to and from recreational activities in the mountainous areas of Colorado, both within the region and adjacent to it. Traditionally, they travel around the same general time. Roadways such as I-70 and US-285 experience extreme congestion during weekend peak periods, such

as Sunday afternoons. Local communities are greatly affected by this congestion, which impacts the ease of making local trips, emergency response to traffic crashes, and noise, air, and water quality.

- *Air quality.* Pollutant emissions from mobile sources, (e.g., automobiles and trucks), are a major contributor of air pollutants. Even with continued technological improvements to automobile pollution control equipment, expected VMT growth may jeopardize air quality.
- *Water quality.* Water pollution is caused by many factors related to regional development, including the construction and operation of the transportation infrastructure. Growth in traffic can cause increased runoff of pollutants created by brakes and tires.
- *Limited funds.* Financial resources for transportation over the next 24 years of the plan are currently expected to be far less than needed to maintain the current transportation system to high standards, let alone expand it. Transportation funding has simply not kept pace with the continued growth in travel demand or the recent dramatic increase in transportation construction cost. [DRCOG, 2011]

To illustrate the regional nature of transportation issues in an environmentally sensitive area and as well to show such a list for a smaller MPO, the following challenges and opportunities were identified in the transportation plan for the Berkshire Regional MPO in western Massachusetts.

**Berkshire Regional Planning Commission, Pittsfield, Massachusetts**

- *Livability:* Livable, sustainable communities offer residents a variety of different modes of transportation, without almost complete reliance on using automobiles. Some of the alternate modes include rail, bus, bike, vanpools, carpools, and walkways. Livable communities reduce the need to frequently travel far by including housing, jobs, shopping, education, and recreation.
- *Climate change and air quality conformity*: The Berkshires are expected to experience warmer temperatures, less snow pack/ice retention and cycles of subsequent drought and flooding impacts, changes in weather patterns and its resulting increase in storm severities, an increase in frequency and severity of heat waves, and shifts and alterations in the distribution of natural plant and animal assemblages—A preliminary study of greenhouse gas (GHG) emissions in Berkshire County suggests that the transportation sector accounts for 39 percent of GHG emissions.
- *Hazard mitigation, severe weather, & water quality:* Berkshire County is affected by a number of natural hazards including flooding, severe winter weather, tornados, and wildfires. Localized flooding causes most of the county's natural hazard damage. Poorly maintained transportation infrastructure and inadequately sized storm water systems contribute significantly to hazardous flooding conditions. Deferring maintenance (grading, ditching, culvert repair, and so forth) because of budget constraints results in soil erosion and pavement damage.
- *Critical animal habitat:* Highway construction, urban and residential development, and other physical alterations reduce natural habitat. Roads isolate wildlife populations into smaller units that are more vulnerable to threats including predators and inbreeding. [Berkshire Regional Planning Commission, 2011]

## D. Formulating a Vision, Goals, and Objectives

A critical step for metropolitan transportation planning early in the process is creating a regional or community vision. This process has many dimensions, ranging from expected or desired future land-use patterns to desired transportation system characteristics. For example, the Metropolitan Washington Council of Governments, Washington, DC, has adopted the following vision statement for the region's transportation system. Note the multimodal nature of the vision, as well as the linkage to growth.

- The Washington metropolitan region's transportation system will provide reasonable access at reasonable cost to everyone in the region.
- The Washington metropolitan region will develop, implement, and maintain an interconnected transportation system that enhances quality of life and promotes a strong and growing economy throughout the entire region, including a healthy regional core and dynamic regional activity centers with a mix of jobs, housing, and services in a walkable environment.

- The Washington metropolitan region's transportation system will give priority to management, performance, maintenance, and safety of all modes and facilities.
- The Washington metropolitan region will use the best available technology to maximize system effectiveness.
- The Washington metropolitan region will plan and develop a transportation system that enhances and protects the region's natural environmental quality, cultural and historic resources, and communities.
- The Washington metropolitan region will achieve better inter-jurisdictional coordination of transportation and land-use planning.
- The Washington metropolitan region will achieve an enhanced funding mechanism(s) for regional and local transportation system priorities that cannot be implemented with current and forecasted federal, state, and local funding.
- The Washington metropolitan region will support options for international and interregional travel and commerce. [National Capital Region TPB, 2015]

In many ways, although the creation of a vision statement can provide planners with some sense of community desires at the beginning of the process, perhaps the major benefit of the visioning process is the participation of many different stakeholders in creating the vision itself. By discussing and debating the different factors that should be included, stakeholders learn about the many facets of transportation that will be important during the planning effort. In one area in particular—the consideration of future land-use patterns—creating a vision provides an important input into the technical aspects of the planning process.

Developing goals and objectives is another key step in the plan development process in that they provide more detail on how the plan's vision will be accomplished. Developing goals and objectives should be informed by substantial input from the MPO policy board, stakeholders, and interested citizens. It is not the planner's role to define goals and objectives, but rather to facilitate a community process that results in a goals statement, translate them into the language of planning, and then use them to guide the technical process. Given the comprehensive nature of transportation planning, goals and objectives should be developed in concert with regional development policies or land-use plans, and should also reflect federally-required planning factors.

Some examples of MPO transportation planning goals and objectives follow:

**Southeast Wisconsin Regional Planning Commission (SEWRPC).** The Southeast Wisconsin Regional Planning Commission (SEWRPC), the MPO for the Milwaukee, Wisconsin, metropolitan area provides a good example of what MPOs often do to develop a vision statement. As noted by the MPO, "using a visioning and scenario planning approach, the VISION 2050 effort was designed to obtain greater public input into the specific design and evaluation of "sketch" year 2050 land use and transportation scenarios, detailed alternative plans, and the final plan, as well as to expand public knowledge on the implications of existing and future land use and transportation development in Southeastern Wisconsin." [SEWRPC, 2014]

Outreach efforts included a regularly distributed VISION 2050 e-newsletter, periodic brochures, media contacts and news releases, and extensive public outreach to minority and low-income groups and organizations, business groups, service groups, community and neighborhood groups, environmental groups, and others. The MPO partnered with eight nonprofit, community organizations to conduct targeted outreach to their constituents. This outreach effort was largely designed to reach and engage minority populations, people with disabilities, and low-income individuals. A telephone questionnaire was used to obtain preferences from the region's citizens with respect to key transportation, community, and social attributes of the region. Figures 16-1 and 16-2 illustrate some of the results of this survey.

**Capital Region Transportation Planning Agency (CRTPA), Tallahassee, Florida.** The Capital Region Transportation Planning Agency, the MPO for the Tallahassee, Florida, metropolitan area adopted the following vision statement for its transportation plan.

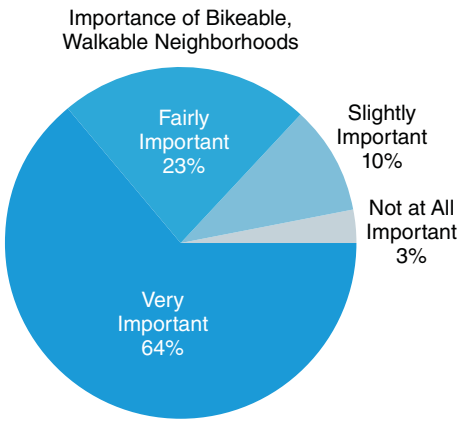
> *"Create an integrated regional multimodal transportation network that provides the most options for moving people and goods economically, effectively and safely while protecting the environment, promoting economic development and maintaining a high quality of life with sustainable development patterns." [CRTPA, 2012]*

**Bend Metropolitan Planning Organization, Bend, Oregon.** The update of the Bend, Oregon, metropolitan transportation plan identified goals and objectives to help "set the tone and guide the development and selection of transportation solutions for the MTP … and serve to guide implementation of the plan." [Bend MPO, 2014] The goals for the transportation plan were:

**Mobility and Balance**

- Provide a variety of practical and convenient means to move people and goods to, from and within the MPO area.
- Develop a transportation system that serves the needs of all travel modes, provides intermodal connectivity, and provides a range of transportation options throughout the MPO area.

**Figure 16-1. Results of Visioning Survey, Importance of Bikeable and Walkable Neighborhoods, Milwaukee, Wisconsin**



Source: SEWRPC, 2014

**Safety and Efficiency**

- Address traffic congestion and problem areas by evaluating the broadest range of transportation solutions.
- Serve the existing, proposed, and future land uses with an efficient and safe transportation network.
- Design and construct the transportation system to enhance safety for all modes.

**Accessibility and Equity**

- Provide people of all income levels with a wide range of travel options within the MPO area.
- Support all Americans with Disabilities Act (ADA) requirements and policies.

**Land Use**

- Integrate land use and transportation by encouraging land-use patterns that provide efficient, compact uses of land that facilitate a reduced number and length of trips.
- Promote development patterns that preserve the life of the existing transportation system.
- Promote development that does not rely on primary access to the state transportation system.

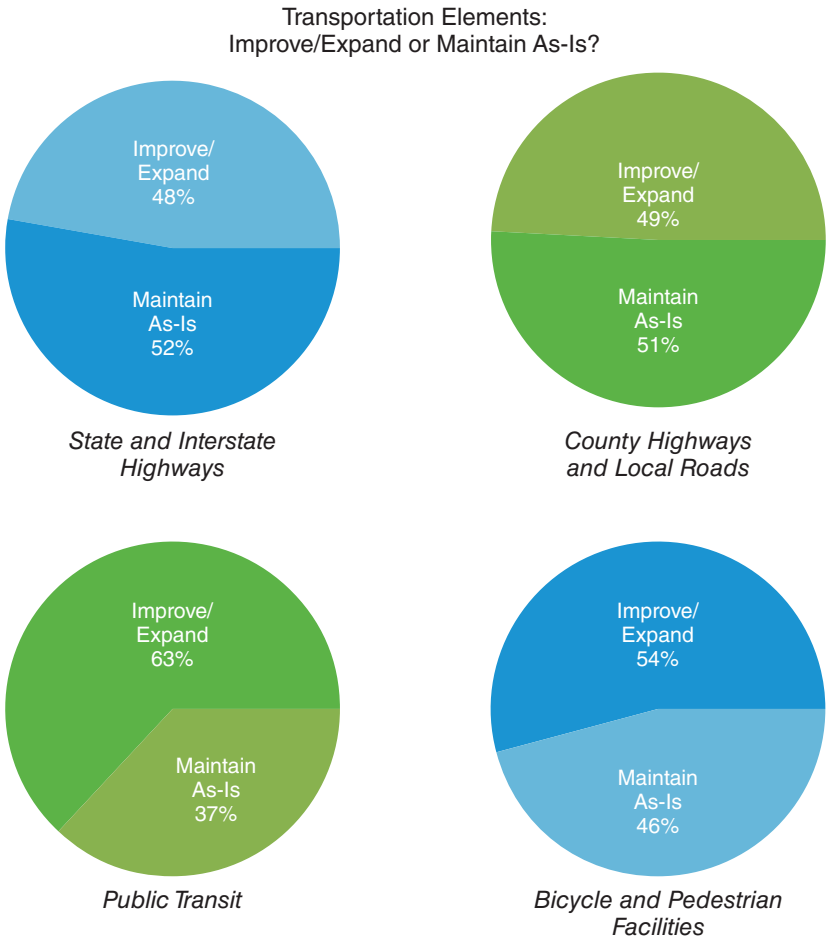
**Environment and Livability**

- Recognize and respect the natural and historical features over which transportation improvements pass to minimize adverse impacts.
- Design transportation improvements that protect the environment by preserving air and water quality, minimizing noise impacts and encouraging energy conservation.
- Use context sensitive design principles when designing and locating transportation facilities.

**Economic Development**

- Implement transportation improvements that foster economic development and business vitality.
- Develop a transportation network with transportation options that enhance linkages between centers of employment, education, medical facilities, and neighborhoods.
- Recognize the importance of intermodal connections and maintain adaptable approaches to trends and opportunities that enhance intermodal connections.

**Figure 16-2. Results of Visioning Survey, Preferences for Road Improvement, Milwaukee, Wisconsin**



Source: SEWRPC, 2014

**Financially Responsible**

- Coordinate and design transportation improvements to assure the expenditure of resources in the most cost-effective manner.
- Maximize the ability to leverage alternative and multiple funding sources for transportation system improvements.

**Metropolitan Council, Minneapolis–St. Paul, Minnesota.** In its recent update of the long-range transportation plan, the Metropolitan Council of Minneapolis-St. Paul, Minnesota, developed an extensive list of goals, objectives, and strategies for improving transportation system performance in the Twin Cities region. The transportation goals and objectives were closely linked to the adopted vision statement for the region's future that was based on the following five principles:

- *Stewardship* advances the Council's longstanding mission of orderly and economic development by responsibly managing the region's natural and financial resources and making strategic investments in our region's future.
- *Prosperity* is fostered by investments in infrastructure and amenities that create regional economic competitiveness, thereby attracting and retaining successful businesses, a talented workforce, and consequently, wealth.
- *Equity* connects all residents to opportunity and creates viable housing, transportation, and recreation options for people of all races, ethnicities, incomes, and abilities so that all communities share the opportunities and challenges of growth and change.

- *Livability* focuses on the quality of our residents' lives and experiences in our region, and how places and infrastructure create and enhance the quality of life that makes our region a great place to live.
- *Sustainability* protects our regional vitality for generations to come by preserving our capacity to maintain and support our region's well-being and productivity over the long term. [MetCouncil, 2015]

The corresponding transportation goals, objectives, and strategies for this vision provide an excellent overview of the types of goals that a large metropolitan area might consider (see appendix A).

**Atlanta Regional Commission (ARC), Georgia.** The latest update of the ARC's regional plan focused on three major policy themes—world-class infrastructure, healthy livable communities, and competitive economy. [ARC, 2016] These three themes served as the foundation for the identification of strategies in the regional plan. Each policy area had a range of goals relating to a mix of land-use, transportation, economic development, and social program strategies. For example, the following goals and transportation-related strategies were listed for the respective policy area:

**World Class Infrastructure**

Goal: Ensure a comprehensive transportation network.

- Expand managed toll lane program.
- Expand region's transit network.
- Maintain the existing transportation system and improve arterial roads and highways.

**Healthy Livable Communities**

Goal: Develop walkable and vibrant communities.

- Invest in equitable and improved access to a variety of housing, including options for aging in place.
- Promote equitable transit-oriented development.
- Develop a regional trail network for bicyclists and pedestrians.
- Create walkable communities through the Livable Centers Initiative.

**Competitive Economy**

Goal: Build the region as a globally recognized hub of innovation and prosperity.

- Improve the movement of freight.
- Boost economic development around Atlanta's airport.

The Atlanta regional plan provides an example of a plan that identifies the interrelationship among the many different planning issues facing a community, and how transportation strategies can play an important role in achieving each.

This step in the planning process—the formulation of community vision, goals, and objectives—should have significant public engagement opportunities in order to lend credibility to the planning process. MPOs and regional planning agencies often spend considerable time providing the public and key stakeholders with a variety of opportunities for input into the visioning, goals, and objectives process. Often, goals and objectives are revisited as the planning process proceeds, reflecting new information or new participants in the planning process.

## E. Identifying and Using System Performance Measures

Performance measures are a set of indicators or measures used to monitor the performance of the transportation system over time. The number of performance measures should be limited to a select few that reflect the information desired by decision makers in determining future directions in transportation investment. Given their importance to local decision makers, these performance measures are also usually part of the criteria used to evaluate different investment strategies.

Performance-based transportation planning can provide better quality and more goal-relevant information to an inherently political decision-making process. By educating and informing the public, in part through the use of customer-oriented outcome measures, decision making can begin to favor more objective evaluation and debate. It is widely agreed that system policies, goals, and objectives are a critical starting point for developing a performance-based planning approach. The concept of outcome measures and the important role of customer perception and satisfaction are now a well-established part of most transportation planning efforts.

In metropolitan planning applications, performance measures need to be readily understood by decision makers and by the public. This supports the concept of a hierarchy of measures, with the measures providing basic information on how the system performs. Some examples of performance measures for different categories of goals include:

- *Accessibility:* Percent of the population within *x* minutes of *y* percent of employment sites, whether special populations such as the elderly are able to use transportation, whether transportation services provide access for underserved populations to employment sites, and whether services are Americans with Disabilities Act (ADA) compliant.
- *Mobility*: Average travel time from origin to destination, change in average travel time for specific origin-destination points, average trip length; percentage of trips per mode (known as mode split), time lost to congestion, transfer time between modes, and percent on-time transit performance.
- *Economic Development*: Jobs created and new housing starts in an area as a result of new transportation facilities. new businesses opening along major routes, percent of region's unemployed who cite lack of transportation as a principal barrier, and economic cost of lost time.
- *Environmental Quality of Life*: Environmental and resource consumption, tons of pollution generated, and fuel consumption per vehicle mile traveled.
- *Sprawl*: Change in difference between urban and suburban household densities; decrease in acres of wetlands; changes in air quality, land use, or mobility.
- *Safety*: Number of crash incidents or economic costs of crashes.
- *Reliability*: Repeatability of trip travel times. It is affected by non-recurring events such as incidents, work zones, special events, weather, or natural disasters.

Table 16-2 shows the performance measures for the Madison, Wisconsin area metropolitan planning program. As noted by the MPO, "the proposed indicators for the Madison area include both "outcome" metrics that measure the effects of system investments and decisions (for example, travel time, mode of transportation, roadway and bridge conditions, # of crashes) as well as "output" metrics that measure the level of activity of a program or supply of a service or facility (for example, transit revenue hours of service, miles of multi-use paths)." [MadisonArea MPO, 2012]

Metropolitan areas in California are subject to state legislation requiring the identification of performance targets as part of the transportation planning process and the periodic monitoring of progress toward these targets. These targets become evaluation criteria for assessing the effectiveness of the transportation plan's recommended actions. Table 7-9 showed how the updated metropolitan transportation plan [ABAG and MTC, 2013] helped achieve the targets … or not. Note that the presentation was organized in terms of those targets met or exceeded, those where progress is being made, and those where the trends are in the wrong direction.

A similar but separate analysis was done looking at the plan's social equity impacts on communities of concern. The conclusions from this analysis were:

- Alongside displacement pressures, housing, and transportation affordability are forecast to continue to be key challenges for low-income households in the future.
- While air quality will improve in the region overall with improved technologies, increased vehicle traffic and congestion in communities of concern raise safety concerns for those areas where walking and biking are more common modes of travel.
- Travel times to jobs and other destinations will increase slightly for communities of concern compared to today, due to higher levels of congestion in the urban core and some trips shifting from driving to transit, walking, and biking. [ABAG and MTC, 2013]

| Table 16-2. Performance Measures, Madison, Wisconsin | |
|---|---|
| Mobility and Accessibility—Improve regional mobility and accessibility for all persons while maintaining a balance between the two sometimes competing concerns.<br><br>Balanced System—Achieve a balanced transportation system through investment. | • Travel Time to Work (by mode)<br>• Mode of Transportation to Work<br>• Miles of Congested Roadways (based on Level of Service)<br>• Transit Revenue Hours of Service<br>• % of Urbanized Area and Population<br>• Served by Transit (weekday, weekend)<br>• Miles of Bike Lanes and Multi-use Paths |
| Mobility of Freight—Enhance mobility and safety for goods movement to support the local economy while maintaining community livability. | • Miles of Congestion on Truck Routes<br>• Miles of Rail Track with Speed Restrictions<br>• Freight Tonnage by Mode |
| System Preservation—Maintain the region's transportation infrastructure and preserve transportation corridors, particularly rail corridors, for possible future travel uses by other modes. | • Roadway and Path Pavement Condition<br>• Bridge Structure Condition (sufficiency rating and weight restriction)<br>• Avg. Age of Metro Transit Bus Fleet<br>• Miles of Metro Vehicle Service between<br>• Unplanned Road Calls |
| Safety—Improve transportation safety through design, operations and maintenance, system improvements, support facilities, public information, and law enforcement efforts. | • Total Vehicle Crashes by Severity vs. VMT<br>• Metro Transit Bus Crashes per 100,000<br>• Vehicle Miles Traveled<br>• Total Bicycle and Pedestrian Crashes and Fatalities |
| Management/Operations—Apply ITS and utilize TDM and TSM strategies to respond to traffic congestion, make efficient use of existing roadway capacity, and make the transportation system more reliable, convenient, and safe.<br><br>Congestion Management—Consider all mobility options and operational strategies (ITS, TDM, TSM) in congested corridors before adding capacity for general purpose travel lanes or building new facilities. | • Vehicle Miles of Travel (VMT)<br>• Freeway Congestion Duration<br>• Total Annual Transit Passenger Trips<br>• Transit Passengers per Revenue Hour<br>• Transit System On-Time Performance<br>• # of New Commuters Registered with the MPO's Rideshare etc. Program<br>• # of State Vanpools and # of Employers Participating in Commute Card Program<br>• [See also CMP Performance Monitoring Plan] |
| Interconnected System—Encourage and facilitate connections between various modes of travel. | • # of Park-and-Ride Lots and Usage<br>• Inter-City Bus Trips per Day, Cities Served<br>• Airport Passenger Volume |
| Environmentally Responsible—Preserves and restores environmental and ecological systems and minimizes energy consumption to the extent feasible. | • Ozone and PM 2.5 Levels<br>• Transportation-related GHG Emissions |

Source: Madison Area MPO, 2012

It should be noted that the transportation profession is debating how to best define desirable performance of the transportation system. For example, more traditional measures would focus on travel speed, levels of service, and capacity measures, where higher speeds, greater levels of service, and more capacity would be defined as more desirable. Especially in urban areas, such a result might not be the best outcome. For example, higher speeds do not mix well with pedestrian and bicycle travel on the same road. With many communities adopting Complete Streets and traffic calming policies, transportation performance measures need to be considered very carefully in terms of the potential outcomes if investments are made to achieve "optimal" performance.

Chapter 7 on evaluation and prioritization methods, chapter 15 on statewide planning, and chapter 17 on corridor planning provide additional discussion on performance measures. See also chapter 9 on road and highway planning and chapter 19 on site impact analysis for a discussion on non-traditional performance measures and in particular on recent efforts to define a multimodal performance metric.

## F. Collecting and Analyzing Land-Use, System Performance, and Condition Data

Transportation planning is analysis-driven. The ultimate investment recommendations are based on a sound assessment of the advantages and disadvantages of each alternative. In addition, analysis is strongly dependent on the availability of high-quality data relating to every aspect of an alternative's performance and its relationship to the surrounding community. Data can range from large demographic and census population files to site-specific traffic counts.

It is beyond the scope of this chapter to provide a detailed description of typical data and data sources used in metropolitan transportation planning (see chapter 2 for a more comprehensive presentation of transportation system data and chapter 3 for land-use and urban design data). However, it is important for those interested in metropolitan transportation planning to understand some of the key characteristics of data collection and management.

The types of data used in a metropolitan transportation planning process will vary by the kinds of issues being examined and the ability of state and local agencies to collect the data. The following list of data on the website for the Pima Association of Governments (Tucson, Arizona) gives an indication of the range of data that can be found in a typical MPO: [PAG, 2015]

- Regional, aerial, and orthophotographic coverages.
- Travel demand forecasts and traffic count information (such as annual traffic counts, traffic volume forecasts, commuting and travel characteristics, and transportation system performance measures).
- Air quality and watershed management data.
- Population estimates and projections.
- Land use and socioeconomic information.
- Census program coordination, information, and demographic analyses.

As the amount of data for transportation planning has increased dramatically during the past several decades, MPOs have developed methods to organize and manage the data. Most of the data sources on the PAG list, and similarly for other MPOs, are based on a geographic information system (GIS) platform. GIS analysis has become a fundamental tool for metropolitan planners. By combining data with a geographic representation, the planner is able to undertake more in-depth technical analysis of transportation issues.

GIS is particularly helpful in linking transportation strategies with land-use strategies. Testing various alternative development scenarios through GIS tools allows for quick assessments of the varying implications of different combinations of transportation investment strategies and land-use patterns. The visual representations are also critical for general public understanding of the differences among the scenarios. An FHWA study that examined the use of GIS tools in transportation planning concluded:

> *GIS tools help support the public process of creating and identifying preferred alternative scenarios*. Planners have found GIS methods helpful in creating realistic land-use scenarios with the input of local staff, stakeholders, and the general public. They also have found the results useful in communicating the implications of

alternative transportation and development choices. As a result, people are able to make better informed decisions.

*GIS technology is enabling the development of more detailed and sophisticated land use and environmental data and analysis tools.* Integrated regional land-use databases are becoming more common. At the same time, GIS facilitates the development of detailed, parcel-level land-use databases that support environmental and community indicator models. GIS further provides data display capabilities to communicate information to policy makers and the general public.

*Even with the use of GIS tools, the comprehensive integration of data sources remains a challenge in most areas.* Land-use data, such as comprehensive plans, zoning and existing development, are maintained by local jurisdictions. Especially for smaller jurisdictions with limited resources, these are often still in hard copy format. Also, data formats are often incompatible among different jurisdictions in the same metropolitan area. In most parts of the country, regional land-use databases still require significant effort to construct and maintain. [http://www.gis.fhwa.dot.gov]

In recent years, efforts have been made to develop database sharing tools, which allow for easy exchange of information. For example, the Transportation, Economic, Land Use System (TELUS) is an information-management and decision-support tool that has been designed for use by MPOs. Funded by the U.S. DOT, TELUS is available for free to MPOs. Some key TELUS components include automated TIP monitoring, mapping, economic analysis, and land use assessment. MPOs also design and build their own custom data and reporting systems.

For up-to-date information on GIS applications in transportation planning, see http://www.gis.fhwa.dot.gov.

## G. Analyzing Transportation System Alternatives

An analysis usually begins by examining current transportation system conditions. This includes an inventory of the physical conditions of different transportation facilities and systems, coupled with data on existing performance. Data would be collected on such transportation systems as freeways/limited access roads, strategic arterial roads, high-occupancy vehicle (HOV) networks, transit services and route structure, "smart" corridors served by ITS, bicycle networks, and pedestrian networks.

A needs assessment requires the planner to analyze the performance of the current transportation system as well as expected performance with improvements. Typically, a travel demand model is run for the current year and future year. A "no-build" run is produced for future years, assuming no improvements are made to the current system or often incorporating projects for which projects have already been committed. These runs are analyzed based on key evaluation criteria, such as mode split, vehicle miles traveled, and vehicle hours traveled. For studies of individual facilities or smaller study areas, it is important to analyze subarea or corridor-level measures as well. By understanding how the transportation system performs—with and without the planned improvements—planners can assess the need to change or refine strategies and investments.

Most transportation planning studies use some form of travel demand model as part of the analysis process. Travel models tend to fall into two groups—demand network models and simulation models. Simulation models are increasingly being used for facility and corridor analysis, and, in recent years, new simulation models have been developed for regional applications as well (see chapter 6 on travel demand modeling).

Since most regional models are calibrated and validated whenever actual data are available (at least once every 10 years with census data), the model's ability to replicate current conditions reasonably well is a prerequisite to forecasting into the future. This often requires model updates or limited modifications during the years between census periods. Note that this timeframe for model update might now change with the adoption of the continuous census data collection strategy in the United States, known as the American Community Survey (see chapter 2 on data collection and analysis).

Model advancements now allow planners to address tolling and other pricing schemes when testing future scenarios. Certain ITS and operational improvements, however, remain a challenge to many models. Chapter 6 on travel demand modeling provides detail on how travel demand models are formulated and used as part of the transportation planning

process. This information will not be repeated here. However, some aspects of how models are used in metropolitan transportation planning deserve some attention, and are discussed below:

***1. Model Assumptions***

Many assumptions often have to be made concerning key input variables for the models themselves. This is especially true when applying models to an urban area, where many different factors can influence travel behavior. Although the information is somewhat dated, the Metropolitan Transportation Commission (MTC) in the San Francisco Bay metropolitan area identified the following key areas where assumptions on future values had to be made when developing its travel demand model for a plan update. These are still valid today. [MTC, 1998]

- Fuel price and availability
- Parking costs
- Auto operating costs
- Bridge tolls
- Transit fares
- Travel behavior assumptions
- Vehicle peaking factors
- Vehicle occupancy factors
- Interregional commuter behavior
- Demographic assumptions
- Network assumptions

To this could be added assumptions relating to vehicle behavior (connected vehicle technology, for example) and the influence on travel behavior of the Internet and social media.

In each case, the assumptions relate to expected future conditions. For example, in developing a plan for the year 2045, what will parking and auto operating costs, tolls, and transit fares be 30 years in the future? These are critical variables for forecasting which mode travelers will choose. Similarly, the degree to which traffic flow will peak during the day, the level of vehicle occupancy, and the amount of interregional commuting will affect which network links will be most congested.

Of particular importance, future population and employment must be forecast not only at a regional level but also distributed into smaller zones, usually by traffic analysis zone (TAZ). These forecasts must be made for specific time intervals all the way to the end of the plan horizon period. This may mean a five-year, 10-year, or even one 20-year forecast depending on the size and concerns of the MPO. See chapter 3 on land use and urban design.

***2. Scenario Planning***

Scenario planning has gained popularity in recent years. Its popularity and success is due in part to its approach of looking at different "what if?" alternatives before deciding on a particular policy direction. For example, scenario planning could look at the effects on transportation investment of different land-use patterns, different pricing assumptions, increasing risks associated with extreme weather, and different lifestyle decisions. Alternatively, different investment scenarios could be examined to determine the effect on system performance, such as on accessibility and mobility indicators. Not only does scenario planning provide key members of the community, such as business representatives, elected officials, and advocates, with the ability to define important trends and trade-offs, it also allows planners to identify which common investments across all scenarios should be undertaken, no matter which future occurs.

Scenario planning follows several steps.

- *Step 1: Research the driving forces*. Understand existing conditions and development trends.
- *Step 2: Determine patterns of interaction.* Consider how the driving forces combine to determine future conditions. A matrix helps to identify these outcomes.

- *Step 3: Create scenarios.* Planners should think through the implications of different strategies in different future environments.
- *Step 4: Analyze the implications.* Scenario planning is a tool for decision making. Showing the difference in the scenario outcomes through the use of visual tools enables the public to comprehend the impacts.
- *Step 5: Evaluate scenarios.* Scenarios can be measured against one another by previously agreed-upon indicators.
- *Step 6: Monitor implications.* Scenario planning is an ongoing process and should be reassessed due to changing conditions. [FHWA, 2011]

A good example of how scenarios can be used in transportation planning comes from Washington, DC. The Transportation Planning Board, the MPO for the Washington region, defined three scenarios in its update of the region's transportation plan based on different combinations of forecasted or desired land-use and transportation characteristics. These forecasts or desired directions were:

- *Constrained Long-Range Plan Land Use:* A cooperative forecast undertaken with the region's communities assumed that from 2015 to 2040, 25 percent of new households and 35 percent of new jobs would be located in targeted growth areas (TGAs).
- *Constrained Long-Range Plan Land Use Aspirations Forecast:* The aspirational (that is, desired) forecast assumed that 57 percent of new households and 58 percent of new jobs are located in TGAs.
- *Constrained Long-Range Plan Transportation Network*: Road and transit investments in the constrained investment plan.
- *Constrained Long-Range Plan Transportation Aspirations Network:* Variable pricing applied on an additional 740 new highway lane miles and 186 existing lane miles. Bus Rapid Transit (BRT) and circulator services are assumed with 274 new buses and approximately a 20 percent increase in service hours. [Kirby, 2013]

Table 16-3 shows the different combination of forecasts and transportation network assumptions that were the basis for the tested scenarios.

The types of analysis that occur in scenario analysis are shown in Figures 16-3 and 16-4. Not surprisingly given the assumed investment in transportation services or targeting of land use, those scenarios that concentrated land uses, provided more transit service, or made the use of the single-occupant motor vehicle more expensive saw the greatest increases in non-motor-vehicle use and the most reduction in vehicle delays.

The Delaware Valley Regional Planning Commission (DVRPC), the MPO for the Philadelphia, Pennsylvania, metropolitan area used scenario analysis to examine the impact of alternative investment levels on system performance and condition. The three scenarios included:

- The "high" scenario was a best-case situation for transportation funding in the region. This scenario assumed a 35 percent increase in reasonably anticipated funding over the life of the Connections 2040 Plan.
- The "medium" scenario was considered the likely investment level for transportation infrastructure. It was based on a continuation of present funding levels.
- The "low" scenario was a worst case development for regional transportation funding; this scenario assumed a 20 percent decrease compared to current transportation funding levels. [DVRPC, 2013]

**Table 16-3. Combinations of Land Use and Transportation (CLRP) Assumptions for Scenario Definition, Washington DC**

| | **Land Use** | **Transportation** |
|---|---|---|
| **2040 Baseline** | Cooperative Forecast | 2012 CLRP |
| **Scenario 1: Transportation component only** | Cooperative Forecast | CLRP Aspirations |
| **Scenario 2: Land use component only** | CLRP Aspirations | 2012 CLRP |
| **Scenario 3: Constrained Long-Range Plan (CLRP) Aspirations** | CLRP Aspirations | CLRP Aspirations |

Figures 16-5 and 16-6 show the implications of varying levels of investment. Experience has shown in many states that providing this type of information to decision makers is very influential in getting them to understand the consequences to the transportation system of not raising revenues.

## H. Evaluating Transportation System Alternatives

Evaluation is the process of determining the desirability of different courses of action and presenting this information to decision makers in a comprehensive and useful form. Determining the desirability of an alternative requires, (1) defining how value is to be measured, (2) estimating the source and timing of the benefits and costs of the proposed actions, and (3) comparing these benefits and costs to determine a level of effectiveness for that alternative. Evaluation thus provides information to decision makers on the estimated impacts, trade-offs, and major areas of uncertainty associated with the analysis of alternatives. Not only does the magnitude of the impact have to be determined, but those who are positively or negatively affected should also be identified. [Meyer and Miller, 2014]

Thinking about the evaluation process should begin very early in planning because the evaluation criteria drive analysis and data collection activities. For example, if decision makers want to know how different alternatives compare with respect to traveler hours of delay, then both data collection and the results of analysis need to produce that information.

Multimodal transportation planning presents a special challenge to the evaluation process. As noted in a review of innovative practices, "multimodal transportation planning is best carried out when all modes are analyzed simultaneously and interactions among the modes are accounted for." [Transmanagement, 1998] Being able to compare modal

**Table 16-4. Questions That Form the Basis of Evaluation**

*Given that a primary purpose of planning is to inform decisions, the following types of questions often define an evaluation process …*

- What is the type of information decision makers want and need to make decisions regarding the benefits and costs associated with different decision options?
- What is the absolute magnitude of the benefits and costs associated with each alternative under consideration?
- What are the benefits and costs relative to all of the alternatives?
- How do the benefits associated with each alternative relate to the alternative's costs?
- To what extent does each alternative achieve the goals and objectives originally specified in the planning study?
- How will different groups perceive the absolute and relative impacts of each alternative?
- How do the benefits and costs of each alternative affect different population groups in the study area?
- What are the economic, community, and environmental impacts of each alternative?
- Are there uncertainties associated with the estimates of benefits and costs that could affect the overall determination of the "best" alternative? If so, how might these uncertainties change key assessment factors?
- What is the overall funding needed to implement each alternative? What is the life cycle cost and the funding needed over the life cycle of each alternative?
- What institutional, legal, or organizational changes are needed, if any, to implement an alternative?

Source: Meyer and Miller, 2014

alternatives in a way that does not bias the results toward one of the modes is a significant goal of the evaluation process.

Although the evaluation process—and the criteria used to compare alternatives—will be targeted on the issues being addressed in the planning study, there are some evaluation questions common to almost every planning study. Table 16-4 lists these questions. The information needed to answer these questions, however, will differ from one study to another.

Presenting the evaluation results in an understandable way is important to the success of the planning process. Tables 16-5 to 16-8 show the traditional way of presenting results. As shown, the evaluation information is divided into major categories—transportation system supply, trip-making behavior, transportation system demand, costs, and natural environment. The cells of the table contain numerical values or percentages, and are compared to a base case.

Some MPOs like to use subjective assessments or symbols to represent the level of magnitude of impact of the evaluation criteria in order to make the relative values more meaningful to decision makers. The effectiveness of either approach depends on the decision makers' level of comprehension and the relative difference in values of the evaluation measures (for example, it is hard to determine the relative value of two pedestrians versus three pedestrians in a walkable community evaluation category).

The reader is referred to chapter 7 on evaluation for more detailed information on the methods and tools that can be used for this stage of the planning process. In addition, [DVRPC, 2003; FHWA, 2011; Oregon DOT, 2013; and Montana DOT, 2015] are excellent references for those interested in scenario planning.

## I. Prioritizing Projects and Program Development

Transportation planning leads to the identification of the most cost-effective strategies or projects identified during the process. In many planning studies, it is left to sponsoring agencies or to the policy-making board of the MPO to determine whether to fund the recommended actions. As noted earlier, in the United States, the LRTP must also include a financial plan, which takes a long-range look at how transportation investments are to be funded in relation to the needs over the time horizon of the plan. Funding sources must be identified, including funding sources

| Table 16-5. Congested Vehicle Miles Traveled by Source, Sacramento, 2008–2035 | | | |
|---|---|---|---|
| **Travel Source** | **2008** | **2020 Plan** | **2035 Plan** |
| **Region Total** | | | |
| Household-generated commute congested VMT (CVMT)[1] | 1,711,500 | 1,767,100 | 2,128,300 |
| Household-generated other CVMT | 921,100 | 988,200 | 1,159,500 |
| **Total Household-Generated CVMT** | 2,262,600 | 2,745,300 | 3,287,800 |
| Commute share of household-generated CVMT | 65% | 64% | 66% |
| Commercial CVMT[2] | 489,100 | 525,300 | 682,900 |
| Externally generated CVMT[3] | 175,800 | 208,000 | 308,000 |
| **Total CVMT** | 3,297,500 | 3,478,600 | 4,278,700 |
| **Per capita rates** | | | |
| Population | 2,215,000 | 2,519,900 | 3,086,200 |
| Jobs | 969,800 | 1,072,200 | 1,330,000 |
| Household-generated CVMT per capita | 1.19 | 1.09 | 1.07 |
| Commercial vehicle + External CVMT per job | 0.69 | 0.68 | 0.75 |
| Total CVMT per capita | 1.49 | 1.38 | 1.39 |
| **Percent Change in Congested VMT per Capita or per Job, Compared to 2008** | | | |
| Household-generated CVMT per capita | n/a | −6.3% | −10.4% |
| Commercial vehicle + External CVMT per job | n/a | −0.2% | 8.7% |
| Total CVMT per capita | n/a | −7.3% | −6.9% |

[1]Household generated CVMT is cumulative vehicle travel by residents of the region on roadways which are at-or-above capacity, for their travel within the region. Household-generated CVMT is split into commute and other shares.

[2]Commercial vehicle VMT is cumulative vehicle travel for moving goods, services, and freight within the region. It includes commercial travel in passenger vehicles, light trucks, and vans as well as in larger trucks.

[3]Externally generated VMT is cumulative vehicle travel from residents outside the region, but who travel to destinations within the region, or travel through the region.

for maintenance and operations of highways, transit, and all other transportation investments. Anticipated revenues from all available sources need to be included, such as federal, state, local governments, and other funding sources. The plan compares the anticipated revenues against costs of the transportation strategies to determine if there are enough funds to cover the proposed investment.

Determining funding feasibility is thus dependent on having good cost estimates. Cost estimates include those costs associated with preliminary engineering, right of way, construction, operation, maintenance, and environmental mitigation. Cost estimates associated with a project when first placed in the LRTP will most likely change as the project

moves from concept to implementation (see chapter 5 on transportation finance and funding, and chapter 7 on evaluation for more discussion on cost estimation).

Forecasting future revenue streams for a long-range plan is a difficult challenge for MPOs. For example, the MPO must make a 20- to 25-year forecast of revenues, which for federal funds goes well beyond the 5- to 6-year statutory authorization period. The current approach to this dilemma is to forecast federal funds based on historic trends for the region, even though federal funding categories and project eligibility have been known to change over time. Nearly all federal transportation funding comes from FHWA or FTA, with funds allocated through formula or discretionary earmarks. The highway funding categories form the core of the federal transportation funding program. Each funding category has specific eligibility requirements although the trend in federal funding has been to allow funds to be flexed from one category to another. When exercised, this flexing option is most often used to flex highway funds to transit purposes.

State transportation revenues must also be included in the forecast. It thus becomes important to understand the state budget process, the likelihood of tax increases, the factors that could influence increasing or decreasing revenues from motor fuel taxes, the use of financial bonding (and thus the need to pay back debt), and the feasibility of road tolls.

Local government revenue forecasts are often the most problematic. Over the time horizon of the LRTP, local governments may supplement their revenues through local option sales taxes, property or other tax increases, and/or impact fees. Because most of these revenue sources depend on voter approval, it is very difficult to estimate with any certainty the availability of such funds in future years (see chapter 5 on transportation finance and funding for more discussion on revenue forecasting).

The financial plan for the TIP is more stringent than that for the LRTP. The state DOT and transit authorities must furnish expected revenue to the MPO to support the programming process. In air quality nonattainment areas, all regionally significant projects must be included in the TIP, regardless of funding source. The TIP must be financially constrained by year. Given this constraint, only projects with demonstrated revenue sources can be advanced. Additionally, in air quality nonattainment and maintenance areas, funds for projects in the first 2 years of the TIP/STIP must be available or committed. In addition to forecasting federal, state, and local revenues, the MPO must also account for any public/private partnerships or other innovative funding proposed by a project sponsor.

Once available revenue and expected project costs are available, the planning process must now identify which projects should receive priority and be programmed in the TIP. There are often more worthy projects than funding available, and this is certainly true for moving transportation projects from the long-range plan into the TIP. Thus, some means for establishing priorities must be developed. The most basic purpose of the TIP is to show the program of projects, strategies, and investments that will be funded over the next 4 to 5 years. It is the one document the public requests most often because it reflects the highest-priority transportation initiatives of the region.

The TIP must be updated at least every 4 years, although many metropolitan areas update more often as priorities change. Each MPO is required to have an amendment process for the TIP which must be documented in the region's public involvement/participation plan. Amendments occur quite often because of changes in engineering design and changes in priorities and costs. Some amendments require significant effort of the part of the MPO staff. For example, in nonattainment areas, amendments that change roadway capacity require a new conformity determination for air quality.

Good information sharing among the planning partners, such as the local governments, state DOT, and transit operators, is necessary for this tracking to be successful. MPOs should adopt policies to reprogram funds that are not being used in a timely way. San Francisco has a "Timeliness of Funds" policy and St. Louis, Missouri, MPO has a "Reasonable Progress" policy. Both policies are essentially "use it or lose it" policies. Delays in highway projects may provide an opportunity to move transit projects ahead without losing the federal funds allocated to the metropolitan area.

Prioritizing projects to move from the plan to the TIP is often the most difficult and contentious aspect of TIP development. Project recommendations can be developed in a number of ways. Project selection should be based on

their level of achievement of the goals, objectives, and policies for the region, and thus MPOs often use a scoring system to determine which projects should be forwarded into the TIP. Some examples follow:

**Puget Sound Regional Council (PSRC), Seattle.** An example of such a scoring process from the Puget Sound Regional Council (PSRC) in Seattle is found in Table 16-9. The MPO board approved the testing of prioritization criteria to assess the effectiveness of the process and the level of understanding. The criteria included:

- *Air Quality*: Air quality impacts to health, the environment, and climate, as well as potential shifts toward cleaner fuels.
- *Freight*: Extent to which projects provide benefits to freight users of the transportation system (travel time and reliability) as well as a reduction in conflicts with other modes of travel, improves access to freight-related areas, and improves key freight-related facilities.
- *Jobs*: Extent to which projects support existing and new businesses and job creation.
- *Multimodal*: Extent to which projects provide alternatives to driving alone. The measure also addresses the extent to which projects incentivize or facilitate individual's use of those alternatives.
- *Puget Sound Land and Water*: Land- and water-related environmental issues, including storm water, hydrological function, critical areas and habitats, and the construction practices and materials in projects.
- *Safety and System Security*: Extent to which projects provide for safer travel, a likely reduction in fatalities or serious injury, and improved system security.
- *Social Equity and Access to Opportunity*: Extent to which projects improve mobility and/or reduce negative impact to minority, low income, elderly, youth, people with disabilities, and non-vehicle-owning populations, and whether they support access to opportunities.
- *Support for Centers*: Extent to which projects support existing and new population and employment in centers. In addition, the measure addresses the extent to which projects support transit-oriented development, development of housing in centers, accessibility to/from/within the center, and compatibility with the character of the community in which a project is located.
- *Travel*: Extent to which projects reduce congestion and delay, and improve flow. [PSRC, 2014]

**Table 16-9. Example Scoring for Freight Component of Plan Projects, Puget Sound Regional Council, Seattle**

| | | | |
|---|---|---|---|
| | **Purpose: System performance benefits for freight. How well does the project provide benefits to freight-related system users by improving travel time, reliability, and efficiency for freight haulers (all freight modes)? and how well does the project reduce conflicts?** | | |
| **Points** | 3 | | The project improves a facility identified as a freight bottleneck through the Washington State DOT's Truck Performance Measures program or other adopted agency plan. |
| | 1 | | The project reduces conflict between freight modes (truck and rail), e.g., grade separation or bridge openings. |
| | 1 | | The project reduces conflict with freight and one or more passenger modes, e.g., through separation of modes such as a pedestrian overpass or separated parallel bicycle facility. |
| | **Purpose: Access to freight-related areas. How well does the project support planned development in Manufacturing and Industrial Centers (MICs) and other freight-related areas?** | | |
| **Points** | Choose 1 | 2 | The project improves access within or to more than one MIC (or between a MIC and a Regional Growth Center). |
| | | 1 | The project improves access within or to one MIC. |
| | 1 | | The project improves access to an area identified in the Regional Freight Strategy as a freight generator. |
| | **Purpose: Improves key freight facility. How well does the project serve designated Freight and Goods Transportation System routes?** | | |
| | 2 | | The project is on a designated T-1 or T-2 route. |
| Total | 10 (max) | | |

Source: PSRC, 2014

Interestingly, in the final version of the prioritization approach, both numerical scores and pie symbols (full, 3/4, 1/2, 1/4, and empty) were used to convey the relative worth of the projects.

**Berkshire Regional Planning Commission (BRPC).** The Berkshire RPC has adopted an approach similar to that at the PSRC although in a much easier format. Every project is assigned a score of 1 point for each of the following criteria, for a total maximum of 3 points. Those projects have 3 points are given highest priority in the programming process. The three criteria are:

- *Regional Connectivity:* Projects that meet this threshold address a transportation link where there is no alternative route of comparable length. In general, these routes are classified within the National Functional Classification System as arterials.
- *Industrial and Commercial Access:* It is important that transportations investments facilitate freight movements. Projects that meet this threshold improve heavily traveled truck routes and access significant employment centers. Projects along NHS routes automatically meet this threshold.
- *Safety:* The most hazardous five percent (5%) of intersections within the region, based on reported crashes converted to an equivalent property damage calculation are eligible for Highway Safety Improvement Program (HSIP) funds. Projects that meet this threshold contain at least one intersection that is HSIP eligible. Projects with the same score are not listed in a particular order of priority. [BRPC, 2011]

**Houston-Galveston Area Council (H-GAC).** H-GAC uses both subjective and quantitative scoring criteria, including benefit/cost analysis, to rank the projects being considered for the TIP. [H-GAC, 2014] Table 16-10 shows the criteria and how they are estimated. They are replicated here in their entirety because the list provides a good example of many of the types of scoring points found in practice today.

Figure 16-7 shows the relationship between system goals, measures, and outcomes, and the types of projects selected as part of the capital program. This figure comes from Edmonton, Alberta, Canada, where the implementation of a light-rail transit line linked directly to goals of shifting mode splits in the region and in transforming Edmonton's urban form.

Chapter 7 provides more examples of approaches for prioritizing projects. In addition, chapter 5 on transportation finance, chapter 15 on statewide planning and chapter 17 on corridor planning describe project prioritization.

## V. MONITORING SYSTEM AND PROGRAM PERFORMANCE

This step in the transportation planning process provides a feedback loop into the early stages of the next round of transportation planning. Performance measures and other means of assessing on a continual basis the performance and condition of a region's transportation system constitute the core of performance-based planning, which in the United States is now the predominant model of transportation planning. This is shown in the example below.

The Broward County's (Florida) new long-range transportation plan has identified numerous measures that will be used to monitor the progress in achieving plan objectives. This monitoring strategy is shown in Table 16-11.

The plan also noted that subjective measures, such as aesthetics and quality of life, are important to a plan's implementation and are monitored through the public outreach and education process.

## VI. PUBLIC ENGAGEMENT

Public participation and engagement is one of the most important elements of the MPO transportation planning process. Public participation enhances the planning process by incorporating the needs of the community, and thus improving the decision-making process. There are many audiences that should have the opportunity to provide input into the regional planning process. These audiences can be as diverse as those simply having an interest in transportation, those doing business in the region, or organized advocacy groups. With the growing awareness of the importance of freight movement and the role of the private sector, private transportation providers should also have the opportunity to participate. Examples include private transit providers, freight and rail operators, and taxicab operators. Planners should also provide participation opportunities for low-income, minority, and elderly populations.

**Table 16-10. Scoring Method, Houston-Galveston Area Council**

| Roadway/Mobility (Non-ITS) Projects—Planning Factors | | |
|---|---|---|
| **Planning Factors 50% and Benefit/Cost 50%** | | |
| Regional Impact | 40 pts | • 20 pts—NHS/Principal Arterial or<br>• 10 pts—Designated Evacuation Route<br>+<br>• 10 pts—Designated Heavy Cargo Route<br>• 10 pts—Fixed Route Transit Corridor or used by other transit services outside of fixed route service areas. |
| Design/Corridor Mobility | 40 pts | • 20 pts—Includes construction of raised medians, innovative intersections (e.g., roundabout, diverging diamond, single point urban interchange, etc.), or other significant safety/access management technique<br>• 10 pts—Project includes a Ped/Bike Accommodation that meets or exceeds AASHTO standards<br>• 10 pts—Project includes a significant ITS or other integrated technology component to increase facility efficiency and reliability |
| Community | 20 pts | • 10 pts—Project is a recommendation in a Regional or local plan/study<br>• 10 pts—Project provides needed connection or capacity identified in adopted Thoroughfare Plan |

| Benefit/Cost Methodology—Roadway/Mobility (Non-ITS) | |

|---|---|---|---|
| **ITS/Operations Projects—Planning Factors, Answer yes or no** | | | |
| **Congestion/Safety** | | | |
| 30 pts max | 5 | | **Incident/Event Management**<br>• Will the system be an integral part to an incident management system? |
| | 5 | | • Is the system on the National Highway System or other component of H-GAC's congestion mitigation process (CMP) network? |
| | 5 | | • Will the system provide notification of a potential problem to facility users? (e.g., dynamic message signs, mobile device alerts, etc.) |
| | 5 | | • Will the system give priority to emergency vehicles? |
| | 5 | | • Will the system give priority to transit or high-occupancy vehicles? |
| | 5 | | • Will the system utilize dynamic management of the facility to enhance travel time reliability? (e.g., ramp metering, variable speed limits, variable pricing, etc.) |
| **Coordination** | | | |
| 40 pts max | 10 | | **System Migration/Expandability**<br>• Can the system expand the regional communications network? |
| | 5 | | • Will the system NOT utilize proprietary systems that will not integrate with other systems in the region? |
| | 15 | 5 | **Integration and Information Sharing**<br>• Will the system tie into a centralized operations center? |
| | | 10 | • Will the system tie into another agency's systems to allow for the sharing of data? |
| | | 15 | • Will the system allow for potential control by another agency in the event of a primary agency's loss of system control? |
| | 5 | | • Will the system collect and provide data available for traveler information access? |
| | 5 | | • Will the system allow for collection of data to address performance measures? |
| **Asset Mgmt/Efficient Operations** | | | |
| 30 pts max | 10 | | **Continuity of Operations**<br>• Will the proposed system enhance continuity of operations in the event of a disruption? |
| | 5 | | • Will the system allow for interagency redundancy? |
| | screen | | **System Lifecycle/Maintenance Issues**<br>• Is the projected lifespan of the system being installed five (5) years or greater? |
| | 10 | | • Do you have a funded operations and routine maintenance program in place? (Please provide a 5-year budget as described in the financial plan worksheet.) |
| | 5 | | • Does the project improve the efficiency of operations/maintenance expenses? (e.g., real-time system health/equipment condition, malfunction detection/diagnosis, etc.) |

**Table 16-10. (*Continued*)**

| | | | |
|---|---|---|---|
| **Transit—Planning Factors, Answer yes or no** | | | |
| **Planning Factors 50% and Benefit/Cost 50%** | | | |
| Coordination/ Gaps in Service | 30 pts | 15 | **Connectivity to Other Modes**<br>• 10 pts—Provides connection to other transit services (Fixed Route/Commuter/Rail/Demand Response/etc.)<br>• 5 pts—Provides pedestrian and bicycle accommodations |
| | | 10 | Documentation of Coordination (agreements/communications) with participating/affected:<br>• 5 pts—Local Gov'ts (counties/cities)<br>• 5 pts—Public transportation providers |
| | | 5 | • Project serves unmet need identified in Regional Coordinated Transportation Plan (RideTheGulfCoast.com) or other locally developed plan. |
| Ridership Plan | 20 pts | | • Documentation showing expected ridership and potential growth. Backed by supporting data, reasonable and viable ridership given type of service and area to be served. |
| Economic Development | 20 pts max | 10 | Transit Oriented Development:<br>• 10 pts—Project is intrinsic part of a joint-use development.<br>• 5 pts—Project demonstrates potential for adjacent transit-supportive development. |
| | | 10 | **Improved Access to Opportunities**<br>• 5 pts—Project is located in an area that meets the minimum recommended activity density threshold per acre (determined by analysis of population and employment density based on center type).<br>• 5 pts—Project provides access to job opportunities, unmet or enhanced needs. |
| Safety, Security & Operations | 15 pts max | 5 | • Project plan details safety measures that will be taken to provide for safe services and connections. |
| | | 5 | • Project plan details safety and security measures that will be present at the facility or on the equipment. |
| | | 5 | • Use of intelligent transportation systems and other operation/service enhancing technologies. |
| State of Good Repair | 15 pts max | 5 | • The bus or facility being replaced/repaired/maintained meet the life expectancy thresholds established by FTA or Preventive Maintenance Schedules recommended by the manufacturer or existing maintenance plan. |
| | | 5 | • Project addresses maintenance needs to maintain FTA State of Good Repair requirements. |
| | | 5 | • Project addresses need for expanded capacity. |
| **Benefit/Cost Methodology – Transit Projects** | | | |
| | | | **B/C Methodology** |
| Project Type(s): Transit<br>Data: Various project related data (P&R spaces, ridership, etc.)<br>Source: Sponsor | | | • Estimate vehicle miles traveled reduction from mode choice model or other appropriate method.<br>• Calculate annualized cost per VMT reduced over analysis period. |

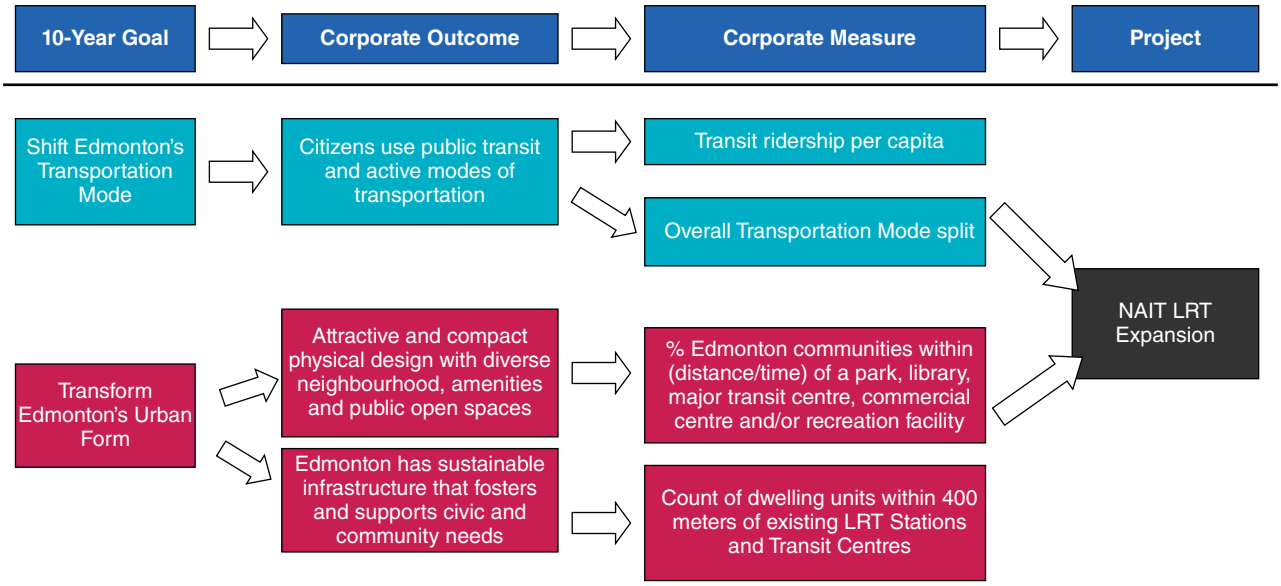
**Figure 16-7. Linking Capital Projects with Goals, Measures, and Outcomes, Edmonton, Alberta, Canada**



Source: City of Edmonton, 2012

TEA-21 called for MPOs to develop a documented public involvement process. This document was to state how the public would be involved in transportation issues and the planning process. The document was also to include information regarding public review of changes or amendments to the TIP or long-range plan. SAFETEA-LU and MAP-21 continued to stress public involvement by requiring MPOs to develop and use a public participation plan. This plan must provide reasonable opportunities for interested parties to comment on the content of the LRTP and TIP. The participation plan must be developed in consultation with all interested parties. All key documents produced by the MPO should be available to the visually impaired as well as in languages spoken in the region.

Chapter 24 presents greater detail on the different types of public involvement strategies and tools that can be used in regional transportation planning.

| Table 16-11. Measures to Monitor Plan Progress, Broward County, Florida | |
|---|---|
| **Move People** | |
| Maintain infrastructure | • All operating and maintenance costs for existing and proposed facilities/services are fully funded through existing or reasonably expected revenue sources. |
| Achieve Level of Service standards | • Increase the proportion of facilities, by mode, operating at or exceeding Level of Service (LOS) standards. |
| Improve accessibility for all users of the system | • Increase the number of jobs within 30 minutes in-vehicle travel time (IVTT).<br>• Reduce gaps in sidewalk and bicycle lane networks. |
| Shorten project delivery | • Reduce the number of projects requiring right-of-way. |
| Maximize transit ridership | • Increase transit mode share. |
| **Create Jobs** | |
| Reduce travel time to economic centers | • Reduce average in-vehicle travel time to central business districts, ports, and regional shopping centers. |
| Promote new development | • Increase transit service to redevelopment areas. |
| Minimize the cost of travel | • Reduce the amount of time and money spent by all travelers. |
| Maximize private investment | • Reduce net cost of public expenditure. |
| | • Increase community/public involvement. |
| **Strengthen Communities** | |
| Ensure benefits and cost are equitable | • Increase number of viable transportation alternatives. |
| | • Increase the number of jobs within 30 minutes IVTT. |
| Reduce accidents, injuries, and fatalities | • Reduce the number of transportation-related accidents, injuries, and fatalities for all modes. |
| Promote redevelopment | • Increase the number of public/private partnerships where the majority of residents make 50% less than the median income. |
| | • Increase the number of jobs within 30 minutes IVTT. |
| Ensure projects consider aesthetic improvements | • Increase the number of projects addressing aesthetics. |
| Provide options for nonmotorized travel | • Increase the number of sidewalk miles. |
| | • Increase the number of bicycle lane miles. |
| | • Reduce gaps in sidewalk and bicycle lane networks. |
| Promote environmental sensitivity | • Reduce energy consumption by person miles traveled. |
| | • Reduce tons of ozone precursors and greenhouse gases from mobile sources. |

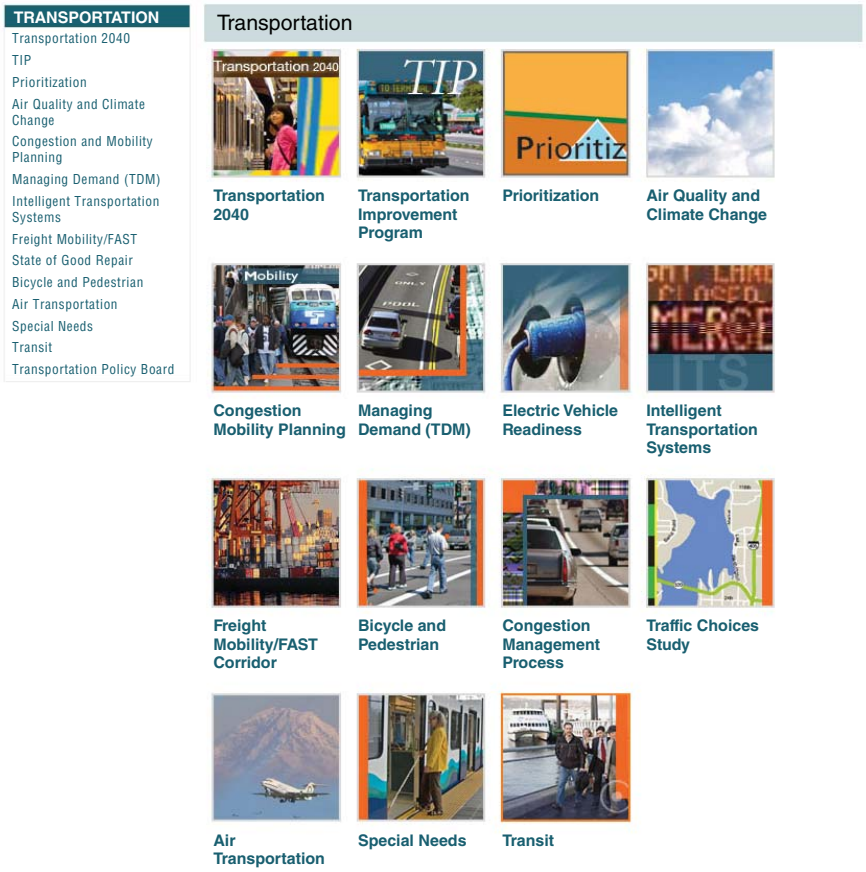
## VII. SPECIAL TOPICS FOR METROPOLITAN TRANSPORTATION PLANNING

Transportation planning is a dynamic process, both in responding to the changing context of a metropolitan area and in addressing new issues as they are added to the regional agenda. While some of the new issues result from federal and state policies, others become important because of the challenges facing the metropolitan area and its local communities. Figure 16-8, for example, is from the website of the Puget Sound Regional Council, Seattle, Washington. It shows the different types of planning studies and efforts that a typical large MPO would focus on. A more detailed list comes from SANDAG in San Diego, California. The following studies show a range of topics that a large MPO might get involved in.

- *State Route 11 and Otay Mesa East Port of Entry*—Improving the efficient movement of people, goods, and services between the United States and Mexico.
- *Riding to 2050, the San Diego Regional Bike Plan*—Establishing a network of regional bikeway corridors and proposes programs to support bicycling as a practical means of transportation.

**Figure 16-8. Typical Planning Issues/Studies Faced by a Large MPO**



Source: Puget Sound Regional Council, http://www.psrc.org/transportation

- *2050 Regional Transportation Plan*—Providing a balanced vision for the evolution of the region's transportation system through 2050.
- *San Diego Forward: The Regional Plan*—Providing a single vision for the San Diego region and an implementation program to make the vision a reality.
- *Chula Vista Light-Rail Corridor Improvements*—Palomar Street Grade Separation Study: Examining a grade separation project along a light rail line.
- *2014 Regional Transportation Improvement Program*—Providing a list of projects over a four-year period to be constructed or implemented.
- *Regional Complete Streets Policy*—Charting a course for addressing the needs of everyone, regardless of mode of travel, in all transportation projects developed by SANDAG.
- *I-15 Integrated Corridor Management*—Promoting individual transportation systems to be operated and managed as a unified corridor network.
- *San Ysidro Intermodal Transportation Center Study*—Identifying a multimodal concept for a world-class transportation center in the vicinity of the San Ysidro Port of Entry.
- *Call Box Motorist Aid Program*—Examining a free motorist aid service designed to help travelers who experience vehicle problems while on the highway.
- *Border Health Equity Transportation Study: A Case Study of the San Ysidro Community*—Looking at mobility challenges in San Ysidro, with particular emphasis on public health.
- *Smart Growth Trip Generation and Parking Study*—Identifying trip generation rates and parking demand associated with smart growth developments.

- *Work-Related Travel Survey*—Providing input into identifying and prioritizing transportation infrastructure projects.
- *I-5 South Multimodal Corridor Study*—Analyzing conceptual alternatives for multimodal improvements along I-5 between SR 54 and Chula Vista.
- *State of the Commute*—Tracking transportation progress throughout the San Diego region.
- *Intelligent Transportation Systems*—Managing performance of local and regional transportation systems.
- *Transportation Enhancement Activities Program*—Supporting smart growth development described in the Regional Comprehensive Plan.

The following special topics provide an overview of issues many MPOs are facing, and will continue to face, in the years to come. In fact, many MPOs have been dealing with these issues for several years.

## A. Congestion Management Process (CMP)

The congestion management process (CMP), previously referred to as the congestion management system (CMS), was first introduced under ISTEA and was the only one of the seven management systems not made optional under later legislation. TMAs are required to develop a CMP that "provides for effective management of new and existing transportation facilities through the use of travel demand reduction and operational management strategies." [FHWA, 2014] The CMP provides decision makers with important information about congestion and thus focuses attention on improving the overall efficiency of the highway network. An important aspect of the CMP provision is that it calls for periodic monitoring and evaluation of congestion reduction strategies.

Because the CMP process forms the basis for the long-range plan and TIP development, the CMP must be implemented regionwide and be developed cooperatively with the MPO's planning partners. In air quality nonattainment areas, federal funds may not be advanced … for any highway project that will result in a significant increase in the carrying capacity for single-occupant vehicles unless the project is addressed through a congestion management process.

See chapter 10 on transportation systems management and operations for more information on the CMP process.

## B. Security

After the terrorist attacks of September 11, 2001, greater emphasis was placed on security planning for metropolitan transportation systems. Because of its role in convening various agencies, the MPO can be a key organization in regional security planning, although security organizations will clearly take the lead. In addition, security is a planning factor that MPOs must consider in developing plans and programs.

The basic elements of a transportation-related security strategy include:

- *Prevention*—This could include facility design, surveillance, monitoring and sensing technologies.
- *Response/Mitigation*—Effective routing for emergency vehicles and evacuation of large numbers of people are part of this element.
- *Monitoring*—Public information becomes critical in this element.
- *Recovery*—The transportation system must go back to normal levels of operation as quickly as possible.
- *Investigation*—This element is primarily a police activity.
- *Institutional Learning*—Conducting an assessment after the incident allows all parties to obtain feedback and take steps to prevent new threats. [Meyer, 2006]

Although the structures of MPOs vary across the country, the role of the MPO as a leader in regional decision making establishes it as a strong choice to participate in security planning. The role the MPO plays in overall systems operation and maintenance are the same for security planning. There are five defined roles that an MPO may wish to serve.

- *Traditional Role*—Primary responsibility with security projects rests with the region's operating and security agencies.
- *Convener*—The MPO acts as a forum for security plans to be discussed and coordinated with each other.
- *Champion*—The MPO aggressively works toward a regional consensus on security planning.
- *Developer*—The MPO develops regional security plans.
- *Operator*—The MPO is responsible for implementing security strategies.

Because of the nature of security planning and the agencies involved with enforcement and protection, the process of considering security as part of the transportation planning process is very much a collaborative process, involving not only the owners and operators of the transportation system, but also agencies whose primary concern is protecting the nation's infrastructure.

## C. Safety

MPOs should incorporate safety into the long-range transportation planning process by providing a forum for safety partner involvement, as well as including a concern for safety throughout all of its planning activities. This can enhance communication and understanding among transportation planners and safety practitioners about the planning processes and opportunities to include safety in long-range planning. Long-range plans should consider the safety of all users in the transportation system including pedestrians, bicyclists, motorists, transit riders, and heavy vehicles.

MPOs include safety as one of the criteria used in prioritizing projects for the TIP. Examples include:

- The Nashville, Tennessee, Area Metropolitan Planning Organization allocates 10 points out of 100 to safety and security concerns.
- The Puget Sound Regional Council in Seattle assigns 10 points out of 90 possible points for safety impacts.
- The Boston MPO provides 29 points out of a possible 154 points (19 percent) to safety considerations.
- The Mid-Region Metropolitan Planning Organization, the MPO for Albuquerque, New Mexico, assigns 7 out of 65 points (11 percent) to safety.
- The Denver Regional Council of Governments (DRCOG) assigns safety points that vary by type of project. For example, for roadway capacity and operational improvement projects, 7 out of 100 points are assigned to safety benefits; pedestrian and bicycle projects can earn 12 out of 100 points for their safety benefits.
- The Bi-State Regional Commission, the MPO for the Quad City metropolitan area of Illinois and Iowa, gives safety 20 percent of the project score for highway projects. The scoring is based on the project's past crash history, severity of the crashes, and crash rate.

MPOs are increasingly adding safety planning to their core mission work programs. An example is the Mid-America Regional Council (MARC) in Kansas City. MARC is part of the Destination: Safe Coalition, which is a partnership between local agencies such as the Kansas Highway Patrol, Missouri Highway Patrol, the state DOTs, and numerous other safety advocates. This coalition provides a framework for establishing the region's safety priorities, as well as coordinating implementation activities. See chapter 23 for more detail on safety planning.

## D. Management, Operations, and Intelligent Transportation Systems (ITS)

Transportation management and operations (M&O) refers to an integrated program to optimize the performance of existing (and programmed) infrastructure by implementing multimodal, intermodal, and often cross-jurisdictional systems, services and projects designed to preserve capacity and improve security, safety, and reliability. Federal law requires transportation plans for metropolitan areas to provide "operational and management strategies to improve the performance of the existing transportation facilities to relieve vehicular congestion and maximize the safety and mobility of people and goods."

Through the use of technology, such as ITS, GIS, and GPS, coordination and collaboration can occur among jurisdictions and agencies. Most importantly, regional collaboration and coordination means operations-oriented planners within transportation and public safety agencies working with MPO planners to create regional operations policies and programs. Data sharing, funding and resource sharing, and development of the regional ITS architecture are a few of the key ways operations professionals can work with metropolitan planners.

Some examples of regional M&O projects include work zone management programs, regional incident management programs, special event management, regional signal coordination, HOV lane development, emergency response and security planning, and the development of regional traffic management centers. The MARC in Kansas City, for example, has established Operation Green Light, which is a regional effort to improve traffic flow and reduce vehicle emissions. This M&O project coordinates traffic signal timing plans between the state DOT and 17 area cities. The effort requires new communication equipment and software so traffic signals can communicate with each other and a central operations center. Ultimately, enhancements to signal timing will improve the flow of traffic on key arterials in the region as well as contribute to reduction in harmful air emissions. See chapter 10 for further discussion of transportation systems management and operations.

Federal law also requires metropolitan areas to have a regional ITS architecture, a framework that outlines how information processing, communication technologies and advanced control strategies will be applied consistently throughout the region to improve transportation system performance. Many MPOs have taken primary responsibility for preparing these plans. Any ITS project that requires federal funding must be consistent with this regional architecture. The ITS architecture should include an operational concept that explains the roles and responsibilities of participating agencies. It also should include agreements required for operations. Any ITS project funded in the region's TIP must be a part of the regional ITS architecture. Therefore, the metropolitan planner must be aware of key ITS strategies and work with local governments to plan and program the most cost-efficient projects.

An example of the types of strategies and actions that can be included in a regional M&O strategy comes from San Diego. The SANDAG "Smart Growth Tool Box" includes the following strategies. [SANDAG, 2013]

**Systems Development Measures**

- Improve the current system by enhancing convenience and travel speed of bus and rail services.
- Implement new transit services that will improve transit in more areas and offer new service types designed to attract new riders to transit.
- Enhance the transit customer experience to make transit easier, safer, and more enjoyable to use.
- Continue to develop and enhance active transportation through bicycle and pedestrian facilities and bike lockers, and implementation of the Regional Bicycle Plan.
- Continue to develop and enhance safe routes to schools plans and strategies.

**Transportation System Management (TSM) Measures**

- Pursue multimodal integration and performance-based management, including performance monitoring and real time modeling/simulation.
- Enhance traveler information capabilities.
- Improve freeway and arterial management.
- Improve transit service management—bus and light rail, including regional scheduling system (RSS), regional transit management system (RTMS), positive train control (PTC), and centralized train control (CTC).
- Support electronic payment services including Compass Card, FasTrak® Open Road Tolling, and smart parking systems.
- Consider advanced technologies including wireless detection, real-time multimodal modeling, and simulation, etc.

**Transportation Demand Management (TDM) Measures**

- Support iCommute—the regional TDM program.
- Support the region's TDM strategy—outreach, education, and financial incentives.
- Encourage TDM programs, including regional vanpool, carpool, buspool, school services (SchoolPool), telework and alternative work schedules, bicycle encouragement programs; and multimodal solutions including first- and last-mile solutions, Compass Card integration, and 511 advanced traveler information services.
- Implement new ways of planning corridors and considering construction mitigation.
- Utilize performance monitoring.

See chapter 10 on transportation systems management and operations planning.

## E. Freight Mobility

Transportation planning historically has focused on passenger transportation, with little attention given to the movement of freight and goods. Beginning in the early 1990s, with a growing concern for freight movement being incorporated into federal transportation legislation, many MPOs began to conduct freight planning. Many added a freight advisory committee to its planning structure, and included freight-oriented prioritization criteria in the programming process. A freight-related performance measure is now part of the federally required system monitoring requirements, with many MPOs, including several additional measures relating to freight movement. Given the importance of the freight and logistics to a regional economy, it seems likely that freight planning will continue to be an important concern to transportation planners in future years.

See chapter 22 on freight planning for further information.

## F. Asset Management

Asset management is a set of guiding principles used to make informed resource allocation decisions. Resource allocation refers to funds spent on programs, projects, and activities. The entire life cycle of transportation projects must be considered. Preservation, operations, and capacity expansion are the three types of investment categories where asset management is most relevant.

The update of the long-range plan provides an opportunity to set policy goals relating to system preservation and resource allocation. By establishing performance measures as part of the planning process, a system for monitoring assets can be established. The metropolitan planner must also have a good understanding of analysis tools used in asset management, such as system physical conditions, real-time operations data, crash statistics, and pavement and bridge management systems. See chapter 8 for more discussion on asset management.

## G. Environmental Justice

Three basic principles serve as the foundation for environmental justice:

1) To avoid, minimize, or mitigate disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority and low-income populations.
2) To ensure the full and fair participation by all potentially affected communities in the transportation decision-making process.
3) To prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations. [FHWA, 2015]

Recipients of federal aid are required to certify, and the U.S. DOT must ensure nondiscrimination under Title VI of the Civil Rights Act of 1964 and many other laws, regulations, and policies. In 1997, the U.S. DOT issued its *DOT Order to Address Environmental Justice in Minority Populations and Low-Income Populations* to summarize and expand upon the requirements of Executive Order 12898 on Environmental Justice. This executive order applies to all policies, programs, and other activities that are undertaken, funded, or approved by FHWA, FTA, or other U.S. DOT agencies. Processes and activities covered by this order include:

- Policy decisions
- Systems planning
- Metropolitan and statewide planning
- Project development and environmental review under NEPA
- Preliminary design
- Final design engineering
- Right of way
- Construction
- Operations and maintenance

MPOs can help local officials understand how Title VI and environmental justice requirements improve planning and decision making. To certify compliance with Title VI and address environmental justice, MPOs need to:

- Enhance their analytical capabilities to ensure that the LRTP and TIP comply with Title VI.
- Identify residential, employment, and transportation patterns of low-income and minority populations so their needs can be identified and addressed and the benefits and burdens of transportation investments can be fairly distributed.
- Evaluate and—where necessary—improve their public involvement processes to eliminate participation barriers and engage minority and low-income populations in transportation decision making.

See chapter 7 on evaluation for further discussion on environmental justice.

## H. Travel Demand Management

Travel demand management (TDM) is a general term for various strategies that increase transportation system efficiency. TDM focuses on reducing the demand for single-occupant vehicle travel. The availability of information about transportation services and conditions has been shown to influence travel demand. Information affects demand by influencing the choices that people make about how, when, where, whether, and which way they travel to their destinations.

Managing demand goes beyond encouraging travelers to change their travel mode from driving alone to a carpool, vanpool, public transit vehicle, or other commute alternative. Managing demand is about providing all travelers, regardless of whether they drive alone, with choices of location, route, and time of travel, not just mode of travel. Real-time traveler information systems can be used at employment centers and to manage critical shifts in demand such as occur for special events, tourist activity, incidents and emergencies, schools, shopping centers, recreation areas, medical facilities, and weather problems.

See chapter 14 for more information on travel demand management.

# VIII. SUMMARY

Metropolitan areas have become a major focus of the nation's economic activity and the center of the social, political, and governmental functions in our society. The importance of these areas has steadily increased since 1920, when, for

the first time, the majority of the U.S. population lived in an urban area. Recognizing the need for the coordinated and cooperative provision of infrastructure, the federal government and, in some cases, state governments have required local governments to plan for the future infrastructure expansion needed to support regional population growth. Nowhere has this influence been more pronounced than in transportation.

Metropolitan-level transportation planning provides the vision and the blueprint for a region's transportation investment strategy. In addition, the transportation planning process usually includes a wide variety of studies and public outreach activities that encompass a range of transportation issues facing a metropolitan region and its communities. In today's environment of more local control and responsibility for the funding and provision of transportation services, metropolitan transportation planning becomes a critical part of a region's strategy to prepare for future challenges. The metropolitan transportation planning process is vital to the success of these areas. It provides opportunities to reach consensus and resolve conflicts.

Planning is a continuous process. The reason for reconsidering priorities and updating transportation plans is that no one can forecast the future with certainty. For nearly 40 years, the MPO has proven itself to be the organization where disparate groups can come together and reach consensus on the future transportation system for a metropolitan area.

How will the MPO as an institution be effective for the next 40 years? The MPO must continually monitor its work and reinvent itself to accommodate changing needs in the region. Political climates change, as do MPO staffs. Even planning partners change as new organizations or authorities are created by state legislatures.

The MPO must continue to be the region's leader in technical tools and data. It must be seen as the "go to" organization for answers to regional transportation questions. The MPO must remain objective in its analysis of various alternatives, with recommendations made from sound technical data. The MPO is the regional leader and can command influence over many planning activities. Key policies developed by the MPO will determine land-use and economic development decisions that have great impact on growth and a region's quality of life.

| Table Appendix A. Goals, Objectives, and Strategies from Minneapolis-St. Paul, MN [MetCouncil, 2015] | | |
|---|---|---|
| **Goal** | **Objectives** | **Strategies** |
| **Transportation System Stewardship** | | |
| Sustainable investments in the transportation system are protected by strategically preserving, maintaining, and operating system assets. | Efficiently preserve and maintain the regional transportation system in a state of good repair.<br><br>Operate the regional transportation system to efficiently and cost-effectively connect people and freight to destinations | Regional transportation partners will place the highest priority for transportation investments on strategically preserving, maintaining, and operating the transportation system. |
| | | Regional transportation partners should regularly review planned preservation and maintenance projects to identify cost-effective opportunities to incorporate improvements for safety, lower-cost congestion management and mitigation, transit, bicycle, and pedestrian facilities. |
| | | The Council and regional transit providers will use regional transit design guidelines and performance standards, as appropriate based on Transit Market Areas, to manage the transit network, to respond to demand, and balance performance and geographic coverage. |
| | | Airport sponsors will prepare a long-term comprehensive plan (LTCP) for each airport every five years and submit it to the Metropolitan Council for review to ensure that plans for preservation, management and improvement of infrastructure at each airport are consistent with the regional aviation system plan. |
| **Safety and Security** | | |
| The regional transportation system is safe and secure for all users. | Reduce crashes and improve safety and security for all modes of passenger travel and freight transport.<br><br>Reduce the transportation system's vulnerability to natural and man-made incidents and threats. | Regional transportation partners will incorporate safety and security considerations for all modes and users throughout the processes of planning, funding, construction, operation. |
| | | Regional transportation partners should work with local, state, and federal public safety officials, including emergency responders, to protect and strengthen the role of the regional transportation system in providing security and effective emergency response to serious incidents and threats. |
| | | Regional transportation partners should monitor and routinely analyze safety and security data by mode and severity to identify priorities and progress. |
| | | Regional transportation partners will support the state's vision of moving toward zero traffic fatalities and serious injuries, which includes supporting educational and enforcement programs to increase awareness of regional safety issues, shared responsibility, and safe behavior. |
| | | The Council and regional transit providers will provide transit police services and coordinate with public safety agencies to provide a collaborative approach to safety and security. |
| | | Regional transportation partners will use best practices to provide and improve facilities for safe walking and bicycling, since pedestrians and bicyclists are the most vulnerable users of the transportation system. |
| | | Airport sponsors and air service providers will provide facilities that are safe, secure and technologically current. |

| Table Appendix A. (*Continued*) | | |
|---|---|---|
| **Goal** | **Objectives** | **Strategies** |
| **Access to Destinations** | | |
| People and businesses prosper by using a reliable, affordable, and efficient multimodal transportation system that connects them to destinations throughout the region and beyond. | Increase the availability of multimodal travel options, especially in congested highway corridors.<br><br>Increase travel time reliability and predictability for travel on highway and transit systems.<br><br>Ensure access to freight terminals such as river ports, airports, and intermodal rail yards.<br><br>Increase transit ridership and the share of trips taken using transit, bicycling and walking.<br><br>Improve multimodal travel options for people of all ages and abilities to connect to jobs and other opportunities, particularly for historically under represented populations. | Regional transportation partners will continue to work together to plan and implement transportation systems that are multimodal and provide connections between modes. The Council will prioritize regional projects that are multimodal and cost-effective and encourage investments to include appropriate provisions for bicycle and pedestrian travel. |
| | | Local units of government should provide a system of interconnected arterial roads, streets, bicycle facilities, and pedestrian facilities to meet local travel needs using Complete Streets principles. |
| | | The Council, working with MnDOT through their Enhancing Financial Effectiveness (EFE) efforts, and other relevant jurisdictions, will continue to maintain a Congestion Management Process for the region's principal arterials to meet federal requirements. The Congestion Management Process will incorporate and coordinate the various activities of MnDOT, transit providers, counties, cities and transportation management organizations to increase the multimodal efficiency and people-moving capacity of the National Highway System. |
| | | Regional transportation partners will promote multimodal travel options and alternatives to single occupant vehicle travel and highway congestion through a variety of travel demand management initiatives, with a focus on major job, activity, and industrial and manufacturing concentrations on congested highway corridors and corridors served by regional transit service. |
| | | The Council will work with MnDOT and local governments to implement a system of MnPASS lanes and transit advantages that support fast, reliable alternatives to single-occupancy vehicle travel in congested highway corridors. |
| | | The Council will support an interagency approach to preserving right-of-way for future transportation projects that are consistent with the Transportation Policy Plan. |
| | | Regional transportation partners will manage and optimize the performance of the principal arterial system as measured by person throughput. |
| | | Regional transportation partners will prioritize all regional highway capital investments based on a project's expected contributions to achieving the outcomes, goals, and objectives identified in Thrive MSP 2040 and the Transportation Policy Plan. |
| | | The Council will support investments in A-minor arterials that build, manage, or improve the system's ability to supplement the capacity of the principal arterial system and support access to the region's job, activity, and industrial and manufacturing concentrations. |
| | | Regional transportation partners will manage access to principal and A-minor arterials to preserve and enhance their safety and capacity. The Council will work with MnDOT to review interchange requests for the principal arterial system. |

(*continued*)

| Table Appendix A. (*Continued*) | | |
|---|---|---|
| **Goal** | **Objectives** | **Strategies** |
| People and businesses prosper by using a reliable, affordable, and efficient multimodal transportation system that connects them to destinations throughout the region and beyond. | *(Objectives Repeated)*<br>Increase the availability of multimodal travel options, especially in congested highway corridors.<br>Increase travel time reliability and predictability for travel on highway and transit systems.<br>Ensure access to freight terminals such as river ports, airports, and intermodal rail yards.<br>Increase transit ridership and the share of trips taken using transit, bicycling and walking.<br>Improve multimodal travel options for people of all ages and abilities to connect to jobs and other opportunities, particularly for historically under represented populations. | The Council and regional transit providers will expand and modernize transit service, facilities, systems, and technology, to meet growing demand, improve the customer experience, improve access to destinations, and maximize the efficiency of investments. |
| | | Regional transportation partners will invest in an expanded network of transitways that includes but is not limited to bus rapid transit, light rail, and commuter rail. Transitway investments will be prioritized based on factors that measure a project's expected contributions to achieving the outcomes, goals, and objectives identified in Thrive MSP 2040 and the Transportation Policy Plan. |
| | | The Council will provide paratransit service complementary to the region's regular route transit system for individuals who are certified by the Council under the Americans with Disabilities Act (ADA). |
| | | The Council and regional transit providers will provide coordinated transit options, including general public dial-a-ride and vanpool subsidies, in areas of the region not served by regular-route transit. Service levels for these options will be based on available resources and needs. |
| | | Regional transportation partners should focus investments on completing Priority Regional Bicycle Transportation Corridors and on improving the larger Regional Bicycle Transportation Network. |
| | | Regional transportation partners should fund projects that provide for bicycle and pedestrian travel across or around physical barriers and/or improve continuity between jurisdictions. |
| | | Regional transportation partners will provide or encourage reliable, cost-effective, and accessible transportation choices that provide and enhance access to employment, housing, education, and social connections for pedestrians and people with disabilities. |
| | | The Council, MnDOT, regional railroad authorities, and railroad companies will pursue short- and long-term improvements to accommodate future freight and passenger rail demand. |
| | | The Council and MnDOT should work together with cities and counties to provide efficient connections from major freight terminals and facilities to the regional highway system, including the federally designated Primary Freight Network. |
| | | The Council and airport sponsors will maintain a system of reliever airports to augment the Minneapolis-Saint Paul International Airport that are accessible within reasonable travel times from all parts of the metropolitan area. |

| The regional transportation system advances equity and contributes to communities' livability and sustainability while protecting the natural, cultural, and developed environments. | Reduce transportation-related air emissions.<br><br>Reduce impacts of transportation construction, operations, and use on the natural, cultural, and developed environments.<br><br>Increase the availability and attractiveness of transit, bicycling, and walking to encourage healthy communities and active car-free lifestyles.<br><br>Provide a transportation system that promotes community cohesion and connectivity for people of all ages and abilities, particularly for historically under represented populations. | Regional transportation partners recognize the role of transportation choices in reducing emissions and will support state and regional goals for reducing greenhouse gas and air pollutant emissions. The Council will provide information and technical assistance to local governments in measuring and reducing transportation-related emissions. |
| | | The Council and MnDOT will consider reductions in transportation-related emissions of air pollutants and greenhouse gases when prioritizing transportation investments. |
| | | Regional transportation partners will plan and implement a transportation system that considers the needs of all potential users, including children, senior citizens, and persons with disabilities, and that promotes active lifestyles and cohesive communities. A special emphasis should be placed on promoting the environmental and health benefits of alternatives to single-occupancy vehicle travel. |
| | | Transportation partners will protect, enhance, and mitigate impacts on the cultural and built environments when planning, constructing, and operating transportation systems. |
| | | Regional transportation partners will use a variety of communication methods and eliminate barriers to foster public engagement in transportation planning that will include special efforts to engage members of historically underrepresented communities, including communities of color, low-income communities, and those with disabilities to ensure that their concerns and issues are considered in regional and local transportation decision making. |
| | | Regional transportation partners will avoid, minimize, and mitigate disproportionately high and adverse impacts of transportation projects to the region's historically underrepresented communities, including communities of color, low-income communities, and those with disabilities. |

# Corridor Planning[1]

## I. INTRODUCTION

A corridor refers to a relatively well-defined geographic area that handles travel flows, usually centered around one or more major transportation facilities (for example, a freeway, commuter rail line, or express bus services). The corridor is often defined in terms of serving a travel shed within which trips are focused in a general linear pattern. Corridor plans determine the need for facilities or services among activity centers or other logical termini, as well as identify transportation investments to complement existing or planned land use. Traditionally, corridors were oriented radially from the suburbs to the center city. With the rapid growth in population and employment in the suburbs during the past 40 years, many corridor studies now focus on suburb-to-suburb trip patterns.

Corridor planning can focus on many different characteristics of corridor system performance. For example, corridor planning can address high-crash locations, increasing levels of congestion, restricted freight movements, changing land-use patterns, and the individual or cumulative effects of each on the current or future corridor transportation system. In this sense, a corridor plan is targeted geographically on needs within the corridor.

The decision to conduct a corridor study should consider its relationship to the regional transportation plan (RTP) update process and whether the study can provide typical solutions to problems found throughout the region. A corridor study conducted at the right time and with clear objectives could thus provide important information to the metropolitan transportation investment decision-making process and the RTP update. Decisions resulting from a corridor plan may lead directly to project definitions, design, and environmental analyses requiring a degree of detail that may be absent from a broader planning process.

This chapter examines the different characteristics of corridor planning, the reasons why corridor plans are conducted, and the steps typically followed. The following topics are covered: the rationale for conducting corridor planning; types of corridor studies that occur in practice, usually defined by geographic scale (for example, local, regional, state, and multistate); the relationship between transportation corridor investments and land use/urban design; major components of a corridor study, with examples provided from recent studies; and types of recommendations that typically result from corridor studies.

## II. NATURE OF CORRIDOR TRANSPORTATION PLANNING

An example of the purposes and characteristics of corridor planning comes from the Washington State Department of Transportation (WSDOT), which notes that such studies "bring together the goals and expectations of all groups involved in the project." [WSDOT, 2015] The description continues,

> *"corridor studies typically respond to a specific problem (high accident locations and corridors, high levels of existing or future congestion, significant land-use changes, etc.) and often involve more than one mode. These studies identify existing and future deficiencies and evaluate alternative solutions. The recommended alternative usually includes a facility description including environmental, operational, and other impacts (with proposed mitigation, if applicable). Corridor planning is accomplished using a long-range outlook (at least 20 years)."*

[1] The original chapter in Volume 3 of this Handbook was written by Donald R. Samdahl, P.E., PTP, Principal Fehr & Peers. Changes made to this updated chapter are solely the responsibility of the editor.

**Reasons for a Corridor Study**

- Developing a strategy to address current or future transportation problems.
- Relating a corridor strategy to a larger system plan.
- Identifying land use strategies that complement transportation investments.
- Identifying improvements to include within a local or regional plan.
- Setting the conditions for setting aside right-of-way within the corridor.
- Allowing more detailed cost estimates to be prepared.

The travel shed nature of a corridor helps define the length and breadth of the study area. Typically, an existing roadway or transit facility will serve as the spine of the corridor, but the travel shed will be much larger than just the immediate areas surrounding the facility. Corridor transportation facilities connect major activity centers and lead to other destinations. Examples of corridors include connections between two cities or segments of major transportation facilities that connect to other facilities (for example, a freeway between two connecting freeways). Corridors may range in length from a few miles in an urban area to hundreds of miles for statewide or multistate areas. From a modeling perspective, the corridor is also defined with traffic analysis zones (TAZs) to expedite the use of travel demand models in analyzing travel demand in the corridor. These TAZs represent the different land-use, trip-generating activities in the corridor (see chapter 2 on data collection and analysis, chapter 3 on land use, and chapter 6 on travel demand modeling).

A corridor plan should have readily understandable beginning and ending points, often referred to as logical termini. These boundaries help focus the analysis and avoid confusion with other transportation plans. Narrowly focused corridor plans examine an individual facility and the immediate surrounding area. However, many corridor plans encompass a broad geographic area that includes all of the travel movements within the corridor. Larger corridor plans within urban areas can have boundaries 5 to 10 miles from the specific facility being studied, while statewide and multistate corridor plans may encompass a swath of up to 50 miles in width.

Corridor plans can focus on the infrastructure characteristics of a single mode, such as a highway, commuter rail line, or bus routes. However, in most cases, corridor studies examine a combination of modes, especially those studies funded by state and federal agencies where such a multimodal examination of alternative modes is required. An important point of departure for such studies is to identify the potential corridor travelers and then determine how they will likely travel in the corridor.

Corridor plans can be conducted at various points within the transportation planning process. Most corridor plans are initiated in response to identified needs arising from a metropolitan or statewide planning process. These broader plans help set the framework for transportation needs, but typically do not examine the detailed facility requirements or services needed within a corridor. Corridor plans can provide the next level of transportation evaluation leading to specific recommendations on transportation investments. In addition, an important characteristic of many corridor studies is the relationship between the corridor study and environmental review processes.

The types of questions posed in a corridor study on I-25 in northern Colorado illustrate the types of questions that many corridor studies should ask at the beginning of the planning effort (see Table 17-1). [Northern Colorado Communities, 2001] Note that these questions relate to land use, transportation, environmental/natural resources, and regional character. Several of these questions are relevant to general corridor studies, while others may be most appropriately asked in the context of a detailed environmental process.

In many instances, the completion of a corridor study permits environmental reviews to be accomplished and project development to proceed. Follow-on, facility-level studies will then examine the detailed design requirements and project-level impacts of the recommended corridor plan. This environmental connection to corridor planning is discussed later in the chapter.

**Table 17-1. Questions Forming the Basis of Corridor Planning, Northern Colorado Land Use**

- Pattern of New Development: What patterns of new development are possible in the corridor, and how do they affect other issues?
- Property Rights: How should individual property rights be protected?
- Agricultural Activities: How does agricultural activity relate to regional character, and will new development conflict with continuing agricultural use?
- Market Considerations: What type, intensity, and pattern of development is the market likely to generate in the corridor over the next 10-20 years, and how does this support or conflict with a regional vision?

**Transportation**

- Capacity and Expansion: How much capacity does I-25 have to accommodate new development, and what are the effects of transit, roadway, or other possible improvements?
- Right-of-Way: What are the ROW requirements for future expansion?
- Access: Where should access be provided or limited, and how will individual community access control plans relate to regional goals?
- Local Network: What local network improvements will be necessary to serve the corridor in the future, and how will frontage roads and parallel service affect the network?
- Interchange Design and Spacing: What changes to existing interchanges are necessary? If there is a need for new interchanges, where should they be located, and how should they be designed to address safety and access goals?
- Travel Modes: What modes of travel will the corridor accommodate, and what are the development and design requirements?
- Linkages: How should communities near the corridor be connected to I-25 and areas along the corridor?
- Consistency and Coordination: How will recommendations of RTPs and local and subarea transportation plans and studies be integrated with the corridor plan?

**Environment and Natural Resources**

- Preservation of Natural Resources: Where and how should natural resources be preserved?
- Drainage, Wetlands and Watercourses: How should drainage, wetlands, floodplains, flood fringes, and watercourses be preserved, and how will they be integrated into new development?
- Scenic Views: Where are the most significant views, and how should they be preserved?

**Regional Character**

- Land-Use Regulations and Policies: How should the plan deal with plans, policies, and regulations that may be in conflict with regional goals?
- Transferable Development Rights: What role will transfer of density units (TDUs) play in implementation of the plan's objectives?
- Local Control and Regional Consistency: How should local control be balanced with regional consistency?
- Design Regulations: What is the appropriate level of design regulation for new development on a regional basis?
- Approved Development and Zoning: Are there conflicts between regional goals and local zoning, and if so, how can those conflicts be resolved?

Source: Northern Colorado Communities, 2001

**Key Points about Corridor Plans**

- One size does not fit all—tailor the corridor plan to the problems being addressed.
- Clearly articulate why the corridor study should be conducted, when it should be initiated, and how the issues will be considered.
- Relate the corridor plan to regional decisions that set the context for the issues being examined.
- Identify logical termini for the study.
- Identify key stakeholders and a public involvement process for informing these stakeholders.
- Identify a timeline for completion of the study.
- Focus on developing and documenting relevant and accurate information that leads to decisions being made within the corridor.

## A. Types of Corridor Plans

Table 17-2 shows how corridor plans can be used to address transportation issues at the local, regional, statewide, and multistate level. Several examples of corridor plans are shown in Figure 17-1. Local plans are illustrated by the 9-mile

**Table 17-2. Types of Corridor Plans**

| Corridor Plan Type | Typical Characteristics |
|---|---|
| Local | • Usually single facility focus<br>• Often single mode (highway, transit, nonmotorized)<br>• 2-3 miles in length<br>• Often land use/urban design component<br>• Limited environmental analysis |
| Metropolitan | • Major highway or transit facility<br>• Single or multiple modes<br>• Several parallel facility options<br>• Several miles in length<br>• Often land use/urban design component<br>• Detailed environmental studies |
| Statewide (intra-state) | • Major highway or rail facility (new or expanded)<br>• Single mode with modal options (e.g., transit, with options of commuter rail, intercity rail, or intercity bus)<br>• Several alignment options (new facilities)<br>• Many miles in length<br>• Sometimes local land use component<br>• Detailed environmental studies |
| Multistate | • Major highway or rail facility (new or expanded)<br>• Intermodal focus, including freight operations<br>• Several alignment options (new facilities)<br>• Detailed environmental studies<br>• Potentially complex institutional coordination processes |

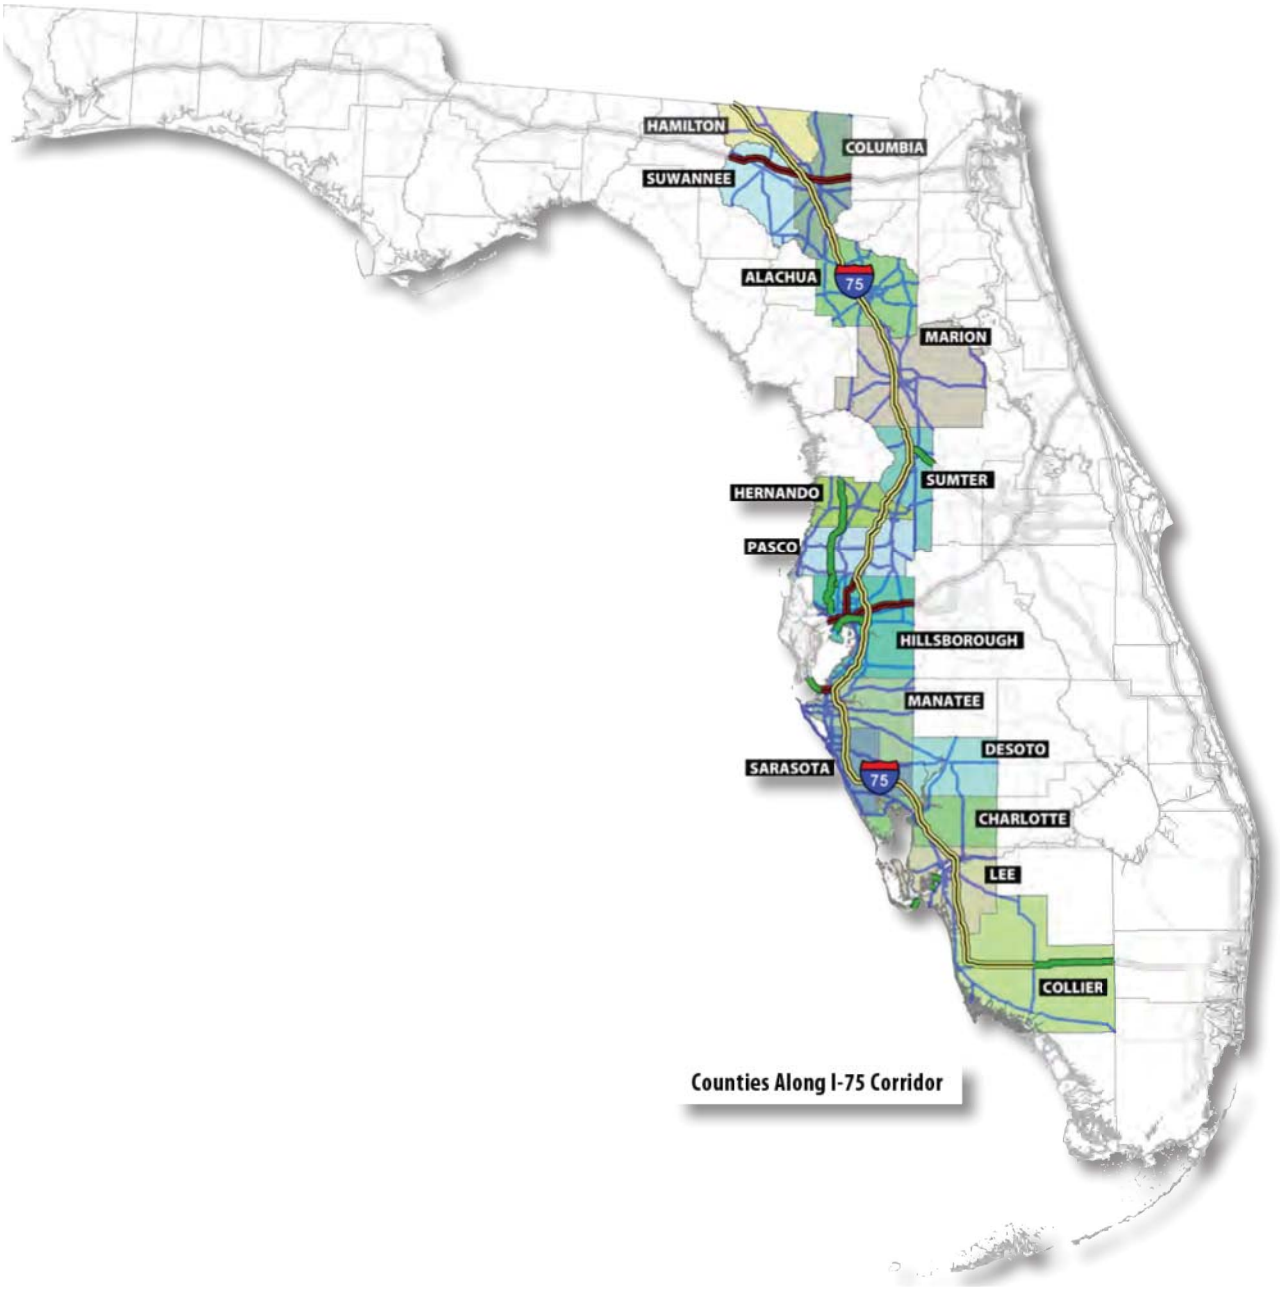
Cicero Avenue corridor (Figure 17-1a) running through the city of Chicago and five southwest suburban communities. [Southwest Conference of Mayors, 2011] Areas within one-half mile were considered as areas of influence and impact. The objectives of the corridor study included:

- Create a cohesive identity for the corridor.
- Maximize the potential of each community's assets along the corridor, including economic activity centers, transportation infrastructure, and natural resources such as trails.
- Optimize mobility and efficiency of all modes of travel.
- Increase safety for nonmotorized users of the corridor, especially at crossings and transit access points.

A steering committee of leaders from the corridor communities along with the involvement of state and local transportation agencies provided guidance to the study. The committee helped identify improvement projects and implementation priorities.

Figure 17-1b shows the study area for the Mid-County Corridor Study in Montgomery County, Maryland. [Montgomery County DOT, 2015] The study was part of a planning/environmental analysis of alternative

**Figure 17-1c. I-75 Corridor Study, Florida**



Source: Florida DOT, undated

transportation strategies to improve the performance of the corridor's transportation system. The objectives of the study were to:

- Improve vehicular safety.
- Enhance the efficiency of the roadway network and improve the connections among economic centers.
- Accommodate planned land use and future growth.
- Provide bicycle and pedestrian connections.
- Enhance emergency response.

The I-75 Corridor Study in Florida is an example of a statewide corridor plan (Figure 17-1c). [Florida DOT, undated] The study corridor includes 15 counties, containing 4.5 million residents, 24 percent of Florida's total population. The purpose of the I-75 study was to assess the travel demand and freight movements along the corridor against

four measures: transportation, emergency management, homeland security, and economic development. Some of the strategies considered ranged from adding capacity to parallel corridors to implementing managed lanes to encouraging travel demand management (TDM) programs.

A multistate corridor plan is illustrated by the Tennessee to Canada I-81 corridor study (see Figure 17-1d). [Cambridge Systematics, 2012] The 855-mile corridor is a major freight corridor with from 11 to 57 percent of the traffic flow on individual segments being trucks. A memorandum of understanding was signed by six states laying out the overall study and the respective responsibilities of the state DOTs, as well as including the 14 metropolitan planning organizations (MPOs) in the corridor. The study recommended that opportunities for coordinated policy and action among the I-81 states be pursued including a review of each state's policies, goals, and strategies on such things as congestion, commercial vehicle safety, promoting connectivity of modes and planning; establishing a central data and information repository using data collection standards and formats developed by the coalition states; and conducting additional studies of critical near-term issues such as coordinated multistate truck origin-destination surveys and studies to identify shared management, investment, and modal strategy opportunities.

**Figure 17-1d. I-81 Multistate Corridor Study**

Source: Cambridge Systematics. 2012

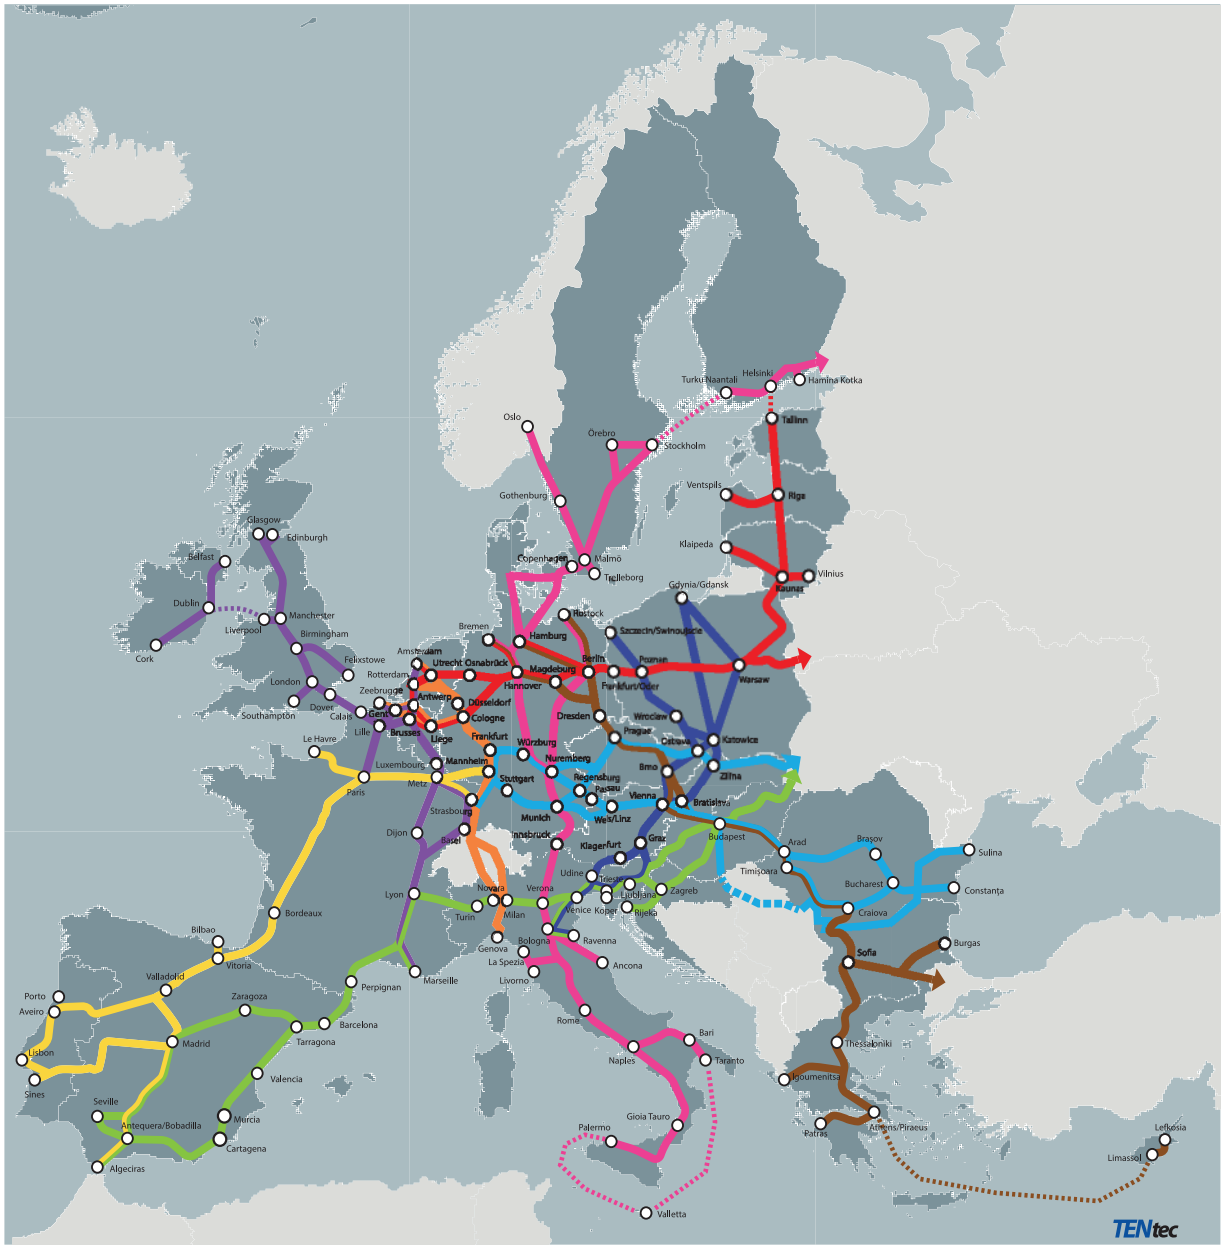
Finally, Figure 17-1e shows that corridor studies can be undertaken at the continental level. This figure shows the major European corridors targeted by the European Union (EU) for major transportation investment. [EU, 2015] The intent of the corridor investment program is to:

- Strengthen the basis for trade flows and citizens' mobility within the Union and with external markets.
- Reinforce territorial, social, and economic cohesion in the Union.
- Enhance the infrastructure basis for an efficient and sustainable mobility system, which stands for future-oriented and high-quality transport services for passengers and freight. [EU, 2015]

Questions that planners should ask when identifying corridor boundaries include: [as amended from WSDOT, 2007]

- What are the logical boundaries for which the study is being conducted?
- What issues are dominant in the area?
- What seem to be the natural travel markets today and likely in the future?
- Is there a perception that the issues are greater than current data suggest?
- Are there population groups, in particular environmental justice populations, that rely on the corridor transportation system even though they do not live adjacent to the corridor?
- Are there major activity centers that rely on the corridor for mobility and accessibility even though they are not adjacent to the corridor?

**Figure 17-1e. European Transport Corridors Targeted for Major Investment**



Source: EU, 2015

- Are there junctions with major routes and local roads, or connections to other modes?
- Are there environmental issues that would require a larger than expected study area, for example, watershed issues that might occur downstream?
- How do jurisdictional boundaries, neighborhoods, environmental features, and route functions relate to each other?
- How are the data aggregated or disaggregated in the study area such that zones or districts can be used as building blocks for a corridor study area?

As has been emphasized in other chapters in this handbook, transportation planning must reflect and relate to other types of plans for the community, region, or state. Corridor plans are no different. For example, they must fit within the context of local, metropolitan, and statewide transportation plans. Table 17-3 illustrates this relationship between corridor plans and other types of planning studies. Note that the table is not intended to be a comprehensive listing of all the plans that might relate to corridor planning. Each of these plans provides important information to decision makers for a particular study area; however, each plan might influence the results of other studies as well. As an example,

| Table 17-3. Relationship of Corridor Plans to Other Planning Processes | |
|---|---|
| **Type of Plan** | **Relationship to Corridor Planning Studies** |
| Metropolitan transportation plan (MTP) | Identifies short/long range actions for regional transportation improvements. Financially constrained. Corridor plan will help refine projects to include within plan. |
| Statewide transportation plan | Describes how the state will accommodate efficient movement of people and goods. Corridor plan helps provide reference points for specific statewide actions. Statewide plan can provide policy guidance to corridor planning activities. |
| Regional and statewide TIPs | Develops program of projects proposed for federal and state funding. Corridor plans may be used as a basis for including projects within the TIP. |
| Regional, strategic or vision plans | Used to identify a long-term vision of transportation improvements that can set the context for the financially constrained MTP. Corridor plans may be initiated in response to these plans or provide input into the regional vision. |
| Local agency comprehensive plans | Focused on the definition of land use and transportation improvements by local governments. Corridor planning efforts can provide direct input to the composition of projects within a comprehensive plan. Local plans can provide constraints on alternatives to be considered within a corridor plan. |

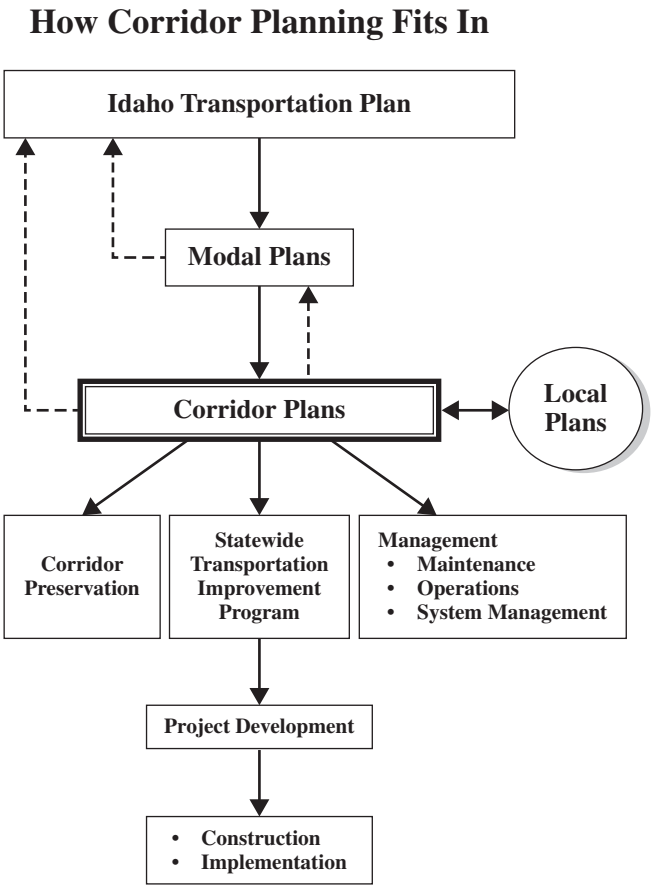
Figure 17-2 shows how corridor studies fit into the overall transportation planning and decision-making processes in the Idaho Transportation Department.

**Figure 17-2. Relationship of Corridor Planning to Other Decision-making Processes, Idaho**



Source: Idaho Transportation Department, 2006

Corridor plans are most commonly tied to some combination of federal environmental planning requirements through the National Environmental Policy Act (NEPA) requirements, a metropolitan transportation plan, or a statewide transportation plan. Planners should coordinate upfront with NEPA reviewing authorities/entities (including federal/state/local) to also help minimize the likelihood of re-conducting technical studies. This coordination can be anything from a simple phone call to keep the party in the loop to asking for assistance in writing the study scope. These relationships are further described in the following sections.

## B. National Environmental Policy Act (NEPA)

The 1969 NEPA established a process for examining the environmental impacts of actions involving federal funding (see chapter 4 on environmental analysis). Many corridor planning studies in the United States examine projects that might be federally funded and thus require a close relationship to the NEPA process. One of the key decisions early in the planning process is to determine what, if any, relationship there needs to be with NEPA requirements and with associated government participants (such as natural resource agencies).

NEPA has three classes of actions that define the level of documentation needed to meet federal requirements: (1) Class I–Environmental Impact Statement, (2) Class II–Categorical Exclusions, and (3) Class III–Environmental Assessments. Environmental impact statements (EISs) are required where the proposed actions will significantly affect the environment. Conversely, Categorical Exclusions (CEs) are appropriate where no significant environmental impacts are anticipated. Studies that do not meet one of these two extremes fall into the Environmental Assessment (EA) category.

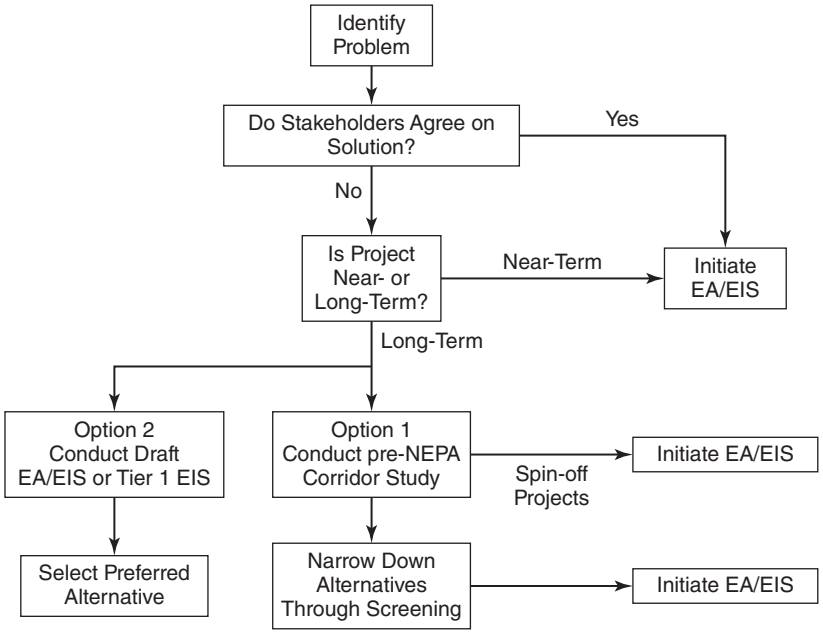
The decision on whether to prepare NEPA documentation and, if so, how detailed it should be, depends on the decision-maker needs for information, project timing, and funding. A decision to follow the NEPA process is often made to make the project eligible for federal funding. At other times, the decision to not follow the NEPA process is made if it is known that future phases of a project (for example, design) will rely on state or local funding rather than federal funding, or if the project is to be fast tracked (also with local funds). Delaying a decision to enter into an EA/EIS study for a long-term solution might also occur because, after a study is completed, the FHWA or FTA (for example) could require a supplemental study be conducted if no progress has been made in implementing the approved project. This is done to ensure impacts are still defined appropriately and mitigated, if necessary. Thus, if some aspects of a project are unclear or controversial, it might make sense to postpone a study until the possibility of a supplemental study is reduced.

Corridor plans can go through several life cycles. For example, a transportation agency might begin with a general feasibility study, which when completed could lead to more in-depth corridor studies. Initial feasibility studies may be conducted outside of the NEPA process, with their purpose being primarily to determine whether there is a need for more detailed study. Such studies should make sure that ideas or concepts developed in the study should transfer to, and be understood in, any future NEPA process. It is also important to publicly disclose these early decisions to avoid having to re-conduct technical studies if the corridor moves into a NEPA process (assuming the regulatory time limitations associated with how long the technical analysis remains valid are not exceeded).

Often corridor plans evolve through a tiered environmental process. The first-tier in this process frames and narrows the scope of the corridor for more detailed examination in a second tier study. For example, a first tier analysis might address the overall needs in a corridor spanning several miles. Florida DOT's Efficient Transportation Decision Making (ETDM) process is a good example of the purpose and need screening for a corridor. [FDOT, 2015a] This process is designed to identify any fatal flaws to a potential corridor improvement before it moves forward in the project development phase. Subsequently, second-tier studies would analyze shorter sections of the corridor at a greater level of detail.

Figure 17-3 shows how corridor studies and NEPA are related. At several points during corridor planning a decision can be made to initiate a NEPA process. Considerations include whether the stakeholders agree on a solution early in the process and whether the project will result in specific actions. More defined solutions and near-term actions are most likely to find their way into a formal environmental process leading to a project decision. In addition, because of the environmental approval process that often follows the completion of a corridor study, planners often find many natural resource agencies involved in varying capacities in corridor studies. Figure 17-4, for example, shows the organizations that were involved with the Inter-County Connector study conducted by the Maryland State Highway Administration.

**Figure 17-3. Relationship between Corridor Studies and NEPA**



Source: Smith, 1999, Reproduced with permission of the Transportation Research Board.

Corridor plans looking at longer-term solutions may or may not follow a formal NEPA process depending upon the decisions anticipated and the expected level of environmental impacts. If the plan is truly looking at establishing a strategic direction in the corridor rather than identifying specific projects, it may be prudent to defer the formal environmental process to a later date. NCHRP Report 435 provides a detailed description of how the NEPA process should be integrated within the corridor planning process. [Smith, 1999]

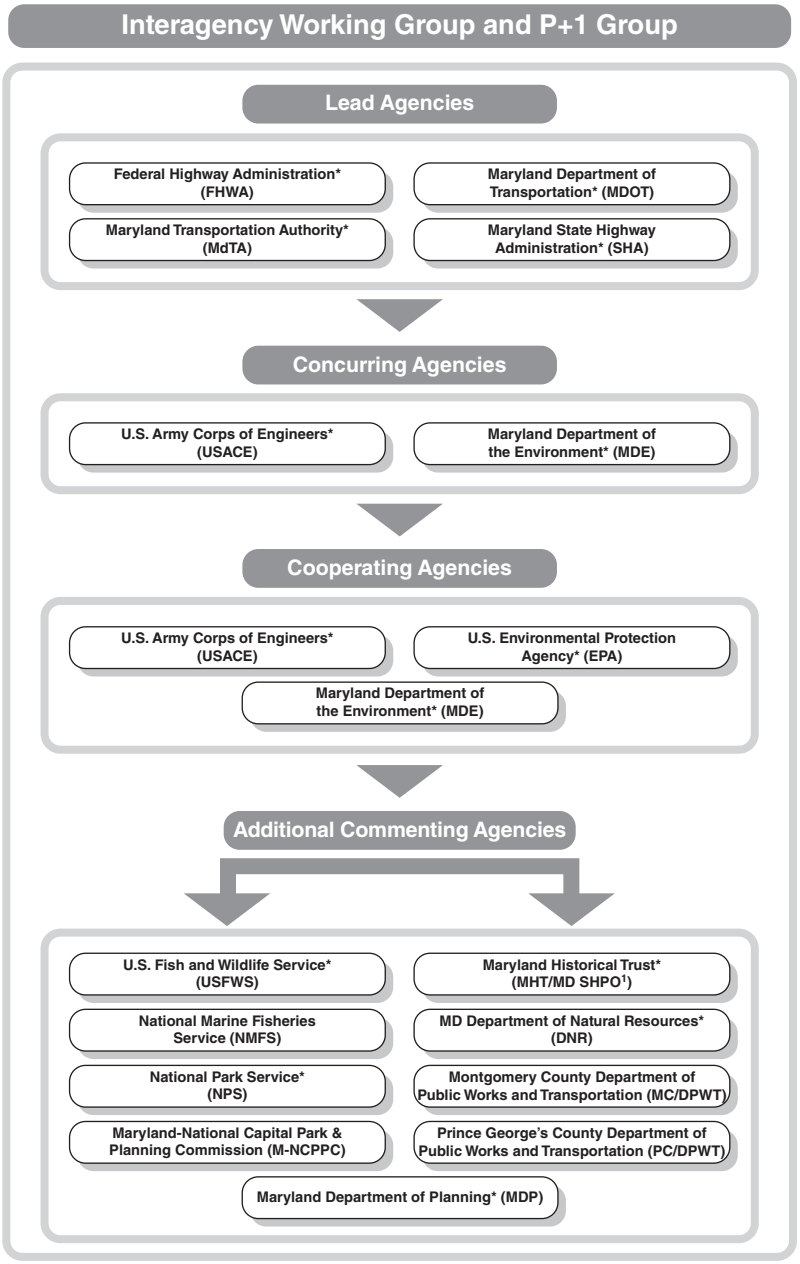
## C. Regional Transportation Plan (RTP)

RTPs establish long-range transportation goals and directions for a metropolitan area's transportation system (see chapter 16 on metropolitan transportation planning). In this context, "region" includes both metropolitan areas as well as nonmetropolitan regions of a state. RTPs typically include a long-range vision and a financially constrained set of projects. A corridor plan can help define the scope and magnitude of projects listed in the RTP.

At the same time, the RTP often serves as the catalyst for conducting corridor plans. The RTP defines specific long-range, multimodal corridor needs and establishes some general priority on implementation. A well-crafted corridor planning process can then refine the feasibility of alternatives within a corridor and establish a decision process to make the selected alternative(s) a reality. In metropolitan areas, the metropolitan transportation planning process can provide insights into transportation needs and solution strategies to be considered in a corridor study. Figure 17-5, for example, shows how corridors in the Philadelphia metropolitan area, whose eventual analysis provided input into the update of the metropolitan transportation plan, have been defined. A similar concept is shown in Figure 17-6, where corridors were defined as an important input into the regional transit plan in Knoxville, Tennessee. [Knoxville TPO, 2013] The purpose of the Knoxville study was to:

- Expand transit opportunities for existing transit users, nondrivers, and promote transit use by new riders.

**Figure 17-4. Institutional Responsibilities for the Environmental Component of the Inter-County Connector, Maryland**

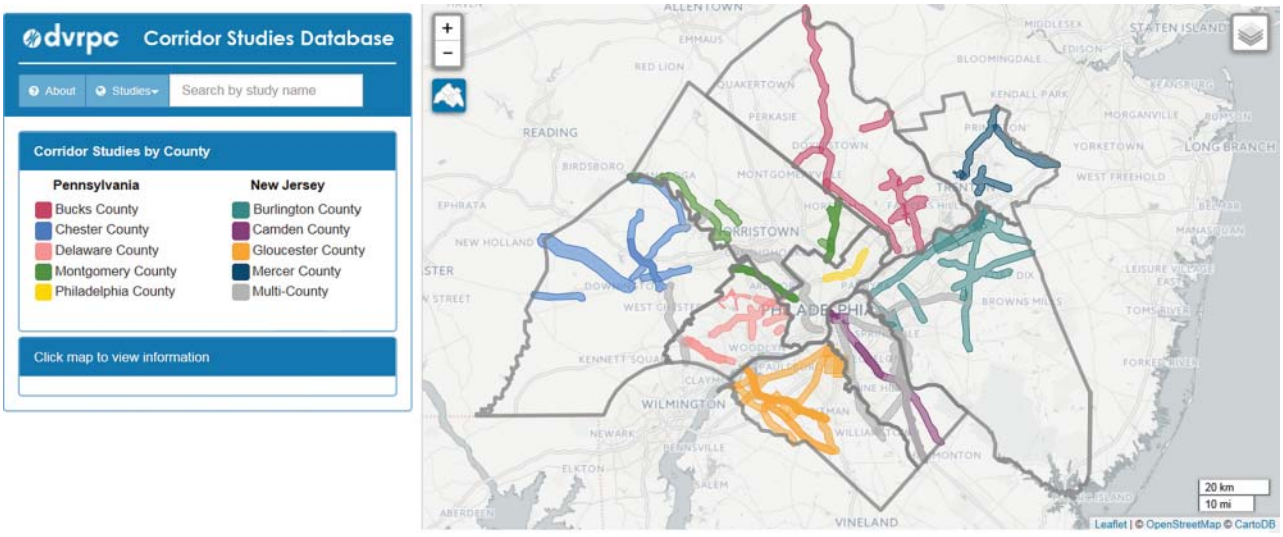


[1] - State Historic Preservation Officer
* - Included in P+1 (Principals Plus One) group

Source: Maryland DOT, 2006

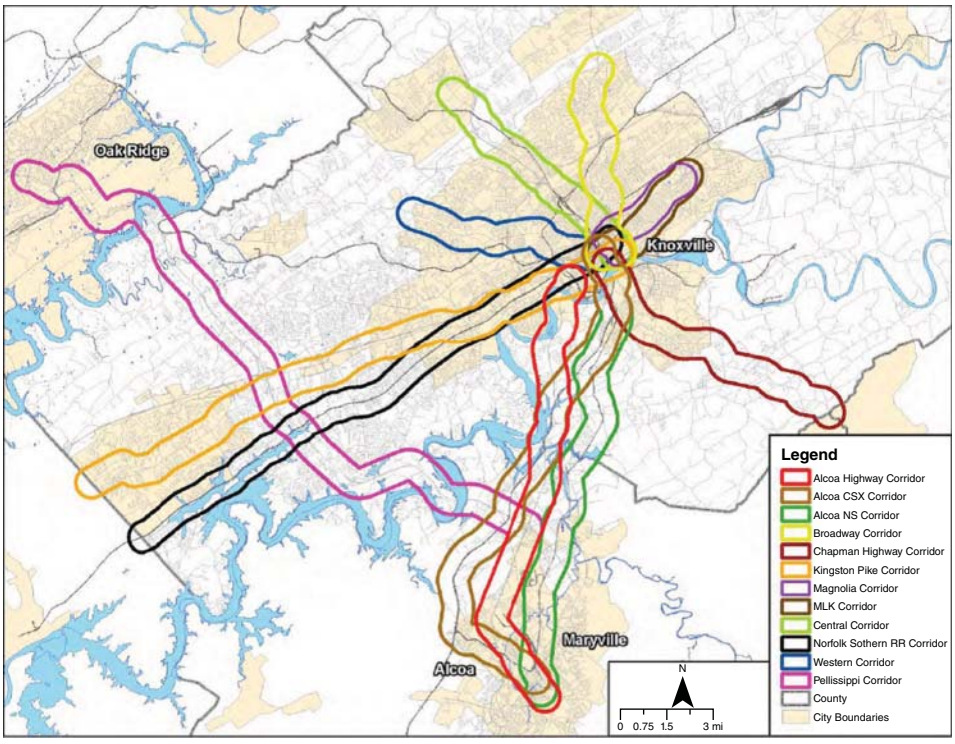
- Enhance Knoxville's image as a world-class city and help the region compete with other metropolitan areas, which are completing and/or already have rapid transit systems.
- Explore the role of transit technologies in creating an efficient transportation system and a more sustainable community.
- Develop and recommend transit supportive land use guidelines, policies, and tools to support transit-oriented development (TOD) and corridor development.

**Figure 17-5. Philadelphia Metropolitan Area Corridor-Based Planning**



Source: DVRPC, 2015

**Figure 17-6. Transit Corridor Plan, Knoxville, Tennessee**



Source: Knoxville TPO, 2013

## D. Statewide Transportation Plans

Statewide transportation plans (STPs) provide a blueprint for state transportation programs and investments. These plans typically cover all modes of transportation: roadways, ferries, public transportation, aviation, freight rail, passenger rail, marine ports and navigation, bicycles, and walking. The STP can provide a framework within which major intercity or statewide corridor plans are developed.

Similar to metropolitan transportation plans, in some cases, STPs can be based on the results of corridor studies. For example, the 2003 STP for Pennsylvania was based on 26 travel corridors that defined the major travel flows within the state. These corridors became the focus of additional analysis and provided more detailed input into subsequent

investment decisions. Many states are now taking a strategic statewide approach to corridor development to better prioritize subsequent corridor planning studies. Statewide planning is addressed further in chapter 15.

## E. Relationship to Land Use/Urban Design

Table 17-1 indicated that corridor studies at the local and/or metropolitan levels often have land-use and urban design components. Corridor studies with much broader applications, that is, state or multistate studies, most often do not. Especially in an urban environment, a corridor investment strategy must take into account expected or desired land uses and urban design principles. One of the trends in local and metropolitan-level corridor studies over the past 20 years has been a much more comprehensive approach toward integrating transportation solutions and land-use/urban design strategies.

Figure 17-7 illustrates this integration with an example from the state of Washington. In this case, an environmental impact statement prepared under the state environmental law developed a preferred alternative that combined both transportation and land-use components. [City of Bellevue, 2007] The study examined the following alternatives:

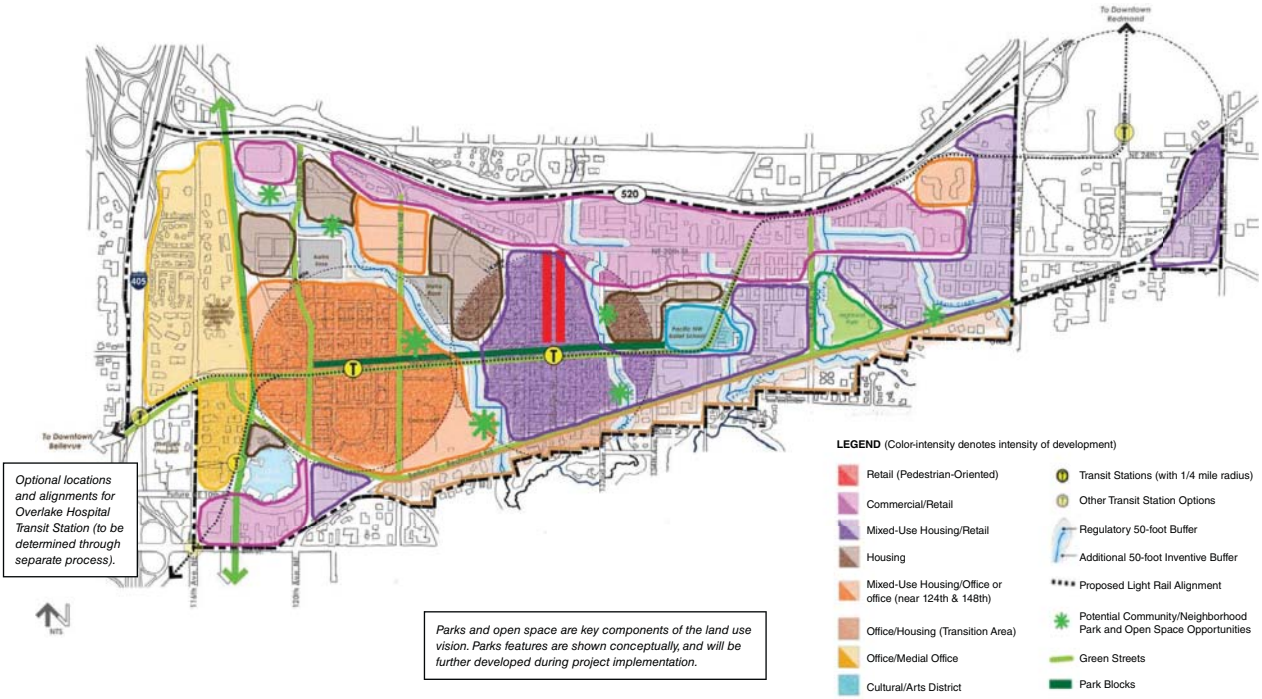
*No-Action Alternative:* The No-Action Alternative assumed no major changes in land use or transportation other than those already programmed as part of existing plans or proposed by other agencies. Based on existing trends, it was estimated that 1.03 million additional square feet of nonresidential space would be developed in the corridor by 2030.

*Alternative 1: Mid-Range Employment and Mid-Range Housing:* This alternative assumed a net increase of 3.5 million square feet of new commercial (office and retail) space and roughly 3,500 new housing units. Two light-rail transit (LRT) stations were recommended.

*Alternative 2: Low Employment and High Housing:* This alternative assumed roughly 2.5 million square feet of new commercial space and 5,000 new housing units. Three LRT stations and associated development nodes were recommended.

*Alternative 3: High Employment and High Housing:* This alternative assumed approximately 4.5 million square feet of new commercial space, along with 5,000 new housing units. Three LRT stations and associated development nodes were recommended.

**Figure 17-7. Land-Use and Transportation Corridor Strategies, Bellevue, Washington**



Source: City of Bellevue, 2007

The final environmental study chose a preferred alternative including four light rail stations, with increased development density in the western half of the corridor by including closely spaced development nodes. These nodes would alternatively include office and medical; office and housing; office, housing, and retail; and mixed-use housing.

Another example of the combination of land use/urban design and transportation issues, only in a different and more limited context, is found in Scottsdale, Arizona. In this case, the city of Scottsdale established design guidelines for scenic corridors that traversed the Sonora Desert. The city designated scenic corridors for several purposes, which included, (1) preserve or encourage the preservation of the natural setting along the roadway, (2) provide views of nearby natural landforms, (3) allow for connectivity of nonvehicle travel buffered safely from motor vehicle traffic, (4) visually link corridors to open space, and (5) buffer adjacent land uses from the adverse effects of traffic along a roadway. Given the sensitivity of the desert environment to disturbance, the city provided both recommended guidelines for roadway design as well as development strategies to minimize the impact on the desert. A desired right-of-way cross section was defined that included width and access requirements; median treatments; provision of bicycle, pedestrian, and multi-use paths; utility easements; landscaping; and drainage structures. A development setback requirement was established to minimize the impact of development immediately surrounding the scenic highway, and development guidelines were established for land uses immediately beyond this setback.

## III. CORRIDOR SELECTION

In some instances, state DOTs or MPOs have adopted a corridor approach as a major strategy for developing their transportation plan. [Carr, Dixon, and Meyer, 2010] In essence, this means they have identified a number of corridors that are important from a transportation perspective and that are candidates for investment. The question then becomes which corridors should receive attention first? There are several examples of how this can be done.

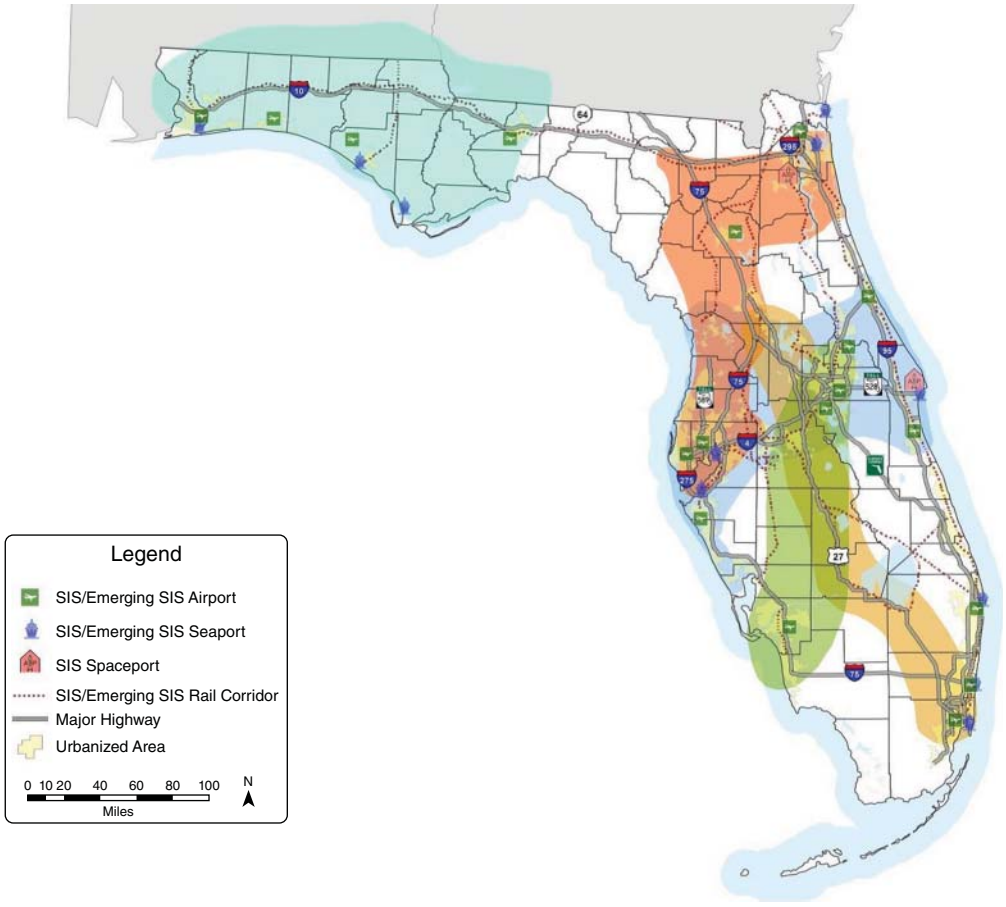
**Guiding Principles for Florida's Future Transportation Corridors Planning Process [Florida DOT, 2015].** Realizing the importance of long-distance travel to the economy of the state, the state of Florida has identified a corridor investment strategy to support economic development. Figure 17-8 shows the corridors that will be subject to analysis. The selection of which corridors to proceed with first is based on the following characteristics of each corridor.

- *Be consistent with statewide and regional visions and plans:* Make decisions about statewide transportation corridors consistent with:
  - The goals and objectives of 2060 Florida Transportation Plan and other statewide plans.
  - Long-range visions about the future growth and development of Florida's regions and, in the future, the state as a whole.
- *Structure planning process:* Develop a structured planning process that:
  - Involves partners early and continuously.
  - Coordinates transportation corridor decisions with land use, economic development, environmental stewardship, water management, and other public and private decisions and identifies opportunities to accomplish multiple objectives.
  - Provides clear decision making points and ensures that issues and recommendations carry forward into future stages.

The corridor needs and strategies identification process is predicated on:

- *Identifying long-term transportation needs:* Define a statewide mobility or transportation connectivity need based on data, consensus forecasts, and statewide, regional, and community visions and plans.
- *Maximizing existing facilities:* Make optimal use of existing transportation facilities.
- *Considering alternatives to highways:* Promote greater use of existing rail, water, and air corridors to move both people and freight.
- *Considering new facilities if needed:* Develop new facilities if existing facilities cannot meet mobility or connectivity needs.

**Figure 17-8. Prospective Corridors for Analysis, Florida**



Source: FDOT, 2015

Corridor locations were determined based on:

- *Enhancing economic development:* Improve transportation connectivity for people and freight to established and emerging regional employment centers and economically productive rural lands.
- *Supporting growth in appropriate areas:* Locate major transportation corridor improvements and, if needed, new facilities in appropriate and environmentally acceptable areas, consistent with adopted visions and growth plans, local government comprehensive plans, and adopted agency plans.
- *Protecting and restoring the natural environment:* Plan and develop transportation corridors in a manner that protects and, where feasible, restores the function and character of the natural environment and avoids or minimizes adverse environmental impacts.

The corridor planning approach should be:

- *Including multiple modes and uses:* Plan enhanced or new transportation corridors, where appropriate, to:
  - Accommodate multiple modes of transportation for moving people and freight.
  - Coordinate locations with existing and new utility infrastructure.
- *Preserving the function of the corridor:* Maximize the use of statewide transportation corridors for interregional and interstate travel and transport though operational strategies, demand management, access management, coordination with surrounding land uses, and development of effective regional and local transportation networks.

**Figure 17-9. Evaluation of Different Transit Corridors in Knoxville, Tennessee**

Source: Knoxville Transportation Planning Organization, 2013

- *Designing modal infrastructure and access carefully:* Plan highway elements of future transportation corridors to be limited access, with interchange locations identified to provide access to economic development activities dependent on long-distance transportation, and to support land uses as identified in local plans. Plan rail and transit elements of future transportation corridors to support compact development locations and to encourage public transportation ridership.
- *Using context sensitive design:* Plan, develop, and implement transportation corridors using context sensitive design practices to the fullest extent possible.
- *Using advanced and energy efficient approaches:* Use state-of-the-art and energy-efficient infrastructure, vehicles, materials, technologies, and methodologies to develop and operate transportation corridors.

**Knoxville Transit Corridors for Potential Investment [Knoxville Transportation Planning Organization, 2013].** Figure 17-9 shows a typical assessment based on evaluation criteria for each corridor. In this case, the study was examining different transit corridors in Knoxville, Tennessee, to determine which ones showed the most potential with respect to a range of criteria shown in the matrix. [Knoxville Transportation Planning Organization, 2013] An evaluation matrix allowed decision makers to examine the results of the study in a consistent manner among the potential corridors. As shown in the figure, three corridors were identified as having the most potential in terms of satisfying transit goals. These three corridors were selected for more detailed corridor planning.

## IV. CORRIDOR PLANNING APPROACH

Several guides have been developed to help transportation planners conduct an effective corridor study (see, for example, [Vermont Agency of Transportation, 2005b; WSDOT, 2007; City of Ottawa, 2009; Center for Transit Oriented Development, 2010; and City of Waterloo, 2013]). Besides the technical analysis process, public engagement occurs throughout the planning process, providing opportunities for input from a variety of interests and stakeholder groups. However, unlike public engagement programs for developing a metropolitan transportation plan, which often includes abstract concepts and undefined projects, corridor-level public outreach efforts should be more focused and targeted on specific problems.

**Figure 17-10. Typical Contents of a Corridor Study, Washington State**

**Sample Table of Contents for a Transportation Corridor Planning Study**

**Executive Summary**

- Primary function of the corridor.
- The 20-year vision for the corridor.
- The goals for the corridor.
- The study process and public involvement.
- Prioritized recommendations.
- Summary of the next steps.

**1) Introduction**

- Purpose of study.
- Study area or corridor, including function, classification, and distinguishing characteristics.
- History of the corridor.
- Corridor location, including base map of the corridor.
- Stakeholders.
- The 20-year vision for the corridor.
- Plan contents.
- Goals of the study.

**2) Basic Information—Existing Conditions**

- Current issues present in the corridor.
- Preservation.
- Safety.
- Mobility.
- Environment.
- Stewardship.

**3) Data Analysis for the 20-year Planning Horizon**

- How will the existing conditions change?
- Modeling.
- Forecasting.

**4) Fiscal Constraints—List of Financial Assumptions**

**5) Recommendations**

- Preliminary recommendations based on goals.
- Screening criteria.
- The Action Plan—Implementation Action Matrix.
- Next Steps for Monitoring Implementation.

A good example of the content of a corridor plan is shown in Figure 17-10, which was offered by the Washington State DOT (WSDOT) as a typical table of contents for a corridor plan. As used by WSDOT, a corridor study focuses on identifying problems and proposing solutions on state highway corridors. These plans are intended to support local and regional planning requirements to implement the state's Growth Management Act. They typically focus on key topics such as route continuity, access management, and future capacity needs.

The content follows a traditional approach of fully documenting existing and future conditions, identifying alternative solutions, and evaluating the alternatives using a set of agreed-upon criteria. A public engagement process is used throughout the study. The end product is a recommendation on a strategy to improve corridor performance.

The following sections describe in more detail some of the important steps that constitute a corridor planning study.

## A. Identify Vision, Goals, Objectives, and Evaluation Criteria (Related to Performance Measures)

Similar to the transportation planning process for statewide plans (see chapter 15) and for metropolitan areas (see chapter 16), corridor planning should begin with some sense of a vision of what the community wants with respect to the corridor transportation system. A vision should then be followed by goals and objectives, which provide more specificity in terms of system characteristics, which in turn lead to evaluation criteria for the assessment of different actions and strategies. The evaluation criteria should reflect the overall performance measures established for the jurisdiction. Thus, for example, if a region has established the number of fatalities or injuries on the transportation system as a key performance measure, a corridor study would want to know how the different strategies help this particular performance measure (or help attain the target values that have been established).

Goal statements are general statements that identify desired outcomes of corridor investment. Corridor goals need to be related to regional goals as articulated within the metropolitan transportation plan and to appropriate statewide planning goals. Articulating goals and objectives must be a collaborative process among the corridor stakeholders and should serve as a constant reminder of the purpose of the corridor study. Objectives, which are derived directly from goals, provide more specific direction in terms of the technical process and the type of community outreach that is appropriate. It is important that the objectives be specific enough to be measured either quantitatively or qualitatively.

Some examples from corridor studies are provided below.

**San Diego—Imperial County Interstate 8 Corridor Strategic Plan [Imperial Valley Association of Governments, 2009]**

Goal 1: Improve interregional collaboration.

- Objective: Establish partnerships or a structural framework for addressing interregional concerns.
- Objective: Establish a collaborative process between I-8 stakeholders, including: Caltrans, SANDAG, IVAG, Tribal Nations, Imperial and San Diego County, and other local governments to address issues of common concern.

Goal 2: Maintain and improve mobility for people and goods.

- Objective: Provide adequate levels of service on the I-8 over the next 20 years and beyond.
- Objective: Improve travel times along the I-8 corridor.
- Objective: Reduce dependency on single occupant vehicles.
- Objective: Implement strategies that reduce the growth in congestion, while improving air quality.
- Objective: Implement strategies that incorporate the management and operations of the transportation system with the overall planning process.

Goal 3: Enhance the quality of life in the Imperial Valley and San Diego County.

- Objective: Improve jobs and housing balance in the Imperial Valley and San Diego County (by developing more efficient land use patterns that accommodate a sufficient housing supply to match population increases and workforce needs for the full spectrum of the population).
- Objective: Implement neighborhood and project designs that promote more walking and biking for healthier communities.
- Objective: Implement smart growth principles such as transit-oriented development around major transit hubs and minimizing of growth in areas that are disconnected from adequate local or regional transportation options.
- Objective: Implement strategies that address transportation safety and security through improved integration of these issues into the transportation planning process.
- Objective: Implement strategies that preserve the unique rural character and viability of communities along the I-8 corridor.

Goal 4: Improve the economic vitality of Imperial Valley and San Diego County.

- Objective: Increase number and diversity of employment opportunities in the Imperial Valley and San Diego County.
- Objective: Increase supply of workforce housing to support a diversified job market.
- Objective: Increase collaborative economic strategies that build on the assets of the two regions.

Goal 5: Minimize negative impacts of growth and transportation improvements on the environment.

- Objective: Improve strategies that protect habitat and environmentally sensitive lands.
- Objective: Implement climate action strategies that reduce the carbon footprint of growth and traffic from the Imperial Valley and greater San Diego region.
- Objective: Improve mitigation of environmentally sensitive lands along the I-8 corridor.
- Objective: Implement strategies that preserve the scenic value of the I-8 corridor.

**Route 29 Corridor Study, Virginia [Virginia, 2009].** The vision for this corridor resulted from numerous meetings with stakeholders and the general public. Seven themes were developed from public input and were viewed as a vision for the corridor.

- Control access points to the corridor.
- Influence the type of access/connection type.
- Enhance overall mobility and reduce congestion.
- Expand travel mode choices.
- Encourage corridor planning for land use and transportation.
- Enhance stewardship role for VDOT to preserve transportation investment.
- Preserve the integrity of corridor as a statewide scenic resource.

Goal statements that related to this vision included:

- Keep people and goods moving smoothly and efficiently within and through the corridor.
- Reduce accidents and enhance travel safety.

- Expand transportation choices.
- Expand the market reach of existing and prospective companies in the corridor and relying on corridor businesses.
- Expand the area from which a skilled labor pool can be drawn.
- Help steer growth to desired areas.
- Preserve and enhance the attractiveness of the region to tourists and residents.
- Provide better traveler information and services.
- Ensure that Route 29, as a viable part of the National Highway System, helps the nation compete in the global economy and move people and goods in an energy-efficient manner.

**University Avenue Corridor Study [Champaign County Regional Planning Commission, 2010].** The vision for this transportation and land use corridor study was stated as:

> *"The University Avenue corridor will support an intensified and diverse mix of commercial, office, institutional, and residential uses at an appropriate density that serves to connect the two downtowns, University of Illinois and medical campuses to sustain adjacent neighborhoods. The corridor will be served by a multi-modal transportation system that facilitates its status as the communities' main east-west thoroughfare, while supporting other modes of transportation. Enhanced building design and streetscape features will help to unify and breathe new life into this urban corridor."*

The following seven goals reflected the most important principles to be addressed through the corridor study recommendations.

- Promote orderly and attractive redevelopment along University Avenue.
- Develop higher density, multimodal nodes at selected intersections.
- Maximize the safety and efficiency of the current transportation network throughout the corridor.
- Provide bicycle connections from the corridor to the rest of the community.
- Improve pedestrian facilities, safety, and access along the corridor.
- Provide more direct transit service and additional transit facilities throughout the corridor.
- Create an enhanced streetscape with unifying elements along the corridor.

When a corridor study is part of an environmental impact process, the goals and objectives become (either implicitly or explicitly) part of the purpose and needs statement (see chapter 4 on environmental analysis). The I-70E corridor study and environmental analysis in Colorado is a good example of this, with the following identified needs.

- *Transportation infrastructure deficiencies:* I-70 was constructed in the early 1960s with bridge and drainage structures designed to last for 30 years. Nine structures on the corridor are now past their anticipated lifespan and are classified as either structurally deficient or functionally obsolete and in need of replacement, rehabilitation, or repair.
- *Increased transportation demand:* The project area is experiencing rapid growth and development. This includes both areas of new development and redevelopment, with substantial residential populations and business activity. The land-use and development trends within the corridor will result in additional demands on the transportation system. Providing access and maximizing the ability to travel through and within the corridor are critical to maintaining the economy. This includes maintaining and enhancing connections between major activity centers near the corridor.
- *Limited transportation capacity:* I-70 serves a growing number of users, ranging from travelers and tourists from outlying areas and DIA to regional trucking to commuters or local traffic. The demand from these users is exceeding the existing design capacity of I-70 and associated interchanges. Within the project area, I-70 is

currently near or over capacity. Between 47,000 and 205,000 vehicles per day (average daily traffic) travel over the project area, depending on the location in the corridor. Forecasted traffic for the year 2035 shows that traffic on I-70 will increase substantially, carrying from 117,000 to 285,000 vehicles per day. This increase in traffic will result in more hours of congestion, longer delays, and increased potential for crashes.

- *Safety concerns:* In the project area, I-70 generally experiences more traffic crashes than the state average for urban freeways. These crashes cause unpredictable and unavoidable traffic congestion, which adds to or worsens the already existing congestion from travel demand that exceeds the normal roadway capacity. The unpredictable nature of traffic congestion on I-70 increases safety concerns for freight carriers, employers, manufacturers, and business interests in the region, as well as commuters and residents who depend on reliability for their daily travel. [CDOT, 2014]

Establishing criteria for evaluating alternatives is one of the most important steps in the corridor planning process. Evaluation criteria, also known as measures of effectiveness, define the information to be developed and presented to decision makers and the public; thus, they should be directly related to the problems being investigated. The criteria should also be meaningful and easily understood to a wide variety of stakeholders. The evaluation criteria will determine the scope and complexity of the technical analysis process, affect the study schedule and budget, and ultimately, drive the decision process. Therefore, it is important for corridor planners to think about how the criteria are to be used as part of the decision-making process.

Evaluation criteria typically relate to one or more of the following system performance categories, depending on the study goals and objectives:

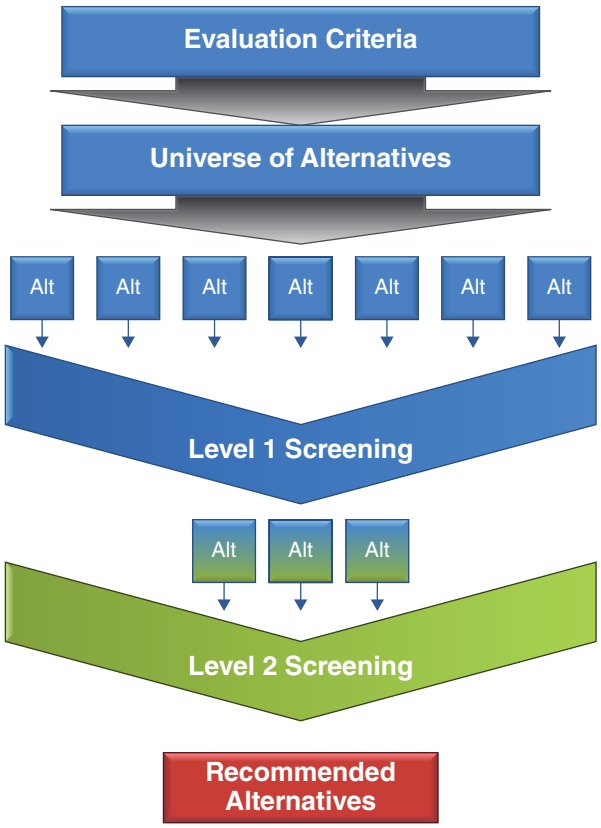
- Transportation performance
- Environmental impacts (natural and built environment)
- Economic impacts
- Cost
- Cost-effectiveness or benefit/cost

The specific criteria to be considered in each category would reflect the goals, objectives, and system performance measures adopted for the study. For example, the criteria used in a corridor study in the state of Washington included: safety benefits, mobility benefits, transit benefits, nonmotorized benefits, environmental impacts, land use and policy consistency, costs, and public support. [WSDOT, 2009]

Evaluation criteria will likely be identified from a number of sources within the planning study area itself. However, maintaining consistency in criteria among similar corridor studies is an important factor in selecting such criteria. Common sources of evaluation criteria include statewide plans, regional and local plans, project selection criteria (for example, those used for prioritization with transportation improvement programs), and funding eligibility criteria (state and federal).

The I-11 and Intermountain West Corridor Study provides another example of the evaluation criteria that can be used in a corridor study. In this case, the corridor spanned two states, with the expectation that the corridor could be expanded to Canada. Figure 17-11 shows the general concept of how the evaluation criteria could be used to screen alternatives to identify the most feasible set for further evaluation. Table 17-4 lists the criteria that were used in the screening process. [i11study, 2013, 2014]

**Figure 17-11. Evaluation Process for the Intermountain West Corridor Study**



Source: i11study, 2013

| Table 17-4. Evaluation Criteria for Screening Alternatives, Intermountain West Corridor Study | |
|---|---|
| **Evaluation Category** | **Proposed Criteria** |
| Legislation | How well does the alternative meet the intent of legislative actions, including MAP-21 and the 1995 National Highway Systems Designation Act? |
| System Linkage | How well does the alternative connect major national and international activity centers from Mexico to Canada through the Intermountain West? |
| | How well does this alternative most directly close gaps and/or develop missing linkages in the regional and national transportation network? |
| | How well does this alternative connect with adjacent segments/sections? |
| Trade Corridor | How well does this alternative connect major freight hubs and high-capacity transportation corridors? |
| Modal Interrelationships | How well does this alternative maximize opportunities for intermodal connectivity (highway, rail/transit, and aviation)? |
| | How well does this alternative accommodate multiple modes in a shared alignment footprint (highway and rail)? |
| Capacity/Congestion | How well does this alternative align with existing conditions or proposed improvements at land ports of entry (as appropriate)? |
| | How well does this alternative relieve existing and projected congestion between and within the major activity centers in Nevada and Arizona? |
| Economic Vitality | How well does this alternative support regional, state, and national economic development goals? |
| Project Status/Transportation Policy | How well does this alternative comply with corridor-related actions taken to date? |
| | How well does this alternative conform to locally adopted transportation plans? |
| Environmental Sustainability | How compatible is this alternative with regional open space, conservation, and land management agency planning? |
| | How well does this alternative minimize environmental impacts (such as drainage, topography, species, and biological connectivity? |
| Land Use and Ownership | How consistent is this alternative with regional land use and growth strategies? |
| | How compatible is this alternative with major land ownership patterns? |
| Community Acceptance | How well is this alternative accepted by the local communities? |
| Cost | What is the overall relative cost of this alternative, where 1 is the highest relative cost and 5 is the lowest? |

Source: i11study, 2013

### Tips on Setting Evaluation Criteria

- Focus the criteria on the key problems being studied.
- Keep the number of criteria small enough to be manageable in the technical analysis.
- Define criteria that are measurable. Do not go beyond the ability of the analysis tools to generate the information.
- Use criteria that can address multiple functions.
- Avoid duplication of overlapping criteria. They should be independent of each other.
- Select criteria that are meaningful for the modes being studied.
- Select criteria that are consistent within a region.

Corridor studies should use criteria that are most meaningful for the study goals and objectives. For example, economic development impacts may be paramount for projects located in rural areas, while transportation performance may be most important in an urban area. Importantly, if a corridor study is serving as part of an environmental analysis that leads to required documentation (such as an environmental impact statement), the criteria should reflect those required by environmental regulations. For example, Table 17-5 shows the criteria used as part of a transit tier 1 evaluation

**Table 17-5. Criteria Used for a Tier 1 Corridor Evaluation Mode Criteria**

**Mode Criteria**

- Travel time competitiveness
- Capital costs
- Cost effectiveness
- Ease of implementation
- Mobility
- Consistency with local plans
- Compatibility with Central Phoenix/East Valley LRT project
- Alternative eliminated in previous studies

**Alignment Criteria**

- Travel time competitiveness
- Directness of travel
- New rider potential
- Proximity and ease of access to activity centers
- Proximity and ease of access to zero-car households and low-income households
- Potential of transit-oriented development
- Economic development potential
- Ease of implementation
- Large business commercial driveways losing full access
- Small business commercial driveways losing full access
- Single family residential driveways losing full access
- Multi-family residential driveways losing full access
- Additional 1/4 mile street traffic signals required
- Additional 1/2 mile street traffic signals required
- Lane miles of parking lanes removed along arterials
- Lane miles of parking lanes removed along collectors
- 15-mph school zones along alignment
- Right-of-way impacts
- Capital costs
- Consistency with local plans
- Consistency with LRT project
- Compatibility with connections to Deer Valley Core and Glendale
- Alternative eliminated in previous studies
- Possible impacts on potential historic resources or sites
- Possible impacts on potential prehistoric resources
- Possible impacts on parks
- Impacts on floodplains, riparian areas, critical habitat
- Possible impacts on major utilities

Source: Valley Metro Rail, 2004

of alternatives, where the evaluation criteria had to satisfy Federal Transit Administration (FTA) requirements. It is interesting to note the difference in specificity between the mode criteria used to select a preferred mode and the criteria used to determine alignment options. The set of alternatives must also include the necessary baseline options (including a "no-build" alternative).

Decision makers will use the results of the evaluation process to decide on the appropriate strategies and actions. In so doing, each decision maker implicitly weighs or applies a degree of importance to the criteria. To aid in this process, some studies explicitly weight the criteria. For example, some studies use points that apply different scores or ratings to each project based on the total number of points assigned. This is discussed later in the chapter and other examples of weighting criteria are found in chapter 7 on evaluation.

## B. Collecting and Analyzing System Performance and Condition Data

A corridor study is usually initiated in response to problems or issues identified by the periodic monitoring of transportation conditions, regional or local plans that identify future needs, the media, public complaints, and the concerns of local officials and others. The problem identification step systematically examines these problems in a manner that helps articulate the types of solutions for solving them. The analysis of these problems is called the *needs analysis* portion of the corridor study. Through needs analysis, the transportation professional examines the current situation and presents a case to proceed with the study or defer the process to another time or situation.

Realistically, both the technical assessment and the public perception of the problem are considered when stating the needs for the study. For example, if the public perceives congestion as being a critical issue in the corridor even though planning officials do not consider it as bad as in other corridors, the study should examine in more detail the potential causes of the public's perception and tailor the analysis accordingly. It is important to focus on factors that can play a meaningful role in defining the problem and shaping the corridor alternatives. Most corridor planning processes emphasize the need for a comprehensive and multimodal approach. However, corridor studies often have limited resources, so it is important to define the most cost-effective ways to solve the problems impacting the corridor during the problem identification stage.

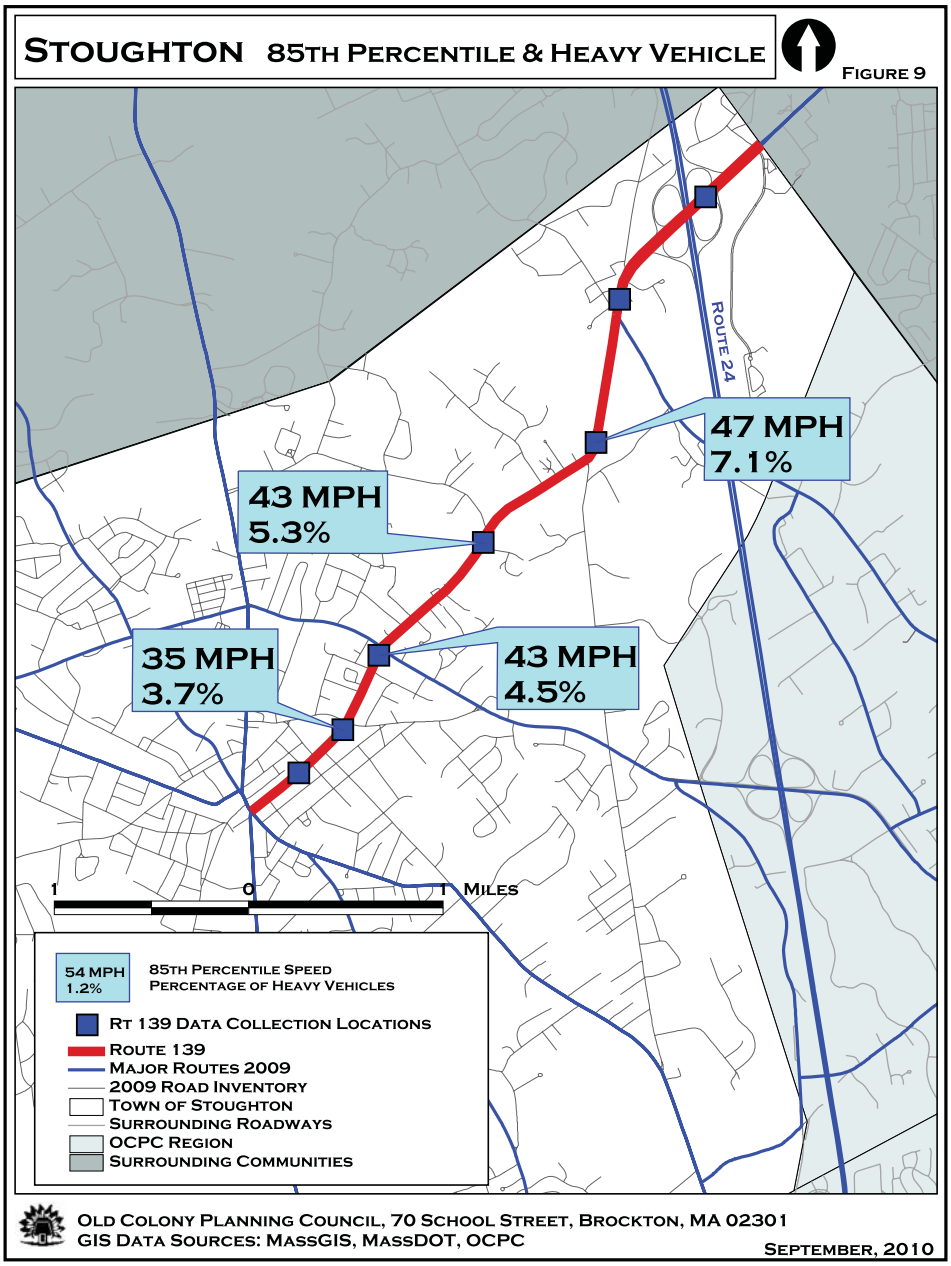
**Problem Identification Process in Corridor Planning Studies**

- Include existing, known problems, as well as anticipated future problems.
- Do NOT frame the problems in terms of a solution—let the problems define the appropriate solution.
- State the problems in an easy-to-understand manner.
- Describe the problems sufficiently to identify the alternatives.
- Seek agreement on the problems from all affected agencies.
- Document the problems in a way that can be integrated with NEPA.

Geographic information systems (GIS) are important tools for identifying problem areas. GIS can provide important information on the conditions and performance of the corridor transportation system in an easy-to-understand manner. GIS-based identification of high-crash locations have been used for many years to illustrate both the magnitude and type of crashes that occur in a corridor. Another advantage of GIS tools is that they are readily used by local planning agencies in identifying local land uses, zoning characteristics, and environmentally or community-sensitive areas. Thus, to the extent that land-use strategies are to be considered part of the corridor study, GIS provides useful information. As alternatives are assessed and evaluated, it is important to have an inventory of wetlands, historic properties, noise-sensitive land uses (for example, hospitals), and other impact areas. A GIS system is a useful means of providing this information and using it for assessing relative impacts of potential corridor strategies.

The first step in analyzing system performance is to examine existing conditions, especially as they relate to the evaluation criteria established at the beginning of the study. Depending on the focus of the corridor study and the types of strategies to be considered as part of the study, the range in data collected on performance and asset condition could be quite large. The following examples come from a corridor study in Massachusetts whose focus was on identifying traffic flow and circulation problems and safety deficiencies. [Old Colony Planning Council, 2010] Existing condition data was collected on roadway characteristics, land use, main route traffic flow characteristics, traffic speed, heavy

**Figure 17-12a. 85th Percentile Speed and Percent Heavy Vehicles, Stoughton, Massachusetts**



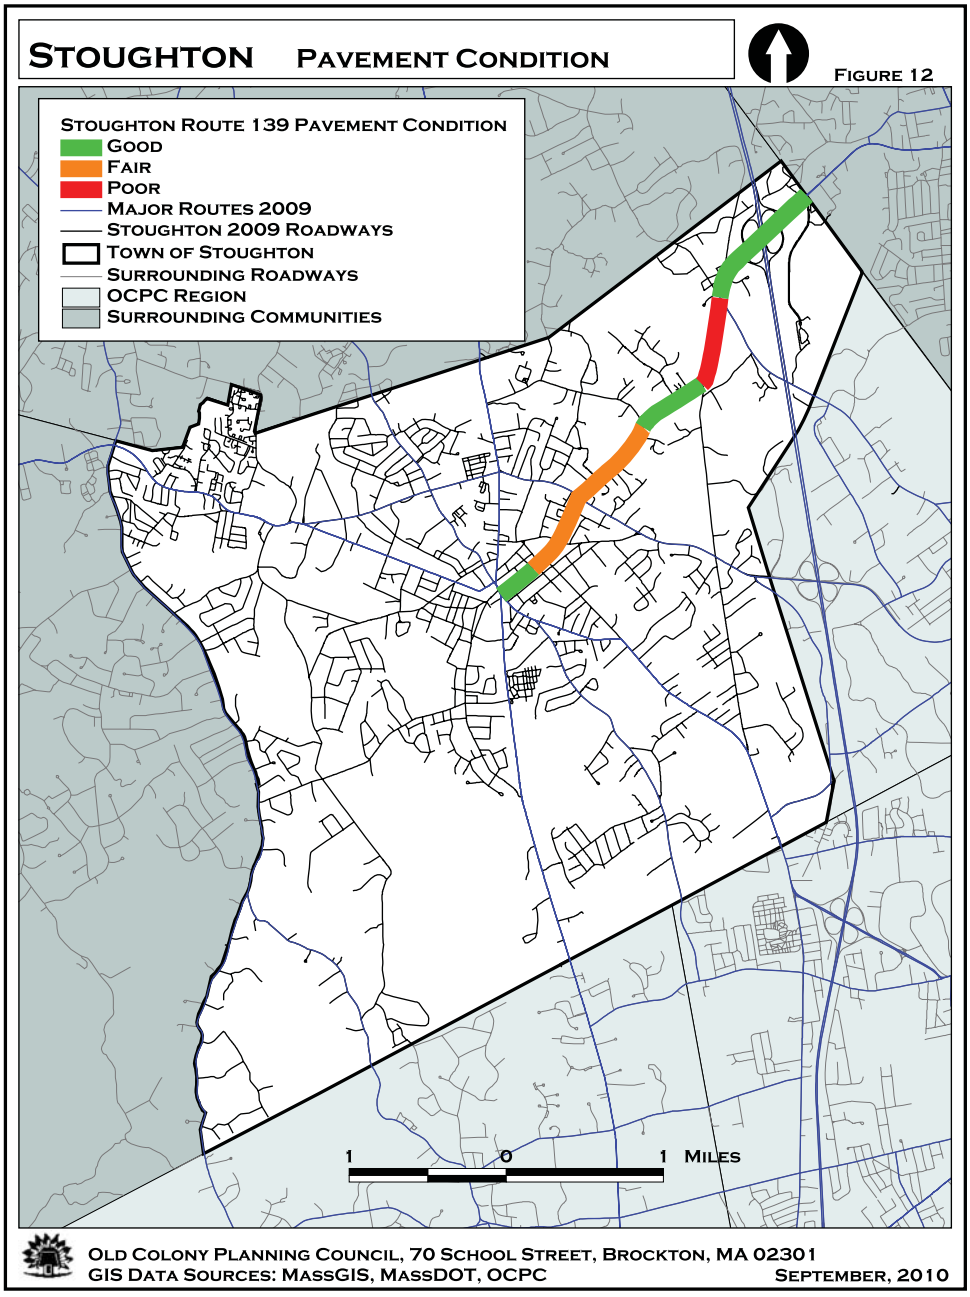
vehicle data, pavement conditions, crashes, existing peak hour operations, pedestrian/bicycle accommodations, and level of service. Figure 17-12a to d shows typical figures that might be found in an analysis of existing conditions.

According to the Washington State DOT's corridor planning guidelines, the following steps should be taken in analyzing existing conditions. [WSDOT, 2007]

**Gather information about each of the transportation system components in the study area including:**

- Highways and streets (public, private, state, and local streets and highways).
- Railroads (freight and passenger).
- Airports (freight and passenger).
- Transit services (public, private, general citizen, and special needs).

Figure 17-12b. Pavement Condition, Stoughton, Massachusetts

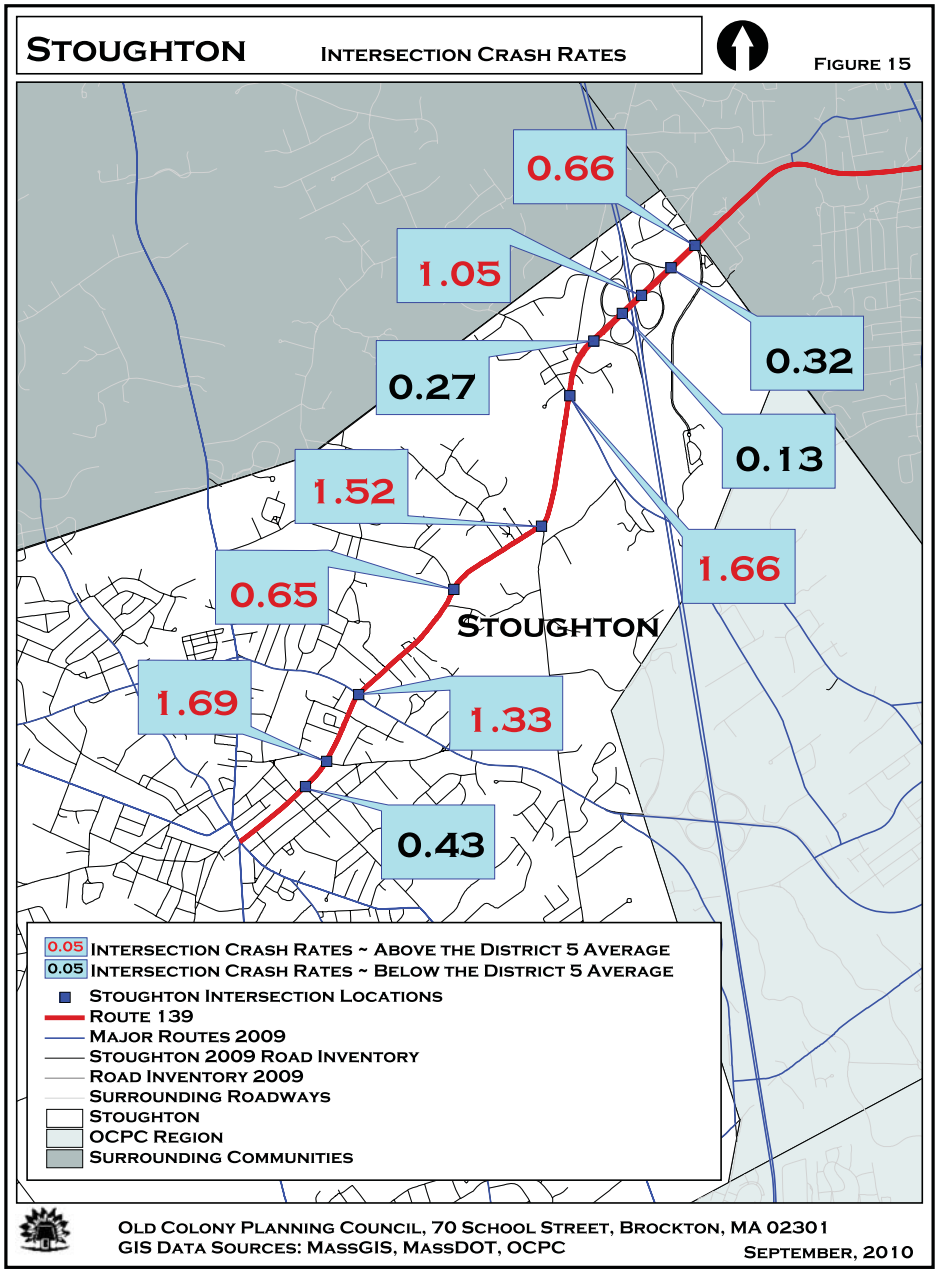


- Bicycle facilities (locations and routes).
- Pedestrian facilities (locations, signalized, and nonsignalized).
- Intermodal connection facilities and stations (park-and-ride lots, railroad and port truck transfer stations, bicycle, pedestrian, and airport transfer facilities).
- Utilities

**Define the role of the corridor by asking the following questions:**

- Is this a Highway of Statewide Significance, Freight Corridor, Scenic Byway, NAFTA Corridor, etc.?
- Does tourism have a central role in the area economy?
- Is there a need for quick farm-to-market trucking?
- Is this a heavy commuter route or a key freight route?

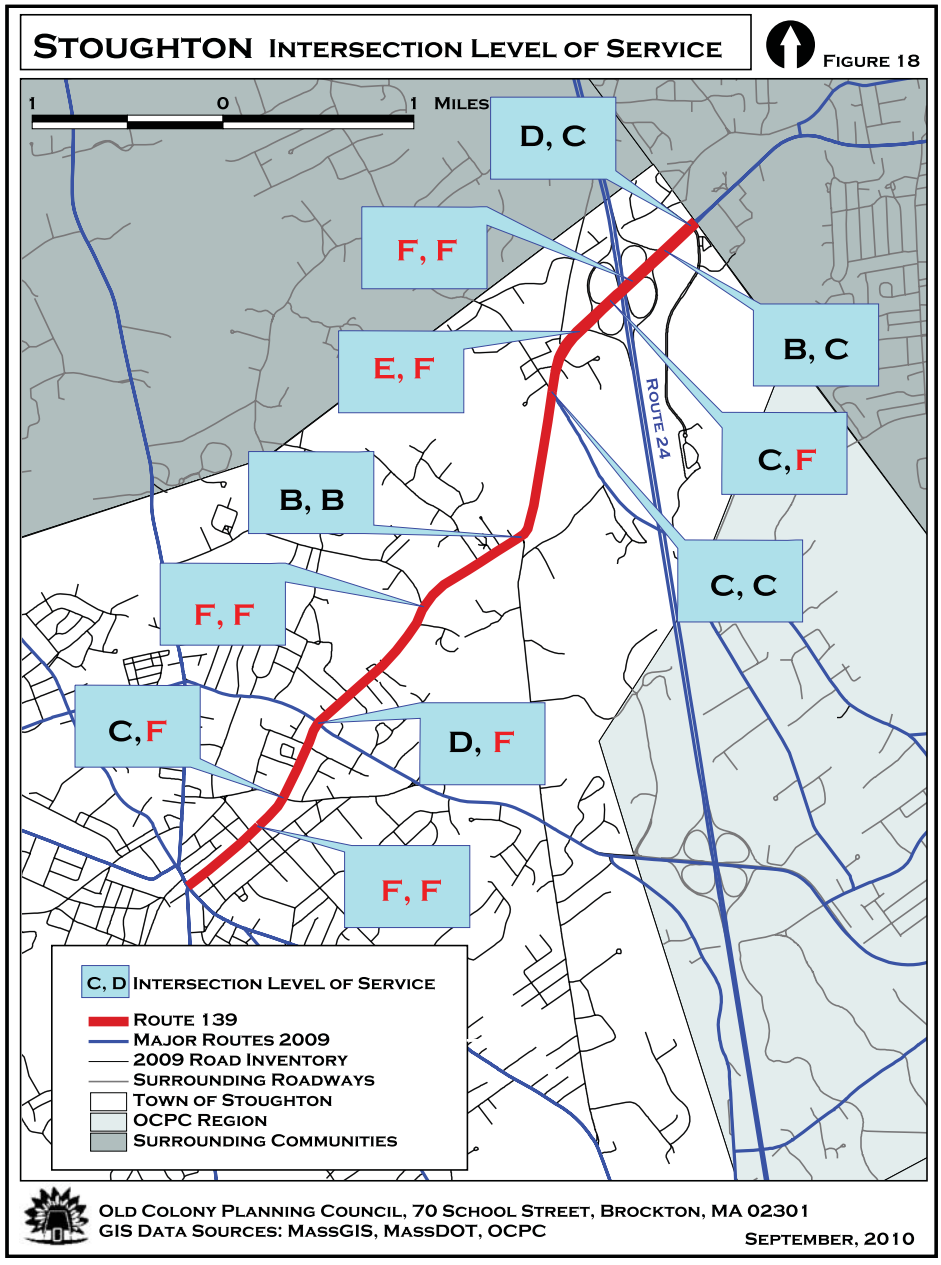
Figure 17-12c. Intersection Crash Rate, Stoughton, Massachusetts



**Research land uses and other characteristics of the region:**

- Census data and the state's population statistics agency.
- Population projections.
- Location of low income or minority populations.
- Employment characteristics, such as journey-to-work reports, commuting pattern studies, labor force data, and employment by industry statistics.
- Land-use assumptions from city and county comprehensive plans.
- Zoning classifications and planned developments for the corridor area.
- Pipeline and large utility locations.

Figure 17-12d. Intersection Level of Service, Stoughton, Massachusetts



Source: Old Colony Planning Council, 2010

- Human and neighborhood characteristics.
- Lists of historical buildings and sites and cultural resources.

**Identify critical environmental factors in the corridor area:**

- Applicable federal, state, and local environmental laws, regulations, and policies.
- Existing environmental studies that include geotechnical, hydrological, and soil types.
- Major geologic and general terrain features.
- Environmental and socioeconomic resources and issues.
- Maps of environmental resources, listed environmental issues, and identified areas that require further analysis.

Figure 17-13 shows another example of how problem areas can be identified, in this case for a hypothetical corridor study. The magnitude of the problems faced at each interchange is indicated by the degree to which the evaluation circle is darkened for each quadrant of the interchange.

**Figure 17-13. Evaluation of Freeway Interchanges**

| Interchange | Geometric | Sight Distance | Signing | Lane Balance | Level of Service | Ramp Opns | Future Volumes | Bike/Peds | Land Access |
|---|---|---|---|---|---|---|---|---|---|
| Jones Road | | | | | | | | | |
| Smith Road | | | | | | | | | |
| Thompson Blvd | | | | | | | | | |
| Denny Pkwy | | | | | | | | | |
| Wagner St. | | | | | | | | | |
| Main St. | | | | | | | | | |

## C. Identifying and Analyzing Alternatives

### *1. Identifying Alternatives*

Identifying alternatives is an important step in the planning process because ultimately the breadth and depth of alternatives shape the range of options available to decision makers. It is also very important in satisfying federal or state environmental requirements to address a full set of reasonable alternatives.

Although the following guidelines for specifying alternatives had been suggested by the FTA in the past for transit projects, they are still valid for virtually all types of corridor alternatives:

- The set of alternatives must address the purpose and need for considering a major transportation investment.
- The set of alternatives must include the necessary baseline options.
- The alternatives should include all reasonable modes and alignments.
- Alternatives designed to address differing goals and objectives should be included.
- The set of alternatives should include all options that have a reasonable chance of becoming the locally preferred alternative.
- The alternatives should encompass an appropriate range of options without major gaps in the costs of the alternatives.
- Where questions remain on feasibility of specific alternatives, other alternatives should provide related fallback options.
- The number of alternatives should be manageable so that decision makers can realistically be expected to understand the implications of each and make an informed choice. [FTA, undated]

While every effort should be made to limit the number of alternatives to a manageable level, the study team should take care to include as wide a range of alternatives as necessary to examine the problems in the corridor and to meet the information needs of decision makers. For simple projects, alternatives identification can be a one-step process and may consist of "No-Action" and "Action" alternatives. In more complex studies, identifying alternatives typically evolves over several steps. Frequently, there is at least a two-step process in defining alternatives—screening the initial alternatives, followed by detailed identification and evaluation of the alternatives chosen for more detailed study. The initial screening process may include a larger number of ideas or concepts that will undergo a simple evaluation, often involving only a few criteria. This process is followed by the development of more detailed alternatives and in-depth evaluation.

Another approach for developing alternatives is called the *incremental approach*. In this process, the study team initially defines a small number of alternatives. Insights gained from this analysis are then used to refine the existing

alternatives or to create new ones. This process would be repeated as needed until a consensus is formed over a preferred alternative.

It is important that the stakeholders agree up front on the process for developing and evaluating alternatives. The study team, however, should be sensitive to the changing nature of these studies and be flexible in accommodating change. Corridor studies have also been known to add alternatives relatively late in the process to deal with new information or changing public and/or political attitudes.

The breadth of alternatives considered in a corridor study will vary considerably based on the study goals and objectives. At one extreme, local corridor plans typically involve the examination of specific roadway connections or locations, such as intersections. In these studies, the alternatives may involve variations of roadway improvement or intersection designs, while modal strategy options could be limited. In urban settings, corridor studies often include transit services, pedestrian and bicycle movements, urban design strategies, and system operations. Because of the possible wide range of strategies, actions, and alternatives that are possible in many studies, transportation planners often conduct a prescreening to determine which of the alternatives are feasible and which have fatal flaws. According to the Washington State DOT, such screening criteria should consider:

- How well each option meets the vision and goals established for the study area.
- The costs of each alternative. While planning level estimates will be adjusted in the scoping process, they are important at this step. Identify low-, medium-, and high-cost options.
- The effects of each option on the study area features, such as environmental resources, and its feasibility regarding environmental issues and regulations.
- The feasibility of each option regarding compatibility and consistency with local and regional transportation plan goals and priorities.
- How each option provides improved access to important educational, medical, major employment, or recreational facilities. [WSDOT, 2007]

Metropolitan, nonmetropolitan, regional, and statewide corridor plans could involve many different modal strategies, often defined by the purpose of the corridor study. For example, a corridor study focusing on transit investments will not likely examine highway capacity expansion options (unless transit is included). The Denver Regional Council of Governments (DRCOG) has implemented a regional corridors program whereby corridors important to the region's transportation system are examined for targeted investments to improve performance. [DRCOG, 2011] Given the large number of corridors that are part of this program, DRCOG has identified the types of strategies listed below that may be considered in nearly every corridor.

**Overall**

- Coordinate land use and transportation decisions and implementation.
- Support urban centers and transit-oriented developments (TODs).
- Complete projects in an environmentally-responsible manner.
- Maintain the existing infrastructure including pavement, subsurface, bridges, traffic management devices and facilities, communications networks, park-n-ride lots, stations, rail lines, multipurpose trails (bike paths), and sidewalks.
- Implement safety improvements as stand-alone projects or within larger projects.
- Conduct a regional vulnerability assessment to identify critical transportation system infrastructure; determine/deploy critical infrastructure protection as required.

**Transit Facilities and Services**

- Implement security and safety features at transit stations, park-n-ride lots, and on vehicles.
- Make modifications to bus routes per changing ridership demands.
- Implement timed-transfer points throughout the system.

- Provide pedestrian and bicycle connections between transit facilities and adjacent neighborhoods and developments.
- Provide bicycle accommodations at transit facilities and on transit vehicles.
- Construct transit-oriented developments (TODs) around appropriate stations and park-n-ride lots.
- Increase Regional Transportation District (RTD) access-a-ride ADA transit service as the fixed-route service expands.
- Increase other specialized transit services to elderly, disabled, low-income, and rural residents.

**Travel Demand Management**

Baseline assumption: A regional program will facilitate and promote use of alternative travel modes, carpooling, teleworking, alternative work schedules, and efficient site development designs in all corridors.

**Physical Improvements as Part of Roadway Projects**

- Construct improvements to current design standards.
- Improve ramp terminal and arterial intersections to serve future volumes (turn lanes).
- Provide acceleration/deceleration lanes in appropriate locations.
- Construct standard paved shoulders on freeways and non-urban arterials.
- Provide appropriate curb/gutter/sidewalk section on urban arterials.
- Provide appropriate space and/or treatments for on-street bicyclists.
- Provide applicable crosswalk markings and devices at locations with pedestrian activity.
- Provide bus lanes and pull-outs in appropriate locations.
- Install traffic signals as warranted.
- Control arterial access per assigned state highway access category.

**System Management Strategies for Relevant Corridor Baseline Assumptions:**

- Link together all traffic and transit operations centers and emergency management centers to support employment of an advanced transportation management system (ATMS) that includes incident management, regional traffic control, and multimodal coordination. Implement/use effective, reliable, and cost-efficient communications infrastructure to support both connectivity between operations centers and connectivity to field equipment from operations centers.
- Operate and maintain (CDOT) a regional advanced traveler information system (ATIS)/51 service. Implement/use effective, reliable, and cost-efficient technology to both collect traveler information data and support traveler information dissemination to drivers in vehicles and travelers on transit.
- Develop, implement, and maintain a unified regional incident management plan.

**Freeways**

- Meter on-ramps to congested freeways; integrate ramp meters with adjacent arterial signals.
- Implement/operate full network surveillance; feed to regional ATIS.
- Operate incident detection where surveillance is deployed.
- Implement/use dynamic message signs (DMSs) to disseminate real-time traffic information, including real-time park-n-ride parking occupancy and transit parking alternatives; from regional ATIS.
- Prepare, implement, and maintain corridor incident management plans consistent with the unified regional incident management plan; operate traffic-responsive signal control along key incident diversion routes.

**Tollways**

- Maintain/upgrade electronic toll collection.
- Implement/operate probe surveillance using toll tags; feed to regional ATIS.
- Implement/operate select (not full) surveillance; feed to regional ATIS.
- Implement/use DMSs to disseminate real-time traffic information, including real-time park-n-ride parking occupancy and transit parking alternatives from regional ATIS.
- Prepare, implement, and maintain corridor incident management plan consistent with unified regional incident management plans; operate traffic-responsive signal control along key incident diversion routes.
- Operate tollway service patrol.

**Arterials**

- Install signals as warrants are met, consistent with CDOT or city/county access management requirements or access management plans.
- Operate existing and new traffic signals using signal system(s) for surface street control.
- Update traffic signal timing/coordination plans on a regular basis.
- Consider application of advanced signal control strategies where needed.
- Implement/operate transit signal priority selectively at signalized intersections adjacent to park-n-ride lots/stations, to favor key bus transfer points, and along heavily used bus transit corridors.

**Transit**

- Implement/operate transit security features at park-n-ride lots/stations and on transit vehicles.
- Disseminate real-time transit vehicle arrival/departure information to transit patrons at park-n-ride lots/stations and key transfer points and feed to regional ATIS and other available means.
- Compile real-time parking space occupancy at park-n-rides; feed to regional ATIS.

Some examples of strategies and actions considered in corridor studies are described below. Table 17-6 shows the types of actions and strategies that are being considered for a state-level corridor study of I-75 in Florida. [Florida DOT,

**Table 17-6. Strategies Considered by Florida DOT in I-75 Corridor Study**

| Strategy Category | Specific Actions |
|---|---|
| Add Capacity to Parallel Corridors and Develop New Parallel Corridors | Add lanes on arterials, improve local intersections, operational improvements, new roadways, and new separated crossings for local connectivity. |
| Transportation System Management and Operations (TSM&O) | Virtual Freight Network, Intelligent Transportation Systems (ITS). |
| Managed Lanes | High-occupancy vehicle (HOV) lanes, truck-only lanes, reversible lanes, express lanes, vehicle-restricted lanes, dedicated bus lanes. |
| Intermodal Logistics Center (ILC) | Intermodal Logistics Centers (ILCs) that may be known as Inland Ports, Freight Activity Centers (FAC), freight terminals or a freight village. |
| Marine Highways | Marine highways and short sea shipping. |
| Parallel Freight Rail Corridors | CSX, Norfolk Southern, Florida Northern, Seminole Gulf Railway. |
| Passenger Rail Services | High speed rail, commuter rail, light rail, Amtrak. |
| Intra-Regional Transit Services | Cross county bus services, express bus services, bus rapid transit (BRT). |
| Transportation Demand Management Programs | Carpool, vanpool, express, bus services, ridesharing, park and ride, telecommuting. |
| Add Capacity to I-75 | Add full lanes, add interchanges, add auxiliary lanes, operational improvements. |

Source: FDOT, undated

undated] Note the wide range of strategies, ranging from adding lanes to the interstate to managing transportation demand to investing in parallel rail routes for freight traffic.

Table 17-7 illustrates the range of roadway, transit, intelligent transportation system (ITS), and demand management strategies to address current and future projected congestion in a multimodal corridor plan in Santa Barbara County, California. [Santa Barbara County Association of Governments. 2006]

Freight movement is also an important consideration in selecting alternatives within major highway corridors. Freight mobility relates to both roadway (trucking) and rail considerations. While truck movements will benefit from strategies focused on general traffic flow improvements, there are both technical and institutional issues that should be addressed within the corridor plan. Rail-oriented strategies typically follow a similar, but separate, study process; however, there are many situations where rail and highway strategies must interface to provide full corridor mobility. National Cooperative Highway Research Program (NCHRP) Report 594, *Integrating Freight into Transportation Planning and Project-Selection Processes*, developed a framework for incorporating freight needs into transportation

**Table 17-7. Multimodal Strategies for U.S. 101 Corridor Study, Santa Barbara, California**

- Add a carpool/HOV lane both directions south of Milpas to County Line—*Major Highway Improvement.*
- Add commuter rail, Camarillo/Oxnard to Goleta—*Major Alternative Transportation Element.*
- Designate new lanes as carpool/HOV—*Encourage Transportation Demand Management.*
- Increase express bus and shuttles with rail and regional transit—*Alternate Transportation Element—possible early action item.*
- Connect local bus and shuttles with rail and regional transit—*Alternate Transportation Element—possible early action item.*
- Bus priority on selected streets through signal priority, queue jumps, bulb-outs at bus stops, etc.—*Alternate Transportation Element—possible early action item*.
- Provide vanpool/carpool/trip reduction incentives—*TDM Element—possible early action item.*
- Encourage telecommuting and flexwork/flextime—*TDM Element—possible early action item.*
- Vary parking rates as feasible by jurisdiction—*TDM Element—possible early action item.*
- Individualize marketing—*TDM Element—possible early action item*.
- Add capacity and install meters at selected ramps—*Operational Management.*
- Use the following ITS technology to inform the traveling public and smooth operations:
  - Freeway service patrol—*Operational Management—early action item*.
  - 511 phone and Internet traffic and transit reports—*Operational Management.*
  - Variable message signs—*Operation Management—early action item.*
  - GPS real-time of arrival information at bus stops—*Operational Management*
  - Phase Improvements north of Milpas
- Implement operational improvements required to address current congestion hot spots—*Major Highway Improvement.*
- Proactively work to reduce peak period traffic through aggressive demand management and rideshare programs—*TDM Element.*
- Monitor need for additional 101 improvements following implementation of operational improvements, commuter rail, TDM and rideshare, ITS, and General Plan updates.
- Add auxiliary lanes and/or additional if needed, funds are available, and there is community support.

Source: Santa Barbara County Association of Governments, 2006

planning, with a major emphasis on corridor plans (see chapter 22 on freight planning). [Cambridge Systematics et al., 2007] As noted in the report,

> *"One way to more effectively link long-range goals with nearer term actions is to define key freight corridors and facilities that contribute to statewide or regional economic competitiveness, mobility, or quality of life. Identifying key freight corridors and facilities within a long-range planning document can have several important benefits. First, it can provide structure and focus to a freight planning program, particularly at a statewide level, by allowing states and MPOs to focus potential investments on those corridors and facilities that have the greatest effect on economic competitiveness, mobility, or quality of life. While specific projects need not be identified, defining key freight corridors and outlining specific objectives for those corridors (e.g., improve access to port/intermodal facilities, implement ITS technologies to improve flow, and improve access to highway facilities to spur economic development) can improve the ability of states and MPOs to identify freight-specific projects and help ensure that those projects are consistent with statewide or regional goals."*

It is important to recognize that a strategy does not equate to an alternative. For example, a study might consider a transit strategy or a strategy that focuses on better land development policies. Such strategies, however, are not specific alternatives. Most major corridor programs consist of combinations of strategies, with each addressing a portion of the corridor needs. Often in high-profile studies, various interest groups promote strategies that need to be considered seriously, if not given a full evaluation. The challenge to the study team is to assemble the best mix of strategies into a set of alternatives that represent reasonable contrasts worthy of evaluation.

**Base Alternative.** All evaluations, not just those for corridor studies, require a basis for comparison. Most studies choose a "No-Action," "Do-Nothing," or "Base Condition" alternative as a frame of reference. The "No-Action" alternative, on first glance, is relatively straightforward; it defines a condition under which no improvements are made. In reality, defining the "No-Action" alternative requires considerable thought and interaction with the study stakeholders.

Table 17-8 presents various options for identifying projects in a base condition. Most base conditions include those projects for which full funding has been secured. The challenge tends to be whether projects are really fully funded or merely *committed* for funding. Committed projects are those likely to occur, but may not have full funding currently available.

**Table 17-8. Selection of a Base Condition**

| Base Condition Option | Advantages | Disadvantages |
|---|---|---|
| Use projects in the applicable metropolitan transportation plan (MTP). | Most logical for most situations. Represents a set of conditions that has been reviewed and approved on a regional basis. | May not be the best choice if the MTP projects do not represent what is reasonable under financial constraint in the vicinity of the corridor being analyzed. |
| Use only projects in the TIP. | Provides greater assurance that projects will actually be in place in horizon year. | Conditions would appear worse and benefits of certain alternatives may look better than they actually would be if more projects were assumed. |
| Use a set of fundable projects that is viewed to be reasonable by the stakeholders. | Can solve dilemma of a MTP that is believed to be unrealistic. | Takes more time to identify base condition. Could be challenged if broad agreement is not reached. |
| Where there is uncertainty as to future major improvements in corridor, use dual base conditions, testing sensitivity of alternatives against each condition. | May remove uncertainty from a decision that could be contingent on other future projects. This approach is particularly advantageous where a potential improvement in the corridor is one part of a larger potential improvement. | Increases resource requirement in analysis of alternatives (but sensitivity analysis may not be needed for all alternatives). |

Source: Smith, S. 1999, Reproduced with permission of the Transportation Research Board.

Typically, two or more base conditions are defined—a short-term or *year of opening*, and a long-term design or *horizon year* (typically 20 to 30 years in the future). The short-term definition is easier because this period typically coincides with known and adopted 6- to 10-year funding cycles. The longer-term "No-Action" alternative is more difficult to define. Many agencies use a conservative point of comparison with only the funded or committed definition. Other agencies use the projects in the statewide and metropolitan transportation plans as the preferred choice for base conditions in that fiscally constrained plans are by definition supposed to contain only those projects for which there is funding. However, in reality, project priorities change and estimated revenues for future years are often uncertain. The important determination is what represents the most reasonable set of conditions to frame a reference for the various "Action" alternatives.

Choosing a base condition for a major high-capacity transit (for example, rail or bus rapid transit) alternatives study can be challenging. The potential for success of a high-capacity transit alternative depends in part on the level of other transit investment assumed in the base regional transit system. It is difficult to evaluate a high-capacity transit corridor without assuming the existence of other regional transit improvements. These improvements may vary depending upon the corridor or transit strategy being examined.

Another challenge in selecting a base condition relates to strategies such as ITS or toll roads. For example, a toll corridor project might be examined in conjunction with the addition of lanes on an adjacent freeway. While the proper base condition for evaluating the freeway lane expansion would be a "No-Action" freeway without the added lanes, the proper base condition for the tolling alternative would be the freeway with the added lanes. This creates the possibility of having multiple base conditions within a single corridor plan and is quite challenging to explain.

Assumptions concerning future land uses can be yet another challenge in defining a base condition. Generally, the base condition should include the regionally adopted land-use forecasts for the given study year. Consistent land-use assumptions should be used in the base year alternative. If land use changes are to be considered in the study, they typically are introduced into the build alternatives.

Finally, it is not unusual for the base condition to change during the course of the study—or after the study—due to changes in land-use forecasts or the inclusion or exclusion of a major transportation facility in the transportation plan for the region. In this situation, the agency should address the issue in a straightforward manner to determine, (1) what impact such a change will have on study conclusions, and (2) whether such an impact will likely occur. In the latter case, sensitivity tests can be conducted to identify the range of likely impacts on the results. At that point, a decision can be made whether to document the results of the sensitivity tests or conduct more detailed analyses.

**Transportation System Management (TSM) Alternative.** For many years in the United States, any alternatives analysis for capital transit investment seeking federal support had to include a transportation system management (TSM) alternative. The TSM alternative was considered a low-cost approach to solving the problems in the corridor. In the federal alternatives analysis process, the TSM alternative was considered a baseline for comparison with all other investment alternatives. Technical guidance from FTA defined the TSM alternative as "the best that can be done for mobility without constructing a new transit guideway. Generally, the TSM alternative emphasizes upgrades in transit service through operational and small physical improvements, plus selected highway upgrades through intersection improvements, minor widenings, and other focused traffic engineering actions."

MAP-21 and subsequent regulations removed the requirement for a specified TSM alternative and defined the point of comparison for incremental changes as the existing system or "No-Build" alternative. The "No-Build" alternative consisted of those transportation investments committed to in the TIP if the project adopted a 10-year horizon or the existing system plus the projects included in the fiscally constrained long-range transportation plan if the time horizon was 20 years. [FTA, 2013]

### *2. Analyzing Alternatives*

The tools used to analyze corridor alternatives vary widely, depending on the scope and breadth of the studies, the common practices within jurisdictions, and the study scope/budgets. The analysis approach should closely relate to the evaluation criteria established earlier in the study. This linkage is one that should be made by the study team early in the corridor planning process. The study team should focus the analysis resources on the most important issues

and avoid data overkill for those topics that are of lesser importance. Since many corridor studies involve two or more phases with differing levels of detail, the analysis methods should be tailored to the appropriate decisions being made.

Screening-level analyses are often conducted using the results of generalized travel model output to establish the relative performance of a wide range of alternatives. At this level, it may not be reasonable to spend considerable resources refining the travel model results. However, once the number of alternatives is reduced to a smaller set, there is often a need for refined data to examine the detailed performance of each alternative.

The analysis approach and types of analysis tools used in corridor studies are similar to those found in other transportation studies, including data collection, travel demand models, sketch planning models, and traffic operations models. In fact, many of the same models and tools are used only at a smaller scale than what would occur at a regional level. Looking at the Washington State DOT list of corridor planning steps described earlier, one could expect that each of the questions asked would require some form of analysis. WSDOT also identified some of the tools that transportation planners could use to analyze corridor performance or some elements thereof, including:

- Micro-simulation model used to analyze roundabout operations.
- Traffic data analysis and reporting spreadsheet.
- Travel demand model.
- Highway capacity software.
- Route optimization model.
- Simulation tool for signalized intersections.
- Signalized intersection optimization and level of service analysis tools.
- Traffic data management program.
- Multimodal microsimulation model to analyze freeways, intersections, arterial, and transit operations in particular transit signal priority.
- Model to identify and evaluate potential carbon monoxide air quality concerns. [WSDOT, 2007]

In addition, the guide noted that travel demand surveys and origin-destination surveys are often used in corridor studies as well.

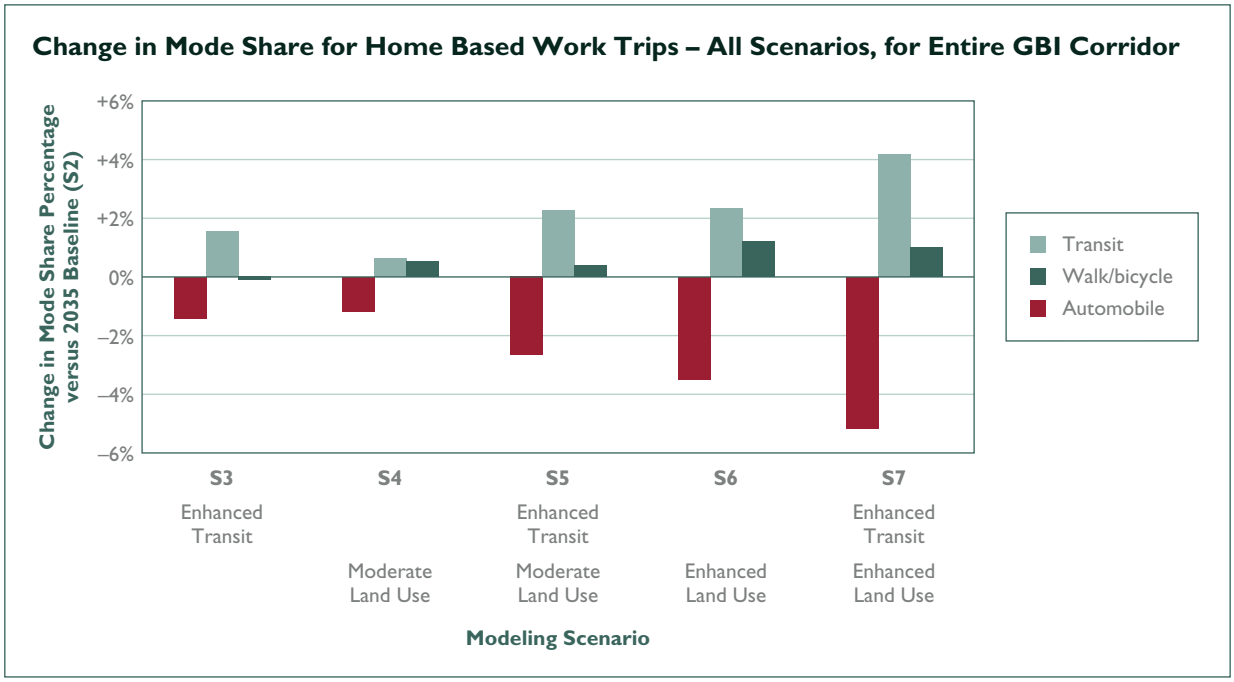
The reader is referred to chapters 2 (data), 3 (land use and urban design), 4 (environmental analysis), 6 (travel demand modeling), 9 (road and highway planning), 10 (network and facility operations planning), 12 (transit planning), 13 (pedestrian and bicycle planning), 14 (travel demand management), 22 (freight planning), and 23 (safety planning) for further description of the analysis tools that can be used to examine different types of transportation and land-use strategies.

## D. Evaluating Alternatives

Good planning practice as well as federal and state environmental regulations require a consistent and valid comparison of the impacts of the alternatives. Evaluation is the process of comparing the analysis results for each alternative with the evaluation criteria defining the major dimensions of comparison. Each alternative is also compared against a common frame of reference, usually the base condition. It is important to be internally consistent with the evaluation criteria with respect to the identified goals and objectives of the study and the performance measures that have been identified for the region's transportation system. The following examples illustrate many different ways that the evaluation process has been conducted in corridor studies. In some cases, planners have used quantitative measures to assess relative worth of the alternative; the assessment is fully subjective in others; and in still others it is a combination of the two.

Figure 17-14 illustrates the concept of land-use and transportation scenarios in the Grand Boulevard corridor study in San Mateo and San Clara Counties in California. The study focused on both land use/urban design and transportation strategies that jointly affected travel behavior. The study used a travel demand model to determine the impact on travel characteristics of the different scenarios.

**Figure 17-14. Evaluation of Different Alternative Scenarios, Champaign, Illinois**



Source: Grand Boulevard Initiative, 2010

Table 17-9 shows a typical presentation of alternatives evaluation. Called an impact matrix (see chapter 7 on evaluation), this table presents the quantitative and subject assessment of the impacts that are important to the study. Decision makers use this type of information to choose an alternative based on all of the information presented to them.

Figure 17-15 shows a subjective approach to corridor assessment. In this example, the Florida DOT was examining different strategies for improving performance of I-75. The relative impact of each strategy, for example, adding capacity to parallel corridors, managed lanes, passenger rail service, and the like, is indicated by the number of symbols in each column relating to corridor goals, for example, enhancing mobility, providing for emergency response, encouraging economic development, and the like. The assessment was conducted by FDOT staff.

In many cases, alternatives evaluation also includes a benefit-cost analysis or some form of cost-effectiveness assessment. In such instances, the results are usually incorporated into the evaluation matrix, similar to the impacts shown in Table 17-9, simply as another impact category to consider when choosing a preferred alternative. One of the key considerations in doing so, at least in the benefit-cost approach, is that project benefits need to be defined in monetary terms. For many types of impacts, this is a significant challenge. See chapter 7 for a discussion of different approaches to evaluation that could be used in a corridor planning study.

Another aspect of evaluation found in many corridor studies is assigning points or using some other way of establishing priorities. There are several ways of doing this, as explained in chapter 7 on evaluation. Table 17-10 illustrates the approach of assigning weights to different evaluation criteria as used in a corridor study in Ft. Collins, Colorado. The corridor team rated each criterion from 1 (low) to 10 (high) in terms of importance. An average weighting was then achieved for each criterion. Once the weight was established, each of the alternatives was evaluated and rated on a 0 to 1 scale. Final scores were calculated as the product of the rating times the weight.

Many evaluation techniques also include "weighting" certain criteria higher than others. This can be done by prioritizing goals up front (for example, if safety is more important of a goal than keeping costs down, an alternative that costs more but produces fewer anticipated accidents will likely rank higher). It may be useful to determine the weighting of goals and criteria during the initial goals identification step.

A more involved process for assigning scores to corridor alternatives comes from Queensland, Australia, where the state transport department conducted a corridor study in southeast Queensland to improve the performance of transit

**Table 17-9. Example Impact Evaluation Matrix, Interstates 39/90 Environ7ental Assessment, Wisconsin**

| Environmental Issue | Unit Measure | Alternatives/Sections | | | |
|---|---|---|---|---|---|
| | | No-Build | Build Inside Lanes | Build Outside Lanes | Reconstruct |
| **Cost$** | | | | | |
| Construction | Million $ | $0.00 | $410.40 | $445.80 | $415.20 |

service and the location of prospective stations. [PB and Queensland Department of Transport and Main Roads, 2009] Twenty-one (21) criteria were used to assess different alternatives including:

**Transport integration**

- Patronage potential (station location delivers patronage).
- Network efficiency (bus and rail network operational efficiency).
- Modal integration/bus interchange (bus, rail, and road integration and interchanging).
- Traffic/network permeability (how well the road network functions, for example, severance and grid structure).

**Engineering costs**

- Construction cost (rail and road impact).
- Operating and maintenance cost.
- Engineering compliance, constructability.

**Economics**

- Promotes new retail (how well can the option deliver these gross floor areas (GFAs), catalyze investment, job creation and timing?)
- Creating residential density (how well can the option deliver these GFAs, catalyze investment, job creation and timing?)
- Development sequencing of rail and land uses. Timing for delivery of the various development components and the options ability to support this, for example, pre-Caboolture to Maroochydore Corridor Study).

**Urban placemaking**

- Quality of built form measured at street level and streetscape, and investment in built form and timing.
- Compact city core.
- Safety.

**Natural environment**

- Impact on Cornmeal Creek/other waterbodies.
- Other natural impact (e.g., significant vegetation).
- Flood risks and climate change.
- Soils and geology.

**Social environment**

- Construction noise and vibration.
- Operation noise and vibration.
- Visual amenity.
- Impact on existing property owners (area of impact and number of owners and owner type—consider acceptance by owner).

Interestingly, the number of criteria was deliberately chosen to "provide a balance between the number of the "harder" transport cost and engineering criteria and the "softer" natural and social environment criteria."

A pair-wise comparison was made between each criterion pair, for example, criterion A was compared to B, then to C, then to D and so on. A "value" was assigned to the preference of one criterion over another, with 3 points representing a major preference; 2 points representing a medium preference, and 1 point representing a minor preference. A value of "0" was used if the two were considered to be of equal value. Table 17-11 shows the aggregated scores for each criterion and the relative weight in terms of the individual score compared to the total number of points.

**Table 17-11. Evaluation Criteria Weighting, Queensland, Australia**

| Goals, Desired Criteria, Functions, Features | Raw Score | Weight |
|---|---|---|
| **Transport Integration** | | 17% |
| Patronage potential | 43 | 7% |
| Network efficiency | 26 | 4% |
| Modal integration/bus interchange | 21 | 3% |
| Traffic/network permeability | 17 | 3% |
| Accessibility* | 0 | 0% |
| **Engineering Costs** | | 20% |
| Construction cost | 28 | 4% |
| Operating and maintenance cost | 23 | 4% |
| Land resumption costs* | 0 | 0% |
| Engineering compliance, constructability | 75 | 12% |
| Benefit/cost ratio* | 0 | 0% |
| **Economics** | | 7% |
| Promotes new retail | 26.5 | 4% |
| Creates residential density | 16.5 | 3% |
| Identifiable office node* | 0 | 0% |
| Benefit cost to community* | 0 | 0% |
| Development sequencing of rail and land uses | 18 | 3% |
| **Urban Place-making** | | 12% |
| Quality open space* | 0 | 0% |
| Quality built form | 16 | 2% |
| Civil space* | 0 | 0% |
| Compact city core | 22 | 3% |
| Safety | 42 | 7% |
| **Natural Environment** | | 31% |
| Impact on Commeal Creek/other water bodies | 46 | 7% |
| Other natural impact (e.g., significant vegetation) | 48 | 7% |
| Air quality* | 0 | 0% |
| Flood risks and climate change | 53.5 | 8% |
| Soils and geology | 54 | 8% |
| **Social Environment** | | 10% |
| Construction noise and vibration | 3 | 0% |
| Operation noise and vibration | 11 | 2% |
| Visual amenity | 8 | 1% |
| Disruption to traffic during construction* | 0 | 0% |
| Impact on existing property owners | 44 | 7% |
| Total | 641.5 | 100% |

*The criteria shaded are those part of the formal evaluation process, but did not receive any points in the evaluation process

Source: PB and Queensland Department of Transport and Main Roads, 2009

The different options were then rated on a scale of 1 (poor) to 5 (excellent), and aggregate scores for four options were estimated as shown in Table 17-12.

A sensitivity analysis was conducted by changing each of the weightings at the category level, keeping the individual weightings within each category at the same ratio. This weighting was increased in each category in turn until the preferred option changed according to the total score. Table 17-13 shows the preferred alternative for each criterion when the weights were changed.

According to the study, the sensitivity analysis showed that:

- Carnaby Street elevated is the preferred option from an economic and natural environment point of view, as well as under the balanced approach.
- Carnaby at-grade becomes the preferred solution if engineering costs become the main criterion, to the exclusion of nearly all other criteria.
- Carnaby subgrade becomes the preferred solution if socioeconomic criteria become dominant. A moderate increase in the importance of the social environment is necessary to make the change.
- At no stage is the existing Caboolture to Maroochydore Corridor Study alignment the preferred option.

## E. Corridor Study Outcomes

Most corridor studies recommend one or more projects and/or alternatives to carry to the next level of implementation. For example, some corridor plans might recommend that the MPO include a project in the metropolitan transportation plan or transportation improvement plan. In other cases, corridor studies could recommend urban design and land-use policies consistent with and supporting the transportation recommendations. In some instances, a corridor study could recommend policies on how to better manage a corridor, such as improved access to surrounding land uses, called access management.

**Table 17-12. Ranking of Options, Queensland, Australia**

| Description | Score |
|---|---|
| Carnaby Street Alignment, elevated | 426 |
| Carnaby Street Alignment, elevated, at-grade | 391 |
| Carnaby Street Alignment, elevated, sub-grade | 384 |
| Existing Caboolture to Maroochydore Corridor Study Alignment | 320 |

The types of decisions resulting from a corridor study include the following:

| Type of Decision | Comments |
|---|---|
| Pick a preferred alternative—not an environmental process | Document the selection process leading to a recommendation of a preferred alternative. Forward decision to appropriate implementing agency(ies). |
| Pick a preferred alternative—leading to an environmental decision | Same as above, plus include process to clear the project through NEPA/state EPA. |
| Designate a range of reasonable alternatives to be studied further | Forward a short-list of alternatives to appropriate agency(ies) for follow-on evaluation and selection. |
| Identify projects for programming—leading to inclusion in the STIP or TIP | Projects could be defined in enough detail that they could be included in the investment programs. |

Once the decision is made regarding a preferred alternative, the challenge becomes how to actually implement this decision. This challenge will vary, depending on whether the implementation period is short, medium, or long.

***1. Short Term***

Decisions to implement an alternative in the short term (up to 5 years) are typically associated with projects that are reasonably well-defined and have design and environmental features fully analyzed. These projects are usually defined in enough detail that they can be included as part of the TIP. In this situation, the following actions should be considered:

- Prepare project description and cost estimates sufficient to include in local/regional TIP.
- Prepare a timeline of actions leading to implementation.
- Identify specific implementation responsibilities among agencies.
- Identify specific funding sources and actions needed to secure funding.
- Prepare a plan to acquire needed right-of-way or other corridor facility needs.
- Utility relocation can take just as long if not longer to coordinate, fund, and execute than right-of-way. A utility relocation/adjustment plan is also helpful.

***2. Medium Term***

Decisions for medium-term alternatives (6 to 10 years) are those either still in the planning and environmental process, where the project scope is not yet defined in sufficient detail to allow engineering to occur. However, the alternatives have usually been identified as part of a transportation plan, which usually entails general project descriptions and cost estimates. In this situation, the following actions should be considered:

- Prepare general project descriptions and cost estimates sufficient to include in a transportation plan.
- Prepare a schedule for plan and project implementation.
- Identify responsibilities among agencies.
- Identify general funding categories and project-specific funding options.

### *3. Long Term*

Decisions that identify long-term solutions (usually 10 or more years) will likely have fewer design details, costs, and funding arrangements identified. In order to move the corridor plan forward, the following actions should be undertaken:

- Identify all project elements, including physical and policy-related features.
- Prepare programmatic cost estimates sufficient to include within local and regional TIPs.
- Prepare a recommended schedule for implementation.
- Define agency responsibilities and secure interagency agreements supporting the recommendations.
- Evaluate options for funding sources.
- Begin pursuing funding opportunities.

Many longer-term decisions may have somewhat vague project descriptions and may even consist of multiple alternatives that should be further analyzed. It is very important to further detail the project elements to develop a consensus on which elements are most important and to fully explain the project to the public.

Tables 17-14 and 17-15 provide examples of implementation recommendations for transportation and land-use strategies from the *Vermont 15 Corridor Management Plan*. [Vermont Agency of Transportation, 2005a] The transportation results produced short-, medium-, and long-term recommendations focused on specific areas within the corridor. The land-use recommendations focused more on policy and design elements that could be implemented in concert with the transportation improvements.

The Delaware *Route 40 Corridor Plan* established triggering thresholds that would result in actions being taken to implement the plan. [Delaware DOT, 2000] Table 17-16 shows the various plan elements that are regularly monitored to identify whether specific triggers have been met. The monitoring activities trigger an evaluation of whether to continue with a plan project on the originally proposed schedule or to move it forward or back as conditions dictate. The monitoring and triggering activities are documented in a periodic corridor monitoring and triggering report, which provides all interested stakeholders with the status of the monitoring efforts and any triggering activities that are initiated. This ongoing process will help ensure that the plan is actively managed over time.

## F. Access Management

This corridor-level strategy, which has received increasing attention during the past two decades, provides more control of access to land parcels adjacent to corridor roads and reduces the potential for vehicle conflicts on major highways (see Figure 17-16). Transportation agencies most often adopt standards for road access. For corridor planning, access management and the associated standards are important considerations for safeguarding the capacity of a roadway. Such standards are often very specific with respect to what will be allowed with respect to road access. For example, Table 17-17 shows the access management standards for the Florida DOT with respect to the state highway system. Such standards often become the focus of development plans where developers want the most access possible ("build us a new interchange") and transportation agencies are trying to preserve the safe operation of the road.

The types of techniques and strategies applied in access management vary according to the types of problems encountered along the corridor. According to the FHWA, access management strategies can include the following types of techniques:

- Increased spacing between signals and interchanges.
- Driveway location, spacing, and design.
- Use of exclusive turning lanes.
- Median treatments, including two-way left turn lanes (TWLTL) that allow turn movements in multiple directions from a center lane and raised medians that prevent movements across a roadway.

- Use of service and frontage roads.
- Land use and driveway access policies that limit right-of-way access to highways. [FHWA, 2015a]

NCHRP Report 548, *A Guidebook for Including Access Management into Transportation Planning*, provides useful recommendations on how access management can be better integrated into the transportation planning process. [Rose et al., 2005] Specifically, this guidebook recommends the following steps for an effective access management program:

- Developing and applying an access classification system that assigns access management standards to roadways in accordance with their level of importance to mobility. This system generally parallels the roadway functional classification system.

**Table 17-14. Sample Implementation Recommendations, Vermont 15 Corridor Study**

| Sample Implementation Recommendations | | | | |
|---|---|---|---|---|
| **Area** | **Purpose** | **Need** | **Recommendations** | **Comments/Next** |
| Jericho Village | Improve safety for pedestrians and cyclists<br>Connect village residential and commercial origins and destinations<br>Enhance community character | Traffic volumes expected to increase 10,900 to between 15,000 and 20,000 vehicles per day; will have negative impact on pedestrian travel and quality of life | ***Short-term***<br>New sidewalk in front of Keith Agency and Village Cup, extending from new VT 15 crosswalk from bridge<br>***Medium-term***<br>Traffic calming devices along VT 15<br>Signage indicating historic district<br>Extensions of historic light policies<br>Bury utility lines<br>Improved access management<br>***Long-term***<br>Sidewalks and bike lanes on both sides of VT 15<br>Additional crosswalks | Endorsed by Jericho Transportation Subcommittee<br>Evaluate possibility of reducing posted speed to 25 mph when measures implemented<br>Conduct feasibility study of extending sidewalks; identify appropriate crosswalk locations |
| Jericho, Intersection VT 15/Lee River Road | Improve intersection safety and efficiency for pedestrians, bicyclists, and motorists | LOS F currently exists on Lee River Road; will worsen as traffic on VT 15 increases. Future conditions satisfy warrants for left- and right-turn lane on VT15 and traffic signal. | ***Short-term***<br>Reconfigure intersection to include one-way exit along north side of Flat Iron with a simple T intersection on south side<br>***Medium-term***<br>Evaluate right and left turns and/or traffic signal.<br>Incorporate proposed streetcar designs | Conduct scoping study to evaluate long-term intersection design alternatives |
| Jericho, rural-suburban road segment (Cilley Hill to River Road) | Maintain a reasonable level of mobility for through traffic and improve local circulation options. | Projected traffic will approach 11,500–15,000 vehicles per day.<br>Existing entrances from side streets and driveways will become more difficult. Vehicles turning from VT 15 will reduce speeds on VT 15. | ***Short-term***<br>Manage access for parcels directly adjacent to VT 15 by following VTrans guidelines.<br>***Medium-term***<br>Provide new street connections between adjacent subdivisions to create a local network accommodating vehicles, pedestrians, and bicyclists. | Include access management guidelines in Jericho zoning and subdivision regulations consistent with VTrans Access Management Category 6.<br>Town of Jericho should map easements to explore possible connections.<br>Evaluate traffic impacts of providing connections. |

| Table 17-15. Example Corridor Land-Use Recommendations, Vermont | |
|---|---|
| **Sample Land-Use Recommendations** | |
| **Town** | **Recommendations** |
| Jericho | • Consider site plan review as a requirement for all developed along VT 15 corridor; and<br>• Include provisions for shared access and driveways in subdivision regulations. |
| Westford | • Consider establishing an overlay district along VT 15 to establish zoning guidelines to implement existing town plan objectives of protecting scenic, historic, and natural resources. |
| Johnson Town/ Village | • Adopt regulatory documents (such as zoning) to implement and enforce town/village Master Plan goals, or delineate VT 15 as a specific planning area and include development guidelines in the Master Plan. |
| Morristown/ Morrisville | • Establish minimum distance between curb cuts, consistent with VTrans Access Management standards; and<br>• Establish design guidelines and/or a landscape plan for the commercial district. |
| Wolcott | • Delineate areas of compact, mixed-use development at major intersections, and minimize development between these areas;<br>• Establish other zoning districts (e.g., residential, agricultural, and commercial) and lot requirement/densities;<br>• Encourage sharing of access and parking for commercial developments; and<br>• Allow Planned Residential Developments to promote concentrated development. |

| Table 17-16. Monitoring and Triggering Elements, Delaware Route 40 Corridor Plan | | |
|---|---|---|
| **Monitoring Element** | **Trigger** | **Resulting Actions** |
| Land development | Major land development activity | Review transportation needs for level of service implications and strategy. |
| Traffic | Deteriorating level of service ("D" or worse) | Implement strategies to: stabilize/reduce demand; or increase capacity. |
| Highway safety | Safety improvements recommended by the Highway Safety Improvements Program review team | Evaluate the compatibility of the proposed improvements with the plan and the need to make adjustments to the plan. |
| Transit service | Transit service changes proposed by Delaware Transit Corp. | Evaluate any ancillary improvements needed to complement the service changes, such as sidewalks or shelters that should be advanced to the plan. |
| Status of projects in design, implemented, or other projects in the region | Transportation improvements not part of the plan but affect the corridor and are proposed for implementation. | Evaluate the compatibility of the proposed improvements with the plan and the need to make adjustments to the plan. |
| Any of the above | | Assessment of potential changes may trigger one of the following options to best respond to the new conditions:<br>Continue project(s) as currently scheduled, move project(s) forward, or move project(s) back. |

| 7 | Both median types | 660′ | 330′ | 1,320′ | 125′ | 125′ |

Source: FDOT, 2014, 2015

- Planning, designing, and maintaining road systems based on this access classification system and related road geometry.
- Defining the level of access permitted to each classification, which includes the following:
  - Permitting or prohibiting direct property access.
  - Allowing for full movement, limited turns, and median.
  - Designating the type of traffic control required such as signal, raised median, or roundabout.
- Establishing criteria for the spacing of signalized and nonsignalized access, as well as access setback distances from intersections (corner clearance) and interchanges.

- Applying agreed-upon engineering standards that include appropriate geometric design criteria and traffic engineering measures to each allowable access point or system of access points.
- Establishing policies, regulations, and permitting procedures to implement the listed components.
- Ensuring coordination with and supportive actions by local jurisdictions exercising their land-use planning authority as well as their development permitting and review authority.

In addition, many state DOTs have adopted their own access management program or plan on their respective websites. See chapter 3 on land use and chapter 9 on road and highway planning for further discussion on access management.

## G. Environmental Process

Corridor studies might or might not follow a formal environmental process. The plans following a NEPA or state-based environmental process will result in a programmatic or project-level decision leading to a categorical exclusion, a finding of no significant impact, or a record of decision or the state/provincial equivalent. These more detailed plans must make sure all of the key decision milestones are reached to ensure that the project can be cleared environmentally.

In cases where further study is needed, a process should be established to follow the project through subsequent environmental studies sufficient to clear the selected project. This process may proceed for a period of months or years until a preferred alternative is fully defined, evaluated, and approved by the respective agencies. During this time, the alternatives may change and the results may be revised based on new information available to the project team. The important action is to keep the process sufficiently alive to avoid repeating the entire corridor analysis process. The reader is referred to chapter 4 on environmental analysis.

## H. Public Engagement

Because of the local nature of many corridor studies, corridor planning requires a thoughtful approach on how to involve the public. Public engagement complements technical analysis in providing information to decision makers. Decision makers will weigh the results of both the technical analysis and public input and make a decision that is in the best interests of the community and/or region. Most studies include the important role of partner agencies in the overall public outreach effort. Involving the public in goal setting and the identification of purpose and need can be helpful in determining evaluation criteria. Taking back to the public a list of alternatives to choose from (developed as a result of their input) is much preferred over a set of alternatives developed solely outside of a public participation process.

From a public engagement perspective, corridor planning is not that different from other types of transportation planning activities. However, what sets many corridor studies apart is the local familiarity with the corridor and the potential controversies that could begin at the very start of the study. Such controversy occurs particularly when corridor strategies involve new facilities or expansion of existing facilities. Many corridor studies also often begin with public disagreements over the identification of the corridor problems and what should be done about them. The public engagement program should clearly articulate the issues in a way that leads people to understand them and to develop informed opinions.

Many corridor studies could benefit from the participation of a public participation specialist. A public affairs specialist deals with questions and public policy issues, most often having a political dimension. A specialist in community outreach helps agencies and communities improve their decision-making process by involving the people most likely to be affected.

Chapter 24 discusses public engagement in much greater detail. Interested readers are referred to that chapter.

Figure 17-17 shows the overall process for corridor planning sponsored by the Virginia DOT. As shown, this process includes all of the steps presented in this section, as well as linking the corridor plan recommendations to other plans and implementation strategies at the end of the study. [VDOT, 2015]

## V. CORRIDOR MANAGEMENT PLANS

*Corridor management plan* is a term that is used to describe two different transportation planning efforts. The first reflects the natural progression from a corridor planning process to efforts to manage corridor system operations, land-use decisions, and future investments. The second is a term that is used as part of the U.S. scenic highway program and is intended to highlight the steps necessary to enhance the historic and scenic nature of an area bisected by a scenic highway or byway.

### A. Managing Corridor System Performance

Corridor management refers to the "management of land development and the transportation facility within an existing corridor to ensure that they develop in accordance with adopted land use plans, roadway improvement plans, access management, future ROW needs, or any specially adopted plans or objectives for the corridor." [Williams, 2000; Hard et al., 2008] A corridor management study "evaluates roadway design and access characteristics, and proposes changes that maintain reasonable access to property, while improving the safety and operation of the highway." Such changes may involve:

- Medians or median opening closures.
- Signal location and spacing.
- Auxiliary lanes.
- Right-of-way needs and requirements.
- Site access and circulation design.
- Land use and activity center concepts.
- Improvements to the supporting roadway network.
- Improvements involving access for other transportation modes (for example, bus pullouts, transitions for special use transit lanes or bus rapid transit, pedestrian crossing treatments).

Corridor management is distinguished from another concept, corridor preservation, which is the practice of acquiring, preserving, or protecting right-of-way needed for a future transportation corridor. Corridor preservation relies on several different land use regulatory and DOT financial options in order to preserve the DOT's ability to use the right-of-way in the future for system expansion.

A study by the Texas Transportation Institute noted the "connected" nature of road operations and land use in many of today's transportation corridors (especially those in urban areas). [Hard et al., 2008] The report concluded that the solutions to the problems lie in coordinated corridor management and preservation activities that help bring together land use and transportation planning decision making among the affected jurisdictions and agencies. Different types of system management and preservation strategies and actions were described in the report. Table 17-18 shows the variety of ways that DOTs could implement both types of corridor efforts. Table 17-19 from the same study shows the institutional authority for using different strategies in Texas. This table shows the important role that cities (or local jurisdictions) have in implementing any plan that has land use as part of the strategy. The reader is referred to chapter 3 on land use and urban design strategies.

### B. Enhancing Scenic and Historic Characteristics of Scenic Corridors

Corridor management plans (CMPs) are also developed for those interested in enhancing the condition and performance of scenic byways. [FHWA 2015b] A CMP specifies "the actions, procedures, controls, operational practices, and strategies to maintain the archaeological, cultural, historic, natural, recreational, and scenic qualities that support the byway's designation." The Brandywine Valley Scenic Byway Corridor Management Plan is a good example of such a CMP. [Brandywine Valley Scenic Byway Commission, 2014] The Brandywine Valley, located between Delaware and Pennsylvania, was the site of one of the most important battles during the American Revolution. Many other events of

P = Policy I = Implementation ● = Specific part of plan or action

Source: Hard et al., 2008

major historical significance have occurred within the corridor, making it an excellent candidate for a historic byway. The CMP is organized into several chapters related to the vision for the corridor, identifying the intrinsic qualities of the corridor, describing the byway itself, recommending strategies for enhancing the historic and scenic nature of the corridor, and implementing the plan.

Similar to a regular corridor transportation planning process, the CMP for the Brandywine Byway conducted extensive outreach with key stakeholders and the public, developed a vision that could guide the planning effort, established

**Table 17-19. Comparison of Corridor Management and Planning Authority among Cities, Counties, and Extra-Territorial Jurisdictions, Texas**

| Tool | CM, CP, or Both | Cities | Extra-territorial Jurisdictions | Counties |
|---|---|---|---|---|
| Comprehensive (land-use) plan | Both | √ | | |
| Transportation plan | Both | √ | √ | limited |
| Zoning | CM | √ | | |

Source: Hard et al., 2008

goals, and developed strategies and actions to preserve and enhance the historic and scenic nature of the corridor. The transportation goal and corresponding objectives for the CMP were:

*Transportation and Traffic Safety Goal: To provide for a multimodal Byway corridor that accommodates all users, ensures safe travel, and provides connectivity and access to facilities, services, and destinations in an attractive setting.*

**Objectives**

- Work with PennDOT, DVRPC, Chester and Delaware Counties, and all municipalities located in the corridor to accommodate and balance the needs of all roadway users including residents, visitors, businesses, public facilities, and institutions by utilizing context sensitive design and multimodal approaches to solving transportation challenges.
- Adopt traffic calming measures, in coordination with PennDOT and the affected municipalities, as a means of self-enforcing posted speed limits, improving pedestrian safety, and encouraging pedestrian and bicycle use of the Byway corridor.
- Plan for both safe access as well as intermodal access to recreational facilities in consultation with PennDOT and pertinent recreational facility providers.

**Table 17-20. Example of an Historic Byway Corridor Management Plan**

| Description | Strategy | Lead Stakeholder | Support Stakeholders |
|---|---|---|---|
| Roadway Functional Classification and Typology | Establish consistent roadway functional classification and typology designations. | Commission, Byway municipalities | PennDOT, Chester, and Delaware County's Planning Commissions (CCPC and DCPC), Delaware Valley Regional Planning Commission (DVRPC) |
| Context Sensitive Solutions | Provide input to context sensitive design treatments for all transportation improvement projects. | Commission | PennDOT, CCPC/DCPC, Byway municipalities |
| Safety | Implement safety enhancements along the Byway and at critical conflict areas. | Commission; State and municipal police forces | PennDOT, DVRPC, CCPC/DCPD, Byway municipalities |
| Traffic Calming | Design and implement traffic calming at key locations. | | Commission, PennDOT, Byway municipalities |
| Roadway Maintenance | Regularly clear debris and overgrowth along roadway edges, particularly along bicycle and pedestrian routes. | PennDOT, Byway municipalities | |
| Bicycle and Pedestrian Routes | Implement safe, continuous, and well-connected bicycle and pedestrian routes. | Commission, Byway municipalities | PennDOT, DVRPC, CCPC/DCPC |
| Existing Bus Service | Enhance SCCOOT Bus Service with improved signage, amenities, and pedestrian crossings. | PennDOT, Transportation Management Association of Chester County (TMACC), Byway municipalities | DVRPC |
| Future Bus Service | Provide connecting bus service to key Byway attractions. | PennDOT, DART, Southeast Pennsylvania Transit Authority (SEPTA) | TMACC, CCPC/DCPC, DVRPC |
| Regional Rail Access | Support improvements for multimodal accessibility at nearby rail stations. | SEPTA, Amtrak, PennDOT | TMACC, CCPC, DCPC, Byway municipalities |

Source: Brandywine Valley Scenic Byway Commission, 2014

The CMP identified the opportunities in the corridor that reinforced the vision, including:

- Planned bicycle and trail improvements in support of the CMP transportation goal provides for a multimodal corridor, which suggests that a comprehensive approach to accomplish this opportunity is through a Bicycle and Pedestrian Master Plan for the Byway corridor.
- In order to meet the transportation goals, consistent roadway classifications and design parameters for the Byway segments among the Byway municipalities and other agencies responsible for the road segments should be provided.
- The Byway corridor has limited public transportation services to serve current and future regional and Byway destinations, to address the goal for a multimodal corridor. It will be important to identify opportunities for expansion of alternative transportation means, notably through private-sector enterprise.
- To accomplish a fully integrated multimodal system for the Byway corridor, off-road trails, paths and sidewalks also can serve as linkages to Byways destinations as well as between missing links of on-road facilities.

Table 17-20 shows the types of strategies and actions that were recommended by the study. As can be seen, the recommendations are much in line with the types of values and goals outlined by the corridor stakeholders. In many ways, this concept of a CMP is an excellent example of context sensitive solutions (see chapters 3 and 9).

## VI. SUMMARY

Although transportation planning can occur at many different levels, one of the most important is the corridor level. Corridor planning can be part of a four-step process consisting of: (1) planning, (2) project development, (3) design, and (4) construction. The purpose of corridor planning is to vet potential projects for inclusion in this four-step process. Through each step, the parameters of the corridor improvement, first identified in the planning stage, get refined and more detailed, with the overall process perhaps taking over 10 years. Corridor planning allows planners to focus on specific transportation problems that affect mobility and accessibility, thus allowing the identification of problem-specific solutions. In addition, while regional transportation planning often deals with general land-use and development policy issues, corridor plans can be very specific about the land-use policies needed in a corridor to complement transportation investment.

Many metropolitan planning organizations use corridor plans as a way to identify projects for their transportation plan. State departments of transportation often use corridor studies as a way to identify multimodal capacity and operations improvements at the regional or statewide level. Many transit agencies also conduct corridor studies to identify the most cost-effective set of transit investments for the corridor's contribution to regional transit system productivity and effectiveness.

Corridor studies provide many advantages in assessing transportation needs and identifying strategies for improvement. Because a corridor study focuses on specific travel corridors, the study team can identify problems associated with specific strategies to improve the corridor transportation system. Engaging stakeholders and the public in a public involvement process for a corridor study tends to be easier than regional efforts, because participants can relate to the locations being discussed and can personalize the potential benefits of the improvements. The land use/urban design component of corridor studies provides important insights into how the transportation decisions affect future land-use patterns and how careful land use planning and urban design can influence the transportation solutions. Finally, the types of improvement strategies identified in a corridor study can focus either on specific-site improvements (for example, improve this interchange) or more regional strategies (for example, expand transit services in the corridor). Thus, the priorities and next steps for implementing the corridor study recommendations can be clearly determined.

It is important to note that corridor planning studies require professional competencies in a variety of disciplines. NCHRP Report 435, *Guidebook for Transportation Corridor Studies: A Process for Effective Decision-making,* recommends training in the following core competencies important to corridor planning: modeling, public involvement and consensus building, economic and financial analysis. [Smith, 1999]

# Local and Activity Center Planning[1]

## I. INTRODUCTION

As noted in chapter 2, the majority of the U.S. population lives in urban areas, which is true of most countries of the world (see chapter 2 on data collection and analysis). According to the U.S. census, there were 3,144 counties (and county equivalents) and 19,354 incorporated places in the United States in 2013. Although not all incorporated jurisdictions are of a size to have their own transportation department or agency, most cities and towns have some transportation responsibility, as do all of the counties. For purposes of this chapter, local planning is defined as county and municipal transportation planning. Whether individually or as a part of a larger planning organization such as a metropolitan planning organization (MPO) or regional planning commission, these governments have staff members whose responsibility is to ensure the local transportation system operates effectively and efficiently.

Although state departments of transportation (DOTs) and MPOs are primarily concerned with state and regional transportation flows, the success of a transportation system often lies in the "last mile." That is, city and local streets provide the connectivity to homes, stores, businesses, and recreation sites that are so important to the livelihood of a community's residents. This is especially true when considering goods movement where the delivery of goods relies on an ability to reach grocery stores, retail stores, warehouses, and distribution centers. A municipal and local-level transportation network that provides effective mobility and accessibility is critical to the overall success of a state or regional transportation system, and to the state and regional economy.

In addition, it is the local transportation system that most travelers experience on a daily basis. Local governments provide sidewalks and bicycle paths, control many of a city's traffic signals, review and approve land-use plans (usually having an important transportation component), enforce the laws and regulations on the use of that system, and maintain many of the roads that provide for local trip-making. As an example of the responsibilities of one of the larger municipal transportation agencies in the United States, the San Francisco Municipal Transportation Agency (SFMTA) defines its efforts as follows:

> *"The SFMTA plans, designs, builds, operates, regulates, and maintains one of the most diverse transportation networks in the world. In addition to four modes of transportation (transit, walking, bicycling and driving, which includes private vehicles, taxis, carsharing, and commercial vehicles), the Agency directly oversees five transit modes (bus, trolley bus, light rail, historic streetcar, and cable car), in addition to overseeing paratransit service, which serves individuals unable to use fixed-route transit service. The SFMTA also partners with regional transit operators who connect the city with the region using four additional transit modes (heavy rail (BART), commuter railroad, regional bus, and ferry) … the SFMTA has a robust planning, design, and construction function that includes reviewing all proposed land use developments with our partners; planning, designing, and building the transportation modal networks (transit and paratransit, streets, signals, bicycle, pedestrian, taxi, commercial delivery, and loading); and providing long-range forecast analyses of the fleets, facilities, and right-of-way infrastructure in the city and their relation to the region. The SFMTA also oversees on- and off-street public parking and manages it … . Last, but not least, the Agency creates and enforces rules on the city's streets, transit system, and parking. Combined, these efforts make an all-in-one transportation agency that directly impacts the daily life of everyone who moves about the city." [SFMTA, 2012]*

Although SFMTA is not typical of most local transportation agencies (given its size and breadth of responsibilities), one can see that transportation planning at the local level can be an important component of a community's mobility strategy, and an often critical input into the overall transportation planning effort in a state or metropolitan area.

[1]Portions of this chapter were originally written by Herbert S. Levinson, P.E., Transportation Consultant, New Haven, CT, USA and Icon Mentor, Region 2 Transportation University Center, City University, New York, NY. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

Local development strongly influences the magnitude and pattern of transportation flows (see chapter 3 on land use and urban design). One of the more important development trends in metropolitan areas over the past 30 years creating both challenges and opportunities for transportation planning has been the clustering of land uses in what are referred to as "activity centers." Activity centers are an important part of the urban landscape. They take many shapes and sizes and include central business districts (CBDs), suburban business districts, colleges, universities, medical centers, office parks, and large transportation terminals. They attract large numbers of people, generate substantial traffic and transit movements, and require often extensive transportation infrastructure. Where they are located, how well they are designed, and how easy they are to reach have an important bearing on their viability and, in a broader sense, on the livability of communities. Safe and convenient transportation access is essential for their continued success.

Local planning and the planning for activity centers are discussed together in this chapter because the steps in the planning process, the data and tools used, and the types of strategies that come out of the planning process are very similar. Clearly, the governmental and decision-making structure is different between the two in that local planning carries with it the authority of the local jurisdiction as realized in comprehensive plans, zoning codes, and subdivision regulations. Activity centers do not have such governmental powers, although many of the larger activity centers have created organizations called transportation management associations (TMAs) to coordinate the strategies and actions that help provide accessibility to the site and the mobility within.

The first half of this chapter focuses on local planning, while the second half looks at activity centers. The following section describes the substance and form of local transportation planning, including a definition of place-making, a discussion of the typical steps in such planning, and the identification of strategies and projects that usually result. Typical data needs and analysis tools are described. The following section examines the characteristics of activity centers, and follows the same approach as outlined above for local planning. The chapter ends by discussing the importance of developing an implementation plan that lays out the funding sources, the schedule of activities, and identifying those who are responsible for furthering the plan's goals.

Note this chapter focuses on urban communities and activity centers in metropolitan areas; rural communities are addressed in chapter 20 on rural community and tribal planning.

## II. LOCAL TRANSPORTATION PLANNING

Transportation planning for local communities and municipalities can either occur as a stand-alone study or as part of a more comprehensive planning effort. A stand-alone effort focuses on the transportation system and the components thereof (such as streets, pedestrian/bicycle paths, and parking). In a more comprehensive planning effort, transportation is usually presented in one chapter of a community's comprehensive plan, which includes chapters on other infrastructure needs, land-use strategies, and related policy initiatives. Transportation planning as part of a comprehensive plan is discussed in chapter 3 and will not be repeated here.

The local transportation planning process follows similar steps as other types of transportation planning. Figure 18-1, which shows the planning process for a subarea study from the city of Houston, lays out the key steps in planning for the study area. This figure will be used to structure the following discussion on local transportation planning, while acknowledging that the process might not be applicable to all county/city/town contexts. In particular, the following sections will discuss identifying issues and opportunities, defining the study area, selecting objectives and performance measures, conducting the technical analysis, and incorporating planning outcomes into the investment and policy programs for the county, city, or town.

### A. Challenges, Problems, and Opportunities

Put in simplest terms, the purpose of transportation planning is to help solve today's transportation problems and to position a community to meet the transportation challenges expected in the future. This means there needs to be some indication of what the problems are today and what they will likely be tomorrow given changes in the economy, population, and technology. As will be discussed later, an initial step in the planning process is analyzing the performance of the transportation system to identify where streets and roads are not performing like they should, where improvements can be made in transit and paratransit services, and how pedestrian and bicyclist movements can be made safer. However, cities also often undertake efforts to better understand the many demographic and economic

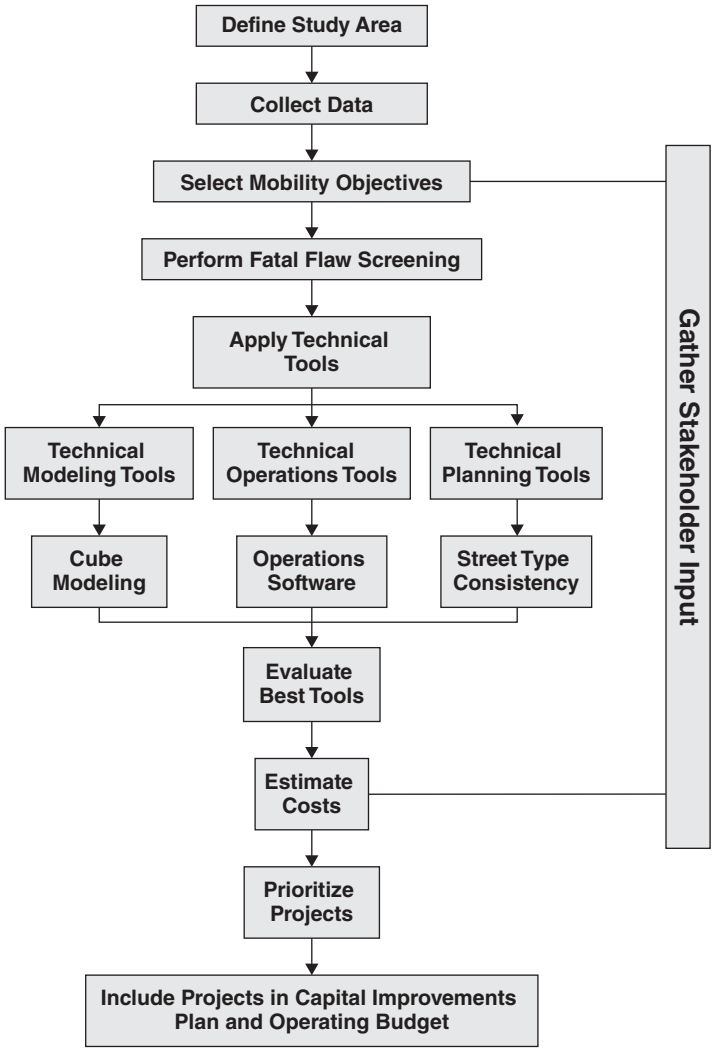
forces that are affecting the provision of city services, and how such trends might affect these services in the future. Such efforts are undertaken particularly by larger cities and often funded by chambers of commerce or local foundations. Such studies are usually not part of the formal transportation planning process, but when they do occur, they provide important input into the challenges and opportunities facing a community.

An example of this comes from San Francisco where the SFMTA outlined the challenges and opportunities for the city as they relate to transportation planning and investment decisions. Table 18-1 shows how it describes some of the societal trends affecting the use of transportation and the opportunities they present to the agency. This information is presented here simply as an example of how one can think about the broader context within which transportation planning occurs. The list also corresponds to the responsibilities that the agency has for transportation in San Francisco.

Depending on the size of the county, city, or town, transportation planning could focus on the community as a whole, or might be targeted on specific geographic areas, or on topics that are of concern to decision makers. For example, the website of the city of Houston transportation planning group lists the following topics as being part of its planning program: [City of Houston, 2015a]

- Major thoroughfare & freeway plan.
- City mobility planning.
- Complete Streets policy.
- Consolidated transportation planning.
- Urban corridor planning/transit corridor ordinance.
- I-69: Driven by Texans.
- Livable centers studies.
- Planning studies—Reports.
- Heights-Northside subregional study.
- Northwest subregional mobility study.

**Figure 18-1. Example Planning Process for a City Subarea, Houston, Texas**



Source: City of Houston, 2015b

As can be seen from this list, the city's transportation planning group is not only involved with the city's transportation plan, but it sponsors subarea studies, corridor studies, city-wide transportation plans focused on particular topics (for example, the thoroughfare and freeway plan), and helps implement transportation policy initiatives (for example, Complete Streets). This range of planning involvement usually does not occur in smaller cities and towns because of limited resources, but for larger cities it is not unusual to see a variety of planning efforts undertaken by the planning department.

Another way of identifying typical planning issues is to look at the type of information found in transportation plans. The transportation plan from Salem, Oregon, provides a good range of topics as follows:

| Table 18-1. Examples of Issues and Opportunities, San Francisco | | |
|---|---|---|
| **Category of Issue** | **Issues** | **Opportunities** |
| General Context | • Projected 25% increase in jobs and 15% increase in population by 2035; more seniors, fewer families with children<br>• Funding, particularly federal and state, is declining<br>• Local and regional funding becomes more important to finance our capital and operational needs<br>• Insufficient resources to operate and maintain the transportation system and to address state-of-good-repair and expansion needs<br>• Different modes are not integrated, systems are hard to navigate and require separate payment<br>• Mixed traffic, circling, and double parking slows down transit, taxis, and deliveries<br>• Electric vehicle parking demand impacts public garages | • Better linkages between transportation and smart land uses can create efficiencies in future development<br>• New funding sources and new funding partnerships can help meet growing needs<br>• New technology and good planning will allow<br>• Integration of all modes, customer information, and payments<br>• Dedicating lanes and spaces for shared mobility can be effective<br>• City is positioned to have a greater voice in regional, state, and federal forums<br>• Transportation system can benefit from zero- and low-emission vehicles |
| Walking | • Population aging<br>• Demand for walking is increasing<br>• Most collisions are preventable<br>• Traffic speeds not compatible with land uses in key locations | • Public support to implement best practices in street design and the Mayor's Directive on Pedestrian Safety<br>• Technology applications for speed enforcement and education<br>• Infrastructure support for walking is cost-effective |
| Transit | • Transit system safety<br>• Transit speeds lowest in the nation; vehicles are operating mostly in mixed traffic<br>• Peak crush loads mean people shifting back to auto, with some switching to bicycle and walking<br>• State-of-good-repair and major maintenance needs<br>• Existing vehicle fleet is difficult for families to use and needs major overhaul<br>• Many stops not fully accessible | • New technology and educational opportunities to improve system safety<br>• Ability to speed transit and increase reliability through cost-effective measures like dedicated transit lanes, all-door boarding, stop spacing, and signal priority tools<br>• Upcoming fleet replacement cycle<br>• Public support to prioritize the funding of mission-critical assets to ensure the preservation of a safe and reliable system<br>• Capital and operations funding through development agreements |
| Bicycling | • Interest in bicycling is growing; mode share expected to double in next five years<br>• Bicycle network connectivity is fragmented<br>• Limited bicycle parking supply | • Expanding bicycle infrastructure is cost-effective: lanes, parking facilities, signals, and marketing yield high returns<br>• Bike sharing provides cost-effective access for inner-urban trips<br>• Business community is open to bicycle parking as prudent customer strategy |

| Table 18-1. (*Continued*) | | |
|---|---|---|
| **Category of Issue** | **Issues** | **Opportunities** |
| Parking | • Parking is not efficiently used and creates congestion through double parking and circling; results in slower transit speeds<br>• Residential parking is not consistent across city<br>• Disabled placard abuse is compromising access to parking spaces for the disabled community<br>• Demand for parking for family vehicles is increasing<br>• State Vehicle Code limits best practices in parking management | • New technologies make it easier to find and pay for parking<br>• Demand-responsive parking pricing<br>• Parking maximums and California's Parking Cash-Out<br>• Law provide incentives for Transit First modes<br>• Growing support to amend the State Vehicle Code to allow flexibility in local parking management and better parking management strategies across the state |
| Taxis/ Rideshare | • Demand for taxis not being met<br>• Improved collaboration is needed for car- and vehicle-share to share growth<br>• Shuttle and ridesharing providers need expanded coordination and partnerships with city | • Public support to identify the number of taxis needed in the city and improve taxi services<br>• Growth of car-share and vehicle-share usage leads to the reduction of single occupant automobile trips<br>• Ridesharing and regional shuttles can mitigate regional traffic coming to the city |

- Street system element
- Transportation system management element
- Neighborhood traffic management element
- Local street connectivity element
- Bicycle system element
- Pedestrian system element
- Transit system element
- Transportation demand management element
- Parking management element
- Intercity passenger travel element
- Freight movement element
- Transportation system maintenance element
- Transportation finance element
- Long-range transportation strategy
- Plan implementation
- Issues requiring future study

This list is not meant to imply that all plans should include these elements; it simply shows the types of topics that planners get involved with. It is interesting to note that the plan includes both a section on finance and implementation, two topics that 20 years ago would not likely have been in the plan (see chapter 5 on transportation finance and funding).

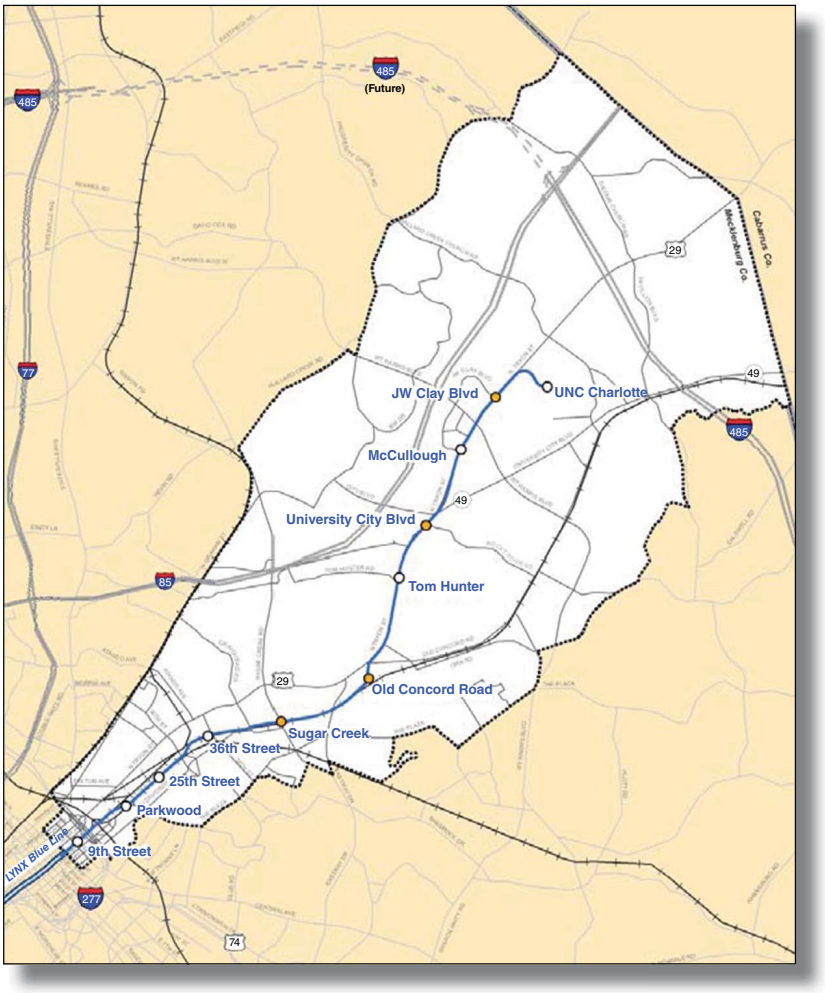
## B. Define the Study Area

The study area boundaries for a local comprehensive transportation plan are usually established as the boundaries of the jurisdiction itself. If a travel demand model is used for the study, the study area will include areas beyond the city or town lines simply to account for the external origins and destinations that are part of the modeled network (see chapter 6 on travel demand modeling). The challenge for transportation planners is establishing the boundaries of studies that examine areas smaller than the entire jurisdiction. In this case, judgments must be made on where the study boundaries are. Some of the factors for establishing such boundaries include:

- Major geographic features that separate sections of the community (for example, a river).
- Major transportation facilities.
- Markets for transportation services (for example, walking distance to transit stops).
- Travel sheds that represent the predominant travel flows in the community.
- Neighborhood or other local boundaries.
- Census tracts.
- Other zone systems with aggregated data (for example, traffic analysis zones).

It will save a lot of time in the data collection and interpretation phase of a study if the study area is consistent with typical configurations of the databases to be used in the study. For example, it is quite common to use census

**Figure 18-2. Corridor Study Boundaries, Charlotte, North Carolina**



Source: City of Charlotte, 2011

tracts or zones as building blocks for a study area. Otherwise, determining the distribution of data between study boundaries can be quite challenging (unless the data being used are spatially defined and the study is using geographic information systems).

Typically, two types of subarea studies are conducted as part of the transportation planning process—subarea and corridor studies. An example of the latter is shown in Figure 18-2 from Charlotte, North Carolina, where the possible extension of a light rail line through the middle of the corridor helps define the potential travel market that is the focus of the study. The boundaries were defined by jurisdiction lines, railroad lines, and local streets (see chapter 17 on corridor planning).

Figure 18-3 shows an example of a subarea boundary from the Houston study mentioned earlier. The boundary of this study area was defined by a well-established neighborhood boundary and by interstate highways to the east, north, and south. In this case, the study area included two major jurisdictions, the city of Houston and Harris County. This made the study more complicated because, "any recommendations resulting from this study must consider implementation processes and considerations of not only the city of Houston, but Harris County as well." [City of Houston, 2015b]

A rather unique approach to defining study boundaries occurred in Denver where the city developed travel sheds as a way of delineating logical boundaries for prospective subarea studies. A travel shed was defined as "a collection of streets and mobility routes that feed into the larger, connected transportation system." [City of Denver, 2008] Twelve travel sheds were identified that shared similar characteristics, such as trips that start and finish in the same area and geographic features that create barriers to travel movement (see Figure 18-4). These travel sheds became the basis for further studies that examined local transportation needs.

Other Projects / Studies

The following areas of the city are being specifically analyzed by major studies that are underway or recently completed:

**I.** 56th Avenue EA

**II.** I-70 EIS

**III.** Valley Highway EIS / Broadway NEPA

## C. Goals, Objectives, and Performance Metrics

As with other planning processes, articulating goals, objectives, and performance measures is one of the early steps in the local planning process. Because transportation is so engrained in the daily lives of residents, the list of goals and objectives (sometimes referred to as policies) is often quite long. The city of San Diego's Mobility Element of its General Plan had 94 distinct policies as part of its plan. [City of San Diego, 2005] The city of Salem (Oregon) had 27. [City of Salem, 2007] The city of Charlotte, North Carolina, had five goals, 16 objectives, and 105 policies. [City of Charlotte, 2011] Clearly, the more local the study, the more issues arise in the planning process causing planners to develop strategies and actions to deal with the issues. Space does not allow for an enumeration of the long list of transportation goals and objectives to illustrate what a typical plan might include. However, the city of Orlando, Florida, goals give some sense of what these statements look like.

*Goal 1*: To develop a balanced transportation system that supports building a livable community and improves access and travel choices through enhancement of roads, public transit, bicycle, and pedestrian systems, intermodal facilities, demand management programs, and traffic management techniques.

*Goal 2*: To sustain the city's long-term land use vision by implementing mobility requirements, within defined mobility areas, which ensure that transportation facilities and services are available for multiple modes of travel for new developments.

*Goal 3*: To develop a financially feasible transportation system which meets the accessibility needs of the city residents.

*Goal 4*: To promote coordinated transportation planning efforts across Central Florida's jurisdictions and transportation agencies. [City of Orlando, 2014]

In addition to these goals, the city of Orlando identified performance measures to monitor progress toward goals achievement. Table 18-2 shows the types of metrics that were adopted for doing this. Table 18-3 shows another example of performance metrics used by the SFMTA in its strategic transportation plan. [SFMTA, 2012]

Readers are referred to chapter 2 and chapter 7 for more information regarding the use of performance measures in transportation planning.

Another example of goals comes from the city of Ann Arbor, Michigan, which identified the following eight goals to direct its transportation planning effort.

- Provide effective access and mobility for people and goods, with minimal negative impacts for all.
- Protect and enhance the natural environment and energy resources, and the human and built environment.
- Promote a safe, secure, attractive, and productive transportation system.
- Invest in transportation infrastructure in a manner consistent with other goals, and within the financial constraints of public/private resources.
- Promote cooperation between the city of Ann Arbor and other governmental entities, particularly the surrounding townships and municipalities and the University of Michigan, in support of transportation initiatives in a manner consistent with the other goals.
- Ensure meaningful public involvement will be part of any transportation project in the city of Ann Arbor.
- Promote a transportation system supportive of and integrated with land use decisions.
- Promote green transportation improvements to reduce vehicle emissions. [City of Ann Arbor, 2009]

One can see in this list the local nature of goals statements in the call-out to the major university in the city as a major participant in the study.

Another study that illustrates how transportation can be viewed as part of a larger market is from Chamblee, Georgia, a suburban city just outside of Atlanta. [Kimley-Horn & Assocs., 2014] As part of the Atlanta Regional

| Table 18-2. Performance Metrics for Monitoring Plan Progress, Orlando, Florida | | |
|---|---|---|
| **Categories** | **Measures** | **Strategies** |
| **Alternative modes of transportation** | Sidewalk coverage near transit stops | The percentage of transit stops within the city with direct sidewalk access shall be increased by 5% by the next Environmental Assessment Review (EAR). |
| | Transit vehicles with bicycle accommodations | All transit rolling stock shall be equipped with bicycle racks. |
| | Transit shelters | The number of transit shelters shall be increased by at least 3 per year. |
| | Designated transit corridors having a weighted average headway of 30 min. or less | At least fifty-one percent (51%) of the designated transit corridors shall be maintained with a weighted average headway of 30 minutes or less. |
| **Urban design and land-use mix** | Urban design plans and standards | Each year, the number of activity centers and infill areas with pedestrian-oriented design standards and/or design plans shall be increased. |
| | Land-use mix in activity centers | A mix of land uses shall be increased in activity centers. |
| **Land-use density and intensity** | Employee/resident population ratio | An employee/resident ratio between 0.98 and 1.3 shall be maintained citywide. |
| | Population density | The citywide population density shall be increased by the next EAR (2014). This strategy may also help reduce VMT per dwelling unit. |
| | Density and intensity of new developments | New development within 1/2 mile of commuter rail stops and in medium or high intensity future land use categories shall be built at a minimum of 12 dwelling units/acre or at a minimum floor area ratio (FAR) of 0.3. |
| | Active ground floor uses near transit | Each year, the amount of pedestrian-oriented retail space within 1/2 mile of the two downtown commuter rail stops shall be increased. |
| **Transportation network connectivity** | Pedestrian connectivity | Each year, at least four (4) miles of new sidewalks shall be built within city limits. |
| | Bikeway connectivity | At least twenty (20) miles of bikeway facilities shall be built by the next EAR. |
| | Street connectivity | A connectivity index of 1.4 or greater shall be maintained in new or redeveloped large-scale, single-family subdivisions and planned developments. |
| | Multimodal transportation facilities | The percentage of major thoroughfare miles within the city with more than two parallel modes (excluding limited access facilities) shall be more than 60% by the next EAR. |
| **Strategic Intermodal System (SIS) and Florida Intrastate Highway System (FIHS) facilities** | Traffic counts and queue lengths at SIS and FIHS ramps within the City | The city shall coordinate the monitoring of traffic counts and queue lengths at SIS and FIHS ramps within the City with FDOT on an annual basis. |

Source: City of Orlando, 2014

Commission's (ARC's) Livable Communities Initiative (LCI) program, Chamblee undertook a study to enhance the economic attractiveness of its city center, which was served by a subway station. The study goals were articulated as:

- Clarify the vision and future market potential of the Chamblee downtown and the MARTA rail station area.
- Provide additional detail and direction to the city of Chamblee comprehensive plans.
- Offer recommendations to improve local zoning regulations and encourage appropriate future development/redevelopment.
- Prioritize public improvement projects, identify funding sources and move key projects toward implementation by providing a five-year action plan.

**Table 18-3. Performance Indicators for a Goal of Making Transit, Walking, Bicycling, Taxi, Ridesharing, and Carsharing the Preferred Means of Travel, San Francisco, California**

| Key Performance Indicators | Targets | | |
|---|---|---|---|
| | FY 2014 | FY 2016 | FY 2018 |
| OBJECTIVE 2.1: Customer rating: Overall customer satisfaction; Scale of 1 (low) to 5 (high) | Establish baseline and improve satisfaction rating by 0.5 point each budget cycle | | |
| OBJECTIVE 2.2: Percent of transit trips that have less than a 2-minute spacing between vehicles by line and route on the Rapid Network ("bunches")<br>Percent of transit trips where gaps in service exceed scheduled headway by more than 5 minutes by line and route on the Rapid Network ("gaps") | Eliminate bunches and gaps for 25% of ridership | Eliminate bunches and gaps for 45% of ridership | Eliminate bunches and gaps for 65% of ridership |
| OBJECTIVE 2.3: Mode Share | FY 2018 mode split goal—private auto: 50%; non-private auto modes: 50% | | |
| OBJECTIVE 2.4: % average occupancy of public metered parking spaces (SFpark areas and SFMTA garages) | Maintain 75%–85% range of occupancy in SFpark areas | | |

Source: SFMTA, 2012

The recommendations from the plan were thus to describe desired (and achievable) land use; recommend a development framework; and identify priority transportation projects, policies, and strategies.

Goals and objectives statements are most often identified via a comprehensive and inclusive public participation process, where opportunities for engagement in the process are provided throughout the community. Given the local nature of the types of strategies and actions that will surface from the plan, getting local participation is often not as challenging as that for statewide or metropolitan-wide planning. See chapter 24 on public participation and community engagement for a discussion on the methods and approaches that are most effective for transportation planning.

## D. Existing Conditions Data

When updating a transportation plan, the planner wants to understand current issues and problems, their magnitude, and the extent to which these problems are widespread. This step in the planning process utilizes existing data and/or collects additional data to identify the current performance of the study area's transportation system. Three studies, from Ann Arbor, Seattle, and Chamblee, illustrate the types of data and data presentations that represent this step in the planning process.

*Ann Arbor*. Two types of traffic volume data were used to evaluate congestion within the city—average daily traffic (ADT) volumes for roadway segments, and peak hour turning movements at key intersections. Roads were identified where the volume-to-capacity ratio was greater than 1.0 (where the volume of traffic on the roadway is greater than the capacity). The a.m. and p.m. peak traffic counts and current traffic signal timings for the intersections were analyzed with a software package and intersection level of service was estimated during the peak hours. Sixteen intersections were identified as being high crash locations based on a 3-year crash record (both crash frequency and crash rate were estimated). Vehicle crashes involving pedestrians and bicyclists were evaluated by using available crash data, and the intersections with an average of one or more pedestrian/bicycle crashes per year were reviewed as well as any location where a pedestrian/bicycle fatality or serious injury occurred. Transit routes were analyzed both for frequency of service and crowding, and the highest ridership corridors were identified. Both on- and off-street parking occupancies were identified as well as the overall parking supply for the city. Tables 18-4 and 18-5 show how the data on level of service and crashes were summarized.

For land use, data was collected on residential, institutional, recreational, industrial, and commercial properties, including both densities and extent. Future land-use maps for the various areas of the city were compared to current zoning.

*Seattle*. The city of Seattle conducted a subarea study of southeast Seattle to anticipate the economic benefits of a new light rail line and to improve mobility and safety in the area. [City of Seattle, 2005] The study area was bounded

by two interstate highways, Lake Washington to the east, and a major city street. One of the first steps in the study was to inventory the area's road network, with the data collected by functional class of road, including:

- *Interstate Freeways*—Roadways providing the highest capacity and least impeded traffic flow for longer vehicle trips.
- *Principal Arterials*—Roadways serving as primary routes for moving traffic through the city, connecting urban centers and urban villages to one another or to the regional transportation network.
- *Minor Arterials*—Roadways distributing traffic from principal arterials to collector arterials and access streets.
- *Collector Arterials*—Roadways collecting and distributing traffic from principal and minor arterials to local access streets or providing direct access to destinations.

- *Commercial Access Streets (Non-Arterial)*—Streets providing access to commercial and industrial land uses and providing localized traffic circulation.
- *Residential Access Streets (Non-Arterial)*—Streets providing access to residential land uses, higher-level traffic streets and providing localized traffic circulation.
- *Alleys*—Travel ways providing access to the rear of residences and businesses and are not intended for the movement of through trips. In neighborhoods with continuous alleys, utilities (such as garbage collectors) prefer to use alleys rather than residential or commercial streets.
- *Major Truck Streets*—Arterial streets accommodating significant freight movement through the city and connecting to major freight traffic generators.
- *Urban Trails*—A network of on- and off-street trails facilitating walking and bicycling as viable transportation choices, providing recreational opportunities, and linking major parks and open spaces with Seattle neighborhoods.
- *Bicycle Streets*—An on-street bicycle network connecting neighborhoods and urban centers and villages and serving major intermodal connections.

An investigation of Census data and other travel databases showed that, (1) only 9 percent of community members lived and worked in southeast Seattle, (2) over 50 percent of the residents traveled north for employment (downtown Seattle, Capitol Hill, Northgate, and further north), and (3) although major employment areas for southeast Seattle residents are within the city of Seattle, residents travel beyond King County for employment opportunities. Looking at community sites and resident travel patterns, the study concluded that major internal destinations included public schools, libraries, and community centers, which tended to be clustered together. In addition, the study noted that the steep topographical grades in parts of the study area created physical barriers for pedestrians. For bicycle trips, the study observed that the area's bicycle network had very few designated bike lanes, and that several bike routes were on roads with high vehicle speeds, and in some cases on roads with damaged pavement. For transit, most transit trips (40 percent) from southeast Seattle were destined to downtown Seattle. The main transit corridors in southeast Seattle were on major north–south arterials, and few transit circulation routes existed to service the area's residents. With respect to goods movement, there was only one city-designated "Major Truck Street" in the study area, and freight traffic spills onto area streets from a nearby freight area when the interstate highways are congested.

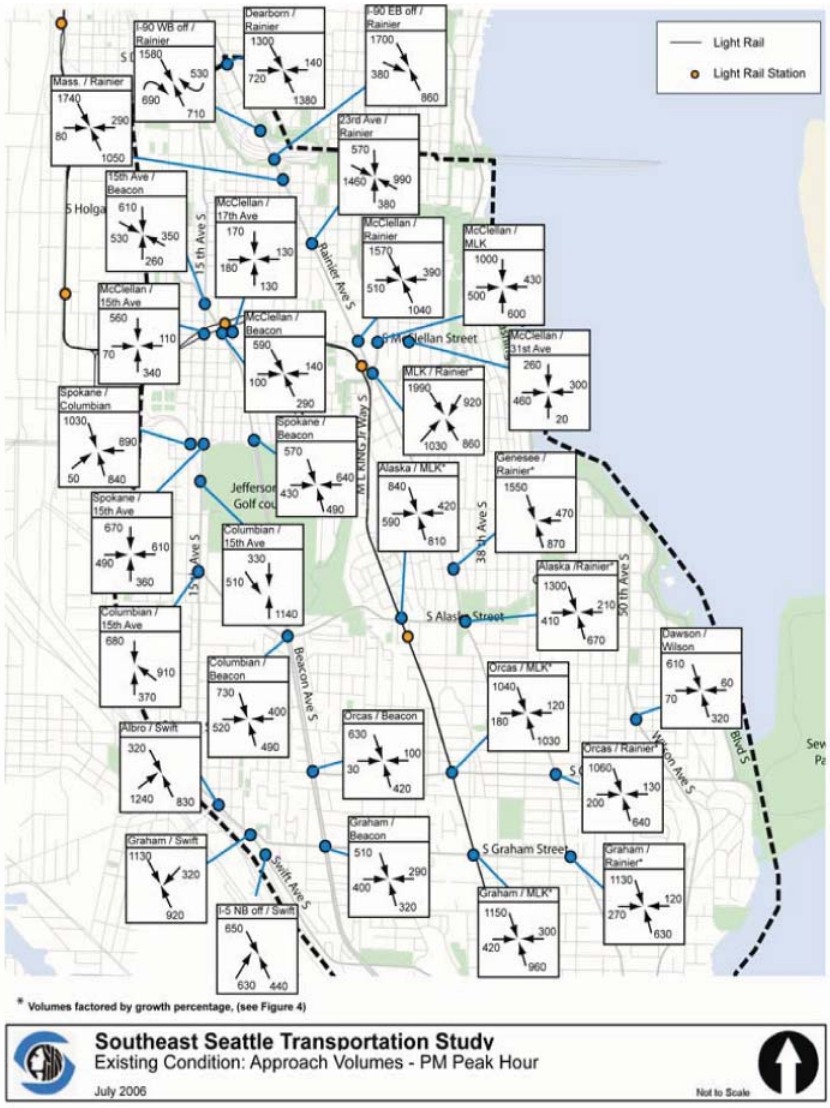
Similar to the Ann Arbor study, the Seattle study identified where most of the pedestrian and bicycle crashes were occurring and noted that many of the crashes occurred at unregulated intersections (no traffic signal or simply a traffic circle) or that did not have marked crosswalks. Traffic counts were taken at all major intersections (see Figure 18-5), and parking utilization data were collected (see Table 18-6).

*Chamblee, Georgia*. This study gathered data on land use and transportation characteristics similar to Ann Arbor and Seattle. However, the Chamblee study also conducted a market analysis to examine the strengths and weaknesses of the study area's economy and transportation system. This analysis set the context for future economic opportunities and for identifying transportation strategies that could enable these opportunities to occur. The Strengths, Weaknesses, Opportunities, and Threats (SWOT) analysis found the following: [Kimley-Horn, 2014]

**Strengths**

- The Metropolitan Atlanta Regional Transit Authority (MARTA) transit station provides comparatively quick access to regional employment centers.
- MARTA-owned parcels adjacent to transit station are well-positioned for redevelopment and location inside I-285.
- Equidistant to Buckhead and Perimeter Center employment and regional retail.
- Comparative housing affordability for areas inside I-285 and west of I-85.
- Strong local school performance.
- Growing higher-income household base, with 21 percent earning over $100k in 2012, more than double the 10% share in 2000.

**Figure 18-5. Intersection Counts as Part of an Existing Conditions Analysis, Seattle, Washington**



Source: City of Seattle, 2005

**Table 18-6. Summary of Parking Utilization in Southeast Seattle**

| Area | Average Parking Utilization (%) | Peak On-Street Parking Utilization | Peak-Period Time |
|---|---|---|---|
| Columbia City (M.L. King Jr. Way) | 48 | 74 | 12-1 p.m. |
| Columbia City (Rainier Ave. S.) | 43 | 52 | 6-7 p.m. |
| S. Henderson St Station Area | 15 | 20 | 8-9 a.m. |
| M.L. King Jr. Way S. at Holly | 37 | 31 | 4-5 p.m. |

Source: City of Seattle, 2005

- Large and growing 25–34 age cohort.
- Strong citizen participation in planning efforts and support for growth in the LCI study area.

**Weaknesses**

- Limited visibility from Peachtree Boulevard.
- MARTA and Norfolk Southern railroad lines bisect the study area, creating a two-sided market.
- Two "competing" nodes of historic downtown and MARTA station along Peachtree Road.
- High share of existing commercial buildings and housing stock are suffering from physical and economic obsolescence.
- Excessive housing vacancy rate of 21 percent in 2012.
- Lack of major private-sector employers.
- Absence of newer hotels owned or operated by major national chains.

**Opportunities**

- Several large vacant or underutilized parcels available for redevelopment, including those owned by MARTA.
- Rapidly increasing share of one- and two-person households creates demand for smaller housing units.
- Growth of Generation Y and Baby Boom age cohorts and national shift toward rental housing create demand for higher-quality apartments.
- New housing will increase demand for retail, professional services, and restaurants.
- Professional office space will accommodate growth for employers seeking close proximity to MARTA station and a mixed-use environment near I-285.
- Office employment growth will support hotels.

**Threats**

- General Motors Plant redevelopment in adjacent Doraville could "steal" market share from Chamblee LCI.
- City zoning codes requiring retail uses to occupy the entire first floor of multi-family buildings and steel/concrete construction are not supported by current land/development economics shaping Chamblee LCI.
- Resistance to rental housing could cause Chamblee LCI to get bypassed in current development cycle.

Market studies such as this provide an important context for understanding the current conditions in a study area, and for defining future economic prospects.

The collective data and data analysis for each of these studies was compiled in a technical report and provided input into forecasted future conditions. Several other chapters in this handbook provide much greater detail on data collection and the process of identifying existing system performance and condition. Readers are referred to chapter 2 on travel data, chapter 3 on land use and urban design, chapter 8 on transportation asset management, chapter 9 on road and highway planning, chapter 10 on transportation systems management and operations, chapter 11 on parking, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, chapter 17 on corridor planning, chapter 19 on site planning and impact analysis, chapter 22 on integrating freight into the transportation planning process, chapter 23 on integrating safety into the transportation planning process, and chapter 24 on public participation and engagement.

## E. Future System Performance and Condition

Transportation planners are primarily concerned about the future. In the context of local transportation plans, this means predicting future transportation challenges that lead to projects or strategies to solve these problems before

they become too serious. Looking into the future means understanding what the population and employment will be like in the plan horizon year, where people will live and work, how they will travel and by what means, and what factors will influence their travel choices. For statewide and metropolitan transportation planning, this usually means a large-scale transportation modeling effort, including updates on socio-demographic data and coding of large transportation networks (see chapter 15 on statewide planning and chapter 16 on metropolitan planning). Such models are also used for local planning, especially for larger cities or large subarea studies. However, in some smaller cities and towns, a less involved approach is used to forecast future conditions. In many cases, the planning study tends to focus on existing conditions and system performance with the assumption that these locations will be the problem locations in the future as well. Or, a slightly more sophisticated approach is to "grow" the population and employment in the traffic analysis zones, apply new trip generation rates, and assign the trips to the network to identify future problems (see chapter 6 for different methods of travel demand forecasting).

When travel demand models are used for local planning, they usually are of two types. The first is a stand-alone model calibrated and validated for the study area. Stand-alone models are usually found in only the largest of cities. The second is to use the MPO's travel demand model, modifying it to local conditions, and making it more appropriate for the scale of analysis. For example, it is not uncommon for additional traffic analysis zones and more links/nodes to be added to the model structure for subarea studies. The modeled network outside of the study area then becomes the "external" inputs into the travel flows into and out of the area. Two advantages of this approach are that the subarea modeling is consistent with the regional model, which is important when seeking funding from MPO programs. The second advantage is that the zonal system and databases are already established (although as noted with some likely modifications needed) so that new data are not necessarily needed to undertake the study.

Two examples illustrate the use of a travel demand model at the local level:

*Houston Northwest Subarea Study*. The City of Houston and the Houston-Galveston Regional Council (H-GAC), the MPO for the region, collaborated on developing a model that could be used for subarea studies in the city. The HGAC regional travel demand model was used, with additional zones and network links added to provide better fidelity in model results for city streets. The study team created four initial scenarios for the Northwest Subarea study that became model runs for testing the impact on system performance. The scenarios were analyzed individually to compare outcomes among different concepts. A combined scenario (Scenario 5) was then developed of the recommended projects and actions. The scenarios were:

- Scenario 1—(Base Build-Out): The Base Model scenario assumes the full development of all major thoroughfares and major collectors as identified in the city's major thoroughfare plan. The effects of such recommendations on traffic volumes and congestion levels were evaluated in this scenario.
- Scenario 2—(Couplets): This scenario was from another study that had been done on some of the areas included in this study. It was included in this study simply for reference purposes only.
- Scenario 3—(Capacity Projects): Scenario 3 combined road expansion (as designated by the major thoroughfare plan) and street reduction projects. The intent was to create a network that safely and reasonably supported a variety of mobility uses. This model was a more financially feasible option than the Base Model.
- Scenario 4—(High-Frequency Transit): This high-frequency transit scenario included transit routes that factored in public input, population growth, job growth, activity centers, and connectivity to other destinations (such as downtown). The increase in service was modeled by doubling the service frequency during the peak hours. Non-peak hour headways were also increased slightly. (The study recognized that it was the regional transit operator what was responsible for the frequency and stop locations of all city bus routes).
- Scenario 5—(Recommendations): The four scenarios were analyzed separately and compared to the 2035 Base Model as provided by H-GAC (with the new future demographics). Scenario results were then taken to stakeholders for feedback. This input and the project team's analysis were combined to create Scenario 5. The result was a network of corridors that needed capacity expansion as well as corridors where existing capacity could in fact be reduced.

For pedestrian and bicycle needs, the city adopted a Complete Streets design approach for those intersections and streets where the analysis suggested there might be problems (see chapter 9 for a discussion of Complete Streets; also discussed in the next section). In addition, the study relied on an already existing Pedestrian and Bicycle Plan to identify specific projects and strategies for the study area. Figure 18-6 shows the recommended bike improvements.

**Figure 18-6. Subarea Recommended Bike Improvements, City of Houston, Texas**

*North Fulton County Comprehensive Plan*. North Fulton County, one of the fastest growing counties in the United States, is located just north of Atlanta. One of the busiest freeways in the region serves as the backbone of longer-distance travel in the area, and many local streets are notorious for their congested conditions. This study was to be a strategic plan identifying strategies to better manage traffic (such as travel demand management) as well as recommending projects where capacity expansion was needed. [City of Alpharetta, 2010] The study team relied on a variety of information sources and data analyses to identify current and future problem areas, including:

- *Public Involvement* was one of the primary methods used for developing a list of transportation needs, particularly current ones. Residents and stakeholders in the area represent an important source of information for those system needs that currently exist.
- *Existing Studies* were reviewed for areas across North Fulton to build a strong foundation for this plan by giving consideration to work done in previous studies.
- *Geographic Information Systems (GIS)* is a software tool used to relay spatial information in the form of maps. Economic, census, land, and transportation data were displayed using this software.
- *Census Data and American Community Survey* data from the U.S. Census Bureau were obtained for the purposes of understanding population and employment trends. This information was used for identifying area employment centers, areas with greater density, and areas with aging populations, lower incomes, lower auto ownership, or a larger disabled population that may have different transportation needs.

- *Coordination with the Atlanta Regional Commission's (ARC's) On-going Planning Initiatives* was necessary to develop the plan in accordance with region-wide goals and strategies. Coordinating with on-going regional initiatives that are being implemented by ARC ensures that the North Fulton plan will be aligned with those goals that extend beyond its borders.
- *Crash Data* statistics were analyzed in order to identify safety needs and trends within the transportation system. These data provide insight into the nature of vehicular, bicycle, pedestrian, and commercial vehicle crashes. Geospatial data were also obtained from the Georgia Department of Transportation (GDOT) so that locations of these crashes could be identified. [City of Alpharetta, 2010]

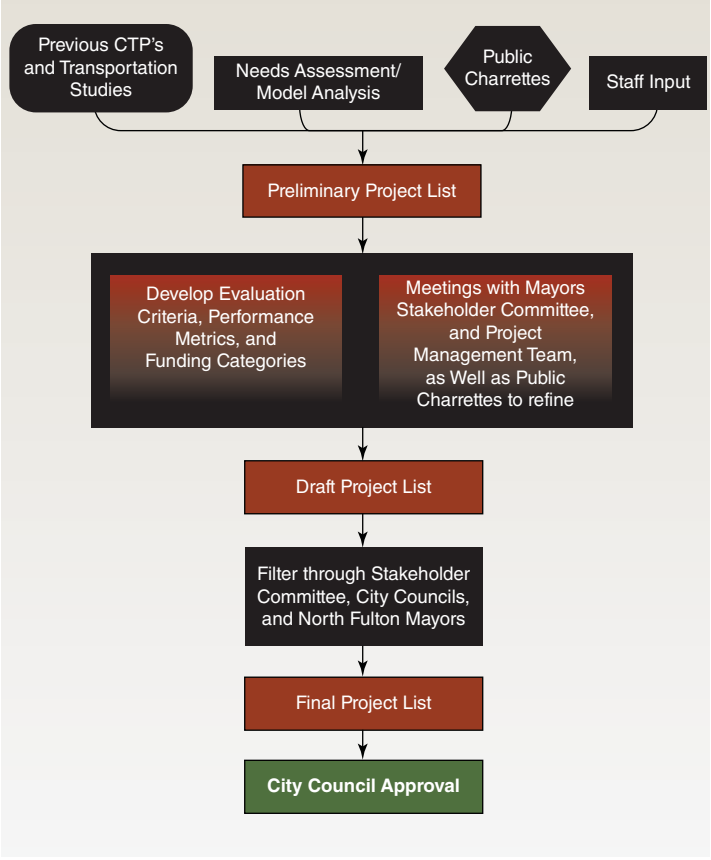
The ARC's travel demand model was used to forecast future traffic on the study area's road network, assuming future land use patterns, demographic forecasts, and existing and planned road projects. The model identified road capacity hotspots and expected ridership on proposed transit services.

With respect to pedestrian movement, a pedestrian LOS metric was used for pedestrian accommodation based on such factors as the presence of sidewalks, sidewalk width, width of any buffer between the sidewalk and the roadway, presence of on-street parking, volume of vehicular traffic, and the like. The network was analyzed for existing pedestrian LOS scores; a study threshold of LOS C was chosen as a trigger point for improvements (LOS B was selected in some areas where large volumes of pedestrians were expected). Roadway characteristics were identified where the threshold LOS was not met, and additional data on the road profile was collected for more detailed analysis. This additional data included characteristics of the shoulder and adjacent grading such as whether the shoulder was flat, sloping, or contained a ditch. These characteristics were used to develop recommended actions. See chapter 11 for further information on pedestrian planning.

A similar approach was used for bicycle LOS, where factors such as width of lanes, roadway lane width, gutters, buffers, and sidewalks, as well as observed roadway characteristics including lane counts, configuration (undivided, divided, or use of a two-way left turn lane), posted speed limit, roadside profile, pavement condition, and cross section type (curbed or open shoulder), were used to calculate a bicycle LOS score. LOS scores were used to identify locations where possible design improvements could be made. Additional data were collected to facilitate the evaluation of potential improvements, including total width of asphalt, presence of a raised median, presence of curb and gutter, and roadside profile (flat, sloping, or ditch). See chapter 11 for further information on bicycle planning. The results of the analysis fed into the evaluation and prioritization process.

Whether coming from a travel demand model or from simple extrapolation of existing population and employment trends, decision makers rely on the type of information produced in these two studies to make informed decisions.

**Figure 18-7. Project Selection in the Context of a Subarea Planning Study, North Fulton County, Georgia**



Source: City of Alpharetta, 2010

## F. Evaluation and Prioritization

Similar to the choice of tools for analyzing current and future system problems, project selection and importantly project prioritization varies from one study to another. As shown in Figure 18-7, which shows the planning process for the North Fulton County study, project prioritization had both a technical and a public/decision-maker component. This is especially found in local planning where every recommended project most likely

affects someone who is known by at least one decision-maker, or where feelings are so strong about problem hotspots that individuals will gladly participate in the planning process to "solve" their problem.

Larger planning studies usually adopt a formal process to prioritize projects, relying on some form of scoring or benefit/cost analysis (while still realizing that local decision makers will have their own calculus for determining priorities). For smaller studies where the focus is on selected intersections and key road segments, the prioritization process is fairly straight-forward and is based on the expected intersection/road performance (which reflects the problems being experienced today). In this case, either level of service metrics or delay measures can be used to assign a priority to proposed projects.

The following two examples of project prioritization illustrate different ways of assigning project priorities:

*North Fulton Comprehensive Transportation Plan*. An evaluation matrix was used to assess the relative priorities of candidate projects. The matrix included factors such as a project's expected reduction in vehicular congestion; the potential in creating new connections; expected improvements to bicycle, pedestrian, and transit modes; and likely environmental/social impacts. Expected costs as well as potential operating and maintenance costs were considered relative to the likely benefits of the project. Monetary benefits were estimated for road projects. The feasibility of construction was considered as well as whether the project is already part of the Regional Transportation Plan. [City of Alpharetta, 2010]

*Southeast Seattle Study*. The city of Seattle uses a 100-point scoring system for prioritizing projects in its capital program. The Southeast Seattle study decided to use the same scoring system, which was based on seven criteria, (1) safety, (2) preserving and maintaining infrastructure, (3) cost-effectiveness or cost-avoidance, (4) mobility improvement, (5) economic development, (6) comprehensive plan/urban village and land use strategy, and (7) improving the environment.

The evaluation criteria were applied to the projects in a multistep process. Early in the study, project staff and community members identified more than 500 potential actions based on past studies and new analysis. This list was then narrowed by combining overlapping actions and by eliminating those that had already been completed or were currently underway. Sixty-three projects were ultimately formally submitted to a Core Community Team (CCT) for review and comment. After the CCT review, preliminary cost estimates were prepared for the actions considered to be high priority. The projects were then scored according to the criteria and weights shown in Table 18-7. An overall priority of high, medium, or long-term was assigned to each project, with roughly a third of the projects in each category.

Evaluation and prioritization are critical steps in a study. Planners should give a lot of thought at the beginning of the study on how evaluation will occur. Not only does this get decision makers to think about what is important with respect to study results, but it tells the planner what type of data to be collected, the type of forecasts that need to occur, and what type of tools will have to be used in the study.

The reader is referred to chapter 7 on evaluation and prioritization methods for more detailed discussion on different approaches.

**Table 18-7. Evaluation Criteria Used in Seattle Subarea Study**

| Evaluation Criterion | Score | Weight | Maximum Points |
|---|---|---|---|
| Safety and Security | –5 to +5 | 4 | 20 |
| Mobility | –5 to +5 | 3 | 15 |
| Infrastructure Preservation/Maintenance | –5 to +5 | 3 | 15 |
| Cost-effectiveness and Implementation Feasibility | –5 to +5 | 3 | 15 |
| Comprehensive Plan/Urban Village Strategy | –5 to +5 | 3 | 15 |
| Environmental Quality | –5 to +5 | 2 | 10 |
| Economic Development | –5 to +5 | 2 | 10 |
| Total Points | | | 100 |

## G. Other Actions and Strategies

The previous section discussed approaches and methods to identify priority projects. These approaches focus mostly on capital projects or service changes such as intersection improvements, pedestrian/bicycle projects, and transit service improvements. However, many local plans often include other types of strategies aimed at reducing single-occupant vehicle trip-making to and from a locale, such as travel demand management (TDM) strategies. As an example, in addition to a list of highway, transit, and pedestrian/bicycle projects recommended for construction, the North Fulton Comprehensive Plan included the following (copied from the report):

**Transportation Demand Management (TDM)**

- *Flextime and Teleworking*—Teleworking (that is, working from home) and flextime (working alternate hours) both reduce trip-making during the peak hours, which can have a significant effect on reducing congestion and air pollution.
- *Transit and Shuttle Services*—There is significant opportunity to increase the use of both transit and shuttle services in North Fulton.
- *Education and Cultural Awareness*—Education and cultural awareness can have a big impact on the choices people make. Many communities routinely sponsor events to raise awareness and educate people about using transit or bicycle travel.
- *Variable Road Pricing and Managed Lanes*—With the planned addition of managed lanes to the GA 400 corridor, variable pricing will likely be used on that corridor to discourage travel during the traditional peak periods. Also, these managed lanes will encourage carpooling and transit ridership.
- *Development Codes*—several specific requirements or limits within each city's development codes have a direct impact on travel. For example, some communities require facilities for bicycle parking and showers/changing facilities at all commercial and large office uses. Preferential parking for carpools and vanpools can also be required.
- *School-Related TDM Strategies*—School-related TDM strategies are an important consideration to any community. Such strategies could include: (1) reducing barriers to non-motorized transportation by improving sidewalks, crosswalks, bicycle lanes, and bicycle parking; (2) implementing parking management at high schools by reconsidering free parking—parking proceeds could then be used to improve facilities for walking and biking to school; (3) organizing school pool programs; and (4) planning over the long term for new school locations to allow a greater percent of students to walk and bike to school.

**Access Management**

Three regionally significant corridors were identified as the primary non-freeway roadways facilitating regional trips through North Fulton, particularly east–west movements. Because of their regional significance, the implementation of a consistent access management strategy along these roadways was recommended. Additionally, strong access management policies should be considered in order to improve arterial traffic flow without the need for traditional widening (see chapter 9 on road/highway planning).

**Advanced Traffic Management Systems (ATMS)**

Advanced traffic management systems (ATMS) allow government agencies to better manage the traffic on the roadway and to disseminate traffic information to drivers. ATMS components include; traffic signal controllers, closed circuit television (CCTV) cameras, dynamic message signs, communication equipment, and control center monitoring equipment and software. The study recommended that North Fulton should, (1) expand the reach (communication) of the existing signal systems, (2) coordinate signals and sync clocks across jurisdictional boundaries, (3) expand CCTV coverage, (4) evaluate the need and potential locations for dynamic message sign deployments, (5) provide center-to-center communication, (6) establish protocols for sharing information and managing traffic across municipalities, (7) identify other potential ATMS strategies (such as transit priority, reversible lanes, etc.) that may be applicable within north Fulton, (8) develop a strategy that is flexible and expandable that allows for future growth as development continues to occur, and (9) develop a system that minimizes recurring costs. [City of Alpharetta, 2010]

The types of strategies included in a plan will vary by community. Some will focus more on land-use strategies, while others will emphasize physical infrastructure improvements. It seems likely that larger cities or smaller communities

within larger metropolitan areas will develop a study design that includes both. As infrastructure dollars become more limited, finding ways to reduce trip generation and the associated impacts means that noninfrastructure strategies and better management of community-oriented mobility options will be the norm for transportation planning.

The Chamblee, Georgia, study included a very wide range of recommendations. [Kimley-Horn & Assocs., 2014] In addition to recommendations on pedestrian, bicycle, corridor, gateway, parking, and transit recommendations, the study recommended action on the comprehensive plan update and land-use policy, urban design priorities, historic resources, market/economic development strategies, lifelong community strategies, and zoning considerations. For example, to take advantage of the proximity of a subway station, the plan recommended:

- Continue to work with developers to ensure that development around the existing MARTA rail station is walkable.
- Seek high-quality development immediately adjacent to the MARTA rail station.
- Develop a regional detention area and community space on the MARTA owned property located at a targeted parcel of land.
- Provide safe and convenient access to future Chamblee Rail Trail extensions.
- Adopt a long-range maintenance plan for parks and green space.
- Seek opportunities for alternative fuel source stations in public or semi-public places.
- Develop brownfield evaluation and designation criteria.

Figure 18-8 shows the recommended transportation actions that came out of the study.

**Figure 18-8. Recommended Transportation Projects, Chamblee, Georgia**

Source: Kimley-Horn & Assocs., 2014

Other chapters in this handbook are particularly relevant to the options that might be considered in local planning. Readers are referred to chapter 3 on land use and urban design, chapter 9 on road and highway planning, chapter 11 on parking, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, chapter 14 on travel demand management, and chapter 22 on freight planning.

## III. ACTIVITY CENTERS

The locations and forms of activity centers have evolved during the past century in response to changing transportation services and population patterns. Central Business Districts (CBDs) grew as main office, retail, and governmental centers during the first half of the twentieth century. Due to a variety of reasons, not the least of which was the construction of large-scale highway networks, the focus on downtowns has declined over the years. Today, most metropolitan areas consist of major activity centers, where the downtown is just one of many. In the Atlanta region, for example, the Atlanta Regional Commission (ARC) has identified 14 distinct activity centers having their own development patterns and transportation flows. [ARC, 2012] In many of these activity centers, organizations have been created to deal with the mobility challenges facing the residents and employees. Called transportation management organizations (TMOs) or associations (TMAs), these organizations are a new participant in the transportation planning process (see chapter 19 on site planning and impact analysis).

### A. Characteristics and Concepts

The term *activity center* refers to a large concentration of development usually containing a mix of land uses, especially office and retail. Activity centers may also include institutional complexes, such as government centers, colleges and universities, and medical centers. Activity centers range in size from a few hundred acres to as much as 6 to 8 square miles. Larger activity centers typically have more jobs than residents; include major amounts of retail space; exhibit mixed office, retail, hotel, residential, or other commercial uses; have higher development densities than surrounding areas; and are recognized as a focal point for activity within the community. Most of the larger centers have also been subject to master planning.

Activity centers usually occur in one or more of the following forms:

- Central business district (CBD).
- Office park of several hundred or more acres.
- Retail center of 100 or more acres.
- Mixed-use center of several hundred to thousands of acres.
- Large office corridor stretching a mile or more.
- Major outlying or suburban office concentrations.
- University, medical center, or other institutional complexes and campuses.
- Major recreational facility with ancillary uses.
- Large retail, dining, and entertainment centers.

Activity centers are usually located where businesses can tap into a large consumer or labor market that is accessible in a reasonable travel time. Historically, they developed at focal points of convenient transit and highway access, such as the CBD, outlying business districts, and large town centers along suburban railroad lines. However, the dispersion of population with the development of urban freeway systems over the past 50 years has dramatically changed where activity centers locate. Freeway interchanges and major arterial roadway junctions have today become primary locations for many activity centers.

The emergence and successful developments of clustered economic activity in areas such as the Silicon Valley (California), Research Triangle Park (North Carolina), and Route 128 in Massachusetts have served as case studies for other regions as they develop similar business agglomerations. These agglomerations—or "clusters"—represent groups of

**Table 18-8. Employment Clusters, Metropolitan Divisions, and Edge Cities in the 20 Most Populous Metropolitan Statistical Areas, 2000**

| Metro Area | 2000 Population | # of Employment Clusters | | | | # of Edge Cities | | |

Source: Marlay and Gardner, 2010

interrelated businesses that choose to co-locate for one reason or another. [ARC, 2012] A study by the U.S. Census that examined the change in metropolitan employment between 1970 and 2000 showed the rapid movement of employment into employment clusters in U.S. metropolitan areas. [Marlay and Gardner, 2010] Table 18-8 shows the change in employment for the 20 largest U.S. metropolitan areas. As can be seen, the number of new employment clusters increased significantly between 1970 and 2000. The study also observed that for larger metropolitan areas (population > 4 million), 37 percent of the employment was located in employment clusters; for medium size metropolitan areas (1 to 3 million), the proportion was roughly 34 percent; and for smaller metropolitan areas (<1 million) the proportion was 25 percent.

## B. Central Business Districts (CBDs)

CBDs are the largest and oldest urban activity center with many dating from a time when most businesses were located in one central area and travel distances were limited. Over the years, downtown areas grew as street railways, rapid transit lines, commuter rail lines, and then buses and automobiles expanded their reach and market areas. Decentralization of urban activity, however, has resulted in accompanying changes in the strength, vitality, and functions of downtown areas. Although the CBD generally has declined in relative concentration to the rest of the metropolitan area, it still represents a major economic activity for a typical metropolitan region and still attracts the highest transit ridership in most major cities in the world.

### *1. Characteristics*

Downtowns are typically located near the population center of the urban region, except where constrained by topography. They generally occupy one to two square miles of area and represent one of the highest concentrations of office floor space and employment density within most urban areas. However, the total number of employees as compared to the region as a whole is small—the average is 7 percent in metropolitan areas over 1,000,000, with New York City the highest at 22 percent (second in the world to Tokyo). [Demographia, 2014] The number of employees per acre ranges from 100 to more than 400 in large cities.

The concentration of employment and mixed land uses results in a large number and variety of CBD trips. The CBD is usually the area with the highest transportation accessibility within the urban area, showing the highest transit utilization (77 percent of commuters into New York City; between 50 and 60 percent for Boston, Chicago, and San Francisco; and around 40 percent for the Denver and Seattle downtowns). CBDs also devote a high percentage of land to transportation purposes—approximately half of all downtown land is devoted to streets, sidewalks, alleys and parking. It generally has less off-street service and loading facilities than developments in suburban areas. Peak period travel is more widely spread than that for outlying business districts.

Some downtowns have expanded beyond their original limits into surrounding areas. Chicago's original CBD was about 1.20 square miles; however, the expanded central area that includes the near north and west sides contains more than 4 square miles and increases the central area employment by about 50 percent.

Good transportation to and from the CBD has been and remains an essential element of a downtown's success. Rapid transit and commuter rail service have supported large office developments in major U.S. cities such as New York City, Chicago, Boston, Philadelphia, and more recently in Atlanta, Baltimore, Los Angeles, San Francisco, and Washington, DC. Other cities have implemented light rail or busway systems to both improve mobility and encourage downtown development. And, in most cases, the downtown area has a very high level of access to the region's freeway system, given that the original purpose of the interstate system was to connect major cities.

### *2. Travel Characteristics*

Travel characteristics for downtowns vary by size of CBD, densities in employment, parking availability and costs, transit availability and fares, relative accessibility by available travel modes, and local transportation policies that encourage non-automobile use in the downtown area. Small downtowns may generate their peak period travel demand over concentrated periods as short as 15 or 20 minutes. Larger and more diverse downtowns generate their peaks over 2 hours or more. The range in characteristics requires that transportation planning efforts be based on careful studies and accurate data for the specific downtown being considered.

Reported characteristics for CBD travel include:

- Except for the very largest downtowns in terms of employment, peak-hour, one-way cordon volumes are generally less than 100,000 persons. This implies corridor movements by all modes that are less than 25,000 persons per hour.
- Per capita trip attractions to the CBD generally decrease with increasing travel time and distance.
- In most cities, CBD trips have grown at a slower rate than the overall growth in the region's total trips. Trips between established neighborhoods and the city center have generally decreased, and trips between suburban areas and the city center have generally increased. As a consequence, average trip lengths have increased and public transport use has decreased in many areas.
- The proportion of work trips to the CBD increases with urbanized area population. In most large areas (population of more than 1 million) more than half of all downtown person destinations are for work trips.
- Pedestrian and parker walking distances vary according to city. They reflect the locations of transit stops/stations and parking facilities in relation to major retail and office concentrations. Median walking distances are approximately 500 to 600 feet, and 80 percent of pedestrians walk less than one-quarter mile, except in very large cities.
- Workers usually park for 6 to 8 hours, while parking for shoppers and personal business trips usually lasts about 2 hours.

### *3. Challenges*

The challenges facing CBDs will vary by city. In some downtowns that are experiencing new growth, for example, Denver, Portland (Oregon), San Diego, and Seattle, the challenge is providing mobility options to serve both the residents and commuters. In others where such growth has not occurred, the challenge is combining transportation strategies with development and urban design strategies to encourage growth to occur. Generally, transportation problems are often found on both access gateways to the city center and within the center itself. However, in many CBDs, peak-hour congestion is more serious on the access facilities than it is in within the CBD. Commonly encountered problems include:

- Inadequate access to regional rapid transit service.
- Congested freeways and access roads to and from freeways.
- Poor freeway operations close to the city center that also may cut off access from surrounding areas.
- Offset, discontinuous, and irregular street patterns.
- Dispersed developments and long blocks that make walking difficult.
- Narrow and obstructed sidewalks that make pedestrian circulation difficult.
- Poorly located parking facilities in relation to the activities they serve and/or that make walking difficult and unattractive.
- Limited off-street facilities in buildings for handling and delivering freight, mail, parcels, and supplies.

### *4. Planning Steps*

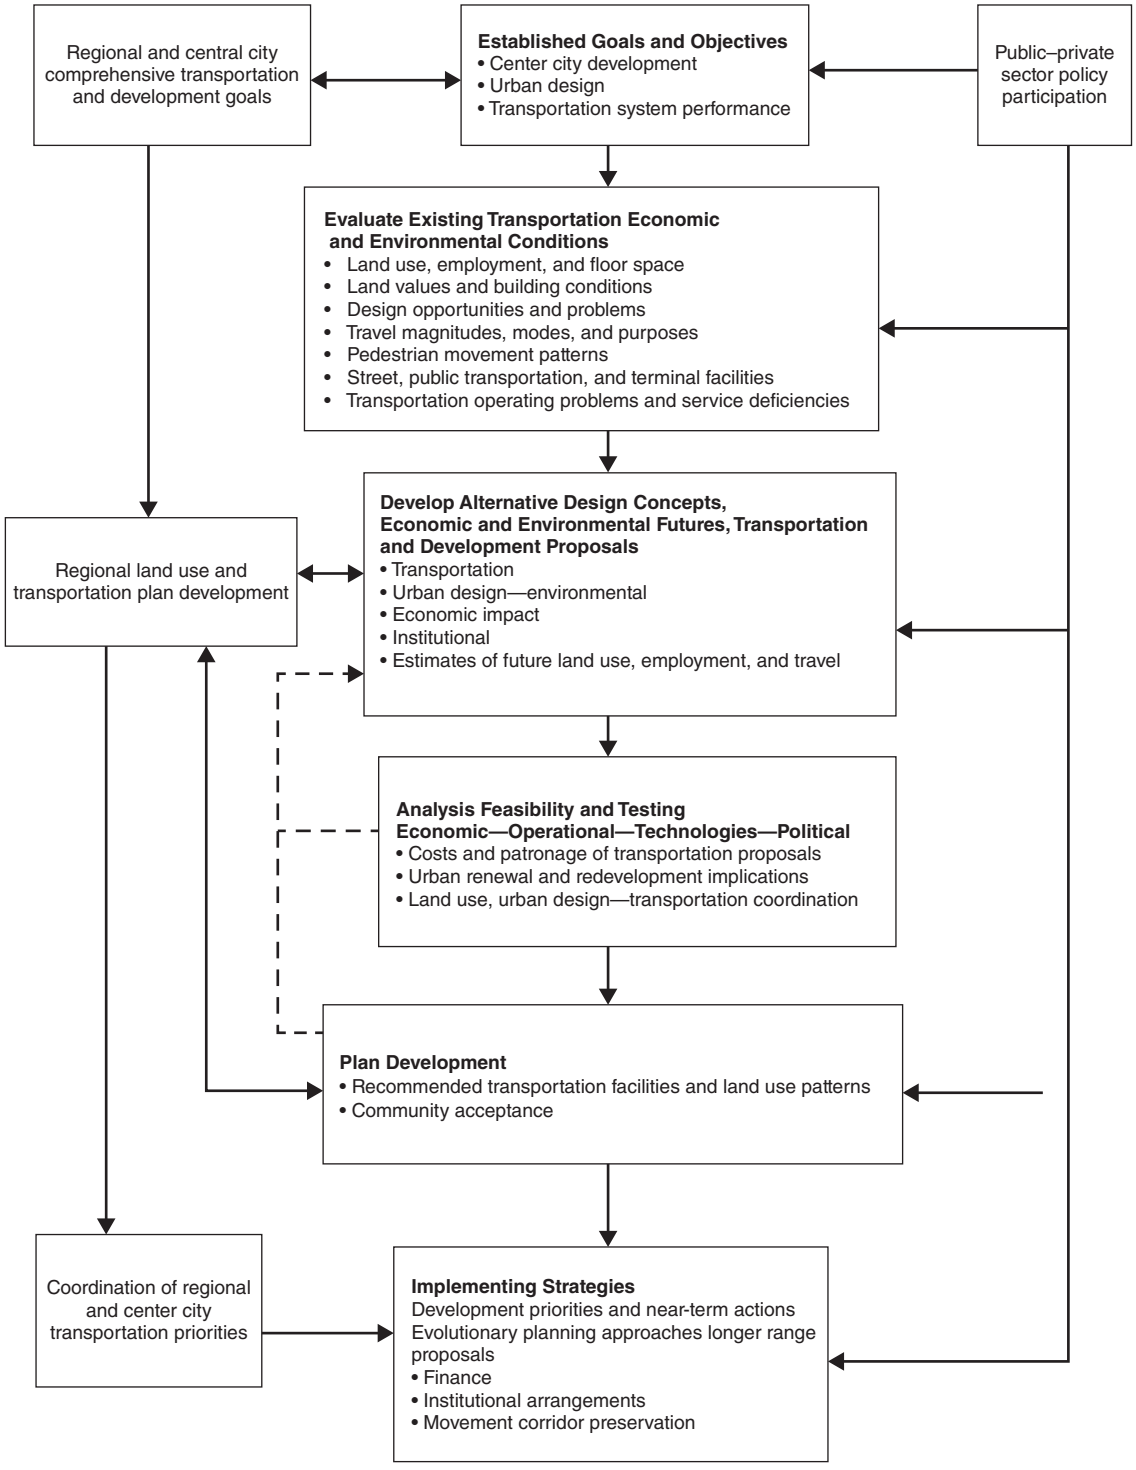
Transportation planning for the city center should be done as a cooperative process with the CBD community. Such planning usually includes transportation planners and engineers, urban planners, landscape architects, land economists and developers. The steps in this process depend upon the type and scale of the planned improvements. Thus, a traffic improvement plan would likely include a different focus and time horizon than a major public transport investment plan that is keyed to downtown development.

Figure 18-9 provides an overview of the city center transportation planning process. Transportation planning decisions and improvement strategies should reinforce CBD economic and environmental objectives. They should be coordinated to improve the accessibility, character, amenities, and economy of the CBD; foster orderly and compact developments; encourage residential areas in the downtown and its environs; and preserve necessary corridors for transportation. Travel by public transit should be encouraged, especially in larger cities. This means not only providing reliable, high-capacity transit services, but also applying parking management and TDM strategies to encourage such use (see chapter 14 on travel demand management and chapter 19 on site planning and impact analysis).

As shown in Figure 18-9, the downtown planning process begins with an articulation of goals, objectives, and/or guiding principles. An example of this comes from Bellevue, Washington, where the city council adopted the following guiding principles to focus the planning effort.

1) *Plan for multiple modes of travel within and to and from Downtown Bellevue:* Develop an innovative multimodal transportation strategy for Downtown Bellevue that updates the existing Downtown Subarea Plan project list.
2) *Accommodate the anticipated travel demands from the 2030 land use forecast:* Ensure that the planned transportation system will accommodate the 2030 forecast for Downtown residential and employment growth.
3) *Advance the adopted vision for Downtown Bellevue:* Ensure that the Downtown transportation system advances and supports the land-use and urban design vision for Downtown Bellevue—articulated in the Downtown Subarea Plan as a vibrant, livable, accessible, and memorable mixed-use Urban Center.
4) *Recognize changes in the regional and local transportation and land-use environment:* Incorporate local and regional transportation projects and plans that have been approved and/or implemented since the Downtown Subarea Plan was adopted.
5) *Integrate City Council direction:* As potential Downtown transportation projects are identified, incorporate City Council direction on regional transportation facilities.

**Figure 18-9. Downtown Transportation Planning Process**



6) *Provide for comprehensive public involvement:* Ensure that the process to update the Downtown Transportation Plan invites broad and inclusive public involvement that engages the diverse Downtown commercial and residential communities, nearby residential neighborhoods, and other community stakeholders.

7) *Minimize traffic impacts on neighborhoods:* Consider measures as needed to protect Downtown residents and nearby residential neighborhoods from significant adverse impacts from traffic and commuter parking.

8) *Involve regional transportation and planning partners:* Coordinate planning for the Downtown Bellevue transportation system with regional transportation and planning partners.

9) *Leverage funding from outside sources to implement projects:* Identify transportation system projects that effectively leverage grant funding opportunities.

10) *Utilize measures of effectiveness to evaluate potential projects:* Use both quantitative and qualitative measures of effectiveness to evaluate project ideas relative to each other and to community objectives. Consider the cost of a project relative to its benefit to mobility as an important metric, in addition to measures such as improved safety for pedestrians and bicyclists, management of traffic congestion, and the efficient use of the available right-of-way. [City of Bellevue, 2012]

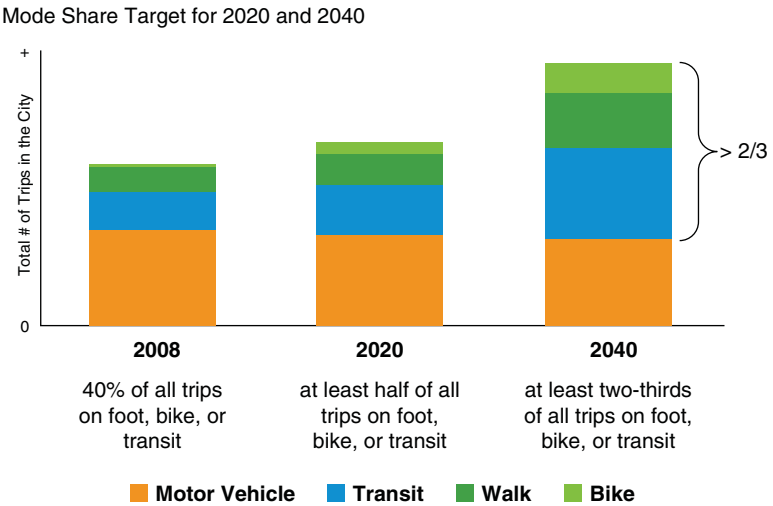
Another way of laying out direction for a plan is to ask key questions that the plan should answer. In Minneapolis, for example, the Downtown Action Plan began with the following questions.

- Which streets need to be modified to encourage more biking?
- Which streets need to be modified to encourage more walking?
- Which pattern of transit service works best for the downtown and which streets need to emphasize the movement of transit?
- Which streets are critical for moving traffic in and out of downtown and which are important for circulating traffic within downtown?
- Where is better freeway connectivity needed?
- What curbside changes or management strategies are needed to address property access needs, such as access to parking ramps, deliveries, drop-off/pick-up, valet, and on-street parking? [City of Minneapolis, 2007]

Along with these questions, the plan was linked to broader downtown objectives of sustaining continued growth, maintaining and improving the quality of life and the character of downtown; and using limited space efficiently, and effectively by moving more people using existing infrastructure. This makes it practical to live without a car if desired, and making downtown attractive and easy to navigate for visitors, customers, residents, and workers.

In a few cases, most notably cities outside the United States, some municipalities have adopted plan targets. In Vancouver, British Columbia, for example, the city has adopted a mode share target for 2040 as shown in Figure 18-10. The transportation plan for the city and the downtown is structured around meeting this target.

**Figure 18-10. City of Vancouver's Mode Share 2040 Target**



Source: City of Vancouver, undated

For larger cities, or for those that want to invest in models, the analysis process for assessing today's transportation system performance and forecasting future values is very similar to the process and tools used for regional transportation planning. Thus, in the Bellevue case, for example, travel demand models were used similar to those used by metropolitan planning organizations (MPOs) (see chapter 6 on travel demand models). Data had to be collected to update the socioeconomic database, and the network coding had to be checked to reflect changes to the network since the model had been last used. As noted in the section on local planning, in many cases, the regional travel demand model used by the MPO is the basis for the models used for city planning, only modified to be more reflective of the planning needs of the city.

Good CBD pedestrian access and circulation are an essential component of an effective downtown transportation system. This may entail providing ample sidewalk space along streets lined with ground floor commercial spaces, good

pedestrian linkages to transit stations, clearly visible traffic controls and signage, and attractive pedestrian focal points or plazas. Sometimes it may be desirable to separate pedestrian movements vertically through grade separation from transit vehicles and cars. The degree of preference given to transit and pedestrians as compared to motor vehicles varies among downtowns. Some cities have limited parking space and vehicle access with the aim of creating a more walkable city and fostering transit use. Examples include the supply caps put on downtown parking in Boston and Portland (Oregon), and the deconstruction of freeway segments in Boston, Milwaukee (Wisconsin), and San Francisco.

Table 18-9 shows transportation planning principles for typical downtowns. As will be seen, some of these access concepts and principles differ from those for suburban activity centers. Principles that are especially applicable in downtown settings include the following:

- Major access and circulation routes should be concentrated on or near the periphery of the area.
- The core area should be devoted to high-intensity uses, with major reliance placed on transit, pedestrian, and bicyclist circulation in large downtowns.
- Transit service, where available, should be provided to major concentrations of employment and patron- or visitor-oriented businesses; transit utilization should be encouraged, especially where roadway level of service, air quality, or other conditions would significantly benefit, or where downtown employment densities are very high.
- Transit priorities and amenities should be provided where transit usage is encouraged.
- Continuity of pedestrian circulation in plan and elevation should be provided.
- Parking should be separated for long-term (employee), short-term (visitor or patron) and errand or service purposes. The most convenient parking, on- or off-street, should be reserved for short-term and errand parking.
- Curb-loading zones should be provided in accordance with actual loading activity and should be located to minimize conflicts with pedestrians and vehicles.
- Parking should be utilized on a shared basis rather than restricted to individual businesses; parking garages serving the public should be encouraged.
- Employee parking should be located away from the immediate downtown core area to the extent practical to reduce traffic circulation in the congested downtown.
- In larger downtowns, free intra-CBD transit service, local bus circulator service, and closer spacing of rail transit stations can enhance circulation.
- Total unit parking demand rates will be lower than for suburban locations. In large areas, the ratio may be as low as one-half of that for suburban developments. In a few of the largest downtowns, it is a small fraction of typical demand rates due to high mode splits and vehicle occupancies.
- Access to downtown developments should be linked directly to parking or transit facilities where possible to facilitate access.
- Pedestrian facilities should be provided with adequate capacity and minimum conflicts with other modes. Grade-separated pedestrian system segments may be appropriate in some larger downtowns.
- Secure and convenient bicycle parking facilities should be provided at major downtown destinations and at transit stations or other multimodal transportation stations.

Typical downtown transportation plans recommend a wide range of projects and policies to improve the performance of the downtown's transportation system. For example, Figure 18-11 shows the pavement and bridge needs in the downtown Minneapolis area. Plans can also recommend physical designs and treatments on downtown streets, as the Minneapolis plan did for street transit lanes (see Figure 18-12). Finally, Figure 18-13 shows the recommended improvements in the downtown area.

In addition to physical improvements to the transportation network, downtown transportation plans can make recommendations on parking policies, movement of trucks and delivery hours, the relationship between land use/urban

**Table 18-9. Transportation Planning Principles for Typical Downtowns**

**Traffic Circulation Principles**

- A hierarchy of downtown streets should be established (for example, major arterials, minor arterials, collector and distributor streets, and local streets) that defines the relative importance of moving through traffic and providing access to property. This hierarchy should be implemented through the use of street design techniques, traffic control measures, and parking regulations.
- Freeways should be sufficiently removed from the city center and should not isolate one side from another. An "inner loop" of one-way streets is preferable to a tight freeway loop with inadequate weaving space.[9]
- Major access and circulation routes should be concentrated at or near the periphery of the area.
- The CBD street system should have sufficient traffic capacity to minimize congestion and handle peak-hour traffic loads during the planning period.
- Non-CBD traffic should be directed away from the core area utilizing alternative or bypass routes.
- The CBD street system should provide adequate access and circulation for CBD traffic.
- The central area street system should provide direct access for emergency and service vehicles.
- The CBD circulation system should connect with both existing and proposed major thoroughfares beyond the CBD (for example, radial freeways and principal arterial streets).
- The CBD street system should provide more than one opportunity to reach a destination.
- The CBD circulation pattern should be easily comprehended by the average driver and provide relatively direct routings without circuitous travel.
- The circulation plan should be designed for incremental implementation with individual elements available for use as they are completed.
- Streets should be designed to provide continuous routings and continuity of capacity.
- The CBD circulation plan should allow drivers to circulate around the blocks or areas that generate high traffic volumes.
- Major downtown streets should be free from conflicts with major at-grade railroad crossings.
- The CBD street network should be regularized by street extensions and closures.
- Complex intersections and multiphase signals should be avoided.
- Streets and land development should not be so large as to make circulation difficult; the street pattern should not cut land areas into parcels too small to permit sound development.

**Parking Principles**

- CBD parking should be accessible from the primary CBD approach routes and located with direct connections to major vehicle entry points.
- CBD parking facilities should be distributed in relation to the directional distribution of vehicular approach to the area.
- The parking system should provide space for explicit use of long-term, short-term, visitor, and errand parking.
- CBD parking system should have sufficient capacity to accommodate present and future peak parking demands, but should not undercut transit ridership. (The degree of preference to transit and pedestrians compared to motor vehicles varies greatly for different downtowns.)
- CBD parking, where possible, should facilitate dual or shared usage of facilities.
- Shuttle buses should connect peripheral commuter parking facilities with ultimate CBD destinations.
- Facilities must be provided to accommodate the needs of regular delivery vehicles, quick-stop service (such as mail and newspaper trucks), and special-purpose vehicles such as construction and maintenance trucks.
- Employee parking should be located away from the downtown core to the extent practicable.

**Table 18-9. (*Continued*)**

- Curb loading zones should be provided in accordance with actual loading activity and located to minimize conflicts.
- Outlying park-and-ride lots along express bus/bus rapid transit, rapid transit, and commuter rail lines should intercept motorists, especially commuters.
- On-street parking should be discouraged along main shopping streets.
- Ground floor retail use of parking garages should be encouraged.
- Open-lot parking should be screened and landscaped.

**Pedestrian/Bicyclist Circulation Principles**

- Continuity of pedestrian and bicyclist circulation between downtown destinations should be a priority.
- A suitable environment for pedestrians should be created. This should include, in addition to other amenities, protection from weather, especially in high pedestrian volume areas. Safe environments should be created for bicyclists as well, especially avoiding conflicts with motor vehicles.
- Pedestrian and bicyclist access from major CBD parking facilities and transit stops or stations to CBD land use should be located to avoid traffic conflicts and enhance safety.
- Major pedestrian and bicyclist ways should be properly defined and identified by landscaping and lighting.
- To maintain safe and convenient pedestrian crossings, streets should have no more than four moving lanes, unless medians with suitable pedestrian refuges are provided.
- Sidewalks and bike lanes should be kept clear of clutter and obstructions.
- Suitable provisions should be made for the mobility impaired.

**Transit Principles**

- Surface transit should be given priority to use street facilities.
- Direct transit access should be provided to primary CBD destinations areas for the convenience of passengers.
- Land uses should be located to capitalize on transit facilities as well as to maximize the market for transit.
- To the extent possible, the principle of through-routing should be applied to all CBD transit facilities to avoid looping and artificial doubling of transit vehicle loads.
- Off-street transit service facilities for transit that passes through CBD should be fostered in CBDs with high employment concentrations.
- Transit stops and stations should have a strong identity.

Source: Adapted from Edwards, J. (ed.). 1999. *Transportation Planning Handbook*, 2nd Edition. Washington, DC: Institute of Transportation Engineers.

design and transportation projects, and institutional relationships among key agencies and downtown stakeholders. For example, the Minneapolis plan made the following recommendations regarding downtown parking:

- The city will encourage private property owners to locate parking facilities, particularly those for employees, outside the core area along one-way streets that provide direct access to/from freeway ramps. New parking facilities will be discouraged along transit spines and primary pedestrian corridors.
- The city will implement pricing practices that encourage parking outside the core, particularly for long-term commuter parking.
- The city will continue to expand the use of electronic message signs to provide direction to available parking facilities to minimize the amount of "search and park" circulating traffic.
- The city will continue to encourage the use of motorcycles and scooters by designating free parking spaces in municipal parking ramps. [ City of Minneapolis, 2007]

## C. Suburban Activity Centers (SACs)

Suburban activity centers are a response to the decentralization of the urban United States and many other Western cities since World War II. As such, they have been established for many of the same reasons as downtowns—high automobile accessibility, convenience to a major proportion of a region's population, and a need for commercial development to support a significant portion of the area's economy. They have joined traditional downtowns as major nodes of economic activity, and therefore as major attractors and generators of trips. These centers have been variously termed *suburban subcenters*, *megacenters*, *suburban activity centers* (SACs), or simply *suburban business districts*.

### *1. Characteristics*

The Urban Land Institute (ULI) has identified four overlapping periods of suburban business district development that has occurred in the United States. [ULI, 2001] This history is important because it places suburban activity centers and their transportation challenges in context. The first wave (1960s) started when retail and then office uses followed resident relocation to the suburbs. The second wave (1970s) continued the development of office and retail clusters at somewhat lower densities, close to executive housing. The third (1980s) and fourth (1990 to today) waves developed even farther from the city center, often in campus-like settings. In many instances, the fourth wave activity centers located along freeways to take advantage of the accessibility afforded by road access.

Suburban activity centers normally contain most or all of the following features:

- Critical mass of floor space—usually more than 5 million total square feet.
- Land-use mix of predominantly office and retail uses (and some entertainment), although not usually within the same building.
- Many more jobs than residents, although the balance in many cases is shifting toward more residential uses.

- Heavy reliance on automobile access, and in some cases located outside of a transit agency's service area.
- Predominantly free parking, and even when there is a parking cost, the first few hours are often free.

Suburban activity centers have been classified in many ways—by age, land use, building form and layout, major transportation mode, and distance from downtown. The ULI suggests classifying them as compact, fragmented, or dispersed (see Table 18-10). Compact suburban business districts are generally the oldest of the three types of suburban business districts, and they have the greatest similarity to a CBD. They are characterized by fairly high densities, a grid street layout, transit availability, and a pedestrian environment that is serviceable or even friendly. Leading examples of compact suburban business districts in the United States that have established a strong sense of place and a pedestrian-friendly environment include Bethesda, Maryland; Bellevue, Washington; Buckhead in Atlanta; and Arlington Heights, Illinois near Chicago (see Figure 18-14).

Fragmented suburban districts are perhaps the most problematic to transform into attractive and lively pedestrian-friendly areas. They are characterized by medium densities, superblock configurations, and relatively

**Table 18-10. Categories of Suburban Business Districts**

| | **Compact** | **Fragmented** | **Dispersed** |
|---|---|---|---|
| Floor/area ratio | 2.5 and above | 0.5 to 2.5 | Up to 0.5 |
| Building coverage | 0.5 or more of lot area | 0.25 to 0.5 of lot area | Up to 0.25 of lot area |
| Lot area (acres) | < 1 acre | > 1 acre | Generally exceeds 10 |
| Street layout | Grid | Superblock | Superblock |
| Land value | High | Medium | Low |
| Buildings dominate space | Yes, buildings built to street alignment. | No, buildings set back from road and separated from surface parking lots. | No, buildings set back from road; often one to two stories in height in campus/park setting. |
| Parking | Structured; managed. | Surface; managed. | Surface; unmanaged. |
| Transportation choice | Wide, frequently includes light and heavy rail transit. | Limited, usually car and bus. | Very limited, usually car with infrequent transit, if any. |
| Pedestrian linkages and interconnection of development | Extensive, encourages pedestrian activity. | Limited, often no linkages; layout encourages patrons to drive to adjoining location. | Very limited, developments far apart and not within walking distance. |

hostile pedestrian environments. They generally do not contain large parcels of vacant or unused land, although they do contain underused land devoted to parking and other low-intensity uses. Their transportation and land-use patterns are often well established and difficult to alter. To transform these patterns usually requires strong public intervention, new infrastructure investment, both public and private redevelopment initiatives, and creative infill development. The most robust of these fragmented U.S. suburban business districts, such as Tysons Corner, Virginia, near Washington, DC, are experiencing strong growth in demand and pressure to redevelop underused land.

Dispersed suburban business districts, the least mature of the three types, are characterized by low densities, superblock configurations, hostile or nonexistent pedestrian environments, and a substantial amount of undeveloped or underused land. Modest intervention by the public and private sectors can be effective in making them more pedestrian-friendly.

### *2. Travel Characteristics*

Travel characteristics and demands associate with suburban activity centers reflect the location, size, uses, density, and auto dependency of each center. The transit share of some major employment clusters outside of CBDs is shown in Table 18-11. As can be seen, the transit share varies widely. Most of the employment centers that have a fairly high transit share are served by a subway station.

Retail centers are often the core of suburban centers just as major department stores were (and sometimes are) located at prime downtown locations. The ability of retail activities to draw from offices and nearby residential areas within the suburban center lowers the average trip generation rates for the activity center itself. Retail center origins and destinations also show differences between large and small activity centers, especially during the midday peak. This reflects the large numbers of office employees who patronize the shops (see chapter 19 on site planning and traffic impact analysis).

A study of suburban activity centers in the mid-1990s showed that hotels in large activity centers draw about one-third of all peak-hour trips from the activity centers themselves; they are more self-contained than offices in the same activity center. Hotels in smaller activity centers had less, but still significant, synergy with the corresponding activity centers; about 20 percent of the a.m. peak hour internal trips were to and from the activity center, and 27 percent of the p.m. trips were internal. [Hooper, 1996]

Parking demands at suburban activity centers are less than those for isolated developments of the same magnitude. This is because certain activities can share spaces when demands occur throughout the day and a sizable portion of retail customers come from offices within the center. (Thus, if 25 to 35 percent of the shoppers come from offices, it is reasonable to assume a comparable reduction in shopper parking generation.)

### *3. Challenges*

The transportation challenges facing many suburban activity centers relate to the dominance of the automobile for access. [Dunham-Jones, 2011] Depending on where the activity center is located, the mode share will be heavily oriented to auto use (note that those employment centers in Table 18-11 with a high transit mode share are served by a subway station). Given the location of many of these activity centers along freeways and at major freeway interchanges, major congestion often does not occur in the activity center itself, but on the major access roads. This has led to the reconstruction of many freeway interchanges whose original design did not intend to handle as much traffic as has occurred. Many of these freeways and major arterial roads are under the control of state and local transportation agencies, and thus the activity center owners do not have direct say on how these roads are managed. This congestion has often been exacerbated with the redevelopment and density increase of new buildings in the activity center, in some cases to compete better with other centers in the region.

Managing an activity center's parking resources is another challenge. This has often led to shared parking strategies (when the tenants were agreeable to such a strategy), construction of parking structures when surface lot capacity was becoming inadequate, and in more urban areas the participation in TDM programs designed to lower the demand for parking.

Typical planning issues for suburban activity centers are listed in Table 18-12. Perhaps the most serious and challenging issue is the ability of larger activity centers to accommodate transportation demand as they grow and intensify. It may be difficult or impractical to provide enough road capacity, and in many cases, parking may be converted to commercial or residential use. This leads to a longer term focus on public transportation in siting and designing

| Table 18-11. Transit Shares of Major Employment Centers Outside CBDs | |
|---|---|
| **Metro Area** | **Transit Mode Share** |
| Atlanta | |
| Atlanta Airport Area | 4.4% |
| Buckhead | 12.4% |
| Fulton Industrial & I-285 Corridor | 2.7% |
| Perimeter Center | 8.5% |
| Chicago | |
| O'Hare Airport/Elk Grove Village | 4.6% |
| Schaumberg | 2.5% |
| Dallas-Ft. Worth | |
| Dallas North Tollway | 1.2% |
| Love Field & I-35 North Corridor | 2.2% |
| Las Colinas-Irving Corridor | 0.4% |
| Houston | |
| Energy Corridor (I-10 West) | 0.7% |
| Texas Medical Center | 7.6% |
| Uptown (Galleria) | 3.3% |
| Los Angeles | |
| Anaheim-Orange | 3.7% |
| Burbank-Glendale I-5 Corridor | 5.6% |
| Century City | 6.9% |
| I-110/I-405 Corridor (South Bay) Corridor | 3.7% |
| Santa Clarita I-5 Corridor | 4.2% |
| Warner Center | 6.8% |
| Portland | |
| Lloyd Center & Inner East Side | 11.6% |
| Portland Airport & Columbia River South Corridor | 4.3% |
| Wilsonville | 1.6% |
| St. Louis | |
| St. Louis Airport Area | 1.3% |
| Westport Plaza–Mid-County Corridor | 1.5% |
| Washington | |
| Arlington-Ballston Corridor | 19.8% |
| Silver Spring | 23.0% |

Source: Demographia, 2010, selected employment centers, Reproduced with permission of Demographia.

centers, improved efforts to manage the transportation system more effectively, or implementing TDM programs to reduce peak demands on the transportation system.

### *4. Planning Steps*

Activity center transportation planning can occur as part of regional, sub-regional, or sub-area planning efforts; as a stand-alone activity center plan; a corridor plan; plans for anticipated development in an approval pipeline, and/or comprehensive land use or zoning plan revisions. Table 18-13 shows transportation planning principles that should guide planning for suburban activity centers. These principles can be adapted to fit specific activity centers.

A general outline of the analysis process is shown in Table 18-14. The type and level of analysis is governed by the study's specific objectives, which should reflect local policies and needs. The steps and procedures include:

- Evaluate existing traffic, transit, parking, bicyclist, and pedestrian systems.
- Evaluate the effects of potential land use changes.

**Table 18-12. Typical Suburban Activity Center (SAC) Transportation-related Concerns and Issues**

**Projected activity center size and character**

- Degree of concentration or sprawl (mixed-use vs. multi-use).
- Densities and square footage by use (actual vs. zoned, announced or planned).
- Rate of development.

**Property access**

- Access on major arterials.
- Priority trade-offs between access and mobility.
- Use of turn prohibitions and access management.
- Protection of roadway and intersection capacity.
- Road, signal, and access spacing.
- Access between properties.
- Access connection design and storage access.

**Site conditions**

- Size, shape, terrain, and visibility.
- Frontal area (opportunities for access connections).

**Service**

- Special service needs.
- Separation of heavy truck traffic.

**Travel demand projections**

- Trip generation internal trip-making.
- Ridesharing.
- Vehicle occupancies.
- Transit use.
- Travel demand management potential (and commitment).

**Parking**

- Parking ratios/synergy with adjacent developments.
- Convenience.
- Fees and impacts on both marketability and demand.
- Conflicts with transit incentives.
- Surface vs. structured supply.
- Use of fringe parking.
- Shared parking/design features.

**Regional access to the activity center**

- Expressway (overall capacity and number and capacity of interchanges).
- Arterial (capacity, directness of service connectivity, and penetration of center).
- Other modes.

**Through traffic**

- Conflicts with access and internal circulation.
- Priority given to through versus local movements.
- Bypasses or grade separations for through traffic.

**Internal circulation**

- Roadway system—capacity, continuity.
- Pedestrian system needs, potential, and priority.
- Transit functions, productivity, and cost factors.
- Transit priority treatments/separate rights of way.
- Conflicts with through and regional access traffic.

**Transportation improvements**

- Freeway and arterial designs.
- Expressway interchanges (more, redesigned).
- Ramp improvements.
- Additional streets or improved continuity/connectivity.
- Transit routes and circulators.
- Rapid transit routes and station connections.
- Travel demand management strategies.
- Parking ratio reductions.
- Provision of amenities to encourage transit use and walking for internal trips.
- Improvement priorities.
- Costs.
- Source of financing for improvements.
- Environmental impacts.

**General roadway system characteristics**

- Capacity to accommodate further density increases.
- Spacing of expressway interchanges, arterials, collectors, local streets, and signalized intersections.
- Continuity in roadway design.
- Special treatments (for example, grade separations, ramps, one-way streets).
- Potential for operational improvements.

**Table 18-13. Typical Transportation Planning Principles for Suburban Activity Centers**

**General**

- Planning for activity center transportation systems should encourage coordination and most effective use of all appropriate modes and forms of transportation.
- Transportation and land-use plans should be mutually supportive.
- Activity center transportation and land use should be arranged so that the highest trip generating land uses are located nearest high accessibility transportation facilities, particularly transit routes and stations.
- The transportation facilities should be aesthetically attractive and, to the extent possible, blend in with or highlight the surroundings and the topographic features through which they pass.
- The transportation system should be comprehensible and easy to use for both frequent users and unfamiliar visitors.
- Adequate system capacity, continuity and connectivity should be ensured by defining and protecting sufficient future transportation right of way early, consistent with local policies on accommodating traffic and potential build-out of development.
- All elements of the transportation plan should be consistent with political and financial realities.
- The plan should be able to be staged with individual elements to be usable as they are completed.

**Roadway System and Traffic Circulation**

- The street system should provide adequate access and circulation for activity center traffic.
- The activity center circulation system should connect with both existing and proposed major thoroughfares beyond the activity center (for example, radial freeways and principal arterial streets).
- The activity center street system should provide more than one opportunity to reach a destination.
- Through traffic should be directed away from the core area utilizing alternative or bypass routes.
- The activity center circulation pattern should be easily comprehended by the average driver and provide relatively direct routing.
- The circulation plan should be designed for incremental implementation with individual elements available for use as they are completed.
- Streets should be designed to provide continuous routing and continuity of capacity.
- The activity center circulation plan should allow drivers to circulate around blocks or areas that generate high traffic volumes.
- Emergency vehicles must be able to reach any portion of the activity center in a reasonably direct manner.
- Given streets should perform specific functions (for example, major arterials, minor arterials collector/distributor streets, and local streets) to the extent that a hierarchy can be identified. This hierarchy should be implemented through the use street design techniques, traffic control measures, and parking regulations. Streets should have an appearance consistent with their function. Major streets should have wider pavements, right of way, and building setback than minor streets to give the appearance of a more important street. Minor streets should encourage slower speeds and pedestrian movement.
- One-way streets should have balance convenience to through-trips with inconvenience to local destinations.
- One-way streets facilitate signal progression, simplify intersections, increase capacity, and reduce crashes, but they may be inconvenient in certain situations.
- Complex intersections and multiphase signals should be avoided.
- Streets and land development should be designed to complement each other. Arterial streets should border rather than sever activity center land-use activity areas. Land parcels should not be so large as to make circulation difficult. The street pattern should not cut land areas into parcels too small to permit sound development.
- Adequate spacing of arterial streets should be provided to meet both capacity and circulation needs.

**Table 18-13. (*Continued*)**

- Efficient use of existing facilities should be considered in addition to physical improvement or construction of new facilities.
- Major roadways should be improved or constructed to appropriate geometric and safety standards; however, needed improvements should not be discarded only because all design standards cannot fully be met due to right-of-way or other constraints. Sometimes reduced standards may be desirable.
- The activity center freeway system should recognize basic principles of route capacity and continuity.
- Care must be exercised to ensure that there is sufficient capacity at interchanges. Collector-distributor facilities may be required to distribute the traffic from the freeway onto several arterial streets. Special ramp configurations, including direct connector ramps, may be desirable.
- Direct connections to the activity center by transit and high-occupancy vehicles (HOVs) via transitways and HOV lanes should be considered during the planning stage.

**Parking Principles**

- Activity center parking should be accessible from the primary activity center approach routes and located at major vehicle entry points.
- Activity center parking facilities should be distributed in relation to the direction of vehicles entering the area of development.
- Parking should provide explicit space for long-term, short-term, visitor, and errand parking.
- The activity center should have sufficient parking capacity to accommodate peak parking demands, consistent with adopted parking policies and the effectiveness of programs to reduce peak vehicle use.
- Activity center parking should facilitate dual or shared usage of facilities by the development and operation of facilities.
- Parking should not be permitted on major thoroughfares.
- Adequate off-street facilities should be provided to accommodate the needs of regular delivery vehicles, quick-stop service (such as mail and newspaper trucks), and special-purpose vehicles such as construction and maintenance trucks.

**Pedestrian/Bicyclist Circulation Principles**

- Continuity of pedestrian and bicyclist circulation among key buildings in the center should be a priority.
- Similar to the CBD, a suitable environment for pedestrians should be established. This should include, in addition to other amenities, protection from weather, especially in high pedestrian volume areas. Safe environments should be created for bicyclists as well, especially avoiding conflicts with motor vehicles.
- Major pedestrian and bicyclist ways should be properly defined and identified by landscaping and lighting.
- To maintain safe and convenient pedestrian crossings, streets should have no more than four moving lanes, unless medians with suitable pedestrian refuges are provided.
- Sidewalks and bike lanes should be kept clear of clutter and obstructions.
- Suitable provisions should be made for the mobility impaired.

**Transit Principles**

- Service should be directly oriented to major destinations in the activity center.
- The most direct possible routing should be used.
- Routes should be designed to be comprehensible to those who are not familiar with the transit system.
- Transfers for activity center trips should be minimized.
- Conflicts of buses with traffic and pedestrians (heavy right turns, garage access, curb parking and loading, crosswalk conflicts, etc.) should be minimized.
- Bus turns and mileage should be minimized.

(*continued*)

**Table 18-13. (*Continued*)**

- Service design should avoid overcrowding.
- Adequate passenger amenities, such as information systems and transit stop signs, adequate seating, queuing space at bus stops, and shelters should be provided where needed.
- Compatibility of the transit system with the activity center environment should be enhanced.
- Transit access to primary activity center destination areas should be provided for convenience and to encourage patronage of retail activities.
- Land uses should be located to capitalize on transit facilities as well as to maximize the market for transit.
- To the extent possible, the principle of through-routing should be applied to all activity center transit facilities to avoid looping and artificial doubling of transit vehicle loads.
- Surface transit should be given priority use of street facilities.
- Activity center transit service should facilitate people movement within the activity center and between any major off-site parking facilities and trip destinations (generally applicable to CBDs).
- Internal transit service should generally be provided only for movements for which transit service is faster than walking.
- Most service should be concentrated on a limited number of streets that serve major generators to provide the highest possible level of service (headway) to all users.
- From the standpoint of activity center development, the most important transit patron is the employee.
- Maximum accommodation of employee loads on transit will most effectively reduce peak-hour vehicular requirements.
- Off-street rail or bus transit may be desirable on approaches to and within activity centers. Stations and stops should be close to principal passenger destinations.

**Pedestrian and Bicycle Circulation**

- Walking and bicycling should be made feasible and desirable by placing related land uses near one another.
- Continuous pedestrian ways and bicycle paths should link all activity center nodes, where appropriate.
- Pedestrian and bicycle access from major activity center parking facilities to activity center land uses should be located to avoid traffic conflicts and enhance safety.
- Major pedestrian ways and bicycle paths should be properly defined and identified by landscaping and lighting.
- To maintain safe and convenient pedestrian crossings, streets should have no more than four moving lanes, unless medians with suitable pedestrian refuges are provided.
- A suitable environment for pedestrians and bicyclists should be established. This should include, in addition to other amenities, protection from adverse weather and secure bicycle storage.
- Just as there should be continuity in the plan of pedestrian circulation, there should similarly be a continuity of elevation. For example, concentrations of pedestrians alighting from buses should be reconciled with possible second-level pedestrian bridges and linkages.
- Provisions for handicapped persons should be made when designing or modifying pedestrian ways.

- Estimate the potential build-out based on the current or proposed transportation system.
- Evaluate the spacing and structure of activity center transportation facilities.
- Determine the size of the various transportation network facilities.
- Modify (usually intensify) an existing transportation plan.
- Evaluate roadway or transit system options and improvements.
- Evaluate potentials for public transport.

| Table 18-14. A General Outline of the Analysis Process | |
|---|---|
| **Purpose/Type** | **Analysis Method** |
| Activity center comprehensive land use and/or transportation plan formulation or revision | Forecast travel needs using anticipated land uses by parcel, parcel group, or zone (depending on level of detail needed); apply regional travel model on a subregional focus or window basis using microcomputer software; analyze needs on corridor or link basis using daily or peak-hour volumes. Test other alternatives (facilities, land use, and/or policies) in similar fashion. |
| Assess needs for specific transportation facilities within an activity center | Focus analysis detail on subarea or corridor(s) within activity center, with zone and network detail increasing closer to area/corridor; proceed as for comprehensive plan. In some cases where question of need is quite basic, a manual analysis may be sufficient to determine if a facility should be included in the plan. |
| Develop revised zoning strategy or plan | May be similar to activity center comprehensive plan process; must have land-use assumptions at sufficient level of detail to show sensitivity to zoning changes at freeway, arterial, and at least collector street level as well as transit; in some cases an assessment of ultimate transportation system capacity to determine how much land-use density can be accommodated. |
| Analyze potential transportation policies | May be similar to comprehensive plan process; level of detail must be sufficient to show sensitivity to policy variations—may need to use parcel-level analysis of trip generation for some policies. Many variations can be evaluated using detailed trip generation analysis followed by activity center network analysis. |
| Assess cumulative effects of several proposed developments | Modify travel model inputs for trip generation by zone and return travel projections; assess changes in traffic assignments by link and resulting transportation facility levels of service and/or improvements requirements. |
| Assess transportation impacts of individual developments | Estimate site traffic manually or using computer-assisted method; analyze site plus non-site traffic needs, including off-site changes for horizon year. |

- Develop a revised zoning strategy or plan.
- Analyze the potential of transportation management policies (for example, pricing, parking ratio limits).
- Assess the cumulative effects of proposed developments of several sites within the activity center's environs.
- Assess the effects of a major new development within an established activity center.
- Prepare a staged improvement plan.

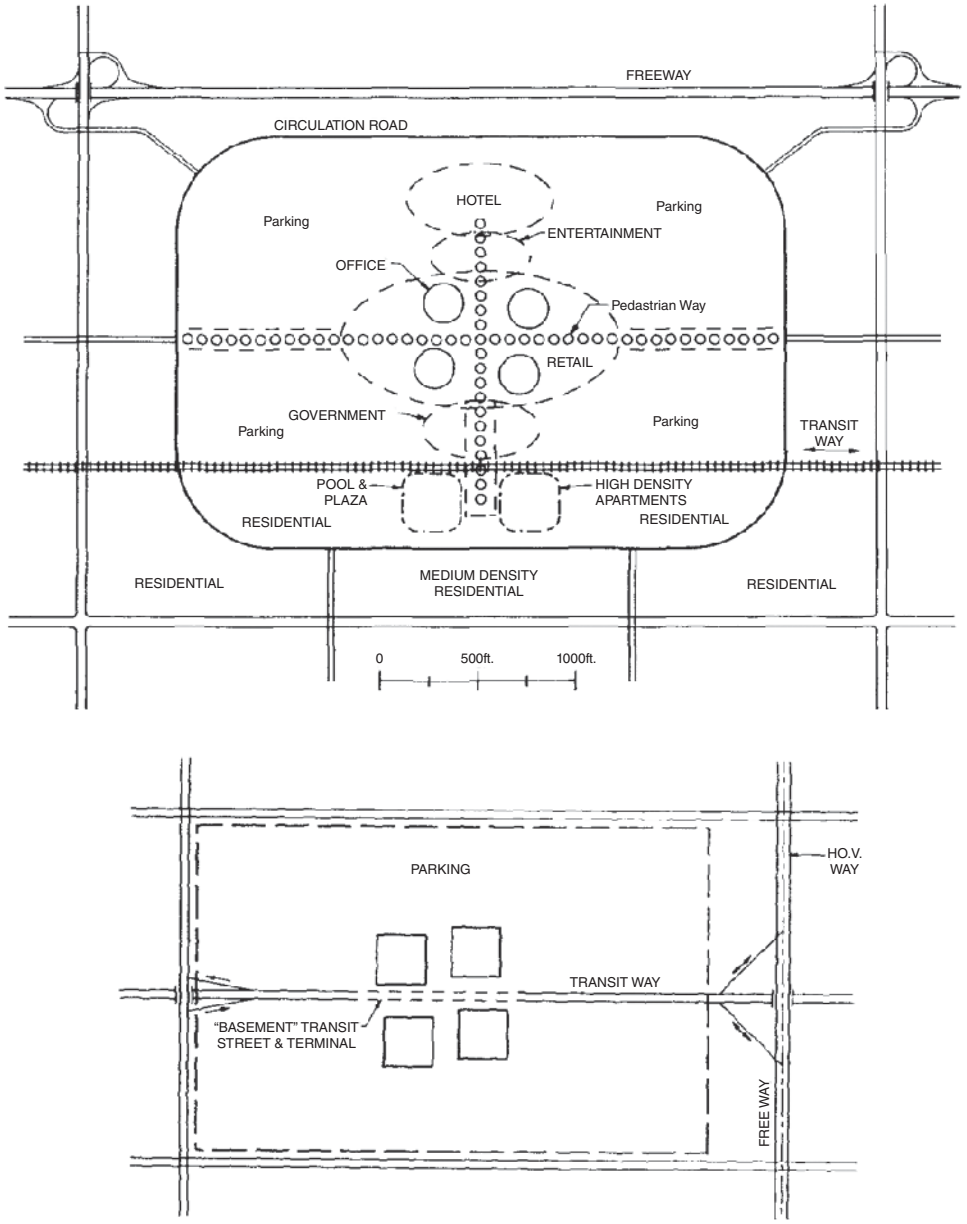
The analysis tools and methods used for analyzing the transportation needs of a suburban activity center are very similar to those used for local planning described earlier and site planning and traffic impact studies, which are described in chapter 19.

### *5. Transportation and Site Planning Strategies*

Providing mobility options to those working or living in a suburban activity center really starts at the site planning stage, where decisions are made concerning the layout of buildings and support infrastructure. Multiuse or mixed-use activity centers can provide several benefits to both the center's patrons and to the surrounding community. The integration of retail, office, residential, and recreational activities, especially in large activity centers, re-creates the traditional city center in suburban settings and reduces the need to travel because many people do not have to go elsewhere to work or shop. Clustering offices, stores, restaurants, and entertainment activities facilitates walking trips and enables each activity to reinforce the others. Intermingling residential and commercial areas or locating medium- to high-density residential areas near the main business centers can increase interaction and reduce vehicle travel. A pedestrian- and transit-friendly design helps achieve these benefits.

Planning should create a sense of place by providing a unique physical form, distinctive open space, mixed land uses, a well-landscaped environment, and an interior pedestrian scale with connectivity to adjoining neighborhoods. Density, diversity, proper design, and good accessibility and circulation are essential. Figure 18-15 shows how various activities can be integrated within a center and its environs to maximize pedestrian flows and facilitate transit use while maintaining good highway access. Pedestrian ways and zones serve as the heart of the development where the major retail, office, and government activities are provided. Residential and parking areas surround the commercial core.

**Figure 18-15. Suburban Activity Center Integrated Vision**



Source: Koepke and Levinson, 1992, Reproduced with permission of the Transportation Research Board.

A grade-separated transit way passes through the center with a station near the commercial core and apartments. A perimeter road provides the framework for internal circulation and connects with approach roads. Direct connections are provided to the center from the parallel freeway.

Transportation strategies include those relating to streets/highways, transit, pedestrians, bicyclists, parking, and TDM.

*Streets and Highways*—Most trips to activity centers in the United States and Canada are made as auto drivers or passengers. (The exceptions are the peak-hour commuter trips to the CBDs of large cities with high employment densities.) Freeway spacing at 4- to 6-mile intervals is desirable in urban areas where environmental conditions permit. Arterial street spacing at one-half-mile to 1-mile intervals should be provided where terrain permits. The high density of activities usually requires closer roadway spacing within the center. Arterial spacing should be one-quarter to one-half mile in activity centers (and no more than three to four blocks apart in CBDs). Spacing decisions are best made as part of an overall development plan that makes it possible to ensure route continuity and adequate rights of way. As new districts within an activity center are developed, it is possible to stage the expansion of roads to serve them.

In some cases, developers may contribute rights of way or fund road improvements through impact fees or other conditions of approval. Such combinations of private, local, and state improvements make an organized staging plan even more important.

Cross sections of boundary and approach roads should provide sufficient rights of way to meet anticipated demands. They should include medians with protected turn lanes, sidewalks, bicycle lanes and buffer areas, management of access and in some cases grade separations at key junctions. Integration of activity center access points and freeway interchanges is desirable. Access points into activity centers should be located where they allow efficient signal coordination along the surrounding roads.

The scale and design of roadways within suburban centers should reflect their function and future usage. Sufficient right-of-way should be reserved for *ultimate* needs, including special provisions for property access. This means that likely access provisions should be included in the analysis process, as should provisions for pedestrian and transit facilities. Urban design and other amenities should also be incorporated in the right-of-way. If needed and appropriate, building setbacks may also be specified to help meet the expected needs.

Cross sections should be sufficient to provide sidewalks, buffer access, turning lanes, and in some cases medians. However, excessive road widths should be avoided to make pedestrian crossings easier and to minimize barrier effects. Intersection capacity and needs should be based on estimated peak-hour intersection approach volumes; they should consider both a.m. and p.m. peaks as well as any other peaks that may result from specific land uses. Because some intersections will need extra turn lanes, attempts should be made to identify these locations early in the process. Heavy turn locations are best identified from the current turning volume patterns, appropriately expanded to account for planned development. Lane requirements for arterials and other major streets should be sufficient to accommodate projected traffic at the desired level of service in the horizon year.

*Transit*—Good public transportation—essential for city centers—is desirable for activity centers as they grow and intensify. Transit service is more effective when parking is limited and/or parking costs are high. It is desirable (where travel demands warrant) to provide transit service between the activity center and the areas where employees and visitors live and park, typically up to about 10 miles for employees.

Bus service to and from activity centers can be supported where there are at least 10 million square feet within less than a square mile and the tributary area has a density of at least seven dwellings per acre. Lesser activity center densities can be supported where the activity center is located along a bus line. A combination of high-density housing in a corridor, a short walk at both ends of the trip and competitive service with the auto on a time and cost basis is the best way to encourage transit use to and from activity centers (such as Bethesda). However, in many centers and their environs, free parking and low densities are the norm resulting in low transit ridership. Standard or customized modal split models can be used to estimate potential transit use (see chapter 6 on travel demand modeling, chapter 12 on transit planning, chapter 14 on travel demand management, and chapter 19 on site planning and traffic impact analysis provide more detailed examples of the type of transit strategies that might be appropriate in a suburban activity center.

*Pedestrians and Bicyclists*—Good pedestrian and bicycle circulation contributes to the amenity, livability, and vitality of activity centers. Many businesses, developers and designers seek to create walkable centers that differentiate their developments as unique, attractive destination environments, rather than simple suburban office locations or malls. Since all trips begin on foot, whether they are from a parking lot, transit stop, or a nearby home or commercial building, pedestrian considerations are an essential component of planning for activity centers. Moreover, they are a critical pre-condition for successful transit. As noted by a nationally recognized firm in urban design, "a healthy walking environment can succeed without transit, but a transit system cannot exist without the pedestrian." [Calthorpe & Assocs., 1997]

Developing a system of effective pedestrian and bicycle circulation requires a fine-grained, interconnected pattern of streets. The superblock pattern that is found in newer suburban developments requires long, circuitous walking routes, even to reach buildings that are nominally adjacent. A block pattern scaled to pedestrians, with buildings oriented to the street, can go a long way toward creating attractive walking opportunities. Pedestrian and bicyclist linkages should directly connect trip generators, provide shelter, or other appropriate amenities, are interesting to walk along and have a minimum of conflicts with vehicles. Readers are referred to chapter 13 on pedestrian and bicycle planning for further information.

Some examples of strategies that have been recommended from subarea studies include:

**Downtown Minneapolis Downtown Action Plan [City of Minneapolis, 2007]**

- Pedestrian network, including primary pedestrian corridors, and skyways.
- Bicycle network.
- Transit network, including:
  - Corridor transit facilities and services.
  - Intra-downtown circulation service.
  - Near downtown neighborhood service.
  - Layover facilities.
  - Auto/street network, including:
    - One-way network.
    - Two-way network.
    - Traffic operations.
    - Management of curbside uses.
  - Travel Demand Management
    - Carsharing.
    - Carpooling.
    - Telecommuting and flextime.
    - Incentives.
    - Parking.
    - Design guidelines.
    - Agency coordination.

**Salt Lake City Downtown Plan [Salt Lake City, 2008]**

- Pedestrian and Bicycle Recommendations
  - Enhanced walkability of downtown sidewalks along all city streets.
  - A network of walkways throughout downtown that will include an integrated system of midblock walkways and a completed network of midblock street crosswalks.
  - Infrastructure for bicyclists that will accommodate all skill levels of cycling:
    - Continuation of designated bike lanes on streets.
    - New markings and signage indicating bicycle/automobile shared use of the right-hand lane on streets without designated bike lanes.
    - Separate bike paths between the sidewalk and streets in some areas of downtown.
    - Legalize responsible bicycle riding on sidewalks in Downtown under specific conditions.
  - Augmentation of the downtown way finding system.
  - New urban design features, monuments, and gateways throughout downtown.
  - Additional bicycle racks and lockers on street and inside buildings.

- Light Rail Recommendations
  - Completion of two loops of TRAX to provide a backbone of rail transit circulation in downtown.
  - Construction of TRAX along 400 South from Main Street to 600 West and the Intermodal Hub—completing an inner loop of rail circulation in downtown.
  - Construction of TRAX along 700 South from 200 West to 400 West, and then continuing north on 400 West connecting to the existing system near Gateway, completing an outer loop that serves downtown and the emerging southwest quadrant of downtown.
  - Further study of streetcar access to Downtown from surrounding neighborhoods not served directly by TRAX.
- Automobile Recommendations
  - More frequent updating of traffic signal timing plans Downtown to support traffic progression.
  - A network of streets that are classified and designed according to a hierarchy of traffic needs allows operational improvements for improved flow into and out of downtown as well as within the core of downtown.
  - Coupled with parking programs and way finding, more efficient access to downtown parking spaces.
  - An expanded network of midblock streets.
  - New urban design elements incorporated into downtown streets.
- Bus Recommendations
  - Revised bus routes downtown.
  - A new bus passenger facility to be located at 200 South and State Street.
  - More attractive and comfortable bus stops downtown, including better information about bus service.
  - Branded bus corridors for circulation within downtown.
- Parking Recommendations
  - Immediate formation of a parking management group to coordinate operating policies of public parking downtown.
  - Way finding enhancements for off-street parking spaces.
  - New zoning policies that foster the development of convenient off-street parking for visitors.
  - New parking meters with more payment options.
  - An enhanced parking validation system for downtown.
- Circulator/Shuttle Recommendations
  - Continuation and expansion of the Free Fare Zone to include the Library light rail station, the Intermodal Hub, and the hotels on 600 South.
  - Improved transit circulation downtown with a combination of more frequent light rail service, branded bus corridors, and a downtown shuttle service.
  - Further study of additional streetcar access to downtown from surrounding neighborhoods not served directly by light rail.
  - Until completion of the light rail Airport Extension, shuttle bus service at 15-minute headways linking the airport, the Intermodal Hub, and the hotels along 500 South and 600 South Streets.

Both of these plans had phased implementation schedules built into the plans, one for 6 years and the other for 10 years. These schedules identified when certain actions would be taken and agency responsibility.

## IV. IMPLEMENTATION OF TRANSPORTATION PLANS

Transportation plans for activity centers and local communities require a cooperative effort among private- and public-sector entities. The cooperation starts during planning, but extends into funding, construction, operation, and other areas. For this reason, implementation priorities, strategies, and responsibilities for implementation should be agreed to by all parties during the planning process. It is seldom possible to make binding financial commitments far into the future because of the many uncertainties surrounding both public- and private-sector funding. Nevertheless, each entity should agree to the responsibilities for rights of way, funding, construction, operation, and maintenance of each plan component. In many cases, joint responsibility may be appropriate. Priorities should be set using criteria consistent with overall participant and activity center objectives with the understanding that the activity center systems must function with each increment of improvement.

In Houston, for example, property owners supported by local businesses in the region's largest suburban center established an improvement district, allowing property owners to pay for improvements and to finance bonds. In Georgia, state law allows the formation of community investment districts (CIDs) that with a required vote of commercial property owners collects a certain percentage of property taxes each year to fund transportation improvements in their area. The CIDs have become an important source of funds for investing in transportation strategies in the region.

The Atlanta Regional Commission's LCI program described earlier led to a variety of institutional arrangements and policy changes in implementing the results of the LCI planning studies. For example, from 2000 to 2014, the following strategies/actions were adopted to implement study recommendations (the number of instances shown in parentheses): historic preservation districts (16), form-based zoning code (16), special zoning districts (20), master streets plan or code (21), street design standards or guidelines (46), architectural design standards (55), overlay districts (56), sign ordinances (57), and zoning ordinance changes to allow mixed use developments (67). [ARC, 2015] In addition, the program has seen the participation of many different types of organizations in making the studies a reality, including downtown development authorities, community or neighborhood organizations, main street programs, community improvement districts, and transportation management associations.

Institutional arrangements should be established to implement the plan's recommendations. Some actions might require legal and political efforts, while others may already be available. Actions that have been used to generate the dollars to invest in transportation include:

- Zoning overlay districts (area with special zoning provisions) or special districts with special provisions to facilitate or ensure plan implementation.
- Special assessment or improvement districts.
- Model joint access agreements.
- Development agreements between developers and local governments to guide long-term, multiphase projects.
- Revised subdivision platting or access policy components or powers.
- Special public authority for district.
- Transportation or thoroughfare plan amendments.
- Urban design guidelines.
- Special transportation system standards or design criteria.
- Additional development review or approval stages.
- Special district association.

Beginning in the 1970s, many downtowns such as Toronto and New Orleans were faced with deteriorating municipal finances. The result was the creation of business improvement districts (BIDs), which allowed property owners to tax themselves to provide the kind of services that could no longer be provided by the city. Originally these programs emphasized trash collection and security, the most visible services to the public. Recently, some have recognized the need for broader involvement in longer-term planning and economic development. Such an institution, with official sanction, may present an excellent means of bringing businesses, developers, and city officials together to address critical needs for downtowns.

The creation of transportation management associations (TMAs) has served a similar purpose in the suburbs to that of the BIDs downtown. While most of the early focus has been placed on operating or promoting commuter assistance programs, today most take an active role in addressing longer-term transportation needs. The proliferation of such TMAs creates a built-in institution in many suburban growth centers that cannot only help identify needs, but also advocate for the implementation of plans. Where there is no formal institution such as a BID or a TMA, it may be useful to create an informal group that can help establish a vision and bring pressure on the appropriate parties to implement their plans when initial enthusiasm has waned.

The reader is referred to chapter 5 on transportation finance and funding for further discussion on alternative mechanisms for providing the dollars necessary to implement a plan's recommendations.

## V. SUMMARY

This chapter has focused on a planning context that is becoming more important over time. Many of the metropolitan areas in the world are following a development pattern in which clusters of land uses, mostly complementary, are becoming centers of economic activity. Traditionally, this was the purpose of the downtown, but beginning in the 1960s with the dispersal of population and employment to the suburbs, more of these activity centers began to sprout up in both suburban and exurban areas. The initial transportation concern with these centers focused on physical infrastructure, how to provide the highway access, and in some cases transit access for employees and visitors. But as these centers have evolved, and with growth have become more congested, many of the transportation planning effort focuses on how to reduce single-occupant vehicle trips. Most of the plans today for activity centers include both physical improvements to the road, transit, and pedestrian/bicycle networks, as well as a consideration for transportation demand management strategies, access management, and parking management.

The planning process for local communities and activity centers is similar in form to that which occurs in state DOTs and MPOs. There should be data collection and analysis to determine existing conditions and performance of the transportation system; goals, objectives, and performance measures need to be articulated; future performance needs to be predicted based on some sense of future population, employment, and land use levels; and projects/actions/strategies need to be prioritized based on their cost effectiveness. The only real difference between local and activity center planning and that which occurs at the state or metropolitan level is the scale of application. For example, although many larger cities and communities in large metropolitan areas use travel demand models for their transportation planning, many of the smaller cities and activity centers do not. Although many local governments examine the range of strategies for reducing congestion (including TDM, parking, and access management), many simply look at the key road segments and intersections. It is important, therefore, for the planner at the very outset of a study to lay out the type of information that will be needed to make decisions at the end of the process, and work backward to determine what type of data will be necessary and what types of tools will be appropriate.

# Site Planning and Impact Analysis[1]

## I. INTRODUCTION

This chapter covers two topics. *Site planning* is the process of placing a proposed development on a parcel of land and assessing different aspects of how it will be built and its compliance with a community's zoning code and comprehensive plan. *Transportation access and impact studies* analyze the likely changes and effects on the transportation system resulting from this new development site. Impact studies recommend on- and off-site transportation improvements to improve access to the site as well as mitigate expected impacts. They identify public safety requirements and the transportation needs of the site and the surrounding road system. Impact studies are often part of a state environmental impact review process, or for major developments, they could be subject to what is called the Development of Regional Impact (DRI) review process. [FHWA, 1992] Both site planning and impact studies are concerned with site trip generation, how these trips arrive and depart, and the paths taken through the transportation network to reach the site, although impact studies focus on these issues at a much finer level of detail.

Site planning and impact studies are an essential part of the development review process in that they assist private developers in the proposal preparation and public agencies in proposal review. They address a wide range of issues and concerns including defining preliminary site and development characteristics, obtaining access (driveway) permits, determining necessary transportation improvements, and preparing overall access management plans. Studies can help developers and permitting agencies to:

- Establish the basic characteristics of the development footprint.
- Assess the number, location, and design of access points.
- Forecast the transportation (traffic) impacts created by proposed development based on accepted practices.
- Determine needed transport improvements to accommodate proposed developments.
- Identify travel demand management strategies.
- Allocate funds in a cost-effective manner.
- Provide a basis for determining the developers' responsibility for on- and off-site improvements.

Site plan reviews provide the community with a means of linking proposed developments to desired development characteristics as defined in zoning codes and ordinances. They also provide critical input when determining the desirability and/or conditions on which variances to these ordinances will be granted. Transportation access and impact studies ensure that safe and convenient access is provided to development sites while maintaining mobility and safety on public roads and other surface transportation facilities. In addition, impact studies provide nearby property owners with a way of making sure that new development does not negatively affect access to their property, and thus downgrade their property values.

Methods for conducting impact studies have been well-defined for many years. However, current experience in many communities suggests that their scope should be broadened to ensure that, (1) adequate access is provided for transit riders and pedestrians/bicyclists, (2) access to a development site does not adversely affect the performance of the surrounding street system, and (3) site design and access do not add to visual blight of the surrounding street environment. In addition, in many communities, such studies not only lay out the physical changes needed to

[1]Portions of this chapter were originally written by Herbert S. Levinson, P.E., Transportation Consultant, New Haven, CT, USA and Icon Mentor, Region 2 Transportation University Center, City University, New York, NY. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

provide better and safer access to the site (for example, building a turn lane at the site entrance), but they also identify travel demand management (TDM) strategies to reduce the number of automobile-related trips generated by the site.

Given these concerns, the key questions in an impact analysis include:

- Can people reach the site safely and conveniently as pedestrians, bicyclists, transit riders, automobile drivers, and passengers?
- Do the site access design, internal circulation system, parking, and building arrangements allow safe and effective vehicle and people circulation and movement?
- Can access be provided without adversely affecting the performance of the surrounding roadways?
- Do planned improvements ameliorate present and future problems?
- Are there ways of reducing the demand for trips to the site?

An example of such concerns comes from the Virginia Department of Transportation (VDOT), which states that a traffic impact statement for a rezoning request should,

> *(1) assess the impact of a proposed development on the transportation system and recommend improvements to lessen or negate those impacts, (2) identify any traffic issues associated with access from the site to the existing transportation network, (3) outline solutions to potential problems, (4) address the sufficiency of the future transportation network, and (5) present improvements to be incorporated into the proposed development. [VDOT, 2014, 2015]*

Some transportation agencies have placed the transportation impact review process within a much broader policy context. Addressing these questions often requires a multimodal perspective, as well as a serious look at access management issues and other policy/sustainability opportunities. The Massachusetts Department of Transportation (MassDOT), for example, notes that its intent in impact reviews is to:

> *Ensure that the transportation impact review process reflects and advances the Commonwealth of Massachusetts' policy goals, in particular those that promote MassDOT's* Project Development and Design Guide Standards on Complete Streets, *the Global Warming Solutions Act, the Massachusetts GreenDOT Policy Initiative, the Mode Shift Initiative, the Healthy Transportation Compact, the Healthy Transportation Policy Directive, the Massachusetts Ridesharing Regulation, and Safe Routes to School policies. [MassDOT, 2012]*

California is another state that has adopted statewide policies relating to sustainability, energy conservation, and greenhouse gas emission reductions (see https://www.wildlife.ca.gov/Conservation/CEQA/Purpose).

The following section describes the administrative requirements for site planning and impact analysis. These requirements dictate the type of information that must be part of a study, and often establish the thresholds of when such a study is necessary. The next section offers definitions of key terms used in both site plan reviews and traffic impact studies. The next two sections discuss the specifics of site plan review and traffic impact analyses. More attention is given to traffic impact studies in that this is where most of the site-related transportation planning efforts occur. This section discusses key issues like the identification of analysis horizon years and performance measures; travel demand models and tools; and the analysis approaches for site-specific, corridor, and network impacts. The next section focuses on on-site transportation design options and strategies, including internal circulation networks and parking management. This is followed by a discussion of access management and the many different types of mitigation strategies that can be considered as part of an impact study. The final section presents a sample table of contents for a traffic impact study.

The Institute of Transportation Engineers (ITE) published a transportation impact analysis *Recommended Practice* in 2010 that provides a detailed, step-by-step description of the analysis process. It is not the intent to replicate the *Recommended Practice* in this chapter. Some key tables and figures from that reference will be used simply to illustrate the important characteristics of the impact analysis process. Interested readers should read this more detailed guide. [ITE, 2010] In addition, many of the mitigation strategies usually considered in a traffic impact study are described in more detail in other chapters of this handbook. Readers are referred to chapter 3 on land use and urban design, chapter 4 on environment and the community, chapter 6 on travel demand modeling, chapter 9 on road and highway

planning, chapter 11 on parking, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, chapter 14 on travel demand management, and chapter 23 on transportation safety.

## II. ADMINISTRATIVE REQUIREMENTS

Administrative rules and requirements established by governments provide the basic requirements for both a site plan review and a traffic impact study process. These vary by jurisdiction, depending on the community definition of what constitutes an impact. Importantly, site planning requirements are part of the zoning process and occur when a development of a certain size is proposed (see chapter 3 on land use and urban design).

ITE [2012] notes that traffic impact studies, as specified in rules and procedures, can be required when:

- The development will generate a specified number of daily trips.
- The development will generate a specified number of peak-hour trips.
- A specified amount of acreage is being rezoned.
- The development contains a specified number of dwelling units or amount of square footage.
- Financial assessments are required and the extent of impact must be determined.
- The development will require a significant amount of transportation improvements.
- A previous transportation impact analysis for a site has been deemed out of date.
- Development will occur in a sensitive area.
- The judgment or discretion of staff can be applied based on previous experience.

Some examples of thresholds that might trigger an impact study include:

**Iowa Department of Transportation (IDOT).** Two types of impact reports are possible. A *traffic impact letter* is required if the average annual daily traffic (AADT) is less than or equal to 500 vehicles, and the peak-hour volume is less than or equal to 100 trips. Volumes over these thresholds require a *traffic impact study*. [Iowa DOT, 2013]

**California Department of Transportation (Caltrans).** The following criteria are considered starting points for determining when a traffic impact study is needed for a state highway in California. [Caltrans, 2002] Such a study is needed when a project:

1) Generates over 100 peak-hour trips assigned to a state highway facility.
2) Generates 50 to 100 peak-hour trips assigned to a state highway facility, and affected state highway facilities are experiencing noticeable delay, approaching unstable traffic flow conditions (levels of service (LOS) "C" or "D").
3) Generates 1 to 49 peak-hour trips assigned to a state highway facility and where:
    a. Affected state highway facilities experience significant delay or unstable or forced traffic flow conditions (LOS "E" or "F"), or
    b. The potential risk for a traffic incident is significantly increased (that is, congestion-related collisions, nonstandard sight distance considerations, increase in traffic conflict points, and so forth), or
    c. There is a change in local circulation networks that impact a state highway facility (that is, direct access to state highway facility, a non-standard highway geometric design, and so forth).

**Oregon Department of Transportation (ODOT).** ODOT will likely request an impact study when, (1) the proposed development is within a quarter mile of the terminal of an interchange ramp, (2) the local development code requires that there be "adequate facilities" to serve the proposed development (often applies to "change of use"

applications), (3) an ODOT preliminary review identifies operational or safety issues related to increased traffic or highway access at the development site, and/or (4) an approach to the state highway will be the development's only or primary access to the roadway network. [ODOT, 2014]

**City of San Francisco, California.** The city of San Francisco requires an impact study when a project:

1) Potentially adds at least 50 p.m. peak-hour person trips.
2) Potentially increases existing traffic volumes on streets in its vicinity by at least 5 percent.
3) Potentially impacts nearby intersections and/or arterials, which are believed to presently operate at level of service (LOS) "D" or worse.
4) Provides parking that would appear likely to be deficient relative to both the anticipated project demand and code requirements by at least 20 percent.
5) Has elements that have a potential to adversely impact transit operations or the carrying capacity of nearby transit services.
6) Has elements that have the potential to adversely affect pedestrian or bicycle safety or the adequacy of nearby pedestrian or bicycle facilities.
7) Would not fully satisfy truck loading demand on-site for an anticipated number of deliveries and service calls exceeding 10 daily trips. [City of San Francisco, 2015]

**City of Tampa, Florida.** The city of Tampa requires an analysis and mitigation of *critical links and intersections* adjacent to a development's major roadway network access point(s) when:

1) The average annual daily traffic (AADT) on the adjacent major roadway link(s) is less than 95 percent of the LOS "D" daily service capacity of the link and the subject development consumes more than 2 percent of the LOS "D" daily service capacity of the adjacent major roadway link(s), and capacity is available.
   or
2) The AADT of the adjacent major roadway link(s) is greater than or equal to 95 percent of the LOS "D" daily service capacity of the link and the subject development consumes more than 1 percent of the LOS "D" daily service capacity of the adjacent major roadway link(s), and capacity is not available.

An analysis of *roadway network impacts* is required when:

1) The AADT of the adjacent major roadway link(s) is less than 95 percent of the LOS "D" daily service capacity of the link and the subject development consumes more than 5 percent of the LOS "D" daily service capacity of the adjacent major roadway link(s).
   or
2) The AADT of the adjacent major roadway link[s] is greater than or equal to 95 percent of the LOS "D" daily service capacity of the link and the subject development consumes more than 2 percent of the LOS "D" daily service capacity of the adjacent major roadway link(s).

*Enhanced network impact analyses* are required when the AADT of a significantly impacted link (as identified in a network impact analysis) operates at greater than 120 percent of the LOS "D" daily service capacity of the link and the subject development traffic consumes more than 5 percent of the LOS "D" daily service capacity of the link. [City of Tampa, 2011]

Another way of defining impact analysis thresholds is for communities to identify when a traffic impact study is *not* required due to the nature of the development itself or because of local conditions (for example, developments designed to encourage transit use). A good example of this comes from Tampa where the following exclusions of the traffic impact study requirement are part of the planning rules. In Tampa, generally, any development that generates more than 100 net daily trip ends per day will likely have to undergo a traffic impact study unless the development is

located in the Downtown Revitalization District, Urban Redevelopment District, or Urban Infill District, in which case the developer must pay the city's transportation impact fee (but does not have to commit to any specific action). If the project is in an approved Transportation Master Plan Area (for example, Tampa International Airport, Port of Tampa, or the University of South Florida), the developer must mitigate site impacts and otherwise conform to the city's land development code and comprehensive plan. Similarly, developments that are serviced by one or more "Primary Transit Facility" service areas must mitigate on-site impacts. Service areas are defined as within a one-fourth mile (0.4 km) of high-frequency bus transit routes, within one-third mile (0.54 km) of a bus rapid transit station, within one-half mile (0.8 km) of a rail transit station, and within one-third mile (0.54 km) of a transit center/transfer center.

Figure 19-1 shows a similar concept from San Jose, California, where areas near transit facilities and neighborhood business districts are identified for special treatment in the traffic impact study process. In planning terms, these are often called overlay districts as defined in zoning codes (see chapter 3 on land use and urban design).

Although one often sees different community threshold criteria for initiating a traffic impact study, ITE [2012] recommends a study be done for any project that generates at least 100 peak-hour vehicle trips per day. As noted, however, the context of such development is a critical consideration—small developments generating fewer trips than this may still require a site access and circulation review to ensure that access connections are located safely.

**Figure 19-1. Special Districts for Traffic Impact Study Requirements, San Jose, California**

## III. DEFINITION OF KEY TERMS

Some key terms used in site planning and traffic impact analysis include:

- *Access management:* Strategies to manage the access to streets, roads, and highways from public roads and private driveways. Requires balancing access to developed land while ensuring movement of traffic in a safe and efficient manner.
- *Analysis hour:* A single hour for which a capacity analysis is performed on a system element.
- *Critical density:* The traffic density at which capacity occurs for a given facility.
- *Critical headway:* The minimum headway in the major traffic stream that will allow the entry of one minor-street vehicle.
- *Critical lane groups:* The lane groups having the highest flow ratio for a given signal phase.
- *Critical speed:* The speed at which capacity occurs for a segment.
- *Cycle failure:* A condition where one or more queued vehicles are not able to depart a signalized intersection.
- *Demand-to-capacity ratio:* The ratio of demand volume to capacity for a system element.
- *Design hour:* An hour with a traffic volume that represents a reasonable value for designing the geometric and control elements of a facility.
- *Design year:* A target year (usually 20 years) following the year the project is open to traffic.
- *Development traffic:* Traffic volumes generated by a development.
- *Directional distribution:* The directional split of traffic during the peak or design hour, commonly expressed as a percentage in the peak- and off-peak flow directions.
- *Fair share:* A strategy of sharing the mitigation costs of the impacts of development on transportation facilities through the cooperative efforts of public agencies and private developers or land owners.
- *Floor area ratio:* The ratio of the total floor area of a building or buildings on a parcel to the size of the parcel where the building or buildings are located.
- *Fully actuated control:* A signal operation in which vehicle detectors at each approach to the intersection control the occurrence and length of every phase.
- *Internal capture:* Trips internal to a development site that otherwise would have left the site.
- *Level of service (LOS):* A qualitative measure describing operational conditions in a traffic stream based on service measures such as speed and travel time, freedom to maneuver, traffic interruptions, comfort, and convenience.
- *Mitigation:* Measures to reduce adverse impacts on the environment, in the following order of preference:
  - Avoid the impact altogether by not taking a certain action or part of an action.
  - Minimize the impact by limiting the degree or magnitude of the action and its implementation, by using appropriate technology, or by taking affirmative steps to avoid or reduce impacts.
  - Rectify the impact by repairing, rehabilitating, or restoring the affected environment.
  - Reduce or eliminate the impact over time by preservation and maintenance operations during the life of the action.
  - Compensate for the impact by replacing, enhancing, or providing substitute resources or environments.
- *Opening year:* The year the project is scheduled to be open to traffic.
- *Pass-by trips:* Trips made by traffic already using adjacent roadways and enter the site as an intermediate stop on the way to another destination.

- *Peak hour:* The hour during the day when the maximum volume is using a facility. Used in determining directional distributions. Note that the peak hour of the adjacent street may not be the peak hour of the development.
- *Planning horizon year:* The target year for estimating traffic impacts.
- *Redevelopment site:* Any existing use that generates traffic and is intended to be developed at a different land-use density.
- *Service flow rate:* The maximum directional rate of flow that can be sustained on a given segment under prevailing roadway, traffic, and control conditions without violating the criteria for a specified level of service.
- *Sight distance:* The distance visible to the driver of a passenger vehicle measured along the normal travel path of a roadway from a designated location to a specified height above the roadway when the view is unobstructed by traffic.
- *Stopping sight distance:* The distance required by a driver of a vehicle, traveling at a given speed, to bring the vehicle to a stop after an object on the roadway becomes visible. It includes the distance traveled during driver perception and reaction times and the vehicle braking distance.
- *Traffic impact statement:* A document prepared in accordance with best professional practice and standards assessing the impact of a proposed development on the transportation system and recommending improvements to lessen or negate those impacts.
- *Transit-oriented development:* An area of commercial and residential development at moderate to high densities within 1/2 mile (0.8 km) of a station for heavy rail, light rail, commuter rail, or bus rapid transit transportation and includes the following: (a) densities of at least four residential units per acre and at least a floor area ratio of 0.4 or some proportional combination thereof; (b) mixed-use neighborhoods, including mixed housing types and integration of residential, office, and retail development; (c) reduction of front and side yard building setbacks; and (d) pedestrian-friendly road design and connectivity of road and pedestrian networks (see chapter 3 on land use and urban design).
- *Travel (or Transportation) demand management (TDM):* A combination of measures that reduce vehicle trip generation and improve transportation system efficiency by altering travel demand, including but not limited to the following: expanded transit service, employer-provided transit benefits, bicycle and pedestrian investments, ridesharing, staggered work hours, telecommuting, and parking management including parking pricing (see chapter 14 on parking).
- *Vehicle miles traveled (VMT):* Number of vehicles using a site times the average trip distance estimated from a network model. Used as a measure of impact on the road network, as well as input to air quality and energy impact analysis.

## IV. SITE PLAN REVIEW DATA

The type of information accompanying a site plan review examines many different nontransportation items, such as legal ownership, a legal description of the property, preliminary dimensions of the development footprint, and the zoning and planning requirements for the site. With respect to the transportation components of a site plan review, and thus transportation-related data needs, the following guidelines from Seattle show typical inputs into a site plan submittal.

- Dimensions and right-of-way limits in addition to roadway widths of adjacent streets (by name), alleys, or other adjacent public property.
- Curbs, sidewalks, and street trees—type, location, and dimensions.
- Street and alley improvement type and dimensions (asphalt, concrete, gravel, and so forth).
- Location of the pedestrian path to each dwelling unit and the primary entrance to each building.

- Location and dimensions of all driveways, parking areas, and other paved areas (existing and proposed).
- Center elevation and developed roadway at 25 feet intervals if a change to access or parking is proposed. Identify existing and finished grade elevation of driveway at property line, and at garage entry, if a change to access or parking is proposed.
- Curb cut width and distance from adjacent property lines (label curb cuts as "existing" or "proposed").
- Identify all physical restrictions to site access (utility poles, rockeries, street trees, Metro bus stops, and so forth) if a change to access is proposed. [City of Seattle, 2013]

In addition to these requirements, the city of Austin, Texas, requires more detail on the following site-related aspects.

- All driveway dimensions and design specifications, such as: driveway widths, driveway curb return radii, and profiles of finished grades; label on site plan when there are several proposed driveway approaches.
- Proposed operation of driveways on site plan (that is, one-way or two-way operation); identifying and labeling all physical barriers to vehicular access.
- On undivided roadways, show existing driveways on opposite side of street within 120 feet of site driveways, or indicate in a note if there are none.
- Physical obstructions (utility poles, trees, storm sewer inlets, and so forth) in the right-of-way, which could affect sidewalk/driveway locations.
- Dimensions of vertical clearance within fire lanes, including tree limbs, for all driveways and internal circulation areas on-site, where overhead clearance is restricted.
- All off-street and on-street parking; number of required and provided parking spaces including location, number and type (standard, compact, handicapped) of actual parking spaces; dimension parking stall depth and width, stall angle, aisle width, and width on internal driveways. Plan should number each parking space, show structural supports, turning radii, traffic circulation, ramp grades in parking garages, and the numbering and location of compact spaces.
- Reduction in on-site parking requirements assumed and the number of spaces credited.
- Handicapped parking spaces meeting state standards.
- Route of travel connecting all accessible elements and spaces on the site that can be negotiated by a person using a wheelchair and usable by persons with other disabilities (indicated by dotted lines, a shading pattern or other identifiable legend).
- Internal circulation system showing vehicular, bicycle, pedestrian paths, and connections to off-site access.
- Note on the plan indicating that each compact parking space must be identified by a sign stating "small car only" and signs posted on-site directing motorists to such spaces.
- Offstreet loading spaces, if required.
- Location and type of bicycle parking.
- Queue spaces or queuing areas for drive-through uses.
- Location and width of sidewalks on site plan, if required by the city of Austin.
- The location and design of all pedestrian sidewalk ramps related to the construction of this site. [City of Austin, 2014]

As can be seen by these two lists, the transportation-related data requirements for site plan review will vary from one community to another. Transportation planners involved with site plans need to be very familiar with the requirements as set forth by the community zoning and/or planning commission. Other examples of site plan review guidelines can be found at. [City of Alexandria, 2013; County of Fairfax, undated]

# V. TRANSPORTATION ACCESS AND IMPACT ANALYSIS

An impact analysis should always begin by establishing the basic terms of reference with relevant public agencies and the developer or owner. These will include, at a minimum, defining the transportation need, identifying impact analysis thresholds as established in requirements, agreeing to a scope of analysis, defining study area limits, establishing the forecast hours (and days) to be analyzed, and defining the study horizon years. The set of feasible travel modes and acceptable methods of determining capacity and level of service should also be established.

The scope of traffic impact studies depends on the type, location, timing, and size of the proposed development. Where walk, bicycle, and transit trips are common (or have potential), both total person trips and vehicular trips should be analyzed. This involves estimates of mode split and vehicle occupancy. In addition, most site impact studies examine the access and movement of commercial vehicles delivering goods to a site. The types of information needed to reach appropriate traffic and development decisions normally include:

- Characteristics of the existing roadway and public transport systems.
- Characteristics of current and proposed nearby developments.
- Estimated future development traffic and access strategies.
- Combined traffic volumes on surrounding and approach roads.
- Traffic growth rates.
- Road system adequacy.
- System needs.
- Access plans.

With respect to access management, site access should maintain the operational integrity of the surrounding road system. This can be best achieved by applying access management principles and designs (see chapter 3 on land use and urban design and chapter 9 road and highway planning). Access management provides (or manages) access to land development while simultaneously preserving the flow of traffic on the surrounding road system in terms of safety, capacity, and speed. It consists of the systematic control of the location, spacing, design, and operation of driveways; median openings; interchanges; and street connections to a roadway. It also includes applications such as median treatments, auxiliary lanes, and the appropriate spacing of traffic signals. [Koepke and Levinson, 1992] An important access management objective is to ensure that the cumulative effects of a series of closely spaced developments do not deteriorate the safety and mobility associated with the surrounding road system.

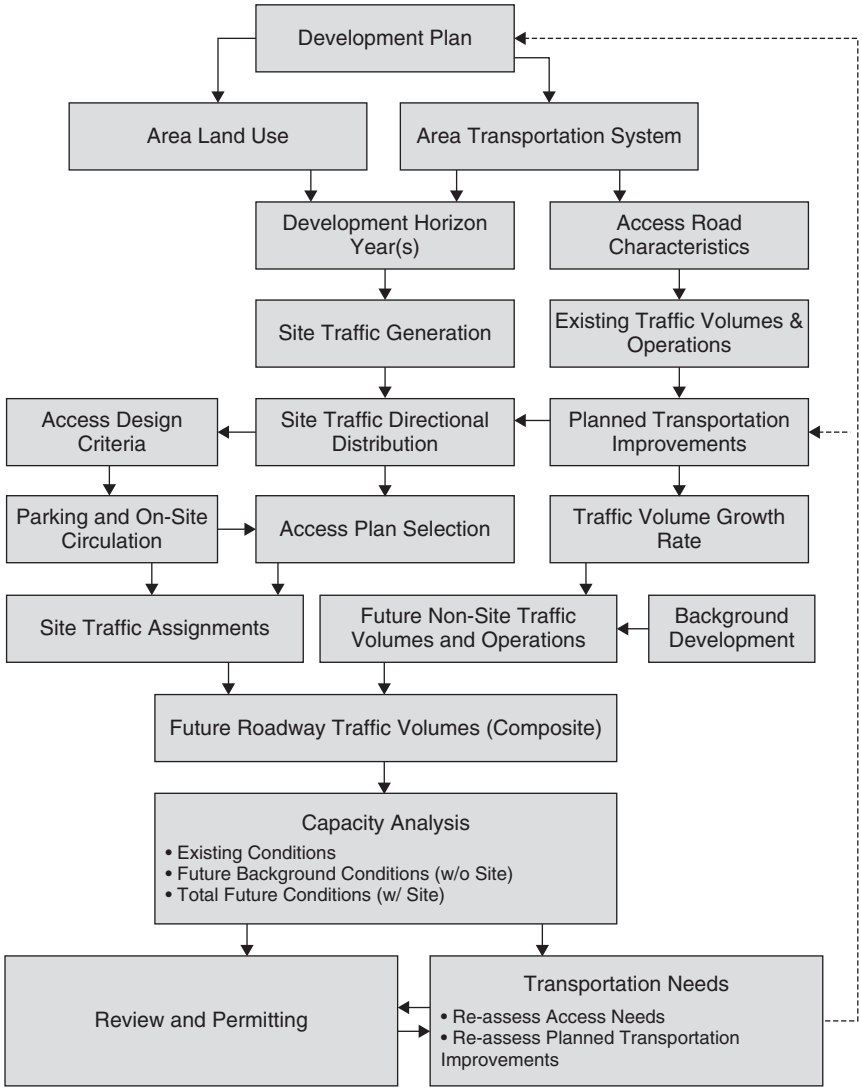
## A. Traffic Impact Analysis Process

Figure 19-2 shows the major steps in a traffic impact analysis. [ITE, 2012] Each of these steps uses data and analysis tools that are discussed in other chapters *(*see, for example, chapter 2 on data analysis and chapter 6 on travel demand modeling). The key outcomes of this process, from the property owner's perspective, are the permits and other permissions granted by public agencies to build the development. Several of the key components of this analysis process are discussed in the following sections.

## B. Study Area Boundaries

Study area boundaries should be based on the type of land use, size of development, street system patterns, and terrain. A frequently used method is to carry the analysis boundaries to locations where site-generated traffic will represent five percent or more of the roadway's peak-hour approach capacity. The study area should include critical (or congested) intersections on the adjacent road network. Table 19-1 gives guidelines for determining study area limits based on the size, type, and trip-generating characteristics of typical land uses. Note that the study area limits for a traffic impact study as shown in Table 19-1 would generally not account for the larger study area needed for a concurrency analysis, where a developer would pay a proportionate share for roadway/intersection improvements

**Figure 19-2. Transportation Impact Analysis Process**



Source: ITE, 2012

needed as a result of the proposed development. Also, traffic impact studies are usually done under the jurisdiction of local governments, but given that development impacts can extend beyond the local roadway network to the state highway system, it is important that local and state authorities coordinate in addressing study impacts and mitigation measures.

The criteria shown in Table 19-1 can sometimes be superseded at the discretion of the jurisdiction's transportation agency. In Massachusetts, for example, intersections or road segments meeting an impact statement threshold of five percent increase in traffic volume may be exempted from study if in the Massachusetts DOT's (MassDOT's) judgment:

- The intersection or segment operates acceptably today and the site development impact will not cause a capacity or safety mitigation need.

  or

- A mitigation for the intersection or segment has been previously identified and no further analysis is warranted (note that site-generated trip assignment may still be required for tracking or mitigation assessment purposes).

  or

- Other reasons are deemed appropriate by MassDOT. [MassDOT, 2014]

| Table 19-1. Suggested Study Area Limits for Transportation Impact Analysis | |
|---|---|
| **Development** | **Study Area** |
| Fast-food restaurant | Adjacent intersection if corner location. |
| Service station, with or without fast-food counter | Adjacent intersection if corner location. |
| Mini-mart or convenience grocery with or without gas pumps | 660 ft from access drive. |
| Other development with fewer than 200 trips during any peak hour | 1,000 ft from access drive. |
| Shopping center less than 70,000 sq. ft.<br>or<br>Development w/peak-hour trips between 200 and 500 during peak hour | All signalized intersections and access drives within 0.5 mile from a property line of the site and all major unsignalized intersections and access drives within 0.25 mile. |
| Shopping center between 70,000 sq. ft. and 100,000 sq. ft. GLA<br>or<br>Office or industrial park with between 300 and 500 employees<br>or<br>Well-balanced, mixed-use development with more than 500 peak-hour trips | All signalized and major unsignalized intersections and freeway ramps within 1 mile of a property line of the site. |
| Shopping center greater than 100,000 sq. ft. GLA<br>or<br>Office or industrial park with more than 500 employees<br>or<br>All other development with more than 500 peak-hour trips | All signalized intersections and freeway ramps within 2 miles of a property line and all major unsignalized access (streets and driveways) within 1 mile of a property line of the site. |
| Transit station | 0.5-mile radius. |

Source: ITE, 2012

Alternatively, intersections or road segments that do not meet the five percent threshold might be included in the study area if in MassDOT's judgment:

- The intersection is highly congested, near or over capacity, and prone to significant operational deterioration from even a small increment in traffic.

  or

- The location is expected to have a significant impact to the state highway system.

  or

- There are local municipality requirements that call for an impact study.

  or

- There are special circumstances related to the location that merit review. [MassDOT, 2014]

In addition, for those studies conducted in urban areas, the study area description should discuss not only potentially affected major highways and roadways, intersections, and interchanges, but also pedestrian and bicycle facilities, and the public transit network that are part of (or could be part of) the study area's transportation system. For example, MassDOT's definition of an urban study area includes:

- Walking, bicycling, and public transit networks, with specific attention to connectivity, desire lines, and gap analysis in order to maximize travel choices and promote these modes. Consideration should be given to the appropriate level of analysis for transit, walking, and bicycling study areas. [MassDOT, 2012]

## C. Horizon Years

The planning horizon year, that is, the future year for estimating traffic impacts, should be consistent with the size and build-out schedule of the planned developments and any anticipated major transportation system changes. Suggested horizon years are given in Table 19-2. A general guide is to set the planning horizon year for when proposed developments will be fully operational and meeting their market goals, usually three to five years after opening day.

| Table 19-2. Suggested Study Horizons | |
|---|---|
| **Development Characteristic** | **Suggested Horizon Year(s)** |
| Small development (<500 peak-hour trips) | • Anticipated opening year, assuming full build-out and occupancy. |
| Moderate, single-phase development (500 to 1,000 peak-hour trips) | • Anticipated opening year, assuming full build-out and occupancy.<br>• Five years after opening date. |
| Large, single-phase development (>1,000 peak-hour trips) | • Anticipated opening year, assuming full build-out and occupancy.<br>• Five years after full build-out and occupancy.<br>• Adopted transportation plan horizon year, if the development is significantly larger than that included in the adopted plan or travel forecasts for the area. |
| Moderate or large multiple-phase development | • Anticipated opening year of each major phase, assuming full build-out and occupancy of each phase.<br>• Anticipated year of complete build-out and occupancy.<br>• Adopted transportation plan horizon year, if the development is significantly larger than that included in the adopted plan or travel forecasts for the area.<br>• Five years after opening date if completed by then and there is no significant increase (less than 15 percent) in trip generation from adopted plan or area transportation forecasts. |

Source: ITE, 2012

## D. Data on Existing (Background) Conditions

Existing transportation and land-use conditions near a proposed development are important inputs into a traffic impact study. Analyses should provide a clear picture of the market influence area of the proposed development and show how well roadways, transit facilities, and pedestrian/bicycle networks function currently. Key steps in conducting the existing conditions analysis include:

- Hold background meetings with relevant public agencies.
- Assemble and collate existing traffic, transportation, and land-use information.
- Conduct a field reconnaissance of physical and environmental features, transportation facilities, services, and conditions in the site environs.
- Conduct a travel time study to help define the "reach" and market for the proposed development.
- Obtain information on transit routes, coverage, frequencies, and ridership.
- Obtain data on pedestrian and bicycle routes and access information.
- Obtain existing roadway characteristics, such as width, travel lanes, traffic controls, and geometric features such as gradients, alignments, and signal lanes.
- Review traffic volume studies at key intersections during peak and off-peak periods for weekdays and weekends (daily and hourly).
- Assess existing service levels and transportation conditions (including volume-to-capacity comparison).
- Determine crash experience for at least a three-year period.

The existing conditions analysis and results should be presented in a clearly understandable manner, with the use of parcel location and land-use maps desirable. Bus routes and service coverage should be mapped. Daily traffic volumes are also useful in defining the exposure of a site to passing traffic. Peak-hour traffic flow maps showing intersection turning movements are essential. Travel lanes, traffic controls, and service levels should be mapped as well. Table 19-3 shows the data that should be collected as part of the background analysis.

| Table 19-3. Suggested Background Data for Impact Analysis | |
|---|---|
| **Category** | **Data** |
| **Traffic Volumes** | • Current and (if needed for analysis) historic daily and hourly volume counts, including peak period counts (site and street peaks).<br>• Recent intersection turning movement counts, including right-turns-on-red.<br>• Seasonal variations.<br>• Vehicle classification counts.<br>• Peak period queue lengths.<br>• Projected volumes from previous studies or regional plans.<br>• Relationship of count day to both average and design days.<br>• Posted speed limits.<br>• Prevailing operating speeds.<br>• Travel times. |
| **Land Use** | • Current land use, densities, and occupancy in vicinity of site.<br>• Approved development projects and planned completion dates, densities, and land use types.<br>• Anticipated development on other underdeveloped parcels.<br>• Zoning in vicinity.<br>• Absorption rates by type of development. |
| **Demo-graphics** | • Current and future population and employment within the study area by census tract or transportation analysis zone (as needed for use in site traffic distribution). |
| **Transportation System** | • Current street system characteristics, including direction of flow, number and types of lanes, right-of-way width, type of access control, and traffic control including signal timings, sight distances.<br>• Roadway functional classification.<br>• Route governmental justification.<br>• Adopted local and regional plans.<br>• Planned thoroughfares in the study area and local streets in vicinity of site, including improvements.<br>• Transit service, usage, and stops.<br>• Pedestrian and bicycle linkage, usage, and facilities (for example, sidewalks and bike paths).<br>• Available curb and off-site parking facilities, and parking regulations.<br>• Safety hazards.<br>• Implementation timing, funding source and certainty of funding for study area transportation improvements (whether funded in current capital improvement program). |
| **Other Transportation Data** | • Origin-destination or trip distribution data.<br>• Crash history (3 years, if available) adjacent to site and at nearby major intersections if hazardous condition has been identified. |

Source: ITE, 2012 as edited

The credibility of a traffic impact study to a large extent will depend on the quality of the data collected. Generally, data on traffic volumes and turning movements should not be out-of-date by more than one year, which often requires the agency or a consultant to collect new data (see chapter 2 on data collection). The peaking behavior of adjacent streets, nearby major highways, and parking facilities is of particular interest.

Not only is it important to collect data that focuses on a site's potential impact (for example, turning movements), but it is also important to collect data on non-site traffic that provide a sense of how background traffic will change over time. In particular, through traffic with no origin or destination in the study area as well as traffic generated by all other developments in the study area should be estimated. Methods to do this are discussed later.

## E. Performance Measures

The site impact-related performance measures of most concern to transportation planners are those required by administrative regulations, as well as those desired by local decision makers. Some examples are presented below.

**City of Cambridge, Massachusetts.** The city of Cambridge, Massachusetts, defines "substantial adverse impact on city traffic" and thus the data that must be provided, as: [City of Cambridge, 2014]

*Project vehicle trip generation weekdays and weekends for a 24-hour period and a.m. and p.m. peak vehicle trips*.

The definition of an impact consists of project-based trip generation in excess of:

- 2,000 weekday or weekend (24-hour) trips; or
- 240 peak hour (a.m., p.m., or Saturday midday) trips.

*Change in level of service at identified signalized intersections*.

An impact occurs with the following changes in vehicle level of service (VLOS) at intersections:

| **Existing Vehicle LOS** | **LOS with Project** |
|---|---|
| VLOS A | VLOS C |
| VLOS B, C | VLOS D |
| VLOS D | VLOS D or 7% roadway volume increase |
| VLOS E | 7% roadway volume increase |
| VLOS F | 5% roadway volume increase |

*Increased volume of trips on residential streets*.

An impact is defined based on two parameters. The first is the increase in project-induced traffic volume on any two-block residential street segment in the study area, in excess of:

| **Parameter[1]: Amount of Residential[1]** | **Parameter[2]: Current Peak-hour Street Volume (two-way vehicles)** | | |
|---|---|---|---|
| | **<150 Vehicles per Hour (VPH)** | **150–400 VPH** | **>400 VPH** |
| 1/2 or more | 20 VPH[2] | 30 VPH[2] | 40 VPH[2] |
| >1/3 but <1/2 | 30 VPH[2] | 45 VPH[2] | 60 VPH[2] |
| 1/3 or less | (No max.) | (No max.) | (No max.) |

Notes:

[1] Amount of residential for a two block segment as determined by first floor frontage.

[2] Additional project vehicle trip generation in vehicles per lane, both directions.

The second is the *increase of length of vehicle queues at identified signalized intersections*. A project-induced lane queue or increase in lane queue in excess of the amount allowed in the following table constitutes an impact:

| **Existing Queue** | **Queue With Project** |
|---|---|
| Under 15 vehicles | Under 15 vehicles, or 15+ vehicles with an increase of 6 vehicles |
| 15 or more vehicles | Increase of 6 vehicles |

*Lack of sufficient pedestrian and bicycle facilities*.

Project impact was defined using three criteria:

Criterion 1: A project-induced increase in pedestrian delay at any study area crosswalk in excess of the amount allowed in the following table:

| **Existing Pedestrian Level of Service (PLOS)** | **With Project Must Have:** |
|---|---|
| PLOS A | PLOS A |
| PLOS B | PLOS B |
| PLOS C | PLOS C |
| PLOS D | PLOS D or increase of 3 seconds |
| PLOS E, F | PLOS D |

*Safe Pedestrian Facilities are sidewalks, crosswalks or walkways on any publicly accessible street or right-of-way (ROW) which meet City design standards, including handicap treatments*

Criterion 2: Safe pedestrian facilities must exist on any adjacent publicly accessible street or right-of-way (ROW); and they must connect to site entrances, interior walkways, and adjoining pedestrian facilities.

*Safe bicycle facilities are on-street bicycle lanes or off-road paths along a publicly accessible street or right-of-way which meet city design standards.*

Criterion 3: Where sufficient ROW currently exists, safe bicycle facilities must be in place or sufficient ROW must be preserved on any adjacent publicly accessible street or ROW, and they must connect to site entrances, interior pathways, and adjoining bicycle facilities.

Some examples of how other jurisdictions define "impact" are presented below.

**Virginia DOT.** The Virginia DOT focuses on three impact areas:

1) Development-generated forecast daily and peak-hour traffic volumes on the highway network in the study area, site entrances, and internal roadways, tabulated and presented on diagrams.
2) Delay and LOS (tabulated and presented on diagrams for each lane group).
3) If there is a significant potential for walking, bike, or transit trips either on- or off-site, analyses should be undertaken of pedestrian and bicycle facilities, and bus route or routes and segment(s) (tabulated and presented on diagrams, if facilities exist or are planned). [VDOT, 2015]

**Atlanta Regional Commission, Atlanta, Georgia.** The Atlanta Regional Commission (ARC) looks at a wide range of criteria when examining developments of regional impact (DRIs). The transportation elements of this review include:

- Traffic generated by the development.
- Capacity of the existing and proposed roads.
- Demand management strategies proposed by the developer.

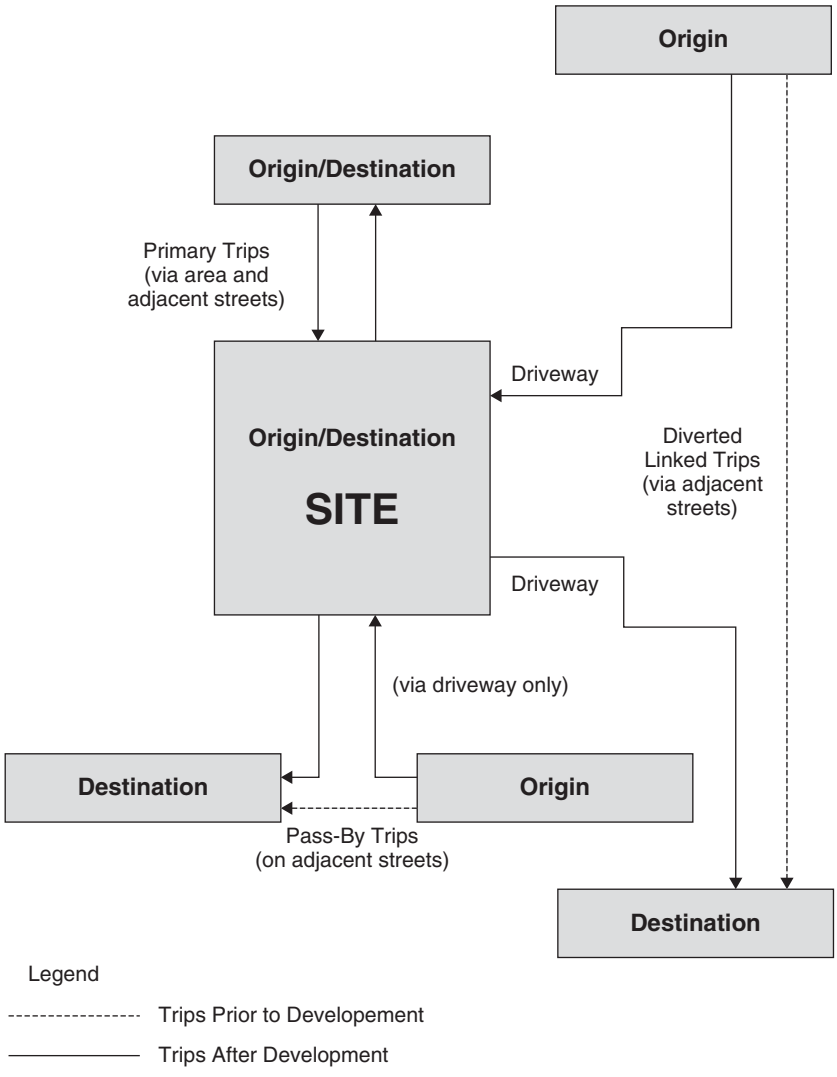
- Air-quality impacts of the DRI-generated traffic.
- Whether the DRI contributes to patterns of development that will reduce average daily miles traveled.
- Rapid transit availability. [ARC, 2013]

As described above, the metrics used for the decision-making process are wide-ranging and emphasize many different issues. Generally, similar direct impacts are measured in almost all cases, such as the number of trips generated, level of service on transportation facilities, and the like. In other cases, these metrics are used as input into further analysis to determine related impacts, such as the amount of motor vehicle-related pollutants generated. The data collected and the tools used for producing this information will clearly depend on information required by the decision-making process.

## F. Travel Demand Analysis

Figure 19-3 shows three major kinds of trips that are part of a site demand analysis. The largest predicted volume will be the *primary origin–destination trips* to and from the development site. *Pass-by trips* are trips made to the site using an adjacent road. Vehicle pass-by trips are not new trips to the adjacent road, but do represent new trips to site driveways (and turning movements). *Vehicle-diverted trips* are those that are attracted to the site, but divert from

**Figure 19-3. Trip Types for Impact Analysis**



Source: ITE, 2012

nearby roads on the road network (not from roads adjacent to the site). Thus, diverted trips are not new to the overall network; they are simply redistributed from their original path.

In addition to these three trip types, there is an "internal capture" of trips for sites that are multiuse and often fairly large. Internal capture reflects those trips that according to the trip generation calculations would be estimated to arrive at the site, but are instead made by a person walking from one part of the site to another (for example, for a cup of coffee or lunch). As such, internal capture trips do not create new trips on the adjacent roads or at the site's driveways.

As an example, assume that a particular land use generates 435 trips as determined by a trip generation equation. Assume that the land use also attracts 40 pass-by trips coming to the site and 25 exiting the site. This means that the 435 driveway trips estimated from the trip generation step would really mean $435 - (40 + 25)$ or 370 new trips on the adjacent roads. Let's assume 10 percent of the trips are internal capture or $0.10 \times 370 = 37$ trips. This means that there will be a final estimated $370 - 37 = 333$ new trips on the adjacent road during the day due to the proposed development.

Anticipated travel demands, traffic volumes, and operating conditions should be developed for each planning horizon year. They should reflect likely growth in background traffic (and transit) volumes during the peak periods; planned changes in the roadways and public transport in the site environs; the type, size, and trip-generating characteristics of the planned development; directions of approach of site traffic volumes and their distribution on the surrounding road system; and combined (site plus background) traffic volumes on roadways and the site environs.

### *1. Background (Non-Site) Traffic Growth*

Several methods can be used for estimating the future volumes of background traffic (see ITE's *Trip Generation Handbook* [ITE, 2012] and the example provided therein on background traffic growth). The simplest approach is to extrapolate from past trends, although this approach is strongly influenced by perturbations in the data (such as the effects of an economic recession). A more detailed approach is to identify major land developments in areas surrounding the proposed development site and assign estimated traffic from these sites to the adjacent road network. The most involved approach is to use a travel demand network model to estimate network link impacts (see chapter 6 for a discussion of travel demand models). Combining the first and second approaches may be desirable in some situations. However, in many major development impact studies, regional and local governments often require the use of computer-based network models to assess likely impacts. No matter which approach is used, the results should be checked for reasonableness. Each method should take into account changes in roadway and transit facilities, such as improving transit service frequency, increasing expressway or arterial roadway capacity, building new roadways, or introducing rail or bus rapid transit lines.

*Growth trends*. Examining local traffic volume growth trends (usually on an equivalent annual basis) works well for short timeframes (less than five years) especially where there is a good local traffic volume database. This approach is simple to use and can produce reasonable results. It is especially well-suited to small developments that will be open in a relatively short timeframe, such as banks and service stations. Generally, at least five years of data are needed. Estimates can be made more reliable by reviewing and comparing growth trends in population, vehicle registration, daily traffic volumes, and peak-hour traffic volumes. Each factor should be indexed to the base (existing) year.

*Build-Up Method*. This method is applicable where there are known projects in the planning horizon (usually five years or less). It involves treating each development (or series of contiguous developments) as a new development. The traffic these developments generate is then assigned to the road system for the design hours under consideration. This approach works best where there is good information on proposed developments. Most jurisdictions only consider approved development for the build-up method, specifically those development parameters that have been vetted and approved by a city or county.

*Subarea Transportation Plan Volumes*. Traffic volumes in transportation plans are usually estimated with the region's travel demand model, which is applied for an assumed transportation network and an assumed land-use pattern. This method is often used for large regional projects that are to be phased in over time. The method is particularly appropriate for use in large population areas and economic growth. Ideally, both daily and peak-hour traffic assignments should be made. With the addition of a new development site, the assumed model inputs might no longer be valid, so using subarea plan volumes needs to occur with caution.

In most cases, and especially for large developments, travel demand models are run with the development site becoming a new traffic analysis zone. This requires the coding of a more refined network. For regional developments, in many

instances, the regional travel demand model is only used for trip distribution, that is, determining which direction trips are coming from or going to from the site. The use of the regional model to assign trips to the local roadway network (the so-called trip assignment process) can be done, if it is part of an agreed upon traffic methodology. However, in those instances, it is good practice to make sure that trips generated by the model match the ITE trip generation estimate for the project minus pass-by trips and internal capture.

Readers interested in additional information on travel demand modeling are referred to chapter 6. Some site-specific analysis aspects of the demand modeling process are discussed below.

### *2. Site Trip Generation*

The number of trips to or from an activity center (person-trips) depends on the type and size of land use. The modes of travel will depend on the site location, development density, character of surrounding areas, and the availability and quality of alternative transportation options. The number of automobile driver (hence vehicle) trips depends on both mode split (percentage of travelers using each available mode of travel) and vehicle occupancy. Some of the key considerations in site trip generation include:

*Person versus vehicle trips*. ITE's multi-volume *Trip Generation* (9$^{th}$ edition) and many trip generation reports prepared by state and local agencies can provide reasonable estimates of the expected number of trips generated. [ITE, 2012] Trip generation rates are available for a variety of settings, although for suburban and exurban settings little or no transit or walk-in traffic is usually estimated. In settings with good transit and pedestrian access, the ITE vehicle trip rates can be adjusted downward to account for the likely percentage of a site's trips that would come as pedestrians or transit riders. Generally, any reduction in vehicle trips to account for pedestrian and transit riders would be agreed to as part of the traffic methodology and require supporting documentation from sites that have similar pedestrian and transit access.

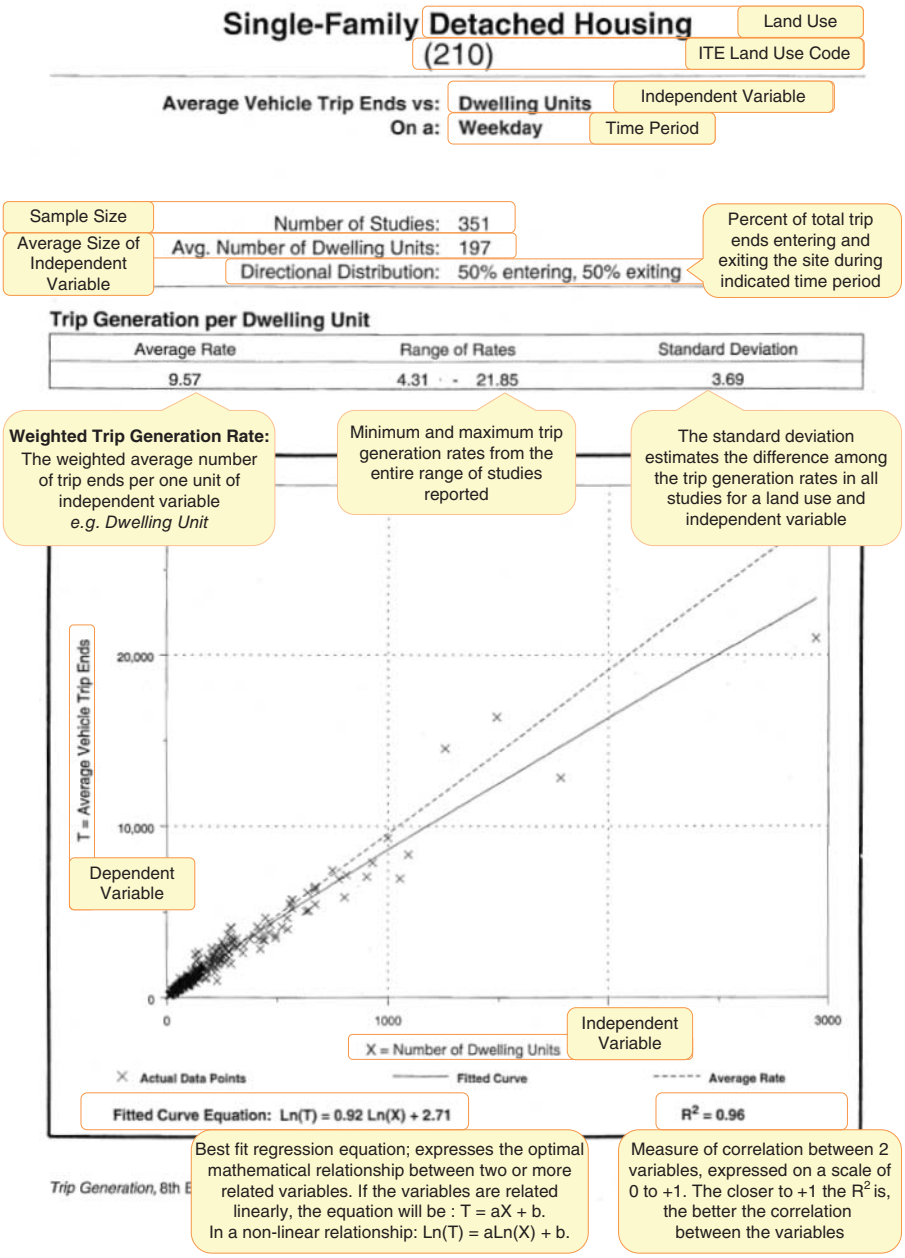
*Trip rates*. Trip generation estimates should be based on local rates for similar types of development. In some cases, it may be desirable to conduct trip generation studies at sites with similar characteristics. Alternatively, rates for similar development in other parts of a state or region may be used where applicable. The important variables in developing trip rates are the independent variables used to estimate trips generated, for example, number of dwelling units, thousands of retail square feet, and the like. Although such variables are given as part of trip generation handbooks and manuals, if it is desired to estimate jurisdiction-specific equations, the choice of the independent variables will be critical. Other means of estimating trip rates include:

- Regression equations can be used when (1) the independent variable lies within the range of data likely associated with the proposed development, (2) there are at least 20 data points, and (3) $R^2 \geq 0.75$. Equations should be used when the actual trip rates decrease as the development size increases. Examples include office buildings and shopping centers.
- Weighted average rates should be used when (1) there are at least three (preferably six) data points, (2) the independent variable lies within the ranges of the data points, and (3) $R^2$ is less than 0.75 or no equation is provided.
- Where the standard deviation is more than 110 percent of the weighted average (for example, the coefficient of variation), additional studies may be desirable (see chapter 2 on data analysis).

The trip rates and trip equations set forth in the ITE *Trip Generation* report and the procedures in the ITE *Trip Generation Manual* are often used by transportation agencies. In some instances, these rates are augmented by additional research (see [Daisa et al., 2013], for example). Equations are preferable to rates where they are available and have high statistical relationship among the key variables. Figure 19-4 shows some of the information that can be found in the ITE *Trip Generation Manual*. [ITE, 2012]

*Analysis hours*. Analyses should be done for the hours of the day when the maximum combined traffic volumes occur on the surrounding road network. They should consider the periods when normal background highway traffic is at a peak as well as when site traffic volumes peak. Given the different activities that occur on individual sites, the study time periods may vary for residential, office, industrial, retail, and recreational developments. Typically, analyses should be done for weekday a.m. and/or p.m. peak hours; however, in some situations, such as major retail developments, Saturday or Sunday peaks should be analyzed. The p.m. peak hour for schools in many instances does not coincide with the surrounding roadway network p.m. peak hour, as the school p.m. peak hour is generally 2–4 p.m. and the surrounding roadway network p.m. peak hour is generally 4–6 p.m. As such, school p.m. peak-hour traffic counts and operational analyses may need to account for this offset from the traditional peak-hour analyses.

**Figure 19-4. ITE Trip Generation Manual Example**



Source: Florida DOT, 2014

Typical time periods that generate peak traffic flows for selected land uses are shown in Table 19-4. Evening hours from 7:00 p.m. to 10:00 p.m. that sometime generate heavy traffic volumes at regional shopping centers should also be studied.

*Multiuse developments:* Multiuse or mixed-use developments bring together office, retail, recreational, and/or residential uses in a single project. Six land uses are the most frequent components of multiuse sites: office, retail, restaurant, residential, cinema, and hotel. This mix of land uses fosters internal travel among various activities, either by car or walking, which reduces the number of vehicle trips entering and leaving the development as compared to the sum of the trips generated by the individual land uses. The number of internal trips (that is, internal capture) varies with the type and size of each use. Past experience suggests that about 20 to 30 percent of the trips to and from retail areas come from office buildings, with the percentages differing for the noon time and p.m. peak hours. Smaller amounts of interchange take place between retail and residential and office and residential. Reported internal capture rates for multiuse centers are shown in Tables 19-5 to 19-8 from NCHRP Report 684, *Enhancing Internal Trip Capture Estimation for Mixed-Use Developments*. [Bochner et al., 2011]

| Table 19-4. Typical Peak Traffic Flow Hours for Selected Land Uses | | |
|---|---|---|
| **Land Use** | **Typical Peak Hours** | **Peak Direction** |
| Residential | 7:00–9:00 a.m. weekdays | Outbound |
| | 4:00–6:00 p.m. weekdays | Inbound |
| Regional Shopping | 5:00–6:00 p.m. weekdays | Total |
| | 1:00–2:00 Saturdays | Inbound |
| | 4:00–5:00 Saturdays | Outbound |
| Office | 7:00–9:00 a.m. weekdays | Inbound |
| | 4:00–6:00 weekdays | Outbound |
| Industrial | Varies with employee shift schedule | – |
| Recreational | Varies with type of activity | – |

Activities in central business districts (CBDs) and other densely developed districts usually draw many patrons from nearby origins. In these cases, rather than dealing with internal capture, the primary destinations for each use should be estimated. Retail stores and restaurants, for example, may draw large numbers of patrons from nearby offices and would have vehicle trip generation rates considerably less than those cited in the ITE manuals.

### *3. Pass-By Trips*

As noted earlier, some of the trips generated by new developments will come from currently passing traffic. These pass-by trips have the effect of reducing the anticipated development-generated traffic volumes on the surrounding road system, although the access (driveway) volumes into a site would remain unchanged.

Trips diverted to boundary roads from other roadways to reach a site would not add traffic to the roadways in an area, but may increase traffic on the roads serving a site. These diverted trips are normally treated as part of a site's generated traffic; pass-by trips are deducted from the boundary road traffic.

The proportion of a site's traffic coming from the passing traffic depends on the type and size of development, and whether an activity is a destination in itself or merely a stop along a trip path, for example, an office building versus a gas station. (Up to 50 percent of all trips to a service station have been found to be travelers passing by rather than people who made a special trip to the gas station). Generally, as developments increase in size, there is a corresponding reduction in the proportion of pass-by traffic. This is apparent from the percentages reported for shopping centers as shown below.

| Net square feet of floor space for shopping centers | Percent of pass-by trips |
|---|---|
| <100,000 | 40% |
| 100,000–250,000 | 30% |
| 250,000–500,000 | 25% |
| 500,000–750,000 | 22% |
| Over 750,000 | 20% |

The percentages of pass-by trips for various land uses are reported in ITE's *Trip Generation* [2012]. Because of limited data and high variability, adjustments should be applied carefully.

*Travel demand management (TDM) impacts*. The primary purpose of TDM strategies is to influence travel demand, usually targeted at reducing the number of single-occupant vehicles accessing a site during peak periods. They work best in activity centers with a large employment base, often with a single or only a few employers. Employer-based TDM programs normally include preferential parking for vanpools and carpools, company endowment of vans, transit passes, ridesharing coordination at large employers, and flextime. Public sector incentives include free parking at freeway interchanges, financial support of public transport, provision of HOV and high-occupancy toll lanes, and developer agreements to encourage ridesharing (see chapter 14 on travel demand management).

As part of the trip generation analysis, summary tables should list each type of land use, its size, and proposed vehicle trip generation rates for daily, a.m./p.m. peaks, and other peak periods of interest. Deductions may then be necessary for internal trips and multiuse sites, TDM actions, and activities displaced by the development.

In some cases, trip reduction policies have been adopted by transportation agencies and are encouraged as part of the traffic impact study. In Massachusetts, for example, the state's *Mode Shift Initiative* has established a statewide mode shift goal of tripling the share of travel by bicycling, transit, and walking. All elements of the site impact analysis and the project proposal—trip generation, mode split, trip distribution, adjustment factors, parking, siting, and others—must show how the proposed mitigation will help achieve this target.

In Calgary, Alberta, active transportation modes such as walking and bicycling must be considered as part of the impact analysis. Where expected volumes cannot be forecast, default values are to be used, including:

- *Very Low-Impact Areas*: 10 pedestrians/hour and 5 bicycles/hour.
- *Low-Impact Areas*: 25 pedestrians/hour and 10 bicycles/hour.
- *Moderate-Impact Areas:* 50 pedestrians/hour and 20 bicycles/hour. [City of Calgary, 2011]

The review is also to include a qualitative assessment of the connectivity of the proposed development to the region's primary transit and cycling network, and the regional pathway system.

*Freight or goods movement*. The following questions relating to truck movements in the study area should be considered in the analysis:

- What is the existing percentage of trucks in the study area?
- Are there existing truck safety issues in the study area? Will the proposed development sustain or improve these conditions?
- How will the specific land uses and businesses for the proposed development affect truck trip generation?
- When will the peak hour of truck trip generation occur?
- How will trucks be routed and circulated on-site and off-site?
- How will queuing at driveways and intersections be affected by truck trip generation?
- Will truck trip generation adversely impact site access?
- Will there be sufficient truck turning radii?
- Will a separate truck access point be needed to minimize conflicts between trucks and other vehicles?
- Will deceleration lanes at the site access point be needed to maintain safety?
- How will trucks affect access, circulation, and operations at the proposed development's access points? For the entire study area? [City of Fontana, 2003; McRae et al., 2006]

Freight planning and in particular truck trip generation is discussed in chapter 22 on freight planning.

### *4. Site Trip Distribution*

The direction of approach of vehicle and transit trips should be estimated for the roadways entering the site environs. Trip distribution for proposed developments can be determined from zip code data, census data, market research, travel demand forecasting models, existing travel patterns, and/or the location of complementary land uses. The relative magnitudes of site-generated traffic should be assigned to the boundary roads and access points based on the specific building footprints and the relative square footage of development at various locations at a development site. Trip distribution will depend upon site-specific factors, such as:

- Existing travel patterns.
- Type and size of the proposed development.

- Size of the influence areas.
- Surrounding land uses.
- Locations of competing developments (for example, shopping centers).
- Population and purchasing power distribution.
- Transport system availability, characteristics, and travel times.
- Planned transportation improvements.

Because a combination of these factors will likely be found at any particular site, local codes and ordinances should not require the use of specific traffic distribution techniques. The analyst should be allowed to exercise appropriate judgment, although assumptions and methods of analysis should be clearly stated.

The Oregon DOT identifies three methods that can be used to distribute trips in the study area. [ODOT, 2014]

*Analogy Method*. The analogy method uses traffic information from a similar development to predict trip distribution for the proposed development. This can be accomplished by various methods including driver surveys, license plate origin-destination studies, and driveway turning movement counts. This method is generally acceptable for small to midsized developments such as:

- Fast-food restaurants where a competing establishment is near the site.
- Service stations where traffic volumes on the adjacent streets are similar to those forecasted at the site.
- Motel sites near an existing motel.
- Residential developments on the fringe of an urban area.
- Sites to be developed for residential use, where the tract is one of the few vacant parcels in a developed area.
- Occupied buildings located in an office complex being developed by phases.

*Travel Demand Model*. A travel demand model can be effective in estimating traffic distribution patterns, especially for very large developments where a large number of trips is to be generated or attracted. Because travel demand models are typically developed in conjunction with a transportation system plan and comprehensive plan, they can provide a reliable forecast for fast-growing urban areas. The traffic analysis zone (TAZ) containing the proposed development should be investigated closely to ensure land uses, development densities, and trip-making characteristics are modeled consistent with existing conditions (see chapter 6 on travel demand modeling). The steps for using a travel demand model include:

- Interpolate the land-use and socioeconomic data sets to project conditions for the build-out year of the development phase or project.
- Verify that the transportation network includes only existing plus committed facilities.
- Create a new traffic analysis zone for the proposed project. Within this new zone, input the amount of development proposed for the project. Apply the model to determine the project traffic distribution.
- Determine total trips generated by the new zone, so that the percentage of project trips assigned by the model can be determined.
- If there are additional roadways that should be part of the study area network and are not included in the model, then a post-model adjustment can be made to distribute traffic to these facilities.
- Calculate the percentage of trips assigned to each roadway segment in the project vicinity.
- Multiply the percentage of project traffic by the external trips generated. [GRTA, 2013]

*Surrogate Data*. Surrogate data uses related information other than direct causal variables to represent the influence and impacts of a development on the distribution of trips to and from a site. An example is using the distribution

of residential population in the region or study area as a surrogate for the direction of trips approaching office and retail land uses. For example, if 50 percent of the residential population relating to a site location is found southeast of the site, one can assume that 50 percent of the site trips would be coming from this direction. This method can accurately estimate trip distribution when used cautiously and for appropriate land uses. It also requires a database of usable socioeconomic and demographic information for various parts of the city.

In cases where market analyses have been conducted for a property or development, it may be appropriate to use the results of this analysis as a means of developing project traffic distribution. This information can be used at the discretion of the applicant, but should be approved by the reviewing agency prior to proceeding with the study.

A synthesis of traffic impact analysis procedures for the Oregon DOT examined best practices in the different methods and tools used by communities and consultants to do site impact studies. Some of the methods used to distribute traffic volumes included:

- Regional travel demand model.
- Existing street circulation system and a review of the existing traffic volumes, circulation patterns, and intersection turning movements.
- Market analysis provided by the retail store.
- Surveys of those who will be using service to determine residence location (by zip code) and mode of transportation.
- Population density and traffic analysis judgment.
- Percentage of local trips versus regional trips and analysis of the distribution of local traffic of residential areas. [McRae et al., 2006]

The report showed that the trip distribution forecasts for two of the sites were within 20 percent of the actual trip distribution after the development was built. New access control, no infrastructure improvements, and stagnant economic growth in the site vicinity were used to explain why this difference occurred. The report concluded that not including expected or predicted other development in the traffic impact study can have a significant effect on trip distribution estimates, especially if the site is not built as assumed.

The Washington State DOT encourages the use of scenarios, especially for large development sites, to account for possible other development impacts. Scenarios can range from simple "existing conditions with and without project," to more complex analyses where scenarios could include: existing, opening year with and without the project, interim years with and without the project, and design year with and without the project. [Washington State DOT, 2004] The DOT recommends for interim scenario networks that only projects or developments within the forecasting process having the highest probability of occurring within a 10-year horizon be included in the analysis. The city of San Jose recommends a "cumulative conditions" scenario to determine the combined effect of multiple pending projects or foreseeable developments with individually limited impacts on the transportation system. [City of San Jose, 2009]

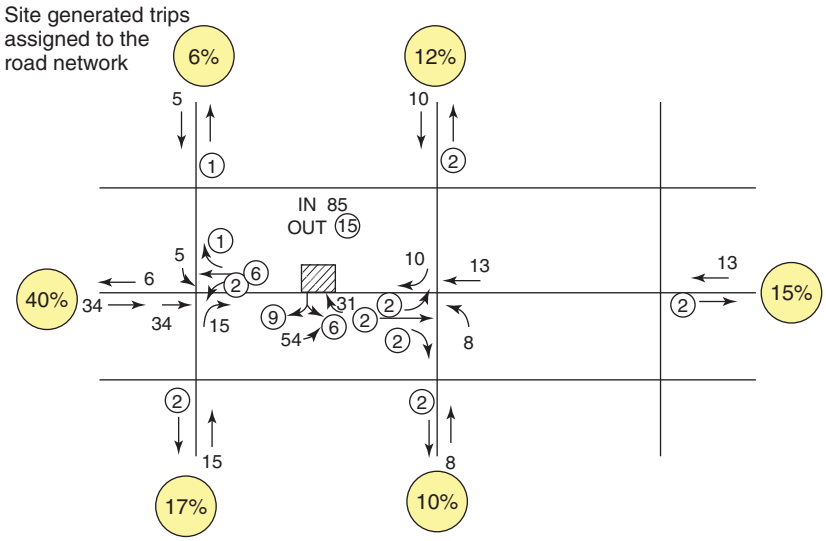
Trip distribution should be expressed as percentages by direction (see Figure 19-5). A table should be prepared showing directions of approach for each community within the trade area. These percentages and their resulting assignment to the road network should then be applied to the anticipated site trip generation to obtain design plans for each part of the road system.

Where transit and walk-in traffic is likely, directions of approach should be estimated for each mode. This requires modal allocations of person trips for each analysis area. The relative origins for each mode can then be assigned to roadways, transit routes, and walkways. In the immediate site environs, transit riders should be assigned to specific bus stops and rail stations, if appropriate. Walk-in trips, which are mainly from nearby areas, should be assigned to the street crossings and walkway system serving the site.

### *5. Trip Assignment*

The combined (composite) traffic volumes for public street and site access roadways should be developed for each future condition analyzed. This involves adding the component of future background traffic and the expected site traffic on each network link and making needed adjustments for pass-by traffic. The traffic volumes should show each

**Figure 19-5. Example Trip Distribution for Site Impact Analysis**



Source: FHWA, 1985

traffic flow for through, left, and right turns. Anticipated pedestrian flows can be superimposed on these diagrams. They should be plotted on site maps and checked for reasonableness. These resulting combined peak-hour traffic volumes should be compared with the available roadway capacity to assess system adequacy, the need for roadway improvements, and the design of site access points. This comparison is done by assigning trips to the transportation network.

Trip assignment involves determining the amount of traffic that will follow certain paths in a roadway network. The trip assignment will illustrate the project-generated trips, by direction and turning movement, on each roadway segment of the study area. The procedure consists of assigning the project-generated traffic to the roadway network according to the trip distribution for each proposed land use, accounting for any turning movement restrictions (for example, one-way streets, ramps, movement restrictions and raised median islands, and so forth), or other unique roadway characteristics including excessive congestion. If using a travel demand model, this process is simply part of the modeling effort. If assigning trips manually to the network, several factors should be considered:

- Traffic assignment should consider logical routings, available roadway capacities, turning movements, and expected travel times (the basic goal of trip assignment is to follow the least travel time path).
- Multiple paths between origins and destinations should be used to achieve realistic results (assuming multiple paths exist).
- Assignments for future years should consider likely land use and traffic conditions in the target year.
- Assignments should be carried through the external site access points and, in large projects, on the internal roadways.
- When a site has more than one access point, logical routing and multiple paths should be used to obtain realistic driveway volumes. [ITE, 2010]

Readers are referred to [Giaimo, 2001] for a good reference on traffic assignment procedures as applied in site impact analysis.

## VI. ANALYSIS PROCEDURES

The type and extent of analysis will depend not only on the characteristics of the development itself, but also on the types of improvements likely to be considered. Typical improvements are shown in Table 19-9 and are described further in ITE [2010].

| Table 19-9. Typical Site Transportation Improvements |
|---|
| **Roadways** |
| • Install a traffic signal or roundabout.<br>• Coordinate signals on common cycles along boundary and approach roads.<br>• Provide right-and/or left-turn lanes.<br>• Add through lanes.<br>• Expand and/or improve intersections.<br>• Channelization, such as turn lanes or raids.<br>• Frontage improvements.<br>• Install two-way left-turn lanes, where appropriate.<br>• Install physical median (the median may be discontinued to allow only left turns into development of minor streets, or provide all movements at intersection).<br>• Remove shrubbery or otherwise improve sight distance.<br>• Widen access drives.<br>• Consolidate or close driveways (develop shared access driveways).<br>• Limit access drives to right turn exits only.<br>• Establish one-way access drives.<br>• Construct a "backage" road.<br>• Widen and/or locate interchange ramps.<br>• Construct "flyovers" or "flyunders" along artery at major junctions.<br>• Reconfigure freeway interchange.<br>• Construct new freeway interchange. |
| **Transit** |
| • Add bus stops/ shelters.<br>• Install a new bus route.<br>• Improve bus service frequency.<br>• Route buses to stops at heart of development.<br>• Establish a transit center within a development.<br>• Develop a new bus rapid or light rail transit route with good pedestrian access to development. |
| **Pedestrians/Bicyclists** |
| • Provide sidewalks on perimeter road.<br>• Install crosswalks, preferably with a central refuge area.<br>• Accommodations for bicycles such as bike lanes, bike boulevard treatments, bike parking.<br>• Construct walks from surrounding roads to development.<br>• Construct weather-protected skyways that connect developments with express transit way stations, or avoid major highway crossing. |
| **Travel Demand Management** |
| • Create transportation management association (TMA).<br>• Establish rideshare programs, subsidized if possible.<br>• Limit and/or price commuter parking.<br>• Carpool incentives, such as preferred parking.<br>• Consider flex-time and telecommute work programs, where appropriate. |

Source: ITE, 2010

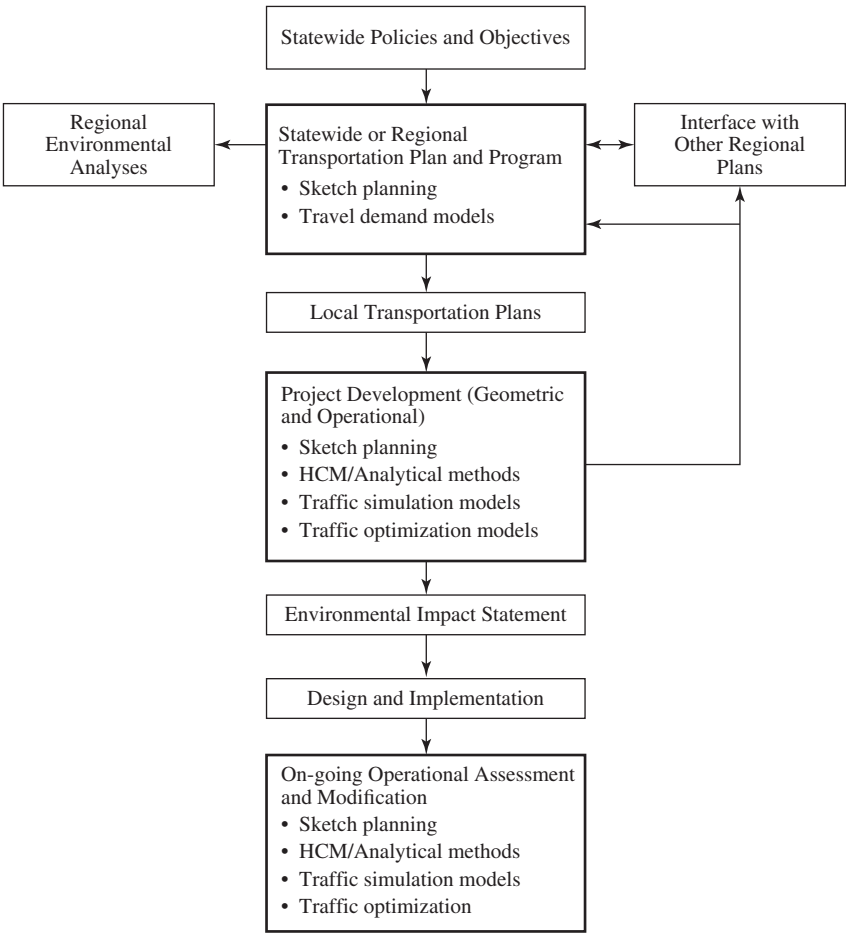
Anticipated traffic, transit, and pedestrian volumes provide the basis for assessing the workability of the existing transportation and recommended improvements. When improvements are added, service-level computations can indicate how well the facilities operate. This is often an iterative process depending on the scale of developments and the amount of background traffic growth. Ideally, needed improvements should be consistent with those planned or programmed by public agencies. Multimodal assessments are essential in densely developed areas and for large mixed-use or commercial developments.

## A. Choice of Models or Tools

The selection of analysis tools and methods will depend on the evaluation criteria agreed upon at the beginning of the study. In most cases, some measure of level of service and quality of service is used to estimate system impact. In the United States, this usually means using procedures from the Transportation Research Board's *Highway Capacity Manual* (HCM) [TRB, 2010] and the *Transit Capacity and Quality of Service Manual* (TCQSM). [Kittelson et al., 2013a] In addition, there are specialized methods and approaches for active transportation modes.

The FHWA *Traffic Analysis Toolbox*, Volume 2, provides a methodology for selecting traffic analysis tools. [Jeannotte et al., 2004] Figure 19-6 shows the relationship among the many different traffic analysis tools used by transportation engineers and planners. The different types of tools, as excerpted from the report, were described in the *Toolbox* as:

**Figure 19-6. Overview of the Traffic Analysis Process**



Note: Boxes outlined by a bold line represent the primary realm of application of traffic analysis tools.

Source: Jeannotte et al., 2004

*Sketch-Planning Tools*. Sketch-planning methodologies and tools produce general order-of-magnitude estimates of travel demand and traffic operations in response to transportation improvements. They allow for the evaluation of specific projects or alternatives without conducting an in-depth engineering analysis. Sketch-planning tools perform some or all of the functions of other analytical tools using simplified techniques and highly aggregate data.

*Travel Demand Models*. Travel demand models have specific analysis capabilities, such as the prediction of travel demand and the consideration of destination choice, mode choice, time-of-day travel choice, and route choice in the highway network. These are mathematical models that forecast future travel demand based on current conditions and future projections of household and employment characteristics.

*Analytical/Deterministic Tools (HCM-Based)*. Most analytical/deterministic tools implement the procedures of the HCM. The HCM procedures are closed-form, macroscopic, deterministic, and static analysis procedures that estimate capacity and performance measures to determine level of service (for example, density, speed, and delay). They are closed-form because they are not iterative. The practitioner inputs the data and the parameters and, after a sequence of analysis steps, the HCM procedures produce a single answer. Analysis/deterministic tools are good for analyzing the performance of isolated or small-scale transportation facilities; however, they are limited in their ability to analyze network or system effects.

*Traffic Signal Optimization Tools*. Similar to the analytical/deterministic tools, traffic optimization tool methodologies are mostly based on the HCM procedures. However, traffic optimization tools are designed to develop optimal signal phasing and timing plans for isolated signal intersections, arterial streets, or signal networks. This may include capacity calculations, signal cycle length, signal split optimization (including turn phasing), and coordination/offset plans.

**Table 19-10. Comparison of Analysis Tools and Spatial Application**

| Analytical Context/ Geographic Scope | Sketch Planning | Travel Demand Models | Analytical/ Deterministic Tools (HCM-based) | Traffic Optimization | Macro Simulation | Meso Simulation | Micro Simulation |

*Macroscopic Simulation Models*. Macroscopic simulation models are based on the deterministic relationships among flow, speed, and density of the traffic stream. The simulation in a macroscopic model takes place on a section-by-section basis rather than by tracking individual vehicles. Macroscopic simulation models were originally developed to model traffic in transportation subnetworks, such as freeways, corridors (including freeways and parallel arterials), surface-street grid networks, and rural highways.

*Mesoscopic Simulation Models*. Mesoscopic models combine the properties of both microscopic (discussed below) and macroscopic simulation models. As in microscopic models, the unit of traffic flow for mesoscopic models is the individual vehicle. Similar to microscopic simulation models, mesoscopic tools assign vehicle types and consider driver behavior, as well as their relationships with roadway characteristics. Mesoscopic model travel prediction takes place on an aggregate level and does not consider dynamic speed/volume relationships.

*Microscopic Simulation Models*. Microscopic simulation models simulate the movement of individual vehicles based on car-following and lane-changing algorithms. Typically, vehicles enter a transportation network using a statistical distribution of arrivals (a stochastic process) and are tracked through the network over brief time intervals (for example, 1 second or a fraction of a second). In many microscopic simulation models, the traffic operational characteristics of each vehicle are based on well-known influences on vehicle dynamics of such things as road grade, horizontal road curvature, and pavement superelevation.

Each tool and method has its own application context. Table 19-10, for example, shows the usefulness of each of the analysis tools with respect to the scale of analysis; Table 19-11 shows the relationship between the tools and type of facility; and Table 19-12 shows similar information for different performance measures.

Source: Jeannotte et al., 2004

Transportation planners should be aware of the strengths and weaknesses of each type of model and tool that can be used for impact analysis. In some cases, jurisdictions provide guidance on which tools are acceptable. Washington State DOT, for example, provides the following information on acceptable tools for travel impact analysis:

- *Freeway Segments*: Highway Capacity Manual/Software (HCM/S); operational and design analysis—macroscopic, mesoscopic, and microsimulation.
- *Weaving Areas*: Design manual (DM), HCM/S, operational and design analysis, microsimulation.
- *Ramps and Ramp Terminals:* HCM/S, operational and design analysis, DM, microsimulation.
- *Multilane Highways*: HCM/S; operational and design analysis—macroscopic, mesoscopic, and microsimulation.
- *Two-Lane Highways:* HCM/S, operational and design analysis.

- *Intersection, Signalized:* Sidra, Synchro, SimTraffic, HCM/S, Vissim.
- *Intersection, Roundabout:* Sidra, Rodel, HCM, Vissim.
- *Corridors:* Sidra, Synchro, SimTraffic, HCM, Vissim.
- *Stop-Controlled Intersections:* HCM/S for capacity, DM Chapter 1330 and the MUTCD for signal warrants (if a signal is being considered).
- *Transit:* HCM/S, operational and design analysis, *Traffic Manual*.
- *Pedestrians:* HCM/S.
- *Bicycles*: HCM/S.
- *WSDOT Criteria/Warrants:* MUTCD (signals, stop signs), *Traffic Manual* (school crossings), DM Chapter 1040 (freeway lighting, conventional highway lighting).
- *Channelization:* DM. [WSDOT, 2014, 2015]

The following discussion on the analysis of facility performance focuses on three types of facilities: intersections, road segments and corridors, and networks. Many of the models and tools described above can be used for analyzing facility and system performance at different scales of analysis.

## B. Intersections

All intersections likely to be significantly impacted by the addition of project-generated traffic, that is, those now likely to experience operational problems or where a traffic signal warrant threshold might be triggered, should be part of the impact analysis. The HCM and accompanying software provides a methodology for assessing the level of service impact on intersections. [TRB, 2010] The reader is directed to this manual for a detailed discussion of the methods and approaches for estimating level of service. For intersection analysis the concept of a "lane group" is important. A lane group is a lane or group of lanes designated for separate analysis, which includes lanes that exclusively serve one movement through the intersection as well as each lane that is shared by one or more movements.

Table 19-13 shows the level of service for signalized intersections as defined in the amount of delay (seconds/vehicle) and the volume-to-capacity ratio of approaching intersection legs. Note that any volume-to-capacity ratio greater than 1.0 is considered LOS F. To give some sense of the type of data that is needed to estimate intersection level of service, Table 19-14 shows required data and the basis upon which the data are input into the calculations.

Level of service impacts should be estimated for transit, bicycles, and pedestrians as well as for automobiles. A variety of methods are used to define the performance of pedestrian and bicycle facilities, including an approach found in the HCM. Transit level of service can be analyzed with the TCQSM. Table 19-15 shows the LOS score and corresponding level of service based on what travelers have defined as being important aspects of walking and bicycling. Based on the perceived desirable characteristics of active transportation options, the HCM software package produces the score shown in the table. Some sense of these characteristics is shown in Table 19-16, which lists the input data for this process.

**Table 19-13. Level of Service for Signalized Intersections**

| Control Delay (s/veh) | LOS by Volume to Capacity Ratio ≤1.0 |
|---|---|
| ≤10 | A |
| >10–20 | B |
| >20–35 | C |
| >35–55 | D |
| >55–80 | E |
| >80 | F |

The city of Cambridge, Massachusetts, provides an example of a pedestrian and bicycle methodology that includes more than just the HCM material. [City of Cambridge, 2014] The city requires an analysis of pedestrian level of service for the a.m. and p.m. peak hour of pedestrian demand at all study area intersections and crosswalks that have project vehicle trips and project pedestrian trips accessing transit. The results are to be reported for each crosswalk. In addition, pedestrian crossing gaps at unprotected crosswalks are to be analyzed (those without signal or stop control) as well as midblock crosswalks. The minimum acceptable gap at each crossing and thus the number of gaps available during the peak hour is computed as:

$$G_{min} = (W/S) + R \quad (19\text{-}1)$$

where,

W = crossing distance (ft)
S = walking speed (3.5 ft/sec. unless otherwise approved)
R = pedestrian start-up time (3 sec. unless otherwise approved)

A yielding survey (a survey of number of vehicles yielding right of way to a pedestrian) should be conducted when the number of minimum gaps falls below 60/hour; and an analysis should be done of pedestrian access to/from the site within a one-block radius and along principal access routes (to and from transit, parking, nearby retail, and so forth).

For bicycles, the analysis should:

- Identify conflicting vehicle turning movements at all study area intersections where bicycle facilities are present or peak-hour bicycle volume exceeds 10 on any approach.
- Evaluate bicycle access to the site along streets and at intersections along all paths where vehicle trips are distributed or on likely suitable alternatives including roadway cross sections, presence of bicycle facilities, and ability to install new on- and off-street bike facilities.
- Evaluate available bicycle parking on- and off-site, including access to parking, quality of facilities, and site security.

Readers interested in other methods for assessing the performance of pedestrian and bicycle facilities should see chapter 13.

Transportation safety should be part of every impact study. For example, the Virginia DOT [2014] requires a crash history for roadway segments or intersections that compares the overall crash record for similar locations, with particular attention to severe crash density and rates. For longer segments, corridors should be divided into sections of similar configuration and environments (for example, cross sections, terrain, and adjacent land-use/driveway density). The analysis should be a trial and error refinement of the most important causal factors. Histograms or counts of the total crashes, deaths plus injuries, and collision types (summing to total crashes) should be presented as part of the crash analysis. Readers are referred to chapter 23 for additional ways to assess safety performance.

Some jurisdictions also require a queue analysis as part of the intersection assessment (a queue is a line of vehicles waiting to enter the intersection). In Massachusetts, for example, both a 50th (average) and 95th percentile "Back of Queue" calculation needs to be provided as part of the study, including graphical representations of 50th and 95th percentile queue lengths at select study intersections. Queue analysis can be conducted using Highway Capacity Software or with proprietary software (such as Synchro™).

Table 19-17 shows a typical report on intersection analysis from the Oregon DOT [2014]. Note this illustration is only for automobile level of service and does not include impacts for non-automobile users.

Per Oregon DOT's impact study requirements, if a new signal is being proposed, the traffic impact study should investigate whether the impact:

- Clearly indicates the need for a traffic signal.
- Downgrades the ability of existing, planned, and proposed public roads to accommodate the traffic away from the state facility.
- Affects study area intersections. [ODOT, 2014]

| Table 19-17. Example Traffic Operations Impact for Traffic Impact Report, Oregon DOT | | | | | |
|---|---|---|---|---|---|
| | | Weekday PM Peak Hour | | Saturday Mid-day Peak Hour | |

| SW Sagert St./SW Martinazzi Ave. | D | F | N/A | Not analyzed | Not analyzed |

Note: LOS and V/C reported for the highest delay of critical movement

Source: ODOT, 2014

In addition, proposed right or left turn lanes at unsignalized intersections and private approach roads must meet the installation criteria in the adopted design manual.

From the perspective of travel safety, most impact guidelines require that adequate intersection sight distance be provided at all study intersections and highway approaches. Intersection sight distance is the standard for the location of approaches to a highway; stopping sight distance is a lower standard that may be used in some cases. Sight distance should meet the jurisdiction's design standards or those adopted from other sources (such as AASHTO's *A Policy on Geometric Design of Highways and Streets*).

The actions proposed for intersection mitigation should be identified and explained in the impact report. Transportation system improvements should be recommended for all locations predicted to fail a performance measure, and should include at least intersection geometry improvements, signal controls and equipment, signal timing, pavement markings, and curb cut locations; pedestrian crossing markings, pedestrian signals, and sidewalks; and bicycle lanes, bicycle signals, off-street bicycle facilities, and the like. Transit-related actions that are oriented to intersection performance should also be included.

## C. Corridors

Freeway and arterial corridors could be affected by the additional traffic generated by a new development. The HCM defines three types of highways that could conceivably be part of an affected corridor for the impact study: freeways, uninterrupted flow highways, and interrupted flow roadways. Interrupted flow roadways are those with intersections. As noted by the Florida DOT, "It is widely recognized that signalized intersections are the arterial's primary capacity constraint; it is appropriate to place more emphasis on the intersections' characteristics than midblock characteristics. Generally, midblock segments have capacities far exceeding those of major intersections and it is rare for significant delays to occur midblock. By weighting the effects of intersections more heavily, a more accurate aggregate estimation is possible." [FDOT, 2013]

In San Jose, California, the traffic impact analysis regulations require an assessment of freeway segments if the project is expected to add traffic equal to at least one percent of the freeway segment's capacity. [City of San Jose, 2009] Freeway segments are evaluated using a procedure based on the density of traffic flow found in the HCM. Density is expressed in passenger cars per mile per lane. For calculating the percentage of project-generated traffic based on the freeway segment capacity, the following ideal capacities are used: 2,200 vehicles per hour per lane (vphpl) for four-lane freeway segments and 2,300 vphpl for six-lane or larger freeway segments. For five-lane freeway segments, 2,200 vphpl is used for the two-lane direction and 2,300 vphpl for the three-lane direction.

The Florida DOT has developed planning software for both arterials and freeways that implement many of the concepts in the HCM as well as the TCQSM. [FDOT, 2013] For example, ARTPLAN is FDOT's multimodal conceptual planning software for arterial facilities that is based on the HCM's urban streets methodology. For automobile estimates, it provides a simplified LOS analysis of the through movement on a road segment or at a signalized intersection. ARTPLAN utilizes average travel speed solely as the service measure. For bicycles and pedestrians, ARTPLAN uses

the planning application of the bicycle LOS methodology and the pedestrian methodologies in the HCM. For bus, ARTPLAN is the conceptual planning application of the TCQSM methodology applied to bus route segments and roadway facilities. It should be noted that the FDOT ARTPLAN software is a generalized tool for assessing LOS, since there are a large number of default assumptions (that is, peak-hour travel characteristics) used in deriving the LOS. The FDOT software provides a good tool for those interested in looking at both automobile and non-automobile travel flows on a network. For use in traffic impact analysis, however, the user of the tool needs to be aware of the key differences between the tool and the HCM, which the guidance document clearly articulates.

The approaches to highway/roadway capacity and level of service estimation are covered in more detail in chapter 9 on roadway and highway planning. Readers should refer to this material because it provides the analysis foundation for determining the impact of new trips being generated on roadway performance. However, several concepts relating to transit level of service will be discussed here because site-related impacts on transit service will likely occur on a corridor basis, not at the intersection or network level.

Transit-related impacts due to a new development present both positive and potentially negative effects (if not mitigated). The positive effect is the additional riders that will now use transit to and from the site, in the process both reducing expected automobile trips and adding new revenues to the transit system. The negative effect from a corridor perspective is that a new stop (or stops) or a deviation of the route into the development site will add additional time to the bus trip time and possibly reduce the level of service to the other riders in the corridor. Mitigating this effect might require an additional bus added to the route to maintain required headways.

The following discussion focuses on two transit impacts—the need for transit amenities at the new development site to attract transit riders, and the potential impacts on the corridor transit service.

***1. On- or Near-Site Transit Service Characteristics***

The types of amenities provided at a bus stop (for example, at the new development site) can influence travelers' desires to ride transit. For example, as noted in the TCQSM, the value of time and how it is perceived with respect to transit service is a contributing factor in one's decision to use transit. Table 19-18 shows the relative weight in terms of value of time of different transit amenities. As can be seen, paying attention to the environment within which transit riders travel can be critical to the success of a site impact mitigation strategy.

Figure 19-7 shows a potential transit rider decision-making process that provides a good indication of the desired types of amenities and service characteristics. For example, the second box in the figure suggests that bus stop locations in reference to a new development are key indicators of transit desirability. The third box suggests the same for schedule information. This figure can be used to determine different mitigation strategies that might be part of an overall TDM program for a proposed development site.

Table 19-19 shows the amount of time it takes on average for a person to cross a road of varying number of lanes to reach a transit stop on the other side. Not only does this add to the access time for a person to reach a transit stop, but it also affects the amount of time a traffic signal must provide for safe crossing.

**Table 19-18. Relative Weights of Transit Amenities According to Riders**

| Amenity | In-vehicle Travel Time Equivalent (mins) |
|---|---|
| Shelter with roof and end panel | 1.3 |
| Basic shelter | 1.1 |
| Lighting | 0.7 |
| Molded seats | 0.8 |
| Flip seats | 0.5 |
| Bench | 0.2 |
| Dirty bus stop | −2.8 |

Note: Positive values indicate a positive feature

Studies reported in Kittelson et al. [2013b] suggest that most transit riders will walk 0.25 mile (400 m) or less to bus stops, or about five minutes. A 2010 study in Montreal found somewhat longer walking distances; about half of those walking to bus stops walked more than 0.25 mile. For rail stations, one can assume a reasonable walking distance is about 0.5 miles (800 m), although this will vary from one locale to another. As suggested by Table 19-18, an unsafe or poorly maintained pedestrian environment, no matter how close to the stop, will discourage transit ridership.

In addition, those wishing to encourage bicycle transportation should examine ways of incorporating bicycles into transit services. Many bicyclists want to bring their bicycle with them on board transit vehicles (in 2011, about 74 percent of new U.S. buses were equipped with exterior bicycle racks, up from 32 percent in 2001). Bicycle racks allow bicyclists to transfer to a bus and use transit to access a site some distance away. Alternatives to bringing bikes on board transit vehicles include providing bicycle storage at the boarding stop and bike-sharing programs.

### *2. Off-Site Transit Corridor Performance Characteristics*

The TCQSM provides detailed explanations of how transit capacity and service performance can be analyzed. In addition, readers are referred to chapter 12 on transit planning for a similar discussion. The key concepts in the TQCSM as they relate to corridor transit performance include:

- Transit capacity is defined by how many people and buses can move past a given location during a given time period under specified operating conditions; without unreasonable delay, hazard or restriction; and with reasonable certainty.
- Capacity can be determined for both buses and persons, and it can be determined both as a maximum capacity, maximizing throughput without regard for reliability or operational issues, and as a design capacity, the number of buses or persons that can be served at a desired quality of service.
- Vehicle speed represents how quickly people and buses can move from one location to another.
- Reliability deals with how well the transit schedule is adhered to.
- Bus transit corridor capacity is constrained by the ability of bus stops and facilities to serve buses and their passengers, the number and type of buses operated, and the distribution of passenger demand.
- Dwell time, the amount of time a bus stays at a stop to allow riders to board and disembark, can vary significantly from one bus to the next. This is due to variations in passenger demand among the routes serving a given stop, variations in demand from one trip to the next on a given route, and variations in the time required to serve a given number of passengers getting on and off the vehicle.
- Potential sources of time variation include: passengers with mobility challenges, individuals with baby strollers or other large conveyances, people with luggage, and so on. Such individuals take significantly longer to board and alight than the average passenger. In saturation conditions, passenger standing loads on some arriving buses could result in longer passenger boarding and alighting times. Passengers loading and unloading bicycles from bus-mounted bicycle racks; passenger questions to the bus driver; and fare payment issues (for example, defective fare media, passengers looking for change or fare cards in their pockets) can each cause service delays.
- The capacity of a corridor bus route is determined by the capacity of the critical stop along the facility. The critical stop will be the bus stop used by all buses that has the lowest capacity.
- As more vehicle loading areas are added to a bus stop, the greater the likelihood that one or more loading areas will be blocked or will block other loading areas. Therefore, the extra capacity provided by another loading area drops with each additional loading area added to the stop.
- When right turns are allowed from the curb lane, queues of cars waiting to turn right may block bus access to a near-side stop. Queues of cars may also block bus access to a far-side stop, but if another lane is available and traffic permits, buses may be able to change lanes to move around the queue. Or "queue jump lanes" can be constructed to allow buses to bypass the congested location. To the extent that buses are blocked, however, some of the traffic signal green time that would otherwise be available for bus movement into the bus stop is made unavailable, reducing the overall stop capacity.
- Bus stop location influences bus speeds and capacity, particularly when other vehicles can make right turns from the curb lane (which is typical, except for certain kinds of exclusive bus lanes and at intersections with one-way streets where right turns are prohibited). Far-side stops have the least negative impact on speed and

capacity (as long as buses are able to avoid right-turn queues on the approach to the intersection), followed by mid-block stops, and near-side stops.

- A traffic signal located in the vicinity of a bus stop and its loading areas will serve to meter the number of buses that can enter or exit the stop. For example, at a far-side stop (or a midblock stop downstream from a traffic signal), buses can only enter the stop during the portion of the hour when the signal is green for the street that the stop is located on. The lower the green time provided to the street, the lower the capacity, and the longer a bus is likely to wait for the traffic signal to turn green again.
- Similarly, at a near-side stop, a bus may finish loading passengers but have to wait for the signal to turn green before leaving the stop. As a result, the bus occupies the stop longer than if it would have if it could have left immediately, and capacity is lower as a result. Due to the nature of bus operations, shorter traffic signal cycle lengths offer more opportunities for buses to move through a given signal during the course of an hour. In comparison, at unsignalized locations well away from the influence of upstream traffic signals, buses can enter and exit stops immediately, subject to traffic.
- The benefits of providing traffic signal preemption strategies, that is, allowing buses to get a green light upon arrival depends on a complex set of interdependent variables, including whether the signal system along the route was already optimized before application. Documented travel time savings from traffic signal applications in North America and Europe have ranged from 2 percent to 18 percent, depending on the length of route, traffic conditions, bus operations, and the strategy deployed. Travel time savings of 8 percent to 12 percent have been typical. The reduction in bus delay at signals has ranged from 15 percent to 80 percent. [Kittelson et al., 2013c]

The concept of level of service is used in transit planning in two ways. First, transit can be included in the multimodal level of service. If done, Table 19-20 shows the types of factors that can be included in the analysis.

**Table 19-20. Transit Factors Included in the Multimodal Level of Service Measure**

| Item | Potential Sources |
|---|---|
| **Transit Operations Data** | |
| Frequency | • Timetables |
| Average excess wait time (mins) | • Archived Automatic Vehicle Location (AVL) data, field data |
| Average passenger load factor | • Archived AVL data, field data, transit agency vehicle data |
| Average transit travel speed (mph) | • Timetables, HCM methods, TRB Quality Manual, field data |
| Average passenger trip length (miles) | • Default, National Transit Database (NTD), field data for NTD, archived automatic passenger counter (APC)/smart card |
| **Transit Amenity Data** | |
| Percent stops in segment with shelter | • Field data, transit agency infrastructure database |
| Percent stops in segment with bench | • Field data, transit agency infrastructure database |
| **Pedestrian Environment Data** | |
| Sidewalk width (ft) | • Field data, aerial photos, infrastructure database |
| Buffer width from sidewalk to street (ft) | • Field data, aerial photos |
| Presence of continuous barrier | • Field data, aerial photos |
| Outside lane, shoulder, and bicycle lane widths | • Field data, aerial photos, infrastructure database |
| Number of through travel lanes in analysis direction (lanes) | • Field data, aerial photos, infrastructure database |
| Motorized vehicle flow rate (veh/h) | • Traffic counts |
| Motorized vehicle running speed (mph) | • Field data, HCM methods, simulation |

The second measure is illustrated in Table 19-21, which represents a quality of service metric, in this case, the level of comfort for those riding the transit vehicles. Several other measures similar to this are found in the TCQSM.

The analysis of transit service as part of a site impact analysis needs to balance the desire to serve new riders at the development site with the potential impacts on corridor service. In almost all cases, the transit agency will make changes to its service to provide transit access to the site, with possible contributions from the developer.

## D. Network/Capacity Analysis

For major developments, in particular, projects will often have off-site road network impacts. These road segments and intersections would have been identified earlier in the process when the study area boundaries were established. For example, as per the development of regional impact (DRI) guidelines from the Georgia Regional Transportation Authority (GRTA), the study network, at a minimum, is to include all access points and/or all accesses on major roads and extend in each direction to the nearest intersection with a major roadway. [GRTA, 2013] All intersections between the development site and these endpoints will be included in the study network.

To determine if additional intersections are required, GRTA recommends a travel demand model be used to assign project-related trips to the network and then compare project traffic assignments to the adjusted two-way generalized roadway service volumes at the appropriate level of service standard. Where the gross number of trips generated by a proposed development exceeds 7 percent of the two-way, daily service volumes at the appropriate level of service standard, the segment will be included in the study network. All signalized intersections and any major unsignalized intersections, which are located within or at either end of roadway segments, are to be included in the study network as well.

Figure 19-8 illustrates how intersections and road segments far from the development site itself might be affected by development-generated traffic.

Once the affected locations have been identified and the traffic volumes assigned, the planner can use any of the tools mentioned above from the Washington State DOT and many others to analyze the impacts of the development traffic. The results of all the analyses discussed above are then summarized and used as the basis for identifying mitigation strategies and other actions that will reduce the impact of the development on the transportation system.

**Figure 19-8. Illustration of Network Impacts of Development-Generated Traffic**

## VII. ON-SITE TRANSPORTATION ELEMENTS

As part of the site plan review process and subsequent traffic impact studies, the traffic engineer and planner need to be concerned about transportation-related site design considerations. As noted earlier, this would include such things as the location and design of vehicular and pedestrian/bicycle access points and proposed road improvements, the location and adequacy of parking areas, and the design of traffic circulation and control within the site and with adjoining properties.

The location of buildings on a specific site, also known as the building footprint, is an important urban design issue that can affect many different transportation considerations. For example, clustering buildings within a development encourages walk trips among buildings, reduces walking distances to buildings and transit stops, and reduces the visual clutter associated with strip development. These objectives can sometimes be achieved by inverting the building footprints so buildings lie close to intersecting arterial streets, where transit can more easily be provided. Two other important design considerations are discussed below.

### A. Internal Circulation

The effective internal circulation of cars, trucks, pedestrians, and bicyclists is one of the key factors in making the development a success. The planning for this circulation begins with the placement of the building footprints and the

provision of sidewalks and bicycle paths. Site planning review often examines the proposed locations of the buildings (for example, is the front of the building close to prospective bus stops? Is parking in front or behind the building? Are buildings close enough together to encourage walking among them?). This along with the overall density of the buildings is often the subject of discussions between the developer and the government agency reviewing the plans.

Once the basic pattern of building footprints has been established, the next step is designing an effective circulation system, one that not only connects the buildings but also connects to the local transportation system. Depending on the jurisdiction, the standards for road, sidewalk, and bike path designs will be established by the planning agency (for example, through subdivision regulations) or be approved by the same agency for application on the site. Design standards relate to such things as lane width, acceptable grades, drainage features, buffer distances between lanes and sidewalks, accepted intersection design controls, and the like.

At a minimum, the site plan review process should include:

- Internal circulation designs that allow all vehicular and non-vehicular circulation to occur on-site rather than spilling over onto adjacent streets.
- Entrance and exit locations, required lanes, and required queuing distances.
- Internal roadway circulation systems to carry motor vehicles, bicycles and pedestrians between access points and parking areas, pick-up/drop-off points, and drive through lanes.
- On-site truck service bays, routes, turning points, and roadway access points (that might be separate from the general access points).
- Appropriate building entrance locations, major parking areas, and pedestrian and bicycle routes.
- On-site landscaping and utility risers to minimize sight distance obstructions. [ITE, 2010]

### *1. Access Points*

One of the most important concerns for those reviewing site plans will be the location and design of the site's access points. It is at these locations where much of the impact on the operations, safety, and efficiency of the local road network will occur. The design of the access points should be based on accepted design standards that reflect such things as the angle of entry (conducive to safe and efficient entry and exit from the site); width (to allow all types of vehicles to operate safely); sight distance (provide for safe operations given local road side conditions); driveway spacing (far enough apart to provide efficient and safe access and exit to local roads); and landscaping elements, utilities, and accessible parking stall space requirements.

ITE [2010] provides the following guidance on access locations:

- Adequate spacing should be maintained from adjacent street and driveway intersections in order to minimize driveway blockage by queues.
- If signalized, the access point should be located to facilitate traffic signal progression past the site.
- Driveways should intercept traffic approaching the site as efficiently as possible.
- Adequate inbound and outbound capacity must be provided in proportion to the distribution of site traffic. A capacity analysis, gap check, or lane adequacy check should be conducted for each access location.
- Two-day driveways should intersect local streets generally at 75- to 90-degree angles.
- The capacity of on-site intersections should be sufficient to prevent traffic backing up onto adjacent streets.
- Traffic safety should be a prime consideration in all access point designs, with special emphasis given to sight distance and stopping sight distance.

### *2. Complete Streets*

Several cities have adopted standards that reflect a Complete Streets or context sensitive solutions (CSS) philosophy toward design (see chapter 9 on road and highway planning). Such an approach recognizes the need to plan and design for all users of the street, and usually adopts a road classification scheme that is different from the traditional functional

**Figure 19-9. Differing Desires on Road Design Characteristics, Charlotte, North Carolina**

| | | Pedestrians | Cyclists | Motorists | Transit* | Neighbors |
|---|---|---|---|---|---|---|
| **Motorists Want Reduced Delays/Increased Capacity** | | | | | | |
| The following elements can increase a street's capacity and/or potentially reduce motorists' delay: | | | | | | |
| **More Travel Lanes** | Each additional travel lane increases the street's capacity, especially at intersections; the mix of through and turn lanes can, up to a point, allow an intersection to process more traffic | ◆ | ◆ | ◆ | ◆ | ◆ |
| **Design Consistency** | By providing a consistent design (number of travel lanes, e.g.,), motorists don't have to unexpectedly stop or merge; however, this may be difficult to achieve | ◆ | ◆ | ◆ | ◆ | ◆ |
| **Grade-Separated Intersections** | Allows uninterrupted flow; particularly useful for high volume intersections, but destroys urban context for other users | ◆ | ◆ | ◆ | ◆ | ◆ |
| **Unsignalized Intersections** | May mean less delay for the higher-volume leg, but more delay for the lower-volume leg; in general, fewer signals means less delay on thoroughfares, but may also mean less connectivity | ◆ | ◆ | ◆ | ◆ | ◆ |

◆ - Positive Impact ◆ - Negative Impact ◆ - Mixed Impact or Use with Caution ◇ - Neutral

Source: Charlotte Department of Transportation, 2007

classification based on a road hierarchy (see chapter 2 on data analysis). For example, Charlotte, North Carolina, has adopted urban street design guidelines for both public roads and roads/streets that are to be built in large development sites. [Charlotte Department of Transportation, 2007] The design guide is based on five street types: main streets, avenues, boulevards, parkways, and local streets. Figure 19-9 shows the basis for this Complete Streets approach to designing roads in that it recognizes road users often have very different perspectives on what is desirable. The design guide has many more figures like this for all of the characteristics desired by five major participants—pedestrians, cyclists, motorists, transit riders, and neighbors.

Using local streets as an example, the design guide notes there is more than one cross-section option available: a "narrow" cross section and a "wide" cross section, both of which have traffic volumes and speeds that are relatively low. The context for this type of road is a land use that is more commercial or a mixed-use type of environment, having limited off-street parking nearby, where short-term visitors are likely, and thus there could be a high demand for on-street parking. This might not be the case for an office park environment where surface parking is offered off-street.

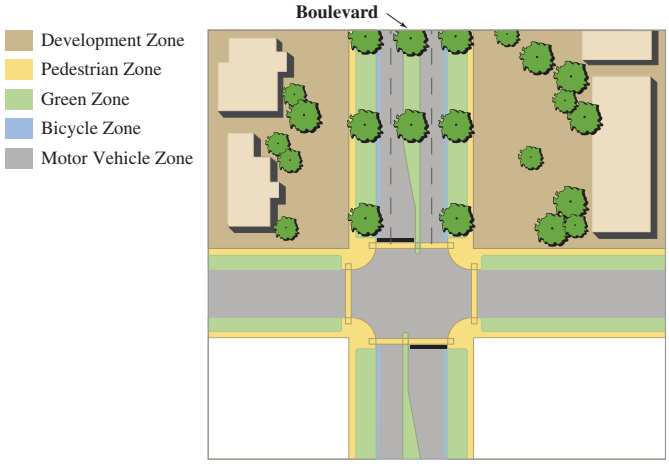
The design guide illustrates different intersection designs based on the desired characteristics of different entering road types. Figure 19-10, for example, shows the intersection characteristics for a boulevard-type road intersecting with other road types, and the desired characteristics relating to development, pedestrians, landscaping, bicycles, and traffic movement. These design concepts are accompanied by a desired level of service for possible combinations of street types and for different road users (see Table 19-22).

Other design guides similar to Charlotte's include: [Boston Transportation Department, 2014; City of New York, 2013; Maricopa Association of Governments (MAG), 2011; National Association of City Transportation Officials (NACTO), undated]. See chapter 9 for more discussion on Complete Streets.

## B. Parking Management

The provision of parking is one of the most important decisions that a developer makes and the public review agency reviews. Many critiques of parking supply, especially in the suburbs, have concluded that "free" parking has had a significant effect on the predominance of the single-occupant vehicle for work trips. Many administrative guidelines for site plan review and for traffic impact studies point to parking as one of the key components for the review. As an

**Figure 19-10. Example Site Intersection Design Characteristics, Charlotte, North Carolina**



**Boulevard Intersections**
*Diagram reflects possible scenarios and intersection may vary slightly in design.*
*For specific information refer to the guideline on Table 4.3*

## Boulevards

| | |
|---|---|
| **Development Zone:** | Land uses and design will vary, but setbacks will likely be deeper than on Avenues and frontage will not always be directly onto the street; in all cases, good physical connections to the street are still important. |
| **Pedestrian Zone:** | Although the balance shifts away from a pedestrian orientation, pedestrians need to be able to travel safely along the Boulevard. This zone should always include sidewalks of adequate width for the adjacent and surrounding land uses. |
| **Green Zone:** | Higher speeds and volumes on Boulevards require significant attention to this zone. To serve the important buffer function between pedestrians and vehicles, as well as enhancing the street for other users, this zone should include grass, landscaping, and shade trees in spacious planting strips and medians. Where a parking zone on a parallel access street is used, the Green Zone should also extend to the area between the parking and the pedestrain zones (back of sidewalk). |
| **Parking Zone:** | Given the emphasis on traffic flow and development characteristics, this zone should generally be removed from the main vehicle zone; it should either be nonexistent or placed on an access street. |
| **Exclusive Bicycle Zone:** | Given the higher speeds and volumes on Boulevards, this zone should get strong consideration for treatment to increase cyclists' safety. Cyclists are generally not comfortable in mixed traffic on these types of streets. |
| **Motor Vehicle Zone:** | A very important zone since the Boulevard shifts more toward an auto-orientation; the number of travel lanes will vary by capacity needs, although the impact to other users should be considered in that decision. |

Source: Charlotte Department of Transportation, 2007

example, the city of Alexandria, Virginia, has included the following language in its site impact analysis guidelines. The city will look for:

- Measures to reduce the reliance on single-occupancy vehicles by employees and others who will travel to and from the proposed use which may include parking fee structures tailored to discourage single-occupancy vehicles, proscription of tenant-employer subsidy of parking costs for single-occupancy vehicles, time and other access restrictions to parking spaces in on-site parking facilities, and programs to support and encourage the utilization of alternative transportation modes.
- Use and accessory use design options, which reduce reliance on single-occupancy vehicles by employees and others who will travel to and from the proposed site, such as the provision of less parking area than that

| Table 19-22. Desired Level of Service for Different Intersection Combinations, Charlotte, North Carolina | | | | |
|---|---|---|---|---|
| **Element** | **Main Street Approach to Blvd/ Main Intersection** | **Avenue Approach to Blvd/Avenue Intersection** | **Blvd/Blvd Intersection or Blvd. Approach to Other Intersection Types** | **Parkway Approach to Blvd/Parkway Intersections** |
| **Level of Service (LOS)** | | | | |
| Pedestrian | LOS B for the entire Blvd/Main intersection | LOS B for the entire Blvd/Avenue intersection | LOS C for the entire Blvd/Blvd intersection | LOS D for the entire Blvd/Parkway intersection |
| Bicycle | LOS B for the entire Blvd/Main intersection, using the average LOS value of only the Blvd approaches | LOS B for the entire Blvd/Avenue intersection | LOS C for the entire Blvd/Blvd intersection | LOS C/D for the entire Blvd/Parkway intersection |
| Motor Vehicle V/C Threshold | 0.95, for two consecutive a.m. or p.m. hours, for the entire Blvd/Main intersection | 0.95 for two consecutive a.m. and p.m. hours, for the entire Blvd/Avenue intersection | 0.95 for both one a.m. and one p.m. hour, for the entire Blvd/Blvd intersection | 0.95 for both one a.m. and p.m. hour, for the entire Blvd/Parkway intersection |
| Median | Atypical, but allowable under special circumstances | Atypical. When provided, should be a minimum of 6 feet at intersections (8 feet preferred if Avenue approaches have land uses likely to generate heavy pedestrian traffic) | Should be provided with a minimum 6 feet at the intersection; 8 feet minimum at Main Streets and at Avenues if the Avenue approaches have land uses likely to generate pedestrian traffic across the Boulevard. | Yes, preferably 9 feet wide at the intersection; preferably 6 feet minimum (for pedestrian refuge) |

Source: Charlotte Department of Transportation, 2007

required under the provisions of this ordinance, shared parking arrangements, the incorporation of residential units (in the case of proposed commercial uses) and other analogous design features.

- Extent to which adjacent neighborhoods may be affected by vehicles associated with the proposed use which park on the public streets, current availability of off-site, off-street parking in the vicinity of the proposed use, and such other design and operational characteristics of the proposed use as the council may determine substantially affect the parking overflow associated with the proposed use. [City of Alexandria, 2013]

Many different strategies have been implemented to manage the supply of parking, ranging from a sharing parking program to variable pricing depending on the time of day and the level of occupancy in the structure or lot. Chapter 11 examines all aspects of parking, including the use of parking strategies as part of a TDM program.

## C. Access Management

Key elements of access management include defining allowable access for various types of roadways, establishing spacing of traffic signals and driveway connections, providing a way to grant variances when reasonable access cannot otherwise be provided, and establishing a means of enforcing standards. The degree of access control and management is determined by statute, deed, zoning, and by operational and geometric design standards. Comprehensive statewide access management codes are found in many U.S. states. Access management codes and ordinances specify when, where, and how access can be provided to developments along a roadway. Access classification systems, an integral part of these programs, define the relevant access with spacing guidelines and relate the allowable access to each roadway's purpose, importance, and functional characteristics.

A functional classification system provides the starting point in assigning highways to access categories. Modifying factors include development density, driveway density, and geometric design features, such as the presence or absence

of a median. A general framework that relates allowable access to functional roadway classes is based on seven access categories, which include:

1) Full control of access (freeways).
2) Access at public street intersections only (expressways).
3) Right-turn access only.
4) Right and left turns in, and right turns out.
5) Right and left turns in and out with turning lanes.
6) Right and left turns in and out with left-turn lanes optional.
7) Locating and designing access based on safety requirements only.

For each type of access, traffic signal spacing guidelines will often be available from the state or local transportation agency. Additional guidelines are set forth in [Rose et al., 2005; VTrans, 2015; TRB, 2015]. Also, see chapter 3 on land use and urban design, chapter 9 on road and highway planning, and chapter 17 on corridor planning.

The location and design of access points depends on whether there is an active access management program for the surrounding roads. Driveways or connections are an important consideration in reinforcing the functional classification of a roadway. In many instances, this is more important than the spacing of intersections. The circulation plan for a development should coordinate site access with that allowed on surrounding roads, assure safe and efficient access between the site and surrounding roads, distribute traffic to parking areas, and allow convenient pedestrian access between parking places and buildings. If the site has sufficient density and the travel patterns are conducive to public transit, transit services should be provided.

An important access objective is to manage left-turn movements by simplifying intersections where driveways intersect with public highways and internal site roads. Possible strategies include channeling the intersections, installing a median within the driveway, eliminating left turns onto the public highway, and sufficiently separating internal roads from the public highway to reduce conflicts and increase storage distances.

## VIII. IMPLEMENTATION ACTIONS/STRATEGIES

### A. Applications and Permits

Preparation of applications and access permits is often an important complement to transportation impact studies. Access plans should reflect access spacing and other requirements set forth in access management programs. A permit application procedure usually requires the following information:

1) Access classification of the roadway on which access is requested.
2) Type of access requested relative to the allowable and types of access.
3) Relevant spacing standards.
4) Highway and intersection capacity.
5) Geometric design considerations.
6) Type of proposed traffic control.
7) Need, if required, for any variances to permit criteria.

The procedures should include guidelines for access denial, where alternative access that is better for overall traffic safety and operation is available.

A similar procedure can be followed in determining the type of control for a specific access point. Key considerations include whether the location meets traffic signal warrants and established traffic signal spacing criteria in order to provide efficient arterial roadway signal progression.

## B. Transportation Management Associations

The concept of transportation management association (TMA) strategy is important to many communities. TMAs are usually nonprofit groups formed by major employers or developers to provide mobility services to their members. Most existing TMAs are found in areas of high suburban traffic congestion, where there are large activity centers, or in rapidly growing urban office complexes. Typical responsibilities include coordinating a staggered work-hours (or flex-time) program, managing a ridesharing program, managing a shuttle bus system to commuter stations, administering parking management programs, and instituting traffic flow improvement programs.

TMAs generate their revenues through membership dues and individual or voluntary assessments. Some operate their own services, while others contract with professional transportation service consultants. They share a common goal, to improve public mobility, and they provide a forum for cooperative public and private decision-making. See chapter 18 on local and activity center for additional information on TMAs.

## C. Transportation Management Plan (TMP)

A TMP is defined as "a site-specific plan of TDM strategies to encourage residents and employees to take public transportation, walk, bike, or share a ride, as opposed to driving alone." [City of Alexandria, 2013] In the city of Alexandria, Virginia, the TMP is required by ordinance through the city's development review process, depending on the size of the development. A TMP is needed for every development exceeding the following thresholds:

- Residential: 20 dwelling units or more.
- Commercial: 10,000 square feet or more.
- Retail: 10,000 square feet or more.
- Hotel: 30 rooms or more.
- Industrial: 30,000 square feet or more.
- Mixed Use: Each use is separately assessed.

Fees are also assigned by development type. For example, for July 1, 2014–June 30, 2015, the standardized city TMP fund rates were:

- Commercial: $0.258 per square foot.
- Residential: $82.418 per dwelling unit.
- Retail: $0.206 per square foot.
- Hotel: $41.209 per room.
- Industrial: $0.103 per square foot.

The funds raised from these fees help pay for the TMP program, including a TMP coordinator. Smaller developments can join a citywide TMP program; medium-sized developments can join the city program or partner with an adjacent TDM program; and larger developments can partner with an adjacent TMP program or create their own.

Importantly, the city requires that annual surveys be done of residents and employees of TMP properties to measure the effectiveness of the transportation strategies carried out by TMP properties. A TMP coordinator is required to spend funds to support the mode share goals stated in the development's TMP. Every TMP includes a combination of program components to mitigate vehicular traffic, including transit subsidies, incentives for carpool/ vanpool/shuttles, car share and bike share memberships, and marketing.

The Alexandria program illustrates an important part of a site mitigation program, that is, following up to make sure required improvements were made and that they are successful.

## IX. REPORT ORGANIZATION

The exact table of contents for a site impact statement will vary from one jurisdiction to another and will be found in the administrative rules and regulations for that jurisdiction. As an example, the following outline for a site impact study comes from the Washington State DOT [2014].

**Executive Summary**

**Introduction**

- Description of the proposed project with purpose and need.
- "Traffic Impact Analysis Methods and Assumptions" summary.
- Map of project location.
- Site plan, including all access to state highways (site plan, map).
- Circulation network, including all access to state highways (vicinity map).
- Land use and zoning.
- Phasing plan, including proposed dates of project (phase) completion.
- Project sponsor and contact person(s).
- References to other traffic impact studies.
- Other mitigation measures considered.

**Traffic Analysis**

- Traffic impact analysis methods used.
- Existing and projected conditions of the site: posted speed, traffic counts (to include turning movements), sight distance, channelization, design deviations, pedestrian and bicycle facilities, design vehicle, and traffic controls, including signal phasing and multi-signal progression, where appropriate (exhibit(s)).
- DHV and ADT, project trip generation and distribution map, including references and a detailed description of the process involved in forecasting the projected trips, including tables.
- Project-related transportation mode split, with a detailed description of the process involved in determining transportation mode split.
- Project-generated trip distribution and assignment with a detailed description of the process involved in distributing and assigning the generated traffic, including exhibit(s).
- If intersection control additions are employed and traffic signals are assumed, include functionality and warrant analyses. With roundabouts or signals, include existing conditions, cumulative conditions, and full-build of plan conditions with and without project.
- Safety performance analysis.

**Conclusions and Recommendations**

- Quantified or qualified LOS, quality of service (QOS), and other appropriate measures of effectiveness of impacted facilities with and without mitigation measures.
- Predicted safety performance with and without mitigation measures.
- Mitigation phasing plan with dates of proposed mitigation measures.

- Defined responsibilities for implementing mitigation measures.
- Cost estimates for mitigation measures and financing plan.

**Appendices**

- Description of traffic data and how data was collected and manipulated.
- Description of methodologies and assumptions used in analyses.
- Worksheets used in analyses; for example, signal warrants, LOS, QOS, and traffic count information.
- If microsimulation is used, provide a copy of the Confidence and Calibration Report.

An example of a site impact review outline for different development sizes is shown in Table 19-23. This proposed table of contents comes from Alexandria, Virginia, where a great deal of emphasis is placed on mitigating expected traffic impacts through TDM programs.

## X. SUMMARY

Site planning for new development is a process used throughout the United States and in many other countries. An important tool in gauging the impacts of this new development is the use of traffic impact studies. The impacts of this new development on the local transportation system and on surrounding communities are of interest not only to transportation agencies, but also to a range of public groups and stakeholders. Site planning and impact studies are designed to give a community the opportunity to examine what is being proposed and to understand the mitigation strategies that are going to be applied. In many ways, site planning and traffic impact analysis are similar to other transportation planning processes. They start with the identification of goals, objectives, and performance measures; and use models and tools to determine trip generation, trip distribution, mode split, and trip assignment. They are also similar to other transportation planning processes in defining or recommending a set of improvements. However, the boundaries of the study area are much smaller than other planning efforts, and the involvement of the local community is often much greater.

This chapter described the major steps in site planning and traffic impact analyses as they relate to transportation. It also discussed the different types of mitigation strategies that can be considered, both on- and off-site. These strategies include both physical engineering changes (such as to a new road access) and actions to encourage non-automobile access to the site.

The transportation system serving a proposed development site should provide the facilities and services that permit safe and efficient travel by various means of travel. Site plan review and traffic impact analysis both emphasize the importance of assessing transportation access and site impacts when examining the potential effects of new development. State and local transportation and planning agencies have established administrative guidelines that direct the type of information that is to be produced as part of the planning process. These guidelines vary across the United States and other countries, depending on the primary issues of concern. All guidelines include some element of road performance, for example, volume-to-capacity ratios, vehicle delay, levels of service, vehicle miles traveled, and road safety. Respective analyses need to be performed on approaches to key roadways, internal roads and impacts on adjacent developments. Transit, pedestrian and bicyclist service levels should also be computed and assessments performed.

Analyses should focus on the following scenarios, at a minimum: (1) existing conditions—base year, (2) future conditions with build-out (site development), and (3) future conditions with site development and proposed access improvements. Depending on the size of the development and the proposed phasing of implementation, intermediate horizon years might be analyzed as well. Many jurisdictions also require future background conditions without the site development, in order to provide a basis for background improvements needed before project traffic volumes are considered.

The extent and level of detail in a site impact analysis will depend on the size and type of development. Roadway analyses should be done for each key intersection along approach and boundary roads, including site access points. Experience has shown that access points usually can be designed to accommodate anticipated demands. However, more critical conditions may arise at public road intersections in the site environs as a result of heavy turning movements, multi-phase traffic signals and the inability to add more travel lanes.

Source: City of Alexandria, 2013

The analyses should address questions such as:

- How well does the existing transportation system work?
- What roadway, transit, and pedestrian improvements are necessary to serve the development?
- How well will the transport system work with proposed improvements? What are their service levels?
- Can people reach the development conveniently and safely?
- Are the roadways, access drives, and site circulation system clear and easy to use?
- Are sight distances adequate?
- Are there sufficient gaps in roadway traffic to let vehicles and pedestrians cross roadways safely?
- Is transit service available, and does it enter the development site?
- Are stops conveniently located near major trip generators?
- Do stops and stations provide sufficient amenities for passengers? Can they handle the peak demands?
- Is transit service frequent, and does it reach places that passengers want to reach?
- Are major transit stops conveniently connected to major developments?
- Can pedestrians safely and conveniently reach the development from surrounding areas?
- Are pedestrian crossings protected by traffic control signals?
- Do median islands provide adequate pedestrian refuge?
- Are the parking areas conveniently placed in relation to access points and major buildings?
- Are walking distances from parking areas to buildings and between buildings as short as possible?
- Are there enough parking spaces to meet anticipated needs?
- Are there suitable provisions for service and delivery vehicle access?
- Are neighborhood impacts minimized?
- What are the visual and urban design implications of proposed improvements?

The types of mitigation strategies proposed for a site will include, at a minimum, physical changes to the road network. Increasingly, mitigation strategies also include transit, pedestrian, bicyclist, and transportation demand management actions. Many jurisdictions have adopted access management policies that guide how access to the road network will occur. Any site access designed through the site planning process will need to be consistent with these policies.

# Rural Community and Tribal Nation Planning[1]

## I. INTRODUCTION

Rural and tribal nation communities constitute a large portion of the U.S. and Canadian population, as well as a significant portion of the land area of both countries. According to the 2010 U.S. Census, just over 59.5 million people, or 19.3 percent of the U.S. population, lived in rural areas (this was down from 21.0 percent in 2000). The U.S. population also included just over 5 million Native Americans, representing 2 percent of the population. [Bureau of Census, 2015] From a geographic perspective, approximately 56.2 million acres of land are held in trust by the United States for various tribal nations, whereas just over 97 percent of the U.S. land mass is considered rural (or more appropriately, nonmetropolitan).

According to the 2011 Census, more than 6.3 million Canadians were living in rural areas, defined as areas with fewer than 1,000 inhabitants and a population density below 1,000 people per square mile (400 people per square kilometer). The proportion of Canadians who live in rural areas has been dropping and in 2011 was 18.9 percent. Aboriginal people (First Nations, Metis, and Inuit) in Canada make up 4.3 percent of the population. The Assembly of First Nations identifies 634 First Nations communities in Canada. [AFN, 2015]

Even though transportation planning for rural communities and tribal nations occurs within the same regulatory environments as those for more urban jurisdictions (that is, federal laws relating to the planning process), the types of transportation-related issues are different as are the level of resources available for addressing the problems. This results in a number of challenges, including insufficient staffing levels, inadequate funding, and the need for technical tools related to the problems of nonmetropolitan areas. Assessment objectives are often different than those found in urban areas, and are usually more subjective. Rural and tribal nation planners also often face a public and political environment where planning is neither readily understood nor accepted. However, transportation planning for these areas is crucial to their long-term viability, and particularly in the case of transit there may be opportunities to develop unique partnerships and service models that may not be possible in larger centers. In addition, many communities are also actively engaged in developing their economic base and resilience and seek transportation improvements to help foster this.

Although there are differences between urban transportation planning and that for rural and tribal communities, transportation planning for rural and tribal nations are, in many ways, also similar. Both areas often experience inadequate accessibility to economic opportunities and health-care facilities, poor conditions of road infrastructure or roads with poor geometric designs, lack of alternative means of transportation, use of atypical modes of transportation such as farm vehicles and horses, and, in some cases, a peaking of travel demands due to tourism. In addition, where rural communities and tribal nations border larger metropolitan areas, both can face increasing development pressures as growth spreads out from the metropolitan center. This can lead to competing demands and objectives within these communities as some want to take advantage of development opportunities, while others want to preserve their way of life. The main difference between rural and tribal nation transportation planning is that tribes have sovereign nation status, which makes the institutional structure for accepted planning principles and decision making much more complex.

The organization of this chapter reflects both the differences and similarities between rural and tribal nation transportation planning. Both are discussed in separate sections, with each describing the characteristics of the planning

[1] The original chapter in Volume 3 of this handbook was written by Jerry B. Schutz, President, Balanced Transportation Concepts. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

process that are specific to the rural or tribal nation context. However, each section also follows the conceptual framework for planning presented in chapter 1. Thus, each section describes approaches for (1) understanding the problem, (2) identifying a vision, goals, objectives and performance measures, (3) analyzing data that leads to identification of alternatives, and (4) evaluating alternatives, leading to plan recommendations. Each section also describes the public involvement environment for the transportation planning process that presents both opportunities and challenges.

## II. RURAL TRANSPORTATION PLANNING

### A. Context

Rural communities can be defined in many different ways. In some cases, the term is used to denote a small city, town or village that is outside of a metropolitan area, while in others it represents areas of a state defined as "rural' by the U.S. Bureau of Census. For example, many states have formed rural planning organizations (RPOs) usually consisting of several rural counties with responsibilities for planning transportation, economic development, human resource and social services. In some cases, rural transportation planning organizations (RTPOs) have been created to focus exclusively on transportation issues. No attempt is made here to place a population threshold on what constitutes a rural community. While small community planning differs from rural planning in many ways, there are still many similarities. This chapter uses the term *rural* to denote areas that are apart and distinct from larger metropolitan areas. For the sake of simplicity, this chapter will use the term *local agencies* to mean towns, cities, counties and townships, unless otherwise deemed necessary.

One of the few reports that deals with rural community planning, *Rural Communities, Legacy and Change*, divides local governments into three geographically based categories. [Flora et al., 2008] Strong county governments are found in the western and southern regions of the United States, and they are also common in Canada. They often supply services for small communities (many of which are not incorporated), and in some ways they act as regional governments. The counties and municipalities of the Great Plains states and Canadian provinces often supply similar services, but do not have as many functions as those found in the south and the west of the United States. Townships, which are found in the northeast, are the strongest local governments. Counties in this region of the United States do not have nearly the responsibilities counties in other parts of the country.

This categorization does not account for the importance of metropolitan planning organizations (MPOs) and regional planning organizations (RPOs) where they exist. An MPO is an organization in the United States designated by the governor of a state for urbanized areas with populations greater than 50,000 to act as a forum for transportation planning. An RPO is a generic term for a state-enabled organization that coordinates the planning activities for its jurisdiction and often acts as a recipient for federal and state funds. RPOs provide planning resources to local communities and periodically develop regional transportation plans for a region's capital investment strategy. Where rural areas are included within MPO boundaries, the MPO could be an important planning resource for rural communities. As noted earlier, RTPOs have been formed in many states to focus on rural transportation planning.

*Rural Communities, Legacy and Change* discusses the many aspects of population mix and demographic change influencing how a rural community views transportation problems. These population characteristics vary by area of the country and between jurisdictions, but one characteristic, in particular, is becoming increasingly important. Most small rural communities are made up primarily of two groups of residents and business owners—those who were born there or in similar environments and those who have moved into the community from an urban area. The latter group can be further divided into three subgroups—those who moved recently and work in the community, those who moved recently and commute to a nearby urban area, and those who relocated to the community some time ago and understand and appreciate the values of those who were born there.

In general, these groups have distinctly different values and will interact with the planner in entirely different ways. Residents who have lived in the community all their lives will more likely consider change to be extensions of past practice and thus will expect solutions to transportation problems to be as they were in the past. This group will want input into decision making and then generally accept the decision if they think it is fair.

The second group will begin with, "I moved here to get away from traffic congestion, air pollution (and other things), and I don't want to see it happen here." This group does not necessarily see change as being simply a continuation

of the past; instead they often seek changes, such as land-use restrictions, to prevent unwanted growth (unwanted by them). This group is also a leading voice for increased investment in multimodal solutions to traffic problems. A major concern of this group is the construction of multilane highways, which to them equates to destroying the community character by encouraging more growth. This can set up conflict with the first group, especially landowners, who often plan to subdivide their land and sell it when they are ready to retire or pass it on to their children. Members of this second group may still be working in a nearby urban area and contribute to congestion on the local roads.

The third group is made up of individuals who have lived in the community long enough to appreciate local values, but also understand the significant challenges facing a community associated with growth.

Just as with large urban areas, rural communities have their own identity, resulting in different and often competing transportation needs. Rural economies can be agriculture-based, resource-based (timber and mining), tourist-based, or some combination. The nature of the local economy and the vision of its residents for the future lead to a set of transportation infrastructure and service needs that are tailored to that particular community.

## B. Legislative Requirements

As with urban transportation planning, rural transportation planning is often guided by federal transportation legislation. Legislation and ensuing regulations provide direction to rural, metropolitan planning organization (MPO) and state transportation agency planners, and indirectly to local agency planners, whether in metropolitan planning areas or not. An important part of federal legislation affecting statewide transportation planning as it relates to rural areas and small communities is the requirement for consultation during the plan and program development processes. As per federal legislation, "With respect to nonmetropolitan areas, the statewide transportation plan shall be developed in consultation with affected nonmetropolitan officials with responsibility for transportation. The long-range transportation plan shall be developed, as appropriate, in consultation with state, Tribal and local agencies responsible for land use management, natural resources, environmental protection, conservation and historic preservation." [Federal Highway Administration, http://www.fhwa.dot.gov/planning/processes/rural/resources]

States and provinces might also have transportation planning requirements over and above those found in federal legislation and rule making. Where regional transportation planning agencies have been created by state legislation, membership can be either voluntary or local governments might be required to be a member. RPOs often provide planning grants to local communities in return for meeting certain planning requirements, often similar to those of MPOs. State departments of transportation (state DOTs) might also offer technical assistance to these organizations, particularly in obtaining data and developing transportation analysis tools.

Local agency planning requirements, over and above those defined by upper levels of government, provide for the development and support of the local transportation system, coordination with land development projects, identification of projects for the capital improvement program and coordination with the state or provincial highway system and other transportation services. These requirements, when not defined by federal, state, or provincial law, are established by the local governing body.

## C. The Job of Rural Transportation Planners

Rural transportation planners usually work either alone or as part of a very small staff. In the smallest agencies, the planner may also take on additional duties such as development review, pavement management, or any variety of added responsibilities. Thus, specialization in a particular discipline or area of responsibility is difficult. Although most rural planners have to be familiar with a broad range of topics, they will often bring some specialized knowledge to the job, or develop it to meet the needs of the community. Transportation specializations applicable to rural areas and small communities include traffic operations, transit planning, traffic calming, recreational traffic issues, main street planning, and travel demand management.

If the community is part of an MPO study area, the MPO can become a resource for community planning. The primary products required of a MPO are a long-range transportation plan, a transportation improvement plan (TIP) and a unified planning work program (UPWP) (see chapter 16). MPOs develop a variety of other

plans that support or elaborate on their system plans, including sub-regional, corridor, route-specific, modal, access management, travel demand management, nonmotorized, freight, scenic highway, and other types of transportation plans that might include rural areas. Usually, long-range plans provide the overall context for more detailed studies where specific solutions are recommended. To the extent that rural areas fall under an MPO's jurisdiction, the community's plans and projects could be part of a larger vision of what the region's transportation system should look like.

State or provincial DOT planners can also support rural transportation planning efforts, and, in some cases, even undertake a planning study for the community. These planners will usually be concerned with roads on the state highway system, but can also examine local roads or transit services where there is a common interest. One of the primary contributions of many state DOTs to rural planning is their development and support of analysis tools and traffic models that can be used in rural transportation planning. Many rural agencies do not have the resources to support model development, so state DOTs either provide the funds for developing such a tool, or more often develop a standard modeling approach that is used in rural areas throughout the state. Also, because Census units tend to cover much wider areas in smaller communities, information on population density may not be granular enough for decision making anyway.

## D. The Rural Transportation Planning Process

The Federal Highway Administration (FHWA) has identified the following success factors for developing a rural transportation plan. A transportation plan should:

- Set the overall transportation direction for the area and define the transportation future/vision.
- Provide a decision-making structure and incorporate a participatory public involvement process to plan and prioritize improvements to the transportation system.
- Build on existing knowledge, resources, and information to conduct a technical analysis including evaluation of current and future conditions, forecasts, and trends.
- Balance multiple and competing stakeholder objectives and funding expectations.
- Identify and provide a long-range funding program.
- Provide a framework to prioritize expenditures based on policy goals and objectives.
- Focus short-range investments on long-term goals.
- Provide accountability to customers on future direction and actions to get there. [FHWA, 2012]

In addition to the preceding—just as with all transportation planning—it is also crucial that rural plans link to future land use and consider an integrated mix of transportation modes.

Although applied at a different scale, the generic planning process described in chapter 1 (see Figure 1-1) is a useful framework for discussing transportation planning for rural areas. The following sections will focus on the major differences in how several of the planning steps found in Figure 1-1 are applied in a rural context. The reader is referred to other chapters in this handbook for a more extensive discussion of the methods and tools of transportation planning.

### *1. Understanding the Problems*

An articulation of the transportation challenges facing a community depends on whether a study is a systems plan or a project plan. Systems planning usually addresses the broader context of providing basic transportation infrastructure and services. Project planning, such as conducted in a corridor plan, occurs in response to specific or perceived problem(s). Increasingly, it has become common practice to use the National Environmental Policy Act (NEPA) purpose and needs statement format to define the problem when the project and/or program will later be subject to NEPA requirements (see chapter 4 on environmental considerations in transportation planning).

As described earlier, rural communities face unique transportation challenges based on a variety of factors such as geography, lack of public transit options, and longer commuting distances. The National Rural Assembly notes, "rural residents tend to have larger proportions of elderly, young, and low-income people, which also create special transportation needs. And rural residents tend to spend a greater proportion of their incomes on transportation expenses." [National Rural Assembly, undated] Transportation problems facing rural communities can be very similar or very different, depending on the context. For example, depending on location, rural communities might experience road congestion due to encroaching development, a large number of crashes on rural roads, or inadequate access to health facilities for those not able to drive.

One of the first steps in rural transportation planning is understanding the types of transportation problems and challenges facing a study area. This can be done through public outreach such as surveys or public meetings, or by analyzing trend data to determine positive or negative aspects of transportation system performance. Table 20-1 from the Southern Alleghenies Rural Planning Organization's (RPO's) *Long Range Transportation Plan* illustrates the factors it considered as part of the "problem understanding" phase of planning. It is interesting to note that the identified trends not only examined transportation system characteristics, but as well many of the socioeconomic factors in the study area that could affect the use of the transportation system.

In some cases, rural transportation studies focus on particular issues, such as transportation for the elderly, low-income households or those not having access to a car. In such cases, the effort to understand the problems facing the study area is much more focused on particular population groups. For example, the Southern Alleghenies Regional Development Commission conducted a study on coordinated public transit–human services in its jurisdiction. [Southern Alleghenies Regional Development Commission, 2008] As noted in the study, the region is geographically diverse with small urban areas separated by large rural spaces. Travel within the region is typically over long distances via the automobile. The commission identified the following challenges in providing low income persons and welfare recipients with transportation to jobs:

- Automobiles are purchased each month for welfare recipients, because no other means of transportation suits the needs of getting them to work and/or training activities, as well as getting children to child-care facilities.
- In counties providing transportation services, there are still welfare clients in outlying areas … who cannot participate in activities due to inadequate transportation. Also, those seeking jobs on second or third shifts are constrained because the county service does not run late at night.
- A shared ride program is rarely used because clients can only use it if the human service vans are booked with other travelers.
- Costs for van services have greatly increased.
- Van service for welfare clients has been provided in one county through a transportation grant. This service has been successful, but costs to provide service are high in some cases, depending on the location of the client.

In sum, the effort to define the transportation challenges facing a study area not only establishes a context for the analysis that follows, but it also helps the public and other stakeholders understand (in plain English) what the planning process is all about.

### *2. Developing Vision, Goals, Objectives, and Performance Measures*

Establishing a vision, goals, and objectives for a planning process is essential in making sure the results of the planning process relate to community desires. These can come from a variety of sources, ranging from small group discussions to surveys. Most importantly, their definition should reflect public input. Another source is federal and state laws, which often specify goals that should be pursued through the planning process, especially if federal or state funds are being used to support the study and the resulting investment program.

As noted in chapter 7, goals are overall broad statements that express the desired future characteristics of a community and its transportation system. Objectives are very specific, measurable, action-oriented statements that help achieve the goals. Performance measures are indicators of transportation system performance that can be monitored over time

| Table 20-1. Trends Affecting Transportation, Southern Alleghenies RPO | |
|---|---|
| **Demographics** | |
| **Trend/Issue** | **Implication** |
| The region has experienced slight population growth over the past 30 years. | Over that time, the region's population has increased 2.8%. This increase, though not significant enough to impact the region's transportation network, does indicate that the region's transportation needs in terms of total population has remained consistent. |
| The region's population is aging. | An older population will have greater need for public or human services transportation. |
| **Commuting** | |
| **Trend/Issue** | **Implication** |
| Over the past 30 years, more workers are driving to work alone. | The region continues to grow more dependent on the automobile as a primary means for transportation. Carpools have decreased in popularity as a means of transportation. |
| Over the past 30 years, households have begun to have three or more vehicles available. | |
| A higher percentage of those workers living in boroughs walk to work than do those living in townships. | The need for safe sidewalks, crossings, and walkways within boroughs and local neighborhoods remains important. |
| The average worker's travel time to work is 27 minutes, while 62% of workers travel less than 25 minutes to work. | Over the past 30 years, worker's travel times to work have increased slightly. The majority of workers living in the region are commuting within the region, although over the past five years, more workers have become employed outside of the region. Those who do not work within the region are likely to work in either Blair or Cambria Counties.<br>However, there has been a growing increase in workers that are traveling further distances for employment. |
| Since 1990, the percentage of workers commuting 90 minutes or more to work has doubled. | |
| Most workers living in the region also work in the region. | |
| **Economic** | |
| **Trend/Issue** | **Implication** |
| Over the past decade, the region's economy has switched from a manufacturing economy to a services-based economy. | Over the past 10 years employment in the Manufacturing industry has declined, and is projected to continue to do so. The region's economy is transitioning into more of a health and service based economy, which will require different transportation needs. |
| Employment projections estimate that employment in the Manufacturing industry will continue to decrease while employment in the Health Care and Social Assistance sector will continue to increase. | |
| The region's average unemployment rate has consistently remained above the statewide average over the past 10 years. | The region's economy has not experienced significant growth over the past decade. The region has experienced a significant increase in unemployment in 2007. |
| The percentage of persons below the poverty level has increased since 1999. | |
| **Bridges and Roadways** | |
| **Trend/Issue** | **Implication** |
| Travel on the region's roadways has been declining since 2005. | Over the last five years, travel in the region has been negatively impacted by increases in unemployment and gasoline prices. As the economy begins to improve, it is expected that travel will also increase again. |
| The region has a large network of state-owned, local-owned, and other agency-owned roadways to maintain. | 6.57% of all state-owned roadways in Pennsylvania are located within the region, along with over 15% of Pennsylvania Turnpike miles and 10% of miles of roadways owned by other agencies (PA DCNR, PA Game Commission, etc.). |

| Table 20-1. (*Continued*) | |
|---|---|
| **Bridges and Roadways** | |
| **Trend/Issue** | **Implication** |
| Half of all linear miles of roadways in the region are local owned roadways. | The region has a large local roadway network that is the responsibility of local municipalities and counties to maintain. |
| Roadway conditions are best on primary arterial roadways. | Most conditions on primary arterial roadways are considered to be good or excellent. Only about half of all secondary roadways are considered to be in good or excellent condition. |
| The region has an extensive bridge system that is growing structurally deficient. | The region's bridge needs to reach condition goals by 2033 exceed the current funding levels available. Just over 18% of all state bridges and 41% of local bridges greater than 20 feet in the region are structurally deficient. |
| **Other Modes of Transportation** | |
| **Trend/Issue** | **Implication** |
| The region lacks adequate passenger and rail freight opportunities. | Much of the region is underserved by both passenger rail and rail freight. Limited passenger rail service hinders intercity connectivity and strengthens dependence on the automobile. Limited rail freight opportunities impede economic development and goods movement as well as increase congestion on the road network. |
| Rail freight traffic is increasing. | An increase in rail freight traffic will impact motorist and pedestrian safety at grade crossings throughout the region. |
| The region is underserved by public transportation. | The rural nature of the region creates challenges for providing public transportation. As the region's population continues to age, the demand for public transportation will continue to grow. |

to show progress in achieving plan goals. According to the FHWA, the success factors for the development of policy goals and objectives include:

- Roles should be specified in terms of who will be making the policy decisions and whether those roles are advisory or decision making.
- Development of policy goals and objectives should involve local officials and provide for broad stakeholder and modal involvement.
- Goals and objectives should have sufficient specificity to guide plan development.
- Goals and objectives should be tied to action and be meaningful to stakeholders/customers.
- Decisions should be made for timelines and mechanisms for modifying and updating polices.
- It should be determined how local, county, and regional policies coordinate with the statewide plan. [FHWA, undated]

As an example of goals, Clinton County, Pennsylvania, as part of its comprehensive plan, identified very specific goals and associated strategies designed to achieve the goals. [Clinton County, 2014] Located in north central Pennsylvania, Clinton County is a rural county with a population of 40,000. The comprehensive plan goals built upon a set of goals and objectives that had been identified as part of the 2009 comprehensive plan. The transportation goals and strategies included:

*Goal*: Address the lack of public transportation options by encouraging the development of alternative mobility systems, including transit and bicycle/pedestrian facilities, where appropriate.

- *Strategy*: Develop a public shuttle bus service.
- *Strategy*: Advocate establishment of bus service for special events and specific destinations.
- *Strategy*: Evaluate the need for park and ride facilities in outlying areas.
- *Strategy*: Increase bicycle and pedestrian facilities and connections.

*Goal:* Improve access for trucks to Western Clinton County to assist with economic development in the area.

- *Strategy:* Work with local officials and SEDA-Council of Governments (SEDA-COG) to identify specific improvements and to have them added to the Pennsylvania DOT (PennDOT) *Twelve Year Program*.

*Goal*: Encourage the continuation and expansion of rail service in the County.

- *Strategy*: Continue to work closely with the SEDA-COG Joint Rail Authority to identify opportunities for rail service improvements within Clinton County.
- *Strategy*: Monitor operations of Norfolk-Southern and their future plans.
- *Strategy*: Work with existing and potential new businesses to identify rail needs and issues.
- *Strategy*: Work with the Economic Partnership to promote the County's existing rail services as a potential asset for new business development.
- *Strategy*: Explore opportunities for better connection to other transportation modes, including air, road, and transit.
- *Strategy*: Explore the potential for additional leisure excursion trains.

*Goal*: Make Piper Airport an integral part of the County's transportation and economic development network.

- *Strategy*: Continue to support needed improvements to the airport facilities as identified in the PennDOT *Twelve Year Program*.
- *Strategy*: Improve connectivity with other modes of transportation.
- *Strategy*: Continue efforts to attract additional charter services at the Airport.
- *Strategy*: Market sport pilot licenses and the light-sport aircraft industry.

*Goal*: Organize to ensure that US 220 is upgraded to I-99 status.

- *Strategy*: Establish strategic alliances with adjacent counties and SEDA-COG to reinstate projects to continue the upgrade US 220 to Interstate standards and completion of I-99.
- *Strategy*: Develop improvements that are coordinated, improve the visual and safety standards of the PA 150 corridor.

These goals emphasized a range of interests for the county, from ensuring a better environment for pedestrians and bicyclists to promoting an upgrade of a state highway to interstate status (for economic development purposes). For rural communities, the focus on economic development goals and mobility/accessibility needs is not uncommon.

Performance measures should reflect the types of goals identified by the study. The following performance measures were adopted by the Southern Alleghenies RPO for its long range plan. [Southern Alleghenies RPO, 2012]

Maintenance/Preservation

- Number/deck area of structurally deficient bridges
- Percentage of poor international roughness index (IRI) of roadway mileage
- Percentage of funds devoted to system preservation

Economic Vitality

- Unemployment rate
- Estimate of new jobs created

Safety

- Number of fatalities or major injury crashes
- Number of roadway safety projects completed

Environmental/Land Use

- Number of municipal access management ordinances
- Number of Greenways-related projects implemented

Accessibility and Mobility

- Public transportation on-demand ridership
- Passenger rail ridership

Bicycle and Pedestrian

- Number of Enhancement Projects

Education

- Number of outreach activities conducted
- RPO newsletter open rate

Maximize Benefits

- Percentage of project let dates on or before projected date

Figure 20-1 shows the range of performance measures that are used by rural county transportation planning agencies in California. [Caltrans, 2006] Unlike major metropolitan areas where numerous system performance measures are fairly common, the types of performance measures often found in rural communities relate to the physical condition of the infrastructure. Thus, for example, pavement and bridge condition measures are used to define the most critical road segments for maintenance or reconstruction. In the context of a transportation plan, however, performance measures should link to and reflect community expectations such as safety, economic development, and accessibility. See chapter 7 for more discussion of goals, objectives, and performance measures.

**Figure 20-1. Performance Measures Used in Rural Counties, California**

### *3. Identifying Needs (through Data Collection) and Analyzing Alternatives*

Data collection is an important step in any planning effort. Among the data needs for transportation planning are land-use information, traffic/vehicle and person counts, road geometry data, crash data, traveler preference information, and financial data. Collecting many of these data can be expensive, and many rural communities cannot afford the type of data collection needed for effective transportation planning. Compounding the problem is that data in high-growth areas become outdated quickly.

Data collected on existing systems help identify transportation needs, which then can be analyzed to achieve the most cost-effective program of investments. There are three possible approaches for developing a usable database: (1) using generic data collected from similar communities, (2) applying quick response methodologies that have default values incorporated into the analysis approaches, and (3) pooling resources with other agencies to collect the needed data. One source of generic data for modeling in smaller communities is illustrated by the National Cooperative Highway Research Program (NCHRP) Report 365: *Travel Estimation Techniques for Urban Planning*. [Martin and McGuckin, 1998] This report provides default values for different variables and factors that are used as input in transportation analysis tools.

Caution needs to be exercised when using generic data. Most importantly, the data are usually defined as average values. Averages can hide many of the differences that may be important in a rural context. The usefulness of such data is proportional to the number of samples making up the average value, the relevance of the sample to the study context and the central tendency of the data. A data series that is spread across a wide range will not be useful, whereas a cluster of data points for rural communities within the dataset might be. These types of data should be used only when no other possible source is available or as a check on the validity of local information and on the default values included with model software programs.

For analysis tools, metropolitan transportation planners commonly rely on computer-based travel demand models to forecast future travel demand and then identify corresponding transportation network deficiencies (see chapter 6 for a discussion on the basic steps in travel demand forecasting). Setting up and maintaining a travel demand model is a large investment for a rural community and may not be necessary or relevant to the studies being conducted. In fact, for a community with modest, but steady growth, there is probably little reason to invest in one. Many of the model steps, such as trip generation, trip distribution, mode split and trip assignment, can be done with simple spreadsheets or with manual templates (see, for example, [Perone and Carr 2006; Maciejewski, 2009]). Similarly, in the case of transit planning, manual ridership counts undertaken by drivers and onboard passenger surveys are low cost and simple ways to assess existing service, while community workshops, travel surveys mail dropped to residences (depending on community willingness to participate), and fieldwork to identify community nodes and densities are some basic additional tools to plan for transit to new areas. In other cases, where a rural community is part of a larger study area, such as being within an MPO study boundary, the existing regional travel demand model can be used to analyze travel trends and patterns.

Transportation analysis usually focuses on transportation system performance in at least two target years, the current year and the future build scenario. Additionally, it often includes at least one more, the forecasted year without the proposed transportation investment. One of the biggest obstacles to setting up a model can be getting 20-year land-use forecasts as well as projections for population, employment and travel demands. The 2012 Clay County, North Carolina, *Comprehensive Transportation Plan* illustrates the types of analysis approaches often used in rural communities to forecast these variables. [North Carolina DOT, 2012] The approaches for obtaining population, employment, and traffic volume projections included:

Population

Population trends were estimated using data from the U.S. Census Bureau and data from a survey conducted by the county. Population counts and data were compared between the 2010 and 2000 Census data, and the annual growth rate was assumed to continue over the plan time horizon.

Employment

Future employment conditions within Clay County were obtained from discussions with a steering committee that included representatives from those involved in economic development. This included approximate locations and number of jobs for proposed employment centers.

Future Traffic

Annual Average Daily Traffic (AADT) volumes across the county from 1991 to 2009 were obtained, and growth rates for 1991–2009 and 2000–2009 were analyzed to note any effects of the economy on local growth. Two main methods were used to project this data to 2035. The first method used a linear regression model using all the data from 1991 to 2009. The second method was applying an exponential growth factor to project to 2035. The majority of the projections were made using the linear regression method. In those areas where no growth or a reduction in traffic resulted, the exponential model was used to obtain a conservative estimate.

All of the projections were adopted officially by the respective county boards.

Identifying alternatives is fundamental to transportation analysis. In many cases, the investment alternatives are very straightforward given the problems and eligibility requirements of funding programs. Road improvements and bridge deficiencies can be resolved with a limited number of engineering applications. The more difficult analysis process occurs when decisions focus on major new infrastructure or service provisions. This is where the process of analyzing alternatives becomes important and often more complex.

Depending on preliminary analysis results—and often on public reaction, especially for controversial projects—iterating through different alternatives definitions is now a common step in the planning process. This iteration can result in refined definitions of the alternatives and even produce new alternatives. However, this iterative process can be very lengthy and cause study delay, especially for controversial projects. The best way to avoid such delays is to identify the alternatives using a planning process that is as transparent as possible, provide the community with many opportunities to become involved, and support the process with data-driven analysis.

The discussion so far has assumed that the alternatives being considered are project-specific. Many other types of strategies can be considered as part of a planning study. [Easter Seals, 2006; 2012] For example, access management is one approach to improving road safety and maintaining the ability to handle traffic over time by using road medians, intersection spacing and design, driveway location and design, and control of access to abutting land parcels. Three useful references on access management are the *Access Management Manual* [TRB, 2003], *Guide for the Geometric Design of Driveways* [Gattis et al., 2010] and *A Guidebook for Including Access Management in Planning*. [Rose et al., 2005] The American Association of State Highway and Transportation Officials (AASHTO) manual, *A Policy on Geometric Design of Highways and Streets,* 6th edition, is an industry standard, which incorporates access management techniques throughout. [AASHTO, 2011] Interested readers are also referred to FHWA's website on access management, http://ops.fhwa.dot.gov/access_mgmt/resources.htm.

Intelligent transportation system (ITS) technologies are another emerging transportation strategy for rural communities (see chapter 10 on transportation systems management and operations). FHWA provides helpful information on applying ITS technologies in rural settings on its website. It offers a "rural ITS toolbox," which categorizes the tools into seven areas:

- Emergency services
- Tourism and travel information
- Traffic management
- Rural transit and mobility
- Crash prevention and security
- Operations and maintenance
- Surface transportation and weather

The key step in applying ITS in any community is to develop a *regional architecture* that promotes consistency in applications across the state and community. By determining the types of ITS services needed, the best technology platforms can be identified. To be effective, the development of a regional architecture requires the involvement of

| Table 20-2. Linking Transit ITS to Caltrans' Non-Urban and Rural ITS Goals | |
|---|---|
| **Caltrans Goal** | **Transit ITS** |
| *Safety*<br>Provide the safest transportation system in the nation for users and workers | Transit ITS includes systems such as an on-board security cameras and silent alarms that improve the safety of transit for passengers and drivers. Vehicle tracking allows transit and emergency management to remotely track vehicles and monitor conditions. |
| *Mobility*<br>Maximize transportation system performance and accessibility | Transit ITS includes systems to improve fixed-route and demand-response management. They provide transit providers with more accurate information for planning and scheduling, thereby improving on-time performance and increase service. |
| *Delivery*<br>Efficiently deliver quality transportation projects and services | Transit ITS can improve efficiency by generating more complete information for planning and scheduling, and by giving rural/non-urban transit providers the ability to respond more quickly to customer needs. |
| *Stewardship*<br>Preserve and enhance California's resources and assets | Transit ITS includes many systems, such as real-time transit information, that encourage increased transit ridership, thereby reducing congestion and sing-passenger trips. |
| *Service*<br>Promote quality service through an excellent workforce | Transit ITS can provide transit staff with improved tools and more comprehensive data with which to perform their jobs, resulting in a more productive workforce. |

Source: Caltrans, 2012

both public and private organizations. Table 20-2, for example, shows how California views the potential role of ITS transit technologies in helping to achieve agency goals in non-urban and rural areas.

Many rural transportation studies also consider potential and innovative transit service as a viable investment alternative. [Ripplinger and Brand-Sargent, 2010] In most cases, transit in rural areas (and for tribal nations) historically have had, and continue to receive, a greater portion of their operating costs funded through federal formula programs, at a higher rate than their urban counterparts (See the 5311c program at http://www.fta.dot.gov/grants/15926_3553.html, and the 5311 program at http://www.fta.dot.gov/documents/MAP-21_Fact_Sheet_-_Formula_Grants_for_Rural_Areas.pdf. Federal grants can also cover a significant portion of capital acquisitions).

Many states have federally supported transit services and human service transportation programs that serve rural communities. In others, private organizations have been established to provide rideshare services. In most cases, the rural transit services are heavily subsidized by government funds, with fare structures covering only a portion of the operating cost in recognition of the fact that transit is ensuring basic access to health and services for citizens over distances that would otherwise be cost-prohibitive to serve. In the case of transit options in rural and tribal nations communities, in addition to collecting ridership, population, and travel pattern data, it also often helpful to collect information on existing transportation assets and community organizations within the area. For instance, some local governments may already own vans or small buses that could potentially form part of a transportation solution, while community service agencies that may already be in place to deliver health and outreach programs may be good candidates to help oversee dispatch or delivery of transit programs.

While financial and technical resources are usually much scarcer than they are in larger centers, rural and tribal communities usually have stronger social connections and a greater willingness to develop creative solutions through partnerships. For instance, the Skeena Regional Transit System in British Columbia operates through a funding partnership and shared services model that includes three First Nations (tribal) communities, two small municipalities, a regional government, a health authority, a private operator, and the provincial transportation agency, BC Transit.

Similarly, British Columbia's Mt. Waddington Transit System is operated by a similar tribal/local government/provincial partnership and is able to leverage much greater service to its area through it operation by the local community service agency. Since the community service agency also delivers services like a Volunteer Transportation Network and a meals-on-wheels program for seniors, it is able to better coordinate transit with these volunteer options. In turn, the transit funding provided to the agency helps ensure the longer term financial sustainability of the volunteer programs.

| Table 20-3. Rural Community Transit Statistics, British Columbia ($2014 CAN) | | | | | | | |
|---|---|---|---|---|---|---|---|
| **Transit System** | **Pop.** | **Vehs.** | **Service Hours** | **Rides per Hour** | **Cost per Ride** | **Trips per Day (M-F)** | **Service Description** |
| 100 Mile House | 3,300 | 3 | 1,988 | 4.0 | $18.94 | 7 scheduled, dial-a-ride | Systems are mostly self-contained with little or no service in surrounding rural areas; may have limited connection to urban center via Health Connections route. |
| Ashcroft-Clinton | 2.264 | 2 | 1,976 | 1.5 | $46.13 | 3 scheduled, dial-a-ride | |
| Bella Coola | 3,300 | 2 | 3,521 | 5.2 | $13.61 | 6 scheduled, dial-a-ride | |
| Boundary | 3,985 | 2 | 1,606 | 4.4 | $15.89 | Dial-a-ride | |
| Kaslo | 2,700 | 1 | 586 | 2.9 | $36.95 | 2 scheduled, dial-a-ride | |
| Princeton | 2,724 | 2 | 1,976 | 3.4 | $19.92 | Dial-a-ride | |
| | | | | | | | |
| Clearwater & area | 2,331 | 3 | 2,092 | 3.0 | $23.44 | 6 scheduled, dial-a-ride | Systems provide service between multiple small rural communities within their regions, with no or limited connections to urban centers. |
| Hazeltons' Regional | 2,158 | 2 | 2,553 | 5.7 | $14.82 | 5 scheduled, dial-a-ride | |
| Mt. Washington | 6,513 | 3 | 4,285 | 7.1 | $11.65 | 20 scheduled, limited dial-a-ride | |
| Nakusp | 1,759 | 1 | 1,976 | 3.1 | $24.09 | 2 scheduled, dial-a-ride | |
| | | | | | | | |
| Agassiz-Harrison | 5,664 | 4 | 5,379 | 7.3 | $9.55 | 10 connections, deviations | Systems provide daily connections to neighboring urban centers as well as some level of local service within the community. |
| Okanagan-Similkameen | 1,647 | 1 | 1,690 | 5.0 | $16.57 | 4 connections | |
| Osoyoos | 4,845 | 1 | 1,454 | 3.3 | $17.68 | 2 local/connections, dial-a-ride | |
| Nelson-Slocan Valley | 2,800 | 4 | 5,792 | 7.2 | $12.59 | 4 connections | |
| Pemberton Valley | 3,675 | 2 | 1,953 | 13.3 | $8.51 | 7 local, 4 commuter | |
| Port Edward | 544 | 1 | 2,063 | 16.9 | $6.84 | 7 connections | |

Source: [BC Transit, 2014]

The section under "Paratransit and Specialized Services" in chapter 12 provides a good overview of the many creative transit service types that can be used to serve small community, rural, and tribal public transportation needs. Another key resource is the TRB Transit Cooperative Research Program (TCRP) Report 101: *Toolkit for Rural Community-Coordinated Transportation Services*, as well as other resources described at the end of this chapter. As an example of possibilities and performance, Table 20-3 shows the population, ridership, and service types of all transit systems in British Columbia serving total populations of 7,000 or less.

### *4. Evaluating and Prioritizing Alternatives*

Sufficient funds are seldom available to implement all study recommendations. This is especially true for rural communities. Thus, it is important to establish some means of determining which of the many alternatives being considered provide the most cost-effective investment of limited dollars.

*Evaluation Criteria*. Evaluation criteria or measures of effectiveness (MOEs) serve as the basis for analyzing alternatives. Evaluation criteria are directly related to the goals and objectives established for the study (see chapter 7 for more discussion and examples of evaluation criteria). Thus, for example, if a study goal is to provide a safe road network, and a corresponding objective is to reduce the number of fatal crashes, then an evaluation criterion for investment alternatives would be the level of crash reduction expected for each alternative. Many different evaluation criteria can be identified for a study, depending on the study's goals. [Amekudzi and Meyer, 2005] A word of caution is warranted, however. In most cases, the more evaluation criteria included in a study, the more data that have to be collected and the more analysis that must be undertaken. In communities where resources are limited, it is important for decision makers, planners, and the public to determine the most critical set of criteria (the type of information that will be produced during the analysis process) that will guide the decision-making process.

Not surprisingly, data availability again becomes a key factor in the usability of evaluation criteria. If data are not available, too costly to obtain, or difficult to forecast into the future, a criterion will not be useful unless sketch planning methods are used (see chapter 6 on travel demand modeling). However, sketch planning methods sacrifice accuracy for efficiency. These methods have more application in systems planning than project planning, where more information should be available and where decisions are being made that will shortly thereafter result in the construction of actual projects.

*Safety*. Road safety is one the most important issues in rural communities. In most cases, road congestion is not as significant an issue as it is in larger metropolitan areas, except where seasonal tourism overwhelms local streets or where rapid economic development is occurring due to proximity to a metropolitan area. Road crashes in rural communities on two-lane roads are often statistically more serious than crashes in the rest of the state and nation. In 2012, rural areas accounted for 53 percent (16,443) of the fatal crashes and 54 percent (18,170) of the fatalities. [NHTSA, 2014]

Traffic safety analysis is often the purview of transportation engineers, but transportation planning should incorporate safety considerations into recommendations and into planning documents (see [Washington et al., 2006]). Chapter 23 discusses safety and transportation planning in more detail.

*Environmental Factors*. Transportation planning of all types must consider the impacts of investment on the natural, built, and social environments. Environmental regulations do not differentiate between the resources available to small communities and large ones, so there are no shortcuts available to small communities. Several environmental considerations are often found to be especially important in rural community (and tribal nation) planning. Air quality is a concern that can be regional in nature or site-specific. In recent years, many small communities have been added to the list of air-quality nonattainment areas as a result of additional EPA requirements. Little documented experience exists for small communities dealing with these issues, but that experience is evolving rapidly. An excellent source for obtaining this information is the website for the Transportation Research Board (TRB) Committee on Transportation Planning for Small and Medium-Sized Communities at http://www.trb.org/ADA30/ADA30.aspx.

Water quality, habitat disruption, archaeological and historic resources, community cohesion, and aesthetics are other environmental issues that are often of great concern to transportation studies in rural communities and tribal nations. Potential impacts in each area result not only from the physical construction of a transportation facility but could occur as a secondary impact from economic or community development that follows the new transportation investment. Thus, the evaluation process for sensitive natural and community environments must consider potential indirect and cumulative effects of transportation improvements.

*Prioritization*. Several transportation analysis software packages score alternatives with respect to overall effectiveness and study goals, but few recommend a best alternative for the decision maker. Even with those that provide a relative comparison among alternatives, the users must still assign scoring weights to the different measures that reflect the level of importance to the ultimate decision.

Chapter 7 provides a more detailed description of evaluation tools and methods. This information will not be repeated here; however, it is important to note that the most appropriate evaluation methods for rural community transportation planning will most likely include cost/benefit analysis and scoring methodologies. The range of alternatives and the number of alternatives to be evaluated are fewer than for large metropolitan areas, where thousands of projects must be considered. Thus, prioritizing projects rural transportation planning is usually more straightforward and easily applied.

Rural transportation planning occurs within the context of statewide planning, and thus a rural transportation plan must be cognizant of relevant state plans and prioritization criteria. State DOTs have often established criteria to prioritize projects in rural areas. For example, the Texas DOT developed a plan in 2012 for rural transportation

investments that used the following criteria to assign priorities (only two goals were used for the prioritization). [TxDOT, 2012]

**Goal: Connectivity**

- State trunk highway system
- System gap
- Commodity flow by truck to/from county (annual tonnage)
- Composite travel time to/from population/employment centers
- Hurricane evacuation route

**Goal: Mobility**

- Population within a 5-mile buffer
- Cost per future VMT
- Current volume/capacity
- Forecast volume/capacity
- Forecast level of service change with project
- Truck percentage
- Existing truck traffic
- Projected truck traffic
- Existing average daily traffic
- Forecast average daily traffic
- Safe passing needs

The criteria were assigned weights (that is, indicators of relative importance) by rural transportation stakeholders who participated in the plan development process.

***5. Involving the Public***

Public outreach efforts in transportation planning for rural communities are often very different than for larger metropolitan areas, primarily because of the familiarity that participants have with each other and with local decision makers. Thus, although it is quite common in larger metropolitan areas to use websites, focus groups, surveys and newsletters to reach those potentially interested in a transportation study, in rural communities, community meetings are probably as effective if not more so than other outreach efforts. This is especially true if the community meeting is held under the auspices of locally elected officials or other community leaders (see chapter 24 for more details on public participation and engagement).

It is important to note again that federal law requires consultation with planning partners for nonmetropolitan transportation planning. Such consultation is an opportunity to understand different partners' concerns relating to transportation system performance, coordinate the planning and implementation of potential improvement strategies, and promote a cooperative approach toward public outreach during a study.

## III. TRIBAL NATIONS

### A. Context

As of 2013, there were 566 Indian tribes, bands, nations, pueblos, rancherias, and Alaska Native villages recognized by the U.S. government (note: this section will use the terms tribal nations and tribes to represent all of these communities). The states with over 10 percent of their population being Native American include: Alaska (19.5 percent),

Oklahoma (12.9 percent), New Mexico (10.7 percent), and South Dakota (10.1 percent). [National Congress of American Indians and the Leadership Conference Education Fund, 2013] The federally recognized Native American tribes range in population from 200,000 for the Navajo Nation to six for the Augustine Band of Cahuilla Indians in California. [Myers, 2014]

Tribal nations exist in a variety of settings, some sharing reservation land, some with reservations straddling state lines, and some with no reservation lands. However, each often has similar concerns and needs for a transportation system that provides access to and from jobs, residences, recreation, cultural centers, services, shopping, and other destinations. This transportation system should provide convenient and affordable transportation, while being consistent with community values and preserving cultural heritage and the natural environment.

An important aspect of tribal transportation planning is it must take place within the cultural value system of tribal members. This is well-described in a Washington State DOT *Tribal Transportation Planning Guide*:

> *Tribal transportation planning takes a unique approach to the traditional planning process by setting community goals specific to a tribe's ancestral lands, unique culture, and circumstances.*
>
> *The development of options and recommendations in a tribal transportation plan considers the usual natural, built and social environments under an overlay of guiding cultural and environmental values. Elected Tribal Council and tribal community members who base decisions about the future on a developed plan may expect to see these values incorporated into the document.*
>
> *Tribal communities expect that their own patterns of travel and movement, their own pace of life, that of wildlife, and sometimes undisclosed, pathways and culture, will provide guidance for plans and projects on tribal lands. Tribal transportation plans must maintain cultural integrity, and consider environmental quality within themes of preservation and protection of ancestral lands, and the right of tribal members to live and travel to these places regardless of accessibility. [Washington State DOT, 2009]*

Recognizing tribal nations as sovereign creates a layer of complexity for the planning process that does not exist for nontribal governments. Adding to this complexity is the fact that many tribal lands contain a mix of federal, state, county, township, municipal and tribal roads and, in some cases, other types of transportation facilities. As noted by Myers [2014], for example, the following Native American people use very different forms of transportation:

- Native villages of Alaska have ice roads, unique roadways maintained on and off major waterways. Methods of transportation include snowmobiles, dogsleds, boats and bush planes.
- The Indians of Puget Sound in Washington state use a variety of boats for travel, work, and moving freight.
- The Yurok and Hoopa on the Klamath River in Northern California use jet boats and other types of boats to fish, travel, and deliver supplies.
- The Indians of the Southwest use on- and off-road vehicles, as well as animals, to travel the desert and the harsh High Plains areas.
- The Great Lakes tribes and the eastern seaboard tribes use on- and off-road vehicles as well as boats, with surface facilities ranging from unpaved roadways to expansive waterway routes.

Thus, although much of the focus on tribal transportation planning is on unpaved and unsafe roads, in many cases, other forms of transportation should be addressed as well.

For issues that transcend transportation, the National Congress of American Indians is "the major national tribal government organization." [http://www.ncai.org] Another group, the Intertribal Transportation Association (ITA), holds a national conference annually, publishes a quarterly newsletter and has subcommittees that address specific issues.

## B. Legislative Requirements

The history of U.S. federal legislation relating to tribal nations reflects changing attitudes on how Native Americans should be treated and supported. This section will not present this history that spans well over

150 years (see [Glaze and Amdur-Clark, 2014] for a detailed history of this history). Most importantly for today's world, the policy of the federal government is to promote self-determination and self-governance among tribal nations. Much of the recent legislative history in tribal transportation has focused on programs to foster such an outcome.

For example, Moving Ahead for Progress in the 21st Century (MAP-21), the U.S. transportation law passed in 2012, established the Tribal Transportation Program (TTP), known formerly as the Indian Reservation Roads program. For transit, it changed the Public Transportation on Indian Reservations Program from a grant to a formula allocation program. Title 23, Section 135 of the U.S. Code requires states to consider a tribe's concerns in carrying out their planning processes and to consult with them in developing the state's long-range transportation plan and the statewide transportation improvement program (STIP). MPOs have similar requirements. [Note: As of the January, 2016, only draft MAP-21 regulations for guiding tribal nation transportation planning have been produced by the federal government; readers are encouraged to check the FHWA website on guidance (http://www.fhwa.dot.gov/hep/guidance/#t23) for the most up-to-date federal rules and regulations concerning Tribal transportation planning.]

The most recent U.S. transportation legislation passed in 2015, Fixing America's Surface Transportation (FAST) Act, provided funding for the Tribal Transportation Program and authorized funding for the Tribal Transit Program. It also establishes and expands a Tribal Self-Governance Program within the U.S. DOT. The law also included a provision for tribal data collection, a reporting requirement for tribes that receive Tribal Transportation Program funds to report on the description of projects funded, the current status of projects, and the number of jobs created.

Transportation law also requires that coordination and consultation with tribal nations should occur during corridor plans, multimodal studies, modal studies, and any other transportation study where jurisdictions overlap. A state or MPO can perform these studies for an area entirely within tribal lands, if agreed to by the parties. Other transportation agencies can and should coordinate with tribal nations. Cities, counties and townships may have roads that enter or cross tribal lands. Ports and other freight service providers could be adjacent to or use tribal nation land. Transit agencies can provide important services to tribal nations, and these nations may also be funding partners with transit systems. Special transit services such as dial-a-ride can provide dedicated operations, and if appropriate, fixed-route bus service can provide a reliable and higher capacity level of service (see [Stoddard et al., 2012]).

The Bureau of Indian Affairs (BIA) and the FHWA operate the Tribal Transportation Program, which supports planning and provides funding for road projects on tribal nation land. As noted by the FHWA, "the Tribal Transportation Program (TTP) provides funding for safe and adequate transportation and public road access to, within, and through tribal reservations, tribal lands, and Alaska Native Villages. TTP projects range from board roads for all-terrain vehicles on the marshy Alaskan tundra to significant road construction." [FHWA, 2013] For a project to receive TTP funding, it must appear in the tribe's long-range plan and be in the TTP transportation improvement program (TIP). Planning funds come from a national TTP tribal allocation and must be approved by the Bureau of Indian Affairs. FHWA and Federal Transit Administration (FTA) allocations to states and MPOs for transportation planning purposes can also be used for TTP planning in some cases. These funds, when used to study tribal transportation problems, will usually be administered by the state or MPO.

Legislation related to Aboriginal people in Canada may be accessed through Aboriginal Affairs and Northern Development Canada at, https://www.aadnc-aandc.gc.ca/eng/1100100010023/1100100010027. Similar to the United States, Canada, has treaty obligations to aboriginal peoples, primarily to the First Nations, Inuit, and Métis.

## C. The Job of Tribal Nation Planners

If a tribe has well-defined needs and a community consensus exists on where limited funding should be allocated, selecting funding priorities might be relatively straightforward. However, where there are numerous needs and where types of projects differ greatly, additional approaches to prioritize needs will likely be needed. Helping to identify priority investments is one of the most important responsibilities of the tribal nation transportation planner.

As with rural communities, tribal nations can help address unfunded needs and other transportation issues by partnering with other agencies and organizations. In most cases, these agencies would be the state or provincial DOT, an MPO (if the tribe resides in an MPO study boundary), or an RPO/RTPO. Because of the sovereign nation status of tribal nations, a formal partnership with such agencies can be complex, but there are examples where this has been

done successfully. In the state of Washington, the Swinomish Tribe has full membership on the Policy Board of the Skagit Regional Transportation Planning Organization (RTPO), the Lummi and Nooksack Tribes have membership on the Transportation Policy Board of the Whatcom County Council of Governments, and the Pascua Yaqui Tribe in Arizona is a full partner in its MPO. Similarly, within British Columbia, the Westbank First Nation is a member of the Sustainable Transportation Partnership of the Regional District of Central Okanagan, which coordinates transportation programs and projects within the Kelowna area.

Perhaps the most important strategy for a tribal nation conducting transportation planning for the first time is to examine the work done by other tribes. This can lead to one-on-one relationships among the tribes and their planners. Some helpful resources include:

- *Transportation Decision-Making Information Tools for Tribal Governments, Developing A Long Range Transportation Plan*. [FHWA, 2005]
- Related sites for tribal transportation planning, http://www.tribalplanning.fhwa.dot.gov/reference_related.aspx.
- Many states have developed their own tribal transportation planning guides, with California, Minnesota and Washington being some of the best examples. The Navajo Nation's Transportation Plan 2009 is another example of a comprehensive transportation systems plan. [Navajo DOT, 2009]

## D. Transportation Planning for Tribal Nations

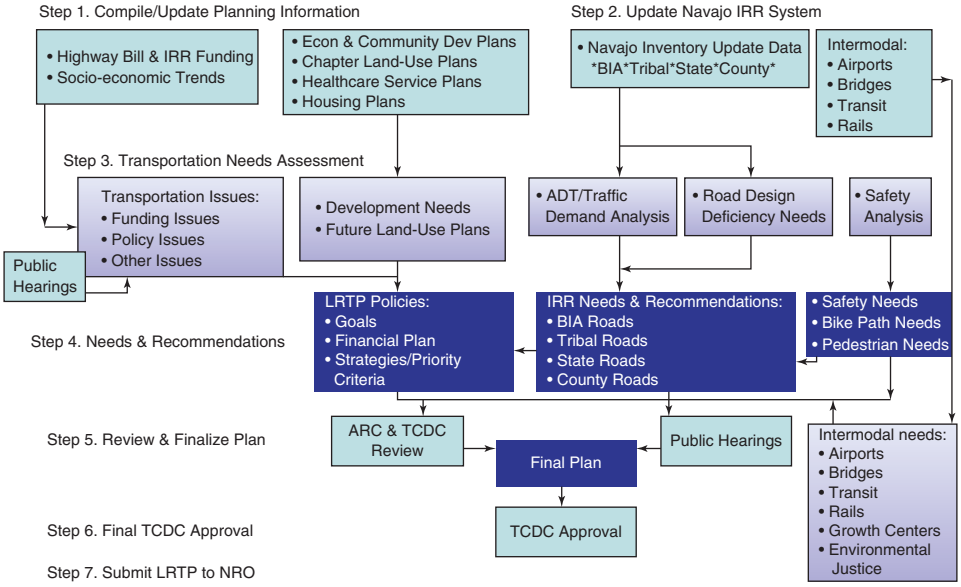
The primary challenges facing tribal nation transportation planning include addressing different/overlapping/often conflicting demands for transportation, and identifying transportation strategies that are most appropriate to a tribal nation context. Given a diverse set of strategies and actions, identifying the most appropriate methods to undertake planning in tribal nations becomes a necessary first step. Research and guidance exists on appropriate planning methods; some of this information is integrated into the general literature on transportation planning, but is scattered among many different sources. Consolidated information is available on some specific topics such as intelligent transportation systems (ITS), transit, and safety. [Caltrans, 2012]

According to FHWA and BIA draft planning regulations, a tribal long-range transportation plan should include:

- An evaluation of a full range of transportation modes and connections between modes such as highway, rail, air, and water, to meet transportation needs.
- Trip generation studies, including determination of traffic generators due to land use.
- Social and economic development planning to identify transportation improvements or needs to accommodate existing and proposed land use in a safe and economical fashion.
- Measures that address health and safety concerns relating to transportation improvements.
- A review of the existing and proposed transportation system to identify the relationships between transportation and the environment.
- Cultural preservation planning to identify important issues and develop a transportation plan that is sensitive to tribal cultural preservation.
- Scenic byway and tourism plans.
- Measures that address energy conservation considerations.
- A prioritized list of short and long-term transportation needs.
- An analysis of funding alternatives to implement plan recommendations. [BIA, 2014]

An example of the steps for a tribal transportation plan is shown in Figure 20-2, which is the transportation and decision-making process for the Navajo Nation, the largest tribal nation in the United States. This process shows some similarities to other planning process steps, such as the development of a transportation improvement program

**Figure 20-2. Transportation Planning Process for the Navajo Nation**



Source: NDOT, 2009

(TIP) and the identification of needs. However, there are also some differences, particularly in the role of the BIA, which must approve the allocation of construction dollars.

### *1. Understanding the Problems*

Tribal nations face similar types of transportation problems as rural communities, while at the same time experiencing challenges that are specific to a tribal study area. The Tribal Transportation Planning Organization in the state of Washington has identified the most important transportation challenges as being:

1) High crash rates on reservation roads, attributable to many factors, including poor road design and condition.

2) Inadequate funding, and an overwhelming multiplicity of funding sources and application procedures.

3) Incomplete transportation data on crashes, traffic counts, and others combined with multiple jurisdictional involvement in data collection and analysis.

4) Lack of adequate reservation transportation planning staffing to pursue all funding possibilities and interact with all potential partners.

5) Geographic isolation and remote locations of transportation facilities and roads on or near Indian reservations is a barrier to efficient and cost-effective delivery by providers of fire, safety, maintenance, and public transit.

6) Incomplete Indian Reservation Road (IRR) Inventories, and the challenges of meeting complex BIA rules and regulations for update of the inventory.

7) Inequities in implementing IRR Funding brought about by changes in the regulations.

8) Outdated tribal Transportation Improvement Programs (TIPs) that no longer reflect current priorities and needs of tribal communities.

9) Historical frictions with local governments to form partnerships and collaborate on regional transportation projects.

10) The need for funding that is consistent and adequate. A dwindling federal budget, with an appropriation for the IRR (Now Tribal Transportation) Program that falls short of actual needs on reservations. [Washington State DOT, 2009]

The Navajo Nation *Comprehensive Transportation Plan* illustrates the types of transportation problems facing the Navajo communities (the Navajo Nation consists of portions of Arizona, New Mexico, and Utah):

- The Navajo Nation is the largest tribe in both land area and population, but due to inadequate funding for the Navajo IRR Program, 76 percent of the Navajo-BIA road system is unpaved.
- Community transportation survey respondents identified the following important topics
  - Safety improvements were the highest transportation goal, ranked above economic development, access to recreation, connection to transit and connection to freight;
  - Safety improvements (roadway striping, signage, traffic control, guard rail and street lights);
  - Road improvements (paving existing dirt or gravel roads);
  - Road maintenance (pothole repair and blading of dirt roads); and
  - Bridge improvements.
- The poor condition of local roads, coupled with increased traffic and safety issues have become a primary concern for chapters, school administrators, health care providers, and tribal and transportation leaders. Lack of paved roads has been identified as affecting quality of life. [NDOT, 2009]

The plan further identified the characteristics of special problems facing the transportation system. For example, the road safety problem was defined as follows:

- From 1999 to 2007, the Navajo fatality rates made up 15.34 percent of total crash fatalities in the state of Arizona. (The Navajo Nation represented 1.6 percent of Arizona's population in 2010).
- Compared to the 1992–1996 statistics, the crash total for 1999-2007 (1,253 crashes annually) had increased by 26 percent.
- Approximately 41 percent of the crashes resulted in injuries, a rate that was 10.5 percent higher than the rest of the state.
- Single-vehicle crashes represented 55 percent of the total crashes and 43 percent were two-vehicle crashes.
- A large majority (86 percent) of the crashes occurred in clear weather.
- Dry road conditions characterized 73 percent of the crashes, 8.2 percent occurred on snow-packed roads, 5.8 percent happened on loose sand and gravel, and 4.7 percent occurred on wet roads.
- The causes of crashes were driver inattention (20 percent), driving under the influence (DUI) (17 percent), animals on the road (16 percent), and speeding (14 percent). Only 1 percent of the crashes involved pedestrians. DUI crashes were 2.9 times the statewide Arizona rate.

The Fond du Lac Reservation illustrated the range of transportation modal issues that could be covered in a transportation plan. [Arrowhead Regional Development Commission, 2011] The types of actions covered: road condition and safety issues on a major interstate highway running through the reservation, trunk highways, county state-aid highways, county roads, township roads, and tribal roads; the Fond du Lac transit system; and bicycles/ pedestrians.

It is interesting to note that many of the issues and problems facing the Navajo (and similar) Nation are different from those identified in state and metropolitan transportation planning. There is much more emphasis on the need for paved roads, access to community facilities (especially health centers), and the strong enabling characteristic of transportation investment in spurring economic development. In addition, many of the factors contributing to road crashes differ as well.

### *2. Developing a Vision, Goals, Objectives, and Performance Measures*

Similar to other planning studies, tribal nation transportation plans should establish a vision for the study area, and identify the goals, objectives, and performance measures that can be used to achieve this vision. The Navajo Nation *Comprehensive Transportation Plan* identified the following transportation goals:

- Provide a comprehensive transportation system that encompasses all modes of transportation, including rail, bus and air.
- Provide safe and efficient transportation network to and within the Navajo Reservation.
- Improve overall road and bridge conditions to achieve a reduction in the number and severity of traffic accidents.
- Develop the necessary multimodal transportation system to foster and support economic development and increase employment opportunities.
- Provide a high level of connectivity between growth centers, including Shiprock, Tuba City, Chinle, Fort Defiance, Window Rock, Crownpoint, and Kayenta. [NDOT, 2009]

Program-specific objectives were identified for each infrastructure area. For example, the road investment program was determined based on:

- Upgrading and improving class 2, 3, and 4 roads to meet design standards and management system requirements to correct deficiencies and improve overall travel mobility and accessibility.
- Improving travel safety and reduce accidents on the Navajo-BIA roads.
- Meeting existing and future transportation needs in order to promote community and economic vitality.

The airport investment program had the following goals and objectives:

- Develop a system of safe, efficient airports which meet acceptable development standards of federal, state, and local agencies, as well as the aviation industry.
- Plan for future growth of the aviation system consistent with national, state, and local air transportation needs through continuous updating of the Navajo Nation Aviation Systems Plan and to take actions to land bank and avoid operational restrictions at existing and new airports.
- Provide a system of airports, which will provide a minimum level of service and meet acceptable performance standards.
- Identify improvements needed to ensure adequate access to all system airports and users.
- Enhance opportunities for local economic development and improved employment consistent with local growth policies and plans.
- Finance aviation facility development to maximum feasible extent with innovative techniques taking full advantage of private sector initiatives and opportunities to assist in developing and operating facilities in the public aviation system.
- Establish operating procedures, budgets and an organizational structure to ensure proper maintenance of all Navajo Nation airports.
- Provide a framework for aviation planning and programming to meet needs in areas of airport development, airspace utilization and air navigation facilities and services.

Interestingly, the plan identified growth center-specific street goals and objectives that recognized the unique cultural and environmental nature of different communities in the Navajo Nation. For example, the street plan goals and objectives for the Shiprock community were:

- Create networks of streets to expand the use of land for the purpose of economic development toward the south and serve the government center.
- Create two street networks separated by the San Juan River, each providing an efficient distribution of traffic to reduce congestion and accidents.
- Provide an alternate crossing of the San Juan River towards the west.

- Create alternate routes and increase accessibility.
- Minimize environmental and cultural impacts by conserving areas adjacent to the San Juan River for recreation, and building new improved routes on existing dirt roads.
- Strengthen the historical sense of the place by creating a new government/town center upon the old settlement area known as the Shiprock chapter house/BIA compound.
- Enhance multi-modal options and mobility by providing a pedestrian bridge across the San Juan River, safely linking the two primary development areas within Shiprock.

Another example comes from the Warm Springs Reservation Transportation Plan in central Oregon. [Confederated Tribes of the Warm Springs Reservation, 2014] The goal and objectives for this plan included:

Traffic Safety

- Improve vehicular, pedestrian, and bicycle safety, particularly in the Warm Springs Community.
  - Provide additional pedestrian/bike paths.
  - Provide sidewalks with streets that serve urban level development.
  - Provide crosswalks at appropriate locations.
  - Include "Traffic Calming" techniques in the design of new residential streets.
- Support safety improvements to SR 26 throughout the reservation corridor.
- Implement a system to record and track "crash" data on reservation roads.

Access

- Provide access to future housing areas and other developments planned by the tribes.
- Ensure that roads that provide access to homes in rural areas of the Reservation have an all-weather surface.

Maintenance

- Develop and implement a maintenance program for tribal and BIA roads to protect the public investment in the existing road network and to enhance traffic safety.
- Establish and fund an annual budget for maintenance functions.

Transit

- Maintain funding for operations and maintenance and capital needs through grants from the state and FTA.
- Coordinate with regional transit providers when there are opportunities to improve efficiency, maximize service, or reduce costs.

One sees in this list an emphasis on safety and accessibility to reservation facilities and services. These are often the two most identified goals in tribal transportation plans.

### *3. Identifying Needs (through Data Collection) and Analyzing Alternatives*

Tribal transportation planning uses data on a variety of community facilities, services, and land uses as input into the planning analysis. Data are usually collected on the following:

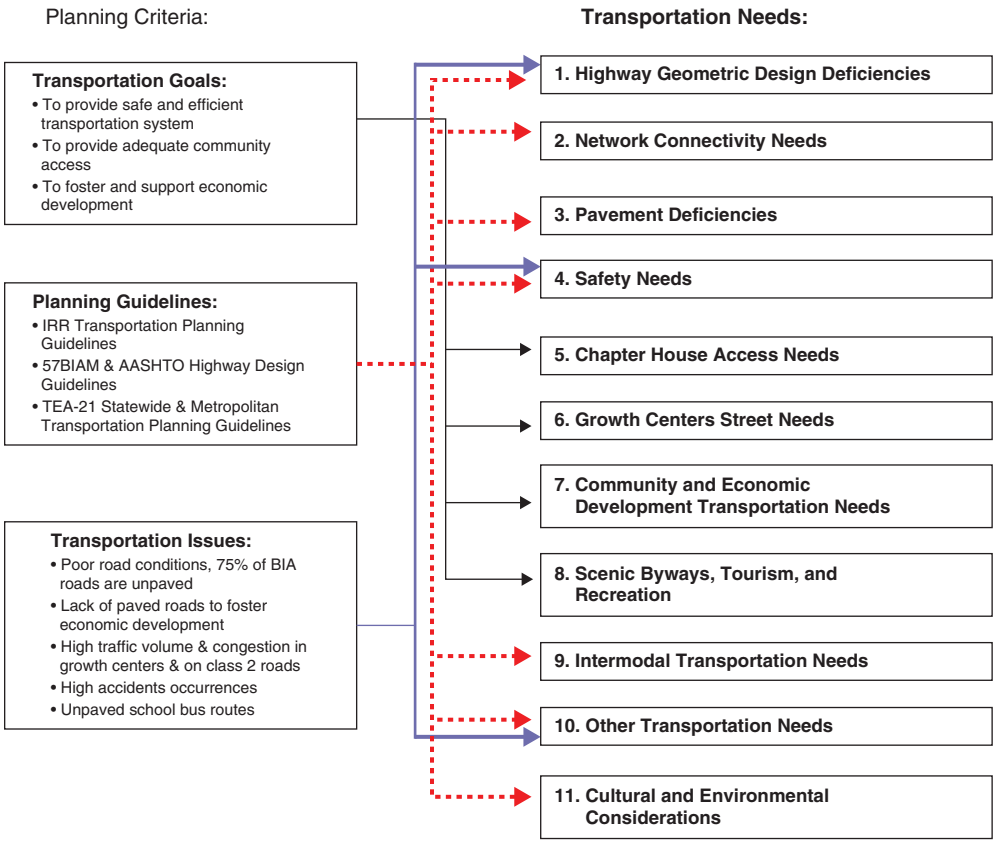
- Crashes
- Current land and development characteristics
- Development plans and proposed development sites

- Demographic information on population and employment
- Environmentally sensitive areas, for example, natural habitats or wildlife refuges
- Funding levels, usually over the past 5 to 10 years
- Historic/cultural sites
- Infrastructure inventory, for example, miles and location of roads or trails
- Pavement/bridge conditions
- Public attitudes and desires, usually through surveys
- Traffic operations, for example, turning movements and signal timings
- Transportation performance, for example, congestion or delays
- Transportation use, for example, volumes, pedestrian/bicycle counts, transit riders
- Topographic data

Data collected on existing systems help identify transportation needs, which then can be analyzed to achieve the most cost-effective program of investments. Figure 20-3 shows the needs assessment process for the Navajo Nation *Comprehensive Transportation Plan,* and shows how transportation needs (and thus data needed for planning) are defined for different modal networks (such as roads, airports, and intermodal facilities) and for different economic contexts (such as growth centers and tourist sites).

A Wind River Indian Reservation study on pedestrian and walking is an example of a study that is more targeted on a particular topic. Thus, the data collection and analysis is not as broad as in a more comprehensive transportation plan.

**Figure 20-3. Planning/Needs Assessment Process for the Navajo Nation Transportation Plan**



Source: NDOT, 2009

| Table 20-4. Survey Data on Factors Influencing Mode to School, Wind River Indian Reservation | | | |
|---|---|---|---|
| | Percentage | | |
| **Issue** | **Yes** | **No** | **Not Sure** |
| Distance | 12.7% | 56.4% | 30.9% |
| Convenience of driving | 24.1 | 51.9 | 24.1 |
| Time | 24.5 | 43.4 | 32.1 |
| School activities | 26.4 | 49.1 | 24.5 |
| Speed of traffic | 43.7 | 38.0 | 18.3 |
| Amount of traffic | 42.6 | 34.4 | 23.0 |
| Adults to walk/bike with | 50.0 | 21.2 | 28.8 |
| Sidewalks or pathways | 59.0 | 19.7 | 21.3 |
| Safety of intersections | 44.8 | 37.9 | 17.2 |
| Crossing guards | 39.6 | 35.4 | 25.0 |

| Weather or climate | 46.9 | 32.8 | 20.3 |

Source: Wind River Indian Reservation, 2012

[Wind River Indian Reservation, 2012] The Wind River Indian Reservation, located in eastern Wyoming, had experienced several pedestrian/vehicle injuries and fatalities in the years preceding the study. Surveys were used to solicit information from parents and school children on issues relating to transportation to school. Table 20-4 shows some of the results of the parent survey, which was aimed at identifying those factors that influence the mode used to access schools. Using such data, the planners were able to identify a program of improvements to enhance the safety of walking and bicycling in the Reservation.

The project alternatives considered in tribal transportation planning are straightforward given the problems and eligibility requirements of funding programs. Thus, for example, the goals stated for the Navajo Nation road network lead to a limited number of potential investment strategies—enhanced maintenance, pavement rehabilitation, road reconstruction, and new paved roads. Similarly, bridge deficiencies can be resolved with a limited number of engineering applications. The more difficult analysis process occurs when decisions focus on major new infrastructure or service provisions. This is where the process of analyzing alternatives becomes more important and often more complex.

### *4. Evaluating Alternatives*

The evaluation process is very similar to that described for rural areas. In some cases, such as that for intersection improvements or the application of safety countermeasures in high crash locations, the evaluation approach can be quantitative. For example, crash modification factors (CMFs) can be used to determine the likely reduction in crashes given the implementation of certain countermeasures (see chapter 23 on safety). Or, traffic intersection software can be used to determine the future operational characteristics at key intersections and then assess the benefits of intersection improvements. Table 20-5, for example, shows the expected intersection performance for key intersections in the Warm Springs Reservation for the year 2030. [Confederated Warm Springs Indian Reservation, 2014]

In many cases, information from the data analysis is presented in public forums and attendees are asked to prioritize the projects based on the information produced by the transportation planning process. The transportation planners then apply the results of the analysis, consider tribal priorities, incorporate anticipated development schedules, and identify available funding to define the projects that should receive priority.

### *5. Involving the Public*

Public participation for tribal transportation planning uses many of the same techniques and tools as other planning studies, but only provided for different types of groups. Depending on the size of the study, the planning process might simply rely on an advisory committee or public meetings as outreach opportunities, or for larger studies, a public involvement plan could be developed that outlines the key audiences/stakeholders for the study and the types of techniques and strategies that will be used to reach them. An example of the latter will be used below to illustrate the characteristics of a public involvement outreach effort.

| Table 20-5. Example Intersection Analysis, Confederated Tribes of Warm Springs | | | | | | | |

Source: Confederated Tribes of Warm Springs, 2014

As part of the Hualapai Indian Tribe long range transportation planning effort, a public involvement plan (PIP) was developed by the Arizona DOT to "describe in detail how the Arizona Department of Transportation (ADOT), the Hualapai Indian Tribe and the project team will solicit public input; inform and involve the public, tribal officials, agencies and stakeholders." [ADOT, 2013] The goals of the PIP were to: (1) engage stakeholders to help ensure the final report incorporates agency and public input, (2) provide clear and accurate information that encourages informed public participation and input, (3) provide multiple, convenient ways for interested parties to provide comment, and (4) provide multiple means through which the public can learn about the project.

Key stakeholders were identified and interviewed for their thoughts on the transportation challenges facing the Tribe. These stakeholders included:

- Tribe Law Enforcement Liaison Board
- Tribe Education Committee
- Transportation Enhancement Review Committee
- Department of Soil & Water Conservation
- Boys & Girls Club
- Grand Canyon Resort Corporation Board
- Game & Fish Committee
- Youth Camp Planning Committee
- Hualapai Youth Council
- Head Start Policy Council
- Health Board
- Hualapai Justice System Advisory Board
- Tribe Cultural Advisory Team
- Tribe Recreation Committee

The plan recommended establishing a technical advisory committee consisting of representatives from agencies having technical knowledge and expertise valuable to the study. In addition, it was recommended to establish a study website, hold open houses and other public meetings, reach out to the Tribal Council, tribal elders and other key groups in the tribe, and establish a telephone comment line. As noted above, such a public involvement plan is usually not prepared for a tribal transportation planning study, but it does show the types of outreach strategies that can be used.

### *6. Transportation Safety Planning*

Transportation safety, in particular road safety, has consistently surfaced to the top of the major issues facing tribal nations. The prominence of road safety in tribal transportation planning has been acknowledged by both the federal

government and state DOTs that coordinate planning efforts with tribal nations. The FHWA has produced technical guidance on how to develop a tribal transportation safety plan. [FHWA, 2015] A transportation safety plan was defined as "a collaborative and comprehensive document that identifies transportation safety issues and strategies to address them. Effective Transportation Safety Plans lead to projects that make the transportation system safer." Such plans are to be data- and evidence-driven such that they can:

- *Identify problem areas:* Data can help tribes develop priorities by identifying the locations with the most serious safety problems and the greatest potential for improvement.
- *Evaluate safety strategies:* Data can be used to track or measure progress by creating and comparing "before" and "after" conditions at a project or community-wide level.
- *Assess outcomes:* Data are essential for tracking progress and evaluating the outcomes of projects and programs to understand their effectiveness.
- *Justify funding:* Tribes often have to demonstrate that a safety problem exists to be eligible for grant funding under federal safety programs.

The guidance identified a seven-step process for conducting transportation safety planning in tribal communities.

Step 1: Establish a Safety Leadership Framework.

a. Identify a champion.
b. Convene a working group.
c. Identify and contact stakeholders.
d. Develop a vision, mission statement, and goals.
e. Gain tribal council support.

Step 2: Collect and Analyze Safety Data.

a. Gather data.
b. Supplement limited data.
c. Analyze data.

Step 3: Determine Emphasis Areas.

a. Identify potential emphasis areas.
b. Prioritize emphasis areas.

Step 4: Research and Identify Potential Strategies.

a. Research strategies.
b. Identify potential strategies.
c. Identify target outcomes.

Step 5: Prioritize and Incorporate Strategies.

a. Prioritize and select final strategies.
b. Identify responsibilities for each strategy.

Step 6: Draft the Plan.

Step 7: Evaluate and Update the Transportation Safety Plan.

a. Evaluate the transportation safety plan.
b. Update the transportation safety plan.

| Table 20-6. Illustrative Strategies and Outcomes for Tribal Safety Transportation Plan | | | | |
|---|---|---|---|---|
| | **Strategies** | **Target Outcomes** | **Organizations and Individuals Responsible** | **Target Date of Completion** |
| **Education** | Conduct public education and outreach sessions to raise motorists' awareness of pedestrian and bicyclist safety needs. | Conduct public education | Conduct public education | Conduct public education |
| **Enforcement** | Strictly enforce laws regarding yielding to pedestrians. | Reduced incidence of crosswalk violations | Transportation Safety Plan champion (for example, Wind Lake Tribe law enforcement officer) | On-going |
| **Engineering** | Implement effective engineering counter measure, such as pedestrian crossing islands. | Reduced risk for pedestrians through increased visibility | Wind Lake Traffic Engineering Chief Safety Engineer | Dec. 2014 |
| **Emergency Medical Services** | Improve the response time of emergency services in the case of pedestrian crashes. | Increased response time to pedestrian crashes | The Wind Lake Reservation EMS coordinator | On-going |

Source: FHWA, 2015

The guidance provided an example of the type of outcomes from transportation safety planning, shown in Table 20-6. The strategies were organized in four categories—education, enforcement, engineering, and emergency medical services. In addition, target outcomes were identified for each type of strategy along with target dates.

An example of how this approach has been applied to a tribal nation is found in the Red Lake Nation *Transportation Safety Plan*. [Red Lake Nation, 2015]

## IV. SUMMARY

Much of the interest and focus of transportation planning is on statewide and/or metropolitan issues. Many of the planning tools and data collection techniques are oriented to this scale of urban and metropolitan planning. However, there are important and significant transportation challenges facing rural and tribal nation communities as well. In some cases, given the economic status and isolation of some of these communities, these challenges are even greater than those found in metropolitan areas. The transportation planning process for rural communities and tribal nations follows similar steps to other planning efforts. The types of problems tend to differ, however. Typically, more emphasis is placed on road safety and conditions, accessibility to community centers, and the need to preserve heritage and cultural resources. Data availability and data management are particularly difficult in rural and tribal nation studies simply because of the costs involved. Many of the planning tools, such as demand models, may not be appropriate for use in such contexts. Additionally, the types of strategies used for public outreach need to be more targeted to the populations being served.

Even with these challenges, the need for effective transportation planning is probably even greater for rural communities and tribal nations than other contexts simply because effective transportation investment can make a significant difference in the lives of rural and Native American residents.

Note: Besides those references already mentioned in the text, the Community Transportation Association of America has Rural and Tribal Passenger Transportation Technical Assistance Programs, as well as other resources. FTA has a Rural Transit Assistance Program (RTAP) with a rural toolkit that highlights TRB Transit Cooperative Research Program (TCRP) Report 101: Toolkit for Rural Community-Coordinated Transportation Services. The American Public Transportation Association has an online publications section and a TCRP section where reports on rural transit can be selected. All of the TCRP reports are available for sale or in downloadable PDF format. FHWA's Local Technical Assistance Program (LTAP) and Tribal Technical Assistance Program (TTAP) are a tremendous resource for small community and tribal agencies.

# Recreational Areas[1]

## I. INTRODUCTION

Visits to recreational areas and major parks have been one of the fastest growing travel markets in the United States—and in the world—during the past 50 years. Primarily due to increasing population, but also because of increasingly accessible remote parks and recreational areas, planning for the access to, and circulation within, recreational sites has become part of the transportation planning field. Recreational attractions, especially national parks or wildlife refuges, often have unique ecological value to a nation; thus, the resources they represent need to be managed sustainably. This requires a strategic perspective on how visitors, workers, and those who deliver goods access and use a park's transportation system. In many locales, the road and path networks are in themselves fragile and often not designed to handle large volumes or heavy vehicles. The vulnerability of these networks to climate change and extreme weather events that could shut down a park leads to a concern for incorporating resilient transportation design into recreational transportation planning.

There are many different types of recreation areas. In the United States, there are over 400 units of the National Park System and over 6,600 state parks. Recreation areas are also managed by other federal agencies, including the U.S. Forest Service, U.S. Fish and Wildlife Service, and the Bureau of Land Management. At the state and local levels, recreation areas can include lakes, rivers, and the seashore; and there are also privately owned recreation areas. While the concepts of transportation planning for recreation areas apply to all of the above, many of the examples in this chapter are from U.S. national parks.

This chapter describes the unique characteristics of transportation planning for recreational communities, with primary focus on large parks or recreational areas. The next two sections present characteristics of recreation travel and of the transportation systems that visitors use. The following section discusses the transportation-related characteristics of the visitors themselves, and how these characteristics lead to transportation system needs. The transportation planning process for recreational areas is presented in the following section, organized by the major planning steps shown in Figure 1-1. The importance of communication with both recreational visitors and with surrounding communities is explained in the next section, and the final section discusses some of the future challenges facing transportation planning for recreational areas.

## II. CHARACTERISTICS OF RECREATIONAL TRAVEL

Understanding the characteristics of travel that occurs in a study area is an important first step in any transportation planning process. This is particularly true for recreation-related transportation planning, given that the characteristics of recreational areas themselves, the transportation systems that serve them, and the people who visit are very different from commute travel or travel for other trip purposes.

Tourism and recreational travel is increasing in terms of activity, importance, and transportation complexity. In the United States, 18 units of the National Park System each had more than four million visitors in 2014 and 42 units each had more than two million visitors. Growth in the visitation at all types of recreation areas has caused increasing levels of road congestion, greater stress on the natural environment and, in many areas, refocused attention on air quality concerns from transportation sources. These issues affect one of the underlying attractions of vacation

[1]The original chapter in Volume 3 of this handbook was written by Anne E. Dunning, Ph.D., Associate Professor, Department of Planning, University of Kansas. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer

spots—experiencing a vacation-quality environment. When on vacation, people want to escape from the daily exposure to traffic congestion, parking difficulties, crowded transit systems, and poor environmental quality. Transportation systems in recreational communities need to make visitors feel comfortable (despite a degree of unfamiliarity with the system), well-served, relaxed, and satisfied with the travel experience.

Recreational communities are defined as any community whose economy depends heavily on tourism. This definition can be interpreted loosely because a wide range of communities prefer to identify themselves as recreational destinations. National parks have *gateway communities*, most often located immediately adjacent to the parks. However, communities located several miles from park entrances also identify themselves as gateway communities. The reason for this is not surprising . . . . major recreational attractions can positively affect economies and resources over large areas. For instance, 3.88 million visitors to Yosemite National Park in 2014 spent $405 million in the communities near the park. That spending supported 6,261 jobs in the local area and had a cumulative benefit to the local economy of $535 million. [National Park Service, 2015]

Although some large cities target much of their economy on attracting tourists (for example, Las Vegas, Nevada, and Orlando, Florida), most recreational communities are small- to medium-sized cities. Thus, whereas major cities have transportation systems geared to the local population with some consideration for visitors, many smaller recreational communities have a local year-round population and a substantially larger tourism population. Transportation systems in these communities are often focused on handling the influx of visitors, rather than on the mobility needs of the relatively small local population.

Recreational travel differs from urban travel in important ways:

- Peak demand can occur at unusual times, for example, around meal times and at sunset, rather than at the start and end of the business day. Recreational destinations near urban areas might have heaviest visitation on weekends, whereas remote destinations might have consistent traffic on weekends and weekdays.
- Although many recreational areas are in remote locations, recreational visitors typically come from metropolitan areas, making visitors sensitive to travel time and transit frequency. Thus, transportation systems need to provide vacation-quality service. If transit service quality fails to meet high standards, tourists might choose other destinations for their vacations.
- Although transportation planning often focuses on visitor mobility, transportation for recreational areas must accommodate the commuting needs of the local workforce. In addition, unless year-round visitation merits continuous service, transit and the operation of the local transportation system must also consider the travel demands of a seasonal workforce.
- At many recreational areas, more than half of the users of the transportation system might be visiting the area for the first time; thus, there is a special need for effective information dissemination on the transportation services available to visitors.
- Many recreational areas are attractive because of the beauty of difficult terrain and climates, which might require special vehicles and driving skills. Unique ecosystems and the presence of wetlands might also necessitate special ecological protection. Because of the often ecologically sensitive nature of the recreational site, transportation planning for recreational communities should demonstrate heightened sensitivity to environmental sustainability and quality of life. These traits attract visitors to recreational areas in the first place, and they must be maintained or enhanced.
- Recreational areas featuring natural attractions might create challenges with the interaction of wildlife and transportation operations. Highway safety engineers in these areas need to design for the safety of both drivers and wildlife, public relations professionals need to sensitize unfamiliar drivers with the unique local dangers, and environmentalists need to work with transportation professionals to protect smaller species and plant life from the threats of pedestrians and vehicle traffic damaging habitat.
- Planning in recreation areas must accommodate the requirements and needs of multiple jurisdictions given that the movement of visitors could entail travel on public and private venues, local streets, state highways, and possibly federal lands. Somewhat different from the metropolitan context, however, is the greater participation in the planning process of organizations and groups whose purpose is primarily to protect the environment.

- Recreational travel demands place a great deal of stress on the local transportation system. Often, the funding for system improvements will rely on fares or other fees obtained from the visitors themselves. Where transportation system funding comes from other governmental sources, the significant seasonal variation in travel demand is not reflected in the traditional allocation formulas that distribute funds according to residential population.

In the most popular U.S. national parks, the most common transportation issues are entrance station congestion, parking congestion, and crowding on transit systems.

## III. CHARACTERISTICS OF TRANSPORTATION SYSTEMS SERVING RECREATIONAL AREAS

The following characteristics are important considerations for improving transportation system performance in recreational areas.

### A. Modes of Travel

Part of the transportation analysis for recreational areas includes matching modal attributes with the characteristics of the recreational area and of the travel markets that are likely to generate visitor demand. An important characteristic of many recreational communities is the multimodal nature of accessing many of their attractions, such as a waterfront inn that is accessible by taxi, motor vehicle, bus, bicycle, walking, or boat. Given this diversity in mode use, it is important that the transportation system itself fosters intermodal connectivity, such as visitors putting a bicycle on a bus rack to access distant bicycle trails.

The mode that people use to access a recreational area influences their travel behavior and mode choice when circulating within the area. If visitors rent a car to visit, they will likely use that vehicle during their stay. If visitors arrive at an airport and find convenient public transit or taxi options to take them to their destinations, they might never need a private vehicle to enjoy the recreational site. Transportation planners should thus view gateways as modal portals to recreational areas, points where visitors make decisions on which modes they will use. By focusing on such early travel decision points, planners can influence travel demand throughout the recreational area.

Some recreational destinations in remote locations, such as islands or in Alaska, cannot be accessed easily or at all by road vehicles. Visitors at these locations use local modes such as boats and small airplanes to reach the destination, and nonmotorized or shuttle systems might be the norm for internal circulation. For example, half of the visitors to Alaska's Denali National Park and Preserve arrive by cruise ship in Anchorage, Alaska, take a railroad to the park, and use Denali's bus system for sightseeing. Modal planning in these types of locations frequently focuses on assuring sufficient capacity to handle the demand.

*Passenger Cars and Light Trucks*. Congestion caused by private motor vehicles is a growing problem in many recreational areas. Dealing with this congestion with traditional infrastructure approaches (such as adding more road lanes) is often infeasible given natural barriers, historic preservation requirements, jurisdictional difficulties from local governments, lands owned privately or by the state or federal government, and so forth. In Glacier National Park, for example, the most congested road facility is the Going-to-the-Sun Road, which is listed on three historic registries. Due to its historic designation, it cannot be widened beyond its historic two, 11-ft (3.4-meter [m]) lanes. This historic width, combined with mountain switchbacks, prevent modern recreational vehicles (RV) and large pickup trucks from using the road.

In many recreational areas, much of the road congestion is associated with parking. Many visitors drive to a parking location and then walk a short distance to see an attraction. For highly desirable sites, this can cause substantial backups at the parking lots, with vehicles waiting in line for spaces to become available. If local hotels have built sufficient parking capacity within walking distance of recreational attractions, this problem might be alleviated. Where demand for parking exceeds supply of designated spaces, visitors often create informal parking spaces along roadsides, which can damage sensitive ecosystems.

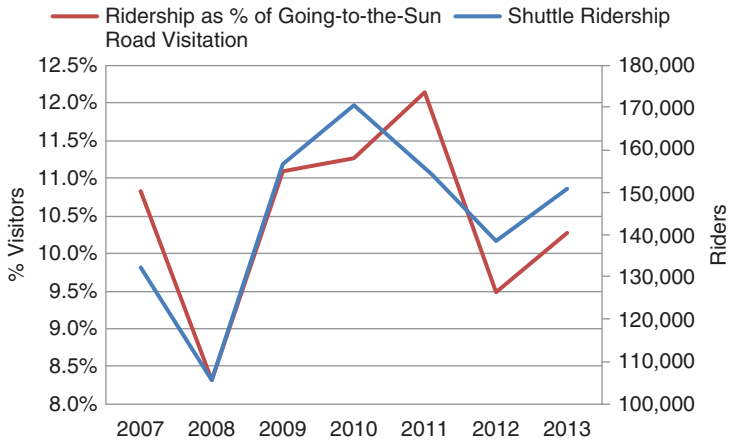
Traffic safety problems also emerge in unique forms. Drivers could be unfamiliar with road networks and the best locations for available parking. These distracted drivers are often on the same streets with families and children roaming

local villages or hiking along the road. Further challenges arise in the form of difficult driving terrain in mountains and along winding coastlines.

*Nonmotorized Modes*. One of the distinctive characteristics of many recreational communities is the large amount of visitor walking. According to the National Park Service *Transportation Planning Guidebook,* "Bicycling and walking, particularly when combined with affordable and efficient transit service, are effective and pleasurable alternatives to automobile travel. For these alternatives to gain popularity, they must be safe, enjoyable and convenient. Ideally, visitors should learn about alternatives to automobile travel before they leave home so they can take advantage of pedestrian, bike, and transit facilities, and services available within the park." [NPS, 2014] The *Guidebook* outlines the need and means to provide signs, distinguish bike lanes, improve crosswalks, enhance shoulders, create safe zones, enhance bridges, build route linkages, enforce rules of the road, raise visibility, reduce obstructions, and regulate trail time. The *Guidebook* endorses facilities for transit compatibility with bicycles, bicycle storage, and bicycle rentals.

*Transit*. Transportation studies in recreational areas often begin with an examination of potentially viable public transit services. Public transit could lead to fewer parking requirements and reduced traffic congestion (to the extent that auto users are substituting transit modes for their auto trips). Figure 21-1, for example, shows the transit ridership for Glacier National Park in terms of ridership and percent of total visitors. The eight-year average of ridership was 144,000 per year for an operating season that lasted approximately 10 weeks.

**Figure 21-1. Transit Ridership, Glacier National Park, 2007–2013**



Source: Glacier National Park, 2012

To be effective, public transit systems in recreational areas must offer vacation-quality service that people will consider preferable to private vehicle travel. In some cases, this is helped by policies restricting vehicle use, such that transit is the only means of accessing some areas. Where no such restrictions apply, marketing campaigns should be used for the different traveler markets visiting the recreational site.

Within the broad definition of public transit, several types of vehicles and services exist. *Rubber-tire transit* (primarily buses of various shapes and sizes, including open-air shuttles and buses configured to look like trolleys) provides the greatest service flexibility to transit operators. Where demand emerges either due to long-lasting trends or a temporary event, capacity can be allocated to meet the need.

Bus services can serve both tourists and employees. A high proportion of the people who operate recreational area attractions have no private vehicle, and high land values make affordable housing scarce. Outside Myrtle Beach, South Carolina, for example, service workers ride buses for two hours each way to access minimum-wage service jobs. Local affordable housing is most likely the solution to this problem, but public transit serves as a stop-gap measure.

One of the biggest disadvantages of buses is that they use existing roadways and thus often get caught in congestion just like other vehicles. This disadvantage can be mitigated with entrance gates dedicated to buses and signal preemption (in urban areas) to activate a green light for transit vehicles. The other primary disadvantage of buses relates to visitor uncertainty of where the bus will go, but sound planning and marketing can address this problem. Although information dissemination is a key factor for transit success, simple geometric design can sometimes deliver the message even more powerfully. Zion National Park found that bus pullouts on the side of the road oriented visitors to the direction of the bus, whereas stops located in parking lots confused visitors and led to numerous questions on the bus routes.

Except in highly urban park environments, *rail transit* (light rail, monorail, streetcar, and, less likely in recreational settings, heavy rail and commuter rail) is not likely to be an option for park visitors. Rail systems offer little flexibility for evolving service demands. One particular rail mode deserves special attention in a discussion of rail for recreational areas. Monorail has assumed a reputation (rightly or wrongly) as a rail technology intended for recreational sites. Few cities have adopted monorail since it debuted at the 1962 Seattle, Washington, World's Fair, although Disney theme parks and Las Vegas now have such systems. While the Disney Company does not report ridership to government agencies, the Monorail Society [2013] reports monorail ridership in Florida's Disney World exceeds 150,000 riders per day.

*Snowmobiles*. The use of snowmobiles has grown significantly over the past several decades. In 2014, there were 1.4 million registered snowmobiles in the United States. (Minnesota and Michigan far surpassing other states) and 594,276 registered snowmobiles in Canada. [International Snowmobile Association, 2014] Similar to the jet ski, snowmobile use is often criticized because of the associated environmental impacts of noise and air pollutants. While some parks, such as Glacier National Park, have prohibited snowmobiles in the park, other parks that already allow snowmobiles have done so in a carefully managed way.

*Modes That Need Intermodal Connections*. Several commonly used travel modes in recreational areas are not usually the subject of transportation plans, but their use often requires intermodal connections to personal vehicles or transit services. *Boating and personal watercraft,* both motorized and nonmotorized, have become very popular in many recreational areas. Boaters typically participate in a range of activities. Only 8 percent spend their time boating, while 80 percent of rental boaters (40 percent of nonrental boaters) engage in picnicking and 15 to 20 percent of boaters go hiking. Island communities, parks and resorts frequently foster travel by *small airplane*; Alaska has the highest frequency of general aviation activity in the United States because harsh winter conditions make maintenance of small runways at origins and destinations more pragmatic than building (and plowing) highways connecting long distances.

*Cruise ships* bring unique transportation planning challenges by depositing thousands of passengers into a community over a short period of time. Communities might find their transportation infrastructure significantly affected if many cruise ships arrive at similar time. All of the passengers arrive without private vehicles; therefore, pedestrian areas, transit, and bus tour services will likely serve the majority of transportation needs for cruise ship passengers.

Aerial touring allows people to view sites from the sky, typically in helicopters or small planes. Some controversy has arisen over their use in certain types of recreational areas. The noise of aircraft engines interrupting the solitude of nature has resulted in years of conflict between preservationists and the aerial touring industry. The National Parks Overflights Act of 1987 (49 USCS § 40128) established more stringent noise standards for national parks.

## B. Peak Travel Activity

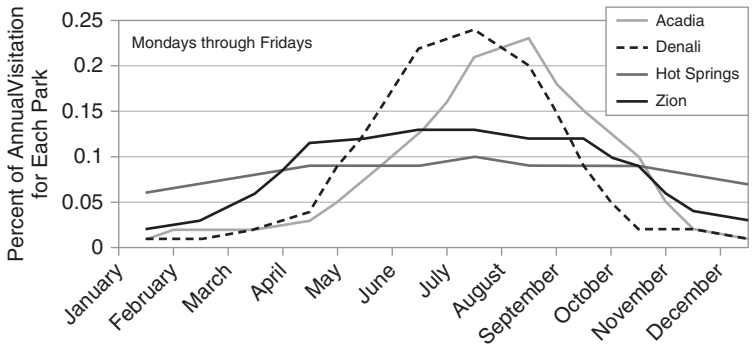
Peak travel activity in recreational areas differs substantially from that found in urban transportation systems. Peak travel can occur by time of day, day of week, and month of year. Visitation at recreation areas can spike on summer holiday weekends.

*Annual Peaks (Month of Year)*. Recreational areas typically have three types of seasons: peak, shoulder seasons, and off-season. The peak season refers to the months of the year when the most visitors go to a recreational area. Peak season in the United States typically occurs in the summer months of June, July, and August when schoolchildren have summer vacations. The length of peak season varies from park to park; weather and climate usually determine the time and duration of peak seasons.

*Shoulder seasons* occur during the weeks leading into the peak season and the weeks immediately following. Visitation in recreational areas transitions from low off-season numbers to the high visitor count of the peak season. Similarly, after the peak season, the time in between peak season and low season often sees a moderate number of visitors. Shoulder seasons refer to these times of moderate visitation.

During the *off-season,* recreational areas usually host only a small number of visitors. Frequently, attractions, businesses, and amenities close off-season because they cannot financially justify keeping staff and continuing operations.

**Figure 21-2. Duration and Intensity of Peak Visitation Seasons in Four National Parks: Acadia in Maine, Denali in Alaska, Hot Springs in Arkansas, and Zion in Utah, 2015**



Source: Data from United States, National Park Service Traffic Counts

The geographic location of a recreational area can affect the duration and intensity of its visitor season (see Figure 21-2). Recreation within a day's drive of cities might have a steady stream of weekend visitation throughout the year, as in the case of Hot Springs National Park (Arkansas), but most recreational areas get the majority of their visitors during

the summer (except, of course, those sites catering to ski tourism). Northern destinations, such as Denali, Alaska, and Acadia, Maine, have few summer months with passable roads, whereas southern attractions without such limitations might start their peak season earlier and end later. The desert heat of Zion National Park in Utah with average summer temperatures of 95°F to 107°F (35°C to 42°C), results in lower summer visitation compared to locations in cooler climates.

The length and intensity of seasonal visitation influence local transportation service. Most notably, transportation services and infrastructure are often unnecessary and unused in the off-season. Recreational areas with steep peaks of short duration face difficult challenges of providing sufficient capacity for a couple of months to meet visitor needs and then maintaining the costs through the long off-season. Infrastructure-based transportation systems, such as road networks and bicycle pathways, do not suffer substantially from seasonality except that congestion is felt most at the height of the peak. Intelligent transportation system (ITS) technologies (see chapter 10) can generally be switched off when the demand no longer justifies their operation (and cost). Service contracts are often negotiated accordingly.

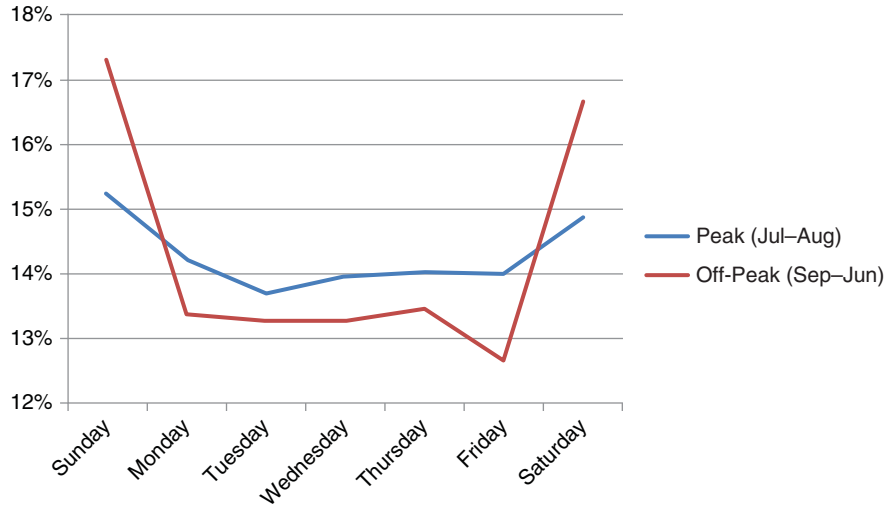
Transit operates best where a large number of people want to move between a concentrated number of points, so the crowds of a high peak season can move efficiently on transit. However, a short season with a high peak means that a large number of drivers need to be hired for short-term work. With a lower peak and a longer season, a smaller number of people need transportation over a longer period of time. A transit system in this type of area requires a smaller number of seasonal drivers, but might have difficulties amassing enough riders to justify the cost of transit operations, particularly if the area has dispersed visitor destinations. Furthermore, recreational areas with long visitor seasons might need to operate before Memorial Day and after Labor Day, which might make it difficult to hire drivers, many of whom drive school buses when not working in seasonal transportation.

*Weekly Peaks (Day of Week)*. Weekly peaking behavior also depends on the type of recreational area. Vacation destinations in remote locations that require substantial pre-trip planning and often lodging reservations tend to encourage longer stays. In such locations, little difference exists between weekend and weekday visitation. However, recreational areas within or near population centers often attract shorter trips on weekends.

Glacier National Park, a destination park, sees little variation in visitor volumes from day to day, but some differences emerge when weather and wildfires turn away casual weekend visitors. Vacationers traveling over long distances tend to continue with their plans, as indicated by the stability of weekday visitation (see Figure 21-3).

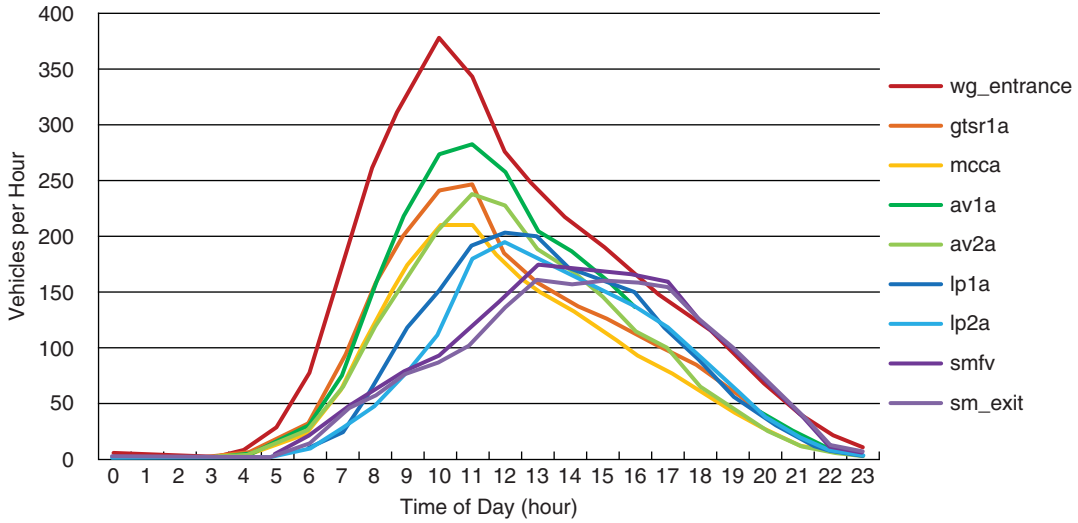
*Daily Peaks (Time of Day)*. Urban areas display distinctive peaking during the mornings and afternoons on weekdays when commuters travel to and from work. Smaller peaks occur at lunchtime and when school days end for children. Recreational areas also experience the phenomenon of people leaving their lodging at similar times to visit attractions, but the demand often does not follow the traditional dual-peak pattern (see Figure 21-4). Whereas urban peak traffic hours occur around traditional commute times, recreational peak hours for traffic and riding transit often occur around events, meal times, and sunset. Morning peaks start later in most recreational sites.

**Figure 21-3. Percent Traffic by Day of Week, Glacier National Park, 2012**



Source: Glacier National Park, 2012

**Figure 21-4. Vehicles per Hour at Different Locations on the Going-to-the-Sun Road in Glacier National Park by Entrance to Park, 2012**

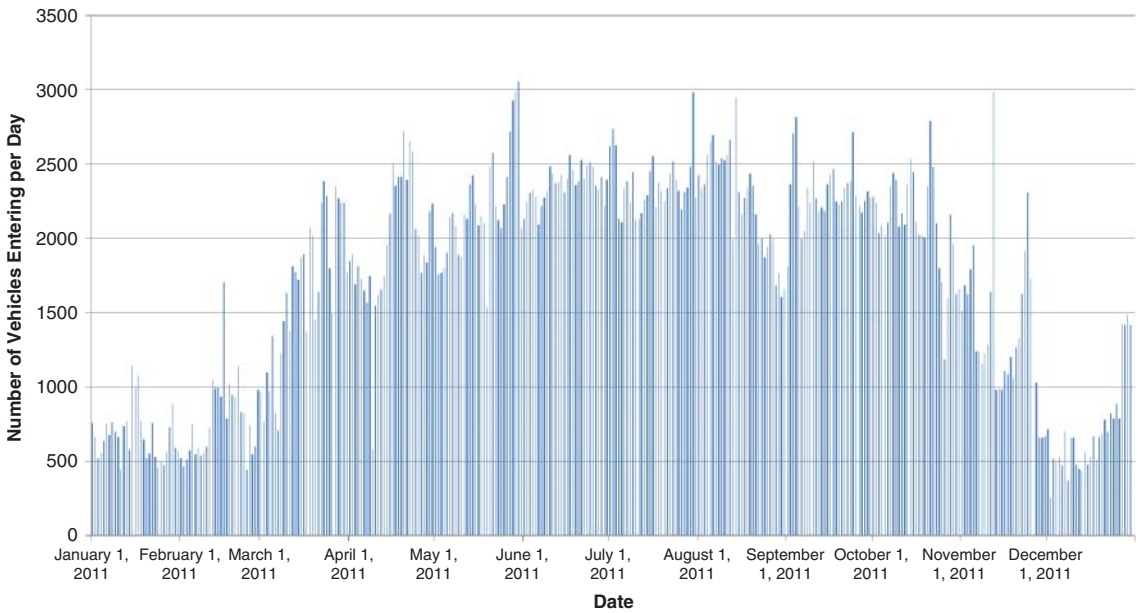


Source: Glacier National Park, 2012

If a recreational area features special events, the event schedules likely determine peak activity. Frequently, mountain climbers start their journeys before dawn, which might create a special need to ensure clear roads earlier than in metropolitan areas. Fireworks at night bring increasing volumes of traffic up to the start of the event, cause distracted drivers and congestion during the show, and create a sudden surge of transportation demand back to lodgings after the finale.

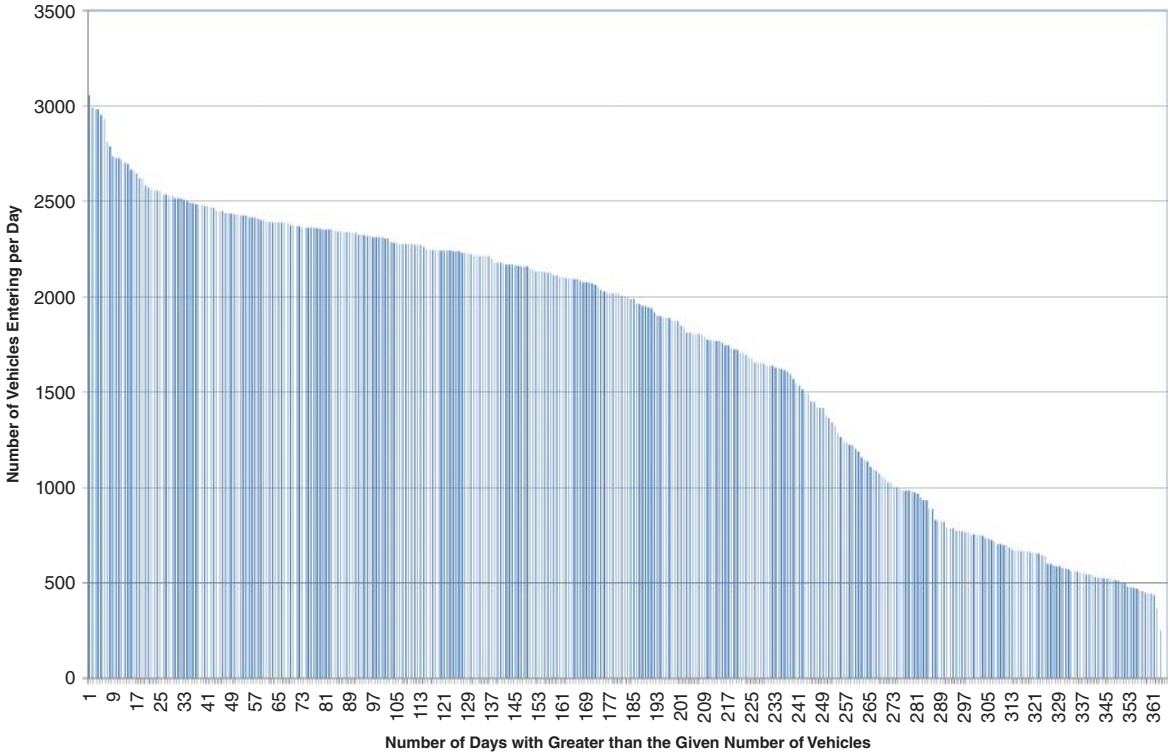
*Day of the Year*. Variation in recreational area visitation can also be portrayed by each day of the year. For example, Figure 21-5 shows the number of vehicles passing through the South Entrance Station at Zion National Park for each day in 2014. Spikes in visitation are evident for Presidents' Day, Spring Break, Easter, Memorial Day, Independence Day, Labor Day, Veteran's Day, Thanksgiving, and the Christmas–New Year's Day period. Similar day-by-day profiles have been found for other National Park units. In some parks the "shoulder seasons" are narrow and in other parks the shoulder seasons are quite wide. Some parks exhibit spikes on many weekends. Figure 21-6 takes the number of vehicles entering on each day of the year and presents the data in a highest to lowest histogram format. This format

**Figure 21-5. Vehicles Entering Zion National Park, Day of Year, 2014**



Source: Courtesy of Dr. Jonathan Upchurch

**Figure 21-6. Vehicles Entering Zion National Park, Ranked Highest to Lowest, 2014**



Source: Courtesy of Dr. Jonathan Upchurch

reveals the challenge of accommodating transportation demand on the 10 highest days of the year. This effect likely holds in most recreational areas, whether they be national parks, state parks, or other types of recreational areas.

## C. Travel Companions and Vehicle Occupancy

People typically do not visit recreational areas alone. The National Park Service estimates visitation based on average vehicle occupancies ranging around 2.8 or 2.9 passengers per vehicle. This average occupancy contrasts with the 2010 United States national average vehicle occupancy of 1.67, which includes all trip types. Given a higher number of people traveling together in recreational areas, transportation planners should be sensitive to the following:

- Transit fare structures should consider the total cost for groups, rather than individuals. A $10 individual fare amounts to a $40 out-of-pocket cost for a family of four. The family will compare $40 for transit against a $15 parking fee and make its mode choice accordingly.
- Rest areas, rest facilities, and shopping areas should be designed with potentially large pedestrian volumes as a design standard.

## D. One-Way Transportation

Certain recreational activities, typical in natural settings, result in visitors ending a trip several miles away from where they began. In parks where one-way backcountry hiking, river boating, or paragliding attract large numbers of participants, transportation planners can reduce surface transportation and parking congestion by providing transit service. One-way modes might require special provisions depending on the characteristics of the recreational area. For example, where river boating is highly popular, transportation planners might need to establish a reservation system to prevent river congestion from becoming a safety hazard. In such situations, a scheduled transit service between launch and take-out points will reduce traffic and parking problems. In areas with a small but significant number of boaters, an on-demand service might make sense.

Public provision of one-way transportation might become challenging in situations where the visitors do not wish to return to their point of origin. In the case of river boating, people typically want to return to where they left their vehicles and need some means of return. In the case of general touring, people typically do not want to see the sites a second time as they head back to their parked vehicle. For instance, Yellowstone National Park handles substantial auto volumes, yet many people who visit that park do so as part of a tour of other parks in the region, such as Grand Teton and Glacier National Parks. Visitors who enter from the south might wish to leave to the north, making it difficult to leave vehicles at the south entrance, take a bus tour during the day, return in the afternoon and drive back through the park in the evening to continue the journey to the north exit. These types of travel patterns suggest the need for good trip data and analysis so that planners can understand the underlying motivations for trip-making in the recreational site.

## IV. TRANSPORTATION-RELATED CHARACTERISTICS OF VISITORS TO RECREATIONAL AREAS

Recreational visitor demographics vary by type of recreation available in an area. Amusement parks can be expected to draw families with children, resorts might lure adults, and historic attractions might draw mostly seniors and educated hobbyists. Transportation services for each visitor market will most likely require their own special characteristics. However, there are some factors germane to most recreational visitors.

### A. Time Sensitivity

Travel demand research has repeatedly shown that travel time and travel cost are the primary factors affecting travel choices. Although people frequently take vacations to "get away from it all" and leave demands on their time behind, transportation planners should not mistakenly assume that recreational travelers have little time sensitivity. Visitors often have a limited number of days away from work, and that time is valuable. Some visitors at recreational sites are there for conferences rather than vacations and must often adhere to strict schedules. Even people who are relaxing must meet golf tee times, dinner reservations, bus schedules, ferry departures, and airplane flight times. Young parents with tired children are often not willing to wait a long time for a bus or to sit in traffic. At the other end of the spectrum, seniors might find it difficult to stay out all day without a chance to rest.

Core concepts of travel time should thus be considered carefully in recreational area transportation planning. As in urban contexts, time spent sitting in congestion or waiting for buses feels more onerous to travelers than time spent in moving vehicles.

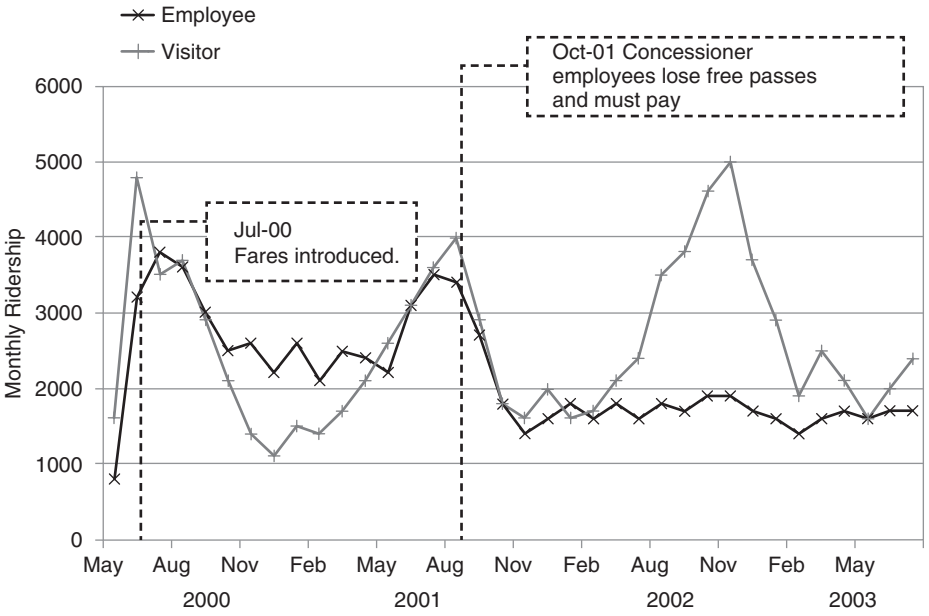
### B. Cost

Travel costs influence travelers' decisions, in particular, costs associated with actual expenses for a trip. If public transit requires a fare, but there is no charge for parking a car, much of the travel will occur by car. Conversely, if drivers must pay to park, while transit is offered free, transit services will be more attractive. Figure 21-7 shows the aggregate mode shift experienced at Yosemite National Park when park concession employees lost free passes on the park's shuttle service … the seasonal peak in commuter ridership disappeared as employees took private vehicles to work.

### C. Service Flexibility

Transportation systems should meet as many visitor travel needs as is cost effective. Thus, accessing the recreational site itself is probably the most important purpose for a transportation system in such a community, but services might also be needed for connecting to grocery, religious and medical facilities, intermodal transfer centers (such as airports or ferry terminals), and other business/restaurant locations. If visiting a restaurant for breakfast requires a private vehicle, that vehicle will likely stay on the road throughout the day, or if a bus route fails to reach a popular store, visitors will rely on the motor vehicle to shop there. To the extent possible, transportation options should be flexible to meet the majority of intended trips. Of course, special transportation services often cannot serve every trip purpose in a study area; system design inherently includes service/cost trade-offs that should be considered during the planning process.

**Figure 21-7. Transit Ridership in Yosemite with Loss of Fare Subsidy**



Source: Data from United States National Park Service Traffic Counts

## D. Personal Belongings

People on vacations tend to have more luggage and personal belongings than for nonrecreational trips. Not only does this luggage include the normal change of clothes and toiletries, but it often encompasses a range of specialty items such as beach gear, ski equipment, cameras, and bicycles. Handling luggage on public transit services can be a challenge, thus, some form of personal storage might be necessary for certain types of visitors. Security concerns at amusement parks might even prohibit visitors from carrying backpacks or substantial camera equipment.

## E. Information Needs

Visitors to recreational sites are often not familiar with the local transportation network. Drivers are unfamiliar with the roads or road closures; transit riders do not know the locations of stops and the time needed to access them; and pedestrians have little awareness of how to navigate the community. This lack of familiarity suggests the need to disseminate information. This information should be available via website to allow visitors to plan their itinerary, as well as on-site so visitors can obtain information while they attempt to use the transportation system. It also makes the training of front-line employees (hotel clerks, waiters, and so forth), as well as traffic management personnel, vitally important.

## F. Safety

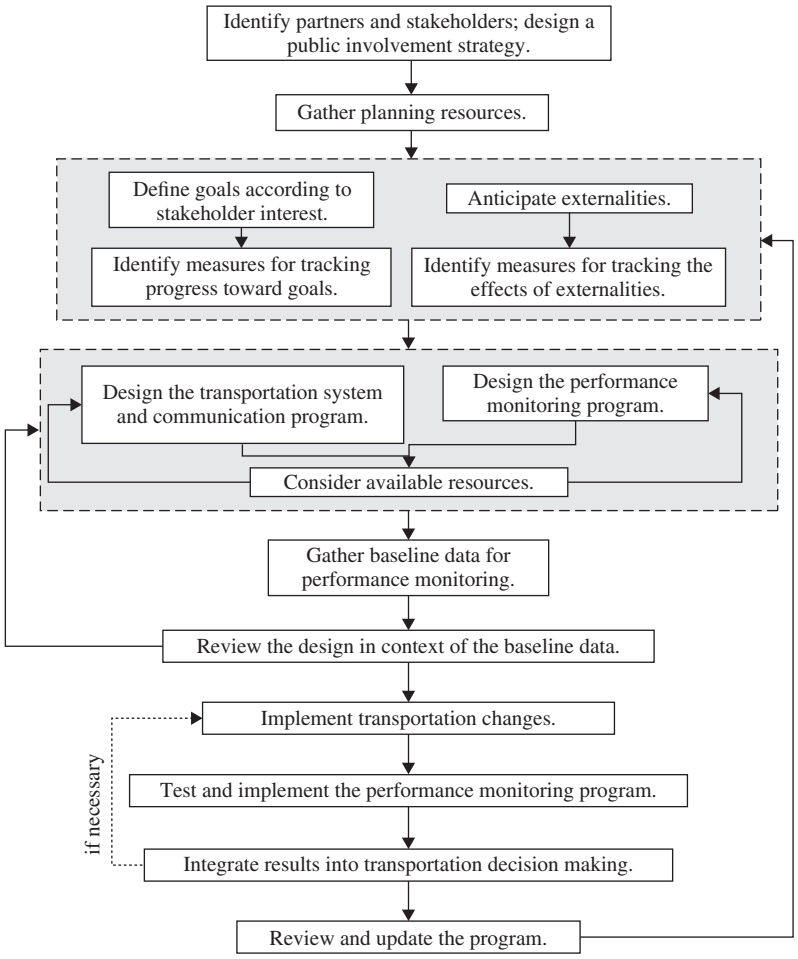
Travelers unfamiliar with their surroundings can also cause safety problems. Visitors will be distracted by sights and confused by trying transportation services and modes for the first time. In some situations, travelers might even cause special needs for emergency access. For example, rangers at Glacier National Park must routinely rescue people driving on the Going-to-the-Sun Road because some drivers panic when they see the steep cliffs at the road edge. [Glacier National Park, 2014]

# V. TRANSPORTATION PLANNING FOR RECREATIONAL AREAS

Recreational planning is the process of examining the transportation access to recreational areas along with the circulation of visitors, workers, and goods distributors within such sites. Transportation planning for recreational areas is illustrated in Figure 21-8. This process is similar in structure to the overall transportation planning process presented

in Figure 1-1, as well as reflects the guidance for national park planning developed by the National Park Service. [NPS, 2014] The following sections provide more detail on the planning steps shown in Figure 21-8.

**Figure 21-8. Transportation Planning for Recreational Areas**



Source: Dunning, 2005

## A. Partnering and Public Participation

Transportation planning in general involves multiple parties, each having a stake in the outcome. This is certainly true for recreational transportation planning. In addition to local stakeholders (see Table 21-1), a number of state and federal government agencies could provide expertise and financial support for transportation systems, depending on the type of recreational area being considered. Such involvement is unlikely for local parks and recreational areas.

Transportation planners in the National Park Service (NPS) have found that partnerships among government agencies, private firms, nonprofit organizations, and other stakeholders have led to transit systems that have been well-received by park visitors and gateway communities. For example, when community partners participated in the planning process at Zion National Park, a planned transit design changed from a park-only system to a two-loop system serving the gateway community and the park. The resulting system reduced the need for parking inside the park and provided auto-free access to restaurants and shops for visitors. [Shea, 2001] Transit planners for Acadia National Park also give credit to partnering for creating a system that provided for the needs of patrons and employees of local businesses, as well as park visitors and staff. [Volpe Transportation Systems Center, 2003]

**Table 21-1. Recreational Area Stakeholders**

| Local Group or Sector | Possible Representatives |
|---|---|
| Business community | Chambers of commerce<br>Tourism agencies<br>Park concessionaires |
| Local population | Elected representatives (mayors or council people) Town managers |
| Local economic development planning | Town planning departments<br>Planning commissioners |
| Transportation operators | Transit operators<br>Private taxi and tour operators<br>Traffic control centers<br>Emergency responders<br>Towing companies |
| Attraction administration | Varied titles in public, private, and nonprofit sectors |
| Holders of general local knowledge | Varied titles |

Source: Dunning, 2004

When the Commonwealth of Massachusetts and the Cape Cod National Seashore wanted to develop a transportation plan for Cape Cod, Massachusetts, one of the most environmentally sensitive areas in the United States, the Secretary of Transportation for Massachusetts appointed members to an advisory task force representing the following groups:

- U.S. Congress (local delegation)
- Office of the Massachusetts Secretary of Transportation
- Cape Cod Commission
- Cape Cod Central Railroad
- Cape Cod Chamber of Commerce
- Barnstable County Human Services
- Southeastern Massachusetts Private Motor Carriers Association
- Barnstable Assembly of Delegates
- Lower Cape Health and Services Coalition
- Massachusetts Highway Department
- Cape Cod National Seashore
- Woods Hole, Martha's Vineyard, and Nantucket Steamship Authority
- Cape Cod Regional Transit Authority
- Transit Dependent Consumer, [Federal Transit Administration, 2012]

Many opportunities were also provided for public input into the planning process.

Partners in the process must have an ability to introduce their needs into the planning process and to influence service design. This requires information dissemination and often education on the specific nature of the transportation challenges facing a recreational area. For instance, local businesses need information on what to expect with changes in transportation accessibility and how to create benefits or mitigate potential impacts of transportation services. If business owners know what they can expect and what is happening, they will respond with more of a sense of involvement in the planning process. This level of partnership with businesses requires more than a short e-mail list and established committee meetings. It requires personal communication, published materials, and information sessions. It entails explanation on many different levels and to many diverse interests.

Interaction with the communities affected by recreational travel needs to occur during the transportation planning process as well as on an ongoing basis. In particular, those individuals who are serving visitors on a daily basis need to be informed of the transportation options available to visitors. Zion National Park offers a model example of how this can be done. Organizers of the Zion Canyon shuttle educated front-line workers in the gateway community of Springdale, Utah, which is located directly outside the national park's border. When seasonal employees were able to inform people about the shuttle, ridership on the town route increased and eased congestion at the entrance gate to the park. The local chamber of commerce also collaborated with this effort to give visitors information about the types of businesses located near transit stops.

Potential means for communicating with local communities include:

- *Pre- and early-season orientation sessions* for all seasonal employees who interact with the public, whether employed by recreational venues, with concessionaires, or by local businesses, should provide the employees with answers to typical transportation questions.
- *Websites and local newspapers* should post planning milestones and reports about transportation options, so the local public knows what infrastructure, service changes and development to expect.

- *Transportation planning representation at town and chamber of commerce meetings* provides another essential means of communicating transportation system strategies to the public affected by the system.
- *Published multimodal maps and schedules* provide useful handouts that can be taken by visitors to better plan their transportation routes.

Effective communication channels should avoid misunderstandings that could lead to loss of credibility in transportation providers. The Island Explorer shuttle at Acadia National Park offers an example. Soon after service began, local businesses who believed they were doing all the advertising for the system, wanted to see more aggressive marketing of the service. However, with ridership demand regularly reaching or exceeding capacity, marketing efforts for the Island Explorer had been purposely limited. Some means of making sure both groups were informed of the status and operations of the services would have avoided this misunderstanding. [Daigle and Lee, 2000]

Recreational community leaders commonly express frustration over the portrayal of their community's transportation system performance in the media. For example, Yosemite National Park businesses noted that when the media reported that the park was closed due to traffic congestion triggering the implementation of a Restricted Access Plan, visitors expressed concern that they would not have access to the park. In reality, riders on the Yosemite Area Regional Transportation System (YARTS) shuttle had guaranteed access; the Restricted Access Plan only delays entering vehicles until space is created by vehicles leaving Yosemite Valley. [Nelson and Tumlin, 2000]

## B. Goals, Objectives, and Performance Measures

Planning partners need to identify the goals and objectives associated with a planning study. This could entail determining what kind of visitor flow and mobility levels are desired, what kind of outcomes they would like to see in the region, and how to attain the desired future. The design of the transportation system will differ depending on the intended results, and performance monitoring should target both progress toward these goals and the externalities associated with the selected transportation systems. A comprehensive national study of transit needs for federal lands identified the following goals for park-related transportation planning:

- Enhance visitor mobility and accessibility.
- Preserve sensitive natural, cultural, and historic resources.
- Provide improved interpretation, education, and visitor information services.
- Reduce pollution.
- Improve economic development opportunities for gateway communities. [Cambridge Systematics and BRW, 2001]

Some less common goals have also appeared, such as:

- Create partnerships in the local community.
- Enhance visitor experience by providing services.
- Achieve services comparable to the services offered by other recreational areas in a region.

Another example of plan goals comes from the Alternative Transportation Plan (ATP) for the Mississippi National River and Recreational Area. [HDR, 2011] The plan was developed to "provide NPS with a framework for implementing the development of an alternative transportation system that serves both NPS staff and MNRRA visitors, and for identifying projects in the 72-mile corridor that could support the vision and goals of the ATP." The plan vision was:

> *"Working with partners, the MNRRA ATP will promote a leadership framework for the development of a multimodal transportation system to and along the river that serves as a catalyst for the region's sustainable cultural, economic, and environmental future."*

The planning goals were:

- Improve and enhance the visitor experience by integrating and enhancing opportunities for transportation, recreation, education, and scenic enjoyment along the Mississippi River.
- Provide access to the MNRRA for everyone through integration into surrounding transportation systems.
- Integrate MRT with area transit and trails to increase visitation to MNRRA without increasing congestion.
- Establish a transportation system to and in the MNRRA that preserves, enhances, and interprets natural and cultural resources.
- Promote development of environmental, economic, and socially adaptable and sustainable transportation and recreational facilities.

Public agency goals do not always align with those of businesses in recreational areas. Business owners do not want to see businesses suffer from changes in visitor mobility. Thus, for example, moving transportation facilities or services to a more efficient location will almost always cause some businesses to suffer even as other opportunities are created.

The next part of the transportation planning process relates to defining desired and acceptable levels of service provisions and likely outcomes, and monitoring overall achievement of study goals and objectives. Defining desirable levels of performance first requires understanding how to measure them. Transportation professionals need to determine which performance measures will indicate progress on achieving community goals and what monitoring of externalities must occur. They must also consider who can best gather these data and the data collection costs.

Given the often large number of stakeholders with interests in recreational areas, many individuals and groups should contribute to the ongoing evaluation of transportation systems. Different stakeholders have access to different types of data, and the data used to monitor system performance should serve the many various interests represented. The types of data required will vary based on local needs and goals (see Table 21-2). Data on travelers' choices come from traffic and ridership counting programs and surveys. These tools can indicate trends in visitation, as well as transportation choices that people make. Analysts need to examine these data in the context of comparable venues and regional and national economic trends.

Trend data often provide insight even without extensive analysis. For instance, tracking traffic counts over time allows the transportation planner to determine where in the road system the greatest increase in volumes is occurring. Wherever possible, automated systems should contribute to basic data collection—traffic counters can provide automatic vehicle counts by time of day. Vehicle counters spread throughout a recreational area offer a sense of circulation within the area. Because parking poses a challenge in many places, automatic counters at parking entrances and exits or parking meters monitoring duration of stay could offer important information about visitor flow at major attractions.

Regional airports will track information on airport enplanements and operations. The enplanements indicate how many passengers get onto commercial flights at the airport. Operations show how many take-offs and landings occur. These operations include both tour flights and general aviation traffic to and from the area (the numbers rarely differentiate these two groups). Any airport receiving federal funding must track these air traffic measures, so data are typically readily available for analysis.

Passenger ferry counts come from either private or public sources. Some ferries run as government operations and some companies run private ferry businesses. Private operators might hesitate to share passenger counts because that information might have competitive sensitivity; however, those operators might make willing partners in the transportation planning process. At a minimum, data on the percentage change of ferry passengers against a base year will inform travel demand analysis.

Cruise ship operators do not readily share data on passenger counts due to the highly competitive nature of the business; however, communities with harbors can receive a large amount of tourism traffic via cruise ships. Although the passenger counts might not be available, the number of cruise ship arrivals and the capacity of those ships are readily available and should be tracked over time.

**Table 21-2. Examples of Measures for Monitoring Performance**

| | Measures | | Monitoring | Reporting |
|---|---|---|---|---|
| **Traffic, Parking, and Crowding** | **Input** | • Traffic policies (description)<br>• Parking policies (description)<br>• Private vehicle restrictions (description)<br>• Enforcement (funding and jobs) | Transport departments, state and local government and venues | When changed |
| | **Output** | • Roadway capacity (vehicles per hour)<br>• Parking capacity (count of spaces, locations, and typical distribution of parking durations) | Transport agencies | When changed |
| | **Outcome** | • Vehicle counts at attractions (count by road, time of day, day of week, and time of season; peak periods; and peak hours)<br>• Vehicle counts in the community (count by road, time of day, day of week, and time of season; peak periods; and, peak hours)<br>• Vehicle counts on state roads (count by road, time of day, day of week, and time of season; peak periods; and peak hours)<br>• Local household vehicle ownership (survey)<br>• Parking revenue (amount) | Transport departments, state and local government and venues | Annual |
| **Transportation Safety** | **Input** | • Transportation alternatives in dangerous traffic locations (location count or yes/no)<br>• Marketing for transportation alternatives (funding)<br>• Private vehicle restrictions (yes/no)<br>• Enforcement (funding)<br>• Enforcement staff (employees) | Attraction operators and local governments | Annual |
| | **Output** | • Ridership in dangerous traffic locations (count) | Transit operator | Annual |
| | | • Reduced traffic in dangerous traffic locations (vehicle count) | Transport departments | |
| | | • Visitation in dangerous traffic locations (survey or observation) | Venues | |
| | **Outcome** | • Incident reports (count)<br>• Complaints (count)<br>• Observed near-incidents (count)<br>• Severity (injuries or damage value) | Law enforcement | Annual |
| | **Input** | • Attraction visitor capacity (visitors) | Venues | Decennial |

| | **Measures** | | **Monitoring** | **Reporting** |
| | **Outcome** | • Requests for information (count)<br>• Website hits (count)<br>• Telephone calls (count) | Designated partner | Annual |
| | | • Complaints of confusion (count and percentage)<br>• Perception of information availability and communication (survey scale 1–5)<br>• Wildlife sightings (survey count of sightings and count and percentage of visitors who sight)<br>• Trip purpose (survey count)<br>• Trip destination (survey and stop alighting counts)<br>• Trip origin (survey and stop boarding counts)<br>• Rider satisfaction (survey scale 1–5) | Transit operator | Annual |

Beyond trend tracking, performance measures offer important information when multiple data sources combine into a unique measure. For instance, traffic counts when compared to estimated parking or roadway capacity show the percentage of capacity used, a more understandable measure of need to many of those participating in the planning process. With this information, transportation managers can determine if uncomfortably crowded conditions exist just at extreme peak times or if the problem exists throughout the period of operation.

Safety conditions should be a particular concern for data collection. Most safety conditions reveal themselves through basic tallies of traffic crashes, pedestrian injuries, and visitor complaints about dangerous conditions. If particularly dangerous intersections or other sites exist, transportation engineers should consider conducting annual studies that observe traffic behavior at the site. With well-defined guidelines for observation of incidents and near-incidents, analysts can establish an historic database to indicate trends in safety.

Automatic counting technology can similarly count bus riders, and global positioning systems (GPS) can indicate route and vehicle performance, and when combined with automatic ridership counting can determine the locations of passenger activity. Automated data collection provides consistency in tracking methods. If transit service already exists, transportation planners need to establish a "base year" of operations to serve as a benchmark for comparison with service changes. If no service exists, one aspect of the new service planning will be to define desired performance measures and to establish the process for such monitoring. If the service is to be contracted out, a data monitoring plan will likely need to go into the service contract itself.

Setting levels for acceptable and desired transit performance poses a challenge in regions that have never offered public transportation. Table 21-3 shows typical data that is usually collected by transit operators. Ridership tallies are the most basic numbers to collect. Some transit operators also offer data on driver workforce size, wheelchair-assisted trips, and deadhead time and distance, indicating when buses operate with no passengers aboard (for example, trips from the bus depot to the start of a route). Beyond these widely used metrics, transportation planners should consider whether measures of local relevance should appear in the performance monitoring program.

Transit ridership data offer some indication of how visitors feel about transit service. Increased ridership can indicate one of two things (or a combination of the two): either more people are taking transit or existing riders are taking more trips by transit. Factors such as the perception of transit service quality, the level of perceived congestion on the road network and areas restricting private vehicles will affect trip-making for both visitors and local residents. Demographic characteristics of the different traveler markets will likely affect both the proportion of people using transit and the number of trips taken per person.

| Table 21-3. Transit Operator Performance Measures |
|---|
| • Annual fleet inventory including make, age, and mileage of vehicles/vessels |
| • Annual inventory of other facilities (maintenance, storage, shelters, etc.) |
| • Ridership by route and month |
| • Revenue by route and month |
| • Accident/safety record |
| • Operations and maintenance cost |
| • Headways |
| • Dates and hours of operation |
| • Fares |
| • Vehicle miles of service by month |
| • Vehicle hours of service by month |
| • Missed trips |

The ease of collecting information on tour buses will depend on the structure of each recreational area. Places with open access to all sites might have difficulty monitoring them, but places with managed venues probably track tour buses in some way. For instance, most national parks charge fees for tour buses to enter park boundaries, so park fee-collection offices should have information on either the number of tour buses or the amount of money collected from tour bus operators.

The visitor is the primary unit of analysis in evaluations of recreational transportation mobility strategies. Visitor surveys provide the most direct means of getting information on visitor behavior and provide a means of assessing how visitors might react to transportation options. A survey program should start before major transportation changes are initiated and continue after, usually one or two years after, to determine what changes have occurred. Visitor surveys should also be conducted periodically (no less than every 5 years) to monitor changing trends or visitor characteristics. The information from this type of survey program will allow transportation planners to provide appropriate transportation strategies in the places where they are needed and give local businesses information to develop strategies to attract and serve customers better (see chapter 2 on data collection and analysis). Understanding what transportation options college students, young families, or the elderly use most frequently will help planners target supporting services to the needs of particular demographic groups. Demographic profiles will also help in planning for target groups that are reticent to use service options that local leaders would like to promote.

Visitor surveys often include questions on daily expenditures, durations of stay, and other economic variables. The results can show the places people frequent and the modes of transportation used. These surveys also classify visitors demographically. When designing visitor surveys, analysts should include questions that will allow isolating visitor spending by visitor category. For example, how much do return visitors spend in the park compared to first-time visitors? How much do daily visitors spend (and where) compared to those who camp in the park for multiple days? It is good practice to ask some of the same questions from one survey to the next to allow comparisons over time; some questions will be removed, and new questions will be added.

Local businesses often have data and information that could be useful to transportation planners. For example, business listings and data on store activity can offer important insights into local economic health and trends, while business surveys and interviews can tap into visitor demographics. Business composition in the local economy could change as a result of transportation changes that affect visitor needs. Businesses and concessionaires in and around Zion National Park found that fewer people bought souvenirs after access to Zion Canyon was restricted to buses and nonmotorized modes. Visitors who previously would have put souvenirs in the trunks of their cars knew they would have to carry the items on the bus or on the trails, so they reduced the amount of items they had to carry. On the other hand, demand for service industries increased. For instance, local businesses noted an increase in bicycle rentals because people felt safe riding on roads with reduced traffic volumes.

A business survey provides information on employment trends in hiring, layoffs, seasonal and permanent employment opportunities, the duration of seasonal employment, and the turnover of employees. If transportation planners want to conduct a business survey as part of the planning study, they should start with a complete business listing. The business listing may already exist. Some local governments keep detailed lists of businesses, though they might record businesses coming into existence without recording the ones that have gone out of business. Local chambers of commerce can play a strong role in securing this listing; however, chamber membership alone does not necessarily describe local business communities accurately. At a minimum, the business list should indicate the business name, address, and the type of business. The address can be used to analyze how close businesses are located to transportation services, such as transit stops. In small communities, business revenues are likely too sensitive to obtain because anonymity cannot be guaranteed.

An example of how surveys can be used as part of a planning process is found in the development of the Mt. Hood Multimodal Transportation Plan. As part of this planning effort, interviews were held with key stakeholders, including the partner agencies and staff, mountain resorts, business operators, and interest groups. These interviews were used to "determine stakeholders' wants, needs, and core values that were used to guide project selection." [Evans and Assocs. 2014] Two public surveys were also used. The first was aimed at identifying travel patterns and public support for safety and types of travel options. A second survey focused on public support for a set number of project options that had been identified as part of the process. Table 21-4 shows the results of the project selection survey and the desires of three market audiences, Portland Metropolitan Area (PMA) residents, village residents, and Hood River Area/East of Mt. Hood residents ("all respondents" includes these three), with respect to transportation system improvements. Shaded areas in the table indicate the project was selected as part of the top 5 for that respondent group.

**Table 21-4. Survey Response on Priority Projects, Mt. Hood Multimodal Transportation Plan**

| | Percent of Respondents that Selected a Project as a Top 5 Priority | | | |
|---|---|---|---|---|
| **Prioritized Projects** | **All Respondents (1,862)** | **PMA (1,434)** | **Village Residents (200)** | **Hood River Area/East of Mountain Residents (112)** |

## C. Ecological Impacts and Benchmarks

The ecological impact of transportation systems and of their use will usually be much greater in recreational areas than that found in nonrecreational areas because of the sensitivity of the surrounding natural or cultural environments to disturbance. Active recreation areas such as amusement parks might not be as affected, but natural and heritage recreational areas often attract visitors to unique and sensitive resources. Impacts can occur in a number of ways:

- Diminished air quality and viewsheds from vehicle emissions.
- Impaired groundwater quality from asphalt pavement runoff.
- Vegetation loss due to driving, parking, riding, or stepping on species.
- Erosion in mountainous and beach areas from human activity.
- Reduced nesting and breeding due to invasion of habitat.
- Severed migration routes due to facility rights of way.
- Wear and tear on historic structures.

While private vehicles are often blamed for many of the negative ecological impacts, destructive impacts can come from other forms of transportation as well. For example, Zion National Park found that its transit system was very effective in delivering large numbers of visitors to trailheads at shuttle bus stops. However, the intense pedestrian activity caused trampling of vegetation. The transit system also created crowded conditions in terms of numbers of people in one place at one time.

The transportation system should be designed with the local ecology in mind. In areas with endangered species, transportation facilities and parking (formal and informal) might need to be relocated. Where vehicle emissions diminish viewsheds, public transit vehicles should be equipped for alternative fuels that minimize the pollutant emissions of most concern. Before designing the transportation system, an inventory of ecological assets and threats should be conducted to create a context-sensitive solution appropriate to the local area.

Many recreational areas already have established air or water quality monitoring. Changing numbers of visitors, the number of trips per visitor, and mode choice will alter the way that the movement of people interacts with the environment. Moving people from cars to transit will reduce some environmental impacts and create or exacerbate others. For instance, moving visitors from gasoline-powered private vehicles to diesel-powered buses will reduce nitrous oxide emissions, but might increase particulate matter in the air. This trade-off makes sense in an area with sensitivity to nitrous oxides and a capacity to handle more particulate matter. When recreational regions initiate transit service, supporting groups implicitly accept the trade-off between the environmental impacts of public and private vehicles and judge that the local environment can better tolerate the impacts of transit vehicles. Performance monitoring for recreational transit should include ways to measure both environmental improvements and the negative consequences of transit.

Measures to determine trends and changes in environmental quality have commonly appeared in transportation analysis, but sensitive natural environments might require new types of monitoring. Typical measures include common air pollutants and visibility. For noise pollution, the National Parks Conservation Association conducted a study over a President's Day weekend to determine the pervasiveness of snowmobile noise pollution in Yellowstone National Park. Assigning volunteers to survey each of 13 sites for 20 minutes of each hour between 9:00 a.m. and 1:00 p.m. on both days of the weekend, the study found the human ear could detect the sound of snowmobiles more than 75 percent of the time at most sites. Mitigating factors, such as high winds, were documented in the study.

Many other measures could be developed to address local needs and concerns. Such measures might include the area of vegetation loss incurred when informal parking damages natural roadsides. Yosemite National Park's general management plan specifically designated the need to reduce glare created by vehicles. Wildlife sightings and traffic incidents affecting wildlife could also serve as important environmental indicators. Stakeholders in the transportation planning process need to determine what environmental impacts of transportation will most affect the sensitivities of their specific local region to indicate the types of measures needed in performance monitoring.

## D. Analysis and Evaluation of Strategies and Actions

Transportation planners can use a variety of tools to analyze transportation needs and potential solutions of recreational areas. The traditional transportation four-step model can be applied to certain types of recreational areas (depending on the size and complexity of the study area), but a number of unique considerations must enter into the analysis and modeling effort (see chapter 6 on travel demand modeling). For example, whereas most models try to minimize travel time for those traveling in a network, in recreational areas, people want to spend more time seeing and experiencing the environment. Other differences relate to the input variables that precede the actual modeling of travel behavior, the most important being land-use patterns.

Land-use patterns affect where trips come from and where they go. For example, if residential patterns are spread throughout a community, it would be very difficult to serve the community with transit. Strip development along highways also discourages transit and pedestrian use. Alternatively, development around transit stops can put complementary businesses, such as restaurants, hotels, and gift shops, within walking distance of each other. In this scenario, visitors have easier access to local amenities, and they spend less time looking for parking or going from one place to another. Complementary businesses receive the benefits of sharing customers through agglomeration. Policy makers in recreational communities should familiarize themselves with the current literature on transit-oriented development to see how modern principles for integrating transit into community development can apply within local community character to facilitate pedestrian and transit mobility (see chapter 3 on land use and urban design).

Among the different types of land use, parking is one of the most important in defining trip patterns. Local leaders in many recreational areas are realizing that they cannot satisfy ever increasing demands for parking without seriously damaging the resources and quality of life that define their areas. In some cases, physical barriers such as buildings and natural features prevent parking expansion. In other cases, local leaders want to set policy limits regarding how much infrastructure will support private vehicle traffic. In California, the Yosemite Valley Plan calls for reduction of parking capacity in response to a goal in the park's 1980 general management plan to eliminate private vehicles in the valley. However, even if all visitors take transit, parking must exist somewhere to handle the vehicles that visitors use to reach recreational areas.

### *1. Trip Generation*

Whereas typical trip generation approaches pay particular attention to residential areas as the starting point for the first trips of the day, analysis of recreational communities needs to focus primarily on hotel districts and entranceways to the community. Some trip generators and trip generation characteristics of the study area that might have a particularly important influence on travel demand depending on whether the recreational area serves as a vacation destination or a short-term outing include:

- Major hotels and concentrations of small bed and breakfasts
- Campgrounds
- Day trips and other arrivals from outside the area following the seasonal peaking trends discussed earlier
- Housing for seasonal service workers
- Local owner-occupied housing

There is little question that movement for work is different than movement for recreational purposes. Both cases need to be considered in the trip generation step. Such differences also mean that in almost all cases a trip origin-destination survey will be needed to understand the travel characteristics of the recreational area being studied.

### *2. Trip Attraction*

Visitors do not behave the way they do at home; travel origins and destinations have very different characteristics than more traditional work-based trips. More trips are made to specialty stores and restaurants, while grocery shopping might fall to an unusually low frequency. Typically, the major trip attractors in recreational areas are easy to identify because they appear in all of the tourism literature. Businesses that support dominant forms of local recreation will also receive above normal patronage, such as scuba supply stores near the ocean. Identifying trip attractors will most likely require some data collection and could be part of the survey mentioned above, unless the community already has developed trip flows based on historical trip patterns.

### *3. Mode Split*

Predicting how many trips will be made by each available mode is probably the weakest part of the analysis in a recreational community context. Most mode split research has been focused on the work trip and the desire of travelers to choose modes that provide the fastest means of arriving at their destination. As previously mentioned, this basic assumption of traveler behavior is inappropriate for recreational communities. Riding a bike on nature trails or using a heritage trolley in a historic downtown might be selected as the preferred experience in lieu of the most efficient trip. The duration of a visitor's stay might also affect mode split, though it could have conflicting effects. A visitor who has time in an area might feel more willing to try new transportation options than someone who feels rushed into using familiar modes. Conversely, a visitor who stays in a recreational area for several days might grow tired of tourist transportation systems (particularly if the same tour information is given on every trip) and default back to private modes. Mode split data will be unique to many local areas. Mode split analysis for recreational communities needs to consider both the often wide variety of modes available to visitors and the fact that they have not established routine travel patterns.

As crowding has become more of a problem in many recreational areas, researchers have attempted to determine the effects of crowding on visitor experience and their modal and recreational choices. Visual preference surveys and self-assessment techniques for crowding norms have offered some insights, though the results are not always consistent. The self-assessments in combination with contingent valuation, which measures the validity of respondent self-assessment, offer some means of adding validity. [Manning et al., 2001] A complete discussion of current thought on evaluating crowding can be found in Manning's *Parks and Carrying Capacity* [2007].

### *4. Route or Path Assignment*

The primary difference between route choice between recreational and nonrecreational areas lies in traveler motivation. People do not necessarily assign themselves to the shortest path routes from origin to destination, the basic assumption in urban models. Travelers might take scenic loops or they might return "the long way" because they are familiar with that route. Whereas scenic views might be more important than speed for visitors, locals might excel at taking back routes to avoid visitor traffic. In most cases, the size of the network is much smaller than what is typical for urban road networks. Finding reasonable paths through such networks is not as challenging as it is for networks that have thousands of links in the network coding.

The results of analysis feed into the evaluation process. Evaluation is one of the most important steps in planning because information is summarized and presented to decision makers for selecting desired actions (see chapter 1). Evaluation criteria serve as the basis for the evaluation process. Such criteria should be related to the goals and objectives established for the planning process as well as reflect the different target "markets" for transportation investment, for example, through traffic, local travelers, winter visitors, and summer visitors. It is prudent also to keep the number of evaluation criteria to a manageable level so that decision makers can focus on those issues of most importance. As an example, the following evaluation criteria were used to assess the relative worth of different transportation strategies for the Mt. Hood (Oregon) National Forest. [CH2MHILL, 2012]

- *Increased transportation options*—Does the strategy provide additional transportation options or expand existing transportation options?
- *Leverages existing transit*—To what extent would the strategy utilize, expand, or integrate with existing transit services/systems or modes that are in place today?
- *Leverages existing or creates new transportation demand management (TDM) programs*—To what extent would the strategy leverage existing or create new TDM programs?
- *Improves safety*—To what degree would the strategy increase safety or promote safe transportation conditions? Higher ratings will be assigned to strategies that are qualitatively determined to improve safety along U.S. Route 26/Oregon State Route 35 (OR 35). Strategies that meet this criterion may indirectly improve safety through reducing congestion on U.S. 26/OR 35, or may meet the criterion directly through a safety-oriented program.
- *Considers unique needs of seasonal recreation markets throughout the year*—How well does the strategy address the varying needs of recreational users season to season? For example, does the strategy consider seasonal changes in gear-hauling needs, destinations, and trip durations?

- *Considers unique needs of employees*—How well does the strategy meet the needs of employees within the study area? Consider the places from which employees commute, such as Sandy, Portland, and Hood River, and the time of day of their commute.
- *Considers unique needs of residents*—How well does the strategy meet the needs of area residents, including circulation between mountain communities?
- *Reduces freight or through traffic demand in the U.S. 26 and OR State Route 35 corridors*—TDM strategies can be aimed to reduce freight or through traffic demand in the U.S. 26 or OR-35 corridors by suggesting different routes, time of day for travel, and perhaps even mode. Strategies aimed at reducing or shifting demand would receive higher ratings.
- *Increases economic opportunities for commercial enterprises*—Could the strategy help support and expand existing businesses and promote new business opportunities along U.S.-26/OR-35? Consider full range of winners and losers, for example, a strategy that increases economic growth in one area may become a limiting factor for economic growth in another area.
- *Provides financial or travel time incentives for alternative modes of transportation*—What financial incentives would users (both forest visitors and employees) receive by using the travel alternative offered by the strategy?
- *Provides implementable and financially sustainable solutions*—Is it possible to implement the strategy within the five-year window of this pilot program? Could the strategy be financially sustainable for multiple years after the project study period? Is there committed funding for implementation (grants for capital expenditures are more easily obtained than funding for operational costs)?
- *Benefits from support of multiple entities/partnerships*—Does the strategy provide for implementation by multiple entities? And does the strategy form partnerships to support it, financially or otherwise? Does the strategy identify a lead entity to implement, and does that entity support the strategy?
- *Higher magnitude of benefits*—What is the magnitude of benefits? Do the benefits accrue to many or few users/markets? Do the benefits accrue over a greater number of user days? Strategies that benefit more users, markets, or number of user days receive higher ratings.
- *Equity*—Consider the distribution of benefits and impacts from the strategy, and work toward fair access to transportation options for all users, all ages, and all abilities. Strategies that minimize burdens on different populations and user groups, particularly the transportation disadvantaged (low-income, transit dependent, minority, elderly, and children) would receive a higher rating.
- *Capital costs*—What is the order of magnitude capital cost for the strategy?
- *Operating costs*—What is the order of magnitude operating cost for the strategy?
- *Affected parties support*—Does the strategy have the support of affected parties? Affected parties could include agencies or businesses that would be responsible for implementing a strategy. For example, does the implementing agency support the strategy? Does the implementing or affected party have a legal barrier to implement that may not be able to be overcome in the near term?

Each of the criteria was then assessed qualitatively with a "full circle," meaning accomplishment of the criterion; "half circle" meaning some lesser accomplishment; and an "empty circle" meaning no accomplishment. For example, the measures of achievement for the circles were:

- Full circle: Greatly increases alternative options for transportation or expands existing transportation options (two or more additional options)
- Half circle: Moderately increases alternative options for transportation or expands existing transportation options (one additional option)
- Open circle: Minimally or does not increase alternative options for transportation or expand existing transportation options

Other forms of evaluation, such as quantifying changes in system performance or using benefit/cost methods, are sometimes used. The reader is referred to chapter 7 on evaluation and prioritization methods for further discussion of such methods.

## E. System Needs and Recommendations

As shown in Table 21-5, the types of strategies that can be considered as part of a recreational planning study ranges from traditional road improvements to the application of intelligent transportation system (ITS) technologies. The importance of modal presence cannot be overstated when designing a service. Presence indicates the degree to which transportation options are incorporated into visitor experience. As one aspect of presence typical for transit systems, service identity and visibility make a transit system recognizable with its logos, vehicle design, and stop design, among others. Equally important, presence captures how visitors see a transportation option as part of their experience in a recreational area, such as a pedestrian area, bike trail network, or a horseback ride to a vista. As an example of a transportation option with strong presence, the Red Bus of Glacier National Park appears in most brochures as an activity that would appeal to visitors as a signature experience, and when the buses went out of service for vehicle reconstruction in 1999, people complained that they did not see the buses running. The following sections examine the types of strategies that can be considered as part of a transportation planning study.

**Table 21-5. Priority Strategies for Improving Multimodal Transportation at Mt. Hood, Oregon**

| | Type | ID | Project Description | Timeframe |
|---|---|---|---|---|
| Implementation Plan Projects- Group A Action Plan (0–5 years) | Pedestrian & Bicycle | PB-1 | Mt. Hood Highway US 26 bike/ped intersection improvements in coordination with potential transit stop locations in Clackamas County. | 0–5 years |
| | | PB-3 | Mirror Lake Project: Safety improvements including relocating trailhead and adding parking. | 0–5 years |
| | | PB-5 | Mt. Hood Highway shoulder widening analysis for bicyclist use. | 0–2 years |
| | | PB-7 | Bike/ped info and wayfinding along Mt. Hood Highway. | 0–4 years |
| | | PB-8 | Bike intersection improvements at OR 35 and Historic Columbia River Highway (HCRH) (E. State St.) in Hood River. | 0–2 years |
| | Public Transit | PubT-2 | Bus: Mountain Express extension of service to the ski areas from Sandy. | 0–4 years |
| | Safety and Road Improvements | Safe-1 | OR 35 intersection improvement updates to signage at Central Vale Dr./Booth Hill Rd. (Milepost [MP] 93.5). | COMPLETED |
| | | Safe-2 | US 26 roadway departure safety improvements between MP 47.2 and 48.9—rumble strips. | 0–5 years |
| | | Safe-3 | US 26 roadway departure safety improvements between MP 44.9 and 46.6—rumble strips. | 0–2 years |
| | | Safe-4 | US 26 roadway departure safety improvements between MP 36.9-39.77 and 42.6-43.2—rumble strips. | 0–2 years |
| | | Safe-5 | OR 35 roadway departure safety improvements between MP 60 and 93.75—rumble strips and curve warning signage. | 0–2 years |

## F. Infrastructure

### *1. Roads*

Roadways usually serve as the backbone of a recreational area's transportation network, which means that they largely shape both visitors' first impressions and subsequent visitors' experience. Roadway capacity indicates how many vehicles a road can accommodate in a given amount of time. Terrain, speed limits, points of access to parking lots and driveways, onstreet parking, and vehicle size can reduce the amount of throughput a roadway can accommodate. Many of these factors are exaggerated in recreational areas as roads wind through mountains, popular recreational areas have many stops downtown, and people drive recreational vehicles (RVs). Wide lanes and large parking lots might accommodate these needs; public transit in heavily visited areas (even a simple loop in the restaurant district) might be another viable option. In some cases, policies restricting oversized vehicles might be necessary. For instance, the Zion-Mount Caramel Tunnel was constructed before the advent of RVs. Drivers of oversize vehicles must reserve passage through the tunnel and pay a fee for opposing traffic to be stopped because the lanes cannot accommodate two-way traffic with an oversized vehicle.

Road design generally follows design standards for recreational areas as found in transportation agency design guidelines and the operating principles found in the *Highway Capacity Manual*. [TRB, 2010]

Several questions should be asked as part of the infrastructure design process, including:

- To what extent are the roads simply a means of getting to a visitation site versus serving as a visitor experience?
- How do roadways impact local natural or cultural resources? For example, does traffic noise impinge on ambient noise levels?
- Can context-sensitive design principles (see chapter 9 on road and highway planning) be used to better integrate road design with the environmental context? What is the right local balance of infrastructure cost versus aesthetics in design?
- Can roads also be designed to safely handle other means of transportation, such as bicycles?
- What are the appropriate trade-offs between preserving a roadway's historic characteristics and improving the roadway's design to provide better operation and safety?

Given that approximately one-third of the land mass in the United States is owned and managed by the federal government, the types of design principles and standards used by responsible federal agencies become important guidance on how roads, bridges, and culverts should be designed. The following definitions from the Federal Lands Division of the Federal Highway Administration are helpful in understanding the different terminology in roadway design that might find their way into the planning process.

**Policy**. Guiding principle; general course of action to be followed without exception. Where policy is cited the source of the policy is also referenced, when applicable and appropriate.

**Standard**. A fixed reference to guide the outcome and content (product) of the work . . . . Standards are established where there is a consistent level of risk, or there is a consistent technical or performance expectation for a specific product to work well in most cases . . . .

**Criteria**. Tests or indicators, in addition to standards, used to measure/judge achievement of applicable policy or standard objectives. Criteria may vary from project-to-project . . . .

**Standard Practice**. Standard practices are established methodology that the Office of Federal Lands Highway (FLH) imposes to guide the approach to the work, and which will generally produce a consistent outcome that meets FLH expectations. Standard practices are established where a certain process or method is necessary, in addition to or as assurance, for achieving a sufficient end result product . . . .

**Guidance**. Suggested actions to meet policies and standards, and expectations for applying discretion . . . .

**Discretion**. Where the practitioner is expected to exercise engineering judgment to apply an optimum technique or solution that is within an acceptable range of values. [FHWA, 2012]

Readers interested in National Park-related road design considerations are referred to http://www.nps.gov/transportation/library_manuals.html.

Scenic roadway capacity can be reduced by people stopping to view scenery or wildlife, thus reducing capacity for emergency access as well as the general traffic. Vehicles tend to move in platoons behind one slow leader, making pullouts for slow-moving traffic important considerations in road design. Topography and the built environment might limit options for infrastructure development and, in some cases, policy standards might restrict the use of traditional capacity expansion to address such problems. For instance, early in the management of the National Park System, federal park administration guidelines limited road widths to two lanes accommodating cars and trucks; recreational vehicles (RVs) as a consideration were added later. [Albright and Schenck, 1999]

Wayfinding signs and directions to information centers are important given the large proportion of unfamiliar drivers on the roads. The enhanced need for information must be considered in light of information overload for slightly disoriented drivers. Sign warrants should adhere to the design principle of confronting drivers with only a single simple decision to make at a given time. Sign ordinances might be considered for limiting the amount of on-street advertising in confusing areas, though on-street advertising might be an important means of attracting customers to businesses. The safety implications of signs along roads need to be discussed in the local context.

The extreme conditions of many remote recreational areas might require special road management systems. Glacier National Park sends a maintenance vehicle onto the Going-to-the-Sun Road once or twice a day to remove rocks that have fallen onto the road, and snow plows might be necessary in any month of the year. Deserts and coastal areas with substantial sand might require special engineering to keep sand off the road surface and from creating traction hazards. High winds and other dangers specific to local recreational areas pose their own unique challenges for maintaining the integrity and performance of road infrastructure.

Given the nature of parks and recreational areas, roadways might impinge upon wildlife mating grounds, migration routes, or other habitats in ways that can endanger a species over the long term. In such cases, road designers should consider wildlife overpasses and underpasses as possible mitigation measures. [Morrall and McQuire, 2000]

### *2. Parking*

Transportation planners for recreational areas spend considerable time thinking about parking. Private vehicles crowd lots around attractions; shopping areas fill up at meal times and people often park on the side of scenic roads. Even in recreational areas where nonmotorized modes or public transit dominate, the private vehicles that transport people to the area must be stored somewhere.

Many parks experience a daily tide of vehicles flowing into the park early in the day and flowing out of the park later in the day. Peak parking accumulation thus occurs in the midday to midafternoon time period in many parks.

Parking supply can take numerous forms. The City of Hot Springs, Arkansas, for example, built a new parking garage across the street from the city's signature bathhouses. In other instances, parking expansion faces obstacles. For instance, many national parks have limited land for parking where most visitors want to go. In other cases, adopted policy limits how much infrastructure will support private vehicle traffic. For example, the Yosemite Valley Plan calls for a reduction in parking capacity in response to a goal in the park's 1980 general management plan to eliminate private vehicles in the Yosemite Valley. [Yosemite National Park, 1980]

The strategy chosen for a park-and-ride plan will affect the way that visitors interact with a transit shuttle system and with local businesses. Bryce Canyon and Zion National Parks in southwest Utah use strikingly different parking plans. At Zion National Park, the local parking strategy expects many visitors will leave their vehicles parked at their hotels or in town. Two parking lots with about 550 spaces accommodate some vehicles next to the visitor center near the park entrance, and the gateway community provides a small overflow parking lot just outside the park. However, these two lots combined cannot accommodate all of the vehicles for the 3.5 million annual boardings of the Zion Canyon Shuttle. Indeed, in 2012 these two lots filled to capacity on 109 out of 153 days during peak season.

Whereas Zion disperses much of its parking demand across the gateway community and among local businesses, Bryce Canyon National Park concentrated its parking at one dedicated location. The park utilizes a parking area in the gateway community outside of the park.

Each parking strategy has strengths and weaknesses. A dedicated staging area offers a secure place to leave vehicles, use restroom facilities, and obtain general information on the park. System designers want to create the feeling of entering park lands from the point of accessing transit. On the downside, the staging area defeats one of the well-documented benefits of transit—commerce has an opportunity to develop where people change modes of transportation. People are far less likely to get off a bus to buy a souvenir than they are to stop in a store while they wait for a bus after they get out of their cars. With no businesses around the parking lots, the staging area does not provide potential economic benefits to the gateway community.

Another economic consideration relates to parking fees. Such fees can be used to generate public funds or to shape travel behavior. Parking fees serve as effective means of encouraging carpooling or mode shift. [Golias, Yannis, and Harvatis 2002] Given that many visitors already arrive in multiple occupant vehicles, implementing a carpooling program is not an effective strategy in recreational areas, so high parking fees should be used only in locations with high-quality transit service or where a convenient pedestrian environment that serves the visiting population well. Town parking lots in Provincetown, Massachusetts, charge $25 to $35 per day in the municipal lot, and people are willing to pay it because parking is scarce. [Town of Provincetown, 2015]

Most discussions of parking capacity refer to the number of passenger vehicles that a parking area can accommodate. Because vehicle sizes differ, parking capacity for passenger vehicles must accommodate large recreational vehicles (RVs). RV hookups might also be necessary, but private, dedicated campgrounds typically provide for this need.

### *3. Pedestrian Walkways and Paths*

Pedestrian environments should receive the attention they deserve from transportation planners and from the traveling public (see chapter 13 on bicycle and pedestrian planning). Recreational areas, in particular, offer situations where pedestrian access could be the ideal mode. In many cases, the pedestrian environment of the recreational area defines the quality of visitor experience. The average hike in national parks lasts four to five hours. One in 10 hikers stays overnight, and these people are typically young. Short hikes and nature walks, however, appeal to people of all ages. [Dunning, 2005] The Americans with Disabilities Act (ADA) of 1990 has focused attention on providing at least some trails with wheelchair access in each trail area, though the natural features of many remote areas create obstacles to making all trails accessible.

In urban areas, recreational communities create unique local character through sidewalks, shopping and restaurant districts, street festivals and so forth. Many major cities have historic trail tours, such as the Atlanta, Georgia, Martin Luther King, Jr. Historic District; the Boston, Massachusetts, Freedom Trail; and the Washington Mall in Washington, DC.

### *4. Bicycle Paths, Lanes, and Trails*

Bicycle use in parks will vary from one park to another. The Grand Teton National Park created a bicycle system plan and a pedestrian circulation plan as primary recommendations in its most recent transportation study. As noted, "This initiative intends to increase the share of visitor and employee travel by bicycle, improve opportunities for bike touring, and enhance the quality and safety of the Grand Teton visitor experience through selective implementation of bike lanes (that is, wide paved shoulders), stand-alone pathways, traffic calming, bicycle signage, bicycle/transit integration, and improved bicycle parking." [NPS, 2006]

The Great Smoky Mountains National Park created time periods with motor vehicle restrictions to allow bicycles and pedestrians safe and unthreatened use of the 11-mile loop road through an historic district. [Byrne, 1999] The road often has bumper-to-bumper traffic, particularly in the summertime, making bicycling dangerous. As a test, the park closed the road to motor vehicles for one day a week from sunrise to 10 a.m. The closure was so popular that the park extended it to two days a week (Wednesdays and Saturdays). On Saturdays in December, the park keeps the loop road closed to motor vehicles until noon.

In contrast, Glacier National Park forbids bicycles on hiking trails, citing environmental reasons. The concern of mountain bikers leaving the trails and abusing the natural resource has guided park policy. Most of the hiking trails in the park lie in areas proposed for wilderness designation, which means they must be treated as if they are so designated until Congress accepts or rejects the proposal. The Wilderness Act of 1964 states that "there shall be no temporary road, no use of motor vehicles, motorized equipment or motorboats, no landing of aircraft, no other form of mechanical

transport and no structure or installation within any such area." [Public Law 88-577 16 U.S. C. 1131-1136] In Glacier National Park, the use of any type of nonmotorized wheeled vehicle (that is, canoe dolly, cart, and so forth) on backcountry trails is prohibited. Persons with disabilities as defined in the ADA may use wheelchairs on trails.

Aside from parks, many urban recreational communities have established bicycle networks as key components of their transportation systems for visitors. Fire Island in New York and Mackinac Island in Michigan are notable examples where motorized vehicles have a substantially diminished presence compared to bicycling.

From a design perspective, bicycling facilities exist on separate bike paths (Class 1), on demarcated bike lanes (Class 2), or on designated bike routes with shared right of way (Class 3). Average cyclists can sustain speeds of 10 miles per hour (mph) on level terrain, making trails ranging from between 3 and 6 miles to between 10 and 30 miles desirable. Trails should avoid short gradients exceeding 10 percent and sustained gradients of 4 to 8 percent. Effective design can mitigate concerns of threats to safety, trail user conflicts, and resource damage. Best practice attempts to separate bicyclists from other trail user, where possible, and provide safe bicycle access on park roadways. The design criteria for paths, lanes, and trails can be found in the adopted design guidance for a particular park or park jurisdiction (see FHWA [2008, 2015b] for a good resource on both federal and non-federal design guidance, and ways to encourage bicycle use in national parks).

In the United States, federal-aid funds may be used for bicycle and pedestrian projects where eligibility criteria are met. These projects are broadly eligible for all of the major funding programs where they compete with other transportation projects for available funding at the state and metropolitan levels. [FHWA, 2015a] This funding has been used for a variety of nonmotorized transportation options, such as turning abandoned railways into trails, providing streetscapes in urban areas and providing basic sidewalks. These types of nonmotorized facilities have a place in recreational areas. Readers interested in bicycle and pedestrian transportation in national parks are referred to the following website: http://www.nps.gov/transportation/pdfs/Federal_Transit_BikePedPlan.pdf.

### *5. Trails*

Table 21-6 shows nine commonly identified trail types. Trails will sometimes follow utility line rights of way where the environment has already been disturbed. Rails-to-trails initiatives in recent decades have put trails along abandoned railways, such that the trails have gentle grades and curves and possibly connect to town centers. For nature trails, hiking trail classifications range from short trails to long loops for day hikers; overnighters traverse cross-country trails. Hikers can share low-demand equestrian trails, but horse excrement, accelerated erosion, spooking of horses, and different trail length leads to a recommended separation. [Fogg, 1990]

Urban trails (sidewalks) should be designed with a capacity to move masses of people comfortably, depending on levels of visitation. Sidewalks on the Strip in Las Vegas are 15 feet (4.6 meters) wide with substantially more capacity in the plazas of casinos. While that width of sidewalk would overwhelm most recreational areas, sidewalks greater than a 3-foot (0.9 m) width should be considered, especially if utility poles and street furniture block pedestrian right of way.

Beyond the requirements of the ADA, transportation planners for recreational areas must recognize that a disproportionately high proportion of the visiting population might require extra consideration for accessibility. Retirees already constitute a large proportion of touring populations, particularly in the fall after children return to school. The retiring baby boomers have money and time to travel, but as their numbers increase, their physical requirements will also increase. Sidewalks must have ramps, ramps must have tangible indicators to alert the blind of an approaching roadway, and crosswalks need audible messages. Transit station platforms need widths to accommodate wheelchairs. Wayfinding information must be available for people with various disabilities. Rest areas and assistance should be available at reasonable intervals to accommodate people as they tire.

**Table 21-6. Commonly Identified Trail Types**

| Nonmotorized | Winter Use | Special Use | Water |
|---|---|---|---|
| Hiking | Cross country skiing | All-terrain vehicle | Canoe, raft, or boat |
| Bicycling | Snowmobile | Motorcycle | |
| Equestrian | | Off-road vehicle | |

Source: Fogg, 1990

For trails in northern climates, summer hiking and bicycling trails can turn into winter cross-country ski trails, though skiers require wider trails and gentler curves than often found with summer backcountry trails. Snowshoeing might take the place of hiking. In most cases, the most pressing issue associated with winter uses is the adequate marking of where such paths are, especially in areas that receive high snow pack or drifting snow.

## G. Transit Service

Although transit services also require infrastructure to support vehicle operations and passenger movement, this chapter considers transit separate from the infrastructure discussion because of the passenger orientation of successful service. The following website from the U.S. Federal Transit Administration (FTA) provides examples of the types of transit services that are available in national parks (http://www.fta.dot.gov/documents/TransitInParks2011POST.pdf).

Transit service serving recreation areas can take a variety of forms. It can bring visitors from other locations to the recreation area. Or, it can be service within the recreation area that distributes visitors to various locations. Within U.S. national parks, transit service is sometimes mandatory (private vehicles are not allowed on the roadway) and is sometimes voluntary (the visitors have a choice of using transit or their private vehicle).

Bus systems can typically enter service with minimal start-up costs by using the existing road network for right of way. Initial capital funds are devoted to buying vehicles and building shelters. The importance of building shelters, erecting signs, and installing intelligent transportation system (ITS) technology (see next section) cannot be overstated for bus-based systems. Easy-to-understand route structures and system amenities are critical for this mode because recreational transit systems serve a market that is unfamiliar with the area. Visitors could be confused where multiple routes meet and where bus stops do not make the direction of the bus obvious. In other words, when a bus pulls to the side of the road and still points in the direction of travel, passengers understand where it will go, but when it goes off the road into a cul-de-sac or parking lot, passengers unfamiliar with the area lose orientation.

The strategy of where to place bus stops also affects how people interact with the system. Different functions are served by fixed bus stops and situations where passengers must request stops by flagging the bus driver. Experience suggests flag stops benefit neither visitors nor gateway community businesses as much as fixed stops. For visitors, people do not know where to ask to stop when they are visiting an unfamiliar vacation community. For businesses, no one will ever accidentally get off at a flag stop and decide to wander into a souvenir shop.

Bus stop structure largely follows from pre-established priorities, such as where parking exists or whether businesses need to pay to have a bus stop in front of them. Common sense can also dictate many of the decisions, such as putting stops near major activity centers (scenic attractions, large hotels, or popular restaurant areas) and avoiding places that contain safety hazards. Geographic analysis of local businesses can determine where stops would serve the largest number of tourism-oriented businesses. As a general rule, many transit planners assume that most people will walk no more than one-quarter mile (400 meters) to one-half mile (800 meters) to a bus stop depending on the context, so businesses within that distance of a fixed stop can be considered well served by transit. [Kittelson et al., 2013]

Depending on system size and established priorities, transit plans might also require the construction of fueling stations and maintenance facilities. Locating fueling stations can be tricky because they need to be centrally accessible to buses yet out of sight. New fleets of 50 or more vehicles within metropolitan areas and supported by federal funding need to incorporate alternative fuel components under the Energy Policy Act of 1992, necessitating consideration of the supply line for the fuel and location of the fueling station. Executive Order 13423 of January 23, 2007, strengthened the requirements for federal agencies operating fleets, which affects federal recreational areas operated by the National Park Service, U.S. Forest Service, U.S. Fish and Wildlife Service, and Bureau of Land Management. Cost efficiencies might be available if other fleets (public or private) in recreational regions can be identified and converted to selected alternative fuels. The U.S. Department of Energy's Clean Cities program offers support for building local and regional coalitions for alternative-fuel and vehicle-technology initiatives. [USDOE, 2015]

For rail transit, few regions with recreation-oriented economies have achieved sufficient year-round volume of activity to justify the cost of rail infrastructure; however, notable exceptions exist such as Disney theme parks and Las Vegas. Right-of-way for rail typically requires substantial reconfiguration of existing infrastructure when new rail is installed. Right-of-way acquisition is the most expensive aspect of start-up, which makes rail expensive to install over distances unless the system will use existing abandoned or shared tracks (see chapter 12 on transit planning).

Characteristics of travel demand and the cost structure for operating transit in recreational communities are important factors when considering service options.

- Operating costs largely occur only during peak and possibly shoulder seasons, with many systems lying dormant during the off-season. Recreational communities can save or spend money on transportation services by altering the dates of operation. Operations-based systems require consideration of labor costs and the availability of skilled workers (typically drivers) who want to work for only part of the year.
- Capital costs for infrastructure and vehicles occur upfront and need payment regardless of time of year or robustness of visitation. Capital-based systems thus require stable demand and a steady revenue stream.

Bus-based systems incur high operating costs because systems require one driver for every operating unit (or for every two in the case of articulated buses), but capital costs can be minimized by using existing roads for operations. Rail-based systems incur high capital costs for acquisition of right of way and rail construction, but an installed system can move large numbers of passengers with relatively low operating costs per passenger.

Fare structure is another important consideration in transit service planning. In rural areas, transit operators typically recover a smaller proportion of fares than their urban counterparts. Thus, most discussions of recreational transit finance will likely begin with an underlying understanding that transit service requires a subsidy. With this subsidy often coming from public agencies, it is not surprising that broader public policy goals become part of the goals and objectives for transit services, such as reducing auto emissions, reducing the number of registered complaints about parking availability, or raising the number of wildlife sightings in natural recreation areas. One possible option for charging a fee for the transit service is to bundle the cost as part of a park entrance fee, and thus transit would be considered part of what visitors are paying for, and perhaps used more often.

In recreational areas, transit vehicles must provide service attractive enough that people will choose to spend their vacation time using the service. The National Park Service conducted a vehicle-design workshop to identify special considerations for transit vehicles in recreational areas. The workshop resulted in a recognition that the characteristics of a given region determine the unique needs for fuel type, propulsion, seating, cargo, safety options, and vehicle size. Comfort and unobstructed views emerged as primary considerations in recreational areas. Recognizing the needs of foreign visitors, automated language translators were recommended for onboard messages. Another consideration is that national parks emphasize maintaining the historical nature of the park roads and paths, and thus minimize the number of parking spaces. Integrating transit service into this perspective on infrastructure could be very difficult.

In urban areas, transit services allow passengers to stand in the aisle while the vehicle is moving. Not all recreational areas are conducive to allowing standees. Topography affects the ability of buses to accommodate standing passengers safely. In Yosemite National Park, for example, when ridership exceeds the number of seats in the vehicle, drivers deny boarding to people waiting for the bus because buses traverse winding mountain roads.

Another consideration for transit in recreational areas is accommodating the needs of short-distance travelers on longer distance bus services. Thus, for example, buses need to accommodate bicycles, skis, and other paraphernalia necessary for the next leg of passengers' trips. Acadia National Park has an extensive network of bicycle trails that visitors enjoy during the day, but as afternoon brings fatigue, many of the visitors ride the bus back to their hotels. Buses equipped with bicycle racks can typically handle two bicycles and sometimes as many as four. Demand quickly overwhelmed the capacity of bicycle racks on Acadia's Island Explorer shuttle buses; transportation operators sent a trailer to carry bicycles in the late afternoon.

## H. Intelligent Transportation Systems (ITS)

Providing information to park or recreational area users on the performance of the transportation system or on the shortest routes to desired destinations is an important means of providing the most efficient system operation possible given prevailing conditions. Variable message signs indicating when the next transit vehicle will arrive or where parking is available provide visitors with confidence that they are in the right place and not working with outdated information. Traveler information 511 service has been adopted in many localities across the country and can be used as another source of information on system performance.

ITS technologies could play an important role in some (especially larger) recreational communities (see chapter 10 on transportation systems management and operations for more discussion on ITS technologies). On the pragmatic level, the operational expense of transportation technology requires a minimum threshold of congestion to make the system worth supporting. In addition, in very large national parks, internet network connectivity is very poor and the primary source of information is the telephone, which also has spotty service. Thus, in some cases, unless the park is going to provide a dedicated network within the park, the opportunity to apply ITS solutions is limited.

However, because parking is a major focus of transportation systems in recreational areas, innovative parking technologies can substantially affect traffic efficiency. Real-time parking information at Acadia National Park and its gateway communities changed the way people traveled: 43 percent of visitors using parking information changed the time they visited destinations; 38 percent of parking information users changed their destinations and 44 percent of the people who looked at the real-time parking information decided to take the bus instead. The average number of vehicles parked outside designated spaces in eight high-demand lots fell from 325 in 2001 to 274 in 2002 even though total visitation had increased. Real-time parking availability information has been shown to spread demand over time, change destination choices and alter mode split, but in many recreational situations, parking lots serving remote destinations are themselves located far from the last transportation option. For instance, parking lots on mountain tops and other scenic viewpoints can fill beyond capacity, frustrating people who have driven 30 minutes or more to learn that the lot is full.

With ITS technology still making initial forays into park and recreational community environments, new ideas for customized innovation continue to emerge. Denali National Park and Preserve has fixed cameras on wolf dens, eagle nests, and other unique areas of ecological intrigue, such that a wireless-equipped bus arriving near a targeted area will respond to a sensor and broadcast the camera feed onto a monitor in tour buses.

Real-time information regarding bus departures can help many transit systems overcome difficulties associated with low-frequency routes. Surveys of transit riders have shown that people will consult schedules whenever buses depart at intervals greater than 10 minutes. The real-time information of global positioning system (GPS)–equipped buses gives confidence in the reliability of transit where first-time visitors have no experience riding the system. Experience with Acadia National Park's Island Explorer has demonstrated that visitors respond to technology and make choices accordingly, as evidenced in the 2002 survey of visitors that showed that 80 percent of bus riders made the decision to ride at least in part due to seeing signs with real-time bus departure information. [Daigle and Zimmerman, 2003] Good examples of ITS transit applications in parks is found at http://www.nps.gov/transportation/pdfs/ITS_In_Parks_2011_Update.pdf.

## I. Demand Management

Although most transportation strategies will be similar from one locale to another, there will likely be some strategies that are very specific to a particular community. One such strategy includes transportation demand management (TDM) actions, which are aimed at managing travel demand usually in lieu of building more capacity (see chapter 14 on travel demand management).

While few recreational areas would want to reduce the number of visitors to their areas, many would like to manage the demands on the transportation system to make it more efficient. Transportation demand management for recreational areas can take several forms. It might mean encouraging mode shifts, encouraging greater activity at under visited sites, or flattening demand such that peak loads are not as severe. Many parks practicing demand management have onsite communication systems with no opportunity for visitors to get advance information before making a long journey to the parks. Table 21-7 shows example TDM strategies for a transportation study of Mt. Hood in Oregon.

At many attractions, large percentages of visitors go to the same destinations. For instance, most first-time visitors to Yellowstone National Park will likely visit Old Faithful. As a result, these destinations receive large crowds, resulting in congested parking conditions, wear on the natural resource, and a diminished visitor experience due to perceptions of crowding. Meanwhile, other attractions might have capacity to handle far more visitors. Policies for spreading visitor demand can take the simple form of instructing seasonal employees to recommend two or three site visits, alternating as each motor vehicle enters the site. For example, the first car at the entrance gate hears about attractions A and C, the next car hears about A and D, and the third car hears about B and C. Consequently, if A has traditionally received all three cars, it now only receives two-thirds as many. Glacier National Park identified the need to level the use of park

| Table 21-7. Transportation Demand Management Strategies for Mt. Hood, Oregon | |
|---|---|
| **Strategy** | **Potential Impact** |
| Develop a Transportation Management Association or other organization to coordinate transit and TDM programs. | High |
| Transportation System Management and Intelligent Transportation Systems. | High |
| Increase and extend existing public transit. | High |
| Increase and extend existing private transit. | Medium/Low |
| Advertise and improve carpooling information sites. | High/Medium |
| Create a "one stop" Mt. Hood traveler webpage with dynamic information on parking, weather, road conditions, travel time, and available transit. | High |
| Increase cell phone coverage on the mountain. | High |

resources in its transportation and visitor use study when the Going-to-the-Sun Road was being rehabilitated. This plan established *use leveling* as a means of reducing congestion and crowding during a period of reduced accessibility and mobility in the park. [Glacier National Park, 2014] Other parks can extend this concept to handling typical surges and spikes in visitation.

## J. Supporting Policies

Land-use, pricing, and development design policies can influence how well transportation systems perform. Planning agencies, chambers of commerce, transit operators, and other agencies can each make policies that affect travel behavior and have repercussions on local economies (see Table 21-8). Land use tremendously influences travel behavior and traffic flow for all modes, yet often communities of small and medium sizes that economically depend primarily or solely on recreation do not have the planning expertise for sustainable land use. Also, the long-term nature of changes in land use makes it difficult to identify the role of land use without a trained eye. The process of transportation planning for recreational areas should include the education of local leaders on the significant future impacts that land-use strategies (or a lack thereof) will have on local mobility.

| Table 21-8. Policies Potentially Affecting Travel Behavior | |
|---|---|
| **Agency** | **Policy** |
| State or local departments of transportation | • Parking policies<br>• Modal infrastructure development<br>• Traffic signal preference for buses<br>• Communications policies |
| Chambers of commerce or visitors' bureaus | • Discounted membership for businesses advertising or encouraging recommended transportation options<br>• Training and education programs for seasonal workers<br>• Transportation information dissemination<br>• Communication policies |
| Transit operators | • Route design<br>• Fare policies<br>• Communication policies |
| Localities | • Zoning<br>• Parking guidelines for businesses<br>• Communications policies |

At the start of transportation planning processes, planners should document relevant policies across all agencies and look into policies in comparable communities and model sites for ideas on other policies worth considering. The local list of policies should reflect changes in policies. Records should indicate when policies begin, so future analysis can identify the influence of the policies in trend data.

## K. Additional Types of Studies

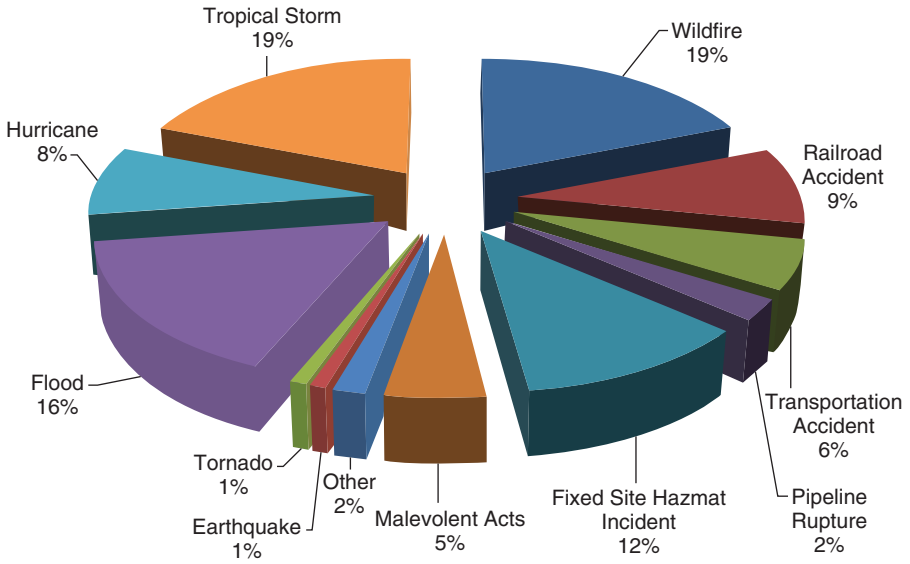
Recreational travel often has a unique influence on the economy, environment, demographics, financial solvency, and many other aspects of a recreational community. Because of this, a number of different types of studies might be necessary before implementing transportation system changes. Important types of studies to consider include: (1) environmental impact assessments, (2) economic evaluations, (3) socioeconomic and equity analyses, (4) financial impact analysis, and (5) project evaluation. Examples of these types of studies are found in [National Park Service, 2006; Thomas et al., 2014].

Evacuation planning has grown in importance since the 1990s, especially for coastal communities where evacuation in response to extreme weather events can overwhelm the transportation network. Evacuations are not solely related to recreational areas; entire states and metropolitan areas can be affected by evacuation-causing events. However, such planning is discussed in this chapter simply because recreational areas could be considered one of the challenging contexts for evacuations . . . . most areas have a limited transportation network and most recreational travelers are unfamiliar with this network. These challenges become particularly acute with dealing with some population groups that are particularly vulnerable (for example, of the 853 Hurricane Katrina storm-related fatalities in Louisiana, at least 584 (nearly 70 percent) were over the age of 60 and 388 (nearly 45 percent) were over the age of 75). [Wolshon, 2009]

Figure 21.9 shows the different types of causes for evacuations. Although somewhat dated, the relative distribution of evacuation causes is most likely similar today (although with climate change, the frequencies of severe weather-related evacuations might increase). Importantly, the focus of evacuation planning and the different types of strategies involved varies by whether advance notice is available of an upcoming event (e.g., hurricane) or whether there is no advance warning (for example, earthquake). In both cases, clearly identifying the roles and responsibilities of the different agencies that will be involved with evacuations need to be part of the plan.

Wolshon [2009] summarized the planning approach used by the U.S. Army Corps of Engineers for evacuation planning, which is similar in concept to the overall planning approach described in Chapter 1. This approach includes the following steps:

**Figure 21.9. Principal Causes of Large-Scale Evacuations in the United States (1990 to 2003)**



Source: Dotson and Jones, 2005

- Define evacuation transportation zones based on storm scenarios. These zones represent origin and destination zones that will be used in the analysis.
- Develop dwelling unit data for each zone, including detailed characteristics of the population, number of dwelling units, and number of vehicles.
- Identify the transportation network (usually roads) that can be part of an evacuation network, and key characteristics such as capacities and potential use of contraflow lanes.
- Forecast the number of expected evacuation trips based on historic data or surveys. This must consider the number of people and vehicles that will go to local public shelters; homes of local friends and relatives; local hotels, motels, churches, and other types of local destinations; and all destinations outside the local area. As noted by Wolshon [2009], in nuclear power plant travel analyses, a variety of day-night, weekday-weekend-holiday, summer-winter, and clear-rainy-snowy conditions are assessed.
- Distribute trips among evacuation transportation zones, resulting in origin-destination matrices for each storm scenario.
- Assign evacuation trips to the road network that connects the origin and destination zones, and identify bottleneck points.

As discussed in chapter 1, this approach relies very heavily on the four-step planning process described earlier.

Information on evacuation planning can be found in a variety of sources. Many public documents have been released, including the following two from federal agencies:

- Federal Highway Administration: *Using Highways During Evacuation Operations for Events with Advance Notice Routes to Effective Evacuation Planning Primer Series*, Accessed August 16, 2015 from http://ops.fhwa.dot.gov/publications/evac_primer/00_evac_primer.htm
- National Oceanic and Atmospheric Administration, Planning and Impact Assessment Reports: http://coast.noaa.gov/hes/hes.html?redirect=301ocm

Interested readers are also encouraged to review [Wolshon, 2009].

## VI. NEED FOR INFORMATION AND COMMUNICATION

Given the first-time experience for many visitors, the dissemination of information concerning transportation system options is an important element of a transportation strategy. In addition, however, the often diverse set of stakeholders interested in effective transportation services requires the exchange of information and communication among those involved in providing such services and the community groups affected by them. Communication encompasses educating and keeping informed the people designing and operating transportation systems (planners, engineers, and political leaders), the people using the system (visitors), and the people who interact with the people using the system (local businesses, front-line workers, and local citizens). Communication plays a vital role in shaping public opinion and influencing travel choices.

### A. Communication with the Visiting Public

Except for targeted information campaigns that are part of start-up services, transportation planners cannot expect a strong public familiarity with their recreational transportation systems. The tourist population of recreational areas, where typically more than half of the people visiting are doing so for the first time, will not know about the transportation options available to them. Public service providers in some communities benefit from residents gaining familiarity with the services over time and sharing their knowledge with newcomers. Knowledge also carries over from year to year as some visitors and seasonal workers return. The largest need for outreach to all of the publics impacted by recreational traffic comes when changes are made to the transportation system—the time when most resources are typically dedicated to making the change rather than working on public relations.

Tourism industry market researchers monitor the best ways to disseminate information to the visiting public, and parks often include in visitor use surveys questions about what information sources people use to plan their recreational visits. Typical media include travel guides, tour books, and Web pages about recreational attractions and surrounding businesses and amenities. Once visitors arrive in the local area, they refer to sources such as local tourist publications, visitor centers, chambers of commerce, and local residents. Messages that target one audience will sometimes filter to other audiences, and some groups might fall into more than one category. For instance, local citizens frequently use the same recreation amenities as the general visiting public, and the information that goes to local citizens often is picked up by visitors.

With respect to transportation, visitors need to know about and understand transportation options before they will be willing to use them. This means that information on options, venues served, schedules, and stops must be readily available at entrance points to recreational communities, at visitor lodging, and at other easily accessible locations. For real-time information, various ITS technologies such as kiosks and variable message signs can be used to provide information on the current status of transportation services.

Planners for each locality need to tailor communication programs to their own situations. Visitor surveys can help identify how visitors get information on their recreational regions. Past surveys have indicated that the widening use of the internet has gradually changed the sources people use to get information, particularly since the late 1990s. On the other hand, traditional media, such as tourism guidebooks and telephone inquiries, continue to influence vacation planning. Transportation operators should design public communication programs consisting of different media, where this strategy is informed by research that is updated through regular visitor surveys (see chapter 24 on public participation and engagement).

### B. Communication with the Local Community

Sometimes even the most thoughtful public outreach efforts can have unintended reactions. When the Maine Department of Transportation designed a campaign to publicize its 511 tourism information network, part of the campaign involved showcasing the ITS information outreach implemented in and around Acadia National Park. The Bar Harbor Chamber of Commerce objected for fear that alerting visitors to full parking lots might scare potential visitors away.

Although some might object to the media reporting congested conditions, in reality, the media are often the most effective means of getting the message out. Developing good relationships with radio, internet, newspaper, and television outlets is an important part of the transportation planning and transportation system management processes.

## VII. SUMMARY

People have long used recreational areas as places to get away from the perceived ills of urban society—traffic congestion, pollution, and crowding. But these characteristics of modern society are following them into their vacations. Transportation planning is becoming increasingly important to maintain vacation-quality visitor experience in recreational areas. Given that recreational areas serve special roles in unique locations, they also differentiate characteristics that need to be considered in transportation planning. While priorities will vary depending on recreational community types, locations, and cultures, any community dependent on tourism for the majority of its economy will consider visitor experience and quality of life paramount in transportation system design. Information and communication are critical from the basic word of mouth of front-line employees to sophisticated intelligent transportation systems.

Transportation planning for recreational areas needs to take into consideration a wide range of impacts, thus the need for a systems approach toward planning. A systems approach anticipates externalities and trade-offs among desired goals and prepares stakeholders to understand the trade-offs necessary for achieving the best transportation strategy for the community. These trade-offs form the basis for balancing the interests of different stakeholders and the best interests of the recreational site. After adopting desired goals and operational objectives, monitoring system performance provides critical information on the extent community goals are being achieved, the associated costs, and the external effects generated. Transportation planners, recreation managers, and transportation system operators can use this information to achieve more effective and sustainable outcomes.

The potential positive and negative consequences of transportation initiatives can affect many people in different ways. Transportation planners for recreational communities need to adopt an open planning approach to prepare for the impacts of system changes and to create the most desirable effect for a given local environment. Rather than focusing on economic, environmental, financial, or any other specific type of impact, transportation must be considered through a systems approach that anticipates and educates people about externalities and trade-offs among goals.

Rather than asking what impacts transportation changes can be expected to generate, transportation planners should articulate the types of impacts they intend to create. These objectives formed in local context need to balance across the interests of different stakeholders and the trade-offs inherent in pursuing any given objective.

For those wanting additional information, an excellent resource for information on transportation in park areas is found at the Federal Lands Transportation Institute, Resource Library http://www.fedlandsinstitute.org/ResourceLibrarySearch/Repository.aspx.

# Integrating Freight into the Transportation Planning Process[1]

## I. INTRODUCTION

For many years, the transportation planning process focused almost exclusively on passenger transportation. The models developed, the data collected to support these models, and the resulting policy and investment strategies were each concerned primarily with the movement of vehicles and people. Freight movement entered into planning consideration primarily as a truck–passenger car equivalent factor used to estimate freeway capacity. With the passage of the Intermodal Surface Transportation Efficiency Act (ISTEA) in 1991, transportation planners and policy makers became more interested in the concept of intermodal transportation as applied to both passenger and freight movement. Although much of the freight and goods movement in a typical state or metropolitan area is the responsibility of private firms, a large portion of this movement occurs on the highway network and thus has significant implications to those responsible for planning, building, and managing the road network. In addition, laws, operating regulations, and zoning codes can have a significant impact on freight operations, and thus the interface between the freight sector and public decision making is an important part of the transportation policy framework.

Transportation planners need to know how much freight and what type of goods are moving on the transportation network, and from which distribution/ warehouse centers these flows are originating. These and other data about the mode of transportation, vehicle or vessel characteristics, and types of facilities used are needed to track and monitor system conditions and performance to assess the many ways freight affects the transportation system. The U.S. economy depends on an interconnected transportation network to move a vast array of raw materials and manufactured goods. More than ever, consumers can buy imported fresh foods at their local supermarkets, receive goods they purchased over the internet, and track express packages online to know their whereabouts at any given time. These everyday occurrences are made possible by a vast transportation network combined with freight delivery services and continuing improvements in freight logistics, which are due in large part to advancements in information technology.

Public agencies charged with operating and maintaining the U.S. transportation system are increasingly challenged by the strain that freight movements are putting on the system. This chapter was developed to assist planners in integrating freight into their planning process. The next section provides an overview of domestic freight flows in the United States. This is followed by a discussion of the impact of freight flows on the community and on the transportation system. The fourth section presents the freight planning process, including the institutional aspects, the need for system designation, data collection, and the models and analysis tools used to identify and assess different freight-related strategies. The next section describes some of the important aspects of freight terminal planning and design. The final section offers thoughts on some of the key aspects of integrating freight concerns into the transportation planning process.

## II. OVERVIEW OF DOMESTIC FREIGHT FLOWS

The amount of freight the U.S. transportation system carries is impressive. Freight traffic carried by air, truck, rail, water, and pipeline totaled more than 20 billion tons and an estimated 6.2 trillion ton-miles in the United States in 2013—an increase of more than three trillion ton-miles from 2001. This 100 percent growth in ton-miles, the primary physical measure of freight transportation output, represents a 0.9-percent compound annual growth rate between 2001 and 2013, the latest year for which complete data are available. Table 22-1 summarizes domestic freight flows by tons and value for 2013. In 2013, trucked freight accounted for about 70 percent of the domestic freight tonnage and

[1]The original chapter in Volume 3 of this handbook was written by Dr. Paula Dowell, Principal, Cambridge Systematics, Inc. Changes made to this updated chapter are solely the responsibility of the editor.

| Table 22-1. Shipments by Mode, Value ($2007) and Weight (2013), United States | | |
|---|---|---|
| | **Tons (millions)** | **Value ($2007 billions)** |
| **Truck** | 13,955 | $11,444 |
| **Rail** | 1,858 | $577 |
| **Water** | 808 | $284 |
| **Air** | 15 | $1,167 |
| **Multiple Modes**[1] | 1,554 | $3,065 |
| **Pipeline**[1] | 1,539 | $1,003 |
| **Other** | 333 | $363 |
| **Total**[2] | 20,063 | $17,983 |

[1]Intermodal includes U.S. Postal Service and courier shipments and all intermodal combinations except air-truck.

[2]Data do not include imports and exports that pass through the U.S. from a foreign origin to a foreign destination by any mode.

Note: Numbers may not add to total due to rounding.

Source: FHWA, 2013; BTS, 2015

64 percent of the domestic freight value. Trucking dominance in domestic freight movements is expected to continue in the future.

### Terms Used in Freight Planning

*Commodity*—A way of classifying the type of freight being shipped. Commodities in the same class are assumed to have the same value per ton, density, and handling characteristics. The most common classification schemes for commodities include the Standard Transportation Commodity Classification (STCC) of the American Association of Railroads and the Standard Classification of Transported Goods (SCTG) developed by the U.S. and Canadian governments.

*Shipment*—A shipment is a single movement of goods, commodities, or products from an establishment to a single customer or to another establishment owned or operated by the same company as the originating establishment (for example, a warehouse, distribution center, or retail or wholesale outlet). Full or partial truckloads are counted as a single shipment only if all commodities on the truck are destined for the same location.

*Value of shipments*—The value of shipments is the market value in dollars of goods shipped by businesses. It represents the net selling value, excluding freight charges and taxes. However, it does measure the value of shipments of materials used to produce or manufacture a product, as well as the value of shipments of the finished product itself.

*Tonnage of shipments*—This measure represents the total weight of a shipment reported by businesses in pounds. As with the value of shipments above, the tonnage of a product could be counted multiple times depending on the number of times the product is transported in the production and consumption cycle.

*Ton-miles*—Ton-miles measure the shipment weight multiplied by the mileage traveled by the shipment. Mileage is calculated as the distance between the shipment origin and destination zip codes. For shipments by truck, rail, or shallow draft vessels, the mileage excludes international segments. For example, mileage from Alaska to the contiguous states exclude any mileage through Canada.

The U.S. Census Bureau periodically undertakes a survey of freight movement in the country, which provides a snapshot of several characteristics of the U.S. domestic freight market of interest to transportation planners. For example, the latest survey results (2012) showed: [Census Bureau, 2015]

- Most U.S. freight shipments by value and tonnage move less than 250 miles (402 kms), representing slightly more than 77 percent of the weight and slightly more than 60 percent of the value of the shipments

surveyed. However, trips exceeding 250 miles represented 84 percent of the ton-miles estimated in the surveyed data. Only 4.5 percent of the shipments (by weight) traveled more than 1,000 miles (1,609 km.), but this represented about 32 percent of the ton-miles.

- Package delivery services have experienced significant growth. Packages less than 500 pounds (227 kgs.) accounted for 25 percent of the value of shipments carried and grew by 14 percent between 2007 and 2012. The total value of packages weighing less than 50 pounds (23 kgs) increased by 24 percent.
- By value, the top five commodity types moved by freight were: mixed freight, gasoline, motorized and other vehicles, electronic and other equipment, and pharmaceutical products.
- By weight, the top five commodity types moved by freight were: gravel and mixed stone, gasoline, coal, fuel oils, and non-metallic mineral products.
- By ton-miles the top five commodity types moved by freight were: coal, prepared foodstuffs and fats and oils, agricultural products, cereal grains, and basic chemicals.
- Shipments exceeding 50,000 pounds (22,680 kg) comprised 64 percent of the ton-miles and 51 percent of the tons shipped, but only 16 percent of the value. The changes in the prior 5 years for these heavier loads were a 1.6 percent decrease for ton-miles, 4.3 percent decrease for tons, and 3.6 percent increase for value.
- Hazardous materials are categorized into nine different classes in the U.S., ranging from radioactive residue to contaminated blood. The 2012 survey estimated that 2.58 billion tons of hazardous materials were transported in the United States. Of this amount, trucks carried 54 percent, pipelines carried approximately 24 percent, and the rest traveled by rail, water, and air. However, the travel mode varied by type of hazardous material. For example, trucks carried 98 percent of explosives, 59 percent of flammable liquids and 63 percent of what are referred to as Class 2 gases.

One caveat with these trends is the uncertainty of what commodity markets will look like in the future. For example, Caplis and Phadnis [2013] conducted a study on the characteristics of future markets by using scenario analysis. They found the forces that appeared to have the most impact and the most uncertainty on future markets were the level of global trade, potential re-domestication of manufacturing currently overseas, and resource availability (for example, petroleum fuel). Trends they concluded would continue from the past included high and volatile fuel prices, increased use of battery vehicles, widespread use of sensing technologies in managing transportation networks, and increased use of virtual working and online retailing. The aging of the population (and the impacts on consumer spending) and increasing urbanization were determined to be a "given."

In addition, often not discussed in descriptions of freight movement, the transportation of data can be an important stimulant in freight movements (for example, more efficient ordering of goods) or it can become substitute for freight trip-making. For example, 3D printing could have a dramatic impact on the movement of goods; simply send the product dimensions and it can be manufactured on site rather than having to ship it in.

Each freight mode has its own historical and expected growth trends. The U.S. DOT Bureau of Transportation Statistics (BTS) is a useful source of freight modal data. Some of the key characteristics of each freight mode described below come from BTS reports.

## A. Trucking

There were 2.4 million truck tractor trailers registered in the United States in 2012. [FHWA, 2015] The trucking industry, both for-hire and private own-use, transported more than $12 trillion worth of shipments, weighing more than 13.8 billion tons, and generating about 2.5 trillion ton-miles in 2012. The primary driving force behind trucking's increasing modal share has been the growth in the service sector, which combined with manufacturing has become more important to the national economy. The two major impacts of truck movements on an urban area's road system are: (1) their effect on the capacity of roads serving major travel flows (trucks take up more space and are not as mobile as passenger cars), and (2) the congestion and safety consequences of trucks accessing distribution/warehousing and other major destinations, often on local roads.

Urban goods movement, sometimes called urban freight and service activity, is an important consideration for metropolitan transportation planning. National Cooperative Freight Research Program (NCFRP) Report 19,

*Freight Trip Generation and Land Use*, for example, concluded that: (1) the average commercial establishment in an urban area generates about 2.5 freight trips/day and about 0.3 service trips/day; (2) 40 percent of the traffic is generated by establishments of less than four employees; and, (3) the retail/accommodation/food services sector generates about 40 percent of the traffic. [Holguin-Veras et al., 2012] The service component of this traffic has greater demand on curbside space as service vehicles park for extended periods of time. Providing locations for pick-ups and deliveries is a challenge in many dense urban centers where road space is shared with many different groups.

In some metropolitan areas, land gateways are important ports of entry into the United States, not only for the economic activity it generates, but also for the amount of travel demand placed on the region's transportation network. For example, in 2013, the top five land gateways from Mexico handled just over five million truck containers, with Laredo, Texas, handling just over four million. [BTS, 2015, Table 1-54] On the Canadian border, the top five crossings handled 3.8 million truck containers, with Detroit, Michigan, handling 1.5 million. [BTS, 2015, Table 1-52]

At a broader policy level, some argue that more freight should be carried on railroads for environmental and road capacity reasons. The U.S. Internal Revenue Service (IRS) has observed that, in general, under 100 miles, truck/rail competition occurs only on shipments weighing more than 60,000 pounds, that is, trucks carry most of the freight. At 100 to 300 miles, competition occurs on shipments weighing between 60,000 and 90,000 pounds; at 300 to 500 miles, competition occurs on shipments weighing between 30,000 and 90,000 pounds; and at 500 miles or more, competition occurs for commodities weighing between 10,000 and 60,000 pounds. As noted, "for trips under 100 miles, it is private carriers who are providing the competition. For trips over 100 miles, it is the for-hire motor carriers who are doing so. The only exception is for loads weighing between 30,000 and 60,000 pounds moving between 100-200 miles. Here, private trucking seems to be the carrier of choice." [IRS, 2015]

One of the potentially important changes in truck operations is the development of autonomous trucks, that is, trucks that will "drive themselves" or at a minimum have such advanced vehicle technologies that drivers will simply have to make sure the vehicle is operating efficiently. The widespread application of such technology could have significant impacts on both the trucking and railroad industries, as well as on the type of infrastructure provided by transportation agencies (for example, truck-only lanes).

## B. Rail

Freight railroads transport an array of commodities and products, ranging from manufactured goods to bulk resources, such as coal and grain. In 2013, seven Class I railroads (the largest railroads) in the United States transported 1.76 billion tons of originating freight, using 28.8 million carloads and 12.8 intermodal car loads (container or truck on rail car). U.S. railroads carried about 3 percent of the nation's freight shipments measured by value, and 11 percent by weight. [FHWA, 2013] Coal and chemicals accounted for 50 percent of the rail tonnage in 2013. With respect to urban transportation, the major impact of rail flows is twofold, (1) in those communities with rail/highway at-grade crossings, long trains can disrupt the operation of roads, and (2) railroad intermodal yards can attract a large number of trucks delivering or picking up goods, possibly contributing to congestion on the local roads.

The railroad industry in particular, as the freight sector in general, is very sensitive to the state of the economy. During the economic recession of the early 2010s, rail revenues declined as fewer goods were transported. The railroad industry did not have the capital to reinvest in its infrastructure. By the mid-2010s, this had turned around and railroads were investing in track and new yards to handle expected increases in freight volumes.

## C. Inland Water and Maritime

Some component of nearly 9 percent of the total tonnage transported in the U.S. in 2012 occurred on water. [Bureau of Census, 2015] The total tonnage of U.S. waterborne freight, including domestic commerce and international trade, was nearly 576 million tons in 2012, up from 404 million tons in 2007. In 2012, water transportation carried 74 percent of the weight and 47 percent of the value of U.S. international merchandise trade. [FHWA, 2013]

Seaports are important contributors to the national economy as well as to the economies of individual states and metropolitan areas. In 2013, nine of the top 20 freight gateways into the United States (by value) were seaports, with the Port of Los Angeles at the top spot, handling $213 billion worth of trade. [BTS, 2015, Table 1-51]

The inland waterways system includes 12,000 miles of commercially navigable channels, with over 200 lock chambers. In addition, inland water transportation includes freight movement on the Great Lakes and intra-coastal waterways. More than 566 million tons of freight move through the inland waterway system annually, valued at more than $152 billion. It is estimated that the inland waterways and rivers carry the equivalent of about 51 million truck trips each year. [ASCE, 2013] The types of vessels and thus the type of cargo moved include tankers, container barges, gas, roll on-roll off, bulk, and general cargo. In 2013, the three largest ports of entry for tonnage handled at U.S. ports and terminals for vessels over 1,000 gross tons were the Sabine-Neches waterway (Beaumont, Texas); New Orleans, Louisiana; and Houston, Texas. These top three handled primarily petroleum products.

An Inland Waterways Trust Fund based on a $0.20 per gallon tax on barge fuel has been established by the federal government to invest in the inland waterways network. Currently, the tax revenues raised is approximately $85 million per year; however, the estimated investment needs are an average of $900 million annually. [ASCE, 2013]

## D. Air Cargo

In 2014, all-cargo carriers and other commercial airlines generated 65 billion freight revenue ton-miles. [BTS, 2015b] Air freight revenue ton-miles have grown faster in the international market than in the domestic market. For example, in 2014, the domestic air cargo market, measured in revenue ton-miles, grew by 3.36 percent whereas growth in the Pacific market alone grew by 6.01 percent. Ton-miles from the international market now exceed those from the domestic market. Air cargo accounted for a much larger proportion of the value (22.5 percent) than the weight (less than 1 percent) of overall freight movement.

In 2013, Memphis, Tennessee (Federal Express consolidation center), handled the largest amount of domestic air cargo, some 22 billion pounds. Anchorage was second (many flights from Asia land in Anchorage, Alaska, to go through customs) with Louisville (UPS consolidation center) in third place. [FAA, 2015] John F. Kennedy (JFK) International Airport in New York City is the leading overall gateway for U.S. international air freight by value.

## E. Pipelines

Transportation planning seldom examines the movement of liquid commodities by pipelines. However, substantial volumes are transported by the nation's pipeline network. In 2012, U.S. pipelines carried just over 1.5 billion ton-miles (2.41 billion ton-km) of crude oil, petroleum products, and natural gas—approximately 8 percent of the total freight ton-miles by all modes. Natural gas liquids accounted for about one-third of this total. In 2014, the United States imported more than 3.37 billion barrels of crude oil and petroleum products, and pipelines helped to transport a large proportion of these imports on some part of the journey from points of entry to refineries, terminals, and markets for final consumption. [EIA, 2015a] Additionally, there were more than 2.6 million cubic feet of natural gas imports coming from Canada by pipeline each year into the United States. [EIA, 2015]

## F. Intermodal Freight

A particularly important element of the international trade handled at seaports has been the increasing use of containers as a means of transport. In 2013, just over 44 million 20-foot equivalent container units (TEUs) of merchandise moved in and out of U.S. ports, up 35 percent from the 32.7 million containers in 2003. [World Bank, 2015] These container units arrive and leave the seaports either by rail or truck, or by some intermodal truck-rail combination. The Ports of Los Angeles and Long Beach, California, handle the largest number of containers in the United States, reflecting increased trade with Asia and Pacific Rim countries. In terms of growth rate, Savannah, Georgia, has consistently shown the fastest growth in annual percent change over the past several years. Beginning in 2003, the revenue generated from intermodal services produced more revenues for the Class 1 railroads than coal, accounting for 43 percent of gross revenue. The widening and deepening of the Panama Canal could have a significant impact on the movement of international containers into the United States.

# III. IMPACT OF FREIGHT FLOWS ON THE COMMUNITY, FREIGHT SECTOR, AND TRANSPORTATION SYSTEM

The growth in freight movements affects transportation agencies in many ways. With respect to physical infrastructure, larger and heavier vehicles cause more damage to roads than lighter and smaller vehicles. For many years, transportation

engineers, for example, have examined the effect of heavy vehicles on bridge and pavement designs. With respect to economic development, modern economies depend on the ability to move resources and goods. Therefore, providing such accessibility and mobility becomes an important part of a national, state, or metropolitan economic development policy. Finally, similar to other transportation facilities, freight terminals and operations have an effect on the environment and communities that is often of great concern to community leaders and residents.

## A. Community Impacts

National Cooperative Highway Research Program (NCHRP) Synthesis Report 320, *Integrating Freight Facilities and Operations with Community Goals*, identified numerous freight-related issues of concern to community officials. [Strauss-Wieder, 2003] As noted in the report, the need for understanding the relationship between a freight facility or operation and the surrounding community is becoming more important for several reasons: (1) the amount of freight traffic is increasing, (2) the general population is less involved in goods production and therefore may not be as familiar with the steps needed to produce and deliver goods to consumer markets, (3) the continued growth in U.S. population and land development increases the likelihood of conflicts between different types of uses, and (4) there is continuing pressure to keep freight transportation costs low. In a survey of U.S. communities, the following freight-related issues were raised by community officials. [Strauss-Wieder, 2003]

**Traffic Flow and Congestion**

- Volume—The volume of trucks affects available road capacity for other transportation users.
- Operational characteristics—Trucks accelerate and decelerate at different speeds than passenger vehicles.
- Road geometrics—Trucks, especially larger trucks, require different lane widths, turning radii, and turning lane requirements.
- At-grade rail freight crossings—Freight trains, particularly long trains, can cause significant backups when traveling through at-grade crossings.
- Trucks at commercial and retail establishments—Larger trucks backing into or parked at the loading docks of retail and commercial establishments can block roads. Trucks double-parked outside of buildings also contribute to congestion.
- Truck parking on shoulders and ramps—Inadequate truck parking and rest areas have resulted in trucks parking along shoulders and ramps, a practice that can affect roadway operations.

**Safety and Security**

- Safety of at-grade rail crossings, given the significant damage that a train-vehicle collision causes.
- Movement, handling, and storage of hazardous materials.
- Vehicle size, speed, stopping distance, sight obstruction, and weather-related impacts to pedestrians, bicyclists, and drivers.
- Trespassing and potential injury or loss of life along rail corridors.
- Safety concerns on roadways with heavy truck volumes.

**Economic Development**

- Assessing how to best use freight transportation assets to achieve economic development goals.
- Implications of off-shoring of manufacturing and the implications of such operations returning to the United States.
- Air and rail service to retain or attract businesses.
- Determining situations where existing freight transportation operations and facilities conflict with an area's economic development goals.

- Leveraging an area's freight transportation assets to attract industries.
- Maintaining or developing rail service to retain or attract business to areas.

**Environmental Concerns**

- Release of invasive aquatic species from vessel ballast discharges and the effect on harbors and waterways.
- Environmental implications of hazardous materials spills and accidents on waterways and in communities.
- Potential impact on low-income and minority communities as a result of freight operations and facilities (environmental justice).
- Vehicle and facility-specific air pollutant emissions.
- Potential impacts of freight facilities and operations on endangered species and habitats.
- Impact of the light given off by freight facilities on nearby communities during nighttime operations.

**Noise and Vibration**

- Noise resulting from train whistles and train movements.
- Noise from aircraft engines, especially cargo aircraft that operate at night, and sometimes from older equipment.
- Noise associated with the loading and unloading of trucks at retail stores and freight facilities abutting residential areas.
- Noise and vibrations associated with higher levels of freight traffic.
- Vibrations from heavy truck traffic, heavier and more frequent trains, marine channel deepening, and aircraft operations.

**Land Use and Value**

- Marine freight operations competing with other land uses for waterfront property.
- Potential alternative land uses for property currently occupied by freight facilities.
- Productivity of and economic value generated by the land used by freight facilities.
- Rail line reactivations or increases in rail operations on rights of way adjacent to residential neighborhoods.
- Non-maintenance of rights of way, allowing litter and overgrowth to occur.
- Increases in truck volumes on local roads.

These types of issues are important starting points for transportation studies aimed at enhancing the economic development opportunities associated with freight facilities and operations, while at the same time doing so in an environmentally sensitive way. In most cases, these types of issues surface during the early stages of a planning study and often are incorporated into the goals and objectives statement.

California has been leading the way in researching the health effects of ozone emissions from freight transportation. Diesel particulate matter (diesel is a major fuel used in freight transportation) is of special concern to human health because 50 to 90 percent of the particles are very small (that is, ultrafine) and can readily enter into and deposit within the lungs, passing through the bloodstream at the cellular level. However, it should be noted that ultrafine particulate matter is not exclusive to diesel emissions; ultrafine particles originate from combustion processes using any fuel, including gasoline, compressed natural gas, and liquid natural gas. Table 22-2 shows the health effects and valuation of freight emissions contributing to particulate matter (2.5 microns) for California in 2012, and projected to 2030 and 2050.

| Table 22-2. California Statewide Health Effects and Valuation (2013 $) Associated with Freight Emissions Contributing to PM2.5—Uncertainty Ranges** | | | |
|---|---|---|---|
| **PM2.5 and NOx** | **2012** | **2030** | **2050** |
| Mortality | 1,700–2,700 | 770–1,200 | 830–1,300 |
| Hospitalizations* | 43–770 | 19–340 | 20–370 |
| ER Visits† | 600–1,300 | 260–570 | 280–620 |
| Valuation (billions) | $16–$24 | $7–$11 | $7–$12 |

*Includes respiratory and cardiovascular hospitalizations

**Uncertainty ranges only reflect uncertainty in the concentration-response function, and do not reflect uncertainty in emission projections, spatial interpolation, and aggregation.

†Includes asthma and cardiovascular emergency room visits

Source: CARB, 2015

In recent years, the California Air Resources Board (CARB) has focused its attention on the pollutant emissions from the freight sector and possible strategies to reduce emissions. CARB has adopted and implemented over a dozen regulations, as well as agreements with industry and incentive programs, to reduce freight emissions. As shown in Figure 22-1, these efforts, along with the benefits of national and industry initiatives to reduce freight-sector emissions, have had an important impact on air quality in California by reducing the most important freight-related pollutant emissions.

Some illustrative strategies being pursued by CARB to reduce emissions even more in the future include (not a complete list): [CARB, 2015]

**Figure 22-1. (a): California Statewide Nitrous Oxide (NOx) Emissions from Freight Sources (tons per day); (b): Statewide Sulfur Oxide (SOx) Emissions from Freight Sources (tons per day); (c): Statewide Particulate Matter (PM2.5) Emissions from Freight Sources (tons per day); (d) Statewide Greenhouse Gas (GHG) Emissions from Freight Sources (million metric tons CO2-e per year)**

*For cleaner combustion*:

**Trucks**

- Develop and propose strategies to ensure durability and in-use performance.
- Develop and propose increasing flexibility for manufacturers to certify advanced innovative truck engine and vehicle systems in heavy-duty applications.
- Develop and propose California-specific standards for new heavy-duty truck engines to provide benefits above national standards.

**Ocean-Going Vessels**

- Define criteria for "Super Low Emission Efficient Ship" and achieve early implementation of clean technologies (liquefied natural gas, Tier 3, or better) for newer vessels via existing and enhanced seaport incentive programs (for example, Green Ship, Ship Index, etc.).
- Develop and propose amendments to the At-Berth Regulation to include other vessel fleets and types to achieve additional emission reductions.

**Locomotives**

- Develop and propose a regulation applicable to all non-new locomotives to maximize the use of Tier 4 engines, liquefied natural gas, for better line-haul, medium horsepower, and switch locomotives (provide credit for zero emission track miles and zero emission locomotives).

**All Sectors/Freight Hubs**

- Collect data (such as facility location, equipment, activity, and proximity to sensitive receptors) from seaports, airports, rail yards, warehouse and distribution centers, truck stops, etc. to identify and support the proposal for a facility-based approach and/or sector-specific actions to reduce emissions and health risk, as well as efficiency improvements.

*For zero emissions*:

**Delivery vans/small trucks**

- Develop proposal to accelerate penetration of zero emission trucks in last mile freight delivery application with potential incentive support.

**Large spark-ignition equipment (forklifts, etc.)**

- Develop proposal to establish purchase requirements to support broad-scale deployment of zero emissions equipment.

**Incentive programs**

- Develop modifications to existing incentive programs to increase the emphasis on and support for zero and near-zero emission equipment used in freight operations, including introduction of truck engines certified to optional low-$NO_x$ standards.

Because of the societal impacts associated with freight transportation, one often finds many public policies, laws, and regulations that regulate the operations and performance of freight equipment and land uses. Table 22-3 shows some of the policies often used by government agencies, and the potential impact on the freight industry.

## B. Impacts on the Freight Sector

Many of the impacts associated with transportation system performance, both improving and deteriorating conditions, are first encountered by private freight carriers. Travel time, cost, reliability, accessibility, and/or safety benefits or costs are system performance characteristics of concern to the carriers. NCHRP Report 463, *Economic Implications of Congestion,* identified five classes of trips affected by congestion. Three of these cost categories were business-related costs, including regional freight delivery (vehicle operating costs, driver wages, and inventory/logistics costs),

| Table 22-3. Examples of Freight System Impacts from Public Policies | |
|---|---|
| **Type of Policy** | **Potential Impacts** |
| Direct taxes or charges to carriers (fuel taxes, vehicle excise taxes, tolls) | Change in carrier costs<br>Change in shipper costs<br>Shifts in modal share between truck and rail<br>Change in freight volumes in corridors |
| Environmental regulations that increase equipment or fuel prices | Change in carrier capital and operating costs<br>Change in shipper costs |
| GHG cap and trade program | Loss of rail carrier revenue<br>Increase in carrier fuel costs<br>Possible short term loss of jobs and economic activity during the transition |
| Renewable fuel standards | Potential increase in rail carrier revenue<br>Increase in carrier costs |
| Air cargo screening on passenger flights | Degraded service in air cargo<br>Shift to all-cargo carriers |
| Fingerprint rules for outbound ships and planes | Increase in carrier costs |
| Rules that directly change operations (truck route restrictions, parking restrictions, restrictions on rail operations) | Increase in carrier costs<br>Change in freight volumes in corridors<br>Degraded service |
| Land-use policies that affect location of freight facilities | Increase in carrier costs<br>Increase in shipper costs<br>Possibly degraded service |
| Dredge spoil disposal policies | Increase in shipper costs<br>Shifts to other ports |
| Driver hours of service rules | Increase in costs for some carriers |
| Truck size and weight rules | Change in fuel use<br>Change in shipper costs |
| Truck speed limits and speed governor rules | Decrease in fuel costs<br>Increase in capital costs for some carriers<br>Change in profitability for some carriers |

Source: ICF et al., 2011

interregional freight delivery, and regional services delivery (such as those relating to professional services, package delivery, and couriers whose time in transit is incorporated into the cost of service).

Depending on market conditions, the impact on carrier performance and costs is typically passed onto freight shippers and their customers. The freight shippers (rather than the carriers) are the ultimate users or customers of the freight transport system. Additional benefits or costs may accrue to shippers as a result of the ability or necessity to restructure their business. Examples of restructuring costs to shippers arising from the deterioration of system performance include the costs of introducing redundancy into freight deliveries and increasing inventory stocks to avoid stock-outs. Ultimately, shippers must reconfigure their business operations and logistics processes to mitigate the effects of inefficient freight transportation.

Changing costs to carriers and shippers have implications for the receivers of freight shipments as well—primarily retailers and wholesalers. These can have further consequences for the market pattern of the production, distribution and sales of supply materials, intermediate goods, and final products for other businesses. These effects can occur locally, regionally, nationally, and globally.

The ultimate consequence of freight transportation operations is on business productivity, which directly affects profitability. Higher freight transportation costs lead to higher prices and/or lower returns for shareholders. Ultimately,

the consumers, workers, and owners bear the burden of inefficient freight transportation or obtain the benefits from improved freight transportation system performance.

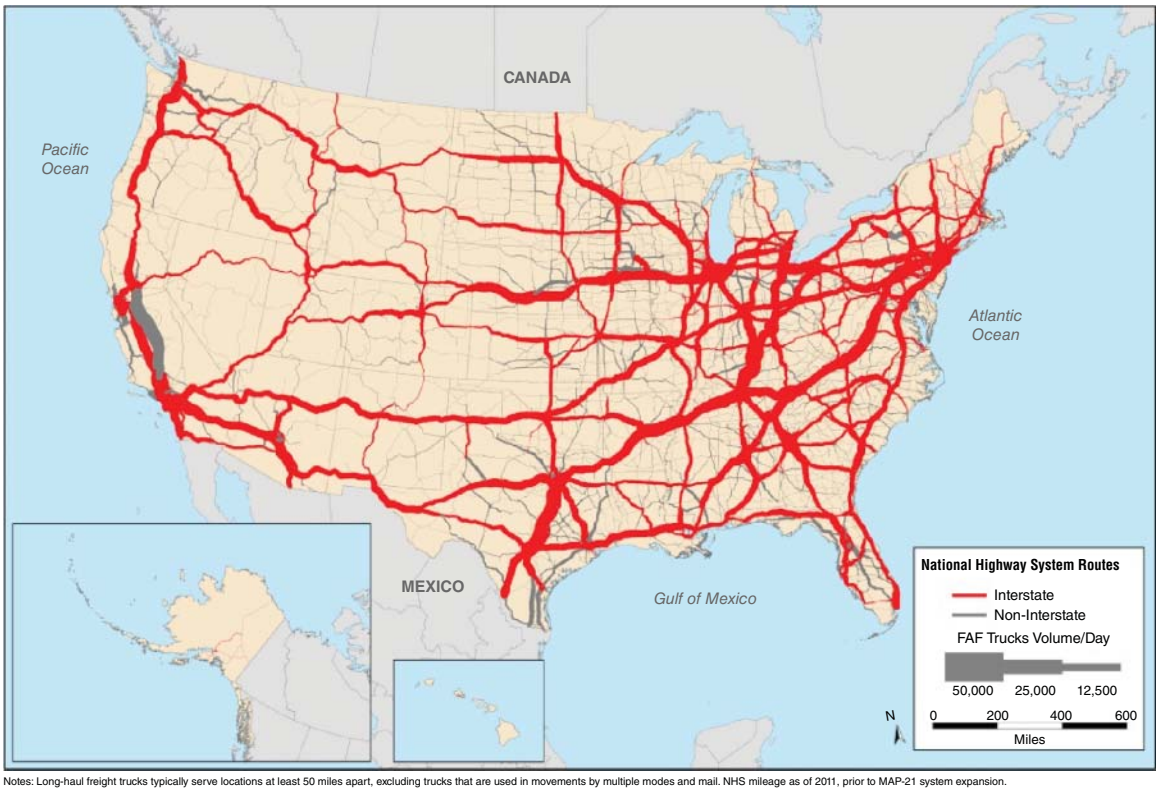
## C. Transportation System Impacts

Increasing freight demands on the nation's transportation system will likely increase the number of bottlenecks in the system. These bottlenecks can occur at major terminal locations where the sheer volume of arriving cargo overwhelms port access facilities and services, or they can occur along the mainline, such as on major metropolitan freeway systems where truck movements mix with passenger vehicles. Congestion levels have been increasing in the United States as well as in other developed nations. The Texas Transportation Institute [Schrank et al., 2015] reports that between 2000 and 2014, the cost of highway congestion in the nation's urban areas increased from $114 billion to $160 billion, an increase of 40 percent. U.S. DOT estimates that the cost of congestion across all modes of transportation could be three times as high if productivity losses, costs associated with cargo delays, and other economic effects were included. Among these are losses accruing to auto drivers, freight carriers, businesses, consumers, and the public.

Forecasts indicate that freight demand and truck traffic will continue to grow. Figure 22-2 illustrates the projected truck flows on U.S. highways in 2040. Demand along key east–west interstate highway corridors, as well as north–south corridors serving trade to and from Canada and Mexico, will increase. The map also suggests that nearly all urban areas can expect significant growth in the number of trucks using their road system, while rural interstates can expect more moderate growth. Figure 22-3 shows those segments of the U.S. national highway system expecting more than 10,000 trucks per day in the year 2040. As shown, many of the nation's major urban freeways experiencing peak-period congestion in 2040 are also major truck routes.

Freight movements affect not only the capacity of the U.S. transportation system but also its operations and maintenance. The U.S. highway system, especially the Interstate Highway System, has made trucking possible. Bridge design and pavements allow for trucks weighing at least 80,000 pounds gross vehicle weight to travel long distances

**Figure 22-2. Estimated Average Daily Long-Haul Truck Traffic on the National Highway System, 2040**



Notes: Long-haul freight trucks typically serve locations at least 50 miles apart, excluding trucks that are used in movements by multiple modes and mail. NHS mileage as of 2011, prior to MAP-21 system expansion.

**Figure 22-3. Peak-Period Congestion on Segments of the National Highway System with More Than 10,000 Trucks Per Day, 2040**

Source: BTS, 2015

without reconfiguring. Along with weather and geologic conditions, heavy vehicles are largely responsible for the wear and tear on U.S. highways. According to data submitted by the states, freight trucks (heavy, single-unit, and combination trucks) comprise 21 percent of the volume of traffic on U.S. rural interstate roads, but cause more than 97 percent of the damage to pavements, as calculated by the impact of an equivalent single-axle load (ESAL), a term used by pavement engineers to measure the effects of heavy vehicles on pavement. On the urban Interstate Highway System, heavy trucks comprise 9 percent of total traffic volume, but are responsible for 96 percent of pavement damage. [AASHTO, 2012]

Another important system impact reflects the interconnectivity of the freight system. In many markets, the choice of freight mode is influenced by the respective price of moving freight by one mode versus another, the reliability and convenience of delivery, and the security associated with making sure goods arrive without damage or pilferage. Whenever a change in the market occurs, or when some other event causes disruption in the freight network such as a port strike or a bridge/tunnel failure on a major freight route, other parts of the freight system will likely be affected. Examples of such disruptions have occurred in the United States over the past several decades, including numerous hurricanes, major labor strikes at ports, the closure of rail lines due to snow or floods, and the shutdown of the national aviation system during 9/11. Internationally, disruptions in supply chains have also been caused by health concerns, such as the avian flu.

As noted by NCHRP Report 732, *Methodologies to Estimate the Economic Impacts of Disruptions to the Goods Movement System*, the economic impact of severe bottlenecks and disruptions could affect a wide range of supply chain participants, not just the ocean carriers, truckers, railroads, and shippers that are using the network to transport the goods. These participants include public agencies, local labor unions, local retailers, warehousing and distribution providers, and potentially a significant number of consumers and economic organizations throughout the United States.

The types of actions or strategies that can address the issues discussed above are shown in Table 22-4. Some of the strategies are applicable to all freight modes while others are meaningful for one or two. The planning process focuses on which strategies make most sense in the specific context of a planning study.

**Table 22-4. Practices to Balance Freight Transportation Facilities and Operations With Community Issues**

| | Issue Areas | | | | | | Freight Types | | | | | |

## IV. FREIGHT PLANNING

Freight planning encompasses many of the same steps found in any transportation planning process. The vision, goals, and objectives of a general transportation planning process usually include topics relating to freight and goods movement. Just as in other planning efforts, a freight planning study uses data, analysis tools, and a set of evaluation criteria targeted at finding the most cost-effective strategies and actions for implementation. [Holguin-Veras et al., 2015]

There are many different types of freight-oriented transportation planning studies. At the most general level are the standard transportation planning studies conducted periodically for a state or metropolitan area. The challenge in these studies is to incorporate freight considerations commensurate with the freight problems facing the state or community. Many agencies have also been conducting freight-specific planning studies that focus exclusively on truck, rail, air, water, and intermodal freight movements in and through a study area. Thus, for example, it is not uncommon to find state rail plans, air cargo plans, and seaport/river plans. A final type of freight planning study is one that examines a specific freight issue, such as truck parking or enforcement strategies. The following list from the San Diego Association of Governments (SANDAG), the metropolitan planning organization (MPO) for the San Diego region, gives a sense of the wide range of freight-related studies that might occur in a regional planning process:

- *State Route 11 and Otay Mesa East Port of Entry:* This innovative project will improve the efficient movement of people, goods, and services between the United States and Mexico.
- *Analysis of Freeway Operational Strategies Related to the Use of Managed Lanes by Trucks:* Analyzes different strategies for accommodating and managing trucks on the region's freeways.
- *Freight Gateway Study Update:* Provides a forecast of regional freight traffic in San Diego and Imperial Counties through 2050.
- *Port of San Diego Freeway Access Improvements:* Includes improvements at Bay Marina Drive at I-5, Civic Center Drive at Harbor Drive and I-5, and 10th Avenue at Harbor Drive.
- *LOSSAN Freight Rail Corridor:* Improvements include double tracking, curve realignments, and the addition of crossovers to increase capacity and enhance reliability.
- *South Line Rail Freight Capacity Project:* Provides expanded freight operations through the construction of improved San Ysidro Yard capacity, trackage, and train control safety improvements.
- *State Route 905:* The completion of SR 905 will provide a critical connection to the Otay Mesa Port of Entry.
- *Goods Movement Strategy and San Diego Forward:* The Regional Plan considers the importance of freight and goods movement to the region's economic prosperity and seeks to balance regional and national freight priorities. [SANDAG, 2015]

Not all MPOs have such a repertoire of freight planning activities. However, this list does provide some indication of the types of issues that transportation planners and engineers might be involved with in transportation planning.

The following sections discuss some of the key aspects of a freight transportation planning process. Space does not permit an exhaustive coverage of every aspect; however, as previously noted, many freight planning activities share characteristics with the general transportation planning process. See chapter 2 on data collection, chapter 4 on environmental considerations, chapter 6 on travel demand modeling, and chapter 7 on evaluation for additional information on freight-oriented planning studies.

### A. Institutional Structure

As noted earlier, traditional transportation planning did not usually include freight concerns in the planning process. As such, representatives of the freight sector seldom participated in transportation planning. As more planning studies began to consider freight issues, and as freight-specific planning was undertaken in an increasing number of states and metropolitan areas, it became apparent that the participation of freight interests in the planning effort was essential. One of the important lessons in early freight-oriented transportation planning efforts was the

need for a study structure that promoted the participation of carriers and shippers. The following examples illustrate a variety of planning/program approaches.

*Atlanta Freight Advisory Task Force*. As part of a regional freight transportation planning process, the Atlanta Regional Commission (ARC), the MPO for the Atlanta metropolitan area, created a freight-advisory task force. The task force, which meets quarterly, includes representatives from railroads, trucking companies, the airport, chambers of commerce, major shippers, local planners, and a local university. The objectives of this task force are to:

- Provide input on policies and improvements for freight mobility.
- Identify freight mobility characteristics and needs.
- Highlight the significance of freight to the region.
- Improve safety of the transportation system.
- Prioritize freight transportation needs and investments.

*Albany, New York, Goods Movement Advisory Committee*. The MPO for the Albany, New York, region created a goods movement task force that brought together private freight operators and public freight planners to share information on local freight issues and events. The task force provides input into the long-range transportation plan update as well as individual planning projects. Given the importance of goods movement to the region, the task force has evolved into a permanent freight advisory committee.

*Philadelphia Goods Movement Task Force*. The Delaware Valley Regional Planning Commission (DVRPC), the MPO for the Philadelphia metropolitan area, has included freight representatives in the transportation planning process for many years. DVRPC's freight advisory committee, the Delaware Valley Goods Movement task force, is open to all trucking, railroad, port, airport, shipper, freight forwarder, economic development, and member government representatives. The task force is co-chaired by the state DOT and the MPO. The adopted objectives of the task force are to:

- Ensure the participation of the freight industry in the planning process.
- Identify improvements to facilitate the safe and efficient movement of freight.
- Implement regional congestion and intermodal management programs.
- Improve communications and data and technology sharing.

Task force members have participated in technical studies, identified capital improvements to transportation facilities, and promoted greater consideration of freight movement in short- and long-range plans.

*Oregon Freight Advisory Committee*. The mission of the Oregon Freight Advisory Committee (OFAC) is to advise the Oregon Department of Transportation (ODOT), Oregon Transportation Commission (OTC), and Oregon legislature on priorities, issues, freight mobility projects and funding needs that affect freight mobility, and to advocate the importance of a sound freight transportation system for the economic vitality of Oregon. The OFAC bylaws state that it should, among other activities:

- Serve as a forum for discussion, an opportunity for joint action, and a source of knowledge and advice for state transportation decisions affecting freight mobility.
- Promote the cross-sharing of information between private and public sectors on freight issues.
- Advocate the importance of freight mobility to the economic well-being of the state of Oregon and the region.
- Champion a sound multimodal freight and goods delivery network.
- Communicate and coordinate regional priorities with other organizations, including ODOT regions, area commissions on transportation, MPOs, regional partnerships, regional investment boards, ODOT advisory committees, economic revitalization teams, and the like.
- Inform and advise the OTC and ODOT director on policy, issues, freight mobility projects, and funding requirements that affect freight mobility.

*Washington State Freight Mobility Strategic Investment Board (FMSIB)*. One of the more institutionalized structures for including freight representatives in transportation investment decision making is found in the Washington State FMSIB. In line with its mission to create a comprehensive and coordinated state program to facilitate freight movement between and among local, national, and international markets, FMSIB has provided funding for projects and technical assistance for project sponsors and freight advocates. The board also has included in its mission statement a goal of lessening the impact of freight mobility on communities.

These examples of institutional structures to provide freight sector input into transportation planning simply illustrate the different ways that such involvement can occur. The exact form for a particular study will depend on the desired role for such participation, and the degree to which freight participants will find the effort valuable.

## B. Goals, Objectives, and Performance Measures

As in other planning processes, freight planning studies usually start with the identification of goals, objectives, and performance measures.

### *1. Goals and Objectives*

Some examples of goals and objectives for freight studies include:

**Atlanta, Georgia [ARC 2008]**

**Goals**

- Create a level playing field for freight in the regional planning process.
- Address the differing regional and corridor needs of freight movement and activities.
- Minimize the cost and improve the reliability of goods movement within the region.
- Improve goods movement in terms of ease, reliability, and transportation system-related cost.

**Objectives**

- Improve the movement of goods in the region by encouraging expedient and cooperative multimodal shipment of goods.
- Improve the physical characteristics of the transportation system for freight-related transportation between shipping and receiving points.
- Understand and address issues of concern to the freight community.

**Melbourne (Australia) [Melbourne, 2012a and 2012b]**

- Melbourne will have innovative and efficient freight and logistics infrastructure, optimizing the flow of goods locally and globally. Melbourne's freight system will strengthen the municipality's economy. It will be environmentally sustainable, and freight traffic will be designed and managed to enhance the municipality's livability.
- The major freight task associated with the Port of Melbourne is enabled by efficient road and rail infrastructure.

**New York City [New York Metropolitan Transportation Council, 2015]**

- Improve transportation of freight by removing burdensome government regulations and restrictions.
- Improve the physical infrastructure of the transportation system for freight-related transport between shipping and receiving points.
- Improve the reliability of overall movement of freight in the region by encouraging multimodal shipments.
- Improve the reliability and overall movement of freight in the region by expanding alternatives for trucks.

**San Diego [SANDAG, 2014]**

- Increase economic growth and prosperity that supports communities and businesses.
- Reduce environmental and community impacts from goods movement operations to create healthy communities and a clean environment, and improve quality of life for those communities most affected by goods movement.
- Provide safe, reliable, efficient, and well-maintained goods movement facilities.
- Promote innovative technology strategies to improve the efficiency of the goods movement system.
- Preserve and strengthen an integrated and connected, multimodal goods movement system that supports freight mobility and access, and is coordinated with passenger transportation systems and local land-use decisions.

**Stockholm, Sweden [2015]**

- Enable more reliable delivery times.
- Facilitate commercial freight vehicles.
- Promote the use of clean vehicles.
- Advance the freight delivery partnership between the city and other stakeholders.

**Vermont Agency of Transportation [2015]**

- Establish a demographic and economic profile of the state that identifies major and emerging industries and recognizes trends and opportunities in trade between Vermont and domestic and international markets.
- Provide an up-to-date assessment of the condition of the state's freight infrastructure and the impacts of current and future freight traffic.
- Assemble, through analyses and stakeholder involvement, a comprehensive list of infrastructure, operational, institutional, and regulatory needs.
- Develop packages of programs, policies, and projects that address Vermont's freight needs and position the state's economy to be competitive today and in the future.

### *2. Performance Measures*

As in other modern transportation planning processes, performance measures are used to monitor the performance of the transportation system with respect to freight movement. The value of performance measures to the freight transportation planning process was best described in a freight planning effort for Alameda County, California:

- *Linking Strategies to Vision and Goals*. Performance measures can be developed and applied to help link plan strategies to the vision and goals of the plan. Linking performance measures to the Vision and Goals is central to developing a performance-based project evaluation process.
- *Needs Assessment and Strategy Development*. Performance measures can be applied to assess condition, performance, and use of the transportation system. They also help identify system gaps where additional projects, programs, or policies may be needed.
- *Project Evaluation and Prioritization*. Performance measures can provide information needed to know when and where to invest in projects and programs that provide the greatest benefits. Performance measures can help determine which projects, programs, and policies should be included in high-priority strategies and can also help in the analysis of tradeoffs and/or synergies between different projects, programs, and policies.
- *Managing Performance*. Applying performance measures can improve the management and delivery of programs, projects, and services. The right performance measures can highlight the technical, administrative, and financial issues critical to governing the fundamentals of any program or project.

- *Communicating Results*. Performance measures help communicate the value of public investments in transportation and provide a concrete way for stakeholders to see an agency's commitment to improving the transportation system and help build support for transportation investments.
- *Strengthening Accountability*. Performance measures promote accountability with respect to the use of taxpayer resources and reveal whether transportation investments are providing the expected performance or demonstrate the need for improvements. [Cambridge Systematics, 2014a]

As noted in other chapters, the U.S. federal government is responsible for identifying national categories of performance measures, with the state departments of transportation (state DOTs) and MPOs expanding the list. Freight is one of the areas where performance measures are to be identified. As an example of state-level performance measures, the following list comes from the Washington State DOT. [WSDOT, 2014] Performance measurement occurs in what the DOT is calling Freight Economic Corridors, which handle the most important freight flows in the state.

**Truck Freight Performance Measures**

*Reducing*:

1. Truck travel time—Annual hours of delay, defined as travel time above the congestion threshold in units of vehicle hours for commercial vehicles on the Interstate Highway System. To evaluate project proposals, WSDOT uses regional travel demand models to estimate the reduction or change in truck travel time.
2. Direct truck operating cost—Using the value of time collected from national truck carrier surveys, the following formula is used to determine direct cost: *change in commercial vehicle hours traveled x truck operating cost per hour = change in direct truck operating cost*.
3. Truck engine emissions—The U.S. Environmental Protection Agency's (EPA's) Motor Vehicle Emission Simulator (MOVES) modeling system estimates emissions for mobile sources covering a broad range of pollutants and allows multiple scale analysis. WSDOT uses regional factors derived from MOVES for the analysis.

*Improving*:

1. Economic output—Defined as employment, and regional and state economic output. WSDOT developed a methodology to account for the economic output of highway projects with truck freight benefits.
2. Network resiliency—Defined as the ability to reduce closures of the state's designated Truck Freight Economic Corridors that are due to severe weather or natural disasters and lasting 24 hours or more.
3. Reliability—Spot speed data collected as part of the DOT's performance monitoring program. The formula for the 80th percentile reliability index is:

$$Freight\ RI_{80} = \frac{80th\ Percentile\ Travel\ Time}{Agency\ Travel\ Time}$$

**Waterway Performance Measures.** Performance goals for the state's coastal deep-draft and shallow harbors, waterways, and the Columbia-Snake River waterway include improving the state of good repair by:

- Maintaining the federally-authorized navigation channel depths.
- Blocking the spread of invasive species.

**Potential Freight Rail Performance Measures.** The state's Rail Plan recommends that WSDOT "should partner with other state agencies, stakeholders, and shippers to identify key performance measures that will help to inform the condition of the system to users and provide guidance on any public funding for infrastructure improvements. WSDOT should look at planning goals and consider important industries in the state when identifying the measures." Data availability will also be key.

Examples of potential performance measures:

- Benchmark container freight rates to Chicago from Canada, Los Angeles/Long Beach, and the Pacific Northwest.
- Monitor train on-time performance on key corridors.

**Potential Air Cargo Performance Measures.** A potential performance measure for Washington's air cargo facilities includes improving airport ground access by coordinating with airports and modal planners to identify needed ground access improvements to enhance truck access.

Another state example is shown in Table 22-5 from Florida.

An example of freight performance measures from an MPO is shown in Table 22-6. This example comes from Savannah, Georgia and reflects the region having one of the nation's fastest growing seaports (and thus the emphasis on combination trucks).

**Table 22-5. Freight Performance Measures, Florida DOT**

| Mode | Performance Measure | Mobility | Reporting Period |
|---|---|---|---|
| Highway | Combination truck miles traveled | Quantity | Daily |
| | Truck miles traveled | Quantity | Daily |
| | Travel time reliability | Quality | Peak Period |
| | Combination truck hours of delay | Quality | Peak Period |
| | Combination truck average travel speed | Quality | Daily |
| | % miles severely congested | Quality | Peak Hour |
| | Vehicles per lane mile | Utilization | Peak Hour |
| Aviation | Tonnage | Quantity | Yearly |
| Rail | Tonnage | Quantity | Yearly |
| Seaport | Tonnage | Quantity | Yearly |
| | Twenty-foot container equivalent units (TEUs) | Quantity | Yearly |

Source: Florida DOT, 2016

**Table 22-6. Example Freight Performance Measures, Savannah, Georgia**

| Mode | Example Freight Performance Measures | Parameters |
|---|---|---|
| Highway | Combination truck miles travelled | Determined using combination truck traffic volume and segment length. Combination truck is defined as FHWA Classification 8-13. |
| | Truck miles traveled | Determined using truck traffic volume and segment length. |
| | Travel time reliability | Freight travel time reliability is defined as the percentage of travel greater than 45 mph on freeways. |
| | Combination truck average travel speed | The calculation of combination truck average travel speed is identical to the methodology for (passenger) vehicle's average travel speed, except that combination trucks are assumed to have a lower free flow speed. The free flow truck speed is assumed to be equal to the speed limit. |
| | Vehicles per lane mile | Vehicles per lane mile (freight) is calculated as the summation of each roadway segment's peak hour vehicle miles traveled divided by the number of lane miles. |
| Aviation | Tonnage | All air cargo landed at public airports. |
| Rail | Tonnage | Tons of freight carried by rail mode originated or terminated for a specific area. |
| Seaport | Tonnage | International and domestic waterborne tons of cargo handled at both public and private terminals in port areas for a specific area. |
| | Truck equivalent units | Includes international and domestic waterborne cargo handled at both public and private terminals in port areas for a specific area. |

Source: CDM Smith, Inc., 2014

| Table 22-7. Freight Performance Measures, Portland, Oregon | |
|---|---|
| **Performance Measure** | **Description** |
| Hours of truck delay in the p.m. peak and mid-day | Tracks delay as a result of congested roadways. The current baseline data compares hours of truck delay for the entire City street system with regional delay. Enhancements to current measures include truck delay at key intersections and along freight corridors, and distinguishing between causes of congestion by reoccurring vs. non-reoccurring events. Intersections and truck streets should be selected based on their direct accessibility to freight terminals and transfer facilities. |
| Travel time in Intelligent Transportation System corridors for average p.m. peak, a.m. peak, and off-peak | Evaluates the travel time performance in corridors using ITS technology to manage system operations. Expand the current selection of corridors to include those critical for freight movement including Rivergate, Airport Way, Columbia Blvd, US 30, and interstate freeways in Portland. Track travel time for truck trips in addition to auto trips, as is current practice. |
| Assessment of unmet pavement need | Tracks success in reducing pavement maintenance backlog. Assess and report on pavement condition in Freight Districts and along major freight corridors. |
| Employee participation in Transportation Management Associations (TMA) | Tracks progress in expanding the use of and participation in TMA programs to encourage use of alternatives to the single-occupancy vehicle for work commute trips. |
| Annual truck collisions/million vehicle miles of travel | Measures the number of reported collisions involving trucks and other modes, including rail, as reported for all City locations. |
| Elimination of weight-restricted bridges on truck streets | Tracks progress in rehabilitating or replacing weight-restricted bridges. |
| Assessment of truck complaint resolution | Evaluates the number of freight-related complaints received by PDOT and status of resolution. |

Source: City of Portland, 2006

An example from a city comes from Portland, Oregon, shown in Table 22-7. Note the performance measures range from operational characteristics (hours of delay) to infrastructure condition (pavement condition) to public complaints.

## C. System Designation

One of the important initial steps in freight-related transportation planning is identifying the facilities, services, and/or market areas that serve freight movements. This usually entails designating a specific freight network (for example, truck routes, major railroads, or air cargo airports) or those portions of the transportation network used by substantial numbers of freight movements (for example, major roads with large volumes of trucks). In addition, this system designation can also identify locations where freight movements intersect with passenger movements (such as at railroad/highway crossings), creating the potential for crashes.

State DOTs and MPOs have used a variety of strategies for identifying a freight system. For example, the Washington State FMSIB identifies a freight corridor as:

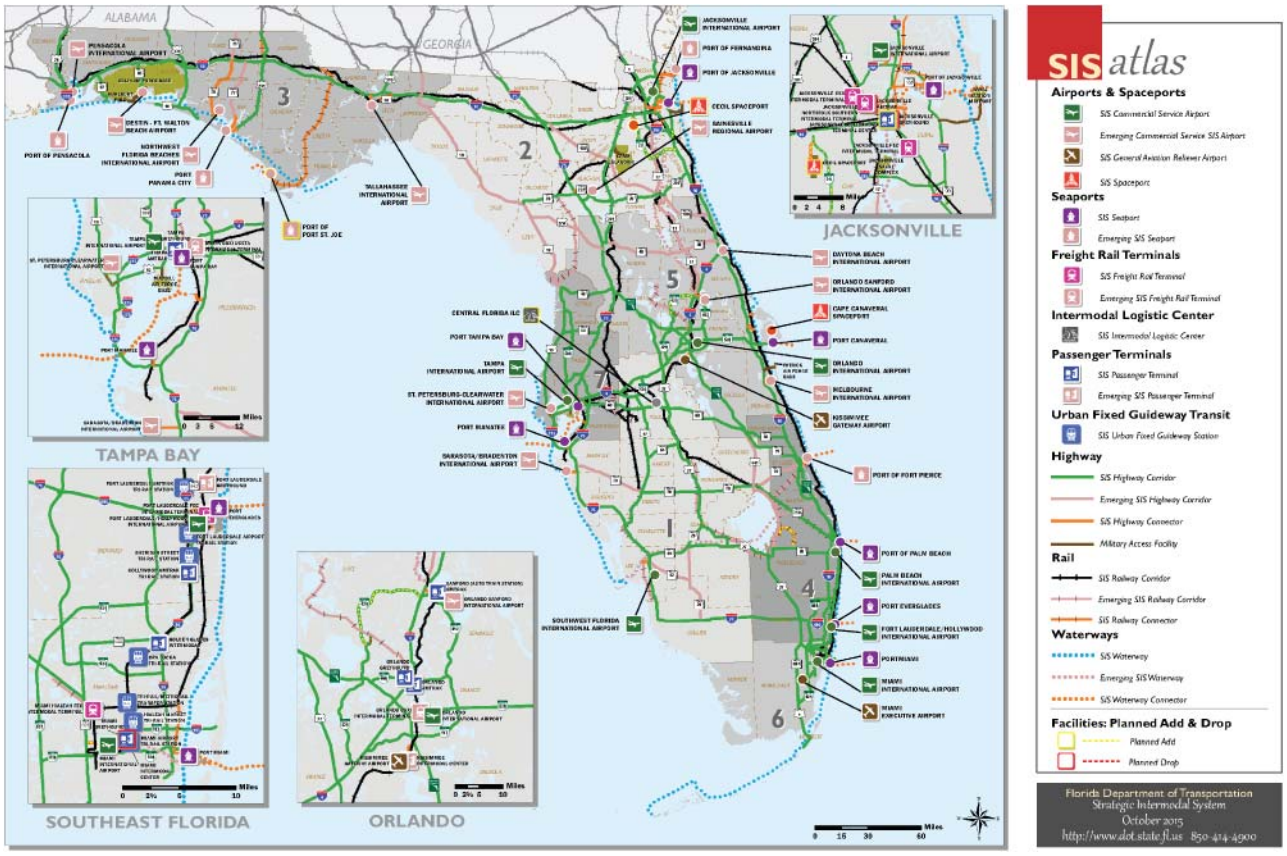
"A transportation corridor of great economic importance within an integrated freight system that:

- Serves international and domestic interstate and intrastate trade;
- Enhances the state's competitive position through regional and global gateways;
- Carries freight tonnages of at least:
  - Four million gross tons annually on state highways, city streets, and county roads;
  - Five million gross tons annually on railroads; or
  - For facilities to be built in the future, new links to strategic corridors that enhance freight movement may qualify, even though no tonnage data exists." [State of Washington, 2008]

The Virginia DOT identifies transportation corridors of statewide significance for both passenger and freight movement. The criteria for the selection of these corridors include those corridors that:

- Involve multiple modes (that is, highway, rail, interregional transit, airport, port) or are a freight corridor and extend beyond an individual region.
- Connect regions/states/major activity centers.
- Provide a high level/volume of transport, including:
  - Class I rail.
  - Commercial and/or reliever airports.
  - Interregional public transportation and stations.
  - Interstate highways.
- Provide a unique statewide function and/or addresses statewide goals:
  - Evacuation route or critical redundancy.
  - Security (military access, STRAHNET, STRACNET).
  - Tourism.
  - Truck route.
  - State bicycle route or interregional trail.
  - Economic development.

**Figure 22-4. Florida's Strategic Intermodal System**



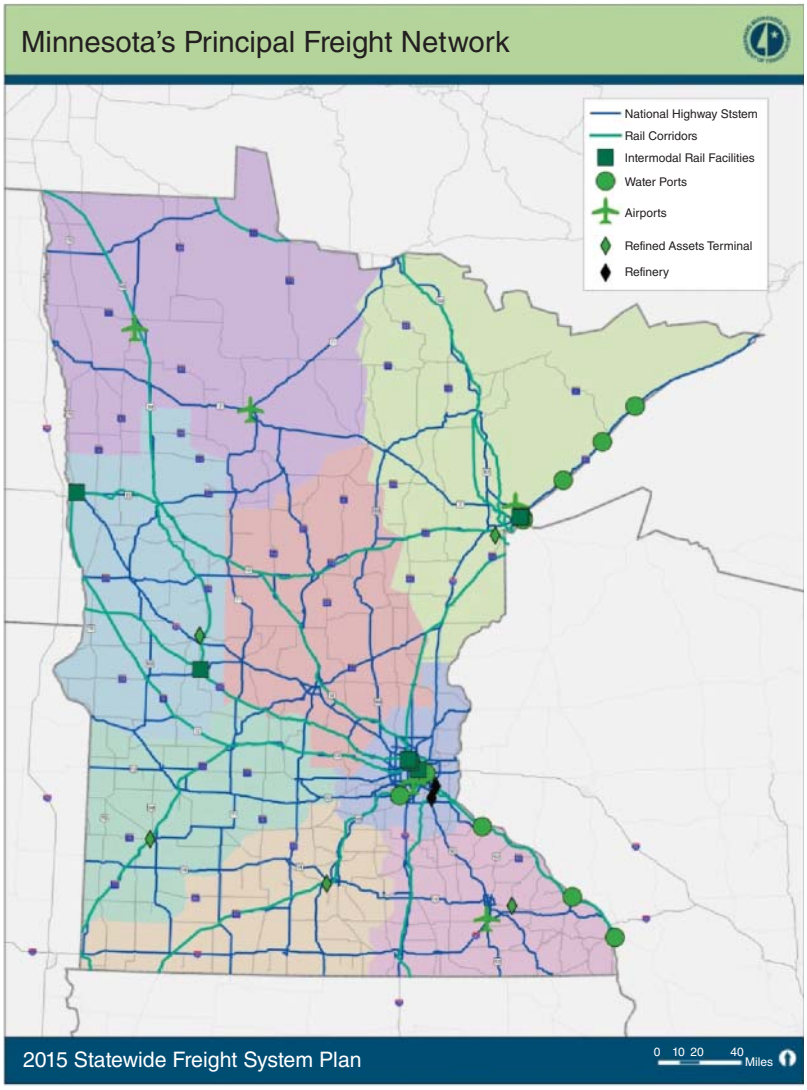
Source: Florida DOT, 2014a

One of the most extensive freight network designations comes from Florida where the state has identified a Strategic Intermodal System (SIS). This network includes all facilities of a certain threshold and significance enabling freight movement in the state. The following list shows the freight-oriented facilities that are part of this network (the intermodal network includes passenger intermodal facilities as well). [Florida DOT, 2014a, 2014b] Figure 22-4 shows the SIS network in Florida.

- Commercial service airports
- General aviation reliever airports
- Spaceports
- Seaports
- Freight terminals
- Intermodal logistics centers
- Freight rail corridors
- Waterway corridors
- Highway corridors
- Intermodal connectors

Figure 22-5 illustrates a type of truck route designation found in most jurisdictions. In this case, the truck network is viewed as connecting the major economic centers in the state of Minnesota. In many cases a truck route network is simply defined as those roads having the highest volume of trucks.

**Figure 22-5. Designated Freight Network in Minnesota**



Source: *Statewide Freight Plan*. St. Paul, MN: Minnesota Department of Transportation, 2005.

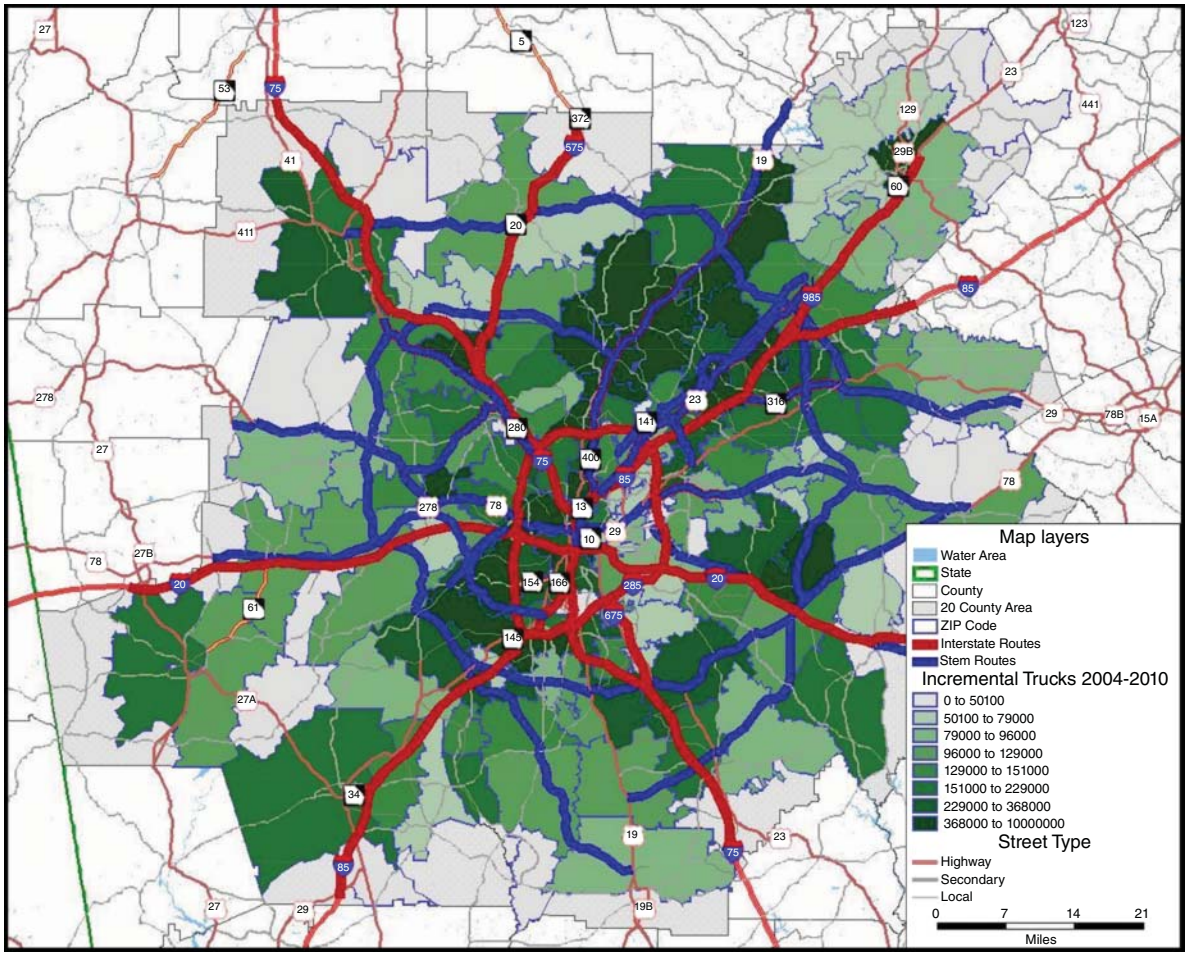
Figure 22-6 presents a slightly different representation of truck routes from Atlanta, Georgia. It shows the major highways serving truck movements in and through the metropolitan area. It also shows those areas in the region expecting to see large increases in trucks originating from their area during the period from 2004 to 2010. Not surprisingly, many of these areas are adjacent to the designated truck network.

Although major planning studies begin with some sense of the major freight systems and networks in their study area, these systems are often refined as the planning study progresses. Many times the designated networks are outdated or major new areas of growth have occurred that lead to an expansion of existing networks.

## D. Data Collection and Analysis

As with most types of planning, freight studies depend a great deal on the collection and analysis of data. One of the challenges with data collection for freight studies is that much of the data needed to understand freight flows is often proprietary and held by private companies. Not surprisingly, these companies are not anxious to put data

**Figure 22-6. Priority Freight Road Network and Zones of High Future Truck Volume, Atlanta, Georgia**



Source: ARC, 2008

and information on their services and production characteristics into the public domain. Therefore, transportation planners often have to rely on existing databases or must collect data through a variety of means. Such data can relate to statistics on inbound and outbound freight flows and commodity types as well as survey information from shippers, carriers, and other handlers of freight. Tables 22-8 to 22-10 and Figures 22-7 and 22-8 show the types of data typically used in freight planning. Table 22-11 shows some of the data sources used in the San Francisco Bay area freight study to "fine tune" estimates for commodity flows.

Several different types of trip movement are of particular interest to transportation planners. New applications of global positioning systems (GPS) and geographic information systems (GIS) provide planners with important information on truck flow patterns. [Zmud et al., 2014]

### *1. External-Internal Movements*

External-internal freight movements, which have one end inside and the other end outside of a study area, are primarily intercity movements. They represent a study area's interaction with other nearby areas as well as those located far away. In some cases, external-internal freight movements include international trade. These freight movements are related to the economic base of an area and usually involve several modes of transportation, such as truck, rail, air, water, and pipeline. Furthermore, external-internal movements usually involve different modal freight terminals located in a study area.

For planning studies related to these movements, commodity-flow data are useful. For studies involving external-internal movements, the area's MPO should work closely with other agencies, such as the state DOT, chamber of commerce, and in some cases airport and seaport authorities.

### *2. Through Movements*

Through (external-external) movements have both trip ends located outside the study area. Although these trips do not affect the local street network (except for those roads serving truck service areas), they can sometimes cause serious problems. For example, heavy volumes of large trucks passing through an urban area can contribute to traffic congestion as well as environmental impacts. Rail movements through an area can cause delay and safety problems at rail-highway grade crossings.

In many cases, solutions for freight-movement issues include capital-intensive actions, such as bypass facilities for large trucks and grade separation of busy rail tracks. Often, studies covering a large area beyond the urban area may be needed to identify other types of solutions, such as shifting freight to other modes. For problems relating to through movements, a coordinated effort of local and state agencies is needed.

### *3. Internal Movements*

Internal (such as intra-urban) freight movements almost always occur by truck. The majority of these movements are for pick-up and delivery (PUD) of freight items using single-unit trucks and vans. However, large combination trucks also move freight between terminals and hubs located inside an urban area. Internal freight movements have a hierarchical pattern and require different sizes of trucks. For example:

- PUD movements between major activity centers such as an airport and a hub terminal of a freight company (such as the United Parcel Service) often use large combination trucks.

- PUD movements of containers from one rail terminal to another are known as rubber-tired interchanges and are common in certain large urban areas such as Chicago and Memphis, which are served by multiple rail services.
- PUD movements between warehouses and distribution centers on one end and stores and offices at the other end may use medium-sized trucks.
- PUD movements between a break-bulk truck terminal at one end and offices, homes, and stores at the other end usually use small trucks and vans.

In addition to trucks and freight-carrying vans, freight planners should be aware of service vehicles/automobiles and small vans used by plumbers, electricians, office equipment maintenance personnel, and others providing similar services. These vehicles often have commercial license tags, but do not carry large amounts of freight. An important question for transportation planners is whether these vehicles should be given the same privileges as trucks in using certain special areas such as curbside loading zones.

Although planners and traffic engineers may not need to analyze internal freight movements by commodity flow, they should be aware of the variety of freight items carried by trucks inside an urban area. These include construction materials, food products, consumer goods (such as television sets and furniture), petroleum, small packages, and mail.

**Table 22-10. Data on Existing and Future Freight Movements in San Francisco**

| County/Region | 2012 Tons (1,000s) | 2040 Tons (1,000s) | CAGR* (2012–40) Tons | 2012 Value ($ millions) | 2040 Value ($ millions) | CAGR* (2012–40) Value |
|---|---|---|---|---|---|---|
| Entire Bay Area | 454,246 | 728,767 | 1.7% | 643,836 | 1,484,944 | 3.0% |
| Alameda | 143,863 | 232,239 | 1.7 | 234,667 | 487,577 | 2.7 |
| Contra Costa | 148,901 | 226,063 | 1.5 | 105,306 | 206,682 | 2.4 |

Much of the data described can be collected locally. However, most freight studies rely on data collected and tabulated nationally. A useful source of national freight data is found in "Data Sources Related to Freight Transportation," http://www.ops.fhwa.dot.gov/freight/freight_analysis/data_sources/index.htm. Many of these have a national scale of application, thus planning studies will most likely have to manipulate the data to make them relevant to the specific context and scale of the study.

Transportation planners must often collect original data for a planning study. In such cases there are a variety of techniques and tools that can be used (see chapter 2 on data collection for a more detailed discussion of relevant tools). A 2008 regional freight study in Atlanta illustrates the different types of data collection tools that might be employed in a freight study. [ARC, 2008] A survey of truck drivers was conducted at selected locations on the region's major freeway network. Hand-held computers were used to expedite data collection and a printed map was available to allow drivers to trace their route through the road network. The types of data collected included date and time stamp, weather conditions, vehicle type, trip origin and destination, number of stops in the study area, trip frequency, trip purpose, facilities visited, vehicle load status, routes avoided, and route flexibility. The sample was just less than 10 percent of the total volume passing by the survey sites.

Some findings from this data collection included:

- 95 percent of the survey sample was tractor trailers.
- 37 percent of the trucks had no origin or destination in the Atlanta region while 20 percent had both an origin and destination in the region.
- The most significant generators of the freight movements were warehousing and distribution (46 percent), manufacturing (17 percent), retail (11 percent), airport-related, including construction (10 percent), other construction (4 percent), and rail yards (4 percent).
- 30 percent of the trucks were empty.
- 85 percent of the drivers had some flexibility in their routes.
- 3 percent were carrying hazardous materials.

Another data collection effort obtained information from major carriers on what they perceive to be the major bottlenecks in the region's road network. The information collected included locations of poor merge areas, inadequate interchange capacity, narrow lanes, poor intersection geometric design, and lack of signing and pavement markings.

A business stakeholder survey was also conducted online with shippers and carriers that were major freight movers in the region. The information collected from the survey included business type; number of deliveries to warehouses, distribution centers, and businesses; day of week that deliveries occur; time of day for deliveries; number of inbound and outbound loads; the destinations of loads; and routes taken. The important findings from this survey included:

- Delivery location security was the biggest concern among the respondents. From a carrier perspective, focus on the security of the cargo and trailer assets was paramount. Poor lighting, access, and inadequate staff levels inhibit secure and safe freight transfers.
- Monday, Tuesday, and Wednesday were recorded as having the highest amount of shipping activity, which mirrored the carrier responses.
- The peak season for the shippers occurred during the spring months (March, April and May) and late fall to winter months (September through December). Retail and food shippers often have the same delivery schedules due to the various products offered. For example, clothing retailers see an upward shift in late summer due to back-to-school promotions followed by the holiday season.
- From a shipper perspective, the most important element that influenced outbound transportation was cost, followed by service performance.

Rail service was perceived as a cost-effective mode of transporting goods, but was rated only "fair" in on-time reliability. Security was noted as a potential liability because of the potential for cargo theft.

Targeted stakeholder interviews were held with 70 public- and private-sector officials. The selection of candidate stakeholders reflected industry type, county location, and size (including both small and large companies/agencies). An important requirement was to reach the sectors generating economic growth in the study area. Those interviewed provided information on both freight-related issues facing the region and suggestions on the types of strategies that should be adopted to deal with them.

A freight task force can also act as a primary means for stakeholder outreach. Task force members participated in a variety of activities including soliciting stakeholder candidates to participate in interviews, defining goals and objectives, reviewing the needs assessment findings, providing input into the project selection and prioritization process, and identifying "quick-start" projects.

An excellent source of freight-related data created by the FHWA is found at: http://www.ops.fhwa.dot.gov/freight/freight_analysis/data_sources/index.htm.

## E. Needs Analysis and Models

The freight analysis process can examine a range of questions concerning the movement of freight in a study area. Such analysis is applicable not only for large metropolitan areas, but also for small- to medium-sized communities. [Cambridge Systematics, Inc. et al. 2007] The most recent version of the Federal Highway Administration's (FHWA) *Quick Response Freight Manual* provides an overall framework noting the types of questions that can serve as the basis for a freight analysis:

- *Why* freight moves—the economic/industrial/commodity factors giving rise to the demand for freight.
- *Who* moves freight—the logistics factors determining the spatial relationships, shipment sizes, and frequencies influencing shippers and receivers, and other factors governing shipments.
- *What* moves freight—the modal factors determining the costs and service levels covered by the modes that carry freight—truck, rail, water, and air.
- *Where* freight moves—the vehicles/volumes factors concerned with the movement of freight on the various modal networks to various destinations.
- *How* freight moves—public policy that sets the rules and regulations under which freight must operate. [Beagan et al., 2007]

Identifying current and future system needs is an important step in freight planning. Determining current needs is usually undertaken by examining system performance data, such as congested areas, areas of slow freight operations, or locations with high truck or rail crash rates. Surveys and interviews of shippers and carriers are an important tool for identifying problems in the existing transportation system. Table 22-12 shows in general terms the types of needs and issues related to freight system performance in the San Francisco Bay area. [Cambridge Systematics, 2014b]

The more challenging task is to forecast future freight movements. Using the above questions from the *Quick Response Freight Manual,* the forecasting process must examine these topics from the perspective of future conditions and demands. For example, understanding why freight moves requires an examination of the changing future economic factors in a study area influencing the quantity of freight moved and the corresponding travel patterns. Table 22-13 shows the types of data necessary for model calibration and validation (see chapter 6 on demand estimation), and Table 22-14 shows typical costs for the data collection methods used to obtain such data.

Perhaps even more challenging, the analysis must consider future modal factors affecting the costs and service levels of different modal options. However, the uncertainty associated with this issue is large: What types of fuels and fuel costs are likely to exist in 20 years? What new vehicle or infrastructure technologies could provide increases in productivity in one mode versus another? These questions are almost impossible to answer with any level of certainty; thus, the analysis should employ sensitivity assessment and other means such as scenario analysis.

The *Quick Response Freight Manual* describes a range of models and analysis approaches that can be used to predict future freight growth, along with detailed descriptions of how these tools can be used. The following paragraphs, based on the manual, provide a shortened description of the most common tools.

| Table 22-12. Goods Movement System Needs and Issues by Functional Area, San Francisco Bay Area, California | |
|---|---|
| **Goods Movement System Needs and Issues by Functional Area Function** | **Needs and Issues** |
| **Global Gateways:**<br>Major maritime facilities and international airports that handle freight, as well as passenger cargo | • Port of Oakland land constraints, deficiencies in cargo handling equipment.<br>• Intensifying port competition.<br>• Marine terminal congestion and its associated impacts on drayage drivers and neighborhoods.<br>• Need for improved communication between truck drivers and marine terminal operators.<br>• Impacts and opportunities for heavy haul networks around ports.<br>• Expanding demand for bulk export facilities.<br>• Conflicts between industrial/warehouse space needs to support growth and impacts on neighborhoods.<br>• Changing mix of air cargo (less computer-related exports) and uncertain growth in domestic markets. |
| **Interregional and Intraregional Corridors:**<br>Primary highways and rail lines that serve to connect the megaregion to the rest of the state and to domestic markets beyond | • Congestion and delay on shared use freight corridors with passenger traffic, such as I-880 and I-580, and Capitol Corridor.<br>• Truck safety issues along freight corridors due to merging and weaving.<br>• Pavement and bridge condition issues along freight corridors.<br>• Rail bottlenecks, especially along Martinez Subdivision.<br>• Safety issues at rail-highway grade crossings.<br>• Increasing need for third party logistics space and local access to integrator (for example, Federal Express, UPS) hubs at OAK, Port of Oakland and connections to inter and intraregional corridors. |
| **Local Goods Movement System:**<br>Roads supporting local pickup and delivery, and last-mile connectors—roads that provide critical connections between major freight facilities (global gateways, domestic rail terminals, warehouse/industrial centers, and industrial parks), and the interregional and intraregional systems | • Public health impacts on neighborhoods with intense freight activities.<br>• Land use conflicts in traditional industrial corridors.<br>• Lack of truck parking/neighborhood parking encroachment.<br>• Conflicts between trucks and other street users (autos, pedestrians, bikes, transit) on collector routes and in commercial areas.<br>• Cut through traffic to avoid congestion on major corridors.<br>• Lack of truck route connectivity across city boundaries.<br>• Local road and street pavement damage.<br>• Problems with roadway and street design that impede truck deliveries. |

### *1. Growth Factors*

One of the most straightforward approaches to forecasting future freight movement is to examine trends and predict future volumes based on historical growth factors. Several growth-factor methods can be used.

*Straight Line or Linear Projections*. This method simply extrapolates past growth into the future by assuming the rate of growth as determined between two historical points continues into the future. For example, if freight flow occurs at a volume of $F_1$ at year 1 and at a volume of $F_2$ at year 2, the predicted freight flow at a future year 3 can be

|---|---|---|---|---|
| **Data Collection Method** | **Cost Description** | **Type** | **Average Cost** | **Comments** |
| Vehicle Classification Counts | Unit cost per site for conducting 24-hour vehicle classification counts | Manual counting | $650 | To reduce costs availability of count data from existing counting programs should be considered. |
| | | Video counting | $500 | |
| | | Automated counting | N/A | |
| Roadside Intercept Surveys | Unit cost per site for conducting 24-hour intercept survey | Roadside interviews | $5,000 | Actual costs of data collection can vary significantly depending on characteristics of the site, the quantity and quality of data collected, and the firm collecting the data. |
| Establishment Surveys | Cost per survey | Mail-out/mail-back survey | $100 (10% response) | N/A |
| | | Telephone survey | $250 (20% response) | |
| | | Combined mail and telephone survey | Expected to be higher than telephone surveys | |
| Travel Diary Surveys | Cost per survey | Not assisted by GPS | N/A | Cost major issue in GPS-assisted surveys because of equipment costs and installation costs on trucks. |
| | | GPS assisted | N/A | |

Source: Beagan et al., 2007

mathematically denoted as:

$$F_3 = F_2 + \frac{(F_2 - F_1)}{(T_2 - T_1)}(T_3 - T_2)$$

where:

$F_i$ = Freight flows in year $i$
$T_i$ = Year $i$

*Compound Growth*. Often, growth in traffic volumes is expressed as a certain percent per year. Given the base of growth changes from one year to the next (that is, next year's growth uses this year's growth plus the percent change as the basis for next year's change), the growth in volume is not linear. This is called the compound growth rate. Analysts can use the simple interest equation:

$$F_2 = F_1 (1 + i)^n$$

where $F_2$ stands for a future dollar value, $F_1$ is a present value, $i$ is the interest rate and $n$ is the number of time periods, to calculate the value of $i$, which is the compound growth rate. In this case, $i$ or the compound growth rate, equals:

$$i = \left[\left(\frac{F_2}{F_1}\right)^{1/n}\right] - 1$$

The future freight volumes ($F_3$) would be estimated where the F values are the same as before and the $T_3 - T_2$ is the number of years in the future the freight volume is to be calculated.

$$F_3 = F_2 (1 + i)^{(T_3 - T_2)}$$

Planning studies often use the growth in economic or commodity demand to determine the future freight volumes. In this case, the compound growth factor approach is used to determine the future economic values and then a modal factor is used to estimate how many freight movements this would imply. The trip generation factor (the number of

trips generated per unit of economic activity) is usually based on historical records. As noted in the *Quick Response Freight Manual*, "For most commodity groups, the relationship between value of output (measured in constant dollars) and volume shipped (measured in pounds, tons, cubic feet and such) may change over time. These changes may be due to a change in the mix of commodities being produced within a given commodity group (for example, more aluminum and less steel) or a change in the average real value per ton of major products within the group. These changes may result in a changing value per ton in either direction . . . .when there are one or two commodity groups of particular interest, some consideration should be given, at least in an informal way, to determine how real value per ton for these groups has been changing and how it is likely to change during the forecast period."

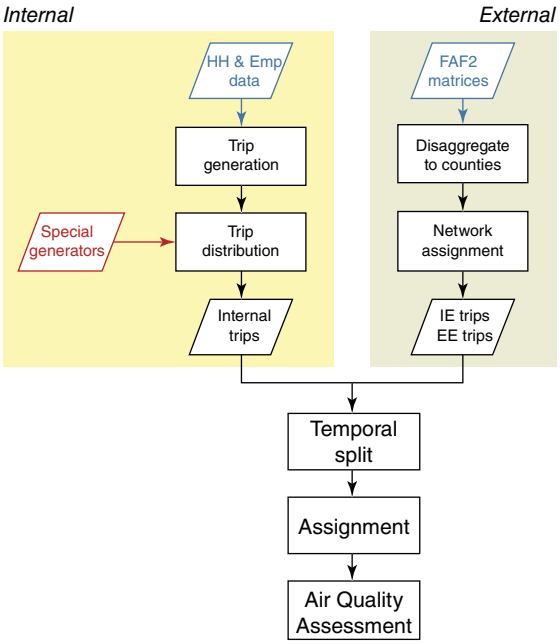
As previously noted, one of the important strategies for incorporating uncertainty into the analysis is to conduct a sensitivity assessment. This is done by changing some of the key assumptions in the analysis, such as the compound growth rate, to see if the results or conclusions change in any significant way. According to the manual, key assumptions incorporated into the forecasting process, and thus candidates for sensitivity assessment, include:

- Economic growth—both nationally and locally.
- Growth in the economic sectors generating significant volumes of freight handled by the facility.
- Transport requirements of these sectors, which may be affected by increased imports or exports or by changes in production processes.
- Modal choice, which may be affected by changing transport requirements or changing cost and service characteristics of competing modes.
- Facility usage per unit of freight volume, which may be affected by changes in shipment size or container size.
- The availability and competitiveness of alternative facilities.
- Value per ton of output.
- Output per employee (if employment is used as an indicator variable).

### *2. Four-Step Model*

For those states or metropolitan areas having a four-step demand model, a more sophisticated analysis of freight flows can often occur. See chapter 6 on urban travel demand modeling for more detail on this approach to modeling, as well as [Beagan et al., 2007; Bassok et al., 2013; and Southworth, 2010]. As shown in Figure 22-9, this modeling approach consists of four major steps—trip generation, trip distribution, mode split, and network assignment. Each step uses mathematical relationships to determine an output, for example, the number of tons for trip generation. Some of these relationships can be determined using historical data from the study area, while in others national default values can be used.

**Figure 22-9. Four-Step Freight Model for Truck Flows, San Diego**



Source: SANDAG, 2008

*Trip Generation*. Trip generation models are based on a set of annual or daily trip generation rates or equations by commodity by zone. Based on the zonal activity factors of either population or employment, these rates are then used to determine the annual or daily commodity flows originating or terminating in the geographic zones. Given most metropolitan areas have a system of traffic analysis zones (TAZs), these zones usually serve as the reference for trip generation in metropolitan areas. For states and multistate studies, counties often serve as the zonal unit. The key differences between trip generation for passenger demand modeling and for freight transportation are shown in Table 22-15.

It is important to classify trucks by type of truck and/or trip purpose/sector. Classification schemes include the FHWA vehicle classification system (see chapter 2), gross vehicle weight ratings, type of goods carried, number of

| Table 22-15. Key Differences in Trip Generation between Passenger and Freight Modeling | | |
|---|---|---|
| **Characteristic** | **Passenger** | **Freight** |
| Demand generated. | Passenger trips. | Tons produced or consumed at a given location. |
| Traffic generated. | Car trips, bus trips, etc. | Truck trips, van trips, etc. |
| Influencing variables. | Income, land use, family structure, car ownership, activity concentration. | Economic activity performed, line of business, business size, land use. |
| Correspondence between demand and traffic generated. | Very tight, almost one to one in areas where transit share is low. | Very loose due to: (1) the role played by the shipment size that leads to a situation where large businesses, while generating large amount of cargo, produce proportionally less traffic because of their large shipment sizes; and (2) the indivisibility of freight trips that translates into small businesses generating proportionally large freight trip generation in relation to the demand generated. |

Source: Holguin Veras et al., 2012

tires/axles, and body type. For example, a 2007 regional model update in the Seattle, Washington region defined three types of trucks—light trucks (four or more tires, two axles and less than 16,000 pounds), medium trucks (single unit, six or more tires, two to four axles and 16,000 to 52,000 pounds), and heavy trucks (double or triple unit, combinations, five or more axles and more than 52,000 pounds). [Puget Sound Regional Council, 2007] In addition, the regional model used employment in the following industries as factors in estimating the number of truck trips—agriculture/forestry/fishing, mining, construction, manufacturing (products), manufacturing (equipment), transportation/ communication/utilities, wholesale, retail trade, finance/insurance/real estate (FIRES), and education/government.

Trip generation includes both the number of trips produced in and attracted to each zone. Equations (usually linear regression models) are developed for both types of trips either by each commodity group or truck type. In addition to the truck trips generated in the TAZs, it is often important to segregate freight trip-generating activity associated with special trip generators such as airports, ports, or major distribution centers.

Holguin Veras et al. [2012] provides an excellent reference for freight trip generation.

*Trip Distribution*. This step in the modeling process uses the information produced in trip generation to determine the origin-destination pairs of freight trips in the study area. The important variables for distributing the trips are the productions and attractions by zone, and the impedance (usually some measure of travel time) between each zonal pair. A popular approach to estimating origin-destination flows is the use of a gravity model that approximates travel attraction by level of economic activity or "mass" occurring in each of two zones and is inversely proportional to the impedance between the two.

The key to a valid trip distribution approach is ensuring that the predicted trips match what is observed on the road network. For the gravity model, this is done by comparing the trip length distributions of the modeled trips to historical data and modifying the travel "friction factor" for different truck trips until the distributions closely match. The Seattle modeling exercise developed the following friction factor equations to accommodate different types of truck types and trip lengths:

- Light Trucks, Short Trips = {EXP(3.75 − 0.08 × "daily travel time"). max. 1}
- Medium Trucks, Short Trips = {EXP(4.75 − 0.05 × "daily travel time"). max. 1}
- Light Trucks, Long Trips = {EXP(2.1− 0.005 × "daily travel time"). max. 1}
- Medium Trucks, Long Trips = {EXP(4.2 − 0.003 × "daily travel time"). max. 1}
- Light Trucks, Kitsap Pen. = {EXP(4.0 − 0.05 × "daily travel time"). max. 1}
- Medium Trucks, Kitsap Pen. = {EXP(5.0 − 0.10 × "daily travel time"). max. 1}
- Heavy Trucks, All Trips = {EXP(4.0 − 0.10 × "daily travel time"). max. 1}

Travel demand models are also developed on a time-of-day basis; travel demand is thus usually estimated by different time periods.

*Mode Split*. This step identifies which mode of travel commodities and products will use between a specific origin and destination. This step is not needed in studies where the only feasible mode is truck. Where different modes are possible, the mode choice is often classified by average distance traveled, with the logic being that some modes (such as rail) might be preferable for longer distance trips than others. Some examples of mode split approaches from selected studies include the following: [Beagan et al., 2008]

*Indiana Commodity Transport Model*. This mode split model identified nine individual modes (such as private truck, for-hire truck, rail, and air) and eight multiple or combined modes (such as truck and air, truck and rail, inland water, and Great Lakes). In addition, each of the modes was categorized by length of trip, for example, less than 50 miles, 50 to 99 miles and up to "greater than 2,000 miles." Categories were calculated based on data from a base-year commodity flow survey and the probabilities for modal transport of commodities by distance. These probabilities were then used with future year trip tables to estimate the mode split during the timeframe for the study.

*Florida Intermodal Statewide Highway Freight Model*. This model estimates annual tons shipped by truck, bulk/ carload rail, container/intermodal rail, air, and water. A logit model (see chapter 4) was developed based on observed modal shares in a base year and is then used to predict future modal percentages (by tons). The determining factor in a logit mode split model is the utility function associated with each mode, where the utility function represents the travel costs associated with the mode. Thus, for example, the cost for truck travel was defined as $0.0575 per mile traveled; for rail, $12 +$0.025 per mile; and for intermodal, $26 + $0.028 per mile. In addition, a cost per hour of service was incorporated into the utility function. The model results estimated the number of tons split among the available modes of travel. Each tonnage amount was then converted to trips by using the historical data that had established this relationship.

*Cross Cascades Corridor Study*. This study was undertaken by the state of Washington to examine interregional passenger and freight travel patterns between Seattle and Spokane, Washington. The mode split component of the travel demand model included the following freight modes: air freight, rail freight, heavy truck freight and medium truck freight. The determination of the modal distribution of freight movements depended on the monetary values of time, distance and cost. Logit models were used to assign probabilities of freight choosing one mode versus another. Some of the characteristics associated with the freight cost functions are shown in Table 22-16.

*Network Assignment*. This step in the modeling process assigns trips to the freight networks. As noted earlier, one of the steps that must occur prior to this is to convert tonnage or other measures of trip volumes to trips. This is done using conversion factors based on historical relationships between average tons moved per trip. With respect to rail, air, and water assignments, in which the networks are less extensive than the road network, the assignment process follows a rules-based approach. This means that tonnage predicted to go by one of these modes does so subject to the supply constraints and operational characteristics of the service being provided. For truck assignments, in which trucks are using the road network (along with everyone else), the model determines the performance characteristics of the highway network by time of day, such as network path travel times, and then assigns truck trips based on least-cost routes. The more sophisticated models use a stochastic assignment process that takes into consideration some level of uncertainty on how trucks will be routed through the network.

A state freight plan will analyze all of the freight modes that are of state significance and thus very different analysis tools will likely be used. For example, the Georgia Statewide Freight and Logistics Plan analyzed nine different freight modes using a variety of methodologies, including: [Georgia DOT, 2015]

| | |
|---|---|
| Marine Port Projects | Recent reports |
| Rail Projects—Crescent Corridor | Previous analysis |
| Rail Projects—Other improvements | Top-down estimate using previous reports |
| Highway Projects—Add capacity | Georgia DOT statewide travel demand model |
| Highway Projects—Improve interstate Interchanges | "Off-model" analytical technique |
| Highway Projects—Urban "bypasses" | Georgia DOT statewide travel demand model |
| Highway Projects—Rural freight corridors | Georgia DOT statewide travel demand model |
| Highway Projects—Safety projects | "Off-model" analytical technique |
| Air Cargo Projects | Qualitative descriptions from discussions with airport staff |

| Table 22-16. Factors in Freight Cost Functions, Washington State | | | |
|---|---|---|---|
| **Mode** | **Terminal Cost** | **Distance Rate Range (including terminal cost)** | **Dollars/Ton-mile Assumed** |
| Light truck | $0 | $0.04–$0.10 / ton-mile | $0.10 |
| Medium truck | $20.50 | $1.25–$2.50/mile | $0.08 |
| Heavy truck | $25.63 | N.A. | $0.10 |
| Rail freight | $37.50 | $0.02–$0.04/ ton-mile $2.20–$2.73/mile | $0.03 |
| Air freight | $70.00 | $4.90–$7.50/ ton-mile | $3.00 |

## F. Evaluation and Prioritization of Freight Strategies

The needs analysis leads to a set of strategies or projects to improve a region's or state's transportation system. The range of feasible project types can be quite large. For example, the types of strategies that surfaced from the Atlanta regional freight planning study included: [ARC, 2008]

- Mitigate interchange bottlenecks.
- Maintain and enhance intermodal connectors.
- Add mainline rail capacity.
- Implement rail grade separations.
- Use intelligent transportation systems (ITS) technologies.
- Implement management and operations strategies—public-sector operational techniques to optimize freight travel (traffic signal timing, signage, and geometric design restrictions on weight or clearance) and private-sector operational techniques to optimize freight travel (off-peak operations, consolidated deliveries, and regional drop yards).
- Preserve lands for freight uses.
- Implement institutional changes to improve feasibility of freight projects of regional significance (public-private coordination and/or partnerships).
- Enhance freight network safety.
- Improve data and analytical methods.
- Promote regional approaches and leadership.
- Enhance public awareness of freight transportation.
- Expand highway infrastructure.

Notice these strategies range from the more traditional infrastructure-oriented road improvements to improving the MPO's freight data and analysis capability. Some of these actions might be very difficult to evaluate with any quantitative methodology; thus, it is not surprising a variety of approaches are used to evaluate freight strategies. Another example of the types of strategies that could be considered to meet freight-related needs is shown in Table 22-17 from the Metropolitan Transportation Commission (MTC) in the San Francisco Bay area.

Beagan et al. [2007], Rhodes et al. [2012], Bassok et al. [2013], Holguin-Veras et al. [2015], and Cambridge Systematics, Inc. [2015] are good references for the types of strategies and projects that can be used to improve freight system performance.

Evaluation consists of examining the relative merits of different freight strategies to determine which ones will produce the best benefits for the least cost. Figure 22-10 shows an evaluation framework for freight planning. [Cambridge Systematics et al., 2011] As can be seen, the major categories of impacts are expected changes in travel distance, travel time, and travel quality.

| Table 22-17. Summary of Needs and Strategies of the Bay Area Regional Goods Movement System, Metropolitan Transportation Commission, San Francisco Bay Area | | |
|---|---|---|
| **Types of Needs Identified** | **Description of Need** | **Key Potential Strategies to Address Need** |
| **Safety** | | |
| Highway | • Highest crash locations on I-880, I-580, I-80<br>• Crash rates highest near high volume interchanges | • Interchange improvements, mainline, auxiliary lanes, truck interchange bypasses, and geometric improvements<br>• ITS technology and traveler information, truck safety programs, improved signage for truck movements |
| Rail | • Potential hazards from increased movement of crude oil by rail to regional refineries and potential of crude by rail traversing region to Central Coast refineries | • Monitor and advocate in federal regulatory proceedings and state and federal legislation for increased rail tank car safety standards, hazardous materials transport operations safety procedures, and information to local first responders on hazardous materials transport through cities<br>• Consider policies to support the recommendations of the California Interagency Working Group that studied the crude by rail issue<br>• Coordinate regional efforts to work with railroads to ensure training and information exchange between railroads and first responders regarding hazardous spill emergency response |
| Local streets and roads | • Analysis from Alameda County suggests high levels of truck-involved crashes on local roads at freeway access locations.<br>• Potential safety hazards on high speed rural commuter routes that also provide access to areas of goods movement activity (for example, wineries and agricultural producers) | • Signalize freeway access and ensure signal timing considers acceleration/deceleration characteristics of trucks<br>• Turn lanes with adequate storage for trucks at freeway ramp access points |
| **Infrastructure Condition** | | |
| Highway | • Selective highway pavement and bridge conditions needs along north U.S. 101, east SR 4 | • Targeted bridge or pavement improvements<br>• Identify/establish programs to maintain roadways in a state of good repair |
| **Congestion, Mobility, and Travel-Time Delay** | | |
| Global Gateways | • Gate queues at Port of Oakland<br>• Truck delays at grade crossings at Port of Oakland<br>• Rail delays accessing Port of SF<br>• Limited bulk terminal capacity for growing demand (all ports)<br>• Congestion at OAK access roads | • FRATIS and ITS at Port of Oakland and access roads around OAK<br>• Projects to reduce queuing and crossing delays at Port of Oakland<br>• Expansion of bulk and cold storage terminal improvements (all ports)<br>• Rail lead (spur) improvements at Ports of Oakland and SF<br>• Longer-term expansion of intermodal terminal capacity |

Table 22-17. (*Continued*)

| Types of Needs Identified | Description of Need | Key Potential Strategies to Address Need |
|---|---|---|
| **Congestion, Mobility, and Travel-Time Delay** | | |
| Highway | • Significant delay and reliability issues on many truck corridors (I-880, I-80, US 101, SR4, I-580, I-680)<br>• Critical freight bottlenecks (I-80/I-680/SR12) | • Interchange improvements, mainline, auxiliary lanes, truck interchange bypasses, and geometric improvements.<br>• Improved signage for truck movements<br>• ITS based solutions coordinated with arterial systems.<br>• Long-term development of alternate modes (for example, short-haul rail) |
| Rail | • Growth in international intermodal traffic and bulk movements (along with potential growth in crude oil by rail shipments) straining Martinez, Oakland, Coast, Niles and Stockton Subdivisions<br>• Impacts on capacity on Martinez Subdivision created by switching of trains on the mainline.<br>• Future needs to expand domestic intermodal terminal capacity in Oakland to reduce truck traffic from Central Valley intermodal terminals. | • Capacity improvements on Martinez Subdivision (sidings and increased track in selected locations)<br>• Expanded capacity and coordinated strategy for Niles and Oakland Subdivisions to make better use as southern route to Port of Oakland<br>• Future expansion of intermodal terminals at Port of Oakland (OHIT Phase 2 expansion).<br>• Industrial rail spur program to improve industrial access (also promotes economic development in locations such as Contra Costa Northern Waterfront, North Bay agriculture production areas, industrial areas near Ports of San Francisco and Redwood City). |
| Local Streets and Roads | • Poor LOS on certain major and minor arterial truck routes | • Selective widening projects<br>• SMART corridors including arterials<br>• Signal timing and prioritization projects on truck routes |
| **Passenger System** | | |
| Global Gateways | • Potential truck conflicts with autos on Cesar Chavez accessing Port of SF<br>• Potential conflicts with bike and pedestrian trails on truck routes on access to marine terminals at Port of Oakland and Port of Richmond<br>• At-grade rail crossing delays for autos near Port of Richmond | • Improved access planning for autos in South Waterfront area of Port of SF<br>• Physical separations for bike and pedestrian routes at Port of Oakland<br>• At-grade crossing safety and grade separation program |
| Highway | • Truck traffic conflicts with passenger traffic | • Projects and programs to allow selective use of passenger only facilities. |
| Rail | • Expansion of Caltrain, ACE, and Capitol Corridor services will strain capacity on several lines<br>• Expansion of SMART commuter service limits growth of NWP shortline services. | • Expanded track and sidings to allow for freight and passenger separation wherever possible.<br>• Potential ROW acquisition or trenching through Emeryville on Martinez Subdivision<br>• Coordinated strategy to separate freight and passenger services on Oakland, Niles, and Coast Subdivisions<br>• Revisit operating window restrictions for freight on Caltrain Corridor in light of new FRA rulings |

(*continued*)

Table 22-17. (*Continued*)

| Types of Needs Identified | Description of Need | Key Potential Strategies to Address Need |
|---|---|---|
| **Passenger System** | | |
| Local Streets and Roads | • Arterial truck routes are often on high frequency bus routes<br>• Bike and pedestrian routes on certain truck routes | • Time of day managements to reduce conflicts<br>• Bike and pedestrian physical separations where feasible<br>• Multiple use delivery pullouts |
| **Multimodal Connectivity** | | |
| Global Gateways | • Grade crossing improvements<br>• North rail access to intermodal terminals<br>• Local circulation improvements | • Port of Oakland 7th St Grade separation project<br>• Local circulation improvements at Port of Oakland and OAK<br>• Port of Oakland rail access improvements |
| Highway | • Limited E-W connections to Central Valley and interior U.S. | • Projects to improve key corridors that provide alternatives to I-580, such as SR 12/SR37, SR4, and SR 152 |
| Local Streets and Roads | • Locations with poor connectivity between freeways and major freight hubs | • Advocate for state and federal programs to improve first/last-mile connectors<br>• Provide guidance for truck route planning<br>• New truck route designations with time of day regulation (where routes must pass through residential areas)<br>• Selective upgrading of routes for trucks where better connectivity between major local truck routes is needed |
| Rail | • Industrial rail access needs for industrial shippers on Northern Contra Costa Waterfront, North Bay, San Mateo County | • Industrial Rail Access Program, Short haul rail project |
| **Air Quality, Environment, and Community Impacts (Equity)** | | |
| • PM2.5 emissions from freight have been declining but reductions may plateau in the 2020–2025 timeframe | | • Incentives for engine retrofits to low and zero emission technology<br>• Zero emission vehicle technology demonstrations for trucks.<br>• Low emission rail terminal operations including incentives for conversion to low emission switcher locomotives |
| • Localized health effects of diesel emissions and rail noise/ emissions in major truck and rail corridors (for example, I-880, I-80, SR-4, US101) | | • Programs to target low/zero emission strategies (see above) to corridors with Communities of Concern<br>• Improvements to rail at-grade crossings (including selective separations), quiet zones.<br>• Coordination of truck route planning in industrial areas with restrictions and enforcement in adjacent residential areas. |
| • Vulnerability to sea level rise on major truck, rail, airport, and seaport infrastructure along Bay and other waterfront areas. | | • Adaptation strategies and improvements to diking systems to reduce potential flooding |

| Table 22-17. (*Continued*) | | |
|---|---|---|
| **Types of Needs Identified** | **Description of Need** | **Key Potential Strategies to Address Need** |
| **Land Use** | | |
| • Modal and land-use conflicts and coordination with passenger systems (for example, residential and commercial development in converting industrial corridors can encroach on active rail and truck corridors)<br>• Lack of truck parking and truck services in industrial corridors | | • Land use guidance program<br>• Incentives to preserve buffers around freight corridors incorporated in project plans<br>• Identify sites for overnight and short term truck parking and work with private sector providers to implement truck services in development of these sites<br>• Complete Streets guidance and incorporation in One Bay Area Grants for programs such as delivery windows, curb pullouts)<br>• Night delivery pilot programs |
| **Jobs Programs** | | |
| • Near-term truck driver shortages<br>• Near-term lack of logistics professionals<br>• Continued lack of job opportunities in communities close to freight hubs | | • Training and workforce development programs coordinated through community colleges<br>• Continued local hiring goals for communities close to freight hubs |

The types of costs and benefits associated with different freight strategies can vary widely. National Cooperative Freight Research Program (NCFRP) Report 12*, Framework and Tools for Estimating Benefits of Specific Freight Network Investments*, describes the types of costs and benefits typically considered in a freight study. [Cambridge Systematics et al., 2011] They include:

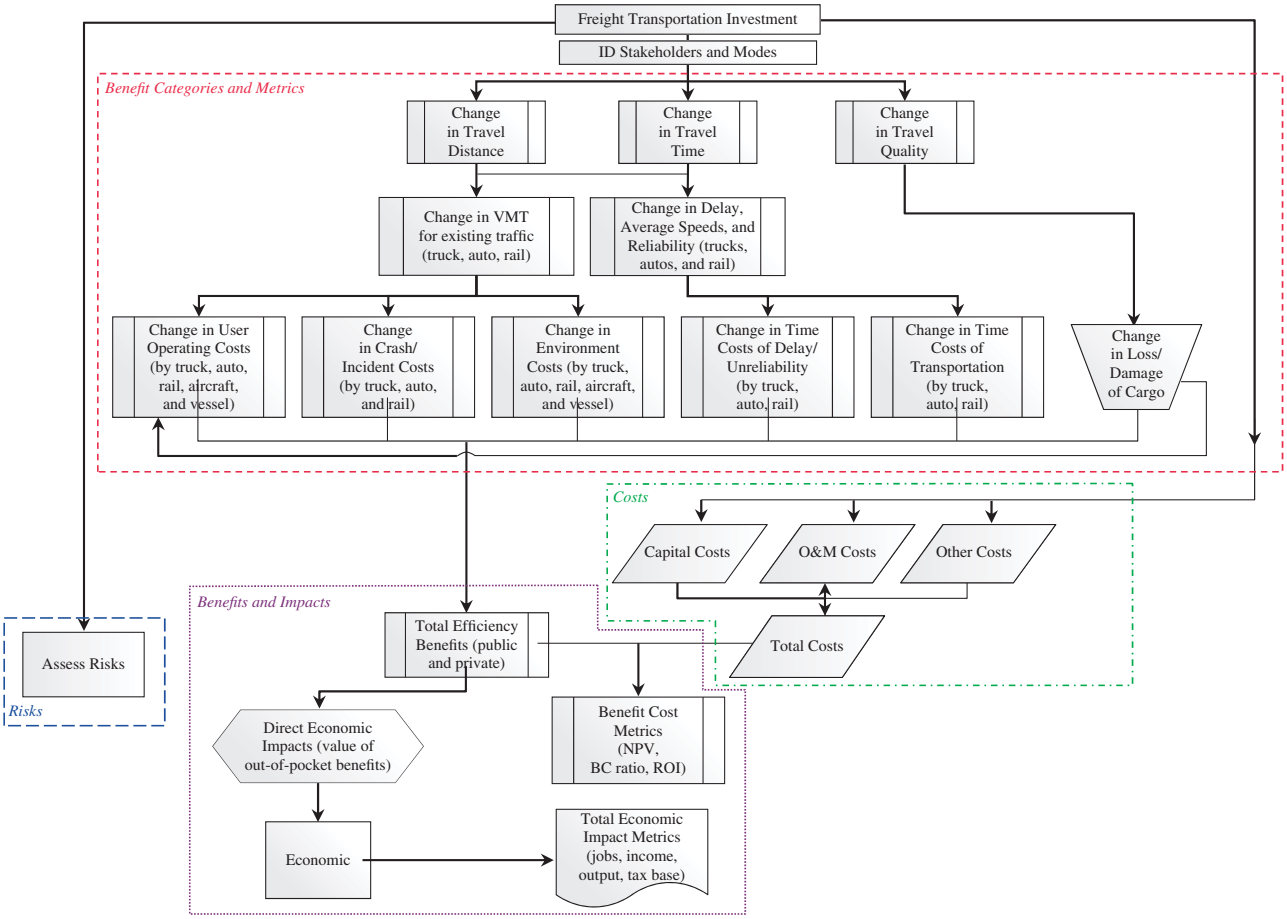
**Cost factors:**

- Facility capital costs, which tend to be dictated by site location and design, as well as the partners involved in the planning process.
- Facility maintenance costs, or the ongoing costs of maintaining a facility to ensure safe operations and upkeep.
- Operating costs, such as labor costs, fuel costs, equipment costs, and the time lost to congestion or to the breakdown of efficient supply chains.

**Benefit and other impact factors:**

- Capacity, which includes alleviating the impact of highway and rail system bottlenecks, as well as the throughput attainable on any transportation infrastructure or facility access point.
- Productivity, or the ability to operate a supply chain from start to finish with maximum efficiency.
- Loss and damage, or maximizing the safety and security of freight operations and movements to minimize loss to the shipper, carrier, or community.
- Scheduling/reliability, or the ability to have predictable and timely delivery of goods, allows for streamlined inventories, less disruption in the manufacturing or supply process, and a more efficient supply chain.
- Tax revenue, such as that received by new industrial land development, distribution center, or other freight-intensive land uses.
- Wider economic development, such as increased jobs resulting from a distribution center, transload, or intermodal facility, as well as multiplier effects to regional economies.

**Figure 22-10. Evaluation Framework for Freight Planning**



Source: Cambridge Systematics et al., 2011

- Safety, or minimizing traffic impacts of freight land uses on neighboring communities, and the safe operation of freight vehicles and facilities.
- Environmental quality, such as mitigation of air or water quality impacts, reduction of truck vehicle miles traveled (VMT), and noise or vibration reduction.

Table 22-18 shows the type of information that can be collected to support the assessment of different types of freight improvement strategies. Many of these evaluation performance measures are estimated by the models described in the previous section.

Another frequently used approach is a subjective assessment of different strategies. In the Atlanta freight planning study, categories of projects were evaluated using criteria based on identified needs, including: [ARC, 2008]

1) *Truck diversion*—How much does the project or strategy shift freight from truck to rail and remove through truck traffic from the region's highway system?
2) *Highway congestion/delay*—How much will the project or strategy reduce highway congestion and delay for both passenger and freight movement?
3) *Rail congestion/delay*—How much will the project or strategy reduce rail congestion and delay for freight movement?
4) *Travel time/reliability*—How much will the project or strategy improve travel time and reliability for both passenger and freight movement?

| Table 22-18. Performance Information for Evaluation | |
|---|---|
| **Analytical Needs** | **Performance Measures** |
| Bottlenecks | • Frequency of delays at intermodal facilities. |
| Commodity flow | • Average cost per trip.<br>• Average shipment time, cost, variability in arrival time for freight shipments (local versus long distance, by commodity, by mode).<br>• Business volume by commodity group. |
| Modal diversion | • Cost per ton of freight shipped. Cost per ton-mile by mode.<br>• *Delay per ton-mile traveled (by mode).* |
| Needs analysis | • *Administrative, engineering, and construction cost/ton-mile (owner cost).*<br>• Average crash cost per trip.<br>• *Dollar losses due to freight delays.*<br>• Economic indicator for goods movement.<br>• *Freight transport system supply (route miles, capacity miles, number of carriers, number of ports/terminals) per "demand unit" (dollar of manufacturing output, ton-mile of commodity movement, capita, employee, etc.).*<br>• Fuel consumption per ton-mile traveled. |
| Operational needs | • Interference of movement at grade crossings—delay time and speed. |
| Pavement and safety | • *Administrative, engineering, and construction cost/ton-mile (owner cost).*<br>• Average crash cost per trip.<br>• Exposure (annual average daily traffic and daily trains) factor for rail crossings. |
| Performance measurement | • Average fuel consumption per trip for selected trips (or shipments).<br>• Mobility index (ton-miles of travel/vehicle-miles of travel times average speed). |
| Project development | • *Average circuity for truck trips of selected O-D pattern.*<br>• Frequency of delays at intermodal facility. |
| Project prioritization | • Dollar losses due to freight delays. |
| Terminal access | • Average travel time from facility to destination (by mode).<br>• *Average travel time from facility to major highway, rail, or other network.* |
| Truck flows | • *Average circuity for truck trips of selected O-D pattern.*<br>• Average speed (passenger and commercial vehicles) on representative highway segments.<br>• Interference of movement at grade crossings—delay time and speed. |

Note: Italics indicate more commonly used performance measures

Source: Cambridge Systematics, Inc. et al., 2008

5) *Freight trip times*—How much will the project or strategy improve trip time for freight movement?

6) *Truck traffic peak/off-peak shares*—How much will the project or strategy shift the share of truck traffic from peak to off-peak times?

7) *Freight vehicle miles of travel*—How much will the project or strategy reduce regional truck vehicle miles of travel?

8) *Freight vehicle hours of travel*—How much will the project or strategy reduce regional truck vehicle hours of travel?

9) *Safety*—How much does the project or strategy reduce truck crashes and improve pedestrian safety along corridors?

10) *Truck emissions*—How much will the project or strategy reduce truck emissions?

11) *Community impacts*—How much will the project or strategy reduce community impacts associated with goods movement along transport corridors and freight-intensive areas, including those in dense areas?

12) *Land-use impacts—transport corridors*—How much will the project or strategy reduce land-use impacts associated with goods movement along transport corridors?

13) *Land use impacts—intermodal/warehouse/distribution facilities*—How much will the project or strategy reduce land use impacts associated with goods movement between intermodal yards, warehouse, and distribution facilities?

14) *Regional economic output/competitiveness*—How much will the project or strategy improve the economic output and competitiveness of the region?

15) *Jobs/economic opportunity*—How much will the project or strategy increase the number of jobs and economic opportunity associated with goods movement in the region, including those immediately in proximity to freight businesses?

16) *Cost*—What is the overall cost of the project or strategy?

The resulting criteria were vetted with the planning advisory committee.

With respect to prioritizing projects, a common method is to assign points to different freight-related criteria. An example of this approach is found in Washington State where the Freight Mobility Strategic Investment Board (FMSIB) has established the following major categories and weights for prospective projects: [Washington FMSIB, 2014]

**Freight Mobility for the Project Area-35 Points Maximum**

- Reduce truck, train, or rail car travel time/delays, 0–25 points
- Increase capacity for peak-hour truck or train movement, 0–10 points

**Freight Mobility for the Region, State, & Nation-35 Points Maximum**

- Importance to the regional freight system & regional economy, 0–10 points
- Importance to state freight system & state economy, 0–10 points
- Direct access to ports or international border, 0–10 points
- Provide a corridor/system solution, 0–5 points

**General Mobility-25 Points Maximum**

- Reduce vehicular traffic travel time/delay, 0–10 points
- Reduce queuing & backups, 0–7 points
- Reduce delay from use of alternative railroad crossing, 0–5 points
- Address urban principal arterials; urban principal arterial 3 points; otherwise 0 points

**Safety-20 Points Maximum**

- Reduce railroad crossing accidents, 0–5 points
- Reduce non-railroad crossing accident, 0–5 points
- Provide emergency vehicle access; essential access route, 5 points
- Otherwise, 0 points

**Close additional related railroad crossings**

- 2 or more additional crossing closures, 5 points
- 1 additional crossing closure, 3 points

Another example is shown in Table 22-19 where criteria were established for prioritizing freight projects, and points were awarded based on the importance of the project characteristic to desired outcomes.

One can also assign weights to the different criteria and then subjectively determine how many "points" each project achieves in the priority category by multiplying the weight times the score (usually from 1 to 3 or 5), and then summing across all criteria. An example of how one can determine weights for the different criteria comes from the Florida DOT where numerous freight stakeholders were asked to rate the importance of criteria on a scale of 1 to 5, where 5 was of highest importance. Table 22-20 shows the results of this weighting.

See chapter 7 for a more detailed discussion of approaches to prioritizing projects.

An increasingly important area for consideration is the relationship between community development and freight land uses. This is particularly challenging when freight facilities and terminals are located in dense urban neighborhoods where truck traffic and noise/vibration impacts could create community concerns. There are also concerns about urban development infringing upon land uses that had traditionally been used for freight purposes. For example, a freight study in Minneapolis-St. Paul found that pressures to redevelop industrial land along rivers and railroads in the metro region threatened the viability of water and rail-dependent industries and freight terminals. More generally the study found that increased non-industrial land development and encroachment upon industrial land uses in urbanized areas may affect the efficiency of operating freight terminals and may lead to conflicts between industry with residential communities, commercial districts, and parklands. [Metropolitan Council, 2013]

Another planning-oriented opportunity applicable to locations outside a central business district involves the development of transportation parks or freight villages. In most urban areas, freight terminals are located in many different locations, some causing conflicts with surrounding development. If the terminals were concentrated at a few

**Table 22-19. Prioritization Criteria for Choosing Among Freight Projects, Miami-Dade County, Florida**

| Category | Item | Points |
|---|---|---|
| Facility Type | Local collector | 1 |
| | County road | 2 |
| | State highway | 3 |
| Adjacent Freight Center Density | Low | 0 |
| | Medium | 1 |
| | High | 3 |
| Truck Average Daily Traffic | <1,000 | 1 |
| | >1,000 | 2 |
| | >2,500 | 3 |
| Project Cost | >$20 million | 1 |
| | > $5 million | 2 |
| | < $5 million | 3 |
| Attraction to General Traffic | Significant | 1 |
| | Moderate | 2 |
| | Insignificant | 3 |

locations along with the businesses that serve them, special strategies could be used to create buffer areas and/or provide special access facilities. From the private firms' perspective, such concentration allows a more efficient production process. This is the logic surrounding freight villages or transportation parks. Freight villages represent a similar concept and include more freight-related activities. Transportation parks would not only help the freight community but also would reduce the negative impact of freight terminals on residential and other sensitive land uses. The implementation of this concept needs proactive land-use planning.

A community's land-use planning process should be sensitive to these issues, and planners should ask the following questions during this process:

- Does the land-use planning process address truck terminals and their current and future locations?
- Does it address warehouses and their current and future locations?
- How are the expansion and/or relocation needs of major terminals—airports, seaports, and rail-truck intermodal terminals—addressed?
- Is access to freight facilities being examined?

The answers to these and other similar questions will reveal the adequacy or deficiency of the existing land use-planning process for freight planning. The following section discusses other aspects of freight terminals.

## V. FREIGHT TERMINALS

This section briefly describes some of the key aspects of freight terminals as they affect transportation planning. A much more detailed discussion of freight terminals can be found in the 3rd edition of this handbook. [Goodman and Lutin, 2009] See also chapter 12 on transit planning, which includes a discussion of terminal concepts relevant to freight terminals, for example, security issues.

### A. Truck Terminals

Terminals of all sizes and shapes form key elements of the truck freight transportation system. While their location and functions are closely related to the public street and highway system, truck terminals are largely, if not exclusively, a private-sector function. They are usually owned and operated by the trucking company (carrier) providing the service.

The terminal's function is defined by workload, volumes by type and source of traffic, service standards, workload availabilities and closeout times for activities, and information needed to plan the terminal. Specific location requirements are defined based on a system operations analysis. The objective is to relate, as specifically as possible, the market characteristics and conditions for the locations where a facility is needed to the overall plan. Finally, an economic evaluation of the facility and its options is prepared, leading to a statement of the detailed requirements for facility design. The steps include a marketing analysis to obtain information concerning the area, such as the trends in the area, growth or decline by industry, and the locations where industry and commerce are expanding.

The first step in developing a terminal site plan is to establish the site specifications, including the general size and configuration of the plot. Next, the search area is defined, alternative sites are evaluated, and the best selected. When the specific plot is known, a plan is prepared making the best use of space and providing for efficient flow (Note: the following information is provided simply to educate the reader on those issues considered when siting a terminal; interested readers should refer to the references in this section for more detail).

1) *Prepare site specifications*. The objective is to determine the size of the plot and its minimal dimensions. The steps include:
   a. Activities and buildings. At this point the dimensions of the dock, its length, and its width are known. The plan should also include the requirements for office, shop, fuel lanes, and any fixed facilities.
   b. Parking areas. The major requirement is for parking of trailers. The facility must be able to accommodate the peak requirements, based on the operations plan. Parking of employee and visitor autos should also be planned for. If line driver parking is required, this must also be included. As a general planning factor, 80 percent of the employees will require a parking space.
   c. Plot size. Depending upon growth projections, the land area required is generally a 25 to 35 multiple of the platform and office space. For a small terminal, such as 12 to 16 doors with a 40-ft (12.2 m) width, the minimal width of the plot will be 280 ft (85.3m). This dimension provides for a 120-ft (36.6-m) apron area for spotting trailers on both sides of the dock. The depth, of course, will depend on the total area required for parking and expansion.
2) *Define search area*. The search area should be defined within about a 5-mile radius. This should be an area well located to support present and future sources of business.
3) *Select site*. The site selection should include the following criteria:
   a. Access. Try to obtain a site within 2 miles (3.2 km) of a state freeway or interstate highway, or with convenient access to another main traffic artery.
   b. Site preparation cost. Obtain estimates for site improvement and determine the length of time required to prepare the land for construction.
   c. Area zoning. Check the zoning requirements and site plan review requirements for proposal.
4) *Prepare a block site plan*. The first step in developing an efficient layout for the plot is to determine a general arrangement of buildings, parking spaces, and activity for the specific plot chosen. Next, prepare a flow chart of what happens in the terminal, including the sequence of steps drivers take from the time they enter the

gate and park their equipment. Allow adequate space in the total employee parking area for the expanded design year, even though all this space may not be paved to begin with.

5) *Design a detailed plot plan*. The plan should show the details of the facility locations, paving, and the construction required.

The preceding material has dealt with the technical processes for developing efficient and well-functioning truck terminal sites. When integrating these technical factors with practice, community and environmental considerations often become important issues. The location of truck terminals can be a major issue and source of controversy. Truck terminals are often not considered desirable neighbors of residential developments. They generate considerable truck traffic on roads leading to the sites, resulting in various types of actual and perceived adverse effects in the vicinity, including traffic congestion, safety hazards, pavement deterioration, visual and psychological impacts, noise, and air pollution. Further, they tend to attract other commercial activities and truck-oriented operations, such as truck repair shops and supply stores. In addition, truck terminals may have other types of physical and psychological effects on adjacent residential areas. For example, the high mast lighting used in terminals for work and security at night can be an irritant for nearby residences, and the noise of trucks moving or idling inside terminals is also undesirable, especially at night.

Suitable locations for truck terminals can be identified through land-use planning studies and engineering studies. Industrial parks are suitable sites for truck terminals. A transportation park may be developed to accommodate a cluster of terminals and, if it is located near a major truck route, then unnecessary travel of large trucks on internal local roads can be eliminated. A transportation park would provide an opportunity and justification for special design features and treatments such as exclusive access roads and buffer strips around the sites.

## B. Freight Rail Terminals

Freight rail terminals in the United States have undergone major changes since World War II, particularly since the 1980 Staggers Act that deregulated the railroad industry. The terminal function has changed and will continue to change in response to the increased integration of ocean shipping, rail, truck, and aviation modes. Prior to deregulation, rail freight movement had transitioned from break-bulk techniques to more use of containerization, that is, trailer-on-flat-car (TOFC) and container-on-flat-car (COFC). Prior to this early period of containerization, freight originally came to conventional rail yards from ships, by local truck, or via individual rail cars at shippers' sidings. This changed when TOFC and COFC, more popularly referred to as piggyback, brought pre-packaged freight in a trailer or a container for loading as a unit (rather than break-bulk loading) onto a flat car.

Use of conventional break-bulk, TOFC, and COFC continues. The following material describes the facilities and systems for these rail freight modes. Following this material, present and future conditions are discussed, such as unit trains, yard consolidations (hubs), and double-stack trains.

## C. TOFC and COFC

*Piggyback* is the popular term used to describe a form of service in which one carrier transports a unit of another carrier. For example, highway motor freight trailers are loaded at the shipper's door or at a warehouse, brought by tractor to a railroad loading ramp or yard, placed on flatcars, and hauled in trains to a destination terminal. The trailers are then unloaded and terminal delivery is made to the consignee's door by truck. TOFC line-haul service is potentially faster than highway haul, while the terminal times are practically equivalent. Much of the expense and nuisance of highway haul—traffic congestion, personnel problems, traffic violations, accident hazards, and restrictive limitations on weight and size—are avoided or markedly reduced. Five systems of TOFC (with variations) are generally recognized:

- *Plan I*: Vehicles of common highway carriers are hauled by rail. The shipper deals with the highway carriers, which, in turn, deal with the railroad.
- *Plan II*: Only the railroad's highway trailers are carried. The public deals directly with the railroad or its highway subsidiary.
- *Plan III*: Anyone's trailer, including those of the individual or private trucker, is carried by rail.

- *Plan IV*: An intermediate or forwarding agency or broker secures the freight, loads it into its trailers and onto its own flatcars and turns it over to the railroad to haul. The third party may be a company owned by one or more railroads, but the shipper deals with the third party.
- *Plan V*: Plan I plus joint rail-highway rates with the highway carrier. The shipper deals with either the trucker or the railroad.

Railroad yards serve varied purposes, including storage, holding, consignment, public delivery, and, on a broader scale, supporting nearby industrial activity. The principal type of yard and its function is the classification yard, which also concentrates enough cars to fill out a train. Classification includes the receiving and breakup of trains and the sorting and classifying of the cars into new trains for road haul, transfer to other yards or railroads, or local delivery. A large classification yard usually contains three yard units: the receiving yard into which trains are moved from the main line preparatory to sorting; the classification yard proper, where the sorting or classifying into blocks of common destinations takes place; and the departure yard, in which the sorted groups or blocks are made into trains and held pending main-line movement.

## D. Intermodal Yards

As noted earlier, one of the key rail freight strategies developed as part of the containerization movement was the land bridge concept whereby traffic between the Far East and the east coast of the United States is transferred from ship to rail to move COFC across the United States to East Coast cities rather than through the Panama Canal. Transit time for certain ships between Japan and the Atlantic seaboard via the canal is 32 days. By transshipping containers to rail cars at western ports, the transit time to the eastern seaboard can be reduced to 16 days. There are no technological problems with this, but there is the matter of returning empty containers and other administrative and regulatory concerns. With deregulation and increasing intermodal business entities and arrangements, ways have been found to overcome these problems. In fact, empty containers are increasingly being filled in back hauls. This has led to increasing use of, and focus on, domestic containerization, particularly for high-density corridors over 500 miles long.

Double-stacking container rail cars is another important intermodal development. In this case, two containers are carried per rail car. The increasing use of double-stack, with its increased per-train capacity, has had definite impacts on right-of-way geometric planning, on the planning and design of the associated intermodal terminals, and on the performance of access roads at container yards. Large railroads are achieving important savings by consolidating many intermodal ramps (yards) into a few strategically located, highly productive intermodal hubs.

## E. Freight Multimodal Terminals

Multimodal freight terminal movements usually involve the following combinations of different modes:

- Truck and rail (for example, piggyback, TOFC, COFC, or Road Railer).
- Ship/barge and truck or rail (ports and containers).
- Pipeline/ship/barge and truck (petroleum distribution).
- Truck and air (air cargo at airports).

Multimodal terminals by nature are land-intensive, and they generate movements of large and heavy trucks. Access roads leading to these facilities and storage space for trucks inside the terminals are important elements of the overall operation. The design of multimodal terminals, in many cases, has failed to provide for the needs of all the modes involved. For example, seaports and rail terminals need to consider adequate access and storage facilities for trucks.

A seaport or river port is a good example of a multimodal terminal. New ports or port extensions become necessary when entirely new traffic has to be handled or when freight volumes are predicted to increase. In principle, new port capacity is justified when the revenues generated by the new capacity and associated economic benefits outweigh the costs. Factors that are not quantifiable in economic terms, such as overall strategic planning for regional or demographic development, often play an important role in port site selection. With these general guidelines in mind, the following elements should be considered for multimodal terminals.

*Linkage to the existing and planned highway network*. Connectivity to the highway network in the port area is a key consideration. Ideally, port facilities should be located adjacent to a major roadway with adequate capacity for high truck volumes. The Newark/ Elizabeth marine terminal complex in New Jersey, for example, is directly served by I-78 and I-95 and is close to I-278 and I-280.

*Linkages to the existing and planned rail network.* The area's railroad system should be analyzed to determine the feasibility of providing rail connections between the port facilities and rail lines serving the area. Direct, grade-separated freight rail access is provided, for example, at the Port of Long Beach in California by the multi-track Alameda Corridor project.

*Linkages to pipelines*. If liquid commodities are to be shipped through the port, the pipeline network should be evaluated to determine if connections to new port facilities are feasible.

For *ocean ports, linkages using waterborne services (barges or short-distance coastal vessels) to smaller ports on rivers or sounds*. Such services operate successfully in Europe.

For *inland waterways, commodities transported via the waterway*. Waterway transportation consists primarily of relatively slow movement of commodities that have low unit value and high unit weight, moved in massive quantities at relatively low cost.

*Number and type of industries located near the port*. Typically, an area establishes or upgrades a port to improve its economic development by taking advantage of the accessibility to the waterway transportation system.

Container ports are another good example of multimodal terminals. Container terminals are, in principle, rapid transfer facilities at the interface between land and sea transport. Inbound containers continue their inland journey to the consignees soon after arriving in the terminal. Outbound cargo often arrives at the terminal not long before the ship sails. Although the most cost-efficient strategy would be for outbound containers to arrive just before ship departure and for inbound containers to leave the terminal almost immediately after being off-loaded, this often does not happen. Thus, both full and empty containers remain in storage much longer than intended, and the throughput capacity of terminals, which is inversely proportional to the average storage time for containers (commonly called dwell time), is greatly reduced. Figure 22-11 shows a typical layout of a container terminal that uses straddle carriers as yard equipment.

The 20-ft equivalent unit (TEU) container throughput for a given time period is often expressed in the following equation:

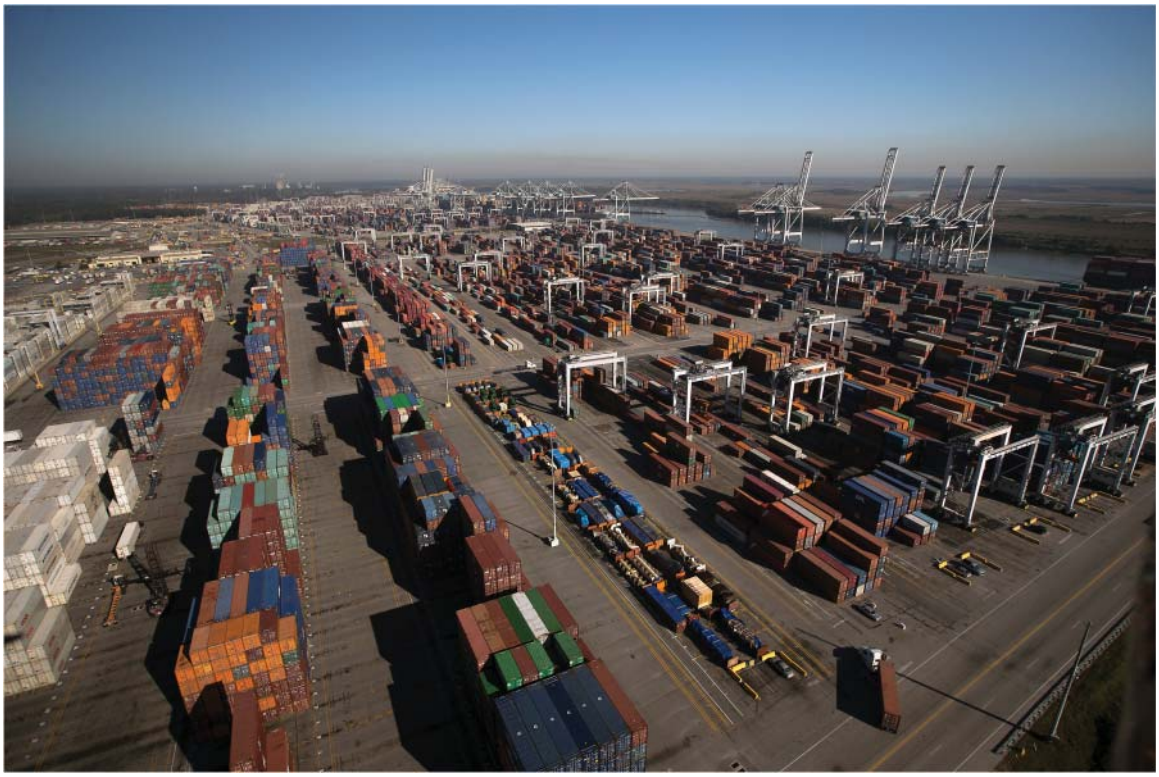
$$C = \frac{L \times H \times W \times K}{D \times F}$$

where:

$C$ = TEU throughput during the period of time
$L$ = Number of TEU ground slots
$H$ = Average stacking height in number of containers
$W$ = Average utilization factor for ground slots
$K$ = Number of days of the period of time
$D$ = Average TEU storage time in days
$F$ = Peaking factor for a combination of higher-than-average TEU throughput, less-than-average stacking height, and more than average storage time

Responding to competitive pressures, ocean port agencies throughout the United States have developed new ways to retain and expand cargo volumes moving through their ports. In the late 1980s, the concept of an inland intercept for an ocean port (that is, a "waterless" inland port) was analyzed and implemented in several locations in the southeast. The Virginia Inland Port (VIP), opened in May 1989, linked to the Port of Hampton Roads. This followed two earlier and somewhat similar inland port projects in the Carolinas, tied to the ports of Wilmington, North Carolina, and Charleston, South Carolina. The VIP facility, located more than 200 miles (322 km) inland at Front Royal, Virginia, provides a rail-truck intermodal terminal linked to the Virginia Port Authority's (VPA's) Hampton Roads terminals by a dedicated Norfolk Southern rail haul. The inland port is positioned to intercept container traffic that is largely

**Figure 22-11. Container Terminal Layout, Port of Savannah, Georgia**



Source: Courtesy of the Port of Savannah

truck-hauled to rival mid-Atlantic ports. For VPA, the new inland port was intended to produce a significant increase in the volume of import-export container traffic moving through the Authority's Hampton Roads terminals.

## VI. SUMMARY

The efficient movement of freight and goods is a fundamental prerequisite for a strong and vibrant economy. Increasingly, this movement has taken a global perspective as the producers and consumers of goods are spread out across the globe. Since the 1980s with the adoption of free-trade agreements and the beginning of steady economic growth, the volume of freight and goods moving in the U.S. transportation system has grown dramatically. Although much of this freight is handled by private firms (railroads, trucking firms, barge companies and air cargo airlines), public agencies are being challenged to support this increase in freight traffic through investments and policy actions that in turn affect transportation service providers across all modes. To help meet the needs of the global trade environment, government agencies responsible for transportation planning must foster integrated modal systems by supplying infrastructure that can support responsive, reliable freight transportation.

Given increasing economic growth and the role international trade will play in this growth, it is likely that freight planning will become even more important in future years. Whereas for years, the movement of freight and the challenges facing freight carriers were considered the purview of the private sector, transportation officials began to realize in the 1990s that the problems facing freight movement can have a significant influence on a state or metropolitan economy and can lead to community impacts that often fall to public officials to solve.

Freight transportation planning examines a range of strategies that can alleviate the problems facing freight movement. These strategies include the more traditional infrastructure projects (for example, bottleneck removal) to the application of ITS strategies to improve the safety and operational productivity of the freight network. Because much of freight movement occurs on the road network, the interplay between the strategies aimed at freight movement and those targeted at passenger movement becomes an important consideration in the planning process. For example,

many metropolitan areas have implemented or are considering implementing commuter-rail service, often using freight-rail tracks. This type of service needs to be examined both from the public policy perspective of providing transit options to the region's commuters as well as the potential impacts on rail movements. In port cities, this interplay between public policy and freight productivity often occurs when examining freight-related community impacts (such as noise, air emissions, and vibration). The planning process can be the forum where the trade-offs associated with such issues can be discussed and compromises negotiated.

As noted in this chapter, freight planning is similar to other types of transportation planning discussed in this handbook. The process begins with a vision, goals and objectives; uses data and analysis tools to understand the likely implications of different strategies; and evaluates and prioritizes the strategies so as to develop the most cost effective implementation program for the state or region. However, there are also differences. In particular, some of the most important challenges related to freight transportation planning include:

- *Participation of freight stakeholders is important to the planning process, but often difficult to obtain*. The public planning process tends to be much more drawn out and open to public discourse than most private company officials are used to. This open and often lengthy process has caused many freight officials to hesitate in becoming involved.
- *Data are always an important foundation for good transportation planning*. Freight data, in particular, have great value in understanding current and expected freight patterns. However, much of the data of greatest use are proprietary to private firms, and not surprisingly, they are not willing to make these data available to the general public. Accordingly, many freight studies rely on national freight databases that are modified for the specific study being undertaken. These national databases often do not have site-specific information, such as origin and destination zones, in a study area. It is often the case that freight data must be collected as part of the planning study.
- *It is important in freight planning that freight networks or systems be clearly identified*. This means that the most important truck routes, rail lines, air cargo airports, water terminals and warehouse/distribution centers should be a basic point of reference for the planning study. In some cases, such networks have been in use for some time, but it is important they be examined to see if economic changes or other growth-related phenomena have affected the usefulness of the current designation.
- *Public funding for projects that will primarily benefit one specific firm or industry sector is not often available*. When public funding is used to build a project or operate a service, the general public should have access to it. Unless a clear public purpose can be identified, it is difficult to use public funds to improve warehouse or distribution centers, on-dock facilities, or to purchase freight-loading equipment for a private company. In recent years, one means of avoiding such a problem has been the use of public/private partnerships where both public and private agencies provide specific contributions to a project and where the public and private benefits associated with each contribution are made clear.
- *Models are an important part of a transportation analysis*. Given the often large markets served by the freight industry, freight modeling efforts use much larger study areas than studies for passenger transportation. In some cases, this could include examining global trade patterns and border crossings. If a state or metropolitan area is strategically important to global supply chains, the transportation planner should use an analysis approach that assesses freight flows much beyond the immediate study boundary.

As more transportation planners become exposed to the importance of freight movement, it seems likely that new and innovative approaches to data collection, modeling and evaluation will be developed. It is important that transportation planners monitor the developments in these areas so that freight planning in their study area will include the latest approaches to integrating freight into the transportation planning process.

# Planning It Safe—Safety Considerations in the Transportation Planning Process[1]

## I. INTRODUCTION

Physical injury is the leading cause of death in the United States for people ranging in age from about 6 months to 45 years. Because it so disproportionately strikes the young, it is also the leading cause of lost years of productive life. Motor vehicle–related injury is overwhelmingly the largest component of injury losses. Reducing the number of motor vehicle–related crashes should thus be a major component of efforts to reduce the death rate in the United States. Although the United States and other industrialized nations have made substantial progress over the past 30 years, the United States still experiences more than 33,000 road-related deaths annually and nearly 2.5 million injuries. [National Highway Traffic Safety Administration (NHTSA), 2014]

Why is safety an issue that should be of concern to transportation planners? Perhaps the best answer to this question is provided in the preface of the transportation safety plan produced by the Houston-Galveston Area Council (H-GAC), the metropolitan planning organization (MPO) for the Houston area. According to the Houston experience, the importance of safety to transportation planning is:

- Similar to other issues that can be linked to the construction and operation of transportation facilities (for example, air quality, economic development and such), travel safety is clearly an issue that can be affected by how the transportation system is designed, constructed, operated, and maintained. Given that transportation planning leads to changes in this transportation system, safety should be thoroughly integrated into an agency's planning process.
- The costs associated with motor vehicle–related fatalities and vehicle crashes are staggering . . . .
- Motor vehicle fatalities and crashes are a leading public health problem in the United States and in the world . . . .
- The impact of trucking on travel safety is increasing. This is coupled with projected huge increases in truck activity over the next decade due to increased trade and, in Houston's case, associated port activity and dispersion of warehouse activity farther from the port.
- Bicycle and pedestrian users experience a disproportionate number of deaths. These problems, along with transit safety issues, have significant effects on lower-income populations.
- A comprehensive safety program includes a range of different strategies and actions involving many different agencies and groups. Thus, there is a need for collaboration and coordination among many to achieve success . . . .
- Statewide and metropolitan transportation planning in the United States reflects federal mandates. In both cases, safety has been identified by Congress as a national priority issue that must be considered during the transportation planning process . . . .
- Crashes represent a major source of delay (referred to as nonrecurring congestion) for states and metropolitan areas struggling with congestion on freeways and other major roads. The time it takes police and/or emergency

[1]The original chapter in Volume 3 of this handbook was written by Dr. Susan Herbel, principal, Cambridge Systematics, Inc. Changes made to this updated chapter are solely the responsibility of the editor.

services to reach an incident, secure the safety of crash victims and other responders, attend to the injured, clear the vehicles from the travel lanes, collect relevant crash-related data, and remove disabled vehicles from the roadway can lead to serious traffic delays on critically important roads. [Levine, 2006]

This chapter describes how safety can be integrated into the transportation planning process at all levels. Special focus is given to how safety can be incorporated into the products of the statewide and metropolitan planning processes, that is, statewide transportation plans (STPs), statewide transportation improvement programs (STIPs), metropolitan transportation plans, and transportation improvement programs (TIPs). This chapter also explains why safety planning that only focuses on traditional transportation planning products should be augmented by new processes and institutional relationships that align efforts across organizational boundaries to achieve reductions in highway fatalities and incapacitating injuries.

The next section presents U.S. statistics on crashes and crash rates. In addition, material is presented on the safety history of transit and nonmotorized modes of travel. The following section provides a brief description of the legislative and regulatory history of safety planning in the United States, and the relationship between the STP and the development of a strategic highway safety plan. The next section describes the characteristics of safety transportation planning and how safety concepts can be incorporated into the different steps of the transportation planning process. Given the importance of the American Association of State Highway and Transportation Officials' (AASHTO's) *Highway Safety Manual* to current practice, the following section introduces the key concepts found in the manual and how they can be used as part of a safety analysis. The final section briefly describes safety lessons learned from other countries.

## II. U.S. NATIONAL STATISTICS

During the past seven years, the number of road-related fatalities in the United States has remained relatively unchanged (although going up or down in any individual year), even with dramatic increases in safety belt use and decreases in the proportion of alcohol-related fatal crashes. [NHTSA, 2014] However, in 2012, as seen in Figure 23-1, the first increase in fatalities in several years was observed. It was the first significant increase since the

**Figure 23-1. Motor Vehicle Crash Fatalities and Fatality Rates, United States, 1964–2013**

early 1990s. Fatality and injury rates, however, have continued to decrease, as shown in Figures 23-1 and 23-2, because total vehicle miles of travel (VMT), the denominator of the crashes per 100 million vehicle miles traveled rate, have increased over the long term (although in recent years it has declined). If the number of crashes per year remains the same as it is today, more than 330,000 people will die on U.S. roadways over the next decade, at a societal cost of nearly $2.0 trillion, using the current monetary value of a statistical life.

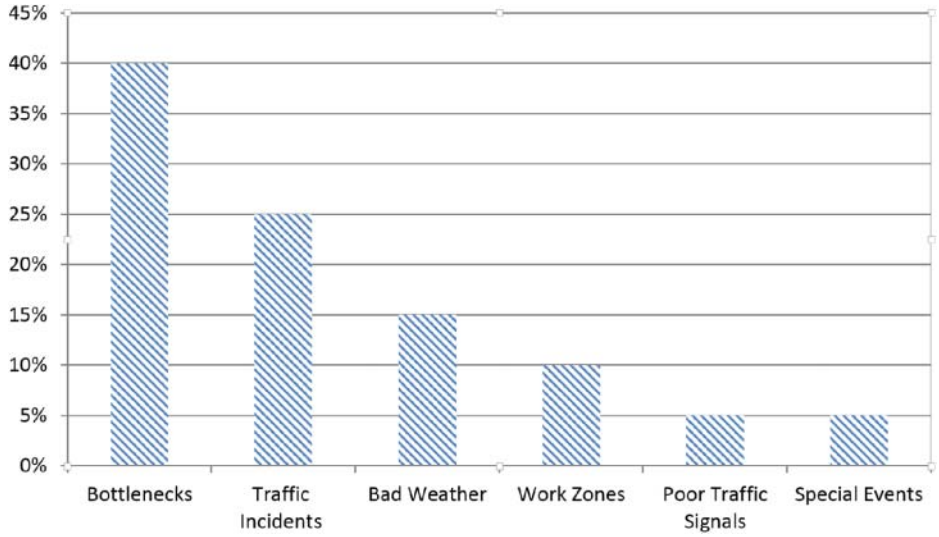
A study by NHTSA concluded that the costs to society of crashes occurring in 2010 amounted to $871 billion in economic loss and societal harm. This included $277 billion in economic costs—nearly $900 for each person living in the United States at that time—and $594 billion in harm from the loss of life and the pain and decreased quality of life due to injuries. [Blincoe et al., 2014] Given this huge loss in human life and the corresponding economic impacts, and given that crashes are to a large extent avoidable, transportation planners should focus on what it will take to improve safety on the transportation system.

While fatal and severe injury crashes appropriately receive the most attention, crashes that result only in minor injuries and property damage also have significant economic impacts. Lost days of productivity, chronic pain, diversion of economic resources into repairs, and increased traffic congestion are each a potential negative consequence of these crashes. Figure 23-3 illustrates this last point. National data suggest that an estimated 25 percent of all congestion is caused by traffic crashes, and in some cases, such as in major urban areas, it might exceed 50 percent. Crashes and other incidents not only cause immediate delay to those caught behind the event, but also have the potential themselves of causing secondary crashes. Crash-caused congestion also tends to slow emergency response, potentially increasing the severity and ultimately the survival rate from crashes.

National statistics also provide good indications of the causes of crashes. According to Blincoe et al. [2014], such causes include:

- *Drunk Driving*—Crashes caused by drivers under the influence of alcohol accounted for 18 percent of the total economic loss due to motor vehicle crashes and cost the nation $49 billion in 2010, an average cost of $158 for every person in the United States. Including lost quality of life, these crashes were responsible for $199 billion or 23 percent of the overall societal harm caused by motor vehicle crashes. Over 90 percent of

**Figure 23-3. Contributing Factors to Congestion in the United States**



Source: FHWA, 2013a

these costs occurred in crashes involving a drunk driver with a blood alcohol concentration (BAC) of 0.08 or higher.

- *Speeding*—Crashes involving a speeding vehicle traveling over the posted speed limit or too fast for conditions accounted for 21 percent of the total economic loss and cost the nation $59 billion in 2010, an average cost of $191 for every person in the United States. Including lost quality of life, these crashes were responsible for $210 billion or 24 percent of the overall societal harm caused by motor vehicle crashes.
- *Distraction*—Crashes involving a distracted driver accounted for 17 percent of the total economic loss and cost the nation $46 billion in 2010, an average cost of $148 for every person in the United States. Including lost quality of life, these crashes were responsible for $129 billion or 15 percent of the overall societal harm caused by motor vehicle crashes.
- *Pedestrians and Bicyclists*—Crashes involving pedestrians and bicyclists accounted for 7 percent of the total economic loss and cost the nation $19 billion in 2010. Including lost quality of life, these crashes were responsible for $90 billion or 10 percent of the overall societal harm caused by motor vehicle crashes.
- *Seatbelts*—Seatbelt use prevented $69 billion in medical care, lost productivity, and other injury-related costs. Conversely, preventable fatalities and injuries to unbelted occupants accounted for 5 percent of the total economic loss, and cost the nation $14 billion in 2010. Including lost quality of life, failure to wear seatbelts caused $72 billion or 8 percent of the overall societal harm due to motor vehicle crashes.

As can be seen in Table 23-1, the increase in fatalities among motorcyclists and pedestrians, cyclists, and other non-occupants is a troublesome statistical trend. In particular, motorcyclist fatalities over the 10-year period grew by 16 percent. Some interesting statistics regarding motorcyclist fatalities in 2013 include: (1) 43 percent of motorcyclist fatalities occurred in single-vehicle crashes; (2) there were 11 times as many unhelmeted motorcyclist fatalities in states that did not have a helmet law as in those that did; (3) 27 percent of motorcycle riders in fatal crashes had blood

alcohol levels of 0.08 or higher; and (4) 25 percent of motorcyclist drivers in fatal crashes were improperly licensed. [NHTSA, 2015] Similarly for pedestrian fatalities, (1) 34 percent (16 years or older) had blood alcohol levels of 0.08 or higher; (2) the age group with the highest fatalities was 45 to 54 years old; (3) 68 percent of fatalities were in urban areas; (4) 31 percent were at intersections; (5) 70 percent occurred at night; and (6) 69 percent were male. For pedacyclists, (1) 20 percent (16 years or older) had blood alcohol levels of 0.08 or higher; (2) the average age was 44 years old; (3) 73 percent of fatalities were in urban areas; (4) 43 percent were at intersections; and (5) 56 percent occurred between 3 p.m. and midnight. (Note: Pedestrian and bicycle crashes are those involving collisions with motor vehicles … in metropolitan areas, the number of collisions between pedestrians and bicycles has been on the rise in recent years.)

Table 23-2 shows the number of fatalities, and Table 23-3 the number of injuries, by transit mode from 2001 to 2011. As shown, the largest number of fatalities is associated with commuter rail, whereas the largest number of injuries occurs with bus operations.

The major focus and commitment to improving roadway safety in the United States during the past two decades has been on enhancing the vehicle's ability to withstand crashes and on changing driver behavior. Yet, as seen in Figure 23-1, the effectiveness of these strategies seems to have leveled off. Similarly, many roadway improvements have focused on modernizing highway ramps and intersections to improve safety, with the result being better traffic flow and higher traffic volumes. These in turn can negate safety benefits. All of this raises the question: What more can be done to improve the safety of the transportation system?

## III. INSTITUTIONAL AND POLICY STRUCTURE IN THE UNITED STATES

In 1966, 50,894 people were killed in the United States in motor vehicle crashes, a fatality rate of 5.5 deaths per 100 million VMT. If nothing had been done to address the problem, assuming historical growth rates, highway fatalities would have increased to more than 100,000 annually by today. However, the federal government and the states have been actively engaged over the past 40 years in reducing the nation's highway fatalities. Safety has long been a major focus of highway project development and a consideration for road investment. However, its role and significance as a component of national transportation policy has changed over time, as summarized in Table 23-4 and in the following paragraphs.

| Table 23-4. Significant U.S. Road Safety Legislation | | |
|---|---|---|
| **Federal Legislation** | **Year** | **Significant Road Safety Features** |
| Highway Safety Act | 1966 | • Created Federal Highway Administration (FHWA) safety grant program.<br>• State highway safety program approved by U.S. Department of Transportation (U.S. DOT).<br>• Created National Highway Traffic Safety Administration (NHTSA).<br>• Included specific initiatives such as bicycle/pedestrian safety, law enforcement, etc. |
| Highway Safety Act | 1973 | • Established methodology for improving roadway safety from an engineering perspective.<br>• Required hazardous location survey, analysis of contributing factors, benefit/cost analysis of mitigation alternatives, and project prioritization.<br>• Methodology was expanded through establishment of the Highway Safety Improvement Program (HSIP) methodology in 1979. |
| Intermodal Surface Transportation Efficiency Act (ISTEA) | 1991 | • Required planning process with emphasis on state department of transportation (DOT)-metropolitan planning organization (MPO) coordination.<br>• Included systems preservation, construction, preservation, mobility, and environmental protection.<br>• Required management systems, including safety, but requirement later withdrawn. |
| National Highway System Designation Act | 1995 | • Made implementation of management systems optional. |
| Transportation Equity Act for the 21st Century | 1998 | • Required DOTs and MPOs to incorporate safety and security together as a priority planning factor.<br>• Led to development of safety conscious planning (SCP) initiative. |
| Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) | 2005 | • Separated safety and security as planning factors.<br>• Established safety as a core funding program.<br>• Established a strong connection between the strategic highway safety plan (SHSP) and the transportation planning process.<br>• Required states to develop and implement strategic highway safety plans. |
| Moving Ahead for Progress in the 21st Century Act (MAP-21) | 2012 | • Required regular update of the strategic highway safety plan<br>• Secretary will establish measures and states will set targets for number of injuries and fatalities (and number per VMT)<br>• States should:<br>  ◦ Use the safety data system to perform safety problem identification and countermeasure analysis that:<br>  • Identifies hazardous locations, sections, and elements.<br>  • Establishes relative severity of those locations.<br>  • Identifies number of fatalities and serious injuries on all public roads by location in the state.<br>  • Considers which projects maximize opportunities to advance safety. |

| Table 23-4. (*Continued*) | | |
|---|---|---|
| **Federal Legislation** | **Year** | **Significant Road Safety Features** |
| | | • Adopt strategic and performance-based goals that:<br>  • Address traffic safety, including behavioral and infrastructure problems and opportunities on all public roads.<br>  • Focus resources on areas of greatest need, and coordinate with other state highway safety programs.<br>  • Determine priorities.<br>  • Establish and implement a schedule of highway safety improvement projects.<br>• Establish an evaluation process driven by SHSP.<br>• Expand the list of participants in SHSP. |
| Fixing America's Surface Transportation (FAST) Act | 2015 | • Little impact on the relationship between transportation planning and safety.<br>• Established a new competitive grant program for passenger and freight rail safety projects.<br>• Increased accountability of states to ensure rail transit safety performance by bolstering oversight in urban areas.<br>• Allowed flexibility in transporting hazardous materials during major disasters and emergencies in an effort to improve the ability to carry out emergency response and relief efforts. |

### *The Highway Safety Act (1966)*

The Highway Safety Act of 1966 established a new method for addressing highway safety problems. The act created a federal highway safety grant program and gave responsibility for the administration of this program to the governors of each state. The governors were directed to appoint a governor's highway safety representative (GR) to administer the program. Funding was provided under Section 402 of the U.S. Code, which became the basic building block of state highway safety programs. The U.S. Secretary of Transportation was assigned the responsibility of approving these programs. To oversee the program, Congress created the National Highway Traffic Safety Administration (NHTSA) within the U.S. Department of Transportation (U.S. DOT).

In effect, the 1966 Highway Safety Act put the federal government in a leadership position in highway safety, but it kept the actual implementation of highway safety programs in the hands of the states, a relationship that continues today. Since 1966, Congress has revised the federal highway safety program a number of times, adding new incentive grants, penalties, and sanctions. Some of the revisions over time have required safety programs to consider factors such as driver and pedestrian safety, bicycle safety, speeding, occupant protection devices, drivers impaired by alcohol or controlled substances, motorcycles, school buses, law enforcement services, and crash data collection and reporting. However, the act did not explicitly address how safety should be considered in the statewide or metropolitan transportation planning processes, nor did it suggest that the state highway safety plan, developed to comply with Section 402, can be eliminated by addressing highway safety within a broader transportation planning process. These NHTSA safety planning requirements are still in force even though federal transportation legislation, the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU), required the states to develop a strategic highway safety plan.

### *Highway Safety Act of 1973*

The Highway Safety Act of 1973 established additional safety programs to reduce the number and severity of highway-related crashes by addressing high-crash locations. States were required to conduct a survey of all hazardous locations, study the causes of crashes at these locations, conduct a benefit/cost analysis of proposed mitigation, and prioritize improvements. This approach was very much an engineering-oriented perspective on how to improve roadway safety. In 1979, the Federal Highway Administration (FHWA) built upon this methodology in establishing the Highway Safety Improvement Program (HSIP). This program provided the basis for selecting locations for safety

improvements. The purpose of the HSIP was to help establish policy for the development and implementation of a comprehensive highway safety program in each state. Three key components were identified: planning, implementation, and evaluation.

***Intermodal Surface Transportation Efficiency Act (1991)***

In many ways, the Intermodal Surface Transportation Efficiency Act (ISTEA) was benchmark legislation that changed the focus of federal transportation policy. In particular, it made system preservation one of the most important goals of federal policy, along with mobility and environmental protection. The goal of transportation investment was to produce a safe, efficient, accessible transportation system that also protected the human and natural environments.

ISTEA required consideration of 23 planning factors for statewide transportation plans (STPs) and 16 for metropolitan plans, under the general headings of mobility and access for people and goods, system performance, preservation, environment, and quality of life. However, nowhere in the legislation was safety specifically mentioned or mandated in the planning process. ISTEA also required the states to develop and implement six management systems, including one for safety. However, this requirement, except for the congestion management system in transportation management areas, was made optional at the state's discretion by the National Highway System Designation Act of 1995.

At the time, the highway safety management system (SMS) was envisioned to be a process to identify and prioritize safety projects in the states. A comprehensive crash database was to serve as the basis for these decisions, and safety performance measures were to be defined and used to monitor safety progress over time. The SMS process also was expected to include a broad-based coalition of safety stakeholders. In reality, most SMS activities were simply efforts to structure crash databases that allowed transportation officials to identify high-crash locations. After the federal requirement for an SMS was rescinded, very few states maintained and expanded their SMS or continued to develop a collaborative process with others interested in highway safety.

***Transportation Equity Act for the 21st Century (1998)***

While ISTEA required states to develop and maintain a transportation planning process, the Transportation Equity Act for the 21st Century (TEA-21) provided more focus on specific issues. The key focus of both of these acts was to encourage coordination between statewide planning and metropolitan planning. In addition, TEA-21 identified seven priority planning factors that were to be considered by both planning processes. Prior to TEA-21, safety may have been incorporated into the vision or goals of a state's long-range transportation plan, but specific strategies to increase safety were seldom included in statewide and metropolitan planning processes or documents. For the first time, TEA-21 required state DOTs and MPOs to incorporate safety/security as a priority factor in their transportation planning processes and activities.

Integrating safety into transportation planning became known as safety conscious planning (SCP). [Herbel, 2001] The goal was to prevent the human and economic losses that resulted from motor vehicle and nonmotorized traveler-related crashes. SCP encouraged states and local transportation planners to work collaboratively with officials concerned with highway safety, data management and analysis, commercial vehicle safety, and other areas to include safety as a key issue in all transportation plans and programs.

***Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (2005)***

The Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) separated safety and security into individual planning factors. Prior to the terrorist attacks of September 11, 2001, security had been addressed at the federal level, primarily through initiatives for airport security, the security of transit drivers, and, to a lesser extent, personal safety of passengers on the transit system. The issue broadened considerably after 9/11, with the security of bridges, tunnels, airports, and other facilities becoming a bigger public policy issue. Evacuation planning, particularly for mobility-limited residents or residents without cars, has also become more pressing as a security issue as a result of Hurricane Katrina in September 2005.

With respect to safety, SAFETEA-LU required each state to develop and implement a Strategic Highway Safety Plan (SHSP) as part of the HSIP requirements. The requirements for the contents of these plans, the stakeholders who must be involved, and eligible funding categories were quite specific, with the eligible funding categories being broadened considerably (see Table 23-5).

In many ways, the SHSP requirement and the new, flexible safety funding resources of SAFETEA-LU strengthened both the process and goals of SCP and the original SMS requirement of ISTEA. These plans were to be based on data analysis and developed in collaboration with a broad range of stakeholders. Importantly, states must have an

**Table 23-5. Strategic Highway Safety Plan Requirements**

| Process and Content | Participants | Eligible Funding Projects |
|---|---|---|
| • Use different types of crash data.<br>• Establish crash data systems to identify problems and analyze countermeasures.<br>• Address engineering, management, operations, education, enforcement, and emergency medical services elements.<br>• Identify hazardous locations, sections, and elements; and establish criteria that indicate relative crash severity of these locations.<br>• Adopt strategic and performance-based goals that address the broad spectrum of safety improvements (including behavioral improvements), focus resources on the areas of greatest need, and coordinate with other highway safety programs.<br>• Advance the state's capabilities for traffic records data collection, analysis, and integration with other sources of safety data; include information on all public roads.<br>• Consider the results of state, regional, and local transportation and highway safety planning processes.<br>• Set priorities for corrective action on high-hazard locations, segments, and elements.<br>• Identify opportunities for preventing the development of new hazardous locations.<br>• Establish an evaluation process to assess the results achieved by the HSIPs.<br>• Produce a program of projects that is consistent with the STIP.<br>• Seek approval of the governor or the appropriate state agency. | • State DOT.<br>• State Highway Safety Office.<br>• Regional transportation planning organizations and MPOs.<br>• Operators of major modes of transportation.<br>• State and local traffic enforcement officials.<br>• State persons responsible for administering the federal rail-grade crossing program.<br>• Operation Lifesaver.<br>• State MCSAP administrators.<br>• State motor vehicle administrators.<br>• Major state and local stakeholders. | • Intersection safety improvements.<br>• Pavement and shoulder widening (including passing lanes).<br>• Rumble strips or other warning devices not affecting bicyclists.<br>• Devices that improve the safety of pedestrians and the disabled.<br>• Skid-resistant surfaces at intersections or high-crash locations.<br>• Bicycle or pedestrian safety or the safety of the disabled.<br>• Hazard elimination at railroad crossings (including separations).<br>• Rail-highway grade crossings (including protective devices).<br>• Traffic enforcement at a rail-highway grade crossing.<br>• Traffic calming features.<br>• Roadside obstacles elimination.<br>• Highway signage or pavement markings.<br>• Priority control system at signalized intersections for emergency vehicles.<br>• Traffic control or other warning devices at high-crash locations.<br>• Collection and analysis of crash data.<br>• Planning emergency communications.<br>• Work zones operational improvements or traffic enforcement activities.<br>• Guardrail installation.<br>• Barriers and crash attenuators.<br>• Structures or other measures to eliminate or reduce accidents involving wildlife.<br>• Installation, maintenance, and construction of signs at pedestrian/bicycle crossings and in school zones.<br>• Construction and operational improvements on high-risk rural roads.<br>• Improvement projects on any public roadway or publicly owned bicycle or pedestrian pathway or trail. |

Source: Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users, Section 148 from Public Law 109-59, Title 6, U.S. Code.

SHSP in place to take advantage of new and expanded safety funding programs. Similarly, the new and expanded dedicated funding programs for safety (Safe Routes to School, Rural Roads, and the like) required that infrastructure investments funded through them be coordinated with enforcement and/or educational strategies.

Some of the specific, safety-related requirements of SAFETEA-LU required states to:

- Consider the results of state, regional, or local transportation and highway safety planning processes.
- Have in place a crash data system with the ability to perform safety problem identification and countermeasure analysis on all public roads. SAFETEA-LU also required states to advance their capabilities for traffic records data collection, analysis, and integration with other sources of safety data.
- Analyze and make effective use of state, regional, or local crash data.
- Develop and implement an SHSP after consultation with a wide range of stakeholders, including governor's highway safety representatives, MPOs, representatives of major transportation modes, traffic enforcement officials, Operation Lifesaver representatives, motor carrier safety program representatives, and motor vehicle administration agencies.
- Adopt strategic and performance goals that address traffic safety(including behavioral and infrastructure problems and opportunities) on all public roads; the goals must focus resources on areas of greatest need and be coordinated with other state highway safety programs.
- Develop an SHSP that addresses engineering, management, operation, education, enforcement, and emergency services elements (including integrated, interoperable emergency communications) of highway safety as key factors in evaluating highway projects. The HSIP was still the means of funding such strategies.
- Determine priorities for the correction of hazardous road locations, sections, and elements (including railway-highway crossing improvements) as identified through crash data analysis.

***Moving Ahead for Progress in the 21st Century Act (2012)***

One of the key provisions of the Moving Ahead for Progress in the 21st Century Act (MAP-21) was the introduction of performance-based planning and decision making into state and regional investment decisions. According to the law, states would set targets for the number of serious injuries and fatalities, and the per-vehicle miles of travel rate for both. If progress toward its safety targets is not made, the state will have to devote a certain portion of its formula funding to the safety program and submit an annual implementation plan on how the state will make progress to meet performance targets. MAP-21 also required states to incorporate strategies focused on older drivers and pedestrians, if fatalities and injuries per capita for those groups increased. [FHWA, 2012] Regular updates of a state's SHSP were required, and there had to be a clear linkage shown between behavioral safety programs (for example, funding of seat belt compliance) and the SHSP.

For transit, the Federal Transit Administration (FTA) was required to issue a National Public Transportation Safety Plan, which was to include safety performance criteria for all modes of public transportation, and minimum safety performance standards for vehicles not regulated by other federal agencies. Each FTA grantee was also required to have a comprehensive agency safety plan that, at a minimum, included methods for identifying and evaluating safety risks, strategies to minimize exposure to hazards and unsafe conditions, a staff safety training program, and performance targets for safety performance criteria and state of good repair standards established in the national safety plan. MAP-21 also required the FTA to establish a system to monitor and manage public transportation assets to improve safety and increase reliability and performance.

All FTA grantees were required to develop transit asset management plans that included, at a minimum, current capital asset inventories and condition assessments, and investment prioritization. Transit agencies were also required to establish and use an asset management system to develop their capital asset inventories and condition assessments, and report on the condition of their system as a whole, with descriptions of the change in condition since the last report (see chapter 8 on transportation asset management).

This evolution in federal safety legislation was accompanied by varying terms to describe the process of considering safety in agency planning and decision making. A variety of terms have been used over the past several decades, such as Safety Conscious Planning [Herbel, 2001] and Safety Integration. Following the passage of SAFETEA-LU,

the term Transportation Safety Planning began to include not only the traditional transportation planning process, but also the development of the SHSPs. Transportation Safety Planning (TSP) is used consistently in this chapter to describe a process, carried out through development of the SHSP, whereby safety is explicitly addressed in transportation planning.

## IV. LAYING THE GROUNDWORK FOR TRANSPORTATION SAFETY PLANNING

Safety needs to play a larger, more prominent role in planning decision making. This will help bridge a gap existing between the engineering side of safety project implementation and other more behavioral components of the overall safety program. States normally disperse safety-related responsibilities among multiple functional agencies. For example, programs that address substance abuse are not administered by state DOTs, but normally by agencies focused on health and human services. In addition, to get substance-impaired drivers off the road requires coordination among enforcement (housed in other local, state, and tribal agencies), the court system (yet another agency), and the agencies providing treatment. Cross-agency coordination is much more complicated to resolve than intra-agency coordination, and includes issues such as diverse missions, data inconsistencies, different budget cycles, and restrictions on funding eligibilities.

It is the planning process that prioritizes projects, thus establishing the overall direction of a state's or region's investment program. In almost every case, road projects have been designed and implemented independently from other safety countermeasures, such as enforcement and education. The planning process addresses a variety of issues that are important to state and local decision makers such as congestion, freight, safety, transit, air quality, system preservation, and the like. Often, safety is part of the initial goals formulation and visioning component of this planning process, but is then not incorporated systematically in subsequent steps. There are a number of reasons why this is so. These include a lack of data demonstrating the safety problem and inadequate tools and techniques to evaluate safety alternatives—for example, how do transportation planners predict safety problem areas 25 years in the future?

Successful integration of safety concerns into the transportation planning process, and ultimately into the decision-making process, requires a change in the orientation and business processes of transportation organizations. There are a number of possible ways to accomplish this, one being the creation of an "umbrella" office that coordinates safety activity in all parts of the organization. Other key elements of this strategy are training and increasing the accessibility of safety data across the organization.

Currently, most state DOTs and regional planning organizations identify and prioritize high-crash locations and implement appropriate solutions as resources become available. However, this is a *reactive* approach. TSP turns this around through a process that has several characteristics:

- TSP is a *proactive* approach in that it is designed not only to address high-crash locations, but also to prevent problems before they happen.
- It is *leadership-driven* and has commitment from upper-level management as well as resources dedicated for its development and implementation. Strong and committed leadership is a prerequisite for effective safety planning. Experience shows that a safety champion is necessary to keep the process moving forward. It takes a person—preferably full-time—to identify and provide items such as data, research, and other information; plan agendas; facilitate and document meetings and decisions; track progress; and address challenges.
- It is a *collaborative* process that brings together the DOT, MPOs, rural planning agencies, regional councils, transit agencies, highway safety practitioners and advocates, motor carrier safety professionals, emergency response, and law enforcement. Elected officials, the public, and other professional communities also need to be engaged in the process. At the state level, TSP includes the state DOT, the governor's representative for highway safety, the state director of motor carrier safety, persons responsible for administering the hazard elimination and rail-grade crossing safety provisions, state and local law enforcement, and other state and local safety stakeholders. At a local level, TSP engages local decision makers and elected officials who are already making decisions about the local transportation system through the metropolitan or statewide transportation planning processes.
- It is *data-driven* in that data are used to identify current problems and seek appropriate solutions. Data-driven approaches provide documentation of a safety problem in the planning phase and provide the evidence

needed to develop a more responsive and effective solution in the design and implementation phase of a project.

- It is a *comprehensive* approach because it includes all aspects of transportation safety—engineering, education, public awareness, enforcement, and emergency medical services. It goes beyond the traditional *hot spot* analysis and looks at corridors and systemwide assessments. It is also multimodal and incorporates strategies related to transit and nonmotorized vehicle users, such as pedestrians and bicyclists.
- Effective TSP focuses on *implementation* from the very beginning of the process because many of the strategies it considers require careful consideration of the steps needed for successful implementation. As an amalgamated process, TSP joins together the hard side (infrastructure) of safety with the soft side (behavioral) to develop a more comprehensive set of strategies benefiting from established decision-making frameworks and processes.

## V. INCORPORATING SAFETY INTO TRANSPORTATION PLANNING

Figure 1-1 (see chapter 1) presented a generic transportation planning process used here to describe how safety can be considered in each step of the planning process. In particular, safety concerns can be incorporated into the following major steps:

- Step 1: Establish multidisciplinary coordination with transportation and safety stakeholders.
- Step 2: Incorporate safety into the vision, goals, and objectives.
- Step 3: Develop safety performance measures and targets.
- Step 4: Collect and analyze crash data.
- Step 5: Analyze and evaluate transportation safety.
- Step 6: Make safety a decision factor.
- Step 7: Include safety in planning programs and documents.

See NCHRP Report 546 [Washington et al., 2006] for more detail on each of these steps. A brief summary of each step is presented in the following sections.

### A. Establish Multidisciplinary Coordination with Transportation and Safety Stakeholders

Improving the safety of the transportation system requires the participation and involvement of many different groups and organizations. In particular, a partnership is needed between the safety and transportation planning communities to support a continued focus on safety in transportation planning. Safety experts and modal experts who address safety in their jobs can make key contributions to the consideration of safety in planning documents.

There is no single recipe for successful collaboration in safety planning. Given different institutional structures, histories of agency interaction, and political influence found in most states and metropolitan areas, this is not surprising. However, there are examples from around the world where such partnerships have been successful. For example, a study of the safety efforts in the State of Victoria, Australia, found that the following institutional factors enabled the state agencies to reduce road fatalities dramatically:

- A history of success with interventions based on legislation and enforcement helped create a political willingness to act.
- Strong relationships existed between the traffic-safety research community and policy makers in each of the government agencies, facilitating evidence-based planning and target setting.
- These relationships have not only helped create sound data sets but also, more importantly, a climate in which the scientific evaluations of interventions are routine.

- Extensive public education on traffic safety was instrumental in creating a climate of community concern for road safety and support for effective interventions.
- The media historically were supportive of effective interventions, which further facilitated political willingness to act. [Washington et al., 2006]

Although Victoria has a different governmental structure than other comparable governmental units, these lessons of success deserve strong consideration in almost any governmental structure. As noted by Herbel and Waldhem [2014], some of the opportunities to foster multidisciplinary collaboration include "establishing a transportation safety committee; creating an ad hoc safety committee to meet during an update of the long-range transportation plan or during project selection; appointing safety representatives to established committees, such as a technical advisory committee or a bicycles-and-pedestrians committee; and identifying and including safety experts in discrete planning activities, such as corridor plans."

See TCRP Report 106 , *From Handshake to Compact: Guidance to Foster Collaborative, Multimodal Decision-Making*, for further guidance on success factors for collaboration efforts. [Campbell et al., 2005]

## B. Incorporate Safety into the Vision, Goals, and Objectives

Why is visioning important? If safety is not in the vision/mission statements of the agencies responsible for transportation and safety, then it will not likely be reflected later in the process. Every planning process, not just transportation, begins with some form of visioning. What are the desired characteristics of the community in the future? How does transportation fit into this vision? A vision might be nothing more than a generalized statement of desired end states, but it provides guidance for the rest of the planning process.

Recently, in many countries, a "toward zero deaths" vision has been adopted by national, state, and provincial governments. As noted by a coalition of U.S. national transportation organizations, "the National Strategy vision is a highway system free of fatalities through a sustained and even accelerated decline in transportation-related deaths and injuries. Safety organizations and professionals embracing this vision agree to aggressively work toward an intermediate goal specific to their jurisdiction or the safety issue on which they focus." [Toward Zero Deaths, 2014]

**Vision Statement Examples**

"The new OTP elevates the standing of safety issues to better reflect ODOT's position that Safety is our number one priority. The upshot is that the OTC has taken a dramatic step to infuse safety discussions at all levels of management of the transportation system. Weaving safety systems into the very fabric of Oregon's transportation systems going forward is the challenge." [Oregon DOT, 2011]

"The mission of Cheyenne's TSMP is to eliminate preventable traffic-related deaths and injuries . . . ." [Cheyenne MPO, 2008]

"To reach destination zero deaths on roadways." [South Central Planning and Development Commission, 2013]

"Zero Deaths – Zero Injuries." [Maricopa Association of Governments, 2015]

The process of developing a vision statement, which usually includes many different stakeholders, is an important opportunity to explain the importance of safety to key stakeholders and decision makers. Usually the data collection and analysis efforts to understand the problem, as discussed earlier, become part of the process of defining the safety vision.

There should be at least one goal, several objectives, and system performance measures that address safety in the transportation planning process. Performance measures are most often related to reduction in crashes, fatalities, and injuries, as well as the monetary savings associated with these reductions. Reductions in specific categories of crashes can be used as performance measures to measure the effectiveness of specific programs. For example, education and enforcement programs targeted toward impaired driving can be measured by reductions in the number of alcohol-related crashes and fatalities. It is extremely important to use performance measures to measure progress and challenge the notion that traffic crashes are unavoidable accidents. Some examples of goals, objectives, and performance measures follow.

In the latest update of the regional transportation plan, the Southeastern Michigan Council of Governments (SEMCOG), the metropolitan planning organization (MPO) for the Detroit region, identified a set of principles to guide development of the plan and subsequent actions. [SEMCOG, 2013] The safety principle was "Creating a Safer Transportation System," and subsequent actions were:

- Improve the safety of all users of all modes.
- Maintain a crash database for use in regional and local safety analysis.
- Focus on key emphasis areas derived from analysis and coordination with other agencies as an efficient way to improve safety.
- Identify and seek funding for improvements to transportation infrastructure to increase safety.
- Facilitate coordinated emergency responses through incident management planning.
- Incorporate future recommendations from the Regional Strategic Highway Safety Plan (SHSP) into the Regional Transportation Plan.
- Promote and coordinate programs that educate people about and market safety.
- Address safety needs of environmental justice population segments, including elderly or disabled people.
- Promote the use of and assist members with auditing services (e.g., road safety, walkable, bikeable) for reducing crashes using low-cost improvements.
- Support appropriate education and enforcement activities to improve safety. This includes building knowledge for necessary legislative initiatives, supporting relevant professional development for law enforcement staff, and educating members of the judicial branch of the consequences of frequently reducing charges.

In light of federal requirements linking transportation planning and the state's SHSP, more and more plans refer to the state's SHSP emphasis areas as the goals for the regional transportation plan. Thus, for example, in Seattle, the Puget Sound Regional Council (PSRC) stated in the latest plan update, "The region explicitly aligns its policies and program direction at the regional level with the state's Target Zero plan. The plan focuses on five key areas: (1) driver behaviors, (2) other users (pedestrians, bicyclists, motorcyclists, and freight), (3) roadway improvements, (4) emergency medical services, and (5) traffic management. The region supports the state's Target Zero goal, and will annually review available safety data for the central Puget Sound region and develop regional program direction that will best contribute to the state's overall goal." [PSRC, 2010]

Another example of this linkage between the SHSP and transportation planning comes from the Phoenix MPO, which explicitly shows how the transportation safety plan for the metropolitan area reinforces or depends on the state's safety plan. The MPO's plan then identifies numerous actions that can be taken by the region to improve transportation safety. Interestingly, the MPO safety plan also recommends:

> Encourage submittal of TIP projects that include safety elements, for improving safer access for all modes, by including safety as an explicit project evaluation criterion for all TIP projects that currently have evaluation criteria as a means of prioritizing a list of projects. Exceptions to this practice are those Transit Maintenance and Operations programs funded through the MAG TIP. [Maricopa Association of Governments, 2015]

In other words, safety should be considered in every project programmed by the MPO. With respect to the SHSP, it might be more opportune for MPOs to adopt those emphasis areas that are appropriate for the region.

Figure 23-4 illustrates a very important concept for integrating safety concerns into the planning and decision-making processes of a transportation agency. The figure comes from the Minnesota DOT (MnDOT), which is considered a national leader in performance-based planning. [MnDOT, 2003] As can be seen with respect to safety, targets that are linked to one another have been established at all levels of the DOT. This hierarchy is an important foundation for ensuring that plan recommendations are implemented and that those responsible for implementation are held accountable. Thus, for example, the state-level safety goal is to reduce fatalities. The district offices of MnDOT will contribute to this goal by reducing the number of high-crash locations. The business plans for the districts have a target of replacing road striping to make sure the stripes are visible to drivers. The operations units in

the districts will contribute to the overall safety goal by adjusting signal phasing at locations where crash records suggest modifications need to be made.

## C. Develop Safety Performance Measures and Targets

As noted in the earlier discussion on legislation, one of the major changes in transportation safety planning (and for that matter, all federally-supported planning) occurred in 2012 with MAP-21 when safety performance measures were required as part of the transportation planning and decision-making process, similar to what was shown in Figure 23-4. MAP-21 required state DOTs and MPOs to track four safety performance measures, including the number and rate (per 100,000 vehicle miles of travel) of fatalities and serious injuries. However, NHTSA and the Governors' Highway Safety Association (GHSA) developed their own required list of performance measures (that must be reported on by the state) that include 10 core outcome measures, one core behavior measure, and three activity measures. These measures are:

Core *outcome* measures—States will set goals and report progress on:

- Number of traffic fatalities (from Fatal Accident Reporting System—FARS): States are encouraged to report three-year or five-year moving averages as appropriate (when annual counts are sufficiently small that random fluctuations may obscure trends). This comment applies to all fatality measures.
- Number of serious injuries in traffic crashes (state crash data files).
- Fatalities/VMT (FARS, FHWA): States should set a goal for total fatalities/VMT; states should report both rural and urban fatalities/VMT as well as total fatalities/VMT.
- Number of unrestrained passenger vehicle occupant fatalities, all seat positions (FARS).
- Number of fatalities in crashes involving a driver or motorcycle operator with a blood alcohol concentration (BAC) of 0.08 and above (FARS).
- Number of speeding-related fatalities (FARS).
- Number of motorcyclist fatalities (FARS).
- Number of unhelmeted motorcyclist fatalities (FARS).
- Number of drivers age 20 or younger involved in fatal crashes (FARS).
- Number of pedestrian fatalities (FARS).

Core *behavior* measure—States will set goals and report progress on:

- Observed seat belt use for passenger vehicles, front seat outboard occupants (survey).

*Activity* measures—States will report progress on:

- Number of seat belt citations issued during grant-funded enforcement activities (grant activity reporting).
- Number of impaired driving arrests made during grant-funded enforcement activities (grant activity reporting).
- Number of speeding citations issued during grant-funded enforcement activities (grant activity reporting).

Table 23-6 lists potential performance measures that could be considered for many different types of safety problems. Additional information on how safety performance measures can be used in transportation safety planning is found in Herbel et al. [2008].

Two examples of MPO safety performance measures are found in Houston, Texas, and Washoe County, Nevada. The Houston-Galveston Area Council (H-GAC), the MPO for the Houston metropolitan area, identified transportation safety as its number one plan goal. [HGAC, 2014] The corresponding performance measures included: the number of traffic crashes per 100 million annual vehicle miles traveled (VMT), bus accidents per 100,000 vehicle miles, transit rail accidents per 100,000 vehicle miles, rail accidents at public railroad crossings, rate of bicycle accidents per 100 million VMT, and rate of pedestrian accidents per 100 VMT.

The Regional Transportation Commission in Washoe County, Nevada, has emphasized transportation safety in its transportation plan for many years. [RTC, 2014a] As noted in its *2035 Regional Transportation Plan*, "planning and building a safe multi-modal transportation system for the travelling public is the most critical goal of the RTC. Safety is involved in all types of transportation: driving, walking, cycling, and riding transit. RTC engages in innovative planning and data analysis, public education, interdisciplinary collaboration, operations, and design, with the purposeful goal of reducing the number of crashes and injuries in Washoe County." [RTC, 2014b] The performance measures identified for monitoring progress toward this goal were: (1) preventable transit accidents per 100,000 miles of service, (2) number of crashes and number of crashes per VMT, (3) number of serious injuries per VMT, (4) number of fatalities and number of fatalities per VMT, (5) miles of bicycle lanes added and percent of the Bicycle Pedestrian Master Plan completed (because providing designated space for bicyclists is an important element of multimodal safety), (6) miles of sidewalk added or enhanced, and (7) percent of the Americans with Disabilities Act (ADA) Transition Plan completed. In addition, the plan established targets for each performance measure:

- Preventable transit accidents: 0 (ongoing).
- Number of crashes and crashes per VMT: Reduce by 50 percent by 2020.
- Number of serious injuries: Reduce by 50 percent by 2020.
- Number of fatalities and fatalities per VMT: 0; Reduce by 50 percent by 2020.
- Miles of bicycle lanes and percent completion of plan: 3–7 percent of plan implemented per year.
- Miles of sidewalk and percent of plan completed: 3–7 percent of plan implemented per year. [RTC, 2014c]

## D. Collect and Analyze Crash Data

The safety problem in a particular jurisdiction can be defined in many different ways and, in reality, it is often a combination of many factors. Examining crash data serves as a point of departure for understanding and articulating safety issues. This is usually an iterative process that begins by looking at the overall number of crashes with special attention to severity—for example, fatalities and disabling injuries. The next step is often to establish crash rates or the number of crashes using an exposure measure such as VMT, number of vehicles entering an intersection, and the like. This step leads to the identification of high-crash locations, road segments, and/or corridors (often referred to as "hot spot" analysis).

An alternative approach to site-specific analysis is referred to as a "systemic approach to safety." The FHWA definition of a systemic approach is one that takes a "broader view and looks at risk across an entire roadway system. A system-based approach acknowledges crashes alone are not always sufficient to determine what countermeasures to implement, particularly on low volume local and rural roadways where crash densities are lower, and in many urban areas particularly those where there are conflicts between vehicles and vulnerable road users (pedestrians, bicyclists, and motorcyclists)." This approach, in essence, relies on the identification of risk factors that could possibly result in crashes. For example, the existence of different types of medians; horizontal curvature, delineation, or advance warning devices; horizontal curves and tangent speed differential; roadside or edge hazard ratings (potentially including side slope design); and driveway density could be indicators of high-risk locations on the road network. Over time, a transportation agency could work to remove or improve the road characteristics that lead to this risk. FHWA has developed a tool that can be used to conduct systemic safety planning (see http://safety.fhwa.dot.gov/systemic/resources.htm#tool).

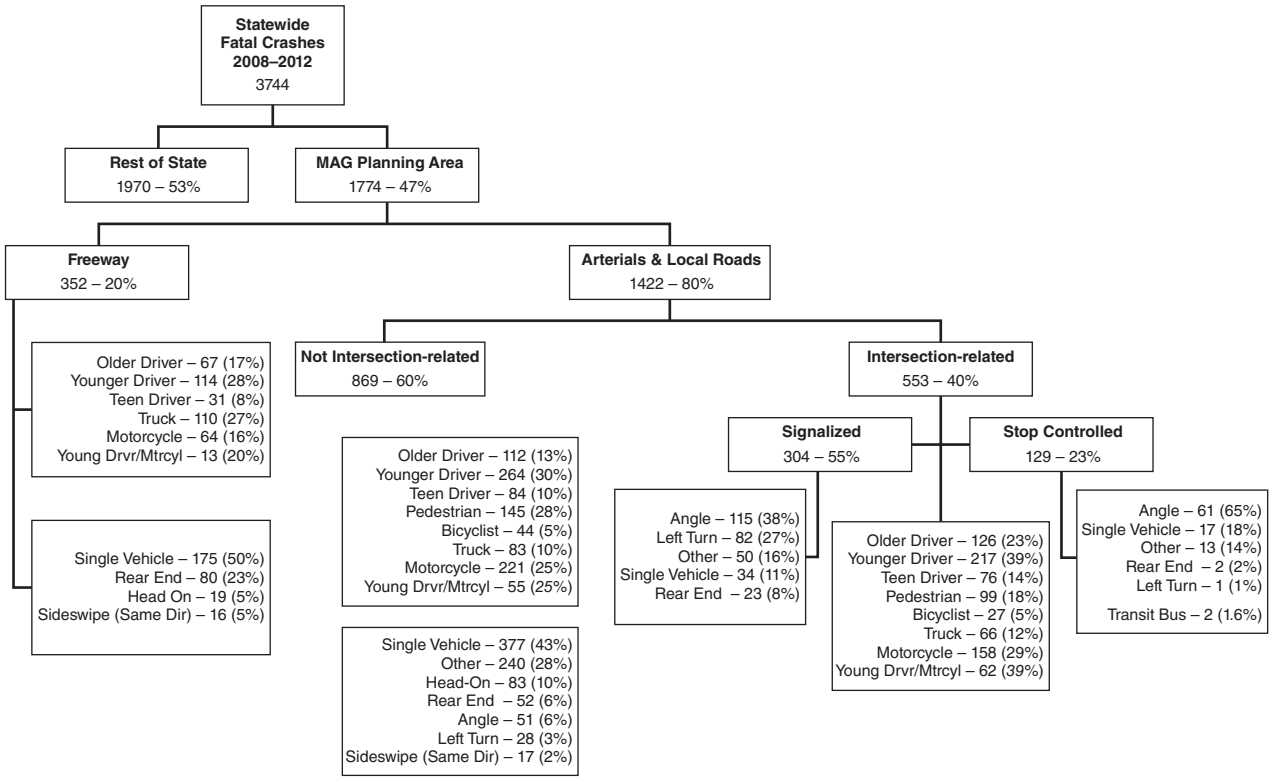
| Table 23-6. Possible Performance Measures for Safety-Related Planning |
|---|
| **Crash Count-Related Performance Measures:** |
| • Number of total reported accidents.<br>• Number of fatalities.<br>• Number of incapacitating injury crashes.<br>• Number of non-incapacitating injury crashes.<br>• Number of injury crashes.<br>• Number of property damage crashes.<br>• Number of crashes under specific conditions (e.g., head-on, rear-end, sideswipe, angle, rollover, red-light running, run off road, pedestrians, bicycles, motorcycles, school-related, railroad crossing–related, rural, urban, intersection-related, day, night, time of day, wet, ice, snow, etc.).<br>• Crashes in work zones.<br>• Crashes by age, gender, ethnicity. |
| **Normalized Accident Rate Performance Measures:** |
| • Crashes per VMT, PMT.<br>• Crashes per capita or per 100,000 population.<br>• Fatality rate per 1,000 MVMT.<br>• Pedestrian fatality rate per 100,000 population.<br>• Bicycle fatality rate per 100,000 population.<br>• Commercial vehicle crash rate per 100 MVMT.<br>• Crashes per licensed driver.<br>• Crashes per entering vehicle (intersections).<br>• Crashes per unit time (month, year, etc.). |
| **Unit Costs and Cost-Effectiveness:** |
| • Cost per event.<br>• Dollars for DUI enforcement versus alcohol-related crashes.<br>• Dollars for clear zone improvements versus injuries for run-off-road crashes.<br>• Cost per activity.<br>• Dollars per DUI-involved officer.<br>• Dollars per clear zone object removed/protected.<br>• Monetary value of crash reduction. |
| **Alcohol- and Drug-Related Crashes:** |
| • Number of 15- to 20-year-old drivers with BACs 0.02 or higher involved in fatal and injury traffic crashes.<br>• Number of young drivers ages 16 to 21 involved in DWI/drug-related crashes.<br>• Number of male drivers ages 16 to 34 involved in DWI/drug-related crashes. |

(*continued*)

| Table 23-6. (*Continued*) |
|---|
| **Other Performance Measures:** |
| • Crash rates by driver.<br>• Crashes by age per 10,000 licensed drivers in the age group.<br>• Number of crash-involved drivers by age.<br>• Gender of crash-involved drivers.<br>• Speed as a contributing factor.<br>• Restraint use by crash-involved drivers.<br>• Restraint use of all drivers.<br>• Restraint use of nondrivers.<br>• Child safety seat use (use/nonuse and correct use).<br>• EMS response times.<br>• Cell phone use.<br>• Enforcement citations (speeding, aggressive driving, traffic violations, etc.). |

For the hot spot analysis, once the high-crash locations are identified, analysts begin looking for contributing factors such as roadway condition, driver demographics (age, gender, and others), environmental conditions (time of day, day of week, month of the year, weather conditions, and the like), behavioral characteristics (alcohol involvement and safety belt use), and type of vehicle involved (including passenger vehicles, large trucks, and motorcycles). Figure 23-5 shows an example of the safety challenges facing the Phoenix metropolitan area, prepared by the Maricopa Association of Governments (MAG), the region's metropolitan planning organization. [MAG, 2015] A regional crash database,

**Figure 23-5. Crash Tree of Fatal Crashes in the Phoenix Planning Area, 2008–2012**

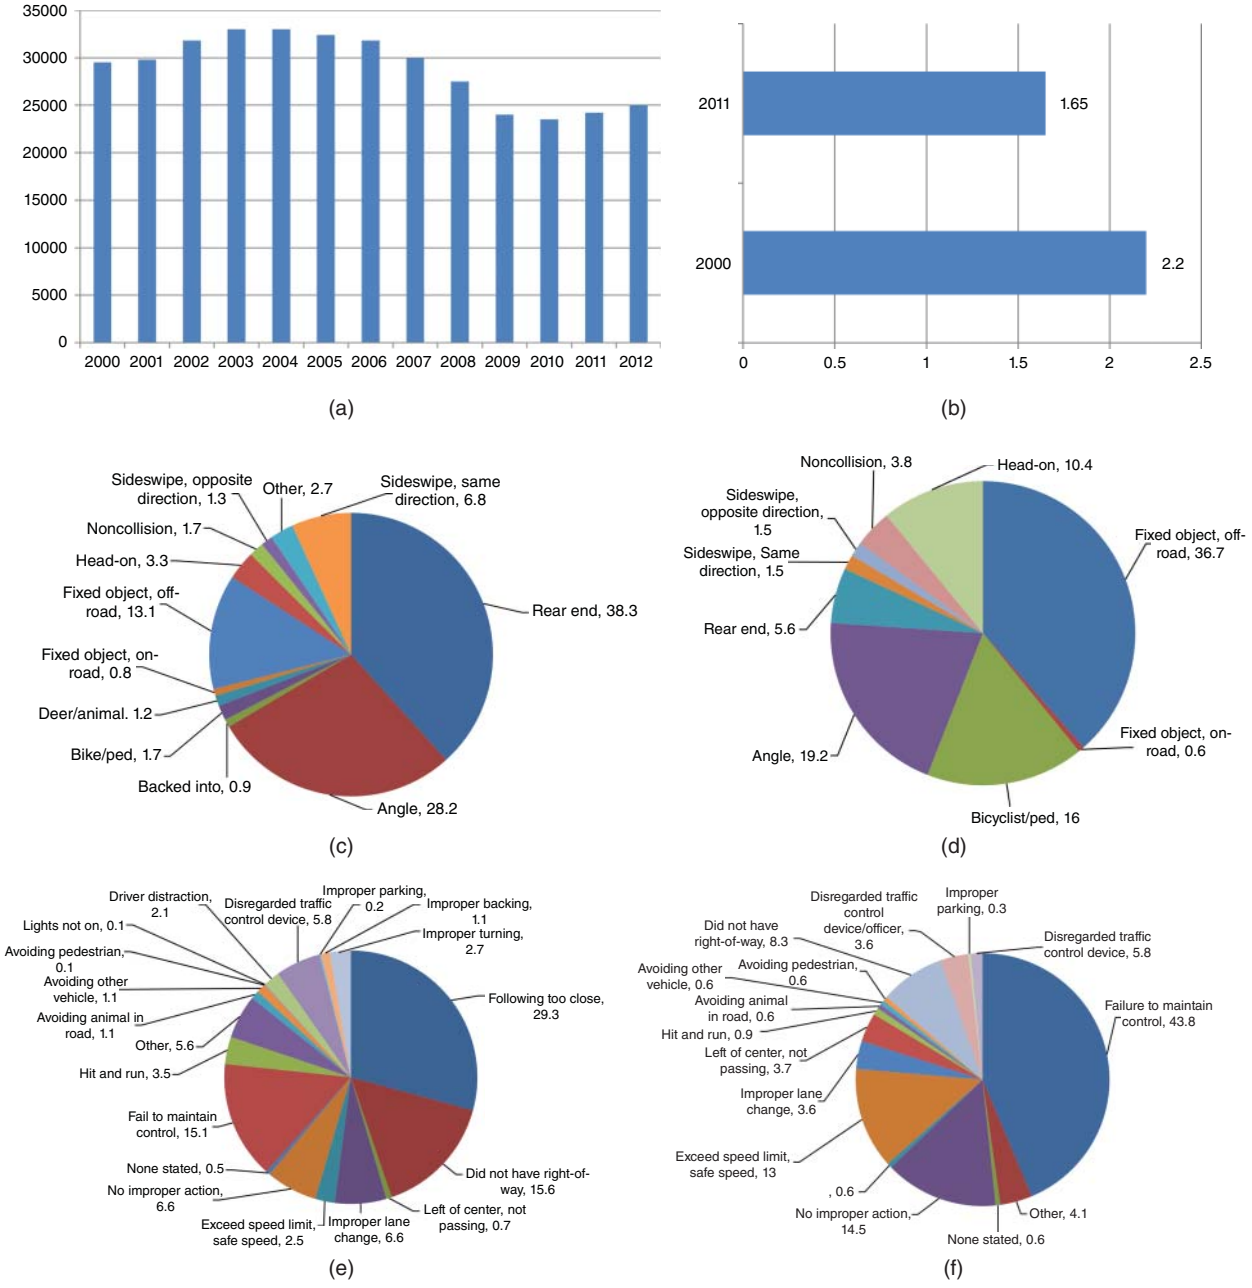


Source: MAG, 2015

called the Regional Transportation Safety Information Management System (RTSIMS), was used to summarize the crash data, with the primary data coming from the state department of transportation's crash database. MAG also compared crash statistics and safety spending among different cities that planners considered to be peers.

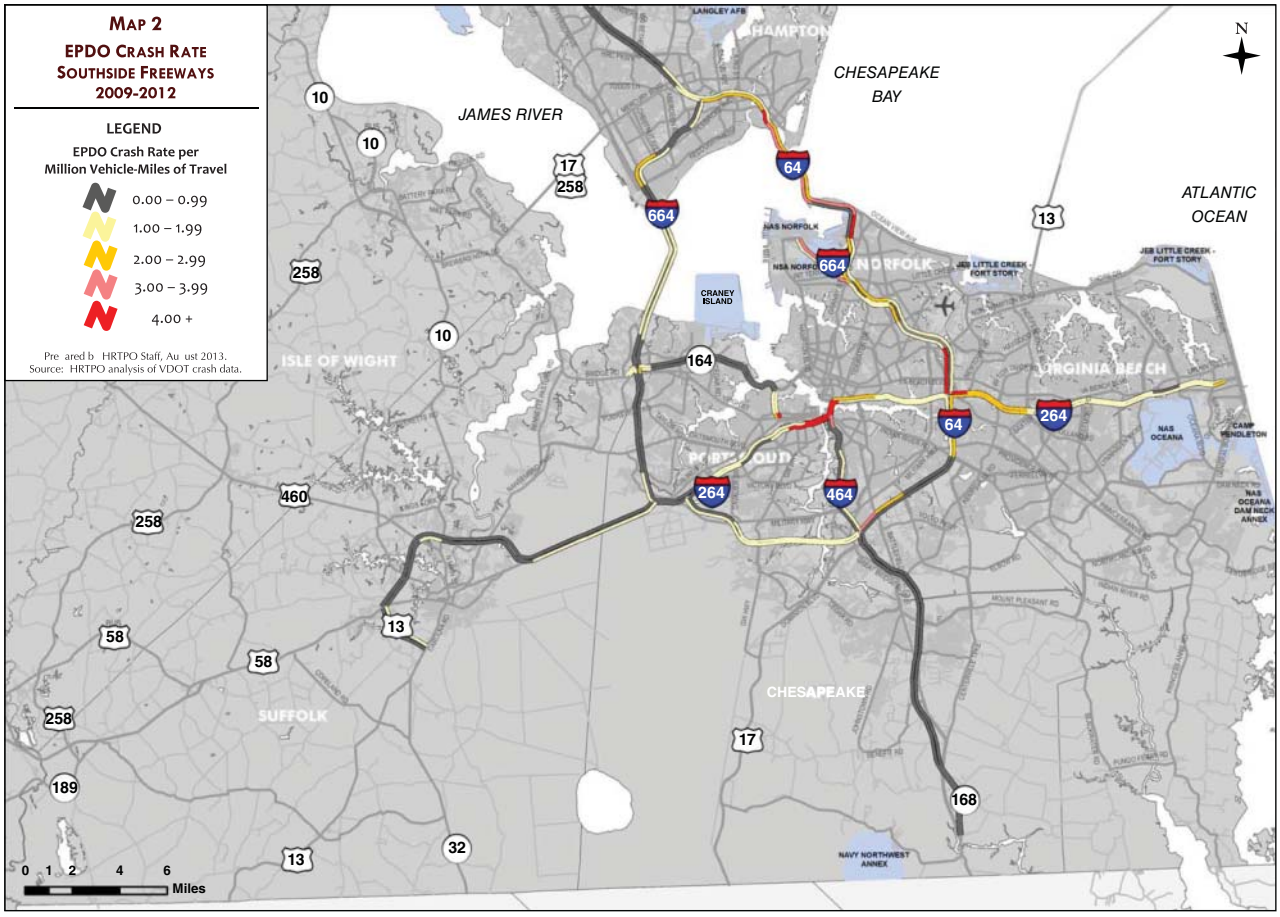
The Hampton Roads Transportation Planning Organization, the MPO for the Hampton Roads (Virginia) metropolitan area, also analyzed the safety characteristics of its region. [HRTPO, 2013] Figures 23-6 and 23-7 show the types of data and information that were part of this analysis. Based on the analysis of such data, the HRTPO concluded that, "Most fatal crashes in the Hampton Roads area are primarily caused by a small number of factors, including drivers traveling under the influence of alcohol and speeding. Many fatal crashes involve more than one of these factors, such

**Figure 23-6. Portraying the Safety Problem in Hampton Roads, VA: (a) Annual Crashes, 2000–2012; (b) Crash Rate (per 100 million vehicle miles traveled), 2000–2011; (c) Crashes by Cause, Percent, 2010–2012; (d) Fatal Crashes by Cause, Percent, 2010–2012; (e) Hampton Road Crashes by Primary Driver Action, 2010–2012; (f) Fatal Crashes by Primary Driver Action, 2010–2012.**



Source: HRTPO, 2013

**Figure 23-7. Portraying the Crash Rate on Key Highways in Hampton Roads, Virginia**



Source: HRTPO, 2013

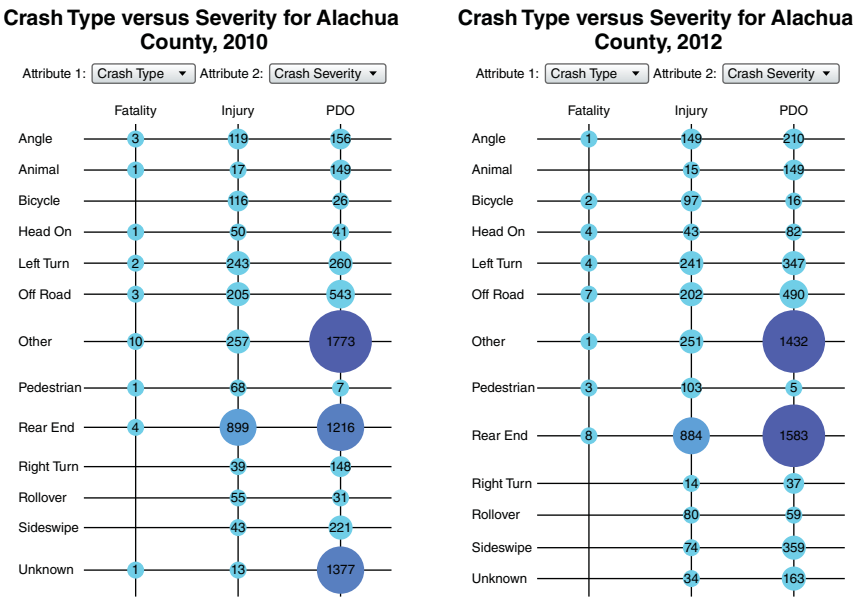
as drivers traveling at a high rate of speed, under the influence, and not wearing safety belts. The number of fatalities involving motorcycle users, bicyclists, and pedestrians is also highly overrepresented compared to their amount of travel." [HRTPO, 2013]

By presenting the data to show the overall safety picture and to identify the most important contributing factors, transportation and safety stakeholders can develop programs and strategies targeting the most important causal factors of crashes—for example, enforcement and education strategies aimed at impaired or distracted drivers.

Educating the public and elected officials is critical to the success of any safety program. In many cases, this is not an easy task because truly effective strategies for reducing fatalities and serious crashes often focus on changing traveler behavior, something that is very difficult to do. In addition, although data such as that shown in Figures 23-6 and 23-7 are important for transportation and safety professionals, they can become overwhelming to elected officials and the general public. In such cases, and where appropriate, safety planning needs to define the problems in understandable and simple terms. (Note: Safety projects that are education-based as well as enforcement projects are found in the Highway Safety Plan and funded as part of the Section 402 program.)

Figure 23-8 from Gainesville, Florida, illustrates one way of showing in very simple terms the types of crashes that are of most importance to a county. Another possible strategy is to compare the societal costs of safety and congestion. For example, the Texas Transportation Institute (TTI) annually produces the list of the most congested cities in the United States. This list receives a great deal of attention, with many public officials declaring that government needs to do better. In most cities, however, the societal costs are far greater for crashes than for congestion. Meyer [2005] estimated the societal cost of crashes in Atlanta in 2001 to be $3.3 billion, compared to congestion costs of $2.0 billion. Comparisons in Kansas City, Missouri, and Houston, Texas, showed similar relationships. By using a measure that can be easily grasped and compared with the benefits of other programs (which is done only for public consumption), officials can gain an understanding of the magnitude of the problem they are facing.

**Figure 23-8. Illustration of Crash Type versus Severity for Alachua County, Florida, 2010 and 2012**



Source: Metropolitan Transportation Planning Organization for the Gainesville Urbanized Area, 2013

Another strategy for educating elected officials and the public has been to compare crime statistics with those of crashes. Using this method, known as the *crash clock*, jurisdictions typically find that the number of deaths and injuries associated with traffic crashes is greater than for crime. While aggregate measures can be an effective way of summarizing the safety problem, other methods can be effective as well, such as illustrating the consequences of impaired driving or focusing on how individual lives can be affected by unsafe driving.

Data are used to identify high-crash corridors, road segments, and hot spots; analyze impacts; evaluate outcomes; and prioritize and select programs and projects. Monitoring performance data can also lead to mid-project implementation corrections to ensure the most effective use of resources. The most obvious data used are those gathered as a result of a crash, but other types may also be beneficial, such as enforcement data (citations, convictions, experience, and observations), roadway (location) data, exposure data, survey data from elected/appointed officials and the public, road safety audits/assessments, and research data.

Safety planning is a data-driven process; however, data quality and availability are often serious challenges to the planning process for the following reasons.

- *Underreporting*—Minor crashes are seldom reported and investigated.
- *Local road*—State DOTs collect crash data on state highways and other major roads; local roads are often underrepresented in the crash database.
- *Field coding*—Filling out police accident reports is often not a priority at crash scenes; officers are focused on treating the injured and returning traffic flow to normal.
- *Reference system*—Different geo-referencing systems are often used for locating crashes, even among jurisdictions in the same state.
- *Inconsistencies*—State databases contain different variables and are presented in different formats.
- *Timeliness*—Data are often two to three years old, if not more.
- *Accessibility*. Some states and regions do not share data with other agencies for fear of liability.

Knowledge of collection methods, methods used to summarize and report the data, quality control procedures, and statistical accuracy is helpful in determining what data and analytical methods should be used.

**Table 23-7. Ranking by MPOs and State DOTs of Most-Used Sources of Data for Safety-Related Transportation Planning**

| Data Sources | MPO | State DOT |
|---|---|---|
| Vehicle crashes | 1 | 1 |
| Vehicle miles traveled | 2 | 4 |
| Roadway inventories | 3 | 2 |
| Injury/fatality | 4 | 3 |
| Pedestrian crashes/injuries | 5 | 6 |
| Bicycle crashes/injuries | 6 | 7 |
| Property damage crash | 7 | 8 |
| Air quality/emissions | 8 | 9 |
| Air transport crashes | 9 | 10 (tie) |
| Water navigation crashes | 10 (tie) | 15 |
| Transit/paratransit incidents | 10 (tie) | 10 (tie) |
| Safety belt/restraint use data | 12 | 14 |
| Emergency medical response | 13 | 16 |
| DUIs | 14 | 12 |
| Rail crashes | 15 | 5 |
| Accident investigation | 16 | 13 |

A number of data sources are useful for transportation safety planning. Table 23-7, for example, shows the results of a survey of state DOTs and MPOs on the types of safety-related data that are most often used in transportation planning. Not surprisingly, vehicle crash data, roadway inventories, and injury data are some of the most important data items for both state DOTs and MPOs. The minimum data elements for safety planning should include crash location, contributing factors, driver characteristics and histories, the manner of collision, crash severity, type of vehicle, exposure data (vehicle miles of travel), and use of safety devices. These data elements are usually found in the following multiple locations:

*Congestion Management System/Process Data.* Transportation management areas (TMAs) are required to maintain a congestion management process (CMP) to evaluate transportation investment alternatives. In many states the CMP includes an extensive database of roadway classification, geometry, and overall traffic volumes and flows. This can be useful in calculating crash rates or for other safety analysis.

*Crowd Sourcing.* Modern communication technologies allow planners to reach a large number of individuals through smart phone apps. Crowd sourcing is a process of asking as many individuals as are part of the network where safety problems exist. The input is not statistically significant given the bias in terms of the narrow sample of the population who responds, but it does provide some sense of where safety planners might want to look.

*Driver History.* Driver histories are recorded for all licensed drivers and unlicensed drivers involved in a crash. The files contain information on the demographics and license status/restrictions, convictions, and sometimes the driver history of crashes. These data can be used to scope and target programs on specific types of driver violations (such as DUI, speeding, red light running, and the like). These data provide only a recent snapshot because data on convictions and crashes (if present at all) are often purged after some time period.

*Fatality Analysis Reporting System (FARS).* FARS was established in 1975 to collect fatal crash data. The system contains high-quality data on all vehicles and occupants involved in fatal crashes. Queries can be run online and archival files can be obtained. City and county codes for each county in the United States are recorded in the database.

*Police Crash Reports.* The first step in any safety analysis is examining police-reported crashes. Crash reports provide a range of data concerning the specifics of the incident, contributing conditions, and status of those involved. Many states have adopted uniform report formats for all crashes reported in the state; others still have police

agency–specific forms. One of the new technologies that could improve the quality and timing of these data is the use of computers, global positioning systems, and uplink capabilities in the police car at the crash site.

*Population Census Files.* The U.S. Census Bureau maintains files on gender, age, and ethnicity within political subdivisions. The data can also be used as denominator or exposure data, particularly for identifying road-user problems, for example, young drivers as a percent of the population in comparison to percent of fatal and injury crashes.

*Roadway Speeds and Operating Performance.* Many states and most major metropolitan areas have traffic operations centers that provide 24-hour surveillance of road operations. Most of these centers use video or imaging technology that permits the collection of real-time data. These data can be used to identify traffic conditions when crashes occur, and, when archived, the data can provide historical information on changing road performance on the network.

*Roadway Inventory, State Highway System*. In most states, the state DOT maintains a roadway inventory database that contains data on road segments (for example, number of lanes and shoulder width and type). A limited number of states have curve and grade information or an intersection/interchange inventory. Many states use video logging for collecting such data, which could also be used to conduct a safety audit along state routes. A federally required Highway Performance Monitoring System (HPMS), which collects more complete inventory data on sample sections on the state's road network, could be used to get a good understanding of the safety performance of different types of roads, especially if the sample size is expanded to include more sample segments.

*Truck Crash Statistics.* The Motor Carrier Management Information System (MCMIS) is managed by the Federal Motor Carrier Safety Administration (FMCSA) with data fed into it by state agencies and motor carriers. It is the most comprehensive truck safety database in the United States. The files contain information on vehicle registration, crashes, roadside inspections, compliance with federal regulations, and enforcement actions.

*Regional Travel Demand Model Data.* MPOs located in air-quality nonattainment areas must conduct an air-quality conformity analysis to show that investments in their plans do not deteriorate air quality. This is usually accomplished through modeling efforts, resulting in systemwide estimates of current and future traffic volumes and flows. Data could be used to calculate crash rates or for other safety analysis.

*Roadway Inventory, Local Jurisdictions.* Local road inventory databases are generally less complete than state databases, with the data elements often maintained by different departments (public works, traffic, and maintenance). Local jurisdictions sometimes have supplemental data on sidewalk and crosswalks, bike paths, and bus stops. The linkage between these data and the road inventory data, however, is often not well established. Table 23-8, from the *Highway Safety Manual*, shows the type of inventory data used to predict the safety benefits of any particular countermeasure implemented in a project. As can be seen, there are a lot of factors (and thus a lot of data) that can be included in a safety analysis. See also Lefler [2014] for a more detailed discussion of the data collection activities of local agencies.

*Traffic Volumes.* Traffic counts are usually available at many locations on the state highway system, from which average annual daily traffic (AADT) is estimated. The collection of the data for AADT estimates occurs at permanent (full-time) counters and *short counts* are done on a two- to three-year cycle. Truck percentages and volumes are usually included in this database, but they are generally based on fewer actual counts, so the data are not as extensive. In many states, the number of permanent count stations is limited by budget considerations. There is a similar problem with short counts, which may vary from year to year. Many agencies supplement counts with volume estimates from either their travel-demand models or the roadway inventory databases previously described. While the quality and accuracy of these estimates vary widely, they do provide analysts with a more complete set of data on the roadway system.

*Vehicle Registration Data.* Registration data are recorded for every vehicle licensed in a state. The file includes information on owners, vehicle types, vehicle identification numbers (VINs), and a variety of other data related to the vehicle. Vehicle registration data are sometimes used as the *denominator* or *exposure* data, for example, the number of crashes per total number of registered vehicles.

*Other Safety Data.* Some enforcement agencies maintain ticket citation (as opposed to conviction) data. These data may be useful for problem identification and for monitoring the degree to which the courts are following through with penalties and fines. Speed surveys are maintained by some state and local agencies, and observed occupant restraint (shoulder belt) use data have been collected by all states since 1998. NHTSA publishes year-by-year comparisons for each state, but the data only represent daytime and front-seat belt use. Land-use data can also be used to identify places with special safety concerns, such as near schools, senior centers, or parks.

### Beware the Caveats

- Reporting thresholds may differ by jurisdiction, so exercise caution when combining state and local data.
- Analyzing FARS data only produces small, unrepresentative samples, and there are problems associated with combining crash/vehicle/person variables.
- Be careful of multiyear analysis of Motor Carrier Management Information System data. The data are much improved since 2004.
- Remember, AADT is an estimate, not an actual count for most roadway segments. Local jurisdictions often do not have AADT, only intersection turning counts.
- Beware of using vehicle registration data as a measure of exposure because it does not include annual mileage per vehicle, and the odometer may contain errors.
- Speed surveys are generally taken at special locations and do not constitute a random sample for that roadway type or jurisdiction.

Although it is important to continually improve data quality and availability, progress in enhancing transportation safety can occur even without good data. For example, if crash hot spots data are not available, interviews with law enforcement officers, truckers, local engineers, and others may reveal crash problems based on observation and experience. A growing number of jurisdictions are using road safety audits or assessments to proactively identify potential safety problems and develop effective countermeasures and solution strategies. See FHWA's road safety audit website at http://safety.fhwa.dot.gov/rsa/ for further information on road safety audits.

In addition, in the United States, states are required by NHTSA to develop a strategic traffic records improvement plan and must have a traffic records coordinating committee (TRCC). The plans are a key step in integrating the various sources of data for improvement and maintenance.

**Best Practice:** The Houston/Galveston Area Council (H-GAC) and the Southeast Michigan Council of Governments (SEMCOG) are able to integrate, analyze, and display their crash data. They disaggregate by type of crash and safety issue, for example: truck/pedestrian/bicyclist safety, location (hot spots), impaired driving, and the like. They also (1) provide safety services, such as training for local engineers, mayors and judges, and school education programs, (2) form partnerships with government at all levels, the private sector, nonprofits, and community groups, (3) review project designs for safety, and (4) encourage their constituents to include safety in designs.

Figures 23-9 and 23-10 show how data analysis can be used to assess the safety characteristics of a project moving through the project development process. [Kentucky Transportation Cabinet, undated]. Planning at the project level and in particular as part of an environmental impact statement is usually more site-specific, and the analysis of crash

reductions is related to specific project characteristics. [FHWA, 2011] As noted in chapter 4 on environmental analysis, a first step in conducting a formal environmental impact study is to describe the purpose and need for the project in the corridor. This needs statement, in many cases, would likely include safety as a motivation for project improvements. Table 23-9 shows the different ways safety could be included in an environmental analysis needs statement.

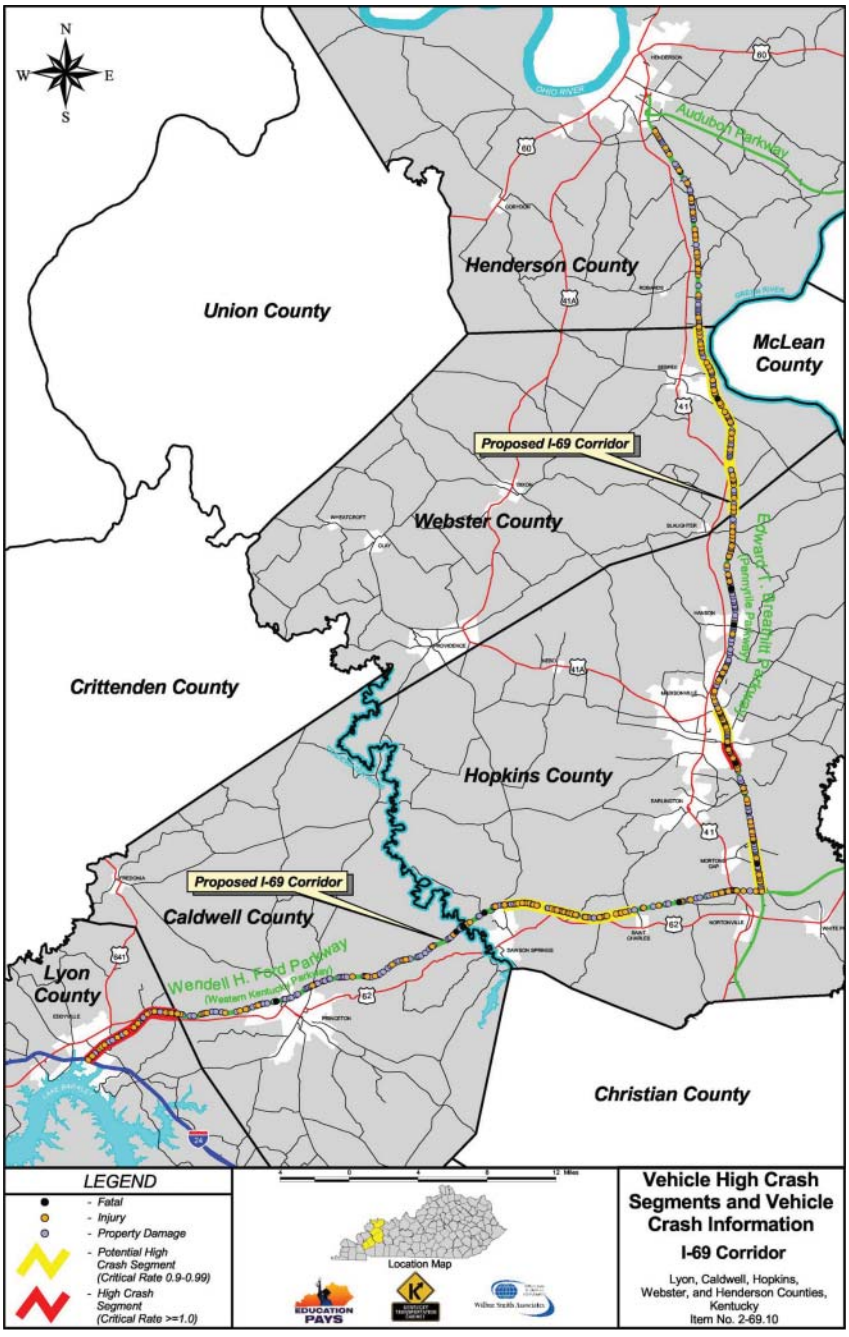
## E. Analyze and Evaluate Transportation Safety

### *1. Identify Safety Countermeasures or Projects*

Safety projects can be standalone projects that are undertaken specifically to "fix" a safety problem (for which there are several federal and state funding programs), or more commonly, safety-oriented actions can be taken as part of any project to enhance its safety characteristics. Safe movement of people and vehicles is the most important criterion for facility design, and every design manual used by transportation engineers begins by talking about safety. A large number of projects are eligible for federal funding. For example, the following types of projects are eligible for Highway Safety Improvement Program (HSIP) funding from the U.S. federal government:

- Intersection safety improvements.
- Pavement and shoulder widening.
- Installation of rumble strips or other warning devices.
- Improving user awareness of and compliance with intersection and interchange traffic control devices.

**Figure 23-10. Crash Types for High- and Potentially High-Crash Segments, I-69, Kentucky**



Source: Kentucky Transportation Cabinet, undated

- Pedestrian and bicyclist safety improvements.
- Safety improvements for people with disabilities.
- Rail-roadway grade crossing safety improvements.
- Traffic calming features.
- Roadside hazard elimination.
- Installation, replacement, and improvement of highway signage and pavement markings.
- Emergency vehicle priority control.

| Table 23-9. Information and Data to Include in Purpose and Needs Statements for Safety-Focused Projects | |
|---|---|
| **Type of Information** | **Example Information to Consider for Inclusion** |
| Roadway performance | Comparison of roadway crash rates to expected crashes for similar facility types given traffic volumes to identify the existence of a safety problem (see *Highway Safety Manual* for analysis techniques). Crash rates for multiple types of road users. |
| Contributing crash factors | Analysis of crash history to indicate predominance of certain crash types. |
| Multimodal safety issues | Safety issues for specific types of road users, including pedestrians, bicyclists, freight vehicles, and transit vehicles. |
| Public perceptions | Safety issues raised by the public as being of concern. |
| Results of road safety audits (RSAs) | RSA results indicating any findings regarding deficiencies/opportunities for improving safety performance. |

- Installation of traffic control or other warning devices at high-crash locations.
- Transportation safety planning.
- Work zone safety.
- Installation of guardrails, barriers, and crash attenuators.
- Improvements for high-risk rural roads.
- Roadway geometric improvements.
- Road safety audits.
- Truck parking facilities.
- Any systemic safety improvements.

For transit, most safety measures focus on making the design of rider/vehicle interfaces safe as well as the operating strategies. Thus, one can find in the literature great attention to how one safely designs the movement of pedestrians near transit lines (see [Korve et al., 2001; Cleghorn et al., 2009; Fitzpatrick et al., 2015; and Roberts et al., 2015]).

It is beyond the scope of this chapter to describe all of the safety actions that can be considered as part of the transportation planning process. Every state has an SHSP, which provides a description of the types of engineering and behavioral actions the state is taking to reduce crashes. In addition, the following references are useful for providing some sense of what types of projects and actions can be considered to improve transportation safety.

### *2. Analysis*

The use of analysis tools for assessing the consequences of different actions is the core technical component of the transportation planning process. However, analyzing the relative effectiveness of alternative safety strategies is challenging because of the difficulties associated with crash data, as discussed in the preceding section. In addition, many of the strategies that target changing driver behavior do not have much evidence of their effectiveness in actually changing behavior. It is difficult, therefore, to estimate the benefits of specific actions. The literature does provide some guidance on the effectiveness of several of the safety strategies that planners and safety officials might want to consider. Specifically, the NCHRP 500 report series of guidebooks [Transportation Research Board, 2004–2006] and the Governors' Highway Safety Association's (GHSA) *Countermeasures that Work* [2013] provide approaches for estimating the effectiveness of different countermeasures. Research is currently under way to develop crash modification factors (CMFs) for engineering and behavioral strategies. [Bonneson and Zimmerman, 2006; Harkey et al., 2008] The FHWA supports a website that introduces crash modification factors (http://safety.fhwa.dot.gov/tools/crf/resources/cmfs/ ), as well as a crash modification factor clearinghouse website (http://safety.fhwa.dot.gov/tools/crf/resources/).

Currently, the most common approach to analyzing the safety benefits of road projects is to estimate the decrease in the number of crashes (by type) that will occur because of the countermeasure, and then use benefit/cost analysis to determine the relative desirability among the alternatives being considered (see chapter 7 on evaluation techniques). Two methods are used to estimate crash reduction. The first uses safety performance functions (SPFs) that have been developed based on historical data and their correlation to road characteristics. An example of a safety performance function for freeways in Virginia is Equation 23-1: [Hampton Roads Transportation Planning Organization, 2014]

$$\text{Predicted crash frequency per year per direction} = e^{\alpha}\, x\, (\textit{One Direction AADT})^{\beta} \times \textit{Segment Length} \qquad (23\text{-}1)$$

The values of $\alpha$ and $\beta$ are estimated based on historical data on crashes on freeways in the Commonwealth of Virginia. In this case the crash frequency can be estimated as a function of the AADT and segment length.

Another example of a safety performance function from the *Highway Safety Manual* [AASHTO, 2010] focusing on vehicle-pedestrian crash frequency per year is shown in Equation 23-2. In this case,

$$\begin{aligned} &\textit{Predicted vehicle-pedestrian crash frequency per year} \\ &\quad = \exp[\mathrm{a} + (\mathrm{b}\, x\, \ln(\textit{Total AADT})) \\ &\quad + \left(\mathrm{c}\, x\, \ln\left(\frac{\textit{Minor AADT}}{\textit{Major AADT}}\right)\right) + (\mathrm{d}\, x\, \ln(\textit{PedVol})) \\ &\quad + (\mathrm{e}\, x\, n_{lanes})] \end{aligned} \qquad (23\text{-}2)$$

Total AADT is the sum of the major and minor road AADT; PedVol is the total daily number of pedestrians crossing the intersection, and $n_{lanes}$ is the maximum number of lanes a pedestrian would have to cross the intersection. The coefficients, that is, a, b, c, d, and e, are found in the *Highway Safety Manual.*

The second method for estimating crash reduction uses Crash Modification Factors (CMFs). A CMF is "a multiplicative factor used to compute the expected number of crashes after implementing a given countermeasure at a specific site." For example, a CMF of 0.70 means 70 percent of the existing crashes will result from implementing a countermeasure. For many high-crash locations, more than one treatment may be implemented at the same time. Table 23-10 shows an example of crash reduction factors used by the Denver Regional Council of Governments (DRCOG) for determining the benefits of projects to be considered for the regional transportation improvement program (TIP).

| Table 23-10. Crash Reduction Factors, Denver Regional Council of Governments | | |
|---|---|---|
| **Improvement Characteristics** | **Percentage Reduction in Relevant Crashes (if applicable crash locations)** | **Example Relevant Crash Types** |
| **Intersections** | | |
| New traffic signal | 20% | Right-angle, turns |
| Upgrade traffic signal (heads) | 20% | Rear-end, red light run |
| Add new approach turn lanes (either left or right) | 25% | Rear-end |
| Add accel/decel lane | 25% | Rear-end, sideswipe |
| Convert to roundabout | 40% | Right-angle |
| Convert to interchange | 40% | Right-angle |
| Increase turn radii | 15% | Turn crashes |
| **Railroad** | | |
| Automatic gate | 75% | Vehicle-train |
| Grade separation | 100% | Vehicle-train, rear-end |
| **Roadside/Bridges** | | |
| Guardrail-install/upgrade | 60% fatal, 40% injury | Run off road |
| Shoulder widening/addition | 20% | Run off road, overtake ped/bike |
| Bridge widening | 40% | Bridge |
| Remove fixed objects | 50% fatal, 15% injury | Fixed object |
| Separated bicycle/pedestrian path | 80% | Overtake ped/bike |
| **Roadways** | | |
| Curve reconstruction | 50% | Run off road, head-on |
| Vertical realignment | 45% | Head-on, limited sight |
| Median barriers | 60% fatal, 10% injury | Head-on |
| Raised median | 40% | Turn crashes, turn-related rear-ends |
| Climbing/passing lane | 15% | Passing, rear-end |
| Lane widening | 20% | Sideswipe (multilane) |
| Ramp geometric reconstruction | 25% | Ramp |
| Widen from 2-lane to 4-lane road | 30% | Rear-end, head-on |
| Continuous center-left turn lane | 30% | Rear-end |
| Shoulder rumble strips | 80% | Run off road |
| Centerline rumble strips | 25% | Head-on, sideswipe |
| Pave shoulder to full width | 10% | Run off road |
| **Other** | | |
| Lighting improvement | 90% | Night-time crashes |
| Close median opening | 30% | Turn crashes |

Notes:

[1]Crash reduction factors are for TIP project scoring guidance only.

[2]The factors are not meant to imply precise predictions of eliminated crashes.

[3]Rates should be applied only to specific applicable sites within the project area.

[4]Rates should only be applied to relevant crash types and crash directions addressed by the improvement.

[5]Do not double-count similar improvement types or eliminated crashes.

[6]Crash reduction factors may be applied to improvement and crash types not shown on this table; however, applicant must provide justifying documentation.

Source: DRCOG, 2015

In addition to the simple reduction factors and performance functions described, many other analysis tools can be used for conducting a safety study. Some tools are oriented toward hot spots that are more specific than corridor-based models and can be used to analyze the impact of geometric deficiencies. Many of these have been developed for use in project design, but could also be used for planning purposes. Some of these tools include interactive- design software packages that allow project designers to modify designs for improved safety purposes (such as the Interactive Highway Safety Design Model [IHSDM], the Roadside Safety Analysis Program, SafeNET, and SafetyAnalyst). Others represent expert systems that provide a data analysis capability and lead the user to identify possible countermeasures, such as the Pedestrian and Bicycle Accident Analysis Tool (PBCAT) and the Pedestrian Safety Guide and Countermeasures (PEDSAFE). All of these tools are described in greater detail in Washington et al. [2006] and Booz, Allen, and Hamilton [2013].

With respect to safety analysis for transit, the FTA has developed uniform guidance on how safety performance and analysis should be undertaken. Since the passage of MAP-21, FTA has been encouraging transit agencies to develop a safety management system (SMS). An SMS is defined as "an organized approach to managing safety, including the necessary organizational structures, safety goals and performance targets, responsibilities and authorities, accountabilities, policies, and procedures for integrating safety into day-to-day operations." [Ahmed, 2011] It is a process that heavily depends on the use of performance measures. With respect to construction of major facilities receiving federal funds, a recipient agency must develop a Safety and Security Management Plan (SSMP) that addresses such things as: (1) project management commitment and philosophy toward safety and security, (2) integration of safety and security into the project development process, (3) assignment of organizational safety and security responsibilities for the project, (4) safety and security analysis and hazard and vulnerability management processes, (5) development of safety and security design criteria, (6) a process for ensuring qualified operations and maintenance personnel, and (7) construction safety and security management activities.

Ideally, all of the analysis tools described in this section would work hand in hand with travel demand forecasting models and be able to forecast future safety characteristics of the transportation system. However, such tools are only now becoming available. NCHRP Report 546 describes one of the first attempts to develop a traffic analysis zone-based prediction tool for use with a travel demand model. The ITS Deployment Analysis System (IDAS) developed for FHWA provides sketch planning-level forecasts of the safety benefits of various ITS and operational deployments. [FHWA, 2013b] It is hoped that these emerging tools will one day enable safety to be considered explicitly in the outputs of the transportation forecasting process. [Washington et al., 2006]

Evaluation synthesizes the results of an analysis to determine the overall benefits and costs of each alternative. Evaluation leads to identifying the most cost-effective set of projects and strategies prioritized based on measures that indicate which factors are most important when implementing a safety program. Evaluation can also lead to other planning outcomes, such as further studies, proposed regulations, and additional policies that affect traveler behavior. For safety to be considered seriously as part of the decision-making process, safety-oriented criteria must be part of the evaluation criteria used to assess the relative benefits and costs of various actions.

## F. Make Safety a Decision Factor

Safety should receive strong consideration when developing STIPs and metropolitan-level TIPs. As illustrated in the following material, several methods are available for doing so. [Park et al., 2016] One of the largest challenges is to prioritize funding for noninfrastructure projects that are not part of the TIP or STIP, such as projects for enforcement and safety education. Often, these are found in separate safety programs.

There are many examples of how safety can be incorporated into the evaluation and prioritization process. The two most common approaches include conducting a benefit/cost analysis and assigning points to each project according to the safety benefits that are likely to accrue. The benefit/cost analysis is straightforward and simply evaluates each project by assigning monetary value to the reduction in crashes expected due to the implementation of countermeasures (the benefits) as compared to the expected capital costs of the project. Chapter 7 describes how this analysis is conducted correctly.

The second approach entails assigning points, out of a total sum of points available to a project, for the project's safety benefits. For example, each project might earn 100 points corresponding to how well it achieves the different

planning goals. Of these 100 points, a maximum of 20 points could be allocated for safety benefits. Each project being considered for the TIP could have a maximum of 20 percent of its ranking due to safety benefits. The following examples illustrate the range in approaches available for establishing project priorities that include safety.

In Denver, DRCOG uses the information from its analysis to assign points to each safety project. Table 23-11 shows the number of points that can be allocated to roadway operational improvement and roadway widening projects, and the possible points for safety benefits. A similar set of criteria was used for new bicycle and pedestrian facilities, although the safety factor was estimated differently (see Table 23-12).

**Table 23-11. Assigning Safety Points for Highway Projects, Denver, Colorado**

**Roadway Operational Improvements**

| Evaluation Criteria | Points | Scoring |
|---|---|---|
| Congestion | 0–12 | Up to 12 points based on the current degree of congestion (V/C ratio) on the existing roadway. |
| RTP Emphasis Corridors | 0–3 | 3 points to projects on emphasized freeways or major regional arterials.<br>2 points to projects on emphasized principal arterial segments. |
| Crash Reduction (Safety) | 0–5 | Based on the project's estimated crash reduction and weighted crash rate, up to 5 points will be awarded. |
| Delay reduction | 0–12 | Based on the project's current estimated vehicle hours of travel (VHT) reduced during the AM peak hour plus the PM peak hour, 12 points will be awarded to projects reducing 200 VHT or more during the two peak hours; 0 points to projects reducing 20 VHT or less. |
| Cost-effectiveness | 0–10 | Based on the project's current estimated cost per vehicle hour of travel (VHT) reduced during the AM peak hour plus PM peak hour: 10 points will be awarded to projects with a cost per VHT reduced of $10,000 or less. |
| Transportation system management | 0–5 | 1 point will be awarded for such things as provision of raised, depressed, or barrier medians for the entire length of the project; access consolidation (driveways, side streets); signal interconnection; provision of ITS infrastructure; provision of infrastructure that implements an approved incident management plan. |
| Multimodal connectivity | 0–15 | Various points for such things as considering transit, pedestrians, bicyclists, and multimodal facilities. |
| Environmental justice | 0–3 | 3 points will be awarded if 75% or more of the project length is located within an RTP-defined environmental justice area. |
| Overmatch | 0–9 | Based on providing above the minimum 20 percent local funding match: 9 points will be awarded to projects with local match of 47 percent or more, 0 points to projects with the minimum 20 percent local match, with straight line interpolation between. |
| Project-related Metro Vision implementation and strategic corridor focus | 0–18 | Up to 18 points. |
| Sponsor-related Metro Vision implementation | 0–8 | Up to 8 points will be awarded for sponsor actions implementing Metro Vision. |
| Total | 100 | |

**Safety Points for Roadway Widening Projects**

| | Estimated # of Crashes Eliminated per Mile (3 Years) | | |
|---|---|---|---|
| **Weighted Crash Rate** | **0–5** | **6–15** | **16+** |
| **0–0.99** | 0 points | 2 points | 3 points |
| **1.0–2.99** | 1 | 3 | 4 |
| **3.00 +** | 2 | 3 | 5 |

Source: DRCOG, 2015

| Table 23-12. Assigning Safety Points for New Pedestrian/Bicycle Projects, Denver, Colorado | | |
|---|---|---|
| **Evaluation Criterion** | **Points** | **Scoring** |
| Safety | 0–10 (out of 100) | Projects will be evaluated on the anticipated improvement of existing safety problems to be made by building new facilities for nonmotorized travel. Three measures of safety improvement will be awarded:<br><br>*Relevant crash history*<br><br>Based on the number of documented injury accidents created by the interaction between motorized and nonmotorized traffic in the area to be affected by the proposed new facility; and occurring over the last 3-year period for which data is available.<br><br>1 point will be awarded for each applicable injury accident, up to a maximum of 5.<br><br>*Conflict factor*<br><br>If the existing facilities are roadways that allow interaction between motorized and nonmotorized traffic, and if the project will build new facilities for the nonmotorized traffic that eliminate or reduce the conflict factor, the project will earn safety points. Based on the speed limit on the existing facilities, up to 4 points will be awarded as follows:<br><br>1 point will be awarded if the existing speed limit is 30 MPH or less.<br><br>2 points will be awarded if the existing speed limit is 35 MPH.<br><br>3 points will be awarded if the existing speed limit is 40 MPH.<br><br>4 points will be awarded if the existing speed limit is 45 MPH or above.<br><br>*Facility lighting*<br><br>1 point will be awarded to projects that will provide ADA/AASHTO-compliant lighting to facilitate nonmotorized travel on the planned facilities, if no lighting is currently available on the existing roadway. |

Source: DRCOG, 2015

A process-oriented approach to prioritization is illustrated by an example from Minnesota. The Minnesota DOT (MnDOT) established numerous task teams whose job was to focus on the many different types of safety challenges facing the state and to consider different types of countermeasures. The teams identified 153 strategies that could potentially provide safety benefits to the state. The teams were asked to assign priorities to these 153 strategies; the rankings were tabulated, and the 153 strategies were pared down to 69 high-priority strategies. MnDOT then held a state workshop that included numerous safety stakeholders, who also voted on priority strategies. This resulted in further reducing the list to 52 strategies. These 52 strategies were presented to the top management team in MnDOT, which selected 15 strategies to implement the first year.

The approach adopted to evaluate and prioritize strategies will likely vary from location to location, depending on the availability of tools and history of using the approaches (see [Metropolitan Planning Council, undated] for a good overview of prioritization practices in the United States). Chapter 7 provides a more detailed discussion on evaluation approaches, including benefit/cost analysis, which is commonly used in safety planning.

## G. Include Safety in Planning Programs and Documents

Ongoing monitoring of the performance and condition of the transportation system feeds back into goals, objectives, and performance measures (see Figure 1-1 in chapter 1). The feedback loop becomes an important input into the next cycle of safety planning, as it not only provides a snapshot of performance at that particular point in time but can also inform decision makers about the experience with previously implemented actions. Monitoring should include the trends and absolute magnitudes of the transportation system safety characteristics.

When practicable, before-and-after studies should be conducted on implemented countermeasures for which very little benefit information is available (see, for example, [VicRoads, 2015]). Hauer [2002] provides a detailed methodology that defines target crashes to which the before-after study can be applied. The book also provides guidance on various versions of a before-after study, including the *naïve before-after study*, the *comparison group* method, the *multivariate* method, and the most advanced *Bayesian before-after method*. Such studies are critically important for developing a knowledge base that can be used in future consideration of different countermeasures. It is not clear at this point if the safety community would benefit from a single, consolidated knowledge base, or whether it will be adequate to tie together existing research sponsored by federal and state sources as well as independent organizations such as the Institute of Transportation Engineers and Society of Automotive Engineers.

Finally, safety should be included in agency efforts to adopt dashboard or tracking programs that present high-level agency performance measures designed for decision makers and the public. The programs are relatively new and are designed to both measure performance across the agency and communicate information on agency performance to the public. The challenge is to find meaningful measures of progress that are easy for the layperson to understand. Figure 23-11 shows a graphic from the Missouri DOT's tracker report that addresses recent trends in traffic fatalities and disabling injuries. Dedicating one to two pages of graphs to various safety measures enables agencies to quickly and effectively inform the public and decision makers about transportation safety trends and to put these trends in perspective.

## VI. THE *HIGHWAY SAFETY MANUAL* (HSM)

The transportation engineering profession has relied on the *Highway Capacity Manual* for decades as one of the definitive manuals on best practice. In 2010, the American Association of State Highway and Transportation Officials (AASHTO) produced the *Highway Safety Manual* (HSM), the first-of-its-kind manual for identifying and analyzing safety problems. [AASHTO, 2010, 2014] The uses of the HSM include:

- Identify sites with the most potential for crash frequency or severity reduction.
- Identify factors contributing to crashes, and associated potential countermeasures to address these issues.
- Evaluate the crash reduction benefits of implemented treatments.
- Conduct economic appraisals of improvements to prioritize projects.
- Calculate the effect of various design alternatives on crash frequency and severity.
- Estimate potential crash frequency and severity on highway networks, and the potential effects of transportation decisions on crashes. [FHWA, 2014]

It is beyond the scope of this chapter to replicate the material found in the HSM. However, Figure 23-12 shows how the manual is organized and logically flows from safety considerations in system planning to project planning and preliminary engineering to design and construction to operations and management. In the planning phase, the manual focuses on the procedures and approaches for identifying sites where safety countermeasures should be considered and prioritization of such countermeasures. At the project planning level, the manual presents approaches for identifying crash patterns for a particular project and methods to predict safety impacts of implemented countermeasures. Transportation planners should be fully aware of the methods and analysis approaches that are found in this important manual.

**Figure 23-12. Organization of the *Highway Safety Manual***

## VII. RELATIONSHIP BETWEEN TRANSPORTATION SAFETY PLANNING AND STRATEGIC HIGHWAY SAFETY PLANNING

Given the requirement for states to develop an SHSP, it is worthwhile to examine the relationship between this effort and the TSP process described in the previous sections. Both processes are based on a collaborative effort that (1) includes representatives from many different disciplines and interests, (2) uses data to identify high-crash locations, (3) analyzes and selects programs and projects that will improve the safety of the transportation system, (4) evaluates outcomes, and (5) is comprehensive and addresses the 4Es of safety—engineering, education, enforcement, and emergency medical services or emergency response.

TSP ensures that the major transportation planning products—the long-range plan, TIP, and STIP—explicitly address safety in the recommended policies, programs, and projects. Through the collaboration required in developing the SHSP, the TSP will hopefully influence the planning cultures of the other agencies as well. Safety considerations in the STIPs and TIPs become part of the SHSP along with the Highway Safety Plan, the HSIP, and the Motor Carrier Safety Plan. The idea is for the SHSP to serve as the umbrella document, and all other plans are expected to draw from it for their safety analyses and strategies.

Meanwhile, the SHSP provides a building block for the long-range transportation plan and, at the same time, safety policies contained in the plan are compatible with those in the SHSP. The SHSP will provide the information necessary to meet the transportation plan's safety goal, and safety-oriented projects/programs will be included in both the long-range plans and the STIPs/TIPs. In other words, transportation plans will build on and incorporate components of the SHSP and implement transportation planning priorities.

Some issues remain unclear—for example, whether SHSPs will address multimodal and systemwide planning issues, or whether they will focus simply on the road network. If they are initially focused on the roadway network, they may link to the transportation planning process only at the beginning stages, or they may also link to the process later at the project/program selection stage. Many states are focusing the SHSPs on multimodal, systemwide approaches, which is the intent of the requirement.

## VIII. LESSONS FROM THE INTERNATIONAL COMMUNITY

European and Australian safety programs have led the world in reducing the number of fatalities on the road network. Sweden, the Netherlands, and the United Kingdom have the lowest road crash death rates per capita in the world. Australia is not far behind and provides "a useful benchmark for America, partly because it is also a federation, but mostly because it is part of the 'new world' where urban form, regional development, and road transport developed more or less contemporaneously." [Washington et al., 2006] A case study from Victoria, Australia, shows what can be accomplished by focusing significant attention and resources on safety. From 1995 to 2004, "the number of persons killed in road crashes in the United States has increased by 2 percent in the last 10 years. In contrast, the number of persons killed decreased in Australia by more than 20 percent in the same period, with improvements in the rates of traffic safety two to three times greater than achieved in America." [Washington et al., 2006] The steps identified in this report that were necessary for developing a successful road safety program included:

- Find a "champion"—an individual or a group—who can help create political and community saliency.
- Introduce new measures of traffic safety performance. Total reliance upon deaths per unit road use is suboptimal. It implies that improvement in this rate is a sufficient goal and accepts that there is a "price" to be paid for mobility and that the greater the road use, the higher that price will be in total.
- Develop an evidence-based strategic plan with objective targets and effective accountability mechanisms.
- Harness all the key players and implement the plan in an integrated, effective manner. The issues to be addressed and the range of acceptable measures will require a partnership among many organizations.

Both the Europeans and Australians have targeted their safety strategies at changing driver behavior—for example, aggressive DUI programs, speed monitoring, and driver education. European research indicates, however, that further reductions in crash levels will require a change in the focus from driver behavior initiatives to actions that make it more difficult for a driver to have a crash in the first place—more specifically, prevention-oriented strategies through TSP.

Much of the transportation safety planning that occurs in other countries follows the same concepts and uses the same analysis approaches that are described in this chapter. For example, Table 23-13 from VicRoads in Australia, the transportation agency for the State of Victoria, shows the types of performance measures that are used by this agency to monitor progress toward safety goals. As seen, many of these measures are similar to what is found in any U.S. state. It is interesting to note some measures that are hardly ever seen in the United States. For example, "the number of people taking risks" and "the percent of people who feel safer" are two measures that are not found in U.S. practice.

**Table 23-13. Safety Performance Measures Used in Victoria, Australia**

| Indicator | Measures | Data Context |
|---|---|---|
| Casualty crash rating | • Risk using exposure, crash reduction factors, ANRAM or "Safe System" compliance.<br>• Frequency of conflict points. | Information Access |
| Fire risk | • Fire risk rating (fuel load). | Project specific |
| Frequency of casualty crashes | • Number of casualty crashes by location (intersection or road length).<br>• Number of casualty crashes by type (intersection, run off road, rollover).<br>• Number of casualty crashes by user (pedestrian, heavy vehicle, public transport).<br>• Number of casualty crashes per 100 million vehicle kms travelled. | Road Crash Information System (RCIS)/ Information Access |
| Frequency of people taking risks | • Number of people taking risks (visual count). | Project specific |
| Incident/hazard response times | • Average response time in minutes.<br>• Percent incidents attended or cleared within 15 minutes.<br>• Percent hazards managed within Road Management Plan response times. | Road operations<br>Project specific |
| Local trips made by walking and cycling | • Percent local trips made by walking and cycling.<br>• Number of road crossings within 20 meters of crossing facility. | Information Access<br>Project specific |
| Occupational Health and Safety risk | • Level of risk assessed using Safe Work Methods Statements. | Project specific |
| Patronage of rest areas | • Number of spaces at rest areas utilized by heavy vehicles during specified times. | Project specific |
| People feel safer | • Percent of people who feel safer.<br>• Percent of people using the crossing facility of the total crossing within 20 meters of facility.<br>• Safety complaints received. | Project specific |
| Risk of harm (non-crash) | • Level of water pollution (oil, heavy metals, and other chemicals).<br>• Number of complaints regarding water pollution. | Project specific |
| Severity of casualty crashes | • Number of fatality crashes and serious injury crashes by location (intersection or road length).<br>• Number of fatality crashes and serious injury crashes by types (intersection, run off the road, or rollover).<br>• Number of fatality crashes and serious injury crashes by user (pedestrian, heavy vehicle, public transport). | Road Crash Information System (RCIS)/Information Access (for vehicle kilometers travelled) |
| Severity of crash rating | • Risk using exposure, crash reduction factors, ANRAM, or "Safe System" compliance.<br>• Frequency of conflict points. | Project specific |

## IX. SUMMARY

Transportation safety is consistently listed as the most important goal of transportation agencies around the world. Yet, roadway-related fatalities in many countries continue to rise, and crashes involving drivers, passengers, pedestrians, and bicyclists remain one of the major causes of death in the world. Many countries, such as Australia, the United Kingdom, Sweden, and the Netherlands, have successfully reduced the number of fatalities and the incidence of crashes by means of aggressive enforcement, driver training, and education policies. In the United States, government programs have been in place for many years to focus resources on this serious problem, but much of this effort has focused on safety-specific programs rather than on ways to include safety in traditional transportation planning.

Transportation planners have a critical role to play in a state or region's safety program. They are involved in the initial steps for planning capital improvement programs at all levels (for example, state and MPO plans). Safety should be an explicit goal of the transportation planning process; thus, transportation planners need to strongly advocate examining safety from many different perspectives. Working with the safety community, integrating safety into the planning documents, and engaging planners in the development and implementation of the SHSP increases the likelihood that planners will encourage local officials to consider safety equally with other competing infrastructure projects and priorities.

Finally, planners have important expertise that can be applied to safety analysis. Planners routinely collect and analyze data, develop alternative solutions, evaluate the benefits and trade-offs among the proposed solutions, identify the most effective and efficient alternatives, evaluate project and program outcomes, and provide feedback to the ongoing planning process. Planners also bring expertise in public participation that can be used to engage a wider range of participants in the process, such as nonprofit safety organizations, the media, and the public. These skills bring great value to the safety planning process and to safety stakeholders, many of whom are not trained or experienced in the planning discipline.

Several keys lead to successful safety integration into the planning process:

- The safety community needs to become a stakeholder in the transportation planning process. Transportation agency safety experts and emergency response and law enforcement personnel are among those who must be at the table as funding criteria are set and projects approved. Achieving transportation safety goals is better served with the participation of safety personnel. Similarly, safety personnel must understand the approval process for transportation program dollars and know that many of these funds can be used to address their concerns.
- Improved analysis tools and processes are needed to analyze safety problems and document the benefits of safety improvements. Efforts are under way to varying degrees throughout the data chain, from collection of data in the field to data storage and processing at DOTs and MPOs, to the development of crash forecasting methodologies, to the integration of safety analysis into travel demand forecasting and simulation models.
- Institutional changes that bring safety concerns into all aspects of transportation planning and project development will likely be needed. These may involve organizational structure changes that bring planning and safety staff closer together or better education and training across agencies.

The ultimate goal is to make the transportation system safer and reduce the unacceptable number of deaths and injuries that occur annually. Policy makers have acknowledged through federal legislation that integration of safety into the planning process can help make this happen. However, it is the combined efforts of the transportation, safety, education, enforcement, and emergency services communities that will ultimately determine whether this goal will be achieved. There are no "silver bullets." The future requires bold, innovative, and comprehensive strategies designed and implemented through collaborative efforts among transportation planners, engineers, law enforcement, safety professionals and practitioners, and others. To make progress, it will be necessary in some cases to restructure organizational priorities and approaches.

## Acknowledgment

The original author expressed appreciation to Dan Krechmer, Cambridge Systematics Inc., for contributing to this chapter.

# Public Participation and Engagement[1]

## I. INTRODUCTION

Including public concerns in transportation planning has a long history in the United States and in many other countries. In the United States, many see the dawn of public engagement as the late 1960s, when there was significant public opposition to the construction of urban freeways in many cities (often called the "highway revolt"). With the increasing desire of public groups to be included in policy decisions affecting their lives, governments at all levels passed legislation to provide opportunities for public participation in planning and project development. The most noteworthy law in the United States was the National Environmental Policy Act (NEPA) of 1969 that required, among other things, public hearings for projects undergoing environmental impact analysis and review. Today, a substantial legislative history serves as the legal and regulatory foundation for citizen participation in transportation planning. Transportation planners need to understand these legal requirements to make sure the planning process and the products of that process satisfy legal requirements.

In addition to the legal perspective, however, providing opportunities for public participation in government-sponsored planning and infrastructure decision making simply makes sense in a democracy. This idea is well stated in the preamble to the Mid-America Regional Council (MARC) (Kansas City metropolitan area) Public Participation Plan.

> *"Public participation is based on the belief that people whose lives are affected by transportation planning and investment decisions have a right to be involved in the decision-making process and influence choices that are made. Directly engaging citizens in this process promotes successful problem solving, yields diverse voices and new ideas, and gives the public a sense of ownership of the developed solutions."*
>
> *[MARC, 2013]*

Public engagement is a two-way street. Not only do citizens learn about what is being planned for their community, but people also have the opportunity to influence these plans. This has never been more evident than in today's world where social media provides an ever-increasing variety of opportunities to stay in touch with what is happening in a community.

A definition of public participation is offered in the next section. The following section then reviews the U.S. federal laws and regulations that require public engagement in transportation planning and project development. The description of a public participation plan (PPP) is described next with attention given to PPP goals and objectives and the large number of strategies and tools that are available to transportation planners. This is followed by a section that looks at public engagement at the project development level. The final sections examine ways of assessing the effectiveness of public participation programs, and provide some "words of wisdom" to those wanting to improve the effectiveness of their program.

## II. WHAT IS THE PUBLIC PARTICIPATION PROCESS?

Every metropolitan planning organization (MPO) and state department of transportation (DOT) in the United States must have a public participation plan (PPP) that outlines the opportunities for public input in the development of the transportation plan as well as other mandated planning and project development processes (for example, an eminent

[1] This chapter was written by Michael D. Meyer, WSP/ Parsons Brinckerhoff

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

domain property taking to facilitate a municipal roadway project). (Note: some use the term "*public involvement plan* (PIP);" for purposes of this chapter the term public participation plan (PPP) will be used). Some definitions of public participation offered by state DOTs and MPOs include (see also, http://www.iap2.org):

> *"Public participation is the process by which interested and affected individuals, organizations, agencies, and government entities are consulted and included in the decision-making process."*
>
> *[DVRPC, 2007]*

> *"Public input provides transportation decision makers with community insights that illuminate the issues being considered. Community input is an important consideration along with technical data, analysis, and professional expertise in helping decision makers reach an informed decision."*
>
> *[Washington County Department of Land Use and Transportation, 2015]*

> *"The Broward MPO's policy on public participation is to create opportunities for all segments of the public to learn and provide feedback about issues and proposals under consideration, particularly those affected by the outcomes and/or those with special needs. This policy lays the foundation to ensure the public is a key participant in the planning and decision-making process."*
>
> *[Broward County MPO, 2015]*

> *"The Montana Department of Transportation will: 1) provide useful, timely information to the public throughout the development of projects, from planning, programming, and preliminary engineering approval through construction, operation, and maintenance; 2) proactively seek public comment and involvement in planning and project development, 3) facilitate open discussion of controversial issues, 4) respond to comments and suggestions, and 5) ensure public comments are fully considered so that useful ideas are incorporated into projects given availability of resources, policy constraints, and as appropriate."*
>
> *[Montana Department of Transportation, undated]*

> *"The importance of public involvement (to the Colorado Department of Transportation--CDOT) during the planning and programming processes is that it: 1) allows the public to provide valuable information to CDOT to help guide the planning and decision-making processes, 2) builds an ongoing relationship between CDOT and the public based on mutual trust, 3) increases community knowledge by providing citizens with new information, 4) encourages stakeholders to become actively involved in plan or program development, 5) provides feedback which helps CDOT understand areas where additional information is required or where misunderstandings exist, 6) identifies potential problems or plans that require an extra level of sensitivity and public education and 7) provides comments to better inform others who are not participating."*
>
> *[Colorado DOT, 2015]*

One of the best descriptions of public participation comes from the Metropolitan Transportation Commission (MTC) in the San Francisco Bay area, which adopted the following guiding principles for its public participation program. [MTC, 2015] The words emphasized (by the author) are found in many definitions of public participation.

- Public participation is a *dynamic* activity that requires *teamwork and commitment* at all levels of the MTC organization.
- One size does not fit all—input from *diverse perspectives* enhances the process.
- Effective public outreach and involvement requires *relationship building*—with local governments, stakeholders, and advisory groups.
- *Engaging interested persons* in "regional" transportation issues is challenging, yet possible, by making it *relevant*, *removing barriers* to participation, and *saying it simply*.
- An *open and transparent public participation process* empowers all communities to participate in the decision making that affects them. All communities matter!

For purposes of this chapter, public participation is defined as a process that openly and transparently provides opportunities for diverse perspectives in the planning and decision-making processes. Because it deals with human behavior, the process is necessarily dynamic and flexible. It relies on building relationships with key stakeholder groups in the community, as well as those often underrepresented in transportation decision making. Planners offer relevant and worthwhile opportunities for the public to voice their opinions, influence decisions, and be informed of how their input has been considered.

## A. Legislative and Regulatory Requirements

In the United States, federal and many state laws require public participation opportunities in transportation planning and decision making. Transportation planners need to be aware of all of the legal requirements that apply to public participation/outreach efforts in their jurisdiction. Many states and smaller locales have replicated federal public participation requirements in their own laws. Below is a discussion of the more relevant federal laws and regulations pertaining to public participation and engagement. Note these laws are relevant for both planning and project level planning, and typically become more relevant if the planning or project area context includes a population that may be protected by these laws.

### *1. Transportation Laws and Executive Orders*

*Fixing America's Surface Transportation (FAST) Act*. This law, passed in 2015, reaffirmed all previous transportation laws in requiring opportunities for the public and other stakeholders to participate in the transportation planning process. In particular, the law added public ports and certain private providers of transportation, including intercity bus operators and employer-based commuting programs, to the list of interested parties that an MPO must provide with reasonable opportunity to comment on the transportation plan.

*Moving Ahead for Progress in the 21st Century (MAP-21)*. This law, passed in 2012, contained specific language outlining federal requirements for public participation processes and procedures. MAP-21 required MPOs to provide everyone with a reasonable opportunity to comment on the transportation plan. Examples of people and groups who should be included in the public participation process are: citizens, affected public agencies, public transportation agency employees, freight shippers and carriers, private transportation providers, public transit riders, pedestrians, bicyclists, the disabled, and other interested parties.

*Civil Rights Act, Title VI*. Title VI of the Civil Rights Act of 1964 prohibits federal agencies and subrecipients of federal funds from discriminating on the basis of race, color, or national origin. Subsequent laws and Presidential Executive Orders have added handicap, sex, age, and income status to the nondiscrimination criteria.

*Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*. This executive order directed federal agencies to identify and address disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations. It also stipulated the need to provide these populations with access to public information and opportunities for public participation in matters relating to human health or the environment.

*Executive Order 13166: Improving Access to Services for Persons with Limited English Proficiency*. This Executive Order requires federal agencies to examine the services they provide, identify any need for services to those with limited English proficiency (LEP), and develop and implement a system to provide those services so LEP persons can have meaningful access, such as language assistance. LEP refers to a limited ability to read, speak, write, or understand English. The Executive Order also requires that federal agencies work to ensure that recipients of federal financial assistance provide meaningful access to their LEP applicants and beneficiaries.

### *2. Non-Transportation Laws*

*Americans With Disabilities Act (ADA)*. The Americans with Disabilities Act (ADA) of 1990 requires equal planning participation opportunities for disabled persons, especially for paratransit plans. These requirements relate to outreach (developing contacts, mailing lists, and other means of notification), consultation with individuals with disabilities, opportunities for public comment, accessible formats (for example, an ASL sign language interpreter), public hearings, summaries of significant issues raised during the public comment period, and on-going efforts to involve disabled people.

*National Environmental Policy Act (NEPA)*. As noted earlier, NEPA is by far the most important law from the perspective of project-level planning. Under NEPA and Federal Highway Administration (FHWA) requirements, state public participation/public hearing procedures must provide for:

- Coordination of public participation activities and public hearings as part of the entire NEPA process.
- Early and continuing opportunities during project development for the public to be involved in the identification of social, economic, and environmental impacts, as well as impacts associated with the relocation of individuals, groups, or institutions.
- One or more public hearings or the opportunity for hearing(s) to be held by the state highway agency at a convenient time and place for any federal-aid project which requires significant amounts of right-of-way acquisition, substantially changes the layout or functions of connecting roadways, has a substantial adverse impact on abutting property, otherwise has a significant social, economic, environmental, or other effect, or for which the FHWA determines that a public hearing is in the public interest.
- Reasonable notice to the public of either a public hearing or the opportunity for a public hearing. Such notice will indicate the availability of explanatory information (such as plans available for viewing at a local library). The notice shall also provide information required to comply with public participation requirements of other laws, Executive Orders, and regulations. [FHWA, undated]

*National Historic Preservation Act*. Section 106 of this law requires agency consultation with Tribal Nations regarding religious and/or cultural significance to historic properties that may be affected by a transportation project.

### *3. Transportation Planning Requirements*

Whenever legislation becomes law, federal agencies may interpret the new legal requirements by incorporating key requirements into the Code of Federal Regulations (CFR), where Title 23 relates to highways). The federal rules and regulations correspond to actions that planners take in their planning efforts.

- 23 CFR 450.210 (a)(1)(ii): Provide reasonable public access to technical and policy information used in the development of the long-range statewide transportation plan and the Statewide Transportation Improvement Program.
- 23 CFR 450.210 (a)(1)(iii): Provide adequate public notice of public involvement activities and time for public review and comment at key decision points, including but not limited to a reasonable opportunity to comment on the proposed long-range statewide transportation plan and Statewide Transportation Improvement Program.
- 23 CFR 450.210 (a)(1)(iv): To the maximum extent practicable, ensure that public meetings are held at convenient and accessible locations and times.
- 23 CFR 450.210 (a)(1)(v): To the maximum extent practicable, use visualization techniques to describe the proposed long-range statewide transportation plan and supporting studies.
- 23 CFR 450.210 (a)(1)(vi): To the maximum extent practicable, make public information available in electronically accessible format and means, such as the World Wide Web, as appropriate to afford reasonable opportunity for consideration of public information.
- 23 CFR 450.210 (a)(1)(vii): Demonstrate explicit consideration and response to public input during the development of the long-range statewide transportation plan and Statewide Transportation Improvement Program.
- 23 CFR 450.210 (a)(1)(viii): Include a process for seeking out and considering the needs of those traditionally underserved by existing transportation systems, such as low-income and minority households, who may face challenges accessing employment and other services.
- 23 CFR 450.210 (a)(1)(ix): Provide for the periodic review of the effectiveness of the public involvement process to ensure that the process provides full and open access to all interested parties and revise the process, as appropriate.

### *4. Project Participation Requirements in NEPA Studies*

- 23 CFR 771.111(a)(1): Provide early coordination with appropriate agencies and the public to aid in determining the type of environmental review documents an action requires, the scope of the document, the level of analysis, and related environmental requirements. This involves the exchange of information from the inception of a proposal for action to preparation of the environmental review documents.

- 23 CFR 771.111(h)(2): State public involvement/public hearing procedures must provide for:
  - i. Coordination of public involvement activities and public hearings with the entire NEPA process.
  - ii. Early and continuing opportunities during project development for the public to be involved in the identification of social, economic, and environmental impacts, as well as impacts associated with relocation of individuals, groups, or institutions.
  - iii. One or more public hearings or the opportunity for hearing(s) to be held by the state highway agency at a convenient time and place for any federal-aid project which requires significant amounts of right-of-way, substantially changes the layout or functions of connecting roadways or of the facility being improved, has a substantial adverse impact on abutting property, otherwise has a significant social, economic, environmental or other effect, or for which the FHWA determines that a public hearing is in the public interest.
  - iv. Reasonable notice to the public of either a public hearing or the opportunity for a public hearing. Such notice will indicate the availability of explanatory information. The notice shall also provide information required to comply with public involvement requirements of other laws, executive orders, and regulations.
  - v. Explanation at the public hearing of the following information, as appropriate:
    - A. The project's purpose, need, and consistency with the goals and objectives of any local urban planning
    - B. The project's alternatives, and major design features
    - C. The social, economic, environmental, and other impacts of the project
    - D. The relocation assistance program and the right-of-way acquisition process
    - E. The State highway agency's procedures for receiving both oral and written statements from the public
  - vi. Submission to the FHWA of a transcript of each public hearing and a certification that a required hearing or hearing opportunity was offered. The transcript will be accompanied by copies of all written statements from the public, both submitted at the public hearing or during an announced period after the public hearing.
  - vii. An opportunity for public involvement in defining the purpose and need and the range of alternatives, for any action subject to the project development procedures in 23 U.S.C. 139.
  - viii. Public notice and an opportunity for public review and comment on a Section 4(f) *de minimis* impact finding, in accordance with 49 U.S.C. 303(d).

- 23 CFR 771.111(h)(4)(i): Applicants for capital assistance in the FTA program:

  1. Achieve public participation on proposed projects through activities that engage the public, including public hearings, town meetings, and charettes, and seeking input from the public through the scoping process for environmental review documents. Project milestones may be announced to the public using electronic or paper media (for example, newsletters, note cards, or emails) pursuant to 40 CFR 1506.6. For projects requiring EISs, an early opportunity for public involvement in defining the purpose and need for action and the range of alternatives must be provided, and a public hearing will be held during the circulation period of the draft EIS. For other projects that substantially affect the community or its public transportation service, an adequate opportunity for public review and comment must be provided.

  2. Are encouraged to post and distribute materials related to the environmental review process, including but not limited to, NEPA documents, public meeting announcements, and minutes, through publicly accessible electronic means, including project websites. Applicants are encouraged to keep these materials available to the public electronically until the project is constructed and open for operations.

Source: HRTPO, 2013

Figure 24-1 shows how the MPO in Hampton Roads, Virginia, identifies the important legal and regulatory requirements that feed into its plan for public participation.

## III. KNOW YOUR PUBLIC AND STAKEHOLDERS

Before discussing specific approaches and strategies for public participation, it is first necessary to ask the question, "Who should be involved in the transportation planning process?" The persons that planners need to reach include: the public, stakeholders, interested parties, and specific target populations. Stakeholders can be defined as "any individual, group of individuals, organizations, or political entity with a stake in the outcome of a decision." [IAP2, undated] These participants in the planning and decision-making processes will likely be identified primarily based on the geographic area of the study.

In some cases, laws and regulations dictate who must be provided an opportunity to participate in planning and decision making (see discussion above on MAP-21). In other situations, it is up to the planning agency or the planner to determine who the key participants should be. The task of identifying stakeholders has been dramatically changed by technology and internet search capability. In addition, some software programs (for example, SalesForce) has allowed a more effective tracking and sorting of people by interest area, organization, and zip code. It has also enabled a more strategic perspective on levels of engagement. The Metropolitan Council in the Twin Cities, Minnesota, for example, defines stakeholders as people, groups, or organizations who care about or might be affected by a Council action. [MetCouncil, 2010] The Hernando/Citrus MPO in Florida identified the following key stakeholders:

- Elected officials.
- Local government staff.
- Transportation agencies (port, airports, transit, etc.).

- Law enforcement and emergency services management, emergency operations centers, chambers of commerce, and economic development agencies.
- Local media (TV, radio, print, etc.).
- Homeowners associations.
- Civic groups.
- Special interest groups (other interested parties).
- Libraries (for public display).
- Federal, state, and local agencies responsible for land use management, natural resources, environmental protection, conservation and historic preservation, and other environmental issues.
- Other parties that would have an interest in the planning and development of the transportation network, including affected public agencies in the transportation planning area.
- Native American Tribal Council.
- Private freight shippers.
- Representatives of public transportation employees.
- Providers of freight transportation services.
- Private providers of transportation.
- Representatives of users of public transportation.
- Representatives of users of pedestrian walkways.
- Representatives of users of bicycle transportation facilities.
- Representatives of the disabled. [Hernando/Citrus MPO, 2014]

Other key organizations could include health authorities, colleges and universities, school districts, major employers, and recreation providers. For instance, a similar list for the Hillsborough County MPO (Tampa, Florida) also included the general public, schools, parent teacher associations (PTAs), community development corporations, chambers of commerce, professional organizations, other business entities, emergency service providers, caregivers for the elderly and for children and persons with disabilities, low income individuals, and LEP persons.

The Colorado DOT identified numerous ways to add to their list of stakeholders (shown in Figure 24-2): user surveys, responding to new requirements from state and federal laws, and reaching out to homeowners' associations, neighborhood groups, outdoor enthusiast/environmental groups, the business community, agencies serving senior citizens, educational institutions, and agencies serving the disabled. The key observation here is that the Colorado DOT is proactively seeking new participants for its planning processes.

Figure 24-3 shows the targeted populations that transit agencies often seek for their public participation activities. As shown, a majority of the transit agencies (over 50 percent) target existing riders, occasional riders, persons with disabilities, and seniors. Table 24-1 shows the reported sources of information that 45 surveyed transit agencies use to identify potential participants in transit planning activities.

Knowing whom to invite to participate in the planning process is an important first step. However, it is also important to know what motivates participation, and what perceived barriers may exist. A public participation survey from the Mid-America Regional Council (Kansas City, Missouri) identified six reasons why people chose to not become involved in transportation issues, summarized in Table 24-2.

In today's social media world, it is also important to understand how people get their information, and how this information is interpreted. Table 24-3 shows statistics from a recent study of how cell phones were used by different population groups. This type of information can be useful when developing a strategy for reaching out to the different publics in a study area.

## IV. PUBLIC PARTICIPATION PLAN

As noted earlier, every MPO and state DOT must have a public participation plan (PPP), sometimes called a public involvement plan. The PPP must describe the agency's overall strategy to provide public participation opportunities in the transportation planning process. Most of these plans describe the legal and regulatory foundations for participation, the schedule of planning deliverables (for example, the long-range plan, transportation improvement program (TIP), and the Unified Planning Work Program (UPWP)), as well as the timing of public participation opportunities. The reference list at the end of this chapter has many excellent examples of how a PPP is organized. There are other common elements to the PPP that are also important. These are discussed below.

### A. Public Participation Goals and Objectives

The PPP should articulate the goals and objectives for the public participation process. Goals reflect the desired result, while objectives reflect the detailed statements of how the goals will be accomplished. There are numerous examples of PPP goals and objectives, most of which offer similar desired outcomes. For example, the following list of goals and objectives comes from Washington County, Oregon:

1) Provide general information about our transportation system, programs, and projects that is understandable, timely, and broadly distributed.
2) Help residents understand the transportation system planning, project selection, project development, design, and construction processes and how they can stay informed or become involved.
3) Help taxpayers understand the relationship between their taxes and the county's various transportation programs and projects.
4) Encourage and provide stakeholders and the public with opportunities for meaningful input concerning the transportation system, project design features, and the mitigation of potential community impacts.
5) Provide all potentially impacted stakeholders equitable access to pertinent information. This may involve providing information through verbal or written language translation or other alternative formats, and/or collaborating with community-based organizations to involve historically underserved communities.
6) Provide program and project-specific information, which may include project needs, goals, and constraints; scope of work; schedule; funding source(s); land use application and other permit status (if applicable); and construction impacts (if applicable).
7) Provide adequate advance notice of pertinent public hearings, public meetings, open houses, and comment periods. Public hearings typically have existing notification requirements that are applicable. Some programs may have existing notification requirements that are applicable. In instances without prescribed notice requirements, a 30-day notice is preferable and a 15-day notice should be considered a minimum.
8) Provide adequate time for public comment periods. For other transportation programs or processes where a formal request for public comments is made, a 30-day comment period is preferable and a 15-day comment period should be considered a minimum.
9) Ensure that public input is documented and provided to decision makers in summary form (and verbatim, if requested) for consideration prior to key decisions. [Washington County Department of Land Use & Transportation, 2015]

Table 24-4 shows how the goals statements from several MPOs relate to different generic goals categories. For example, "awareness" means a public participation program aims to increase public awareness of transportation planning or of a specific transportation plan. "Diversity" means encouraging the participation of a range of population groups, in particular, underrepresented communities. All of the MPOs in the table have a stated goal of increasing public awareness on transportation issues facing their communities and of the planning programs themselves. Other goals reflect various agencies' assigned importance to each goal.

One should be careful interpreting Table 24-4. Just because a goal is missing from a particular category, one should not infer that the MPO is unaware of or unconcerned about that aspect of public participation. It simply means that the goal category was not part of the overall goals statement of the MPO's PPP. The table provides a snapshot of the different types of goals that can be considered as part of the PPP process.

Table 24-4. Example Public Participation Goals by Category, Selected MPOs

| | San Diego, SANDAG [2011] | Atlanta, ARC [2015] | Kansas City, MARC [2013] | Northern New Jersey, NJTPA [2007] | Broward (FL) MPO [2015] | Wilmington, DE, WILMAPCO [2010] |
|---|---|---|---|---|---|---|
| **Awareness** | Raise awareness of the 2050 RTP as the region's updated blueprint for a transportation system that enhances our quality of life and meets our mobility needs for the future. | Be highly visible in efforts to engage the public to participate and in sharing the results of the project with planners, policy makers, and elected officials. | Inform and educate the public. | Provide adequate opportunities to engage in meaningful two-way discussions between the NJTPA and the public about transportation planning issues. | Inform the public of transportation meetings, issues and other relevant events. The public needs to be aware of their role in the transportation planning and decision-making process. | Widely disseminate, clear, complete, and timely information to residents, affected agencies, and interested parties. |
| **Public Input** | Provide the public with opportunities to offer input on the 2050 RTP and its SCS, a new feature of the 2050 RTP required by state climate change legislation. | Be accountable to participants by reporting back to them at regular intervals, and provide a means for all interested individuals to stay informed and involved with the plan. | | | | Create an open and ongoing two-way public participation process that ensures full resident, agency, and interested party participation in, and input into, regional transportation planning. |
| **Dialogue** | Stimulate dialogue about the transportation challenges facing the San Diego region. | Design a community engagement strategy that incorporates a complementary mix of smaller, community-based forums, large-scale public forums and online opportunities for engagement. | Engage the public and encourage continued participation. | Use a range of tools that promote timely, innovative and informative two-way education between the NJTPA and the public. | | Achieve early and continuous participation of the public in the development of transportation plans, projects, and programs. |
| **Diversity** | Develop and incorporate into the plan realistic solutions that address the diverse mobility needs of the region's residents, visitors, and business people. | Partner with other organizations and agencies to maximize participation, with an emphasis on reaching groups that are typically underrepresented in planning processes. | Reach out and build connections. | Make continuous efforts to engage a diverse and wide-ranging representation of those who live, work and travel within northern and central New Jersey. | Include all communities in the planning area to inform and involve, with special emphasis on those communities with people who have been underrepresented and/or underserved. | |

Table 24-4. (*Continued*)

| | San Diego, SANDAG [2011] | Atlanta, ARC [2015] | Kansas City, MARC [2013] | Northern New Jersey, NJTPA [2007] | Broward (FL) MPO [2015] | Wilmington, DE, WILMAPCO [2010] |
|---|---|---|---|---|---|---|
| **Influence on Outcomes** | Build public support for transportation improvements outlined in the 2050 RTP. | | Use input to shape policies, plans and programs. | Promote more direct dialogue between the Trustees and the public-at-large to enhance the public's influence on regional transportation planning and decision making. | | |
| **Evaluation** | | Evaluate the effectiveness of activities, modifying the plan as necessary to achieve desired outcomes. | Evaluate public participation strategies. | Evaluate and upgrade, on a periodic basis, the public participation efforts of the NJTPA to ensure that public participation has a demonstrable impact on the transportation planning and decision-making process in the region. | Improve the public participation process by identifying and incorporating new tools and strategies. | |
| **Compliance** | | | | Maintain both the letter and spirit of federal and state laws, regulations, and guidelines regarding public participation responsibilities of MPOs. | | |

An example of a goals and objectives statement comes from the Wilmington, Delaware MPO (WILMAPCO), which identified its first goal as, "widely disseminated, clear, complete, and timely information to residents, affected agencies, and interested parties." [WILMAPCO, 2010] This was followed by several more specific objectives:

- *Objective 1*—WILMAPCO will identify organizations and individuals representing a broad spectrum of community interests and encourage their participation in transportation planning processes.
- *Objective 2*—WILMAPCO will develop relationships and form partnerships with organizations in the communities WILMAPCO serves and use these partnerships to develop a better understanding of WILMAPCO's mission and activities among their members and constituents.
- *Objective 3*—Coordinate public involvement activities with other similar programs to make best use of staff and resources while minimizing public time demands.
- *Objective 4*—Information will be disseminated through a variety of media.
- *Objective 5*—Transportation planning information will be conveyed in language and in a context that is understandable to the lay citizen.

Another common component of a PPP is a statement of the desirable characteristics of a public participation process. For example, the Colorado DOT public participation plan listed the following "principles" representing desired characteristics of its public participation process:

- Early and continuous participation.
- Timely and accurate information.
- Information accessibility in a variety of forms, including visual/print, electronic, and verbal information.
- Involvement with traditionally underserved communities.
- Reasonable access to meetings.
- Diversified approach, providing communication flexibility and innovation.
- Adequate and timely notice.
- Enhanced stakeholder relationships.
- Incorporation of public comments.
- Timely responses.
- Process review on the effectiveness of the public participation process and any proposed changes.

Good examples of public participation goals and objectives can be found in [WILMAPCO, 2010; MARC, 2013; Hillsborough County MPO, 2014a; Hernando/Citrus MPO, 2014; and Boston Region MPO, 2014]. Please refer to the References section of this chapter for the corresponding web addresses.

## V. PUBLIC PARTICIPATION METHODS AND APPROACHES

A major purpose of the PPP is to identify the types of strategies, methods, tools, and approaches the agency will use to provide opportunities for public participation in the transportation planning process. Not only is it important to identify what types of strategies will be used, but also in what contexts and target audiences they are best applied. Table 24-5, for example, shows the key planning activities for the Denver Regional Council of Governments (DRCOG) and the types of opportunities and methods provided for each activity. This is not to say that these would be the only methods used. Rather, it identifies the major types of public participation methods the DRCOG finds appropriate for planning activities.

Part of the process of conducting an effective public participation process is understanding which types of strategies and methods are likely to be the most effective. To make such a determination, some MPOs conduct surveys of their

| Table 24-5. Key Planning Activities and Public Participation Methods, Denver | | |
|---|---|---|
| **Activity** | **Responsibility** | **Opportunities and Methods** |
| Metro Vision Plan and Metro Vision Regional Transportation Plan | DRCOG | Public interest forums at key points throughout the development process: DRCOG committee review and recommendation; public hearing and comment period before adoption and amendment; staff outreach to communities and organizations using workshops, presentations, questionnaires, website techniques, etc. |
| Transit Element & Pedestrian/Bicycle Element | DRCOG | Ad hoc committees or work groups; DRCOG committee review and recommendation; solicitation of comments and input announced via website and e-mail notification; public hearing and comment period before adoption. |
| Strategic Plan or Topical Programming Documents | DRCOG | Stakeholder and practitioner work groups; DRCOG committee review and recommendation; posting of draft documents on website prior to committee discussion and Board action. |
| Transportation Improvement Program | DRCOG, Local Governments, Colorado DOT (CDOT) and Regional Transportation District (RTD) | Project sponsor conducts public outreach in communities regarding specific projects; DRCOG committee review and recommendation; public hearing before adoption of new TIP or a TIP amendment requiring conformity finding; posting of all amendments on website prior to committee discussion and Board action. |
| Major Corridor/ Subarea Studies | CDOT, RTD, DRCOG, Local Governments | Task forces/committees and public meetings in the study area; meetings conducted in affected neighborhoods; other outreach efforts (for example, newsletter, website, comment forms). |
| Project Development | Implementing Jurisdiction | Task forces/committees and/or public meetings in the project locale at key decision points. |
| Conformity of the RTP and the TIP | DRCOG | DRCOG committee review and recommendation; public hearing on the draft conformity finding. |
| Unified Planning Work Program | DRCOG, CDOT, RTD | Periodic transportation forums to identify key planning tasks; DRCOG committee review and recommendation. |

Source: DRCOG, 2010

study area residents. These surveys asked questions about the public's participation in public participation activities and about which types of information resources are the most or least effective. Tables 24-6 and 24-7 are examples of the types of information gathered in such surveys. This survey was undertaken by the Mid-America Regional Council in Kansas City, Missouri, and was designed as part of the formal evaluation process of the MARC PPP (see later section).

Many different strategies and methods can be considered for a public participation program. The following references are excellent sources of information for such methods: [Context Sensitive Solutions.org, 2005; Morris and Fragala, 2010; National Center for Mobility Management, undated; and FHWA, undated]. A particularly useful guide comes from the Hillsborough County MPO [2012]; tables from this guide are found in the appendix to this chapter.

The following common strategies and methods are presented alphabetically, not indicating priority with respect to use for public outreach. In addition, social media techniques are discussed in the next section and are excluded from this list outright. Importantly, partnering with local governments and other agencies can help identify effective methods of outreach. The International Association for Public Participation (IAP2) has developed a detailed tools matrix [IAP2, undated] and the FHWA has produced a publication, *Public Involvement in Transportation Decision-making*, that provides a useful compendium of tools. [FHWA, undated]

*Advisory Groups*. A local or regional group appointed by the transportation agency to provide input into the planning process. These groups are also sometimes referred to as advisory committees or councils; task forces; local or regional coordinating councils; or other similar names. An example is the DVRPC Public Participation Task Force in Philadelphia composed of appointed members as well as members-at-large. The mission of the task force is to provide ongoing access to the regional planning and decision-making process, review current issues, serve as a conduit for DVRPC information to organizations and communities across

| Table 24-6. What is the Best Way to Engage You in Regional Transportation Issues? Kansas City | | |

the region, and assist the commission in implementing public outreach strategies. Member cities and counties represented on the DVRPC board appoint members to the task force.

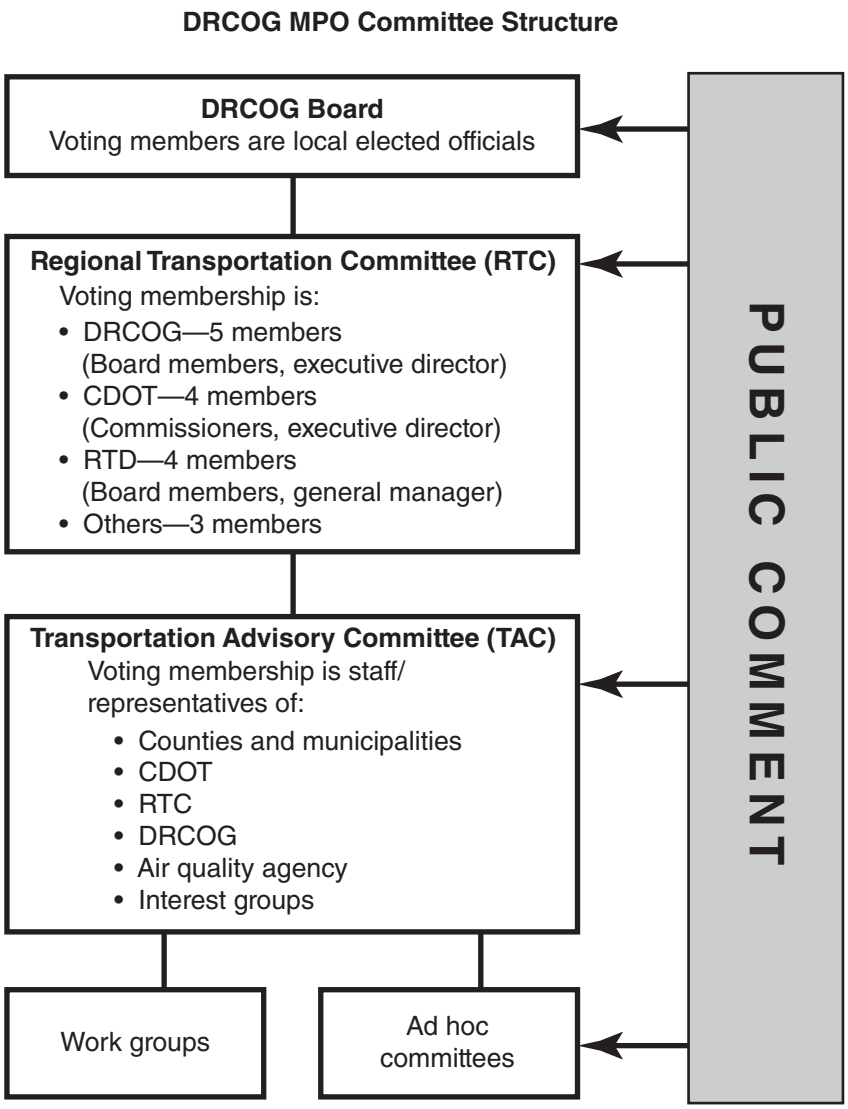
Another example of an advisory committee and how it fits institutionally into an MPO's governance structure is shown in Figure 24-4. This figure shows the Transportation Advisory Committee (TAC) for the DRCOG in Denver. There are 29 members of the TAC representing local counties and municipalities, the Colorado DOT, the Regional Transit District (RTD), the Regional Air Quality Council (RAQC), environmental interests, freight interests, transportation demand management (TDM) and between (TDM) and nonmotorized transportation interests, aging community interests, non-RTD transit interests, aviation interests, business/economic development interests, and ex officio FHWA/FTA representatives.

*Community-based Outreach*. A relationship between a transportation agency and community organizations to engage existing community organizations in disseminating planning information and hosting forums. A good example of this is in San Diego where SANDAG, the region's MPO, has provided funding to eight community groups to conduct outreach, especially in communities that traditionally are not involved in regional public policy planning. The types of involved groups included a disabled advocacy group, faith groups, Hispanic neighborhood collaboratives, adult health-care centers, and a business association.

*Community Engagement Teams*. Teams consisting of local representatives and relevant transportation agencies acting as advisors focusing on specific issues or interests.

*Community Involvement Roundtable*. A form of a citizen advisory group acting as a sounding board for public opinion. Roundtables often formally review plans and make recommendations to the MPO. An example is the Community Involvement Roundtable (CIR) in Broward County, Florida, which is a 45-member citizen advisory group to the MPO whose membership is determined by the Board.

**Figure 24-4. Transportation Advisory Committee, Denver**



Source: DRCOG, 2010

*Community Outreach*. Providing information and/or staff presence at gathering places/community festivals to disseminate project information and engage with the general public. This approach is very useful for engaging a diverse audience.

*Fact Sheets*. Papers or brochures providing summary information on MPO policy, programs, and projects. Fact sheets can be distributed as part of community outreach (see Community Outreach, above).

*Focus Groups*. A randomly selected group of individuals that represents the sociodemographic profile of the study area. Said individuals are asked targeted questions on issues of importance to the transportation agency. Usually, representatives from the agency observe the process and submit questions to the group while in session. Typical focus groups range from approximately 8 to 15 people, include enough representation to garner a cross section of opinions, while not so many people that some attendees are unable to make themselves heard.

*Interactive Voting*. Electronic polling devices used to solicit answers to a series of questions on a variety of transportation issues. Electronic keypads register participants' responses and project them graphically on a screen providing the opportunity for discussion and instantaneously capturing public opinions. Smart phone apps and cell phone texting can also be used for instant polling and voting.

*Interdisciplinary Teams*. A team formed including different types of skills and expertise needed for a particular study. These teams are sometimes called multidisciplinary teams.

"*Invite Us Over*." Asking transportation advocacy groups, professional organizations, transportation-equity organizations, and other such groups to invite staff to attend regularly scheduled meetings to discuss transportation issues that are important to them. This has been used in Boston where MPO staff attends local meetings and makes presentations, answers questions, and gathers comments.

*Key Stakeholder Interviews*. Interviewing key individuals or groups in a study using a predetermined, standard set of questions. Similar questions are asked of each participant so as to compare answers.

*Limited English Proficiency Aides*. Interpreters and translating services made available to serve the needs of population groups not proficient in English. Areas where residents that predominantly speak other languages are identified through a Modern Language Association (MLA) Language Map and by geographic mapping data available through the U.S. Census.

*Local Coordinating Boards*. Members appointed by the transportation agency to act as an official representative of specific groups such as the aging, child welfare, veterans' affairs, and schools. In Florida, for example, the Florida Commission for the Transportation Disadvantaged (FCTD) coordinates transportation services for persons who because of physical or mental disability, income status, or age are unable to transport themselves or purchase transportation to access health care, employment, education, shopping, social activities, or other life-sustaining activities. This assistance is advised by Local Coordinating Boards (LCB).

*Local Media Contacts*. Establishing contacts with local media. Several strategies can be used to get the local media interested in a study, including news releases, inviting reporters to news briefings, meeting with editorial staff, writing opinion pieces/commentaries, displaying ads, using minority media outlets for news releases, placing speakers on radio/TV talk shows, and using public service announcements on the radio and TV. A media kit is a way to disseminate facts and information about the project to numerous reporters. The kit may contain a map or visualization of the proposed project and fact sheets including unique or interesting aspects that make the project news worthy. The kit can be printed or electronic. Media kits are a quick and convenient reference tool for reporters to use verbatim, thus avoiding potential misinformation.

*Mailings/Flyers*. Materials prepared specifically addressing the study and offering information on the current status and providing information on how residents can become engaged in the process. Transportation agencies often work with community-based organizations to distribute flyers or to e-mail targeted database lists.

*Meeting in a Box*. Local citizens or community leaders host a meeting for groups within their communities with meeting materials prepared as a stand-alone kit. The meeting in a box provides everything that is needed for the meeting. The host is responsible for inviting attendees and for securing the meeting location, which may be a school, private residence, or other place of assembly. The host is also responsible for returning the results of the meeting and any comments or notes [Colorado DOT, 2015].

*Mobile Participation Sites*. Roving information centers, usually some form of vehicle (for example, a bus), provide meeting and interaction space to different parts of the region. The Indian Nations Council of Governments (INCOG) in Tulsa, Oklahoma, is a good example of an organization that successfully utilizes this strategy. As part of a transit planning study, INCOG planners traveled by bus to visit 117 stops in 12 different jurisdictions over a four-month period. BC (British Columbia) Transit's Transit Future Bus is similarly used to invite comments at community events and key transit nodes.

*Newsletters*. Either in printed and/or electronic form, periodic newsletters sent to a targeted mailing list can provide the latest information to study stakeholders. One could also take all or portions of the newsletter and submit articles for publication in community/corporate newsletters.

*Polls/Surveys*. Telephone, mail-back, web-based or in-person surveys to gather information on a wide range of issues. The credibility of this data source depends on the sampling strategy and the quality control associated with data collection (see chapter 2).

*Public Hearings*. Formal legal proceedings required as part of project development, and other meetings subject to hearing requirements. In project development, public hearings are usually required for projects that meet NEPA-defined criteria, such as the completion of a draft environmental impact statement (EIS). The hearings may include descriptive presentations, and they all must afford the public the opportunity

to comment on the project/proposed action. Comments for the public record are recorded at the hearing by a court reporter or recording device. Comments for the public record are also usually collected during the pre- or post-hearing comment period, which must last for a standard, predetermined number of days.

*Public Meetings*. Meetings or a series of meetings not subject to legal procedural protocols, but meant to disseminate plan information and garner public input. These meetings can be held anywhere in the affected region, as deemed necessary. The MPO in Kansas City found that citizens are more willing to participate in transportation discussions when the discussions are part of an organization's meeting (for example, YMCA, neighborhood association, and the Rotary Club). If practical, the transportation agency should consider co-sponsorship of such meetings to maximize potential participation.

*Scenario Tools*. A tool that allows users to experiment with various choices, view the implications and results, and provide input on their preferences. Scenario testing can be done either online or at meetings. This provides the public with a better understanding of how difficult choices are made (namely, based on balancing the overall benefits and costs of various plan elements). In San Diego, an interactive web-based visualization tool was used following the release of the draft regional transportation plan that visually demonstrated the priorities, investments, transportation system, and other key elements and concepts in the draft plan. The tool also included a web-based form in English and Spanish for members of the public to submit comments.

*Speakers Bureau*. Individuals trained to deliver a standard presentation and skilled in responding to questions. These speakers are invited to attend community meetings or other groups where the study is on the agenda. The project team may need to "pitch" the presentation to groups and not wait for invitations. This might occur by identifying community groups and contacting them with the offer to present.

*Technical Advisory Committee*. An advisory committee with representatives from the technical staff of non-MPO/DOT agencies. An example is the Complete Streets Technical Advisory Committee in Broward County, Florida, which provides technical assistance and resources to local agencies. Membership includes staff from local municipalities, Broward County government, Florida Department of Transportation, as well as nontraditional transportation agencies like the Broward Regional Health Planning Council, Smart Growth Partnerships, Broward YMCA, and Florida Department of Health.

*Telephone Town Halls*. A "town hall" using telephone call-ins to poll a large number of participants on transportation improvements or other issues. As used by the Colorado DOT, the telephone town hall allows participants to ask questions of DOT staff over the phone.

*Trusted Advocates*. Individuals having strong connections to their communities, a background in community engagement, and the ability to advocate and educate within their communities. Trusted leaders could also be called opinion leaders or champions. Methods of engagement include one-on-one interviews, going door-to-door, tabling (staffing a table at a heavily trafficked location or event), kitchen table meetings/home visits, small-group meetings, and community gatherings. This strategy has been used with great success in the Twin Cities, Minnesota, and Seattle, Washington.

*Video*. Videos produced to educate the public and disseminate information on transportation, such as describing the steps in a planning process. These videos are often placed on social media sites.

*Visualization*. Interactive maps, pictures and/or displays that lead to improved understandings of existing or proposed transportation plans and programs.

*Workshops*. A meeting with a set agenda, usually including participation of workshop attendees. The workshops focus on particular issues (for example, scenario planning for the region) and are usually facilitated by a trained moderator. They offer customized presentations to existing groups and organizations and can be co-hosted with community groups, business associations, etc. The types of tools used in a workshop format can be open houses, question-and-answer sessions, break-out sessions for smaller group discussions on multiple topics, interactive exercises, poster sessions, and charrettes. Workshops use visualization techniques to motivate participant interaction, such as maps; charts, illustrations, and photographs; table-top displays and models; web content and interactive games; electronic voting; and PowerPoint slide shows.

As mentioned earlier, transportation agencies usually develop targeted programs to attract minorities, the elderly, and disabled persons to the planning process. These are particularly challenging groups to involve in planning for a variety of reasons. Table 24-8 depicts example data from the Colorado DOT with respect to reported barriers often

| Table 24-8. Identified Barriers to Public Participation, Colorado DOT | | |
|---|---|---|
| **Barrier** | **Methods** | **How CDOT Addresses the Barrier** |
| Cultural | Research culture, customs, language, and community styles.<br>Identify employees of diverse cultural backgrounds that can help improve outreach and communication.<br>Identify and reach out to local community organizations and leaders. | Working actively with CDOT's Center for Equal Opportunity, cultural barriers are reduced through cultural training for staff and connecting with local community leaders. |
| Language | Identify community bilingual speakers.<br>Ensure materials are in languages representative of where the meeting or outreach is taking place.<br>Provide interpreters. | Working actively with CDOT's Center for Equal Opportunity, to the extent possible, solicit in-house interpreters to assist in dealing with language barriers in the planning process in accordance with Executive Order 13166, "Improving Access to Services for Persons with Limited English Proficiency." Specifically, CDOT has made improvements in providing web pages and major documents in Spanish. |
| Mobility (and other) Disabilities | Ensure facilities are accessible.<br>Provide materials in large print format or Braille for those vision-impaired.<br>Use sign language interpreters.<br>At meetings offer hearing aid amplifiers and other hearing assistance devices.<br>Use telecommunication device for communication via telephone with hearing impaired. | CDOT staff is attentive to any calls or other forms of communication where individuals request assistance to participate in the planning and programming processes. This includes, but is not limited to, meeting access (in compliance with the Americans with Disabilities Act, as amended) or meeting materials in Braille or large print. |
| Economic/Income | Schedule meetings or face-to-face interactions at convenient times and locations.<br>Provide snacks by using local community members or local catering.<br>Provide child care.<br>Provide financial incentives for meeting attendance. | CDOT considers meeting locations in terms of multimodal accessibility and meeting times that help to not only provide participant convenience, but snacks and child care where appropriate. |

Source: CDOT, 2015

faced by these groups. Many of the strategies described above are relevant means of getting these groups involved in transportation planning, as long as group-specific assistance is also available, such as translators, barrier-free meeting locations, travel provision to the meeting sites, and the like.

Simon and Simon [2014] conducted a study for the Transportation Research Board on the types of arrangements transportation agencies can make to encourage those with disabilities, the elderly, and minority groups to participate in the planning process. They found transit agencies used the following primary techniques for the audiences:

*People with Disabilities*—Advisory committees, outreach to advocacy organizations and disability organizations, and formal membership on transit agency advisory committees.

*African Americans*—Outreach to community and neighborhood organizations, church and community leaders, and outreach to targeted transit centers.

*Hispanics*—Outreach to community and neighborhood organizations, use of the media, bilingual staff, and outreach at transit centers.

*Asian Americans*—Outreach to community and neighborhood organizations and outreach at targeted transit centers.

*Limited English Proficiency (LEP) Groups*—Outreach to community and neighborhood organizations, bilingual staff, minority media outlets, and translated materials. Techniques for involving other immigrants included outreach to community organizations, use of advocacy organizations, and reaching out to social service agencies.

The report also suggested that special care is needed to prepare a meeting environment conducive to participation by these groups. Such elements includes hands-on presentations, multilingual translators, sign language interpreters, ADA-compliant locations without physical barriers, child care, refreshments, accessibility via public transportation, and feedback to the participants in a format and medium they can understand.

## VI. EVOLVING ROLE OF TECHNOLOGY AND SOCIAL MEDIA

New technologies have dramatically influenced the approaches and strategies for public engagement:

- Every state DOT and MPO has a website with information on transportation plans, programs, and projects.
- Near instantaneous communications and information portals provide agencies with the means of disseminating information quickly and in attractive, cost-effective ways.
- New visualization technologies provide planners with the ability to illustrate and explain concepts that serve as the foundation of proposed plans and project designs.

Social networking/media is defined as any current electronic form of communication such as chat messaging, text messaging, and social networking sites. Giering [2011] noted that "as social media increases in importance as a public participation tool, practitioners are seeking direction on what to use, when, and how. This is a rapidly evolving field that needs a thoughtful approach to study the benefits of social media, adaptable concepts for its use, the legal and privacy issues surrounding it, and whether or not it improves the overall outcome of public participation efforts."

An example of a new technology-based approach is crowdsourcing. Crowdsourcing is a problem-solving approach in which a sponsor (the one who "crowd sources") seeks input online from those having expertise or interests on particular topics. Participants provide ideas and thoughts that can be shared and refined by others (again, online), which provides the crowd sourcer with a set of strategies or actions that have been vetted by those most knowledgeable about the topic. [Gazillo et al., 2013] For example, crowdsourcing outreach for a planned subdivision could ask community members about the amenities most desired. Following that line of questioning, the online survey could be tailored to refine the top answers and add new choices, based on input received to date. Crowdsourcing is essentially a dynamic survey that changes based on feedback and input from the public.

Bregman [2012] conducted a survey of 35 transit agencies to identify the most commonly used social media platforms. The survey found the most common platforms were:

- Blogs or web logs, where individuals or organizations post commentary or news, frequently on a particular topic, and often invite comments and feedback.
- Social and professional networking sites that encourage members to connect with one another, such as Facebook, LinkedIn, and GovLoop.
- Micro-blogging sites, primarily Twitter, which allow users to post comments and web links.
- Media- and document-sharing sites where members post and share video clips (YouTube), documents (Scribd), and photographs (Flickr).
- Geolocation applications, such as Foursquare, which enable users to share their location with other members of their social network and to earn virtual "badges" for checking into sites.

Several other interesting findings from the survey include:

- Staff availability was the greatest barrier to adopting social media.
- As the line between private and professional communications blurs, public- and private-sector agencies are having to address employee use of social media (perhaps inappropriate use).
- Concern that social media would increase criticism from frustrated riders and disgruntled employees.
- Although internet access for people with disabilities has improved substantially over the past few years, social media applications have lagged, and their heavy reliance on graphics, videos, and user-generated content has created accessibility challenges.
- Concerns about cyber threats and user privacy.

Tables 24-9 to 24-11 show some of the other results from this survey.

An example from MARC in Table 24-12 shows how social media is being used for its transportation planning process as of 2013. As shown, MARC uses primarily Facebook and Twitter for its social media outreach efforts.

State DOTs have also been aggressively pursuing new technologies for public participation efforts. The latest survey (2014) of state DOTs by the American Association of State Highway and Transportation Officials (AASHTO) showed only one state reported not using social media technologies in its social media program. [AASHTO, 2014] Facebook and Twitter were the two highest ranked media, with video- and photo-sharing programs seeing a significant increase in use. In 2014, state DOTs had on average 16 individuals dedicated to their communications teams.

It is important to note that social media platforms evolve so rapidly that the major technology applications used today could be superseded by new and more advanced applications in the future. Transportation planners thus need to be aware of the newest and most-used means of interaction via the internet. Readers are encouraged to access the Pew

**Table 24-9. Type of Information Provided and Social Media Application Used, U.S. Transit Agencies**

| Platform | Twitter | Facebook | Blog | YouTube | LinkedIn |
|---|---|---|---|---|---|
| Agency news | 86% | 80% | 37% | 23% | 3% |

Research Center program on social media for the latest information on social media use (http://www.pewresearch.org/topics/social-media/2015). For example, some of the information available at this site (as of 2015) include:

- Overall, 85 percent of adults are internet users and 67 percent are smartphone users.
- Thirty-six percent of smartphone owners report using messaging apps such as WhatsApp, Kik, or iMessage, and 17 percent use apps that automatically delete sent messages such as Snapchat or Wickr.
- Half (49 percent) of smartphone owners ages 18 to 29 use messaging apps.
- The proportion of Instagram, Pinterest, and LinkedIn users who use each respective site daily increased significantly from September 2014 to April 2015. Fully 59 percent of Instagram users, 27 percent of Pinterest users, and 22 percent of LinkedIn users visit these platforms daily.
- Facebook remains the most popular social media site—72 percent of online adults are Facebook users, amounting to 62 percent of all American adults. Approximately 82 percent of online adults ages 18 to 29 use Facebook, along with 79 percent of those ages 30 to 49, 64 percent of those ages 50 to 64, and 48 percent of those 65 and older. Facebook continues to have the most engaged users—70 percent log on daily, including 43 percent who do so several times a day.

- Instagram continues to be popular with nonwhites and young adults: 55 percent of online adults ages 18 to 29 use Instagram, as do 47 percent of African Americans and 38 percent of Hispanics. Additionally, online women continue to be more likely than online men to be Instagram users (31 percent vs. 24 percent).
- LinkedIn is the only major social media platform for which usage rates are higher among 30- to 49-year-olds than among 18- to 29-year-olds. Fully 46 percent of online adults who have graduated from college are LinkedIn users, compared with just 9 percent of online adults with a high school diploma or less. [Pew Research Center, 2015]

As additional social media technologies come online, state DOTs and MPOs will have to continually explore how the new capabilities can be used effectively in the transportation planning process. Some useful references include: [Brabham 2013; Barron et al., 2013]; and www.nepaandsocialmedia.com.

## VII. PUBLIC PARTICIPATION AND PROJECT DEVELOPMENT

Public participation activities for project planning and development use very similar strategies and tools as described above. However, there are two major differences. First, motivating individuals to help develop a plan with a 25-year timeframe is challenging; many potential participants do not see the long term plan's relevance to their everyday lives. However, a project development process with public participation regulated under NEPA and other federal and state law, especially one that is going through an environmental analysis, will usually focus on very specific concepts and impacts that individuals can relate to. They know where the road or transit alignments are being proposed; they know the neighborhoods that will be affected; and they understand the likely benefits that could occur with the project. It is thus often easier to attract public interest to specific project planning and project development efforts, although the interaction could be more contentious. Second, in cases where the proposed project is significant enough to warrant environmental analysis, federal and state laws will often require formal public hearings, which have legal implications on how the agency responds to public comments.

Some examples of project-level public participation efforts are presented below. Note that the local context, degree of impact, and other factors will influence the selection of tools in each case.

***Warm Springs BART Extension, Bay Area, California***
This project will add 5.4-miles of new track from an existing station south to a new station in the Warm Springs district of the city of Fremont, extending BART's service to southern Alameda County. [BART, 2015] The public participation activities in this study included:

- Five outreach events held in the Warm Springs catchment area and in San Francisco.
- Input from BART's Title VI & Environmental Justice (Title VI/EJ) Advisory Committee.
- Surveys of residents of Warm Springs as well as current riders.
- A multilingual flyer/mailer in English, Spanish, Vietnamese, and Hindi (including reference to the availability of translation services for meetings).
- An oversized copy of the multilingual flyer displayed at BART stations.
- BART website announcements and posted draft Title VI Equity Analysis.
- BART social media announcements (Twitter).
- BART Passenger Bulletin in English (with standard taglines for more information in Spanish, Vietnamese, Chinese, and Korean) at BART stations.
- Announcement broadcasted up to 7,500 times per day on the BART Destination Sign System (DSS) at all BART stations throughout the District, as well as targeted messages at selected stations.
- Advertisements in local print ethnic media.
- E-mail notice to more than 400 local community-based groups and civic organizations.
- E-mail notice to approximately 5,200 recipients on the Warm Springs Project e-mail subscriber list through GovDelivery.

***Virginia Beach Extension Transit Study, Hampton Roads Transit Authority, Virginia***
The Hampton Roads Transit Authority was studying transit improvements in a corridor serving the downtown area of Virginia Beach, Virginia. The study looked at multiple transit improvement scenarios: developing a light rail line extension, a bus rapid transit line, enhanced bus service, or doing nothing [HRT, 2010]. The public participation activities for this project included:

- Newsletters.
- E-mail project updates.
- Press releases and news articles.
- Twitter tweets of major project news and meetings.
- Facebook page.
- Community and business organization presentations.
- Public access cable channel presentations.
- Public meetings and hearings.
- Station area workshops.
- Stakeholder interviews.
- Community advisory committee.

***Public Participation Tools for Project Development, Washington County, Oregon***
The Washington County Department of Land Use & Transportation [2015] in Oregon has developed a set of guidelines for public participation on projects going through the project development process. Public participation tools and strategies for project development may include the following:

- An eSubscription (e-mail list) and/or Interested Parties list to keep interested parties informed.
- Print and e-mail project updates to interested parties list (may include postcards).
- Citizen Participation Organization (CPO) and other community meetings.
- Print and electronic newsletters (county and CPO newsletters).
- Project information signs at project site.
- Project website featuring pertinent documents.
- Social media updates.
- Media releases at major project milestones.
- Open houses.
- Citizen Participation Organization (CPO) and other community meetings.
- Project Focus Group or Community Advisory Committee for select projects with significant community impacts.

For major projects, the Department requires the adoption of a public participation plan with all of the steps presented in earlier sections of this chapter.

## VIII. HOW TO MEASURE EFFECTIVENESS

In his synthesis of transit industry experience with public participation strategies, Giering [2011] observed, "one of the most difficult aspects of synthesizing public participation across the agencies that participated in this effort is defining

"success." There is a need and a desire among agencies to quantify public participation outputs and outcomes in a way that can be used in a benefit-cost analysis. However, no consistent methods emerged." One way of defining success is identifying early in the process specific targets for individual public participation strategies. An example of this are the following metrics for evaluating the public participation plan for a recent San Diego project:

- Increase hits on project website by 10 percent from the baseline of 2,380 hits.
- Display project information at five high-traffic locations in the corridor.
- Make 30 presentations through the speakers bureau program.
- Distribute three issues of Mid-Coast eBlast.
- Participate in three community events.
- Issue three news releases.
- Conduct 15 stakeholder briefings.
- Conduct three meetings of the Mid-Coast Corridor Transit Project Working Group.
- Conduct five scoping meetings during the scoping period.
- Conduct four public hearings/meetings during the Draft Supplemental Environmental Impact Study/Subsequent Environmental Impact Report (SEIS/SEIR) public review period. [SANDAG, 2010]

However, it is important to distinguish quantity from quality. Making 30 presentations with the speakers' bureau says nothing about how effective these presentations were in informing, educating, motivating, or encouraging those in the audience.

To some extent the North Jersey Transportation Planning Authority (NJTPA) [2007] recognized this in its PPP when it identified desired outcomes for different public participation strategies. For example, its goal "Provide adequate opportunities to engage in meaningful two-way discussions between the NJTPA and the public about transportation planning issues," and the strategies of having public meetings, disseminating information via the internet, and interacting with the media were associated with the following outcomes:

1) More engaged members of the public, elected officials, and other stakeholders in the NJTPA planning process.
2) A Central Staff and Board of Trustees more fully engaged with the public.
3) More understanding by the public of the importance of the NJTPA's work, with more trust and credibility in the transportation decision-making process by the public.
4) A better chance to build consensus around tough decisions for the region.

These are laudable outcomes, but they rely solely on relative or qualitative statements with no description provided on how each strategy would be evaluated for success.

A key challenge to PPP evaluation is developing a systematic evaluation framework that examines all aspects of the agency's efforts. Thus, for example, the evaluation should clearly identify the stated goals of the public participation program and how the PPP efforts have helped achieve these goals. Planners should assess the effectiveness of individual tools and techniques in the context of the plan or project study, as well as identify where improvements can be made. Figures 24-5 and 24-6 show an effort to assess systematically the components of a PPP process. A common approach for evaluating public participation efforts is a self-assessment template that consists of a series of questions relating to the implementation of the PPP and the use of the information disseminated to the participants. This yields a standardized, useful evaluation tool that combines the qualitative with the quantitative.

**Figure 24-5. Matching Evaluation Measures to Public Involvement Goals**

## Evaluating Public Involvement

### QUESTIONS TO ASK

### Evaluation Principle 1: Evaluation Measures Match Goals

#### A. Define goals and success criteria during PI planning

Evaluation begins with understanding what public involvement or public information needs to accomplish in your project. Set goals and success criteria during PI planning.

Ask yourself and your project team:

- What are our PI goals?
- What are our definitions of success?
- How will we know when we have fulfilled our goals or reached success?

Each UDOT region takes a slightly different approach to PI. In addition to project-specific goals, ask yourself and your project team questions based on desired PI outcomes of your region. The table below provides an overview of each region's PI approach.

| UDOT Region | Overall PI Approach | Questions to Consider Based on Region's Vision of PI Success |
|---|---|---|
| Region 1 | Customer-friendly Partnering | • Did we provide pro-active information?<br>• Did we create a sense of stakeholder ownership in the project?<br>• Did we coordinate with the appropriate stakeholders? |
| Region 2 | Creation to Completion PI | • Did we consider public involvement or information at every project stage?<br>• Did we inform and engage relevant stakeholders?<br>• Did we build understanding through participation? |
| Region 3 | Strategic Involvement | • Did we coordinate with the appropriate communities?<br>• Did we meet stakeholders' needs?<br>• Did we meet project needs for public input?<br>• Did we effectively communicate with stakeholders? |
| Region 4 | Communicate and Build Relationships | • Did PI support the decision-making process?<br>• Did PI help build relationships with stakeholders?<br>• Did PI help build trust with the public?<br>• Did our approach match community values? |

#### B. Rephrase goals as questions

As shown above, goals and success criteria can be rephrased as questions. Ask yourself and your project team yes/no questions as well as questions that get at *how* and *why* the goal was or was not met.

#### C. Set measurable goals

Set target measurements during PI planning as benchmarks or expectations. Identify ways to measure goals including documenting numbers, cost-effectiveness, evaluating quality and effectiveness, behavior tracking, message retention, and qualitative or quantitative research methods.

**Figure 24-6. Balance Quantitative and Qualitative Measures for Evaluating Public Engagement Programs**

## Evaluating Public Involvement

### TOOL KIT & EVALUATION IDEAS

### Evaluation Principle 2: Balance Quantitative and Qualitative

Numbers only tell part of the story. Numbers are effective to document PI activities and track trends over time. Ask yourself and your team how PI contributed to the project as part of evaluating PI effectiveness. The list below provides some ideas for tools and methods of evaluation.

### By the Numbers

Number of comments

Attendance at meeting or activity

(*Caution*, low attendance does not always indicate failure)

Number of requests for information

Number of Web site hits

Number of new participants

Number of repeat participants

Number of media stories

### Cost-benefit Analysis

Set realistic assumptions (contacts made, readers reached)

Consider ongoing benefits to the project

Look at specific tools

Look at PI plan as a whole

Include value of media coverage (inches of print, minutes of broadcast time)

### Quality and Effectiveness

Rephrase goals as questions (see "Questions to Ask" handout)

Identify how PI contributed to the project

Hold a Lessons Learned Meeting

Use a project evaluation form

Compile a PI evaluation report

Gather consultant or contractor feedback

Conduct a Public Involvement Plan post analysis

Evaluate the accuracy of media stories

Track the tone of media stories (positive, negative or neutral)

**Figure 24-6. (*Continued*)**

Evaluate whether public comments show project understanding

Interview targeted stakeholders

Interview public officials

Conduct random interviews with stakeholders

Include PI in provisions for contractor incentive awards

Invite stakeholder committees to evaluate committee process

## Behavior Tracking

Public satisfaction pre- and post-analysis

Number of phone calls or comments

Tone of comments (negative, positive, neutral)

Leverage appropriate level of quantitative or qualitative research

## Quantitative or Qualitative Research

Public opinion surveys

Questionnaires

Internal surveys

Customer surveys (before and after a project or activity)

Informal surveys at public meetings

Focus groups

Source: Reprinted with permission of Eileen Barron.

A common approach for evaluating public participation efforts is a self-assessment template consisting of a series of questions relating to the implementation of the PPP and the use of the information disseminated to the participants. The following questions form part of the Colorado DOT's efforts to evaluate its PPP program.

**Meetings and outreach**

- How many individuals were identified as stakeholders at the beginning of the planning process?
- How many people did staff speak to?
- Were meetings held in previously unreached geographic areas of the state?
- Did the number of participants increase from previous long-range planning efforts?
- Was the overall turnout/response rate higher than past efforts?
- Was the information gathered used in the regional and statewide plans?

**Website and electronic media**

- How many visitors did the web page receive?
- Was the website updated in a timely manner with the most current information? (i.e., within a day or two of the information being finalized for the Web)

- How many subscribers are there to distribution lists, news feeds, and other electronic interactive media?
- How many times was a document downloaded from the website?
- How many comments were posted on a website?
- How many comments received electronically were addressed in the long-range plan document?

**Outreach method evaluation**

- What outreach method was the most effective and why?
- Was the use of news and/or electronic media increased from previous efforts? Did it result in increased participation?

**Printed materials**

- Were informational documents (brochures, fact sheets, studies, white papers) made available?
- How many newspaper articles were written covering the planning or programming process? [CDOT, 2015]

Table 24-13 is another example from the Washington County (Oregon) Department of Land Use and Transportation.

## IX. WORDS OF WISDOM

Many MPO and state DOT PPPs have identified lessons learned from prior experience with public participation efforts, which suggest guidance on future activities. These are summarized below simply to provide a snapshot of what others have learned about what makes a public participation effort successful. The PPPs that most contributed to this list come from the Boston MPO [2014], Colorado DOT [2015], Hillsborough County MPO [2014a], and the MTC [2015] in the San Francisco Bay Area.

- *Understand Your Public*—There is no one-size-fits-all approach to public participation. Census data can help identify the socioeconomic characteristics of each community; however, it is important to talk to people to really understand their issues and concerns.
- *Be Cognizant of Participants and Their Different Levels of Technical Expertise*—Organize meetings and other events to appeal to the issues and concerns of those who are likely to participate. Informational materials should be clear and available in sufficient detail to allow citizens to form and express their independent views. Make great use of visualization techniques to enhance understanding.
- *Provide a Predictable Process*—The planning process should be understandable and known well in advance. This consistency in the planning process will allow staff, citizens, and officials to plan their time and effectively apply their resources.
- *Be Creative and Flexible in How You Communicate*—The direction and effectiveness of the program should be reviewed periodically to ensure it meets the needs of the public and the transportation agency. This program should continue to evolve and include new avenues of communication to augment the agency's public outreach efforts.
- *Early Engagement Is Best*—Per the MTC, major planning initiatives and funding decisions to provide meaningful opportunities to help shape outcomes are provided throughout the planning process. However, because MTC's Regional Transportation Plan (RTP) is the blueprint for new policies and investments for the Bay Area, updates to the RTP are one of the best places for interested persons to get involved.
- *Access to All*—Participants, regardless of disabilities or language barriers, should feel welcome at public engagement meetings. Respect the views offered by members of the public, and utilize their opinions, and other information offered.
- *Let People Know What Happened with Their Input*—The transportation agency should make sure meeting minutes reflect public comments and document how comments are considered in agency decisions.

| Table 24-13. Self-Assessment for the Public Participation Plan, Washington County, Oregon | | |
|---|---|---|
| **Evaluation Criteria** | √ | **Metric** |
| Gather input by providing meaningful opportunities to participate | | Were efforts made to engage those most affected by the program, project, or service? |
| | | Were community organizations engaged and offered materials to share with their networks? |
| | | If decision-making process, were people invited to share input in advance of decision-making milestone? And, was that input shared directly with decision-makers at meetings? |
| | | How many people visited the project website? |
| | | Were website referrals received from partners, stakeholders or community organizations? |
| | | How many people subscribed to the newsletter |
| | | How many people unsubscribed from the newsletter? |
| | | Did your "interested parties" database grow after the public engagement period began? |
| | | How many people clicked through project e-mails to the website or survey, if applicable? |
| | | How many people opened the e-mail or survey, if applicable? |
| | | How many @ replies, mentions, or comments on social media were received? |
| | | How many people attended a public meeting or open house? |
| | | Were online opportunities to participate also available in other formats? |
| | | Were in-person opportunities to participate held at accessible locations? At various times? And supplemented by online opportunities? |
| | | How many comments were received? |
| | | What types of comments were made? |
| | | What was the demographic make-up of participants? |
| | | Did public involvement activities help build the capacity of people to participate in future public processes? |
| | | Would people provide input in the future? |
| | | Did public input result in modifications or changes to the project? |
| Involve underserved communities such as those with limited English proficiency, diverse cultural backgrounds, low-income, disability, seniors, and youth. | | Was a demographic analysis of the program, project, or service area completed in order to identify race, language proficiency, and income levels? |
| | | Was a four-factor LEP analysis completed to assist in determining an approach to language assistance? |
| | | Was material translated and/or provided to communities that have a limited ability to speak English? |
| | | Were translation services made available upon request? |
| | | Was project information made available at accessible locations such as health care clinics, local and ethnic markets, community centers, and schools? |
| | | How many comments were received in languages other than English? |
| | | Did meeting materials include LUT's non-discrimination and language assistance notice? |
| | | Did meeting materials include an ADA notice? |
| | | Was material provided in alternative formats upon request? |
| | | Were meeting locations accessible and barrier free? |
| | | Were community organizations that serve low-income communities, communities of color, people with limited English proficiency, youth, or persons with disabilities engaged? |

| Table 24-13. (*Continued*) | | |
|---|---|---|
| **Evaluation Criteria** | √ | **Metric** |
| Communicate complete, accurate, understandable, and timely information | | Was the information to be shared tested for clarity by people not involved in the program, project, or service? |
| | | Was the information reviewed for accuracy? |
| | | Were documents deemed "vital" translated into other languages? |
| | | Were people made aware of the availability of information through e-mail, web, or partner networks? |
| | | Were meetings, workshops, surveys, and other opportunities to participate clearly advertised on the project website and e-mailed to the interested persons list? |
| | | Were project-sponsored meetings advertised on the project website at least two weeks in advance? |
| | | Were people given advance notice of project briefings at community meetings such as neighborhood associations? |
| | | Were formal public comment periods advertised with adequate notice (30 days preferred, 15 days minimum)? |
| | | Did people feel their involvement was considered/acted upon? |
| | | Was information clearly advertised on Twitter, Facebook, and other social media sites? |
| | | What type of news or media coverage did the project receive? |
| | | Was information available at least one week in advance of any decisions based on that information? |

Source: Washington County, 2015

- *Coordinate with Partner Agencies and Their Outreach Activities*—Jointly held meetings, especially those that have a strong community presence, are a good way of expanding the potential audience. Potential partners include other municipal agencies (such as local villages) as well as community organizations (such as chambers of commerce, PTAs, and civic associations).
- *Embrace, as Feasible, New Technologies with which to Engage the Public in an Interactive Way*—Stay abreast of evolving social media and new technologies as they emerge.
- *Make Engagement Meaningful*—Credibility and trust are established over time when the public perceives the agency is not just "going through the motions or doing the minimum required by the laws and regulations that govern them," but are demonstrating a genuine commitment to collaborative decision making.
- *Train Staff Conducting Public Participation*—Proper skills and training are critical to successfully engaging the public. For example, staff should have solid verbal and written communication skills, be intimately familiar with the project (and thus able to answer questions), and be able to be direct without being "pushy" when requesting feedback.

## X. SUMMARY

Public participation is a continuous effort of every transportation planning and project development process. For legislative and regulatory reasons, transportation planners need to be aware of the expectations of an effective and successful program. From a decision-making perspective, the decision-making process needs input from a broad array of stakeholders and the public to generate the best decisions for the region. Public participation involves building long-term working relationships and providing meaningful opportunities to influence decisions before they are made and finalized. These relationships will likely be with the more traditional transportation agencies and other groups who have participated in the planning process for decades, but also with community-based organizations, faith-based organizations, citizen advisory committees, and similar types of organizations to broaden the range of opportunities for participation.

Many different types of strategies and tools can be used by planners to reach out to the public and key stakeholders. Capturing the public's interest takes effort and continual attention. In today's world, this includes social media technology platforms that allow transportation agencies to reach citizens. The capacity to create and utilize visualizations,

videos, the internet, intranets, and social networking will continue to change the way we communicate with one another. The basic concept of the public participation plan is that it articulates a strategy for using appropriate strategies and tools to obtain the most effective public participation process possible. Continual monitoring an evaluation of this process allows planners to adjust the PPP, modifying the plan when strategies are no longer appropriate or where new technologies have offered new capabilities.

A recent overview of public participation in transportation by the TRB Committee on Public Involvement identified four key lessons learned from the past decade. [Gazillo et al., 2013] First, efforts to promote transparency through public participation are becoming the norm, but practitioners should never assume public participation will happen on its own and should never become complacent about outreach efforts. Second, increasing diversity in participation requires greater public participation efforts to embrace these populations as well as improve and implement cross-cultural training, if appropriate. Third, practitioners need to be mindful of the balance between encouraging positive public participation and preventing the process to be used for personal gain. Finally, public participation practitioners need to be trained in the skills required to effectively implement successful programs and projects.

**Appendix A. Public Involvement Strategies and Tools, Hillsborough County MPO, Florida [Hillsborough County MPO. 2012]**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Advisory Committees | | ■ | | ■ | ■ | | | ■ | ■ | ■ | Make recommendations on projects, plans and policies to assist the MPO board in making informed decisions from the seven standing committees composed of experts, citizens & special interest groups. The make-up of citizen-based groups should reflect the community's demographic composition. |
| Alternative Media | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | | Use nontraditional means such as: automated voicemail, interactive information kiosks, computer graphic presentations, cell phones, podcasts in English and Spanish, etc. |
| Banners | ■ | | ■ | | | | | ■ | ■ | | Position logo banners inside and outside MPO events. The public can easily find event locations and news media will capture the banners to reinforce MPO brand recognition in news clips and photographs taken. |
| Banner Ad & Wraps | ■ | | ■ | | ■ | | ■ | | | | Highly visible form of advertising an event or plan in general newspapers, community news, and student newspapers. |
| Bicycle Suitability Map | ■ | | | | ■ | ■ | ■ | ■ | | | Reinforces the relevance of the bicycle, pedestrian, and safety planning; a great public relations collateral piece distributed through bicycle shops and other locations throughout Hillsborough County. |
| Business Briefings | ■ | ■ | | ■ | | ■ | | ■ | | ■ | Information is brought to a location where members of the business community gather in order to present background, goals, issues, & status of a project with ample opportunity for attendee response. |
| Celebrity Media | ■ | | | | | ■ | | | ■ | | Create excitement & appeal to a broader market than might normally take interest in transportation planning by creating PSA spots, videos, etc. with celebrity spokes-persons or by having a celebrity attend public workshops to bolster attendance. |
| Chambers of Commerce | ■ | ■ | | ■ | ■ | ■ | | ■ | ■ | | Being active in area Chambers of Commerce, including specialized Chambers, raises MPO recognition and provides a variety of opportunities to make presentations to various working groups and transportation committees that ideally represent a broad cross-section of the local business community. |

(*continued*)

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Charrettes | | ■ | | ■ | | ■ | | ■ | | ■ | A meeting format designed to define issues, analyze problems and alternative solutions in a short, intense time frame to reach consensus on approaches to be taken, usually involving local experts and targeted stakeholders defining values and expectations in the process. |
| Citizens Guide | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Produced and distributed in conjunction with the PPP to provide a concise informative tool for citizens on the various ways they can be involved in transportation planning and LRTP updates. |
| Community Outreach Coordinators | | ■ | | ■ | ■ | ■ | | ■ | ■ | | Professionals or volunteers who have extensive knowledge of EJ populations being targeted, relationships with community leaders within that community, and the cultural and linguistic competency in order to engage EJ communities in MPO planning or project management team. |
| Contests & Games | ■ | | | | | ■ | | ■ | | | Intensify community interest and increase community involvement through a game, gimmick or activity created to get the public's involvement in an idea, proposal or project. |
| Discussion Facilitation | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Group problem-solving guided by a trained facilitator who is neutral to the issues that focuses on a specific project or issue. Discussion is structured without controlling content in order to keep the process open with the full spectrum of opinions receiving due consideration, with the facilitator moving the discussion toward consensus and conclusion. |
| Event Hotline (24-Hour) | ■ | ■ | ■ | ■ | | ■ | | ■ | ■ | ■ | A dedicated and publicized local telephone number available 24 hours a day as an automated system to inform of upcoming public involvement opportunities and to collect recorded comments and/or get information for follow-up. |
| Exhibits & Kiosks | ■ | ■ | ■ | | | | | ■ | ■ | | Inform the community of project activities and opportunities to watch and/or attend in-person meetings or workshops. |
| Field Reviews | | | | | ■ | | | | | | On-site visit to facilitate understanding of existing conditions and to communicate proposed activities from an existing conditions viewpoint. |

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Flexible Database | | ■ | | ■ | | ■ | | ■ | ■ | ■ | • A computer database in which participants, stakeholders, and agencies information is entered in a manner that is easily and efficiently sorted and retrieved based on a variety of criteria.<br>• Provide a means to track responses and to provide effective & timely responses.<br>• An efficient means to achieve contact with the community through targeted mailing lists. |
| Flyers | | | ■ | | ■ | | ■ | | | | Printed announcements of upcoming public meetings or events that are posted and handed out in communities affected by MPO plans. |
| Focus Groups | ■ | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | A meeting with a defined agenda where a set of questions is posed to participants which guides discussion so that public opinion can be more closely gauged. A facilitator is necessary and the number of participants is normally limited. |
| Growth & Transportation Options Visioning Tool | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | An interactive visioning tool Flash-based program using GIS data, developed in conjunction with Tampa Digital for the Planning Commission to help people better understand the relationship between transportation and land use. It allows users to allocate growth and types of development to building land use scenarios using information on available, developable land, environmentally sensitive land, and population. Users can see instantly the impact it has on transportation choices. This tool has applications in live workshops, at free-standing kiosks and with online participants with easily downloadable results. |
| HCTV22 & Cable TV | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | | • Broadcast spots that inform the community about events, meetings & other public participation opportunities.<br>• Live and rebroadcasts of all MPO meetings in HTV22 with reference to MPO website on banner. The schedule is available from HTV at 813/272-5362. |

(*continued*)

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| "Home Games" | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | A method most recently used for the *MPO Transit Study's* Transit Scenarios Workshops providing the ultimate in proactive participation techniques by providing at home workshops for neighborhood or other stakeholder groups to participate at a time and place most convenient, allowing people to participate who may never have attended a public workshop, having a significant impact on overall number of participants. |
| Informational Brochures | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | Develop & distribute informational brochures regarding current transportation issues. Recent & upcoming brochures include a one-page fold-out map depicting LRTP projects, the Ride Guide, Citizens Guide, Transit Concept for 2050 brochure and a Bicycle Suitability Map. Brochures are made available at public events, through public libraries and in the public area of The Planning Commission offices. |
| Interactive Displays | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | ■ | The electronic display of information, which includes computer graphics, photo mosaics, GIS systems, video brochures, simulations, and visualization tools that can be enhanced with interaction, making complex concepts more easily understood. |
| Leadership Meetings | ■ | ■ | ■ | ■ | | ■ | ■ | ■ | | ■ | Meetings where the public receives the latest project information in an atmosphere where community leaders can respond to current information, assess leadership concerns and needs and rally support for project goals and upcoming activities. |
| Advertisements | ■ | ■ | ■ | | ■ | | ■ | ■ | ■ | ■ | Advertise public meetings, public hearings, and required public comment and review periods. See the Notices section. |
| Logos | ■ | ■ | ■ | | ■ | | ■ | ■ | ■ | ■ | Using the MPO Logo or special study logos to create brand recognition through every phase of projects, plans, programs, and documentation. |
| Media Kits & Briefing Packages | ■ | | ■ | | | ■ | ■ | ■ | ■ | ■ | An informational package to provide general project data to media outlets that will be able to disseminate accurate information to interested audiences in a people-friendly format. |

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Media (non-traditional) | ■ | ■ | ■ | | ■ | | | ■ | ■ | ■ | Includes newspapers aimed at ethnic groups, broadcast media serving non-English speakers. |
| Meeting Notices & Agendas | | ■ | ■ | | ■ | ■ | | | | | Mailed electronically or in hard-copy to all citizens who request them in addition to MPO members and Committee members. Posted on the MPO website. See the Notices section. |
| Mobile Devices | ■ | ■ | ■ | | ■ | ■ | | ■ | ■ | ■ | Electronic forms of communication can leverage technology through means such as text messaging, email blasts, and Twitter to broadcast alerts and public notices to mobile devices and smart phones. |
| Mobile Exhibits | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | A portable, stationary or interactive display of project background and current information that can be moved community sites or special events to improve awareness and response collection by stakeholders. |
| Money Game | | ■ | | ■ | ■ | ■ | ■ | ■ | | | An active participant form of surveying used to demonstrate how the public would like to see their tax dollars spent. At the onset of a meeting, participants are given $100 in play money and asked to distribute the money into boxes representing various modes of travel. |
| Newsgroups | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Available 24 hours a day for interested and informed stakeholders. |
| Newspapers | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | An article, advertisement, or announcement generates attention, intended to reach a wide audience to announce a project or meeting and/or stimulate interest community interest. Building relationships with reporters to cover relevant transportation planning activities is key. See the Notices section. |
| Online Communities, i.e., MySpace, Facebook, Yahoo | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Setting up an online community can generate a new level of interest, particularly with the younger generation who may not typically be interested in long range transportation planning. This can be a good discussion forum, as well as a way to broaden notice opportunities. |

(*continued*)

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Open House | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | An informal gathering that provides a forum where questions can be asked or submitted and answered in a comfortable atmosphere that encourages open discussion focusing on issues rather than positions, often tailored to specific area needs. Complex projects can be broken down into smaller components for easier understanding. |
| Participatory Budgeting | | ■ | | ■ | | ■ | | ■ | | | A democratic form of budget-making for all or part of a municipal or state budget, in which volunteer delegates selected from districts or thematic groups (e.g., health, education, transportation) identify projects, the costs of which are estimated by professional staff. The delegates then review and prioritize projects against available funding and present them to elected officials for final approval. |
| Partnering with Community Organizations | ■ | ■ | | | ■ | ■ | ■ | ■ | | | Reaching out to partner with community-based organizations and leaders to promote and hold meetings, facilitate discussions, and obtain feedback on MPO plans. |
| Personal Interview | | ■ | | ■ | | | | | ■ | ■ | Face-to-face discussion about project specific topics and issues with key community stakeholders, community and opinion leaders, agency representatives and other interested parties who represent broader community opinions for the purpose of gathering information and opinions early in the planning process or prior to decision-making. |
| Photo Inventory | | ■ | | | | ■ | | ■ | | | • Assign citizen volunteers to photograph what they like and do not like about their community.<br>• Photos are compiled and organized into an inventory of community problems and assets.<br>• Smart phones can be used to take photos, transmit them and geo-tag locations for easy mapping later on. |

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Plain Language | | ■ | | | ■ | | ■ | | ■ | | MPO plans and presentations should always strive to be clear, concise, free of technical jargon, understandable and inviting to citizens. |
| Plan Documents | ■ | | | | ■ | | ■ | | | ■ | Published by the MPO at regular intervals and include the LRTP, TIP and other plans and reports and disseminated according to the guidelines outlined in this PPP. |
| Postage Paid Comment Cards | | ■ | | ■ | | ■ | | | | ■ | Accompany the distribution, preferable as an attachment, with all plan documents in order to solicit immediate feedback from the public. Tear-off versions of the card are included in all publications printed for widespread distribution. |
| PowerPoint Presentations | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | An excellent tool for reaching out to other agencies and community groups and for presentations to the MPO and its advisory committees, helping to tell our story and explain plans and projects using visuals and allowing for Q&A or discussions. |
| Press Releases | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | Press releases are free and can often generate print, television and radio coverage going beyond purchased legal and display ads to encourage participation at MPO activities and events and to help keep people who cannot attend involved and aware. |
| Project Teams—Citizens Leadership Technical | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Used most recently for the *MPO Transit Study*, this was a great avenue to involve citizens, leaders and technical advisors for a specific project to generate excitement, improve communication, and bolster the effectiveness of public participation goal. |
| Public Hearings | ■ | ■ | ■ | ■ | ■ | | | ■ | ■ | ■ | Advertised meetings held by the MPO to consider the adoption of the plan or program being presented at which public input is encouraged. All comments, whether written or oral, are formally recorded. |

(*continued*)

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Public Participation Workshops | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | • Interactive meetings held throughout a defined community to which all community members are invited, information is shared, project questions are asked and answered and awareness is increased.<br>• Provide information to the community in a forum that allows people to feel comfortable & encouraged to contribute meaningful feedback to the project team in a non-threatening atmosphere.<br>• Held prior to decision-making points in the MPO process. |
| Periodic Newsletter | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Produce & distribute a periodic newsletter concerning transportation issues in the county that promotes best planning practices to neighborhood associations, business groups, professional associations, social clubs, chambers of commerce, interest groups, churches, schools and other groups and associations of those traditionally under served by existing transportation systems. Hundreds of copies are also distributed through the Hillsborough County Public Library system. |
| Radio & PSAs | ■ | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | • News releases will be made available to all local radio media.<br>• Broadcast spots that inform the community about an event.<br>• Inform the community of project activities and opportunities to become more involved.<br>• Partner with radio personalities like WFLA's Jack Harris, who has consistently supported transit and a better transportation network.<br>• Target community reporters at public radio stations such as WMNF and WUSF. |

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Relationship Building | ■ | ■ | | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Building relationships with interagency partners, community leaders, civic groups, faith-based organizations, media, etc. will ensure understanding by the MPO and support all of the public participation goals. |
| Report Public Comments & Results | | ■ | ■ | ■ | ■ | | | ■ | | ■ | Each MPO report developed will include a public and interagency comment section summarizing comments received and any changes made to plans as a result of the comments. |
| Ride Guide | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | A highly informative, user-friendly collateral piece distributed though human services and transportation agencies throughout Hillsborough County. Printed in large font for the elderly market, it is an excellent tool for the transportation disadvantaged and caregivers. |
| Scenario Workshops | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Planners, citizens, technical specialists, community leaders, elected officials doing hands-on planning in a visualization format. Used most recently for the *MPO Transit Study* with a "Home Game" version. |
| Signage | ■ | | ■ | | ■ | | ■ | | | | Making the public aware of public meetings and events by posting signs in the affected areas. |
| Speakers Bureau | | | | | ■ | | | | | ■ | A presentation to interested groups to provide background information and discuss current issues, allowing ample time for interactive feedback. Upon request, the MPO will give presentations to public, private or citizen groups concerning the MPO plans and activities. |
| Student Newspapers | ■ | ■ | ■ | | ■ | | | | | | Articles and notices pertinent to specific school, college and university populations are a good way to engage what can be a hard to reach segment of the community. |
| Surveys & Comment Cards | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Can be used at community events, following presentations, in the newspaper, in the MPO newsletters, accompanying MPO plan documents or direct-mailed to solicit general input from the public or a target audience, or to generate specific technical data. Can also be distributed at the end of MPO events to get feedback on the event itself. |

(*continued*)

Appendix A. (*Continued*)

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Talking Points | ■ | ■ | ■ | | ■ | ■ | ■ | | | | Provides an accurate, uniform message for the MPO and staff to use to address public or media inquiries or when making presentations. |
| Technical Memos | | | | | ■ | | | | | | For long-term projects like the LRTP, the MPO staff and/or project consultants prepare technical memoranda concerning the technical and policy issues. Specifically, these document issues methodologically used and data developed as part of the planning process. |
| Teleconferencing | ■ | ■ | | ■ | | | | ■ | ■ | ■ | A telephone or visual communication meeting between interested parties in two or more locations allowing distance-disadvantaged community participants to be involved in the exchange of ideas and discussions, saving time, gas, and travel inconveniences. |
| Telephone Polling | | ■ | | ■ | | ■ | | ■ | | ■ | Telephone interviews with a randomly generated community cross-section or specific sub-section of the community will provide a current sense of community awareness and particular project issues. |
| The Planning Commission Library | ■ | | | | ■ | | ■ | | | ■ | A central depository for MPO publications and other transportation related materials. It is open to the public and is located at:<br>The Planning Commission<br>County Center Building, 18th Floor<br>601 East Kennedy Boulevard<br>Tampa, FL 33602 |
| Town Call Meetings | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Town Hall style meetings held as a live telephone conference call providing an opportunity to share information, answer questions and poll thousands of participants. Celebrity host & panelists may be used. |
| Town Hall Meetings | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Displaying at events like the BOCC Town Hall Meetings supports all of the PPP goals in various communities throughout Hillsborough County and minimizes costs by partnering with the County's event format. |

**Appendix A. (*Continued*)**

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| Translation into Other Languages | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Speaking the language the people speak to enhance their ability to not only understand the plans, but actually participate in the transportation planning process. Opportunities may exist in more than one language, including sign language, depending on the targeted group or stakeholders in the planning area and may be applied to publications, website, advertisements, hot-line information, customer assistance and presentations. See Accessibility for more information and Appendix E for the MPO's *Limited English Proficiency Plan*. |
| Transportation Fairs | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | An event used to create public interest in a transportation project or program usually of one-day duration. The event is actively promoted across multi-media and involves visual displays or technology demonstrations; thus, encouraging community interest in a program or study, keeping the public interested and informed while allowing for casual input and formal feedback opportunities. |
| twitter | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Used as a rapid news source feed to provide information about all MPO plans, programs and events as well as a tool to providing information about other relevant meetings, events and resources. Also, an interactive tool providing two-way communication for feedback. |
| Videos | ■ | | | | ■ | ■ | ■ | ■ | ■ | | Recorded visual and audio messages for presentation to the community that is easy to understand and visually appealing with the advantage of being used for consistent presentations that can go beyond the capabilities of live presentations or when a live speaker is not available. |
| Visioning | | ■ | | ■ | | ■ | | ■ | | ■ | A series of meetings focused on long-range issues involving a broad spectrum of people to generate ideas, set goals and priorities and to assist in the formulation of policy direction. Determines parameters of short-range planning activities. Provides a venue for the input of a wide range of ideas and potential solutions. |

Appendix A. (*Continued*)

| Strategies & Tools | PPP Goals Supported | | | | | | | | | | Strategy or Tool Description: How Does This Strategy or Tool Work? Could This Strategy or Tool Work for Us in the Future? |
|---|---|---|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | |
| | Visibility | Engagement | Notification | Responsiveness | Communication | Resourcefulness | User-Friendly | Proactive | Accessible | Compliant | |
| VISSIM Software | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Powerful 3-D multi-modal tool applied to simulate future vehicular flows, bicycle and pedestrian traffic, transit operations and conditions at rail stations. Used to model movement and behavior from small surface roads to complex, large-scale transit systems and generate before and after aerial animations of future transportation projects based on existing and future traffic conditions. |
| Visualization Software Programs | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | Samples of visualization techniques range from photo, PowerPoint or video presentations, brainstorming sketches and visual preference surveys to scale models, renderings, maps, aerials, 3-D imagery, and other computer-aided visualization. |
| Walking Tours & "Walkshops" | | | | | | | | | | | Organized group walking tours through a project site or corridor to enable community members to see and or point out problems, assets and resources important to the community. "Walkshops" are mobile workshops geared around group activities, such as photo inventorying and mapping. |
| Web 2.0 Technology & Crowdsourcing | | ■ | | ■ | | ■ | ■ | | | | Web 2.0 refers to new Internet programs designed to foster collaboration between users. Crowdsourcing is a form of distributed problem-solving. Internet-based tools, such as Wikis, webcasts, and online dialogues, can allow users to develop documents collaboratively, for example, corridor plans drafted with direct input from community representatives. |
| Websites | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | ■ | 24-hour accessible online site with web address http://www.hillsboroughmpo.org where the community can immediately access calendars, agendas, members, interactive maps, links to related sites, general study information and most MPO publications with the opportunity to participate in a survey or email feedback. Visits to the site are tracked. www.mpo2035.org created in conjunction with the 2035 Plan. |
