# Table of Contents

Preface ..... xi
Acknowledgments ..... xiii
About the Editor ..... xvii

**CHAPTER 1: INTRODUCTION TO TRANSPORTATION PLANNING ..... 1**
I. Introduction ..... 1
II. Organization of This Handbook ..... 2
III. The Transportation Planning Process ..... 3
IV. Changing Context for Transportation Planning ..... 12
V. Additional Sources of Information ..... 14
VI. Summary ..... 15
VII. References ..... 16

**CHAPTER 2: TRAVEL CHARACTERISTICS AND DATA ..... 17**
I. Introduction ..... 17
II. Transportation System Characteristics ..... 17
III. Urban Travel Characteristics ..... 26
IV. Estimating Travel Characteristics and Volumes ..... 35
V. Modal Studies ..... 61
VI. Statistical Considerations ..... 67
VII. Summary ..... 71
VIII. References ..... 71

**CHAPTER 3: LAND USE AND URBAN DESIGN ..... 75**
I. Introduction ..... 75
II. What Drives Development and Resulting Urban Form? ..... 76
III. Urban Form ..... 88
IV. Urban Design ..... 90
V. Land-Use Forecasting and Transportation Planning ..... 95
VI. Scenario Analysis for Urban Form ..... 103
VII. Highway Facility-Related Strategies ..... 104
VIII. Summary ..... 110
IX. References ..... 111

**CHAPTER 4: ENVIRONMENTAL CONSIDERATIONS ..... 117**
I. Introduction ..... 117
II. Environmental Considerations in Transportation Planning and Decision Making ..... 117
III. General Principles Regarding Environmental Content and Level of Detail ..... 130
IV. Land Use and Economic Development Impacts ..... 133
V. Social and Community Impacts ..... 139
VI. Natural Resource Impacts ..... 146
VII. Construction Impacts ..... 158

VIII. Considering Mitigation Strategies during the Systems Planning Process ..... 159
IX. Summary ..... 160
X. References ..... 160

**CHAPTER 5: TRANSPORTATION FINANCE AND FUNDING ..... 165**
I. Introduction ..... 165
II. Key Concepts and Terms ..... 166
III. Sources of Transportation Funding ..... 167
IV. Transportation Finance Strategies ..... 175
V. Public/Private Partnerships ..... 178
VI. Investment Programming and Revenue Estimation ..... 182
VII. Environmental Justice Analysis ..... 197
VIII. Future Challenges ..... 199
IX. Summary ..... 200
X. References ..... 200

**CHAPTER 6: TRAVEL DEMAND AND NETWORK MODELING ..... 205**
I. Introduction ..... 205
II. Modeling Travel Demand ..... 205
III. Demand Models and Tools ..... 214
IV. Summary ..... 233
V. References ..... 233

**CHAPTER 7: EVALUATION AND PRIORITIZATION METHODS ..... 237**
I. Introduction ..... 237
II. Characteristics of the Evaluation Process ..... 237
III. Case Studies ..... 266
IV. Summary ..... 275
V. References ..... 277

**CHAPTER 8: ASSET MANAGEMENT ..... 281**
I. Introduction ..... 281
II. What Is Transportation Asset Management? ..... 282
III. Recent U.S. History of Transportation Asset Management ..... 284
IV. Asset Management and Transportation Planning ..... 291
V. Asset Management Challenges and Opportunities ..... 311
VI. Summary ..... 312
VII. References ..... 312

**CHAPTER 9: ROAD AND HIGHWAY PLANNING ..... 317**
I. Introduction ..... 317
II. Best Practice for Urban Roadway Systems ..... 318
III. Context-Sensitive Solutions (CSS) ..... 323
IV. Traffic Calming ..... 324

V. Green Roads ..... 328
VI. Complete Streets ..... 330
VII. System Performance and Capacity Measures ..... 333
VIII. Condition Measures and Management Systems ..... 338
IX. State Highway Plans and City Thoroughfare Plans ..... 342
X. Road Investment Programs and Performance Monitoring ..... 348
XI. Summary ..... 350
XII. References ..... 350

**CHAPTER 10: TRANSPORTATION SYSTEM MANAGEMENT AND OPERATIONS ... 355**
I. Introduction ..... 355
II. Understanding Network and Facility Performance ..... 357
III. Planning and Organizing for TSM&O ..... 361
IV. Active Transportation and Demand Management ..... 366
V. Examples of Management and Operations (M&O) Strategies ..... 368
VI. Linking Transportation Planning and Planning for Operations ..... 381
VII. Dissemination of Operations Data ..... 400
VIII. The Connected Transportation System ..... 400
IX. Summary ..... 405
X. References ..... 406

**CHAPTER 11: PLANNING FOR PARKING ..... 411**
I. Introduction ..... 411
II. Parking Management Organizations ..... 412
III. Zoning Requirements ..... 413
IV. Strategies and Decisions for Parking Supply Options ..... 419
V. Parking Management ..... 428
VI. Parking Demand and Needs Analysis ..... 435
VII. Common Land Uses ..... 450
VIII. Shared Parking Methodology ..... 465
IX. Parking Costs ..... 468
X. Financing Parking Facilities ..... 477
XI. Summary ..... 480
XII. References ..... 481

**CHAPTER 12: TRANSIT PLANNING ..... 485**
I. Introduction ..... 485
II. Ownership and Governance ..... 486
III. Contemporary Transit in North America ..... 488
IV. Classification of Transit Modes and Their Components ..... 491
V. Transit Cost Structures ..... 517
VI. System Performance and Quality of Service ..... 519
VII. Transit Planning Procedures ..... 526
VIII. Planning for Passenger Stations ..... 534

IX. Station Design ..... 543
X. Lines and Networks ..... 563
XI. Transit Route Planning ..... 569
XII. Future Transit Issues ..... 573
XIII. Summary ..... 576
XIV. References ..... 576

**CHAPTER 13: PLANNING FOR PEDESTRIANS AND BICYCLISTS ..... 581**
I. Introduction ..... 581
II. Goals and Benchmarks for Pedestrian and Bicycle Planning ..... 582
III. Pedestrian and Bicyclist Safety ..... 583
IV. Evolution of Pedestrian and Bicycle Planning in the United States ..... 585
V. Pedestrian and Bicyclist Planning ..... 591
VI. Pedestrian and Bicyclist Planning/Design Issues ..... 616
VII. Pedestrian and Bicycle Transportation in Asia and Europe ..... 632
VIII. Summary ..... 634
IX. References ..... 634

**CHAPTER 14: TRAVEL DEMAND MANAGEMENT ..... 641**
I. Introduction ..... 641
II. TDM Goals, Objectives, and Performance Measures ..... 644
III. TDM Strategies ..... 646
IV. Potential Impacts of TDM Strategies ..... 667
V. Data, Model Use, and Results ..... 668
VI. Summary ..... 672
VII. References ..... 677

**CHAPTER 15: STATEWIDE TRANSPORTATION PLANNING ..... 681**
I. Introduction ..... 681
II. The Role of the Federal Government ..... 682
III. Statewide Transportation Planning ..... 685
IV. Statewide Modal Plans ..... 723
V. Summary—Continuing State Planning Challenges ..... 725
VI. References ..... 727

**CHAPTER 16: METROPOLITAN TRANSPORTATION PLANNING ..... 729**
I. Introduction ..... 729
II. Legislative Context for U.S. Metropolitan Transportation Planning ..... 729
III. Institutional Structure for Metropolitan Transportation Planning ..... 735
IV. The Transportation Planning Process ..... 739
V. Monitoring System and Program Performance ..... 762
VI. Public Engagement ..... 762
VII. Special Topics for Metropolitan Transportation Planning ..... 768
VIII. Summary ..... 774
IX. References ..... 775

**CHAPTER 17: CORRIDOR PLANNING** ..... **783**
I. Introduction ..... 783
II. Nature of Corridor Transportation Planning ..... 783
III. Corridor Selection ..... 796
IV. Corridor Planning Approach ..... 798
V. Corridor Management Plans ..... 832
VI. Summary ..... 836
VII. References ..... 837

**CHAPTER 18: LOCAL AND ACTIVITY CENTER PLANNING** ..... **841**
I. Introduction ..... 841
II. Local Transportation Planning ..... 842
III. Activity Centers ..... 863
IV. Implementation of Transportation Plans ..... 886
V. Summary ..... 887
VI. References ..... 887

**CHAPTER 19: SITE PLANNING AND IMPACT ANALYSIS** ..... **891**
I. Introduction ..... 891
II. Administrative Requirements ..... 893
III. Definition of Key Terms ..... 896
IV. Site Plan Review Data ..... 897
V. Transportation Access and Impact Analysis ..... 899
VI. Analysis Procedures ..... 915
VII. On-Site Transportation Elements ..... 931
VIII. Implementation Actions/Strategies ..... 936
IX. Report Organization ..... 938
X. Summary ..... 939
XI. References ..... 941

**CHAPTER 20: RURAL COMMUNITY AND TRIBAL NATION PLANNING** ..... **945**
I. Introduction ..... 945
II. Rural Transportation Planning ..... 946
III. Tribal Nations ..... 959
IV. Summary ..... 971
V. References ..... 972

**CHAPTER 21: RECREATIONAL AREAS** ..... **975**
I. Introduction ..... 975
II. Characteristics of Recreational Travel ..... 975
III. Characteristics of Transportation Systems Serving Recreational Areas ..... 977
IV. Transportation-Related Characteristics of Visitors to Recreational Areas ..... 983
V. Transportation Planning for Recreational Areas ..... 984
VI. Need for Information and Communication ..... 1008

VII. Summary ..... 1009
VIII. References ..... 1010

**CHAPTER 22: INTEGRATING FREIGHT INTO THE TRANSPORTATION PLANNING PROCESS ..... 1013**

I. Introduction ..... 1013
II. Overview of Domestic Freight Flows ..... 1013
III. Impact of Freight Flows on the Community, Freight Sector, and Transportation System ..... 1017
IV. Freight Planning ..... 1027
V. Freight Terminals ..... 1059
VI. Summary ..... 1063
VII. References ..... 1065

**CHAPTER 23: PLANNING IT SAFE—SAFETY CONSIDERATIONS IN THE TRANSPORTATION PLANNING PROCESS ..... 1069**

I. Introduction ..... 1069
II. U.S. National Statistics ..... 1070
III. Institutional and Policy Structure in the United States ..... 1073
IV. Laying the Groundwork for Transportation Safety Planning ..... 1079
V. Incorporating Safety into Transportation Planning ..... 1080
VI. The *Highway Safety Manual* (HSM) ..... 1104
VII. Relationship between Transportation Safety Planning and Strategic Highway Safety Planning ..... 1105
VIII. Lessons from the International Community ..... 1105
IX. Summary ..... 1107
X. References ..... 1108

**CHAPTER 24: PUBLIC PARTICIPATION AND ENGAGEMENT ..... 1111**

I. Introduction ..... 1111
II. What Is the Public Participation Process? ..... 1111
III. Know Your Public and Stakeholders ..... 1116
IV. Public Participation Plan ..... 1120
V. Public Participation Methods and Approaches ..... 1123
VI. Evolving Role of Technology and Social Media ..... 1130
VII. Public Participation and Project Development ..... 1133
VIII. How to Measure Effectiveness ..... 1134
IX. Words of Wisdom ..... 1139
X. Summary ..... 1141
XI. References ..... 1142

**Index ..... 1157**

# Preface

The original intent of the update to the *Transportation Planning Handbook* (third edition) was to simply provide more recent references and add material on topics that had surfaced as an important planning topic since the publication of the third edition nine years ago. In updating each chapter, however, it became apparent that much has happened since the mid-2000s in transportation planning. Important changes have included a focus on performance-oriented planning, an increased emphasis on environmental and social justice, a continuing revolutionary change in transportation system and vehicle technology, a similar revolution in the technology of data collection, the expanding options for transportation finance, and a continuing trend in changing socio-demographic characteristics that will fundamentally affect how travel occurs. What had begun as a simple update evolved into a major rewrite when it became apparent that transportation planning is now facing many important challenges and opportunities that were just becoming apparent in the mid-2000s.

In addition to the updates of the chapters found in the third edition, new chapters have been added to this edition reflecting the importance of these topics to contemporary transportation planning. These chapters include transportation finance and funding, highway system planning, travel demand management, local/municipal transportation planning, and public engagement. These chapters were written by the editor.

Finally, the technology of publishing has changed dramatically since the mid-2000s such that we can now cross reference and link key concepts from one chapter to another. This handbook does not repeat concepts that are inherent to transportation planning whether focusing on state, metropolitan, or local planning contexts. For example, Chapter 1 presents an organizing framework for transportation planning that outlines the major steps inherent in any planning process. The chapters on statewide, metropolitan, and local transportation planning simply reference this framework rather than repeat the framework in each chapter. Thus, those who are using individual chapters for teaching and/or reference should be aware that each chapter might reference material in other chapters that is needed to obtain a complete picture of the substance and concepts in a targeted chapter.

The experience in updating this handbook reflects the dynamic nature of transportation planning. As noted by the editor in other publications and in previous editions of the handbook, transportation planning relates to the key policy issues and decision contexts of the day. Although transportation planners in the mid-2000s would recognize much of what planners are doing today, they would be surprised by planning interest in climate change, autonomous vehicles, 3D printing (and its impact on logistics), cloud sourcing as a tool for public engagement, and many other capabilities and issues that have been enabled by changing socio-demographic characteristics and new technologies. The planning process outlined in this handbook is one that is future-oriented, anticipating societal and technological characteristics that will affect future transportation system performance. In addition, it is one that is flexible to allow policy issues and new analysis capabilities to be included as they become important topics to planners and decision makers. In this way, transportation planning will continue to stay relevant to the decisions that decision makers today and in the future will be making to improve the vitality of our communities.

# Acknowledgments

The preparation and production of the fourth edition of the Transportation Planning Handbook has been a collaborative and intensive effort. One person in particular has been instrumental in working with the editor in all aspects of the handbook preparation … from obtaining resource information to reviewing chapters for consistency and quality. This handbook could not have been prepared without the work of Adam N. Rosbury, who deserves much credit for the final product.

The fourth edition has also greatly benefited from the efforts of numerous individuals who helped create the overall outline for the handbook and who volunteered to review individual chapters and in the process greatly improved the quality of the handbook. An initial advisory panel reviewed early versions of the new handbook outline and provided feedback on some of the early chapters. Panel members included:

Thomas W. Brahms

Steven B. Gayle

Jamie Henson

Aliyah Horton

Leslie Meehan

Michael D. Meyer

Richard A. Retting

Donald R. Samdahl

Sam D. Zimbabwe

The following subject matter experts served as volunteer reviewers of the draft handbook chapters:

Bernard Alpern

Joel Anders

Amit Armstrong

William Bachman

Saeed Asadi Bagloee

Eileen Barron

Roxanne Bash

Michael Becker

Wayne Berman

Claudia Bilotti

Mark M. Boggs

Candace Brakewood

Peter Chen

Stan Clauson

Steven B. Colman

Christopher J. Comeau

James M. Considine

Jenna Cooley

Sean T. Daly

Brian E. Dempsey

Karen K.Dixon

Daniel B. Dobry Jr.

Michael J. Dorweiler

Nelson M. Filipi

Rajesh H. Gajjar

Steven B. Gayle

Rebecca G. Goldberg

Sudhir Gota

Fred M. Greenberg

Mark D. Greenwood

Lewis G. Grimm

Perry D. Gross

Daniel K. Hardy

Susan Herbel

James Wagner

Tania Wegwitz

Brian T. Welch

Julie M. Whitcher

Cain Williamson

Philip L. Winters

Tom M. Worker-Braddock

Linda Wu

KC Yellapu

Jiguang ZhaoAmit Armstrong

ITE staff members have also been an important contributor to handbook development. Thomas W. Brahms articulated the original vision for the handbook and provided input on the handbook outline. Courtney L. Day was instrumental in coordinating the chapter review process and in interfacing with the publisher.

Finally, the concept of this handbook was to update the chapters in the third edition of the handbook and to add several new chapters that reflected the changing professional interests since 2009. Thus, much of the material in this handbook was produced by the original authors, updated to reflect more recent references and examples. The original authors included:

Marsha Bomar Anderson

Song Bai

Sandra K. Beaupre

Greg Benz

Wayne Berman

Stephen B. Colman

Jeffrey M. Cosello

Paula Dowell

Anne E. Dunning

Leon Goodman

Jane Hayse

Susan Herbel

Jeremy Klop

Herbert S. Levinson

Jerome Lutin

Michael D. Meyer

Debbie Niemeier

Matthew Ridgway

Jerry B. Schutz

Mary S. Smith

Vukan R. Vuchic

The editor takes responsibility for changes and additions to the fourth edition of the Transportation Planning Handbook.

Michael D. Meyer, Ph.D., P.E., M.ITE,
and F.ASCE, Editor

# About the Editor

Dr. Michael D. Meyer is a senior advisor to WSP/Parsons Brinckerhoff, Inc., Co-founding Principal of Transport Studio, LLC, and president of Modern Transport Solutions, LLC. He was the Frederick R. Dickerson Professor of Civil Engineering and Director of the Georgia Transportation Institute at the Georgia Institute of Technology until 2012 when he retired. From 1983 to 1988, Dr. Meyer was Director of Transportation Planning and Development for Massachusetts where he was responsible for statewide planning, project development, traffic engineering and operations, and transportation research. As Director, Dr. Meyer spent considerable time with the state's transportation planners developing statewide, metropolitan, and corridor-level transportation plans. In addition, he worked closely with local officials in developing institutional collaborations for compatible land-use and development strategies. Prior to this, he was a professor in the Department of Civil & Engineering at M.I.T. He is currently an adjunct professor at Denver University's Transportation Institute.

Dr. Meyer has written over 200 technical articles and has authored or co-authored 28 books or book chapters, many on transportation planning and policy, including a major college textbook on transportation planning. Dr. Meyer has given over 300 speeches or keynote conference addresses over the past 20 years and testified to Congressional committees on a variety of topics relating to transportation policy and planning, including most recently the importance of incorporating sustainability into transportation decision making. He was one of the first researchers in the United States to examine the role of performance measures in transportation planning and decision making, and more recently he has been one of the first transportation professionals to write extensively on the relationship between climate change and transportation system performance. He has received numerous professional awards, and was chair of the Transportation Research Board Executive Committee in 2006.

# Introduction to Transportation Planning[1]

## I. INTRODUCTION

The economic health and quality of life of a nation's communities depend on a well-functioning and safe transportation system. For example, following housing costs, transportation is one of the biggest expenses faced by an average household in the United States and in many other countries. This is usually measured by the actual out-of-pocket costs associated with owning and operating vehicles or paying for transit fares. When one considers the value of time it takes to travel from one location to another, often in congested conditions, this cost increases significantly. The cost of freight and goods movement is also an economic cost passed on to consumers that will vary depending on the price of transportation.

The accessibility and mobility provided by transportation systems can influence land use patterns and, thus, over time affect how we live. The best example of this relationship is the large-scale suburbanization of U.S. metropolitan areas and of those in many other countries after World War II when massive investment was made in suburban freeways. Today, transportation investment is often an integral part of economic and development plans, usually including transit, pedestrian, bicyclist facilities, and actions to manage transportation demand. The importance of transportation investment in transforming communities raises questions of who is benefiting and who is carrying additional burdens after the system has changed. These are questions that are part of many transportation planning studies.

The public is also concerned about the environmental impacts linked to transportation systems and their operation. This has been manifested in many environmental laws and regulations that affect how transportation planning is conducted and the types of data and tools that must be used.

These, along with many other reasons, suggest that the transportation system is a critical component of a successful modern community and economy. Thus, anticipating the challenges and opportunities relating to transportation system performance is critical not only to future transportation system effectiveness, but also to the economic and social well-being of our communities.

This handbook examines many facets of transportation planning. Transportation planning can be a highly technical process, which often relies on computer models and other sophisticated tools to simulate the complex interactions of transportation system performance. It is a public relationship-oriented process in that transportation planners often interact with a wide range of stakeholders and members of the public. Transportation planning can also become intertwined with the politics of any given decision.

Some transportation planners and engineers focus on transportation supply—the facilities and services needed to handle expected demands and characteristics of the infrastructure to provide such service. Others are more interested in influencing travel behavior to promote more cost-effective and environmentally sustainable options for travelers.

Given the breadth of topics and issues that transportation planners can become involved in, transportation planning necessarily includes a wide range of interests, skills, and expertise. Perhaps the most important characteristic of any transportation planning process is to remain flexible given the dynamic nature of community planning and decision making, and the importance of transportation planning providing input into this process. This need for flexibility will be particularly important as the types of investment decisions for transportation systems evolve over the next several decades in response to changing demographic and technology factors.

[1]The original chapter in Volume 3 of this Handbook was written by Michael D. Meyer, WSP/Parsons Brinckerhoff. Changes made to this updated chapter are solely the responsibility of the editor.

## II. ORGANIZATION OF THIS HANDBOOK

This handbook is organized to reflect different levels of user familiarity with transportation planning. Not only do transportation planners need to know about the defining characteristics of the transportation system itself, but given a variety of transportation planning contexts, they must also understand the specific application contexts they are working in. In addition, transportation planning can be applied at a multimodal level, for example, statewide or metropolitan transportation planning efforts where all modes of transportation are considered, or it may target a very specific transportation strategy or element, such as freight planning.

The handbook is organized to answer six major questions:

*What is transportation planning?*

Chapter 1: Introduction to Transportation Planning

*What are the basic concepts for understanding transportation systems and their relationship to the community?*

Chapter 2: Travel Characteristics and Data

Chapter 3: Land Use and Urban Design

Chapter 4: Environmental Considerations

Chapter 5: Transportation Finance and Funding

*What are the types of tools and analysis methods used in transportation planning?*

Chapter 6: Travel Demand and Network Modeling

Chapter 7: Evaluation and Prioritization Methods

Chapter 8: Asset Management

*How does one plan for mode-specific transportation networks?*

Chapter 9: Road and Highway Planning

Chapter 10: Transportation System Management and Operations

Chapter 11: Planning for Parking

Chapter 12: Transit Planning

Chapter 13: Planning for Pedestrians and Bicyclists

Chapter 14: Travel Demand Management

*How does one plan for multimodal transportation networks?*

Chapter 15: Statewide Transportation Planning

Chapter 16: Metropolitan Transportation Planning

Chapter 17: Corridor Planning

Chapter 18: Local and Activity Center Planning

Chapter 19: Site Planning and Impact Analysis

Chapter 20: Rural Community and Tribal Nation Planning

Chapter 21: Recreational Areas

*What are some special planning applications transportation planners should know about?*

Chapter 22: Integrating Freight into the Transportation Planning Process

Chapter 23: Playing it Safe—Safety Considerations in the Transportation Planning Process

Chapter 24: Public Participation and Engagement

Individual chapters provide linkages to relevant information in other chapters of the handbook. For example, transportation professionals interested primarily in chapter 12 on transit planning, will find references to other chapters on travel demand models and data collection that provide more in-depth coverage of a transit-related application. Thus, in some cases, chapters that in other texts would have spent considerable time discussing some aspect of a particular topic (such as transit demand modeling), the reader is directed to other parts of the handbook. Given the breadth of many transportation planning studies, it should not be surprising that, in some instances, almost every chapter in the handbook could be relevant to a particular study.

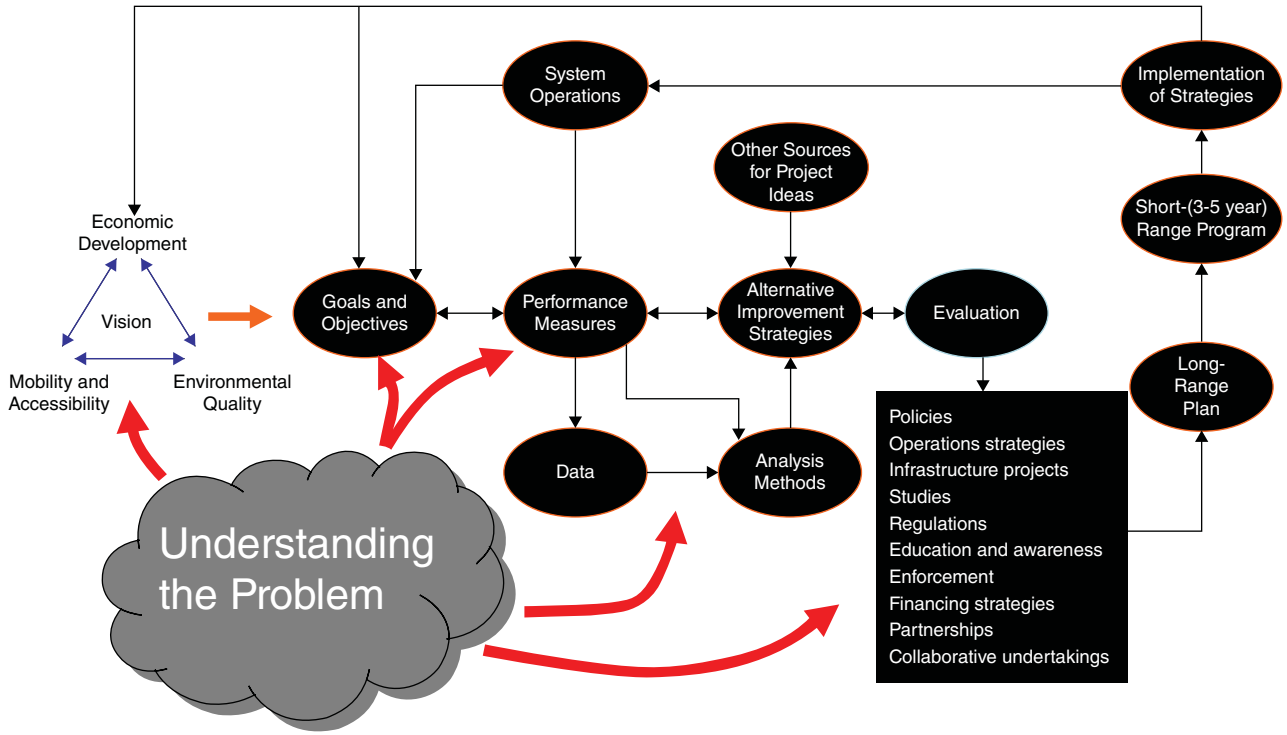
In addition, given the importance of performance measures in today's transportation planning, instead of discussing their definition and role in one chapter, the discussion of performance measures is found in each chapter where appropriate. In this way, performance measures can be discussed with specific reference to how they can be used for different modes and planning efforts.

The remainder of this chapter describes the transportation planning process and the legal/regulatory foundation in the United States for much of what occurs in transportation planning today.

## III. THE TRANSPORTATION PLANNING PROCESS

Transportation planning is often portrayed as an orderly and rational process of steps that logically follow one another. In reality, planning and project development are much more complex, often with many different activities occurring concurrently. Shown in Figure 1-1, the planning process starts with understanding the problems facing a community and ending with a solution to identified problems (projects programmed and designed). In a typical planning context,

**Figure 1-1. Conceptual Framework for Transportation Planning**



Source: Adapted from Meyer and Miller, 2014, Reproduced with permission of M. Meyer.

many of these steps may have already occurred and therefore are not relevant to a particular planning effort. For example, metropolitan planning organizations (MPOs) in the United States have been developing transportation plans for decades, and as a result, a typical planning effort might simply be updating an existing transportation plan. In the context of Figure 1-1, the development of goals, objectives and performance measures might consist of validating those that were developed for the prior version of the plan. Even with these caveats, the planning process shown in Figure 1-1 helps identify important components of the planning process and how they relate to one another. The planning process in Figure 1-1 will be referenced throughout this handbook.

## A. Major Steps in Transportation Planning

The planning process begins with an *understanding of the socio-demographic, land-use, and economic context* within which a transportation system operates. This is followed by becoming aware of the problems, challenges, opportunities, and deficiencies of transportation system performance within this context, be it a state, province, region, or community. This usually entails some form of analysis and assessment of the changing context of transportation system performance and an examination of both the existing and expected challenges facing the transportation system. This initial step is important because a planning agency usually begins a planning study based on the planning and analysis that has preceded it. More often, a transportation plan is being updated, or some specific problems have been identified that require a planning effort to be undertaken. Understanding the nature of the challenges facing a community thus becomes an important starting point for the planning steps that follow.

The next step is *developing a community or study area vision*. The dimensions of the vision portrayed in Figure 1-1 reflect the interaction among desired states of economic prosperity, environmental quality, and social equity/ community quality of life. These three factors have been chosen purposely as defining a vision because they are often considered to be the three major elements of sustainable development; a concept well-developed and accepted in recent years (see chapter 3). The vision can consist of general statements of desired end states or can be as specific as a defined land-use scenario. The visioning process often relies on extensive public outreach and is considered one of the most community-interactive steps of the planning process.

Once a vision has been defined, the next step is to *acquire more specific information* about what the vision means. What is the desired performance of the transportation system? What characteristics of community life can be most positively affected by transportation improvements? This more specific definition of a community's future is usually accomplished by *defining goals and objectives* that provide overall direction to the planning process. These goals and objectives not only help define the purposes of the planning process for the public, but can also help identify criteria to evaluate different transportation system options and alternatives.

Goals and objectives can also lead to the identification of *system performance measures*. Using measures to monitor the performance of the transportation system and the progress of transportation plans and programs is relatively new to the transportation field (see, for example, the performance management requirements of the 2012 U.S. federal transportation law—Moving Ahead for Progress in the 21st Century (MAP-21)). The primary purpose of collecting data on key system performance characteristics is to provide information to decision makers on the aspects of performance that are most important to them. Performance measures can be used to monitor whether congestion, average speeds, system reliability, and mobility options have changed over time. Many planning programs have also developed performance measures relating to such things as environmental quality, economic development, and quality of life. In these cases, transportation is just one factor that contributes to achieving overall community goals.

*Collecting and analyzing data*, the next step of the planning process, is key to understanding the problems and potential challenges facing the transportation system and the surrounding community. This analysis process primarily focuses on understanding how a transportation system and its components work and how changes to the system will alter its performance. A large part of the analysis step is identifying the current status of system performance. Analysis also includes identifying alternative strategies or projects that meet the objectives of the study. Analysis tools, ranging from simple data analysis to more complex simulation models, are used to produce the information that feeds the next step of the process, which is evaluation.

*Evaluation* is the process of synthesizing the information produced during the analysis step (for example, the benefits, costs, and impacts of different alternatives) so that judgments can be made concerning the relative

merits of different actions. As noted by Meyer and Miller [2014], evaluation should incorporate the following characteristics:

- Focus on the decisions being faced by decision makers.
- Relate the consequences of alternatives to goals and objectives.
- Determine how different groups are affected by transportation proposals.
- Be sensitive to the time period in which project impacts are likely to occur.
- In the case of regional transportation planning, aggregate information in a way that allows planners to assess the likely effects of alternatives at varying levels.
- Analyze the implementation requirements of each alternative.
- Assess the financial feasibility of plan recommendations.
- Provide information on the value of alternatives in a readily understandable form and timely fashion for decision makers.

One of the most common ways to ensure that the results of the evaluation process are linked closely to decision making is through the evaluation criteria used to assess the cost-effectiveness of individual alternatives or strategies and that reflect important decision-making concerns. These criteria provide important guidance to planners and engineers on the type of data and analysis tools to be used in producing the desired information.

Note in Figure 1-1 that planning can result in many different products. Studies can recommend the pursuit of specific transportation projects or services; they can recommend changes to institutional structures or funding programs that would make the management of the transportation system more effective. Some studies might recommend specific policy changes, such as how land-use and development plans should be linked to the transportation plan. In the United States, one of the most important products of the statewide and metropolitan transportation planning process is the development of a transportation plan. Much of what is covered in this handbook focuses on the steps necessary to develop such a plan. However, it is important to recognize that the ongoing planning process actually results in many different products aimed at improving the performance of the transportation system and in enhancing the economy and quality of life of the community it serves.

The actual program of action—in the United States called the transportation improvement program (TIP) for a metropolitan area or a state transportation improvement program (STIP) for a state—is connected to the plan through a process called *programming*. Programming matches the most desirable actions that have surfaced through the evaluation process with available funds. Priorities must be set when there are insufficient funds to satisfy all of the funding needs. This process can take many forms, ranging from political considerations to the use of systems analysis tools to assign priorities to different projects or alternatives.

Once a project or action has been programmed for implementation, its design and operation must be further refined, and likely impacts further explored. This process of refinement is called *project development*. Project development takes various forms, depending on the scope and magnitude of the project and the expected effects. Three major steps in project development include: developing project concepts, planning the project in finer detail than typically occurs in systems planning, and preliminary/final engineering. When significant environmental impacts are expected, the project development process will usually (depending on federal and state laws) include an environmental analysis process whose steps are well laid out in rules and regulations.

The final component of the framework is *system monitoring*. Note in Figure 1-1 that system monitoring provides feedback to the definition of goals and objectives and the use of performance measures. Poor system performance can lead to further planning analysis to better understand the dynamics of the underlying problem, or it might very well lead to the identification of new goals and objectives.

The planning process shown in Figure 1-1 is very different from more traditional constructs. First and perhaps most significantly, system planning as shown encompasses a broad set of planning steps. Many books on transportation planning have focused almost exclusively on analysis and evaluation, with the visioning process, program and/or project

implementation, and system monitoring occurring outside the planners' purview. The approach toward planning in this handbook adopts a much broader perspective to transportation planning.

Second, the use of performance measures is a relatively new addition to systems planning, and as shown in Figure 1-1, is a central concept to the overall process. Given the important linkage between planning and decision making that serves as the core concept in the definition of planning used in this handbook, performance measures should focus on the information of greatest concern to decision makers. Performance measures not only help define data requirements and influence the development of analytical methods, but also become a critical way of providing feedback to the decision-making process on the results of previous decisions.

Third, a major purpose of planning is to identify and analyze alternative improvement strategies and projects, which could include traditional infrastructure projects, but also actions to influence travel behavior and system performance. For example, travel demand management (TDM) strategies, such as variable work hours, rideshare programs, and parking pricing, have become important options in many metropolitan areas for reducing demand for transportation. Likewise, many intelligent transportation system (ITS) actions are not really projects as much as they are efforts to better improve transportation system performance through the use of technology. The planning process in Figure 1-1 provides for a much wider consideration of actions and strategies than what is usually considered part of the transportation planning process.

Figure 1-1 was presented primarily as a structure for planning in the United States. Other countries have their own requirements for transportation planning, or in the case of developing countries, they often follow the guidance of international lending institutions, such as the World Bank. However, although the goals and objectives, models and analysis tools, and strategies might be different from those found in the United States, the overall approach to planning in other countries is still similar to what is shown in Figure 1-1.

A final characteristic of planning proposed here is the periodic feedback provided to the original vision definition, goals statement, and identification of performance measures through system management and operations. System management and operations serves as a major source of information on transportation system performance and thus is an important indicator of system deficiencies or opportunities for improvement.

One of the useful aspects of the process shown in Figure 1-1 is that it provides a framework for assessing how comprehensive a planning process is for addressing specific issues. For example, Table 1-1, structured from Figure 1-1, is an example of how to assess the effectiveness of a transportation planning process with respect to safety issues. Similar constructs could be developed for almost any issue of concern to a community.

## B. Linkage to Policy and Other Planning Efforts

Because much of transportation planning has developed in response to the needs of a nation, individual states or provinces and municipalities, a great deal of what a transportation professional does is defined by law. In the United States, for example, the Constitution establishes the structure of government and the powers, responsibilities, and limits of the different branches and levels of government. Those powers vested in the federal government take precedence over the actions and authority of state and local governments. Thus, although state departments of transportation (DOTs) and MPOs focus on state and metropolitan/local issues, respectively, federal law often requires that certain actions be taken. For example, federal law requires that each state and metropolitan area have its own transportation plan. Federal law, interpreted through regulations, requires that the process for developing these plans must have certain characteristics, such as an effective public participation process. In those areas that have not attained air-quality standards as set forth in federal regulations, the transportation system plan, improvement program and selected projects must be found to be in conformance to the adopted air quality plan. It is beyond the scope of this chapter to identify all of the U.S. federal requirements that influence transportation planning; however, some additional description of key laws that transportation planners in the United States will be exposed to is important (for more a more exhaustive presentation of relevant federal laws see [Gayle, 2009; Meyer and Miller, 2014]).

Federal guidance on transportation planning is justified by the importance of transportation to the nation—the economy, national security, and health and welfare of its citizens. It is this national purpose that generates the need for an informed and consistent approach to transportation investment across the nation, especially where federal funds are involved. Congress first established a federal requirement for metropolitan transportation planning in the Federal-Aid

**Table 1-1. Assessing the Consideration of Safety in the Transportation Planning Process**

**Vision**

- Is safety incorporated into the current vision statement of the jurisdiction's transportation plan? If not, why not?
- Is safety an important part of the mandates and enabling legislation of key agency participants in the planning process?
- Is safety an important concern to the general public and planning stakeholders? If not, should it be?
- How is safety defined by the community?
- What type of information is necessary and desired to educate the community on the importance of a safe transportation system?

**Goals and Objectives**

- Is safety incorporated into the current goals and objectives set of the jurisdiction's transportation plan? If not, why not? If so, what, if anything, needs to be changed in the way safety is represented?
- How does the safety goal relate to the community understanding of safety as discovered through the vision development process?
- Does the safety goal lead only to recommended project construction and facility operating strategies, or does it also relate to strategies for enforcement, education, and emergency service provision?
- Does the safety goal reflect the safety challenge of all modes of transportation, that is, is it defined in a multimodal way?
- Are there goal-related objectives that provide more specific directions on how the goal is going to be achieved? Are these objectives measurable?
- Do the objectives reflect the most important safety-related issues facing a jurisdiction?
- Can the desired safety-related characteristic of the transportation system be forecast or predicted? If not, is there a surrogate measure or characteristic that will permit one to determine future safety performance?
- What type of information is necessary and desired to educate the community on the importance of a safe transportation system as it relates to planning goals and objectives?
- If target values are defined in objective statements (for example, fatal crashes will be reduced by 20 percent), have these targets been vetted through a technical process that shows that the target value can be reached?

**Performance Measures**

- What are the most important safety-related characteristics of the transportation system that have resulted from community outreach efforts to date? If performance measures are used, are these characteristics reflected in the articulated set of performance measures?
- Will the safety performance of the transportation system (as defined in the performance measures) likely respond to the types of strategies and projects that will result from the planning process? That is, are the performance measures sensitive enough to discern changes in performance that will occur after program implementation?
- Are the number of safety performance measures sufficient to address the safety concerns identified in the planning process? Alternatively, are there too many safety measures that could possibly "confuse" one's interpretation of whether safety is improving?
- Does the capability exist to collect the data that are related to the safety performance measures? Is there a high degree of confidence that the data and the data collection techniques will produce valid indicators of safety performance? Who will be responsible for data collection and interpretation?
- Can the safety performance measures link to the evaluation criteria that will be used later in the planning process to assess the relative benefits of one project or strategy over others? If so, can the safety performance measures be forecast or predicted for future years?

(*continued*)

Table 1-1. (*Continued*)

**Analysis—Data**

- Given the definition of safety that resulted from the visioning and goals/objectives phases of the planning process, what types of data are needed to support the safety desires of the community?
- Are these data available currently? If not, who should collect these data? Are there ways of collecting these data, or are there surrogate data items that can be used to reduce the cost and burdens of data collection?
- Does the state (or region) have a systematic process or program for collecting safety-related data? If not, who should be responsible for developing one?
- Is there a quality assurance/quality control strategy in place to assure the validity of the data collected? If not, who should develop one?
- Are there opportunities to incorporate data collection technologies into new infrastructure projects or vehicle purchases (for example, surveillance cameras or speed sensors)?
- Does the safety database include safety data for all modes of transportation that are relevant to the planning process (for example, pedestrians, bicyclists, transit, intermodal collisions, etc.)? If not, what is the strategy for collecting such data? Who should be responsible?
- What types of database management or data analysis tools are available to best use the data (for example, a geographic information system)? Are such tools available to produce the type of information desired by transportation decision makers?
- Are there other sources of data in your state or region that might have relevant data for safety-related planning (for example, insurance records, hospital admissions, nonprofit organizations, etc.)? If yes, who should approach these groups to negotiate the sharing of data?
- Are there any liability risks associated with the collection and/or reporting of crash data? If so, how can your agency be protected against such risk?

**Analysis—Tools**

- What is the scale of the safety problem being faced? Regional? Corridor? Site-specific? Are tools available that analyze safety problems at the same scale of analysis?

Source: Washington, Meyer, et al. 2006. Permission granted by the Transportation Research Board.

Highway Act of 1962. To receive federal transportation funds, this law required urbanized areas with a population greater than 50,000 to develop a *continuing, comprehensive* transportation plan that was a *cooperative* venture with state and local governments. This requirement, known as the 3C planning process, still serves as the foundation of today's transportation plans.

The 1973 Federal-Aid Highway Act and subsequent FHWA-Urban Mass Transportation Administration (UMTA) Joint Regulations on Transportation Planning had a profound impact on the institutional responsibilities for transportation planning. For the first time, federally supported urban transportation planning was funded separately: half of 1 percent of all federal-aid funds were designated for this purpose and apportioned to the states on the basis of urbanized area population. These funds were to be made available to "metropolitan planning organizations (MPOs) responsible for comprehensive transportation planning in urban areas." The Joint Planning regulations thus required that an entity called the metropolitan planning organization be established in every urbanized area with a population of more than 50,000.

A multiyear prospectus and annual unified work program had to be submitted specifying all transportation-related planning activities for an urban area as a condition for receiving federal planning funds. The urban transportation planning process was required to produce a long-range transportation plan, which had to be reviewed annually to confirm its validity. The transportation plan had to contain a long-range element and a shorter-range "transportation systems management element" (TSME) for improving the operation of existing transportation systems without new facilities. A multiyear "transportation improvement program" (TIP) also had to be developed consistent with the

transportation plan. The TIP had to include all highway and transit projects to be implemented within the coming five years. The TIP had to contain an "annual element" that would be the basis for the federal funding decisions on projects for the coming year. The consequences of these requirements were that they changed the emphasis from long-term planning to shorter range transportation system management, and provided a stronger linkage between planning and programming. [Weiner, 1992, 2008] Most of these requirements, except the TSME of the long-range transportation plan, are still operative today.

In 1991, the Intermodal Surface Transportation Efficiency Act (ISTEA) ushered in what many saw as a new era for transportation planning in the United States at both the metropolitan and statewide levels. This law fully established MPOs as the central forum for making transportation planning and investment decisions in metropolitan areas; it required a robust public involvement process, and it provided new flexibility in the use of federal capital program funds so that MPOs and states could find the best solutions to their transportation problems, rather than funding projects that fit the eligibility requirements of specific categorical funding programs. Different planning factors were to be addressed in the transportation planning process, including the need for the plan to be multimodal and intermodal, and to better understand the linkage between land use and transportation. ISTEA also required that both the plan and the TIP be fiscally constrained to only those projects that had a reasonable expectation of funding.

Prior to ISTEA, there was no federal requirement for statewide transportation planning, although many states do such planning. Along with the new requirements for metropolitan planning, ISTEA required states to create a planning process that would produce a long-range, intermodal statewide transportation plan and a short-range program of projects. While the process and content of the statewide plan did not have to be as rigorous as the MPO plan, Congress did include a list of planning factors that states were to consider.

The Moving Ahead for Progress in the 21st Century Act (MAP-21) passed in 2012 consolidated numerous categorical funding programs into a much smaller number of programs. For transportation planning, its biggest impact was in its requirement for state DOTs and MPOs to adopt performance measures. [FHWA, 2014a] The U.S. DOT was required to establish performance measures for safety, pavement conditions, bridge conditions, operational performance of the Interstate, operational performance of the non-interstates on the National Highway System (NHS), freight movements, mobile source emissions, and congestion. For transit, the U.S. DOT must "establish a national transit asset management system and performance measures for keeping transit in a state of good repair." States and MPOs were to establish targets for each performance measure, and adopt a "performance-based approach" in planning and programming transportation projects. This performance-based planning and programming approach was more than just imposing performance measures on states and MPOs; it also required MPOs to measure and report on the outcome of investments from the TIP/STIP as they affected the travelling public. [FHWA, 2014a]

In recognition of the important role that freight plays in the national, state, and regional economies, MAP-21 required the U.S. DOT to report biennially on the conditions and performance of the "national freight network," and to develop tools for "an outcome-oriented, performance-based approach to evaluate proposed freight-related and other transportation projects." The transportation goals specified in this law for the federal highway programs included:

- "*Safety* — To achieve a significant reduction in traffic fatalities and serious injuries on all public roads.
- *Infrastructure Condition* — To maintain the highway infrastructure asset system in a state of good repair.
- *Congestion Reduction* — To achieve a significant reduction in congestion on the National Highway System.
- *System Reliability* — To improve the efficiency of the surface transportation system.
- *Freight Movement and Economic Vitality* — To improve the national freight network, strengthen the ability of rural communities to access national and international trade markets, and support regional economic development.
- *Environmental Sustainability* — To enhance the performance of the transportation system while protecting and enhancing the natural environment.
- *Reduced Project Delivery Delays* — To reduce project costs, promote jobs and the economy, and expedite the movement of people and goods by accelerating project completion through eliminating delays in the project development and delivery process, including reducing regulatory burdens and improving agencies' work practices." [FHWA, 2014b]

The most recent federal transportation legislation (as of the date of publication of this handbook) is the Fixing America's Surface Transportation (FAST) Act. This law reaffirmed the planning requirements of MAP-21 and added the following requirements to the metropolitan planning process.

- "Continue to require metropolitan transportation plans and transportation improvement programs (TIPs) to provide for facilities that enable an intermodal transportation system, including pedestrian and bicycle facilities. It adds to this list other facilities that support intercity transportation (including intercity buses, intercity bus facilities, and commuter vanpool providers).
- Expand the scope of consideration of the metropolitan planning process to include: improving transportation system resiliency and reliability; reducing (or mitigating) the stormwater impacts of surface transportation; and enhancing travel and tourism. Specifically, it required the consideration of strategies to reduce the vulnerability of existing transportation infrastructure to natural disasters. [FHWA, 2016]
- Add public ports and certain private providers of transportation, including intercity bus operators and employer-based commuting programs to the list of interested parties that an MPO must provide with reasonable opportunity to comment on the transportation plan."

Given that transportation plays such a critical role in a nation's economy and in promoting the well-being of its citizens, it should be no surprise that transportation is part of many other legislative initiatives aimed at achieving nontransportation goals such as economic development and environmental quality. Again, it is beyond the scope of this handbook to identify all such laws. In terms of impact on transportation planning and project development, the most notable are the National Environmental Policy Act (NEPA), the Clean Air Act (and its amendments), and the Americans With Disabilities Act (ADA). [Gayle, 2009] Chapter 4 on environmental considerations in the planning process discusses these and other laws and regulations relating to environmental factors; chapter 12 and chapter 13 on transit planning and pedestrian and bicycle planning, respectively, describe ADA requirements for transit and pedestrian facilities; and chapter 15 and chapter 16 discuss the laws and regulations relating specifically to statewide and metropolitan transportation, respectively.

State governments also create and enforce laws relating to transportation (where not superseded by federal law). For example, a state can pass laws regulating the licensing and operations of trucks or other vehicles moving freight, but state laws cannot impede interstate commerce, which is protected by the Constitution. State laws are important in transportation for several reasons. First, they create the institutional structure for transportation planning at the state and, in many cases, metropolitan levels. That is, state DOTs and their roles and responsibilities are defined in state statutes, as are the roles and responsibilities of MPOs. Second, local units of government such as cities and counties are created by state governments. These local governments often cannot adopt laws and policies or raise taxes without enabling legislation from the state legislature. For example, in most states, a city cannot adopt a sales tax for transportation purposes without approval from the state. Third, state governments pass laws that can have significant impact on transportation planning. In Washington state and California, for example, state environmental laws require that statewide and metropolitan transportation plans undergo an environmental review to determine potential environmental consequences of the plan's proposed investment strategy. Finally, state governments establish their own sources of funding for transportation investment, which are even more important than federal sources for supporting a state's transportation system.

Similar to federal laws that recognize transportation's influential role in achieving nontransportation goals, other types of state-mandated planning often include transportation as a means of accomplishing program goals and objectives. Some examples of the linkage between transportation planning and other planning efforts are provided below to illustrate how transportation planning influences, and is influenced by, other planning activities.

*Oregon:* In many states, land use planning is the responsibility of local governments with only minimal guidance from state law. In 1973, the state of Oregon established the Land Conservation and Development Commission along with fairly rigorous (at least by the standards of most states) policy requirements for local planning. Subsequent goals adopted by the commission, which by reference have the force of law, cover numerous topics including the relationship between transportation and urbanization. The adopted transportation goal spells out the required content of transportation plans, while the urbanization goal includes adopting urban growth boundaries. In Oregon, state law clearly influences the range of actions to be considered in the transportation planning process. [Abbot, 2014]

*New Hampshire:* Transportation plans often demonstrate the need for future travel corridors in a metropolitan area or state, whether highway or transit. However, once a corridor is designated in a plan, developers may see it as a preferred

development site because of improved access. If future rights of way are built upon, the construction of the planned facility will be more expensive because of higher land acquisition cost. The New Hampshire legislature passed a law permitting the commissioner of transportation to designate corridors for planning purposes that provides both funding flexibility and land use protection (called corridor preservation). [New Hampshire Statutes, 1993]

*Georgia:* Many states require local jurisdictions to conduct comprehensive planning and to prepare plans that foster orderly growth. Georgia's local comprehensive planning law requires the evaluation of the following transportation assets as part of a community's comprehensive plan. [Georgia DCA, 2013]

- Road network: Roads, highways, and bridges.
- Alternative modes: Bicycle, pedestrian facilities, public transportation, or other services for populations without automobiles.
- Parking: Areas with insufficient parking or inadequate parking facilities.
- Railroads, trucking, port facilities, and airports.
- Transportation policies, programs, and projects and their alignment with local land use development policies.

Many states have passed smart growth legislation whose purpose is to guide development in the state and in communities where transportation or other infrastructure already exists or where it can be provided through developer contributions. Chapter 3 describes smart growth efforts in more detail.

Local governments, such as counties, cities, towns, and municipalities, also pass laws to protect the health, safety, and general welfare of their citizens. Local governments can influence transportation planning through their control of local street systems as well as their legal responsibilities for land-use zoning. Zoning ordinances empower local governments to take actions that protect the health, safety, and general welfare of their populace. These local policy and regulatory roles are critical to metropolitan transportation planning because of the close linkage between transportation and land use. As comprehensive plans and zoning codes define the location of different land uses and the density of development, they create over time an urban form that places demands and constraints on the transportation system. In addition, the provision or improvements to the transportation system can influence where development occurs. If both do not proceed in a coordinated fashion, the respective decisions may not always be compatible.

Local governments use a number of legal tools to address traffic impacts, including access management regulations, Complete Street requirements, impact fees and adequate public facilities ordinances. Some notable examples include:

- *Access management* is a strategy to reduce the number of conflict points on arterial streets, thereby increasing both capacity and safety. It is applied primarily where there is continuous retail and commercial development along an arterial road, where the tendency is for each site to have its own driveway access points.
- *Adequate public facilities ordinances* were developed in response to the need for public agencies to provide infrastructure to accommodate the needs of private development. Such ordinances are used to assure that public schools, roads, sewers, police and rescue response times, and/or other infrastructure or services are "adequate" to support proposed new development. For example, large subdivisions were often built with the developer providing only the internal infrastructure. The presumption was that the local government, pleased with the addition to its property tax base, would solve any resulting problems of traffic congestion, overcrowded schools, lack of public parks, demands on sanitary sewers and treatment plants, and so forth. Local governments in growing regions came to understand that the cost of providing all of the supporting infrastructure and services could outweigh the tax benefits of the development. The response was adopted ordinances requiring developers either to demonstrate the availability of adequate public facilities or to build whatever may be necessary to accommodate the needs of the new residents.
- *Traffic or transportation impact fees* are used by governments to internalize the cost of transportation improvements associated with development proposals. Such fees are typically enabled by state law and created by local government ordinance. The revenue generated by the fee is used by the local government to defray the cost of off-site transportation improvements. This model is most often used in high-growth areas as a way to capture the cumulative impact of numerous individual site developments.

More is said about the tools available to local communities and their impact on transportation planning in chapter 3 on land use.

The preceding discussion focused on the U.S. policy and legal context for transportation planning. Other countries have similar structures establishing the legal foundation for planning activities (countries in the British Commonwealth, for example, have a long legacy of comprehensive planning legislation that has included transportation in significant ways). Transportation planning, no matter where practiced, reflects the institutional structure for such planning established by national, state/provincial, and local governments. In addition, transportation planning is influenced by the societal, economic, and technological factors that define the context within which transportation planning occurs. As such, it is important for transportation planners to think about those trends and the likely characteristics of the future that will influence the use and performance of the transportation system.

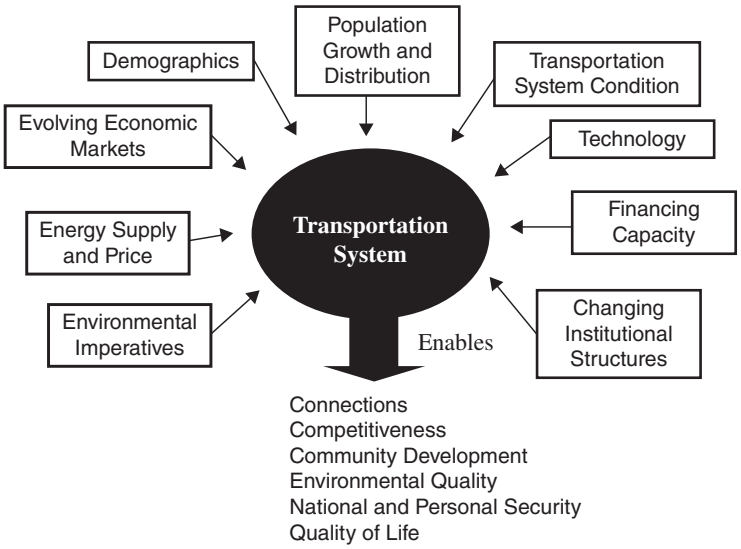
## IV. CHANGING CONTEXT FOR TRANSPORTATION PLANNING

The issues considered in a transportation planning process often reflect the changing characteristics of society as a whole. In addition, changes in economic markets and transportation technology often provide challenges as well as opportunities to enhance transportation system performance. Figure 1-2 presents one way of looking at how these changes feed into a planning vision. As noted by Meyer (2007), the 10 factors likely to influence how transportation systems are planned and perform in the future include:

### *1. Population Growth*

Population growth and where populations locate place increasing pressures on governments at all levels to provide transportation infrastructure and services, even though the mechanisms for providing this service might be very different from historical practice. The United States will see an increase in population over the next several decades, with immigration providing a large portion of this increase. For example, the 30 years between 2015 and 2045 will see 70 million more people added to the U.S. population, more population than currently in New York, Florida, and Texas combined. [U.S. DOT, 2015] In the absence of policies that influence development patterns, a large portion of this growth will likely continue to occur in suburban areas. However, center cities are also likely to experience growth (depending on the metropolitan area), especially as "empty nesters" move back into urban centers.

**Figure 1-2. Changing Context of Transportation Planning**



Source: Meyer, 2007, Reproduced with permission of M. Meyer.

### *2. Changing Demographics*

The aging and changing demographics of the U.S. population will have profound and lasting effects on personal transport and will increase demands for services to population groups that could be very different than today, such as the elderly. For example, on average, Americans over the age of 65 drive half the amount of Americans aged 25 to 64. In 2009, Americans between the ages of 18 and 34 drove 21 percent fewer miles than those in that age group did in 2001. Between 2000 and 2013, the population of low-income Americans in suburbs grew twice as fast as low-income populations in cities. [U.S. DOT, 2015] New demands for housing choices and community services; improved access to cultural and recreational sites; and easy access to interstate travel all lead to a transportation system that is not focused as much on aggregate flows as it is on individual and group travel patterns.

### *3. Evolving Economic (and Thus Geographic) Markets*

Future U.S. economic success will be tied closely to the ability of the nation's economic centers or megaregions to connect to the global economy. For example, in 2008, eleven identified megaregions in the United States included 75 percent of the U.S. population and employment, more than 80 percent of the gross regional products, 92 percent of the Fortune 500 company headquarters, and were the source of over 92 percent of the patents issued in the United States. [Ross and Woo, 2011] This suggests that not only should transportation investment be focused on the nation's major ports of entry and the transportation facilities serving them, it should also be focused on the effectiveness of the internal transportation system in these economic centers.

### *4. Transportation System Preservation*

It is safe to say that system preservation already dominates transportation program expenditure in many countries; this is not an emerging issue as much as a consequence of the age of infrastructure building boom of the 1960s–1970s. Of the 607,000 public road bridges in the United States, about 67,000 were classified as structurally deficient in 2012 and another 85,000 were classified as functionally obsolete. Over the past 10 years, more than 15 percent of state capital spending on highways has gone to bridge rehabilitation and replacement. [U.S. DOT, 2015] Although certainly not one of the most stimulating issues in political forums, preserving and maintaining the existing transportation system infrastructure will increase in importance even more during the next several decades. In most states and metropolitan areas, these needs will dominate investment priorities in the near future.

### *5. Transportation System Resiliency*

Transportation systems tend to be vulnerable to disruption from natural or man-made causes. It is not surprising that the largest number of targets for terrorist attacks around the world is some component of a transportation system. . . . buses in Israel, the Tokyo subway system, buses in London, commuter rail in Madrid, and reported attempts to derail Amtrak trains in the United States. Extreme weather events, such as hurricanes, heavy precipitation storms resulting in floods, extreme temperatures, drought, and tornadoes, also often cause major disruptions to a transportation system. Hurricanes Katrina and Sandy in the United States, for example, caused billions of dollars in damage to roads, bridges, railroads, airports, and ferry terminals. Over the longer term, climate change could exacerbate the risk of transportation system disruption from weather events. Transportation planners and engineers need to be concerned about how to plan and design transportation systems that are not only resilient—that is, systems that can survive and/or recover quickly from disruptions—but also systems that can act as lifelines for emergency relief and recovery after a disaster occurs.

### *6. Technology*

Modern society is largely defined by the technologies used to support individuals' everyday activities and the foundational technologies that keep communities functioning, such as water, transportation, waste removal, and power technologies. Absent any major disruption in the nation's economic structure, new technologies will likely play a significant role in how the nation and individual citizens conduct their business in future years. This is likely to be especially true for the management and use of the transportation system. Of particular interest today is the rapid technological advancements in autonomous (self-driving) vehicles, the application of vehicle-to-infrastructure technologies, and 3D printing (used in long-distance manufacturing). A recent U.S. DOT report on the future of transportation identified the following likely characteristics of technology applications in transportation. [U.S. DOT, 2015]

- Data collection and analysis will become cheap and widespread.
- Payment (for transportation) will be easy, frequent, and inexpensive.
- New methods of payment will enable transportation agencies to develop more targeted user-fee-based revenue streams.
- 3D printing has the potential to disrupt traditional supply chains and counteract the growth of imports by reducing the need for large-scale manufacturing, transportation, and storage.
- Robotics research is advancing across all transportation modes.
- Automation will have a potentially transformative impact across all transportation modes, increasing productivity, improving safety, and enhancing the capacity of existing infrastructure.
- The automation of motor vehicles is likely, and has the potential to revolutionize ground transportation.
- While many emerging technologies could have major safety and security benefits when applied to transportation, in some cases they could also create new vulnerabilities.
- Rapidly evolving technology will demand government flexibility: regulations may be necessary, but in order to advance and encourage innovation, not prevent it. Government must also ensure the primacy of safety as new technologies are implemented.

The implications of these new technologies on transportation system decision making and finance are largely unknown.

### *7. Financing Capacities*

Increasing vehicle fuel efficiency and reduced vehicle miles traveled resulted in an inflation-adjusted federal gas tax revenue decline of $15 billion, or 31 percent, from 2002 to 2012. Over the same period, state gas tax revenues decreased by $10 billion, or 19 percent, adjusting for inflation. The FHWA has estimated that at least $24 billion in additional capital spending would be required from all levels of government to improve highway system performance. [U.S. DOT, 2015] The future will see a much wider variety of financing strategies used to support the transportation system. In the short term, however, the gasoline tax will likely continue as the major source of road financing. New finance strategies will include a combination of public and private initiatives and the application of pricing schemes resulting in some additional financial resources.

### *8. Changing Institutional Structures*

Due to the changing financing strategies of future investment programs and the geographic definition of markets, future institutional arrangements will likely include many different structures and strategies than are seen today. For example, one is likely to see more regional organizations focusing on problems and challenges that cross jurisdictional boundaries. Likewise, given the local nature of many transportation problems, many regions will likely see a growth in transportation-related civic groups. In addition, as noted above, private companies and firms will play a more important role in transportation finance.

### *9. Environmental Imperatives*

One of the most significant factors affecting the future of transportation decision making is likely to be the continuing public and policy concern for preserving and enhancing environmental quality. Traditionally, this has included concerns for air quality, noise, water quality, habitat and wildlife preservation, and the like. In the future, this concern will likely include attention to the emission of greenhouse carbon gases and their long-term impact on the climate. Many areas of the world and in the United States are already experiencing higher-than-normal extreme weather events. Such events coupled with the longer-term challenges given a changing climate (for example, sea level elevation for coastal communities) represent one of the most important emerging environmental imperatives in many communities around the world.

### *10. Energy*

Energy supplies and pricing in the long term could be one of the defining characteristics of how the U.S. transportation system is managed and used. Moving toward energy independence will require a concerted effort over many decades in both developing and implementing new technologies to transform the U.S. transportation system. With the discovery of new sources of petroleum in the United States, it is not clear whether future prices will increase (in relative terms), fluctuate as they have in the past, or remain at low levels due to overproduction. Given that the transportation system is one of the highest consumers of petroleum-based fuels, the price of fuel, and/or the substitution of petroleum-based fuels with alternative fuels, could be one of the most important factors influencing future transportation demand and travel behavior.

Many issues unforeseen today could also become critical considerations for transportation planning in the years ahead. No matter what form these issues take, this handbook's basic approach is that the planning framework shown in Figure 1-1 can be used to provide the best possible approach to problem solving.

## V. ADDITIONAL SOURCES OF INFORMATION

Many different organizations provide information on transportation planning and on the various aspects of how transportation affects a community. Every state DOT and MPO has information on their respective websites relating to the issues facing the state or metropolitan area. Federal agencies such as the U.S. DOT, FHWA, Federal Transit Administration (FTA), and Environmental Protection Agency (EPA) also produce technical guidance and reports on transportation planning topics. For example, one of the most recent reports from the U.S. DOT, *Beyond Traffic,* provides an excellent background on the trends that are likely to affect the future of transportation. [U.S. DOT, 2015]

Among professional organizations, the American Association of State Highway and Transportation Officials (AASHTO), the American Planning Association (APA), the Association of Metropolitan Planning Organizations (AMPO), the National Association of Regional Councils (NARC), and the Institute of Transportation Engineers (ITE) provide books and reports on different aspects of transportation planning.

The Transportation Research Board (TRB) is one of the major sources of information on the latest concepts and approaches used by transportation planners. The TRB *Journal of the Transportation Research Board* annually

publishes articles on a wide-ranging set of topics as well as research reports from the National Cooperative Highway Research Program (NCHRP), Transit Cooperative Research Program (TCRP), National Cooperative Freight Research Program (NCFRP), and the Strategic Highway Research Program 2 (SHRP 2). For example, NCHRP recently published a series of future-looking reports focusing on the following topics that are highly relevant to transportation planning:

- Freight: Economic Changes Driving Future Freight Transportation
- Climate Change: Climate Change and the Highway System: Impacts and Adaptation Approaches
- Technology: Expediting Future Technologies for Enhancing Transportation System Performance
- Sustainability: Sustainability as an Organizing Principle for Transportation Agencies
- Energy: Preparing State Transportation Agencies for an Uncertain Energy Future
- Socio-Demographics: The Effects of Socio-Demographics on Future Travel Demand

Interested readers are referred to: http://www.trb.org/NCHRP750/ForesightReport750SeriesReports.aspx.

SHRP also produced a useful web tool called *PlanWorks*, which allows planners to identify different components of the transportation planning process to obtain information on the data and tools that are available (see https://fhwaapps.fhwa.dot.gov/planworks/DecisionGuide).

It is also not unusual for nonprofit organizations to produce technical guides and information reports on targeted topics, such as pedestrian and bicyclist planning, transit planning, and public participation.

The reader is encouraged to search these and other sources for the latest information on transportation planning.

## VI. SUMMARY

The rest of this handbook describes key components of the transportation planning process and presents tools that transportation planners can use to provide information for those who make decisions. Any transportation planning process consists of multiple steps, with the scope and scale of each step depending on the context of a planning study. Planning begins with "understanding the problems," which could include nothing more than an analysis of the latest data (for example, crash statistics) to a much more involved public participation process that provides planners with a range of input on the challenges facing a study area. The next steps in the process include identifying goals, objectives, and performance measures. This step is critical for defining the criteria to be used later to assess the relative effectiveness of different alternatives and thus in identifying the types of tools and data to be used during the analysis. The following analysis step consists of the data, analysis tools, and models used to identify the likely impacts or consequences of implementing different strategies or actions. This is the step that has received most attention through the decades in terms of model enhancements and improved data collection techniques.

The next step, evaluation, is perhaps most closely linked to the major purpose of planning, that is, to provide information to those making decisions. Evaluation takes the information from the analysis step and determines the trade-offs associated with pursuing one alternative versus another. This usually involves extensive public engagement as well as the application of methodologies, such as benefit/cost analysis, that allow the planner to assess the relative merits of alternatives. The results of evaluation then feed into a plan (in a more formal planning process) or in reality can lead to a range of actions … additional studies, investment strategies, enforcement/education efforts, and so on. In the United States, a formal plan is required for every urbanized area over a 50,000 population. In addition, a transportation improvement program (TIP) is required that lays out the project priorities and agency responsibilities for delivering the capital program. Over time, the impact of these new investments on the performance of the transportation system are reflected in the ongoing monitoring program and then fed back into performance measures … and the planning process begins again.

The transportation planning process lays the foundation for the decisions to improve the transportation system. Accordingly, it is important that transportation professionals understand the key components of the process, and are familiar with the analysis and evaluation approaches that are typically used as part of this process. The following chapters provide such an understanding.

# Travel Characteristics and Data[1]

## I. INTRODUCTION

Understanding how and why travel occurs is one of the most important tasks of transportation planning. Every planning study begins with a review of the data available on the use and performance of the current transportation system. Not only are such data critical for identifying where problems exist today or will likely exist in the future, these data are also often used to develop analysis tools and models that predict future trip-making patterns and behavior. Performance and condition characteristics of an urban area's transportation system also serve as criteria for evaluating the relative effectiveness of investment options. For example, defining and identifying congested road segments not only pinpoints locations where improvements are needed, but also the impact of these strategies on congestion becomes an important measure for determining which set of strategies will be most cost-effective in other locations. Given the importance of data to the planning process, it is not surprising that many transportation planning studies spend a considerable amount of the budget on data collection and analysis.

The type of transportation system information important for transportation planning varies according to the overall goals of the transportation decision-making process. For example, the owners of transportation infrastructure might be concerned about the physical condition of roads and bridges and spend considerable time monitoring asset condition (see chapter 8 on asset management). Those interested in operating transportation systems might focus on characteristics of system use, such as average delay, safety, travel reliability, measures of throughput, and bottleneck locations. Planning agencies concerned about the system's future ability to handle demands might be most interested in measures of capacity as well as operating characteristics.

It is beyond the scope of this chapter to describe all of the possible measures of system condition and performance and, therefore, the data and information produced by the planning process. Interested readers are referred to the biennial report to Congress prepared by the Federal Highway Administration (FHWA) on highway and transit condition and performance for a comprehensive examination of a range of system performance and condition measures (FHWA, 2013a). Subsequent chapters in this handbook discuss in greater detail the system performance measures that are most useful for particular planning issues. This chapter focuses on the most common data and information used in transportation planning.

## II. TRANSPORTATION SYSTEM CHARACTERISTICS

Several characteristics of the transportation system are measured and used in almost every transportation planning process. This section discusses five of these characteristics: functional classification, system extent, system usage, system performance/capacity, and system condition.

### A. Functional Classification

Transportation system data are categorized in a variety of ways to allow transportation professionals to understand the performance of different components of the system for which they are responsible. System-level measures, such as crash rates, pavement condition levels and average travel time, provide a broad overview of how the system is performing, and provide a context for strategic decisions about where additional investment at the

[1]The original chapter in Volume 3 of this handbook was written by Marsha D. Anderson Bomar, Stantec, Inc. Changes made to this updated chapter are solely the responsibility of the editor.

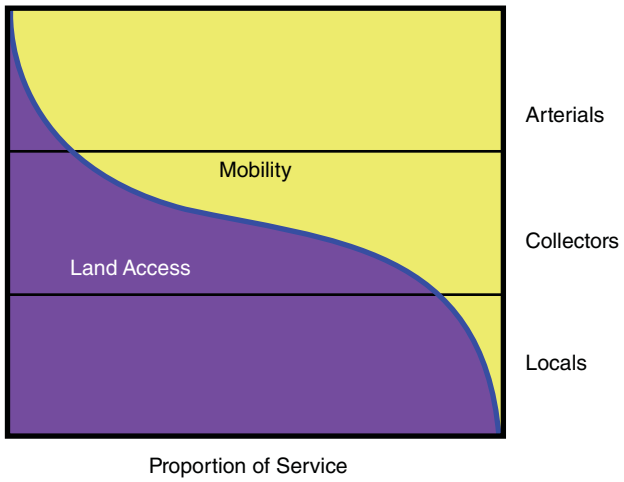
program level might be necessary. A more detailed examination of the data, however, could be useful in understanding where problems exist and what types of strategies might be appropriate. For example, crash rates and the types of crashes occurring on interstate highways are very different from those occurring on rural two-lane highways. Performance characteristics for bus services are very different from those for rail lines. To provide more useful information about transportation system performance, transportation engineers and planners categorize data using different classification schemes.

A basic characterization of the road network used in many parts of the world is to describe different road segments by the function they serve in the network. Roads that are high on the functional classification scale provide mobility, while roads with lower classifications serve an accessibility role (see Figure 2-1). Typical road functional classifications include:

**Figure 2-1. Relationship Between Road Classification and Road Function**



Source: Federal Highway Administration, *Our Nation's Highways 2011* http://www.fhwa.dot.gov/policyinformation/pubs/hf/pl11028/onh2011.pdf

*Interstates* are highest level of arterials with the longest uninterrupted distances and the highest speeds.

*Other Arterials* include other forms of limited access roads as well as connections to major urbanized areas and tie the national defense system (the interstates) to the cities and industrial centers.

*Collectors* involve both land access and traffic circulation. They link local roads to arterials and are generally lower-speed facilities.

*Local Roads* primarily serve the adjacent land use with access to higher-order roads.

In 2013, there were just over 4 million miles of road in the United States. [BTS, 2015] The availability and use of these roads are shown by functional class in Table 2-1. As can be seen, the higher classified roads, that is, the interstates and arterials, constitute 11.2 percent of the nation's road mileage, but 71.9 percent of the vehicle miles traveled (out of a total 2.97 trillion miles).

It should be noted that this traditional way of classifying the role of transportation facilities has been criticized because of its focus on the role of individual facilities in the transportation system, rather than the role they play in the surrounding community. This concept has also been found in design approaches called *context-sensitive solutions (CSS)* and *Complete Streets*, which encourage road designs that better "fit" into the community and natural environment. Chapter 3 on land use and urban design and chapter 9 on road and highway planning discuss both concepts in more detail.

## B. System Extent

The extent of a transportation system relates to the size or number of assets that compose that system. For example, a state or metropolitan area might have *x* miles of interstate highways, *y* number of transit vehicles, and *z* number of airports. This information, which is often incorporated into an *inventory* database, is used to compare one system to another and to calculate productivity factors for agency operations (such as dollars expended per lane-mile of major arterial road or per bus seat-mile). The inventory is also used to define ownership of the different transportation assets. Table 2-2 shows the extent of the U.S. transportation system.

Statistics on the extent of state road networks can be found in the Federal Highway Administration's (FHWA) *Highway Statistics* series. Similar types of information for transit systems can be found in the Federal Transit Administration's (FTA) National Transit Database (NTD). Other statistics on the U.S. transportation system can be found at the Bureau of Transportation Statistics (BTS) website, www.bts.gov, and in Canada at the website for Statistics Canada, http://www5.statcan.gc.ca/subject-sujet/theme-theme.action?pid=4006&lang=eng&more=0.

Source: BTS, 2015a

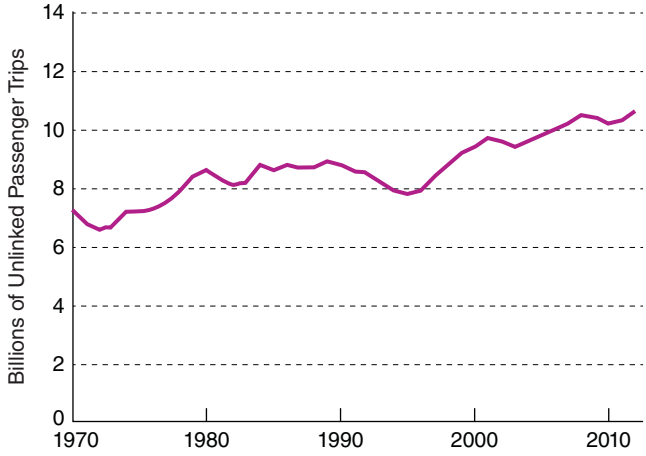
## C. System Use

An important indicator of the value of a transportation system is how much it is used. Existing usage is also the baseline for predicting future system use. Thus, transportation planners spend considerable effort in determining the current travel volumes on transportation systems. Such use is particularly impressive for the U.S. road network. In 2013 an estimated 2.9 trillion vehicle-miles were traveled on the U.S. road network. [BTS, 2015a] This was an approximate 38 percent increase from the level estimated in 1990. The data show that urban vehicle-miles traveled (VMT) outpaced those for rural highways, which is a result of both the substantial growth in urban population during this time period and the redesignation of urban area boundaries to place more road mileage within urban areas. However, since the early 2000s, the national VMT has declined and stabilized, as shown in Figure 2-2. The reasons for this include the dampening effect on travel of a national economic recession, more efficient travel patterns, and more urban travelers who use either other modes or have shorter trips. For a good discussion of the impact of an economic recession on travel, see [BTS, 2015b].

With regard to passenger trips, over 4.9 trillion passenger-miles (a person traveling one mile on a mode of transportation) occurred in 2013 on the U.S. transportation network: 4 billion by cars and trucks, 590 billion via airplane, 56.5 billion via passenger transit and intercity bus systems and 7.3 billion on Amtrak ( the U.S. national rail service). [BTS, 2015b] Approximately 5.9 trillion ton-miles of freight (one ton moving one mile) moved on the U.S. freight system in 2011, with 2.6 trillion moving by truck, 1.7 trillion by rail, 1 trillion by pipeline, 500 billion by domestic water transportation, and 12 billion ton-miles by aviation. [BTS, 2015b]

Figure 2-3 shows the number of unlinked transit trips in the United States from 1970 to 2012. (Unlinked trips are individual trips on a trip segment. For example, a bus trip that transfers to another bus or a rail trip would be two unlinked trips). As seen in this figure, beginning in the mid-1990s, transit ridership in the United States has begun to increase after years of declining or relatively flat growth. From 1995 to 2009, the percent of U.S. daily trips occurring on bus transit rose from 3.0 percent to 3.3 percent, with rail staying at 0.6 percent (motor vehicle trips accounted for 83.4 percent of daily travel). [BTS, 2015] With respect to walking and bicycling, the percent of U.S. daily travel for these modes rose from 5.5 percent in 1995 to 10.4 percent in 2009 for walking and from 0.9 percent to 1.0 percent for bicycling over the same time period.

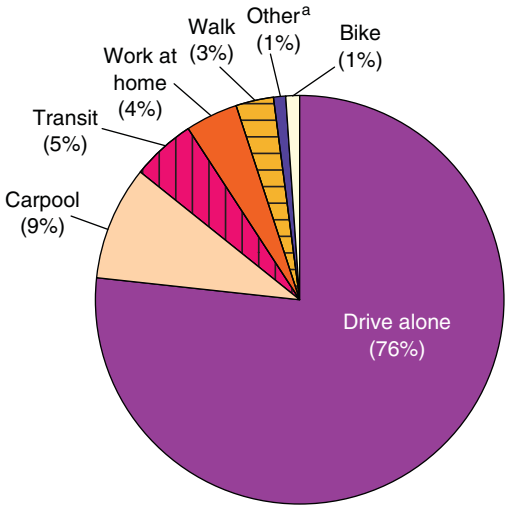
**Figure 2-3. Unlinked Passenger Transit Trips, United States, 1970–2012**



Source: BTS, 2015

The percent of daily travel by mode will vary by trip purpose and by time of day. Figure 2-4 shows the U.S. mode share for commute trips in 2013. As can be seen, the mode share percentages for the commute trip are different than that described above for all trips taken during the day.

**Figure 2-4. Commute Mode Share, United States, 2013**



[a] Includes motorcycle, taxi, and other means

Notes: Percents do not add up to 100 due to rounding.
The *American Community Survey* asks for the mode usually used by the respondents to get to work.
For more than one mode of transportation, respondents select the mode used for most of the distance.

## D. System Performance

Transportation system performance is one of the most visible and important transportation system characteristics to local decision makers and the general public. Traffic congestion and traffic delays have engaged—and will likely continue to involve—transportation planners and engineers in discussions and debates about how transportation problems can be solved. Several characteristics of system performance, including mobility and accessibility, are key decision criteria and are evaluated and monitored by transportation agencies.

### *1. Mobility*

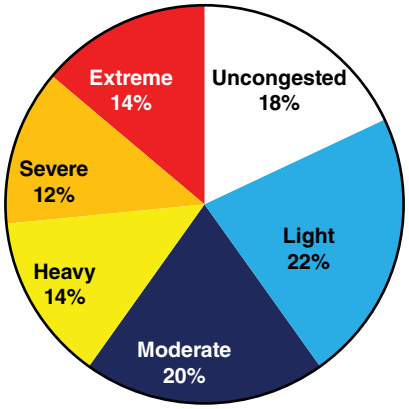
Mobility reflects those travel conditions associated with the ability to travel, such as average speed, delay, congestion levels, and the availability of modal options. Mobility is provided by multiple modes, including many trips that require the use of more than one. For example, driving a car to a work place or school usually includes a walk trip at either end. Many transit trips also include not only walk trips but often transfers to other transit modes. Mobility is thus inherently a part of a multimodal measure of system performance. However, there are very few instances in practice where multimodal measures of mobility have been developed; instead, measures of the individual modal components of a trip are usually reported by planners, for example, levels of congestion on the road network or transit line. The following sections discuss system performance from a modal perspective. The reader should be aware, however, that a true measure of system performance should include the performance contribution from multiple modes.

**Road Mobility.** The Texas A&M Transportation Institute (TTI) and INRIX produce information biennially on levels of congestion on the U.S. road system. An interesting aspect of the *Urban Mobility Report* is that it represents a combination of data sources, including INRIX data, which are collected via global positioning system (GPS) probe vehicles. As noted in the preface to the report, this represents, "hundreds of speed data points on almost every mile of major road in urban America for almost every 15-minute period of the average day of the week. For the congestion analyst, this means 900 million speeds on 1.3 million miles of U.S. streets and highways."

Figure 2-5 shows data from the Institute's *Urban Mobility Report 2015*. [Schrank et al., 2015] According to the report, "average daily percent of vehicle miles traveled (VMT) under congested conditions" is an indicator of the portion of daily traffic on freeways and other principal arterials in an urbanized area that moves at less than free-flow speeds. As shown in the figure, approximately 40 percent of urban travel in the United States in 2014 occurred in extreme, severe, or heavy congested conditions.

Figure 2-6 shows that the change in the hours of delay per automobile commuter has varied by urbanized area size. In areas with over one million persons, 2014 auto commuters experienced an average of 63 hours of extra travel time, a road network that was congested for 6 hours of the average weekday, and experienced an average congestion "cost" of $1,440 (primarily the value of time lost). Even in small and medium-sized urbanized areas,

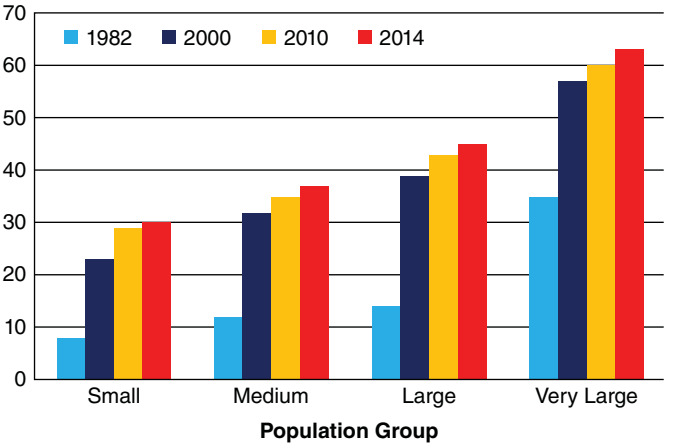
**Figure 2-5. Vehicle Travel in Congestion Conditions, United States, 2014**



Source: Schrank et al., 2015, Reproduced with permission of the Texas A&M Transportation Institute.

the hours of delay have increased (small urbanized areas are those with a population less than 500,000; medium areas have a population between 500,000 and 999,999; large areas have a population between 1 and 3 million; and very large areas have above 3 million in population). Of course, individual urbanized areas will experience different trends. It is interesting to note that while the hours of delay per automobile commuter increased from 18 to 37 hours between 1982 to 2000, the period from 2000 to 2014 saw this average stabilizing between 40 and 42 hours, primarily due to the impact of an economic recession. [Schrank et al., 2015, Exhibit 2] The cost of congestion, estimated as part of the TTI *Urban Mobility* report, consists primarily of travel time delays, crashes, and fuel. This estimated cost rose from a national total of $24.4 billion in 1982 to $160 billion in 2014 (in $2014).

**Figure 2-6. U.S. Congestion Conditions by Year, by Metropolitan Area Size**



Source: Schrank et al., 2015, Reproduced with permission of the Texas A&M Transportation Institute.

The *Urban Mobility Report* also measures the *Travel Time Index (TTI)*, a common metric for congested networks used in many planning studies, especially in larger urban areas. The TTI is the ratio of existing motor vehicle trip travel time to the travel time under free-flow conditions. Thus, a TTI value of 1.18 means that travelers take 18 percent (1.18–1.00) more time to travel than a similar trip with no delays. The national TTI value has increased from 1.07 in 1982 to 1.22 in 2014. Not surprisingly, TTI values in 2014 varied by urban area size: very large urban areas (15 total), 1.32; large urban areas (31 total), 1.23; 33 medium urban areas, 1.18; and small urban areas (22 total), 1.14. [Schrank et al., 2015]

Although travel time has historically been the measure of most interest to transportation planners and system operators, there has been a recent shift in interest from absolute travel time toward travel time reliability. The 2015 *Urban Mobility Report* reported on a measure of reliability called the *Planning Time Index (PTI)*. The PTI is "based on the idea that travelers would want to be on time for an important trip 19 out of 20 times; so one would be late only one day per month (on time for 19 out of 20 work days each month)." [Schrank et al., 2015] A PTI value of 3.00 indicates that a traveler should allow 60 minutes to make an important trip that takes 20 minutes in uncongested traffic (3 × 20). In essence, the 19th worst commute is affected by crashes, weather, special events, and other causes of unreliable travel and can be improved by a range of transportation improvement strategies. Similar to the TTI, the values of PTI vary by size of urban area. Very large urban area freeways had an average PTI value of 3.06 (top three areas were Los Angeles 3.75; Washington, D.C. 3.48; and Seattle 3.41); large urban area freeways had an average of 2.46 (top three areas were Portland, Oregon, 3.27; San Jose, California, 3.24; and Riverside/San Bernardino, California, 3.21); medium-sized urban area freeways had an average of 2.08 (top three areas were New Orleans, 3.46; Bridgeport/Stamford, Connecticut, 3.32; and Baton Rouge, Louisiana, 2.80); and small urban area freeways had an average of 1.76 (top three areas were Boulder, Colorado, 2.48; Stockton, California, 2.27; and Anchorage, Alaska, 2.26).

A recent study forecasts congestion and associated costs for individual households and national economies in the United States, United Kingdom, France, and Germany. The forecasts were based on forecasted levels of urbanization and increased GDP per capita from 2013 to 2030. [INRIX, 2015] The study concluded:

- The combined annual cost of congestion in these countries is expected to increase to $293.1 billion by 2030, an estimated 50 percent increase from 2013.
- The cumulative cost of congestion for the countries combined is estimated to be $4.4 trillion.
- The overall economic impact is greatest in the United States where the estimated cumulative cost of traffic congestion by 2030 is $2.8 trillion.
- The UK (at 66 percent) and London (at 71 percent) will see the greatest annual rise in the cost of congestion by 2030, mainly as a result of seeing the highest increase in urbanization.

- Traffic congestion costs drivers $1,740 in 2014 on average across the four countries. This number is expected to grow more than 60 percent to $2,902 annually by 2030.

**Transit Mobility.** Data relating to transit system performance in the United States are collected by transit agencies and reported to the National Transit Database (NTD), which is managed by the U.S. Federal Transit Administration (FTA). Average transit vehicle operating speed, an approximate measure of the speed experienced by transit riders, varies by transit mode. In 2010, the average operating speed for heavy rail was 20.2 mph (32.5 kph); for light rail, 15.0 mph (24.1 kph); and for bus, 12.5 mph (20.1 kph). [FHWA, 2013] According to the 2009 National Household Travel Survey (NHTS), 49 percent of all passengers who ride transit wait for 5 minutes or less for a vehicle to arrive, and 75 percent wait 10 minutes or less.

In Canada, the average transit commute travel time by public transit is 44 minutes, varying from 39 minutes in Montreal to 49 minutes in Toronto. Not surprisingly, commute times for public transit for commute trips varies significantly by the residential density of the workers' home neighborhood . . . . 51 minutes for the lowest residential density to 36 minutes for the highest residential density. [Turcotte, 2011]

More meaningful transit performance data is collected by transit agencies so as to provide the best service to their customers. For example, on-time performance is a widely used metric that provides customers with a sense of service reliability. Other measures such as dollar expended per revenue mile, farebox recovery, and percent of the population within ½ mile of transit service are used to provide a broader perspective on the effectiveness of the transit system overall. Additional information on transit system performance is provided in chapter 12 on transit planning.

### *2. Accessibility*

Whereas mobility performance reflects the ease with which travelers can make a trip, accessibility relates to a traveler's ability to reach a destination, and includes such measures as percent of employment within a certain distance of a transit station. In broad terms, mobility is more directly influenced by physical characteristics of the infrastructure and operating characteristics of the system. For example, an interstate highway may provide great mobility, but limited accessibility to adjacent land uses, while a driveway to an office building provides excellent accessibility to that facility, but limited mobility. Accessibility is a function of how a transportation network is structured, but it also depends on land use patterns, available modes, and geographic area. When land is developed with greater density and multiple land uses are clustered together, accessibility to goods and services may be enhanced. In a suburban setting, a combination of walking, driving, riding transit, and using parking facilities may be needed to accomplish a set of tasks or errands. In a dense urban environment with mixed land uses clustered together, it might be possible to reach all of the desired destinations by walking or riding a bus (see chapter 19 on site planning and traffic impact analysis).

Moving people is an important goal of most transportation agencies. In an urban environment, however, restricting access to individual properties may be necessary to allow for the smooth, uninterrupted flow of traffic on the adjacent roads (called access management, see chapters 3 and 19). Accessibility determines the adequacy of the transportation system and the value to related activities, such as commerce, employment, recreation, and overall quality of life. A balance between mobility and accessibility is often necessary to achieve community goals.

### *3. Safety*

Transportation safety is often identified as the most important goal of transportation agencies. Therefore, it is monitored by agencies at the national, state/provincial, and local levels. Four important measures are often used to monitor the trends in transportation safety: number of fatalities, number of injuries, fatalities per100 million vehicle miles traveled (MVMT), and injuries per 100 million vehicle miles traveled. The latter two are called fatality and injury rates, and reflect the amount of exposure travelers will have to the transportation system itself. Note that in some cases, the measures could lead to different conclusions. For example, the number of fatal crashes might increase over a particular time period, but because the number of vehicle miles traveled increased at a proportionately higher percentage, the fatality rate might decrease. So, one indicator suggests that the safety problem has become worse, and the other shows improvement.

Table 2-3 shows the change in crash and injury statistics in the United States from 2002 to 2013. As shown, the trend in every category (except in public transit, motorcyclists, and pedacyclists) has been to fewer fatalities. With respect to injuries, the largest increases have occurred for motorcyclists and transit rail (most likely because of the opening of new services).

| Table 2-3. Transportation Fatalities and Injuries, United States, 2002 and 2013 | | | | |
|---|---|---|---|---|
| | 2002 | | 2013 | |
| **Mode** | **Fatalities** | **Injuries** | **Fatalities** | **Injuries** |
| Aviation | 616 | 337 | 429 | 250 |
| Highway | 43,005 | 2,925,758 | 32,719 | 2,313,000 |
| Car occupants | 20,569 | 1,804,788 | 11,977 | 1,296,000 |
| Motorcyclists | 3,270 | 64,713 | 4,668 | 88,000 |
| Light truck occupants | 12,274 | 879,338 | 9,155 | 750,000 |
| Heavy truck occupants | 689 | 26,242 | 691 | 24,000 |
| Bus occupants | 45 | 18,819 | 48 | 13,000 |
| Pedestrians | 4,851 | 70,664 | 4,735 | 66,000 |
| Pedacyclists | 665 | 48,011 | 743 | 48,000 |
| Other | 642 | 13,182 | 702 | 16,000 |
| Rail Crashes With Cars | | | | |
| Highway/road crossings | 357 | 999 | 231 | 972 |
| Transit (as of 2012) | | | | |
| Bus | 78 | 11,995 | 97 | 11,872 |
| Light rail | 13 | 557 | 45 | 888 |
| Heavy rail | 73 | 4,806 | 102 | 7,212 |
| Commuter rail | 116 | 1,483 | 112 | 1,575 |
| Water | 863 | 4,856 | 642 | 3,432 |

Source: BTS, 2015b

**Road Safety.** As noted earlier, there is a difference between fatalities and injuries and fatality and injury rates. Just as the number of fatalities and injuries has declined over the past 10 years, so too has the fatality rate. In 1995, the fatality rate per 100 million VMT was 1.73, which dropped to 1.09 in 2013. [Insurance Institute for Highway Safety, 2015] This decrease in rate was due to an increase in VMT as well as an increase in seatbelt use and vehicle safety improvements. Fatality rates are generally lower in urban areas than rural areas and for higher functional systems than lower functional systems. For example in 2010, the fatality rate per 100 million vehicle miles traveled was 2.5 times higher in rural areas than in urban areas (1.83 and 0.73, respectively).

Chapter 23 on safety provides more information on the current performance of the transportation system. From a planning perspective, it is important to note where crashes occur (for example, approximately 40 percent of the total number of crashes in any given year occur at intersections), who is involved in crashes (for example, males aged 20–24 and 85 and older had the highest rates of crash deaths), and the cause of crashes (for example, speeding has been a factor in about 30 percent of crash deaths since 2004).

**Good sources for transportation safety statistics include:**

- Insurance Institute for Highway Safety (http://www.iihs.org/iihs/topics/t/general-statistics/fatalityfacts/overview-of-fatality-facts/2013#Trends).
- National Highway Traffic Safety Administration (http://www.nhtsa.gov/NCSA).
- U.S. Census (http://www.census.gov/compendia/statab/cats/transportation/motor_vehicle_accidents_and_fatalities.html).

**Transit Safety.** For transit systems, the number of fatalities increased from 280 in 2002 to 356 in 2012, and fell from 0.66 per 100 million person-miles traveled (PMT) in 2002 to 0.54 per 100 million PMT in 2012. Fatalities, weighted by PMT, are lowest for motorbuses and heavy rail systems. Fatality rates for commuter and light rail are, on average, higher than fatality rates for heavy rail, most likely because of the at-grade road crossings that often characterize these services. Incidents (safety and security combined) and injuries per 100 million PMT declined for all transit modes from 2002 to 2012. Incidents and injuries, when weighted by PMT, are consistently lowest for commuter rail and highest for demand-responsive systems.

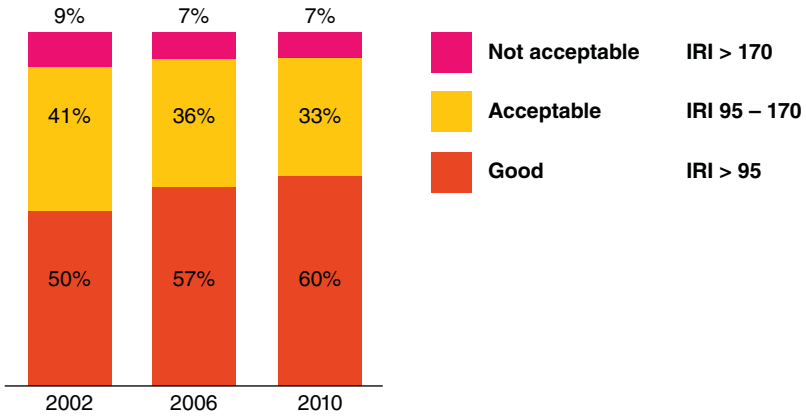
**Other Countries.** Countries with different legal requirements and enforcement strategies have a very different safety record than the United States. Countries like Australia, Denmark, England, and Sweden have applied very aggressive enforcement strategies and as a result have reduced their fatality levels by more than 50 percent. In contrast, many developing countries experience skyrocketing fatality rates as automobile ownership increases dramatically and as motor vehicle–based mobility has replaced slower modes of transportation. See chapter 23 for further discussion on transportation safety.

### *4. System Condition*

A deteriorating physical condition of transportation system assets is one of the significant challenges facing transportation systems in many countries. In many developed countries, for example, much of the highway and transit infrastructure was built 40 to 50 years ago and is nearing the end of its useful life. Most of the transportation plans in U.S. metropolitan areas have the majority of investment targeted at preserving infrastructure. Data on the condition of transportation infrastructure are critical for identifying investment priorities, such as needs related to deteriorating pavement and bridge conditions (see chapter 9 on road and highway planning).

Figure 2-7 shows the percentage of VMT on the National Highway System (higher functionally classified roads) by pavement rated as "good," "acceptable," and "not acceptable" from 2002 to 2010. As seen, the percent of VMT with "good" ride quality increased between 2002 and 2010, primarily because of improved pavements on rural interstates. For urban areas, the percent of "good" ride quality road miles declined, in this case primarily because of deteriorating pavement conditions on lower functionally classified roads. When weighted by VMT, the percentage of roads with "good" ride quality increased in both urban and rural areas, again because of pavement improvements in the higher functionally classified roads that carry more traffic.

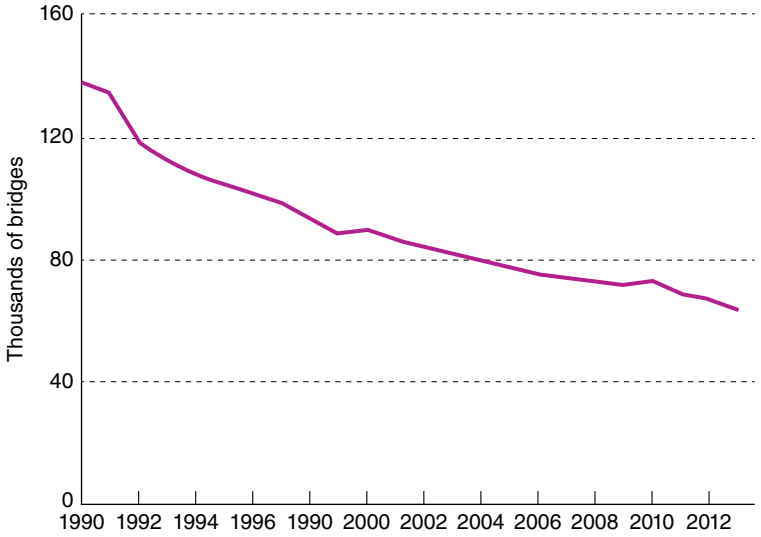
**Figure 2-7. Pavement Condition on the National Highway System, United States, 2002–2010**



Source: FHWA, 2013a

Figure 2-8 shows the change in structurally deficient bridges in the United States between 1990 and 2013. The bridge assessment process (that is, identifying those bridges that are structurally deficient and/or functionally obsolete) is based on load-carrying capacity, deck geometry, clearances, waterway adequacy, and approach roadway alignment. As noted by FHWA, "structural assessments" together with ratings of the physical condition of key bridge components determine whether a bridge should be classified as "structurally deficient." Functional adequacy is assessed by comparing the existing geometric configurations and design load-carrying capacities to current standards and demands. Disparities between the actual and preferred configurations are used to determine whether a bridge should be classified as "functionally obsolete" (see chapter 9 on road and highway planning). [FHWA, 2013a]

**Figure 2-8. Structurally Deficient Bridges, United States, 1990–2013**



Source: FHWA, 2013a

With respect to transit, according to the U. S. DOT's *2013 Condition and Performance Report to Congress*, the condition of the nation's urban bus fleet was at the bottom of the "adequate" rating in 2010, with an average vehicle age of 6.1 years. The average condition of rail vehicles was slightly better, but with an average age of 18.9 years. Of some concern, close to 2,000 rail vehicles exceeded 35 years in age. The report also noted that 19 percent of train communications systems, train control systems, and traction power systems were in "poor" condition, and 17 percent of rail guideway elements (such as track) were in "poor" condition.

What this national data on highway and transit infrastructure and vehicle condition suggest is that there is a serious national backlog in needed investments. As seen over the past 10 years in transportation plans and transportation improvement programs, a large share of future investment dollars is going to be allocated simply to keep the existing infrastructure in a state-of-good repair. This raises a serious question of where the dollars are going to come from to invest in new projects (see chapter 5 on transportation finance and funding).

## III. URBAN TRAVEL CHARACTERISTICS

Urban travel and trip patterns are influenced by numerous factors. The most important patterns relate to the availability and costs (real and perceived) of different modes of transportation. Thus, for example, if a traveler has an option of reaching a destination by driving, taking a bus, or ridesharing, the decision of which to choose depends on that traveler's perception of how much time each will take, how much it costs, how comfortable and safe it is, and what other activities the traveler might want to accomplish during the trip. The trip patterns resulting from the collective trip-making decisions of an urban area's population are also influenced by population demographics, land-use patterns in the metropolitan area, and the travel options that are available for each type of land use.

Table 2-4 shows how some of the key factors that influence travel behavior have changed since 1969. Each of these factors is an important predictor of some aspect of travel behavior. The following sections present data on these and other characteristics of urban travel and the factors influencing it. It should be noted that much of this data was obtained years ago; for example, much of the travel behavior data is collected by the decennial census, thus reflecting travel behavior and transportation system performance and cost characteristics facing travelers at that point in time. Alan Pisarski has developed a report over the past two decades entitled, *Commuting in America*, largely based on an analysis of the latest Census information. This report series has become an important "big picture" study of the factors that affect commuting in the United States—see http://traveltrends.transportation.org/Pages/default.aspx for the most up-to-date information. Much of the information found in the following sections comes from this document.

Although these data are important for understanding historic patterns in travel behavior, they should not necessarily be viewed as a picture of what behavior might be today or certainly what future behavior might look like. Fuel cost, for example, has been historically low in the United States, which has undoubtedly contributed to the high automobile mode share seen in U.S. urban areas. If fuel costs were to increase significantly, it is likely that some travel behavior would change, and if the cost of energy continued to stay high over the longer term, land-use patterns (and the corresponding effect on travel) might also change. Economic conditions are another strong influence on travel behavior—during economic recessions, traveling declines as more people are without jobs and fewer discretionary trips are taken in order to minimize household costs.

**Table 2-4. Change in Factors Influencing Vehicle Travel, United States, 1969–2009**

| | **1969** | **2009** |
|---|---|---|
| Total number of drivers | 100 million | 200 million |
| Average vehicles per licensed driver | 0.7 | 1.1 |
| Average daily vehicle trips per driver | 2.3 | 3.3 |
| Average daily person miles per household | 61.6 | 95.5 |
| Average daily vehicle miles per household | 34.0 | 58.1 |
| Average household size | 3.2 | 2.6 |
| Percent single-person households | 13% | 27% |

Source: FHWA, 2013b

## A. Population Characteristics

Urban travel is heavily influenced by the demographic characteristics of the traveling population. Thus, not surprisingly, transportation planning relies heavily on credible population and employment forecasts. Fifty years ago, the average U.S. household consisted of two young to middle-aged, English-speaking parents, two children, a single wage earner, and minimal disposable income. Today, U.S. households exhibit a range of characteristics, including single adults with no children, many non-English-speaking adults, many older heads of household, and many two-career households of younger adults with substantial disposable income. These characteristics strongly influence where people live, the types of jobs they have, and how time is spent outside the household. All of these activities affect travel behavior.

In the United States and in many other countries, the census is a major source of data on population characteristics. The U.S. Census Bureau provides numerous single-variable tables at different geographic levels, and as well provides special tabulations of key variable relationships (see http://factfinder.census.gov). For many planning efforts, such as establishing the relationships among the variables that influence travel decisions, the Bureau provides public use microdata sample (PUMS) datasets. According to Tierney, PUMS is used by many state DOTs and MPOs for the following reasons:

1) Developing cross-tabulations of variables not readily available from for other sources especially analyses that examine population characteristics of special subpopulations (for example, members of ethnic groups, people of certain ancestries, group quarters residents, or bicycle commuters).
2) Developing cross-tabulations of variables that might already be available to transportation planners, but can now be done with more currency. PUMS data are available on an ongoing basis and thus the most recent data can be used for cross tabulations.
3) Conducting disaggregate analyses at the household- or person-level to develop models relying on the interrelationships among household and person characteristics. PUMS allows the planner to identify variable relationships at the housing unit and person level.
4) Comparing different jurisdictions and regions, PUMS provides common data sets for all regions of the country, which thus allows consistent comparisons.
5) Comparing relationships over time—PUMS data can be used to track changes in housing and person characteristics and changes in the interrelationships between these characteristics over time.
6) Validating other data sources—PUMS data can be used to check relationships based on other data sources, such as travel surveys, demographic estimates, and modeling results. [Tierney, 2012]

The census is an important source of demographic and household data and thus transportation planners should be familiar with how such data is accessed and utilized.

### *1. Population Growth*

Estimating the number of people who will be living, shopping, or working in a study area, usually at some target year (for example, 25 years from today), is often a starting point for many planning studies. The census in most countries is an excellent source of socio-demographic statistics describing national, state, and metropolitan area trends (for the United States, see www.census.gov).

At a national level, the U.S. population is expected to grow over the next 50 years. The current U.S. population is just over 320 million (2015), with a growth of approximately 25 to 30 million each decade. Over the past two decades, substantial immigration to the United States, which is expected to continue albeit at slower rates than historically, has significantly increased the population beyond what would have occurred through natural birth/death rates. Many of these immigrants are 25 to 45 years old and seek jobs, thus immediately becoming part of the commute travel market. Although the U.S. population as a whole is increasing, some regions or communities are expected to grow, while others are expected to lose population. Thus, it is important for every transportation planning study to obtain the latest information on expected population growth or decline in the study area.

The level of population growth is not the only population-related variable used by transportation planners. Another important characteristic is the age distribution of this population. For example, between 2000 and 2010, those older than 55 continuing to work grew by more than 60.8 percent, while the actual numbers of individuals over 55 grew

by only 12 percent. This is an important phenomenon because the number of individuals 55 or older will be 28.7 percent of the population by 2020. The number of individuals in the labor force who are 65 years or older is expected to grow 75 percent by 2020, while the number of individuals in the workforce who are 25 to 54 is only expected to grow by 2 percent. In 2016, one-third of the total U.S. workforce is 50 years or older—a group that may number 115 million by 2020. The extent to which many in this age group continue to work will have important implications for transportation.

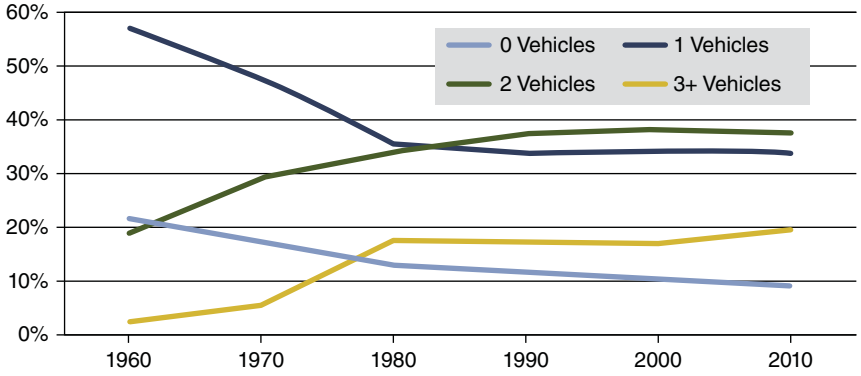
### *2. Household Characteristics and Vehicle Availability*

The household is an important variable in transportation planning because many modeling tools use household characteristics to predict future travel. For example, households with different numbers of workers, automobiles, and/or children will exhibit differences in daily travel behavior. Many data sources, such as those from the U.S. Census, produce and report their information based on households.

As indicated in Table 2-4, the number of persons per household has declined dramatically since 1960, while at the same time the number of households has greatly increased. The number of households has grown at twice the rate of population during the past 40 years, with many of these households being single adults, single parents, elderly, or young childless couples.

Figure 2-9 shows the relationship between households and automobile ownership; the largest shares of households without cars are renters. Figure 2-9 suggests that the percentage of households having a set number of vehicles seems to have stabilized with approximately 38 percent of the U.S. households having two cars, 35 percent having one, 17 percent having three or more, and 10 percent having no vehicles (New York City accounts for 20 percent of the U.S. households without vehicles).

**Figure 2-9. Percentage of Households by Number of Vehicles Owned, United States, 1960 to 2010**



Source: AASHTO, 2013a, Reproduced with permission of AASHTO.

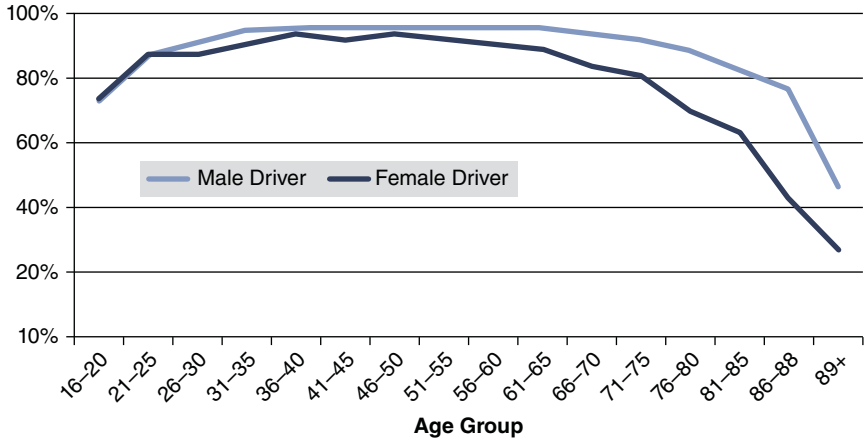
Figure 2-10 illustrates two characteristics of the U.S. population that have an important influence on mode choice. First, the percentage of older Americans having a driver's license has historically been much lower than that for those younger. This, however, is likely to change over time as the younger drivers grow older. Second, most Americans in the 16 to 50 age group have a driver's license, although male drivers have a higher rate of licensure than females.

### *3. Spatial Distribution of Growth*

More than 200 regions in the United States are classified as large metropolitan statistical areas (MSAs). These represent the largest of the nation's urban areas and have populations exceeding 250,000. From 2000 to 2010, the rate of growth in MSAs was mostly in the double digits, with many areas experiencing growth exceeding 20 percent. Some achieved growth rates in excess of 50 percent (see the U.S. Bureau of the Census website for current growth rate data for MSAs, www.census.gov).

One of the defining trends during the past 50 years in the United States and in many other countries has been the rapid population and employment growth in the suburbs. Prior to 1960, the majority of the U.S. population lived in nonmetropolitan areas with the suburbs of metropolitan areas having the smallest percentage of the population. By 2000 this ratio was reversed, with approximately 50 percent of the U.S. population living in the suburbs.

**Figure 2-10. Persons Ages 16+ with Driver's Licenses, United States**



Source: AASHTO, 2013a, Reproduced with permission of AASHTO.

**Table 2-5. U.S. Population Trends by Geographic Area**

| | 1990 | | | 2000 | | | 2010 | | |
|---|---|---|---|---|---|---|---|---|---|
| | Count (millions) | % of U.S. Total | % of Metro Total | Count (millions) | % of U.S. Total | % of Metro Total | Count (millions) | % of U.S. Total | % of Metro Total |
| Total Population | 248.7 | - | - | 281.4 | - | - | 308.7 | - | - |
| Living in Metro Areas | 198.2 | 79.7% | - | 232.6 | 82.7% | - | 262.5 | 85.0% | - |
| Living in Central Cities | 65.8 | 26.5% | 33.2% | 70.3 | 25.0% | 30.2% | 75.3 | 24.4% | 28.7% |
| Living in Other Principal Cities | 12.9 | 5.2% | 6.5% | 23.6 | 8.4% | 10.1% | 24.1 | 7.8% | 9.2% |
| Living Outside Principal Cities (Suburbs) | 119.5 | 48.0% | 60.3% | 138.7 | 49.3% | 59.6% | 163.1 | 52.8% | 62.1% |
| Living Outside of Metro Areas | 50.5 | 20.3% | - | 48.8 | 17.3% | - | 46.2 | 15.0% | - |

Source: AASHTO, 2013b, Reproduced with permission of AASHTO.

Table 2-5 shows the trend in the United States from 1990 to 2010. In 2010, the percentage of the U.S. population residing in MSAs increased to approximately 85 percent. What is interesting about this table is the growth in central city population during this period (indicated in gray areas), although on a percentage of the region basis, the proportion of central city population declined over the 20-year period. Some U.S. cities, such as Atlanta, Phoenix, Denver, and Tampa, saw much greater migration to the central city from domestic origins than from immigrants. In the Atlanta metropolitan area, for example, the last 20 years have seen a movement of population back into the central urban area. The increase in growth rates above might suggest that this is occurring in other parts of the country as well.

One can also see from Table 2-5 the increase on a percentage basis (also shown in gray) of those living in the suburbs, and a corresponding decline in the percentage of U.S. residents living outside metropolitan areas. Table 2-6 shows that metropolitan and nonmetropolitan areas had different growth rates (or decline) in population between 2000 and 2010: [AASHTO, 2013b]

The growth in metropolitan areas exceeding 5 million population is slightly misleading, because only 8 million of this population increase was actual new growth. The remaining 24 million in growth resulted from different U.S. metropolitan areas being combined by the Census (such as Baltimore and Washington, DC), thus putting this combined area into the 5 million population range. As of 2010, there were 8 metropolitan areas with populations exceeding 5 million and 52 metropolitan areas with populations over 1 million in the United States.

| Table 2-6. Metropolitan Area Growth Rates, by Size, United States, 2000 to 2010 | |
|---|---|
| **Metropolitan Area Population** | **Growth Rate** |
| >5 million | 26.6% |
| 2.5 to 5 million | 18.8 |
| 1 to 2.5 million | 6.5 |
| 0.5 to 1 million | 34.4 |
| 250,000 to 500,000 | −18.8 |
| 100,000 to 250,000 | −21.0 |
| 50,000 to 100,000 | −10.0 |
| All metropolitan areas | 12.8 |
| Nonmetropolitan areas | −5.2 |

Source: AASHTO, 2013b, Reproduced with permission of AASHTO.

The implication of this population trend toward urban areas is that many of the future mobility and accessibility challenges in the United States (and in other countries) will be primarily urban in nature.

## B. Travel Characteristics

Whereas the previous sections focused on the characteristics of travelers, transportation planners also use data on the trip itself, such as trip purpose, mode choice, time of travel, and so forth. This section discusses the trip characteristics that are most important to the transportation planning process.

### *1. Trip Purpose*

Travel demand is considered a *derived demand*, meaning that trips are taken to achieve some purpose at a destination. For transportation analysis purposes, therefore, it is important to know why trips are being made. This is referred to as *trip purpose*. Although traditionally many transportation studies have focused on the commute or work trip, in reality the greatest increase in trip-making during the past two decades has been for other trip purposes, especially in family/personal business and social/recreational trips. Figure 2-11 shows the relative magnitude of commute travel as it has changed over time. As shown, work travel has declined as a percentage of total travel as reflected in several different performance measures. Figure 2-12 shows how the number of trips per day for different trip purposes has changed from 1977 to 2009. Note in Figure 2-12 that trip purpose has been aggregated to five major types—work, family/ personal business, school/church, social/recreational, and other. In many transportation studies, additional trip purposes are added to the study, depending on the types of trips that need to be examined (such as airport trips) and the availability of data. As an example, the 2009 National Household Travel Survey listed 36 different trip purposes in its survey form.

Multipurpose single trips are another important phenomenon that has occurred with increasing frequency over the past several decades. Known as *trip chaining*, this travel characteristic presented challenges to transportation analysts who had traditionally based trip modeling on a single-purpose trip. According to Pisarski [2006], the attributes of trip chains include:

- Trips to work with stops are increasing, both in number of workers making stops and number of stops per worker.
- Persons with stops take longer in miles and minutes than they did in 1995 and are longer than those not making any stops.
- People who make stops tend to be those that live a greater distance from work.
- Suburbanites make more stops than urban dwellers.
- Stops are increasing for men as well as for women.
- Women still make the greater number of stops in both work and home directions.
- The greater increase has been by men in the work-bound direction, often just for coffee.
- Use of nonvehicular and nonpersonal auto modes drops sharply for those making stops.

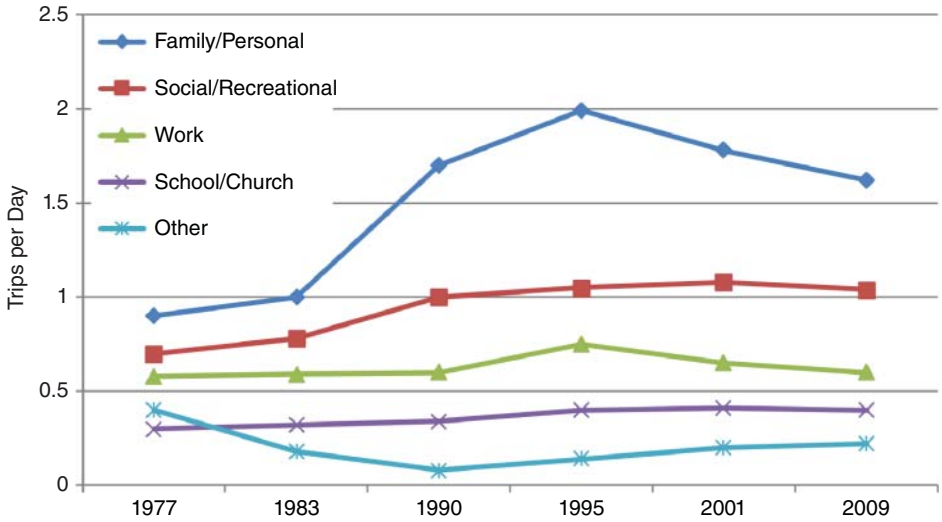
**Figure 2-12. Change in Trip Purpose, United States, (Trips/Day), 1977–2009**



Source: AASHTO, 2013a, Reproduced with permission of AASHTO.

Another qualifier often attached to "trip purpose" is whether one end of the trip occurs at the traveler's home. Thus, transportation planners often use terms such as home-based work, home-based shopping, home-based other, and non-home-based other to describe different types of trips made in a study area. Table 2-7 shows the percentage of these different types of trip purposes found in travel surveys undertaken in the 1990s in the United States. Although somewhat dated, the general percentages as shown for different trip types are similar to what is found today. (Note that travel demand modeling is evolving to a new form called activity-based modeling that no longer relies on such a distinction on individual trips. See chapter 6 on travel demand modeling.)

### *2. Travel Patterns*

Transportation planners are very interested in travel patterns because to a large extent these patterns suggest what is needed with respect to transportation infrastructure and services. Alternatively, transportation officials can influence these patterns through public policies intended to affect land use and household/ employment location decisions. Similar to the trend of increasing suburbanization of population and employment during the past 50 years, the greatest growth in urban travel patterns has been in the suburb-to-suburb trip. Suburb-to-suburb commute travel accounts for 46 percent of metropolitan commuting activity, with only 19 percent of the typical metropolitan area commuting following the suburb-to-central city pattern. Commuting within the central city constitutes approximately 25 percent, and the reverse commute—from central city to suburb—accounts for 9 percent. Not surprisingly given these trip patterns, suburbs account for 53 million of the 107 million job destinations within U.S. metropolitan areas.

| Table 2-7. Trips by Trip Purpose, Selected U.S. Metropolitan Areas, Most Recent Survey | | | | | | | | | |

Source: Reno, Kuzmyak and Douglas, 2002. Reproduced with permission of the Transportation Research Board.

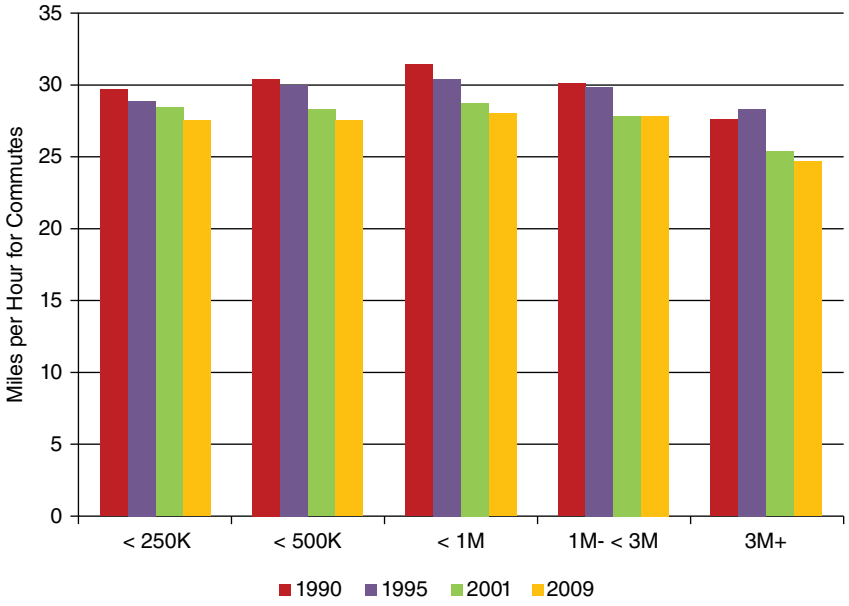
The percentage of the commute trips destined outside of the worker's home county is another characteristic of the growing trend in inter-suburban trips (note that this statistic will vary in different parts of the United States due to the size of counties). During 2006 to 2010, more than a quarter (27.4 percent) of U.S. workers traveled outside of their home county for the work trip. [McKenzie, 2013] In comparison, in 1960, approximately 15 percent of commuting included a work destination outside of the worker's resident county. Between 1990 and 2000, 51 percent of the new workers added to metropolitan areas worked outside of their home county. This longer distance travel has resulted in an increasing average commute trip length.

Average commute travel time has also increased due to longer trip distances and, more importantly, to the level of congestion faced during the trip. In the United States, the average commute travel time in 2011 was 38.0 minutes (measured over 498 urbanized areas), with 47 percent of workers traveling less than 20 minutes and 8 percent traveling more than 60 minutes. With longer trip distances and longer travel times, it is not surprising that average speed has declined as well (see Figure 2-13).

### *3. Temporal Distribution*

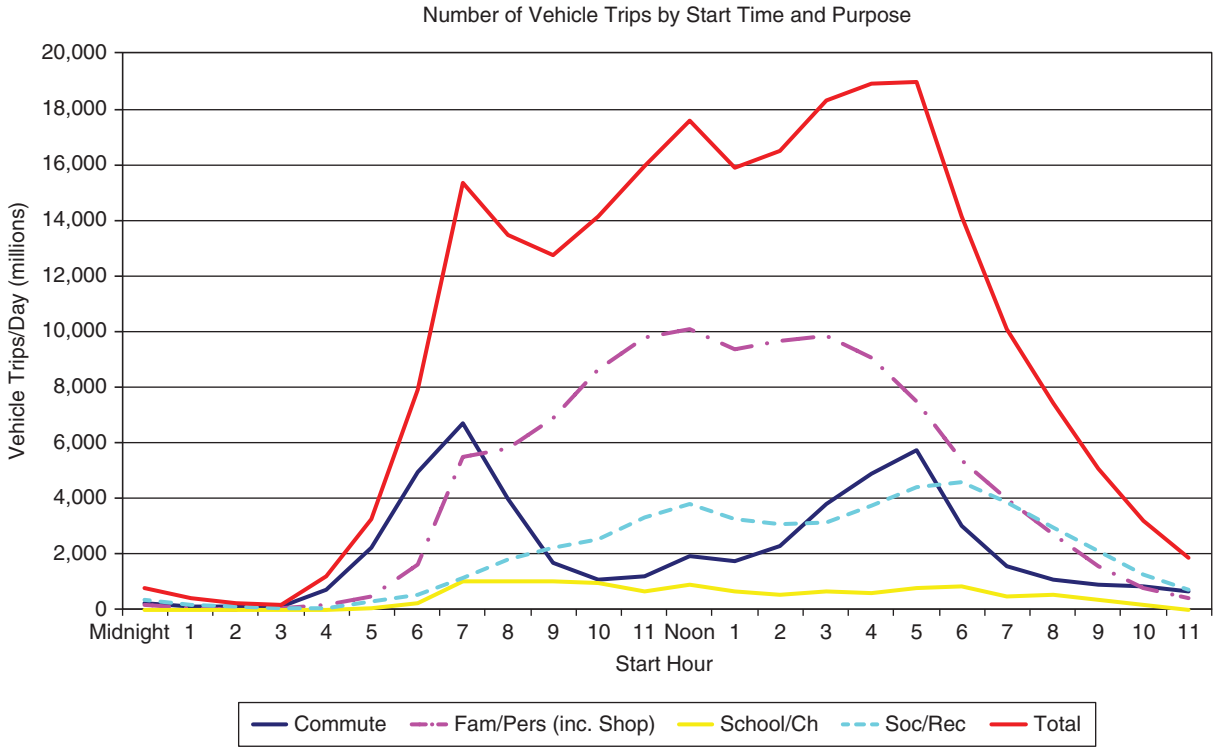
The time of day when trips occur is another important characteristic of urban travel patterns, one that leads to system congestion when many of these trips occur in the same time periods. In most cases, system capacity is available to handle daily trips; if trips were spread evenly over the 12 hours of daytime, there would be no traffic congestion. However, the trip peaking phenomenon reflects individual travelers' combined desires of being places more or less at the same time. Figure 2-14 shows data from the 2009 National Household Travel Survey, indicating the concentration of person trip-making during the daytime. Because of the limited capacity of transportation systems to handle the

**Figure 2-13. Change in Average Commute Speed, United States, 1990–2009 (mph)**



Source: Santos et al., 2011

**Figure 2-14. Typical Percent of Daily Trips by Time Period**



Source: Santos et al., 2011

peak loads, many metropolitan areas have found that travel is beginning to spread out into the very early hours or after the main peak is over. Figure 2-15 shows the percentage of a day's total delay that occurs by hour of the day. As can be seen, the afternoon peak period experiences the most delay of the day.

Unlike commuter trips, which generally peak between 7:00 to 9:00 a.m. and 4:00 to 7:00 p.m., truck trips tend to be at their highest levels between 10:00 a.m. and 4:00 p.m.

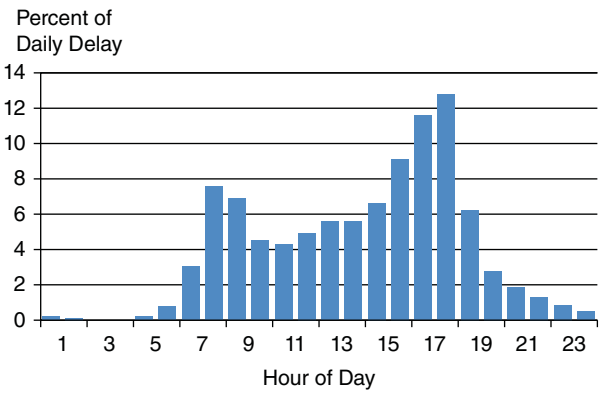
### *4. Mode Usage*

The likelihood of individuals choosing one mode over another for different trip purposes depends on a variety of factors, many of which are often masked when using national data. For example, many urban corridors and activity centers show significant transit ridership, even though the metropolitan area average for transit mode share could be quite small. Thus, the following data should be viewed with an understanding that they represent national numbers, reflecting many different types of transportation contexts.

Both the number and the percentage of urban travelers driving a car have increased significantly since the 1950s. For example, the percentage of U.S. commute trips made in a single-occupant vehicle as compared to all other modes was 64.4 percent in 1980 and increased to 76.1 percent in 2009. Carpool and transit use has slightly increased in absolute number of trips but has declined in market share. Many of the differences in mode use seen historically have lessened somewhat during the past 30 years; however, there are still important differences that can affect transportation service:

- Women still have a higher propensity to use transit than men and use carpools almost the same amount as men.
- Working at home and walking are important transportation modes in higher age groups.

**Figure 2-15. Percentage of Daily Delay by Time of Day, United States**



Source: Schrank, D., B. Eisele, and T. Lomax. 2015, Reproduced with permission of Texas A&M Transportation Institute.

- Higher age groups tend to use transit less than younger age groups, particularly buses and the subway.
- Minority populations tend to use transit much more than Caucasians (African Americans have transit use levels four times that of Caucasians; Hispanics use transit at more than twice the level of nonHispanics).
- Carpooling by Hispanics is double that of nonHispanics (23 percent to 11 percent).
- The higher the household income, the less likely one is to use transit or carpool, until the highest incomes are reached and then the transit share increases (most likely due to increased commuter rail and ferry use). Lower-income households have a much higher use of transit, biking, walking, and taxicabs.
- As metropolitan size increases, transit use increases in both central cities and suburbs; carpool rates are much more stable across different metropolitan area sizes.
- Nonmotorized travel averaged about 14.6 percent of all trips nationally in 2009, which is a decrease in market share from 1990 but represents a larger number of trips than taken in 1990.
- Those who have resided in the United States for only a short period of time tend to use transit (13 percent market share), carpools (almost 26 percent), and walking (6.8 percent) at much higher rates than those who have lived in the United States for a longer time.

Much of urban transportation policy during the last 30 years has focused on increasing the mode share for nonsingle occupant vehicle modes, primarily transit. Understanding the socio-demographic characteristics of those who ride transit and perhaps more importantly those who do not becomes an important foundation for planning studies aimed at enhancing transit ridership. Many transportation plans outline a long list of policies and program initiatives aimed at increasing transit market share; transportation planners need to understand the behavioral aspects of encouraging more people to do so.

# IV. ESTIMATING TRAVEL CHARACTERISTICS AND VOLUMES

Various types of data are used in different stages of the planning process. Needed data will vary by mode of transportation and the purposes for which the data will be used. Table 2-8 shows how different highway-related data might be used depending on what decisions will be made. The following sections provide an overview of the most important characteristics of data collection for transportation planning.

## A. Road Traffic Data Definitions

Traffic volume counts are expressed by specific time periods, with the time period depending on the type of information desired and its application. For example, data can be obtained for intervals of 5, 15, or 30 minutes; 1 hour; a peak 3-hour period; 1 day; 1 week; or the entire year. Transportation planning studies normally focus on longer time periods, such as annual daily traffic, while traffic operations studies generally require peak hour or peak 15-minute periods. It is important to note that daily volumes are typically not differentiated by direction or lane, but are total two-way volumes for a facility at a given location. The following terms are often used in transportation planning studies.

1) *Annual traffic*—the estimated or actual volume at a specific location for an entire year. Annual traffic estimates are used to determine the traffic demand in a given geographic area, establish trends that can be related to future traffic growth, and estimate highway user revenue, especially for toll roads, bridges, and tunnels.

2) *Average daily traffic (ADT)*—average 24-hour traffic volume at a given location for some period of time less than one year. An ADT estimate is valid only for the period for which it was measured. However, adjustment factors can be used to estimate ADTs for longer periods of time based on historical records (thus, for example, an ADT count for a Tuesday could be adjusted for an average weekday ADT based on the relationship between Tuesday's ADT and the historic average weekday ADT). These estimates are used to measure the existing vehicular use of the streets and highways in a study area. Such data can be used to determine facility performance, establish a major or arterial street network, and act as indicators of where additional person-flow capacity is needed. ADT volumes are also used to prepare benefit-cost analyses and to program capital improvements.

**Table 2-8. Examples of How Traffic Characteristics Data Are Used in Road Planning**

| Highway Activity | Traffic Counting | Vehicle Classification | Truck Weighing |
|---|---|---|---|
| Engineering | Highway Geometry | Pavement Design | Structural Design |
| Engineering Economy | Benefit of Highway Improvements | Cost of Vehicle Operation | Benefit of Truck Climbing Lane |
| Finance | Estimates of Road Revenue | Highway Cost Allocation | Weight Distance Taxes |
| Legislation | Selection of Highway Routes | Speed Limits and Oversize Vehicle Policy | Permit Policy for Overweight Vehicles |
| Maintenance | Selecting the Timing of Maintenance | Selection of Maintenance Activities | Design of Maintenance Actions |
| Operations | Signal Timing | Development of Control Strategies | Designation of Truck Routes |
| Planning | Location and Design of Highway Systems | Forecasts of Travel by Vehicle Type | Resurfacing Forecasts |
| Environmental Analysis | Air Quality Analysis | Forecasts of Emissions by Type of Vehicle | Noise Studies, Nitrous Oxide Emissions |
| Safety | Design of Traffic Control Systems and Accident Rates | Safety Conflicts Due to Vehicle Mix and Accident Rates | Posting of Bridges for Load Limits |
| Statistics | Average Daily Traffic | Travel by Vehicle Type | Weight Distance Traveled |
| Private Sector | Location of Service Areas | Marketing Keyed to Particular Vehicle Types | Trends in Freight Movement |

3) *Average annual daily traffic (AADT)*—the average 24-hour traffic volume at a given location throughout a full 365-day year. This is calculated by dividing the total number of vehicles passing a site in a year by 365 days. As noted above, AADT can be estimated based on historical adjustment factors that relate ADT to AADT (in other words, ADT × adjustment factor = AADT).

4) *Average weekday traffic (AWT)*—the average 24-hour traffic volume occurring on weekdays for some period of time less than one year. This measure does not include weekends. Similar to the relationship between ADT and AADT, AWT can be used to estimate AAWT (see next definition) through the use of an appropriate adjustment factor based on established relationships.

5) *Average annual weekday traffic (AAWT)*—the average 24-hour traffic volume occurring on weekdays throughout a full year. This volume is of considerable interest when weekend traffic is light, so that averaging weekday volumes over 365 days would mask the impact of weekday traffic. AAWT is computed by dividing the total weekday traffic for the year by 260. (Note: In some cases, the divisor is 250 to remove holiday traffic so that a true representation of weekday traffic can be obtained.)

6) *Average vehicle occupancy*—average number of persons per vehicle. Vehicle occupancies are obtained by observers recording the number of occupants in each vehicle passing a given point. This is relatively easy for automobiles (except for heavily tinted windows in some limousines), vans, and trucks. Transit vehicle occupancy is obtained based on ride counts from in-vehicle counters or estimated from visual inspection as a transit vehicle passes a given point. The results are expressed in terms of persons per hour or average number of persons per vehicle. New infrared scanning technologies are being developed that could be used to determine the number of occupants of a vehicle as they pass by a given point.

7) *Hourly traffic*—hourly traffic flows in vehicles per hour. These estimates are commonly used in traffic engineering studies, but are also used in planning studies to validate travel forecasting models. Information on vehicle types and turning movements help assess existing or future traffic performance.

8) *Short-term counts*—short-term counts covering 5, 6, 10, 12, or 15-minute intervals. These counts are useful in determining peak flow rates, establishing flow variations within the peak hour, and identifying capacity limitations.

9) *Space mean speed*—average speed of all vehicles occupying a given section of a highway over some specified time period. The equation for space mean speed is:

$$Space\ mean\ speed = \frac{d}{(\sum_{i=1}^{n} t_i)/n} = \frac{n \times d}{\Sigma_i t_i} \tag{2-1}$$

10) *Time mean speed*—average speed of all vehicles passing a point on a road over some specified period of time. The equation for time mean speed is:

$$Time\ mean\ speed = \frac{\Sigma_{i=1}^{n} \left(d/t_i\right)}{n} \tag{2-2}$$

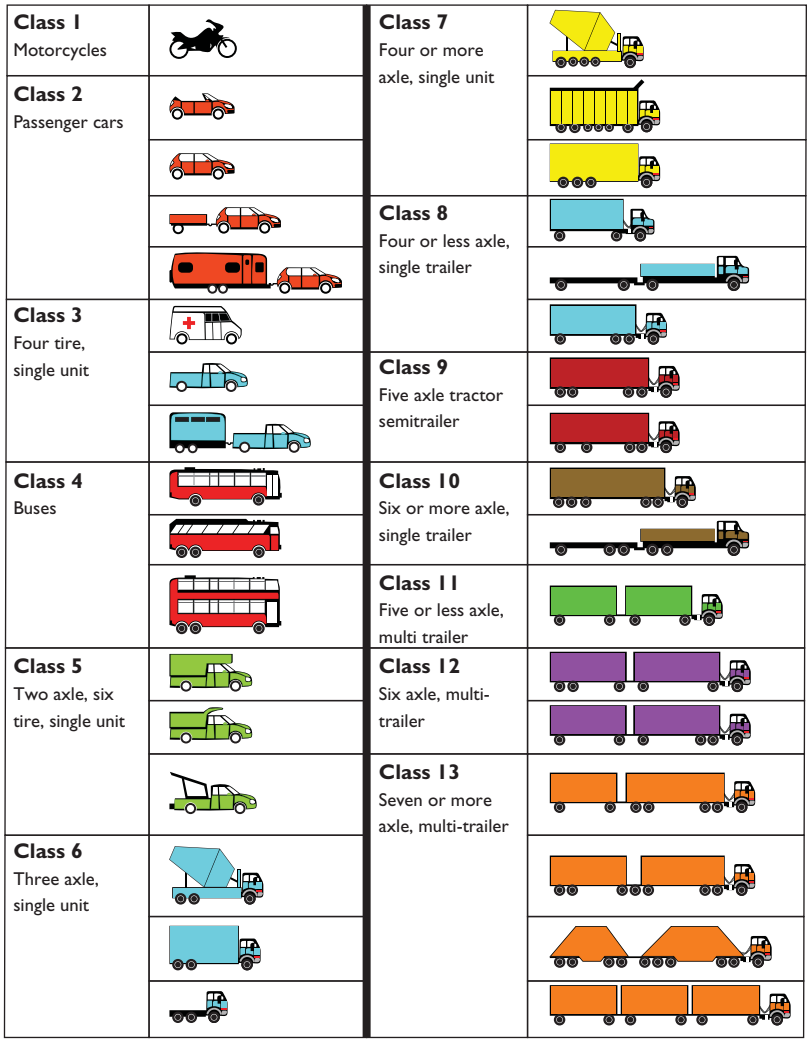
Where:

$d$ = distance traversed (feet, mile, kilometer)
$n$ = number of travel times observed
$t_i$ = travel time of the $i^{th}$ vehicle (seconds or hours)

11) *Traffic density*—vehicles per lane per mile, obtained by dividing the hourly lane volume by the average speed. Traffic density is considered a better measure of street service than flow rate for uninterrupted flow along freeways, expressways, and major arterials. Density continues to increase as congestion increases, while flow rate reaches a maximum value under moderate congestion and then decreases as congestion increases. Should a full stoppage occur, density is at its maximum when the flow rate is zero.

12) *Vehicle classification*—classifying a traffic flow by the types of vehicles found in that flow. For freight planning, vehicle classification data are the basis for estimating annual travel by each type of truck, ton-miles

**Figure 2-16. FHWA 13 Category Vehicle Classification**



Source: FHWA, 2013c

of cargo hauled on highways, and changes in axle and gross weight frequencies on the highways. Vehicle classification data are also used in the development of transportation policy, the allocation of highway costs and revenues, the regulation of size and weight, the establishment of geometric design criteria related to size and weight of vehicles, and the study of pavement and bridge deterioration, as well as for various special studies. Vehicles are often classified based on schemes adopted by the data collection agency. For example, Figure 2-16 shows the vehicle classification scheme from FHWA for classifying vehicles. The classification scheme is separated into categories based on whether the vehicle carries passengers or commodities. The number of axles and number of units, including both power and trailer units, further subdivide nonpassenger vehicles.

13) *Vehicle miles traveled (VMT)*—the amount of travel on a road system estimated by multiplying the daily (or annual) traffic volume on each section or link by its length. Estimates of annual VMT are useful in computing crash rates and estimating pollutant emissions. Where peak-hour traffic counts (or flow maps) are available, peak-hour VMT can be estimated. In urban areas, sampling procedures can be used to estimate daily VMT. The road system should, at a minimum, be classified as freeways, arterial streets, and local streets. Where possible, freeways should be further stratified by lanes or ADTs and arterials should be grouped by lanes, geographic area, or other features. Stratified random sampling procedures (discussed in the last section of this chapter ) should be utilized taking into account the spatial, temporal, link length, and similar variations to obtain a composite variance for each class (see FHWA's Traffic Monitoring Guide [FHWA, 2013c] for more detailed discussion of estimating VMT).

## B. Traffic Count Techniques

Traffic volume estimates are obtained through a variety of traffic counting techniques. Agencies such as state departments of transportation have a systematic and periodic traffic counting program. In other situations, such as in site impact analysis, special counts are taken for use in the analysis (see chapter 19 on site planning and traffic impact analysis).

ADT and AADT counts are usually obtained through machine counts using either with tubes and air switches or permanently located detector sensors (such as inductive loops or magnetometers) and appropriate detector electronic units. Counters are used to obtain 24-hour counts, often without regard to direction. Two separate directional counts at the same location can be summed to obtain a total road volume count. Twenty-four-hour counts are used primarily to develop traffic flow maps and determine traffic trends. Directional counts are used for capacity analyses, planning improvements, obtaining accumulations within a cordon area, and other such purposes.

Many states and cities have established generalized monthly and daily factors for various types of roads to adjust 24-hour counts for a given day to AADT. Two types of data collection are used to define these adjustment factors. *Continuous traffic monitoring data collection programs* are used to collect traffic counts every day of the year. The types of instruments used for such data collection include:

- Automatic traffic recorders (ATRs).
- Automatic, continuous vehicle classifiers used to supplement the ATR program.
- Continuously operating weigh-in-motion (WIM) scales placed to monitor statewide trends in vehicle weights.
- Continuously operating WIM scales used to identify trucks that need to be weighed statically at an enforcement scale.
- Volume and speed monitoring stations that provide facility performance data to centralized traffic management systems.

Another approach involves locating control stations throughout the road network to sample traffic volumes on the major road system. For such *control station counts,* it is desirable to have at least one control station located on each freeway and major street. The minimum recommended duration and frequency of counting is a 24-hour directional machine count every second year. Selected control stations—called key count stations—are used to obtain daily and seasonal variations in traffic volumes. At least one key count station should be selected from each class of street in both the major and the minor systems. Key count stations are counted for one continuous week each year and for one 24-hour weekday each month. These counts provide factors that can be used to adjust other traffic counts taken on shorter time periods.

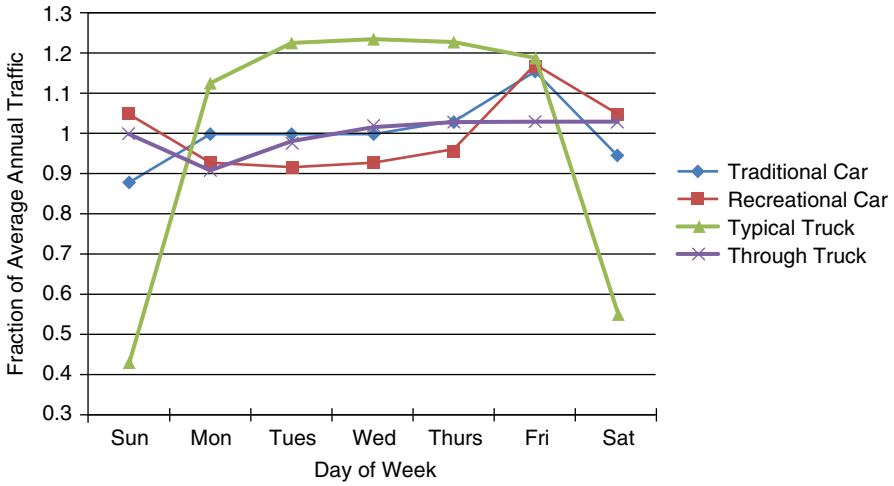
*Coverage counts* are used to estimate ADTs at many different locations throughout the street network. Major streets are divided into segments with uniform traffic conditions, and a 24-hour, nondirectional count is made in each segment. The count is adjusted using the factors developed from the appropriate key count station to obtain the estimated ADT. Coverage counts are normally repeated every 4 years, but significant changes in traffic due to road improvements, land-use changes, or other factors may dictate more frequent recounts. For the minor street network, one 24-hour, nondirectional count should be taken for each mile (1.6 kilometers) of street. Counts are repeated when local circumstances indicate a need.

Traffic volume graphs are sometimes prepared to show the monthly and daily traffic variations at a given location. Figures 2-17a and b give examples of such a graph (note: daily variation was shown in Figure 2-14).

*Hourly traffic counts* by direction of travel can be made for 12, 18, or 24-hour time periods by recording counters. Volumes are recorded in either 15-minute or hourly intervals by printing on paper tape, punching or encoding on machine-readable tape, recording electronically for subsequent insertion in a personal computer, or being digitally transmitted to a central computer.

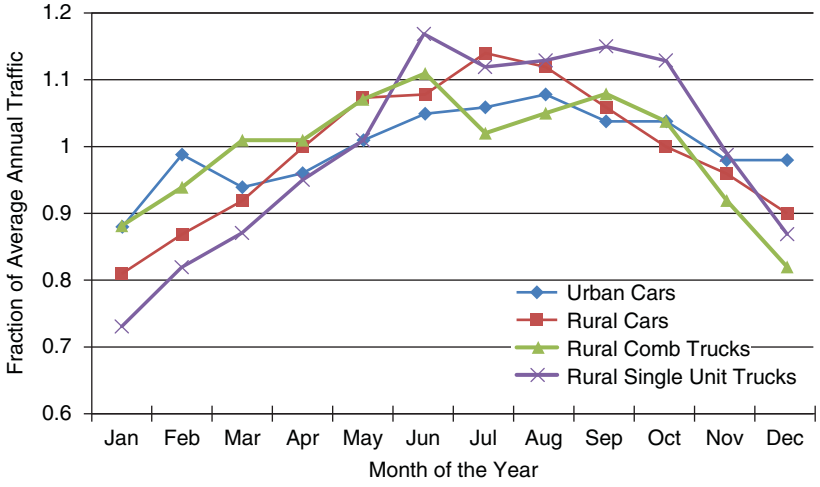
When traffic volume data from coverage counts are maintained at levels of aggregation below that of a daily total, such as by hour and direction, the data have additional uses, such as traffic signal timing, air quality analysis, noise analysis, planning studies, and planning the timing of maintenance and construction activities.

**Figure 2-17a. Temporal Variation in Traffic Volumes. Typical Day-of-Week Traffic Volume Distribution by Vehicle Type, United States**



Note: Typical trucks are primarily local trucks used for pickup and delivery; through trucks are typically trucks traveling long distance.

**Figure 2-17b. Temporal Variation in Traffic Volumes. Typical Month-of-Year Traffic Volume Distribution by Vehicle Type, United States**



Source: Hallenback et al., 1997 as reported in FHWAc, 2013

To compute AADT from a short duration count, the data collected during the short counts must be adjusted to annual conditions. These adjustments include:

- Axle corrections (for counts made with single axle sensors; there would be no correction factor for counts taken by an induction loop that senses vehicles).
- Day of week (for counts taken for less than one week).
- Seasonal (to account for changes in volume that occur from one time of year to another); and time of day (for counts taken for less than 24 hours).

See the ITE's *Traffic Engineering Handbook* for further details. [Pande and Wolshon, 2016]

*Manual traffic counts* are widely used to obtain hour-by-hour variations in traffic flows, traffic composition, turning movements, and pedestrians. This information is used to define the duration and intensity of peak periods, evaluate street capacity deficiencies, assess the need for various traffic controls, develop street designs, and determine the effects of new developments on changed land uses. They also provide inputs for traffic model validation.

*Turning movement counts* are often collected at intersections for a variety of analyses, including signal timing, capacity, impact of physical changes to the intersection, or nearby land uses. These counts are collected in 15-minute increments for at least a 2-hour period in the morning peak, evening peak, and in the vicinity of heavy commercial land use, on a Saturday peak. To avoid the high costs associated with turning movement counts, sample "short" counts are sometimes used. One method is to count each intersection approach for a definite time period (such as 5 to 10 minutes per hour). When intersections are close to each other, it is possible to sample count each intersection on a rotating basis. Counts should be done on a per signal cycle basis rather than for specified time periods. These methods should be used only when traffic conditions are relatively constant throughout the study period.

*Vehicle occupancy counts* are usually estimated through sampling procedures. The number of separate counting efforts needed for a given time period can be obtained by the following equation:

$$n = \frac{Z^2( S_1^2 + S_2^2 + S_3^2 )}{E^2} \tag{2-3}$$

where:

$E$ = Allowable error or tolerance (as a decimal, 5 percent is denoted 0.05)
$S_1$ = Standard deviation of average occupancy across days in a single season
$S_2$ = Standard deviation of average occupancy among seasons
$S_3$ = Standard deviation of average occupancy across time periods during a day (time period of concern) at a location
$n$ = Number of counts at a location
$Z$ = Standard normal variate

The values for standard deviation should ideally come from previous data collection efforts. Typical values of these standard deviations include:

$S_1$ = 0.063
$S_2$ = 0.015
$S_3$ = 0.017

Further details on procedures and applications for vehicle classification and occupancy counts are found in the FHWA's *Guide for Estimating Urban Vehicle Classification and Occupancy* (2001).

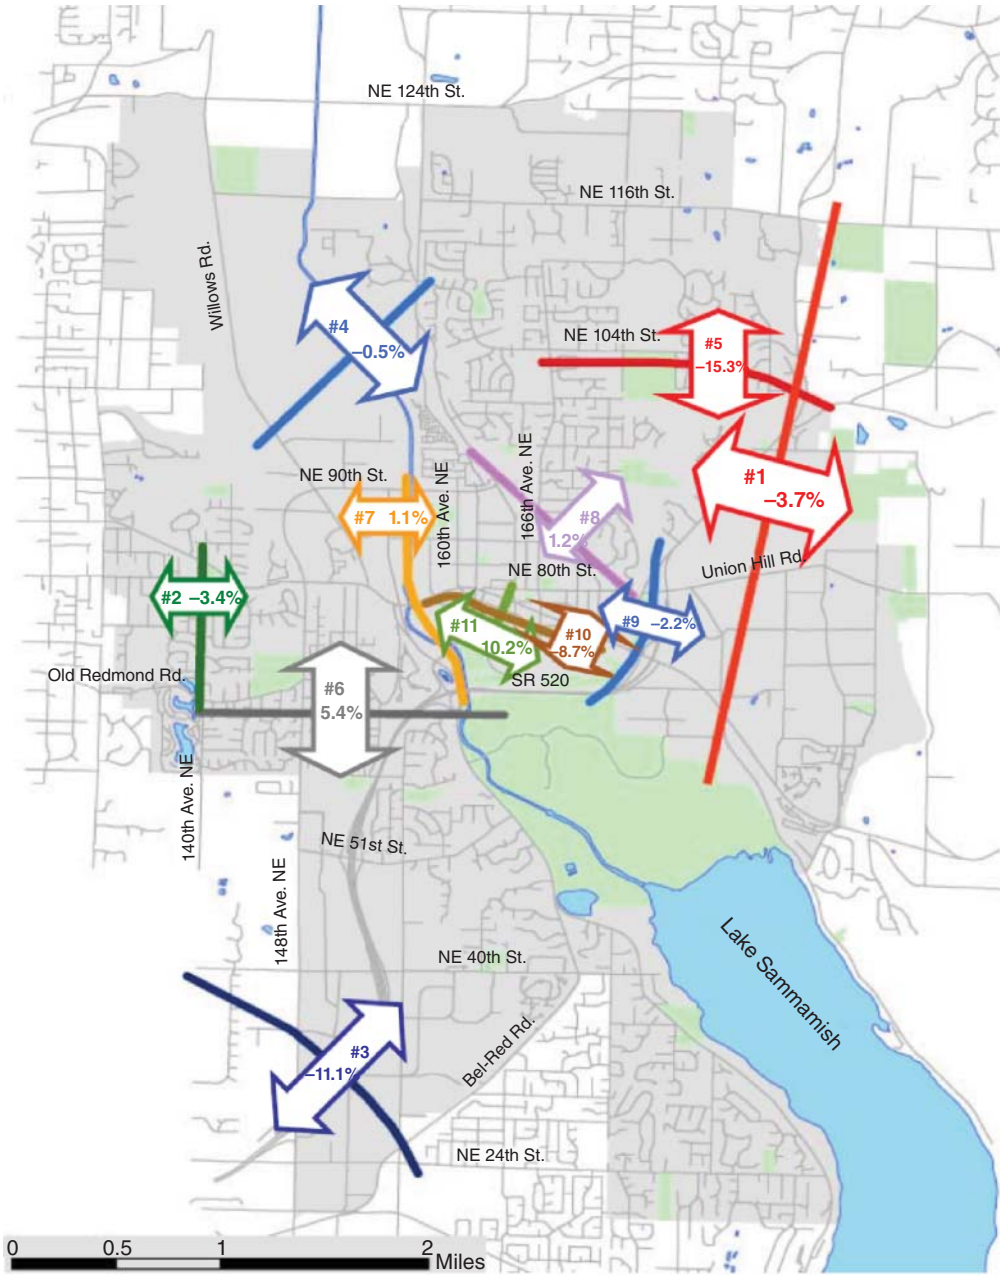
*Screenline counts* are taken at imaginary lines that bisect a study area or a major facility. The screenline is usually drawn along natural boundaries, such as rivers, escarpments, or railroad rights of way, to minimize the number of vehicular crossings and, therefore, the number of counting stations needed (see Figure 2-18). Screenline counts are used in conjunction with origin-destination studies to expand sampled volumes to represent the total (sometimes referred to as the universe) amount for the study area or to check the accuracy of origin-destination trip tables. Trip table crossings of the screenline are aggregated and compared to the actual ground counts at the screenline. The total trip tables are then adjusted to reconcile the differences.

Screenline counts are also used to help calibrate travel demand models and to detect trends or long-term changes in volume and direction of travel due to significant changes in population, land use, commercial and business activity, and travel patterns. In some situations it is not necessary to count all crossings of a screenline as long as traffic or ridership is not diverted to uncounted crossings. Counts might be taken every year or every second year. Counts should be made on an hourly basis to allow hour-by-hour comparisons with origin-destination data.

*Cordon counts* are imaginary lines where the trips crossing the lines are counted by direction of travel. The study area may be an entire urbanized area, a transportation study area, a city, a central business district (CBD), a neighborhood, an industrial area, or any other definable planning area. The counts determine the number of vehicles and people entering, leaving, and accumulated within the cordon area by mode of travel and time of day (including pedestrians and bicyclists). Vehicles are classified by type—bicycles, automobiles, light trucks, heavy trucks, carpools, taxis, buses, light rail transit, rapid transit, and commuter rail trains. Vehicle occupancies are determined for each vehicle type and travel mode (some agencies do not include truck drivers in their summaries of person movement). The counts may cover a full 24-hour period (particularly when recording counters are used), but more frequently cover 16 hours (5:30 a.m.–9:30 p.m. or 6:00 a.m.–10:00 p.m.) or 12 hours (7:00 a.m–7:00 p.m.).

CBD cordon counts are often used to measure the transportation activity generated by the CBD. These counts are repeated on an annual or biennial basis to evaluate trends or changes in activity within the CBD. They are useful in identifying the roles and importance of various transportation modes and in establishing transport policy.

**Figure 2-18. Use of Screenlines in Redmond, Washington, Showing Traffic Growth, 2006/07 to 2007/08**

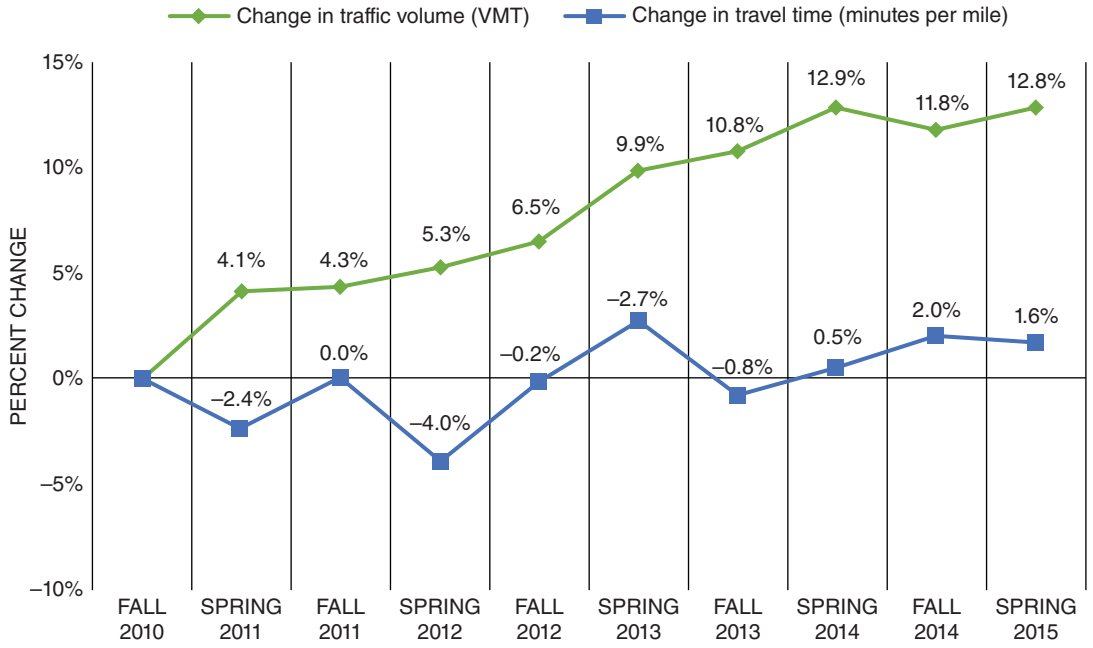


Source: City of Redmond Public Works Department. 2009. Reproduced with permission of the City of Redmond.

Results are summarized in graphic and tabular form to indicate daily and peak-hour person movements, vehicle movements and occupancies by travel mode, and vehicle occupancy and accumulation of people by mode of travel throughout the day**.** An important planning use of the CBD cordon count is to compare transit ridership projections with actual cordon crossings as part of a reasonableness check of ridership forecasts.

Many studies rely on a combination of traffic counting techniques to "tell a story." This is especially true in situations where there is a high variability of travel times and speeds on the facilities being measured. For example, the Georgia Department of Transportation is monitoring the performance on several major arterials in the Atlanta region using a combination of traditional counting methods, probe vehicle studies, and Bluetooth sensors. Data is formulated into biannual reports that highlight changes in performance so that investment decisions can be targeted on those arterial segments that will provide the best incremental benefit. Figure 2-19 shows the changes in traffic volume and travel time since the 2010 start of the regional traffic operations program. Maintaining consistent and reliable performance

**Figure 2-19. Change in Arterial Peak Period VMT and Peak Period Travel Time per Mile, Atlanta**



Source: Georgia Department of Transportation, 2015.

in the face of increasing traffic demand was accomplished through improved signal timing, enhanced communication with drivers on congested locations, and active management strategies.

## C. Data Collection Standards

Traffic monitoring programs usually establish a recommended counting frequency, representing a compromise between the cost of data collection and count accuracy. For example, FHWA's *Traffic Monitoring Guide* recommends that coverage counts be 48 hours in duration and repeated every third year, with growth factors being applied in the intervening two years. As count duration and frequency increase, program cost increases while the level of inaccuracy in AADT estimation is reduced. [Hallenback and Bowman, 1984] A point is reached in this relationship, however, where the marginal improvement in accuracy is not worth the cost of collecting the extra data.

Federal guidance is available for traffic counting programs that relate to roads receiving federal aid, such as the interstate system. Transportation planners should be aware of the data collection standards that apply to the types of travel patterns being monitored. Many traffic counting programs also have a specified minimum level of precision and permissible error. This is discussed in the section on statistics.

## D. Highway Performance Monitoring System (HPMS)

In the United States, the federally required Highway Performance Monitoring System (HPMS) is part of a state DOT's data collection program. Beginning in the mid-1980s, the federal government required states to collect performance and condition data on their road networks and to submit these data to FHWA. The data are collected based on samples and a universe section. Two types of data are collected and reported to the FHWA. [FHWA, 2014] Full extent (that is, systemwide) data are collected on selected networks such as the National Highway System (NHS) routes and all other roads, excluding minor collectors in rural areas and local roads in any area. The data collected relate to inventory (physical characteristics), route (for example, route number and road signing), traffic (for example, Annual Average Daily Traffic–AADT, single-unit truck & bus AADT, and combination truck AADT), pavement (for example, International Roughness Index (IRI)), and any special network designation.

Data are also collected on a random sample of roadway sections that represent attributes at a systemwide level. These sections of the network are referred to as sample panel sections. The sections are selected randomly and are intended to

give a statistically valid representation of a state's road network. The data collected on the road samples are much more detailed and include the data categories listed above. Sample panel data also include geometric characteristics (for example, lane width, shoulder type, and peak parking) and much more data on traffic and pavement characteristics.

Each NHS, principal arterial, and sample section must be counted at least once every three years. Additionally, each state should maintain cyclic count coverage data on all arterial and collector roadways covered by the HPMS sample so that those sections can be accurately assigned to HPMS volume strata. This is necessary to expand the HPMS sample counts into accurate estimates of statewide VMT. Pavement condition data must be collected no more than every two years.

The HPMS data collection effort is particularly important to state transportation agencies because some federal-aid funds are apportioned based on the data collected. In addition, HPMS data are used in a number of key analytical tools, including the HPMS Analytical Package, the Surface Transportation Efficiency Analysis System (STEAM), the Highway Economic Requirements System (HERS), and the ITS Deployment Analysis System (IDAS), as well as in a variety of state-specific planning and performance modeling systems. The HPMS database is also the basis for periodic reports to Congress on the status and condition of the U.S. road network. (See FHWA, 2014 for much greater detail on the traffic data collection program for the HPMS effort.)

## E. Travel Time Studies

Travel time and delay studies are among the most basic and important of transportation analyses. Travel time studies have a wide range of uses and application (see Table 2-9). They provide measures of a facility's or system's operational performance (for example, amount of delay and average speed). They help assess the adequacy of existing and proposed facilities, feed into decisions relating to traffic control and infrastructure changes, serve as an important measure of

**Table 2-9. Uses of Travel Time Measures in Planning and Project Development**

the value of time delay (when combined with an economic estimate of the value of time), and provide inputs into travel demand models. They also help define markets for businesses (for example, how many households live within a 30-minute trip of a store?) and, when conducted on a periodic basis, quantify changes in mobility and congestion.

Travel time-related concepts include the following:

- *Portal-to-portal travel time* is the total time traveling from one location to another. It includes in-vehicle time (time actually spent traveling) and out-of-vehicle time (time spent waiting for transit service, transferring to another vehicle, and time spent in walking between the vehicle and the origin and destination at both ends of the trip).
- *Vehicle travel time* is the time taken by a vehicle to traverse a given network segment. It includes running time, the time a vehicle spends in motion and delay, and the time lost in traffic due to traffic control devices and congestion. For public transit, travel time includes dwell times at stops, which in congested systems can constitute a major source of delay.
- *Congestion* is travel time or delay in excess of that normally incurred under light to free-flow travel conditions.
- *Mobility* is the ability of people and goods to move quickly, easily, and cheaply to their destination, and thus travel time is often a component of system performance measures that relate to mobility.
- *Accessibility* is the achievement of travel objectives within time limits regarded as acceptable. (Note that, with telecommunications technology, people can have accessibility but not be mobile.) For accessibility measures, travel times become a modifier or the primary performance measure, an example being the number of low-income households within a 60-minute transit ride of community health or recreational facilities.

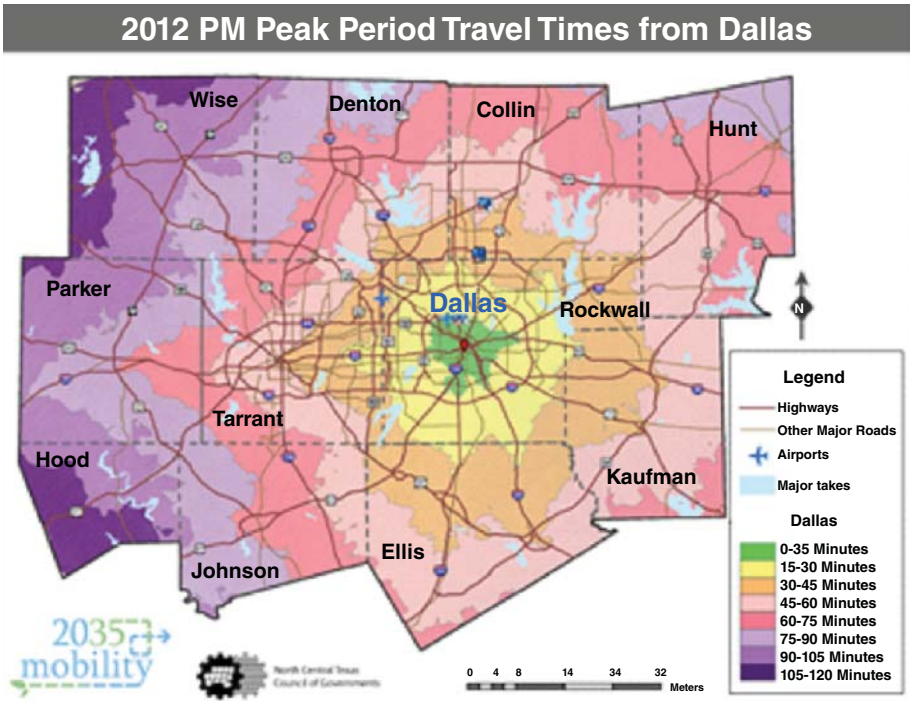
Travel times and delays should be obtained by direct measurement wherever possible. Methods for doing so include test vehicles, license plate matching, aerial photography, interviews, probe vehicles, cell phones, induction loops, sensors, and traffic reporting services. Travel time and delay data can be depicted either graphically or tabulated. Some typical means of conveying travel time and delay information include:

1) *Travel Time Contours*: Travel time contour or isochronal maps show the distance that can be reached from a common origin (often a CBD) in a given time period. They can compare peak and off-peak hours, thereby indicating the amount of congestion in each corridor. Contours can also compare travel times from year to year, thereby indicating the changes in system performance. Isochronal maps are also useful in defining the reach or market area for commercial developments (see Figure 2-20).
2) *Areas or Corridors*: Travel speeds along sections of roadways in a corridor or area can be presented as *speed flow maps* or delineated by legend. Alternatively, the distances traveled in 5-minute time intervals can be indicated.
3) *Routes*: Travel times and delays along a route can be depicted by profiles of speeds and delays along a route (see Figure 2-21) by graphic comparisons of peak and off-peak travel times or by time-space trajectories. Travel time and delay information can be summarized by component such as shown in Figure 2-22; data can also be aggregated by route.

## F. Travel Surveys

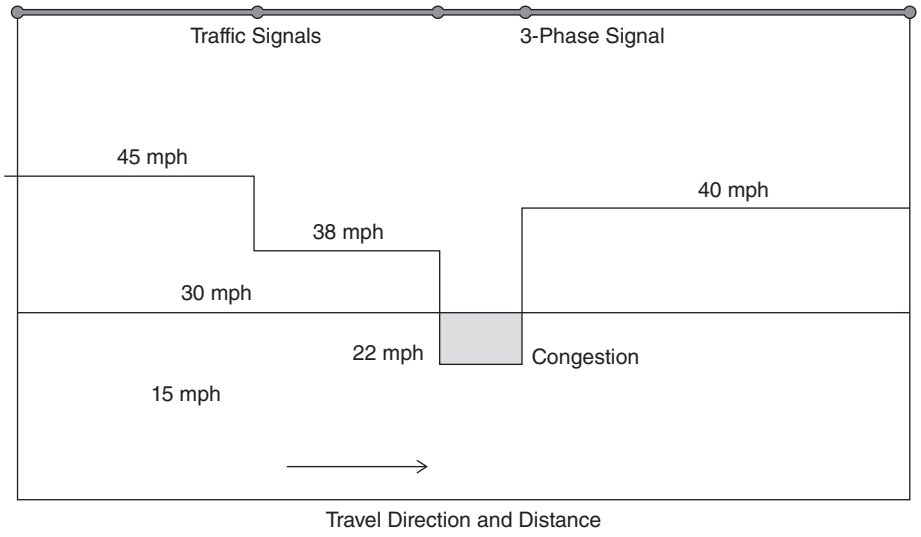
Most of the travel collection techniques discussed previously are designed to collect data at one location over a specified time period. In many ways, these techniques provide a static representation of what is happening on the transportation system. Often in transportation planning it is important to know the characteristics of the travelers as well as more detail on travel patterns, such as where trips are coming from and where they are destined. The primary means of collecting such information is through travel surveys. Travel surveys are designed to obtain data and information on the number, type, and orientation of trips in an area; they also include movements of passengers, vehicles, and cargo. The surveys estimate the nature and magnitude of existing travel and the characteristics of that travel, usually during an average weekday.

**Figure 2-20. Travel Time Contours, Dallas–Ft. Worth**



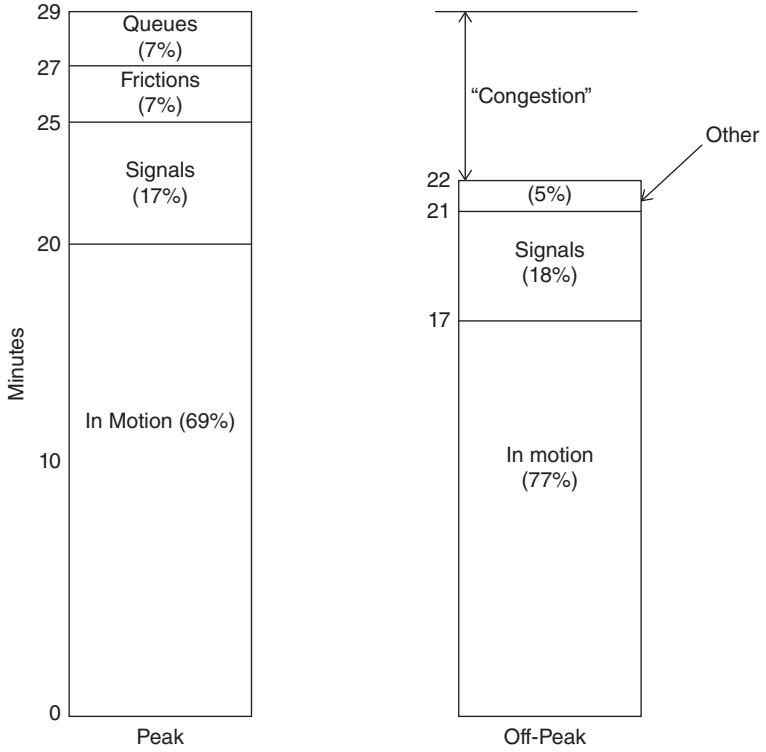
Source: North Central Texas Council of Governments, Accessed Feb. 24, 2016, from, http://www.nctcog.org/trans/data/traveltimes/Dallas.pdf

**Figure 2-21. Illustrative Speed Profile**



Travel patterns are commonly displayed as desire lines in which straight lines are drawn between origin-destination pairs with the width of each line proportional to the number of trips made between the two zones on an average weekday. A different type of desire line chart summarizes the data further and shows the aggregated through-trips, internal-external trips, external-internal trips, and internal-internal trips. Desire-line charts may also be prepared for special zones such as the CBD, a large industrial tract, a university, or a military installation. Contour maps (or isolines) showing the orientation and intensity of travel can also be prepared. Other data collected during the origin-destination study may be presented on maps of the area, sometimes keyed to analysis zones. Examples include population distribution or density, land use, and trip density.

**Figure 2-22. Illustrative Graphic of Travel Times and Delays**



The data collected by travel surveys can provide answers to questions concerning an individual's or household's travel patterns and desires with respect to new services. They indicate:

- When trips are made.
- Where the trips began and ended.
- What mode of travel was used (for example, auto driver, auto passenger, bus rider, taxi passenger, truck driver, bicyclist, or walker).
- Why the trip was made, that is, trip purpose (for example, work, shopping, business, or schools).
- Who is making the trip (for example, the characteristics of the travelers and for some types of surveys, household characteristics).
- How many people are traveling together.
- What travelers would like to see with respect to new transportation services.

Many of the surveys are complex, and there are continual changes in survey designs and methods (for more detail, see the Transportation Research Board's Committee on Travel Surveys website, http://www.fhwa.dot.gov/ohim/trb/reports.htm, and the online *Travel Survey Manual* at http://tfresource.org/Online_Travel_Survey_Manual).

The scope and scale of studies that utilize travel surveys vary widely. Surveys could be used to study a single highway interchange or a transit route, or a series of routes as in a financial feasibility or corridor study. The survey area may contain a single neighborhood, a subdivision, or a commercial development; or it may encompass an entire metropolitan area or state, as often occurs in comprehensive transportation studies.

Table 2-10 shows the common survey populations encountered in transportation planning studies and their use in the transportation planning and modeling process. These surveys generally form part of the comprehensive data collection effort that focuses on a sample of travelers who are assumed to be representative of all travelers in the urban area. The survey methodology with respect to such studies includes: (1) establishing zones for analysis purposes, (2) conducting external (or intercept) surveys, (3) conducting internal surveys, (4) processing data and performing accuracy checks, and (5) analyzing and expanding data.

The initial step in a planning study is to define the study area. For comprehensive metropolitan studies, this area should encompass those parts of the region that will be urbanized in the planning horizon year. A cordon line is established around the study area that minimizes the number of roads (and hence survey stations) that are crossed. Traffic analysis zones, rings, and sectors should be discretely numbered. The size of the zones is governed by survey area size, population density, desired data items, and study purpose. Zones are smaller in the downtown area and larger in the sparsely populated outlying areas. Trips with both origin and destination within the zones should not comprise more than 15 percent of all trips. Once the zonal system has been established, surveys can be used to collect desired data and information. Existing zonal structures, such as those used for a travel demand model, should always be considered when establishing a study framework. This will allow comparisons to be made and data to be shared.

Survey information is required for three categories of trips. Trips that traverse the study area are referred to as *through-trips*, *external trips*, or *external-external trips*. Trips that have either their origin or destination outside the study area while the other end of the trip is in the study area are referred to as *external-internal trips* or *internal-external trips*. The (usually) largest category of trips includes those that have both origin and destination inside the study area, referred to as *internal trips* or *internal-internal trips*. Data for these different categories of trips are collected in two

| Table 2-10. Common Survey Populations and Uses of Data | | |
|---|---|---|
| **Survey Type** | **Common Survey Populations** | **Common Modeling Uses of Data** |
| Household travel of activity surveys | Household within a prespecified study area<br>OR<br>People within a prespecified study area | Trip generation, trip distribution, mode choice, time-of-day of travel, traveler behavior |
| Transit on-board surveys | Transit passenger trips on prespecified set of transit services | Mode choice |
| Vehicle intercept or external station surveys | Vehicle-trips on one or more highway segments, perhaps by direction<br>OR<br>Person-trips by vehicle on those highway segments | Trip distribution, model validation |
| Commercial vehicle surveys | Commercial vehicles garaged within a prespecified study area<br>OR<br>Commercial vehicle trips made by those vehicles | Commercial vehicle travel (generation, distribution, time-of-day) |
| Workplace, establishment and special generator surveys | Employees of prespecified establishments<br>OR<br>All trips to and/or from the establishment | Trip attraction models, parking and transit cost/subsidy |
| Hotel and visitor surveys | Hotel guests at prespecified establishments<br>OR<br>All trips to and/or from the hotel | Visitor models (generation, distribution, time-of-day) |
| Parking surveys | All vehicles parked at pre-specified locations during a prespecified time period<br>OR<br>All vehicle or person-trips to those parking locations | Parking cost (for mode choice) |

Source: Transportation Modeling Improvement Program. Undated. *Travel Survey Manual*. Washington, DC. Accessed from, http://tfresource.org/Online_Travel_Survey_Manual on Feb. 25, 2016.

different types of studies. Through-trip data and external-internal trip data are obtained from *external* studies, while *internal* studies provide data on internal trips.

### *1. External Surveys*

External (or intercept) surveys obtain travel information concerning external and external-internal trips. Separate surveys of rail, bus, and air travel may obtain additional travel information; these studies are specialized and depend on the particular information desired. Most are conducted by questionnaires distributed and filled out during individual trips. Common types of studies include roadside surveys, postcard mail-back surveys, license plate surveys, vehicle intercept surveys, and lights-on surveys.

*Roadside Interview*. Roadside interviews are the most common method of obtaining external travel information for comprehensive studies conducted in a large metropolitan area. Interview stations are established at all major roads and most other roads crossing the cordon line encompassing the study area (attempting to intercept at least 95 percent of the crossing traffic). Extreme care must be taken in locating and setting up the interview stations to ensure that vehicles can be safely stopped for interviews. A large sample of vehicles is stopped (one of the challenges with this method), and the drivers are asked the origin and destination of the current trip. Some studies obtain additional information, such as trip purpose, where the car is garaged, routes followed, and intermediate stops made. Roadside surveys are seldom used in large metropolitan areas today because of survey crew safety and the potential for traffic bottlenecks at interviewing locations. Other less intrusive methods are used.

*Postcard Surveys*. Where traffic is heavy, returnable postcards can be handed to drivers at the intercept stations. This method is often used in conjunction with interview studies, especially during peak periods when it is not possible to delay vehicles long enough to complete an interview (other surveys rely on postcards entirely for their data). Prepaid postcards are coded with survey station identification and time, and they request the recipient to list the origin and destination of the trip and to drop the card in any mailbox. A 20- to 40-percent response rate is common for this type of survey. Data are expanded by hour and to a 24-hour total. Through-trips must be halved because of the double interception of these trips, assuming that the trips have been picked up at two external survey stations as the trips traversed the study area. In some cases, a website address and password are provided so respondents can enter answers by filling out a web form. This may increase the response rate.

*License Plate Surveys*. A license plate study can be used instead of an interview or postcard survey. Even with interviews or postcards, a license plate study may be necessary at freeway crossings of a study cordon line. In this procedure license plate numbers are recorded either visually or with visual image readers along with the time of observation. Manual recording is usually accomplished through the use of tape recorders. Postcards or surveys are then sent to the address where the vehicle is registered. This type of study is conducted only during daylight hours, although where roadway lighting is of sufficient intensity, license numbers can be recorded during other periods. Returns are stratified by time of day. A 30-percent return of the questionnaires is considered excellent, although returns as low as 20 percent could produce statistically valid results. The information received from the returned questionnaires is expanded by three factors. The first is to expand the percentage return to 100 percent of the plate numbers recorded. This factor equals 100 divided by the percentage return. The second factor expands the sample of license plates recorded to the total volume passing the station during each hour the plate numbers were recorded. This hourly factor equals the total volume in each hour divided by the number of plates recorded in that hour. The third factor expands the data to the full 24-hour total volume divided by the sum of the hourly volumes during which license plate numbers were recorded. Other adjustments factors (for example, day of week, month of year) may also be applied. Finally, the through-trips must once again be halved because of the double exposure to intercept stations.

*Vehicle Intercept Surveys*. The vehicle intercept method can be used in small area studies. This procedure requires stations at all entrances and exits to the study area. Each entering vehicle is stopped and a coded or colored card is handed to the driver with instructions to surrender the card as he or she exits the area. Exiting vehicles are stopped and the cards collected, or the notation that they had not received a card is made. A variation of this procedure is to place colored tape on the bumper of the entering vehicle or to tape the colored card to the windshield. Given that the color code indicates at which entry point the vehicle entered the study area, this approach eliminates the need for stopping vehicles at the exits from the area. It also permits the collection of data at intermediate locations within the study area. However, it poses problems in certain weather and lighting conditions. The vehicle intercept survey is used to determine origin-destination travel patterns through a study area. More detailed information on traveler and trip characteristics is not collected with this method.

*Lights-On Studies*. A lights-on study is a variation of the vehicle intercept (or tag-on-vehicle study). This study traces individual vehicles from one entrance point to a maximum of two or three destination points, generally within one-half mile to 1 mile of each other. It is useful in tracing vehicles through a highway interchange or weaving area. Each entering vehicle is requested to turn its headlights on and to leave them on until it passes an exit station. This procedure only works during daylight hours. It is the least reliable of the surveys described, and it is only effective under very limited circumstances. A caution with using this approach is that in many circumstances (for example, in Canada), many vehicles operate with lights permanently on.

### *2. Internal Surveys*

Typical types of internal surveys include household interviews, commercial vehicle surveys, surveys of workplaces and special generators, hotel, and visitor surveys, and transit-on-board surveys.

**Household Surveys.** Household surveys began during the 1940s and became common during the 1950s as part of the comprehensive urban transportation planning process. The initial studies involved home interviews in which respondents were asked to recall the trips made on the previous day. The samples ranged from about 2 percent in areas with populations exceeding 5 million to 20 percent in areas of less than 200,000 population.

Over the past 15 years, survey methods have changed dramatically. Surveys can be done over the Internet or by telephone, involve small samples, and include trips made by walking and bicycling as well as by auto or transit. More than 80 such surveys have been completed in the past 5 years.

The key steps in conducting a household survey are shown in Figure 2-23. An often neglected but important part of the survey process is a pilot survey, which should be used to test the survey instrument, sampling design, and interview process. The typical information collected is summarized in Table 2-11.

Household surveys include: (1) trip-based tools that directly gather information on people's trips over some period using either diary or recall methods, (2) activity-based surveys that gather information on respondent travel-related activities during a set time period, or (3) time-use-based surveys that gather information on all activities in which respondents participate during a set time period. Surveys commonly use motion recorders (such as GPS units) or activity diaries to minimize underreporting of certain trips (such as short trips). They may also be designed to obtain stated response (that is, stated preference) information. Figure 2-24a shows a survey form for a trip diary survey in Albuquerque, New Mexico. Figure 2-25 presents a travel survey instrument for Ames, Iowa.

E Activity List

Pick the code from below that best describes the activity for each place and write the code in column E. *For transit stops or car/vanpool meeting places: Record activity '12'.

| | | | | |
|---|---|---|---|---|
| 01. Home Activities | 04. Retail Shopping | 07. Recreational Activities | 10. Visiting a Place of Worship | 13. Change Modes |
| 02. Workplace Activities | 05. Dining at Restaurant | 08. Banking/Other Office Related | 11. College/University | 14. Loop for Exercise (e.g., running, bicycling, or going for a walk |
| 03. School/Daycare Related | 06. Visiting Hospital/Doctor | 09. Visiting Another Private Residence | 12. Pick-up/Drop-off Passenger | |

If you visit more than 5 PLACES, continue recording on the back of your Travel Log.

Continue with places 6-14 on back

**Figure 2-25. Travel Survey Instrument, Ames, Iowa**

Ames Area MPO metropolitan planning organization

**Regional TRAVEL SURVEY**

One of the first considerations for planning the future of a region is the need for adequate transportation. Because of the time it takes to implement and the investment required, long range transportation planning is vital to successfully shaping the future of any region. We would like your help today in shaping the future of the Ames Region. Thank you for taking time to complete the survey. When you are finished, please return your completed survey in the postage-paid envelope addressed to ETC Institute, 725 W. Frontier Circle, Olathe, KS 66061.

**1. How many operating vehicles (cars, trucks, motorcycles/mopeds, vans) do you have in your household?**
_____vehicle(s)

**2. Please select all the choices that best describe you. (Check ALL that apply)**

| | | |
|---|---|---|
| ___(1) | Employed outside the home | [Answer Q2a-2c] |
| ___(2) | Student (K-12) | [Answer Q2b-2c] |
| ___(3) | Student (University) | [Answer Q2b-2c] |
| ___(4) | Operate home-based business | [GO TO Q3] |
| ___(5) | Not currently employed | [GO TO Q3] |
| ___(6) | Retired | [GO TO Q3] |

**2a. In which city do you work? _____**

**2b. What method of transportation do you normally use to go to work/school?**

___(01) Car/truck–drive alone
___(02) Carpool
___(03) Vanpool
___(04) Walk
___(05) Taxi
___(06) Bicycle
___(07) Public transit (bus/train/shuttle) (CyRide)
___(08) Motorcycle/moped
___(09) Park and Ride
___(10) Other: _____

**2c. How many miles is your place of employment/school from your home?**
**_____ miles**

**3. On a typical weekday, how many one-way trips do you normally make using the following types of transportation?** Please count all trips completed, including return trips to your home. If you make multiple stops on your way, please count each destination you visit as a separate trip. For example, if you stop at a gas station on the way to work, this would count as two trips.

(A) Drive a car/truck alone . . . . . _____ trips

(B) Carpool . . . . . _____ trips

(C) Vanpool . . . . . _____ trips

(D) Ride the bus/shuttle . . . . . _____ trips

(E) Ride a motorcycle/moped . . . . . _____ trips

(F) Walk (to a destination) . . . . . _____ trips

(G) Ride a bicycle . . . . . _____ trips

| T. | Speeding traffic on neighborhood streets | 5 | 4 | 3 | 2 | 1 | 9 |

**5. Which THREE of the items in Question 4 do you think are the MOST IMPORTANT Transportation issues?** [Write in the letters below using the letters from the list in Question 4 in the priority of their importance to you].

1st:_____ 2nd:_____ 3rd: _____

**6. Overall, would you rate the transportation system in the Ames Area as excellent, good, average, or poor?**

___(1) excellent
___(2) good
___(3) average
___(4) poor
___(9) don't know

**7. Do you feel that congestion at rush hour in the Ames Area is better or worse than rush hour congestion in other cities of comparable size that you have visited?**

___(1) Better
___(2) Worse
___(3) Same
___(9) Don't know

| **8. Parking in the Ames Area**<br>**Please rate your satisfaction with the following:** | | **Very Satisfied** | **Satisfied** | **Neutral** | **Dissatisfied** | **Very Dissatisfied** | **Don't Know** |
|---|---|---|---|---|---|---|---|
| A. | Parking availability in residential areas | 5 | 4 | 3 | 2 | 1 | 9 |
| B. | Parking availability in the downtown area of Ames | 5 | 4 | 3 | 2 | 1 | 9 |
| C. | Parking availability on campus | 5 | 4 | 3 | 2 | 1 | 9 |
| D. | Parking availability in Campustown | 5 | 4 | 3 | 2 | 1 | 9 |

**Figure 2-25.** ***(Continued)***

**PUBLIC TRANSIT IN THE AMES AREA**

**9. How would you rate the availability of public transit in Ames?**

___(1) excellent
___(2) good
___(3) average
___(4) poor
___(9) don't know

| **10. Transit Availability in the Ames Area**<br>**Please rate your satisfaction with the following:** | | **Very Satisfied** | **Satisfied** | **Neutral** | **Dissatisfied** | **Very Dissatisfied** | **Don't Know** |
|---|---|---|---|---|---|---|---|
| A. | Availability of information about public transit services | 5 | 4 | 3 | 2 | 1 | 9 |
| B. | Destinations served by public transit | 5 | 4 | 3 | 2 | 1 | 9 |
| C. | Distance to the nearest public transit stop from your home | 5 | 4 | 3 | 2 | 1 | 9 |
| D. | The frequency of bus service | 5 | 4 | 3 | 2 | 1 | 9 |
| E. | Hours and days transit service is provided | 5 | 4 | 3 | 2 | 1 | 9 |

**11. Which of the following are reasons that you do not use public transit (CyRide) more often?** (check all that apply)

___(A) Service is not available near my home.
___(B) Service is not offered to destinations I visit frequently.
___(C) I don't know how to use the service (need information about routes/fees/schedules).
___(D) I had a bad experience with the service (treated poorly, arrived late, did not feel safe).
___(E) It takes too long to get to destinations compared to travel by car.
___(F) The service is confusing to use.
___(G) Service is not offered at the time I need it.
___(H) It's too expensive.
___(I) Buses do not come by stops frequently enough.
___(J) The bus is too crowded when I need to take it.
___(K) I just prefer to drive.
___(L) Other: _____

**12. How close of a walk (in minutes) would a public transit stop need to be located for you to consider using public transit instead of a car?**

___(1) 5 minutes
___(2) 10 minutes
___(3) Other_____

**13. How frequently (in minutes) would a bus or other form of public transit need to be scheduled to arrive at stops for you to consider using public transit instead of a car?**

Every _____ minutes

**BICYCLING IN THE AMES AREA**

**14. Have you ridden a bicycle in the Ames area during the past year?**

___(1) Yes [answer Q14a-f]
___(2) No [skip to Q15]

**14a. How safe do you feel bicycling on major streets?**

___(1) Not very safe
___(2) Safe
___(3) Very safe
___(9 Don't know

**Figure 2-25.** ***(Continued)***

**14b. Have you ridden a bicycle using an on-street bike lane during the last year?**
___(1) Yes
___(2) No

**14c. How safe do you feel bicycling in an on-street bike lane?**
___(1) Not very safe
___(2) Safe
___(3) Very safe
___(9) Don't know

**14d. Have you ridden a bicycle on a shared-use path or trail during the last year?**
___(1) Yes
___(2) No

**14e. How safe do you feel bicycling on a shared-use path or trail?**
___(1) Not very safe
___(2) Safe
___(3) Very safe
___(9) Don't know

**14f. What is the primary reason why you ride your bike?**
___(1) To commute to school, work, personal business, or shopping trips
___(2) For recreational (fitness, leisure) use
___(3) Both (if both, give the approximate percentages for commuting and recreation)
what percentage of your biking travel is for commuting? _____%,
what percentage is for recreational biking? _____%

**WALKING IN THE AMES AREA**

**15. Have you walked along streets in the Ames area during the past year?**
___(1) Yes [answer Q15a-d]
___(2) No [skip to Q16]

**15a. How safe do you feel, walking along major streets?**
___(1) Not very safe
___(2) Safe
___(3) Very safe
___(9) Don't know

**15b. Have you walked on a shared-use path or trail or sidewalk during the last year?**
___(1) Yes
___(2) No [skip to Q15d]

**15c. How safe do you feel walking on a shared-use path or trail or sidewalk in the area where you live?**
___(1) Not very safe
___(2) Safe
___(3) Very safe
___(9) Don't know

**15d. What is the primary reason for your walking travel?**
___(1) To commute to school, work, personal business or shopping trips
___(2) For recreational (fitness, leisure) use
___(3) Both (if both, give the approximate percentages for commuting and recreation)
what percentage of your walking travel is for commuting? _____%,
what percentage of your walking travel is for recreational purposes? _____%

**Figure 2-25.** ***(Continued)***

**ROADWAY ISSUES**

**16. Several intersections in the Ames Area are listed below. Which TWO do you think should receive the top priority for improvement over the next 5 years?** (check up to two items)

___(1) South Walnut/Clark & Lincoln Way
___(2) South 16th & Duff
___(3) Grand Avenue & 13th Street
___(4) Franklin & Lincoln Way
___(5) Grand Avenue & 24th Street
___(6) Lincoln Way & Duff Avenue
___(7) Stange Road & 13th Street
___(8) Welch Avenue & Lincoln Way
___(9) Other:_____

**GENERAL QUESTIONS**

**17. For each of the following system enhancements, please indicate whether you would be very supportive, somewhat supportive, or not supportive. Please recognize that there is an increased cost to some of these elements.**

| | **System Enhancements**<br>**Please rate your support for the following:** | **Very Supportive** | **Supportive** | **Neutral** | **Not Supportive** | **Don't Know** |
|---|---|---|---|---|---|---|
| A. | Having dedicated lanes for bikes on major city streets in the Ames Area | 4 | 3 | 2 | 1 | 9 |
| B. | Limiting the number of access driveways to retail and commercial locations to improve traffic flow along major roads in the region | 4 | 3 | 2 | 1 | 9 |
| C. | Developing major roads in future growth areas that are designed to let traffic flow at least 45-50 miles per hour | 4 | 3 | 2 | 1 | 9 |
| D. | Increase investments in technologies, such as variable message signs that inform drivers about traffic conditions and/or sensors that adjust the timing of traffic signals to maximize traffic flow | 4 | 3 | 2 | 1 | 9 |
| E. | Widening existing roads and building new roads to relieve congestion | 4 | 3 | 2 | 1 | 9 |
| F. | Adding more turn lanes at critical intersections to improve traffic operations | 4 | 3 | 2 | 1 | 9 |
| G. | Installing red light running cameras for enforcement | 4 | 3 | 2 | 1 | 9 |
| H. | Installing high-tech traffic control equipment to give buses priority through signalized intersections | 4 | 3 | 2 | 1 | 9 |
| I. | Support of internet based real time travel information | 4 | 3 | 2 | 1 | 9 |
| J. | Getting access to the interstate on the north side of town | 4 | 3 | 2 | 1 | 9 |

**18. Establishing a vision for updates to long range transportation is vital to shaping the future of the Ames area. How important are each of the following statements? For each one, please rate them by choosing a number between 1 and 5, where 5 means it is "very important" and 1 means "not at all important."**

| | **Importance of Various Issues to Transportation Improvements** | **Very Important** | **Important** | **Neutral** | **Not Important** | **Not at all Important** |
|---|---|---|---|---|---|---|
| A. | Developing a safe and connected multi-modal network, including bikes, pedestrians, transit and autos | 5 | 4 | 3 | 2 | 1 |
| B. | Fostering livability and sustainable development | 5 | 4 | 3 | 2 | 1 |
| C. | Delivering solutions that preserve and enhance the environment and the community | 5 | 4 | 3 | 2 | 1 |
| D. | Supporting area economic opportunities | 5 | 4 | 3 | 2 | 1 |
| E. | Maximizing the benefits of transportation investments | 5 | 4 | 3 | 2 | 1 |
| F. | Addressing community health and quality of life | 5 | 4 | 3 | 2 | 1 |
| G. | Protecting environmental resources | 5 | 4 | 3 | 2 | 1 |

**Figure 2-25.** ***(Continued)***

**19. Transportation improvements are critical, but also costly. The funding for transportation improvements can come from several sources. Which of the following sources of funding would you most support? For each one, please rate them by choosing a number between 1 and 4, where 4 means you are "very supportive" and 1 means "not supportive."**

| Sources for Funding Transportation Improvements<br>**Please rate your support for the following:** | | Very Supportive | Supportive | Neutral | Not Supportive | Don't Know |
|---|---|---|---|---|---|---|
| A. | Increase the gas tax | 4 | 3 | 2 | 1 | 9 |
| B. | Use of tolls | 4 | 3 | 2 | 1 | 9 |
| C. | Increase vehicle registration fees | 4 | 3 | 2 | 1 | 9 |
| D. | Apply a usage fee so that the more you drive, the higher the fee | 4 | 3 | 2 | 1 | 9 |
| E. | Apply a road impact fee for new developments | 4 | 3 | 2 | 1 | 9 |
| F. | Sales tax increase | 4 | 3 | 2 | 1 | 9 |
| G. | Apply a congestion fee so that when you drive in rush hour, the fee is higher | 4 | 3 | 2 | 1 | 9 |
| H. | Property tax increase | 4 | 3 | 2 | 1 | 9 |

**20. Which THREE of the funding sources in Question #19 do you most support?** [Write in the letters below using the letters from the list in Question 19 in the priority of their importance to you].

1st:_____ 2nd:_____ 3rd:_____

***To ensure our survey is representative of the community, please provide the following:***

**21. How many persons in your household (including yourself), ages 16 and older, are dependent on public transit or rides from friends/relatives because they do not have a car or do not drive?** _____ persons

**22. How many persons in your household (counting yourself), are?**

Under age 5 _____
5–9 years _____
10–14 years _____
15–19 years _____
20–24 years _____
25–34 years _____
35–44 years _____
45–54 years _____
55–64 years _____
65+ years _____

**23. Would you say your total Household income is:**

_____(1) Under $30,000
_____(2) $30,000 to $59,999
_____(3) $60,000 to $99,999
_____(4) $100,000 plus

**24. Which of the following best describes your race? (Check all that apply)**

_____(1) African American/Black
_____(2) American Indian
_____(3) Asian/Pacific Islander
_____(4) White/Caucasian
_____(5) Other: _____

**25.** ***Are you currently a student*** **at Iowa State University?**

___(1) Yes
___(2) No

**26. Your gender**:

___(1) Male
___(2) Female

**This concludes the survey. Thank you for your time!**

Please Return Your Completed Survey in the Enclosed Postage Paid Envelope Addressed to:
ETC Institute, 725 W. Frontier Circle, Olathe, KS 66061

Reported response rates for various household survey methods vary by the data collection strategy employed by the planner. In general, response rates for the three major survey types are about 90 percent for face-to-face interviews, 50 percent for telephone surveys, and less than 30 percent for mail-back surveys.

Once the interviews have been completed, the travel data are coded by origin and destination. Each trip end (origin or destination) is coded to the zone where it occurred. The data are then expanded to the full sample by a zonal factor that is calculated by dividing the total number of dwelling units in the zone by the actual number of interviews successfully completed. Other factors are used to convert the data to an average weekday. Further adjustments are made by determining the total number of trips crossing screenlines established in the study area. The survey results are compared to the screenline counts and correction factors are developed.

**Workplaces and Major Trip Generators.** Surveys of travel patterns and trip rates of major traffic generators can obtain targeted information about the non-home end of a trip. The surveys can involve intercept or cordon counts of people entering, leaving, and accumulated within the activity center by mode and time of day. They may also include interviews with a sample of the visitors or workers. Survey forms are distributed to employees at their place of work and are usually administered as self-completed forms.

*Transit Surveys*. On-board transit surveys are usually distributed to passengers as they board a bus or train. Forms are completed by passengers and deposited in a collection box or returned by mail. Response rates range from 15 to 40 percent, varying by type of rider. In some cases an interviewer using a handheld computer or tablet can conduct the survey interactively to increase the quantity and quality of responses.

*Internal Truck and Taxi Surveys*. A separate survey instrument is used to collect information on the movements of trucks and taxis. Vehicles are grouped into classes for which separate analyses are desired (large trucks, small trucks, taxis). For each vehicle class, a sample size is selected based on the market share of the vehicle class to all commercial vehicles in the study area.

Information for taxis is obtained on garage address, description of vehicle, and trips made on a given day. Trip information includes origins and destinations; time of start and end of trip; and number of passengers (for taxis).

Truck surveys may be conducted in urban areas to determine local trip-making patterns. Other truck surveys are conducted to allow analysis of long-distance trips. The former are often done as trip diaries. The latter are often intercept surveys.

Survey accuracy is checked by comparing travel patterns across screenlines with actual ground counts on an hour-by-hour basis. Transit ridership as determined from surveys should also be compared with transit agency records and transit line ridership. Work trips to and from major employment centers can be compared with estimates of the number of people employed in the zone. Allowance should be made for absenteeism.

## G. Parking Needs Studies

The objective of most parking studies is to establish existing and future parking needs by comparing parking supply and demand. The studies obtain information on, (1) parking supply characteristics, such as the number, location, and cost of spaces, or who provides the spaces; (2) occupancy turnover and use of spaces; (3) parker characteristics, including when, where, why, and how long people park and where they are going; and (4) parking space demands and needs for existing or new developments. Parking studies often result in recommended facility locations, conceptual designs, costs and revenues, and financing plans (see chapter 11 for more information).

The key study steps include: (1) defining the study area, (2) conducting a parking space inventory, (3) determining parking occupancies (accumulations), (4) computing parker durations (length of stay) and parking space turnover (parkers per space per day), (5) obtaining basic characteristics of parkers (purpose, fee paid, destination), and (6) comparing parking supply and demands. Step 5 involves interviews with parkers and is normally done as part of a

comprehensive parking study. Alternately, a more limited parking study can be performed in which parking demands are obtained by applying demand data for similar land uses, or by prorating the peak parking accumulation based on the distribution of floor space or employment among areas.

1) *Study Area Definition*. The first step in a parking study is to clearly define the study area. This area should include the traffic generators of concern and surrounding areas within a reasonable walking distance. It should include areas of current problems along with areas that might be affected by growth and change. Each block in the study area should be uniquely identified. Parking analysis zones may include these individual blocks (or groups of blocks) and then be aggregated to districts. Block faces can be numbered from one to four clockwise around the block, with the number one block face being on the north side of the block. Off-street facilities should be keyed to blocks and can be numbered from five up.

2) *Parking Space Inventory*. The existing on-street and off-street space supply should be inventoried by type of space. Curb spaces are usually classified by type of parking permitted—unrestricted spaces; truck, taxi, or bus loading zones; time-limit parking zones; and metered spaces by time limit. Off-street facilities and spaces are classified by type (lot or garage), availability (open to general public or restricted) and ownership (public or private).

3) *Peak Parking Occupancies*. Parking occupancy (or parking accumulation) studies determine the number of parking spaces occupied at various times of the day and identify the periods of peak use. Observations of curb and off-street space usage are made at regular intervals throughout the day. Curb space occupancy of parked vehicles should be done by block face. The number of occupied legal parking spaces, as well as commercial vehicles in loading zones and illegally parked or double-parked vehicles, should be counted. In small study areas, the observer can obtain these data by walking through the targeted sites. In larger study areas the observer may drive. Often there is both a driver and an observer present to count and record the information. Using two people in the car allows more area to be covered. In more modern parking garages, where sensors identify the number of parking spaces available, surveillance sensors can be used to determine space occupancy.

   It may be difficult to observe parking occupancy at large parking areas with frequent evening operations, such as those found around stadiums and regional shopping centers. In these cases, counts of vehicles entering and leaving by time period are necessary. Figure 2-26 shows how parking utilization is represented in a typical parking study.

4) *Parking Durations and Turnover*. Parking durations (the time parked at a given parking space) and turnover (the number of vehicles parked in that space throughout the study period) are useful in parking management activities. They provide a basis for changing time limits or rates, focusing on enforcement, and removing curb parking. Information can be obtained by recording license numbers throughout the study period.

5) *Parker Characteristics*. Characteristics of parkers are obtained at the parking location either by parker interviews or by postcard mail-back surveys. The interviews are designed to obtain information on where people park, trip purpose and frequency, trip origin, primary destination, length of time parked, parking fee paid, arrival and departure times, and distance walked from parking space to primary destination. The data are used to calculate the parking demand of an area on a block-by-block basis. Occupancies, durations, and turnovers can also be obtained at the same time. Interviews are sometimes conducted at representative samples of curb and off-street parking facilities. To reduce costs, an area may be subdivided and the interviews spread over several days.

Surveys of visitors and employees at specific major generators, such as office buildings, shopping centers, hospitals, and industrial plants, provide important ancillary information about travel modes, trip origins, travel attitudes, and pedestrian flows. Employee information is usually obtained by employers and visitor information is usually obtained through direct interviews. Where offices constitute most of the space in a mixed-use development (such as in the downtown), restaurant and retail shops may draw workers for their patrons. Estimating the proportions of primary and secondary destinations requires direct interviews with patrons. The interviews should obtain information on trip purpose, travel mode, and whether the destination is primary or ancillary; they can be conducted at entrances to a trip generator.

Chapter 11 provides more detail on parking studies.

## V. MODAL STUDIES

Transportation planning often focuses on specific modal issues, such as transit service planning, parking studies, pedestrian and bicycle analyses, and freight movement. Each of these topics is covered in more detail in other chapters of this handbook. However, some of the important data collection issues associated with these studies are discussed below.

### A. Transit Studies

Transit studies usually focus on the quality of existing services and help establish the need for service improvements. They also include operations planning for a given route, comprehensive operations analysis, short-range transit development programs, and major transit investment studies. The studies develop information used to analyze the extent of usage, problems of traffic flow and safety, riding patterns, and traveler attitudes. Data are collected for a sampling of routes and coach runs, recording boardings and alightings by stop by time of day.

Figure 2-27 illustrates a study design for a short-range transit operations study often called a comprehensive operations analysis (COA). Note the importance of both technical analysis and input from agency

leaders. Table 2-12 lists some of the common transit data items and the methods used to collect the necessary information. Additional details on transit studies are described in chapter 12.

### *1. Transit Inventories*

Inventories supply essential background information for a transit service analysis. Data include transit network maps; locations of all shops, transfer points, and garages; schedules indicating frequency and hours of service on each route and travel times between various points in the network; a list of the rolling stock supplying the service showing its capacity, age, and condition; and the list of fares.

### *2. Service Coverage*

Service coverage analysis indicates how well the existing (or planned) route network covers the population within the transit area. Typically, areas within one-fourth to three-eighths of a mile of a bus route (or within one-half mile of a rail station) are delineated, and the population within these areas is estimated. The service area population within the specified walking distance is termed the *population coverage*. This concept can be extended to include coverage of employment. The proportion of the service area population within a given distance of a transit stop and also within a specified distance of a workplace represents a total coverage value.

### *3. Ridership Counts*

These studies provide information on passenger boarding and alighting, vehicle loads, and schedule adherence. Such counts are useful in planning services, including the adjustment of routes and schedules, establishing bus stop locations, restricting turns along transit routes, adjusting street patterns and curb parking regulations, and developing transit priority measures, such as bus lanes and tragic signal priorities. Two major types of passenger counting strategies are common in the transit industry.

- *Point Checks*. Point checks obtain data on the number of passenger boardings and alightings and the loads on vehicles at one or more transit stops along the routes surveyed, usually the busiest stops. They may also include studies of dwell times and passenger service times. Point checks are conducted by individuals stationed at transit stops who count passenger movement when vehicles arrive. They may also collect data on transfers where multiple routes intersect.
- *Ride Checks*. Boarding and alighting checks can be performed along an entire transit route by direction of travel and time of day. This makes it possible to develop a profile of passenger loads by location and to compare these levels with the seats that are provided. Ride checks are conducted by individuals riding transit routes and making counts of passenger movement along the route.

#### *4. Automated Ridership Profiles*

Modern transit systems have incorporated automated sensors in vehicles and fare turnstiles that can be used to collect data on ridership. Often referred to as automatic passenger counters (APCs), these data provide reliable estimates of boardings and alightings, as well as a ridership profile along the entire route.

## B. Pedestrian Studies

Pedestrian studies are used for a variety of purposes in transportation planning. They are used to establish safe-route-to-school maps for elementary children, establish the need for traffic controls, and adapt controls to better serve pedestrian movement. The studies provide a basis for sidewalk improvements, and they help justify pedestrian and transit malls, pedestrian skywalks, overpasses, tunnels, escalators, and moving belts. They are especially important in designing access to major pedestrian generators, such as urban stadiums, convention centers, and downtown developments that generate large pedestrian movements. They are also useful in designing access to and within transit stations and terminals and in developing plans for sidewalk amenities and public open spaces.

An aging population requires more emphasis on providing pedestrian facilities and in changing some of the parameters (such as walking speed) that are traditionally used in pedestrian analyses. The provision of special aids for handicapped persons (wheelchair ramps at intersections or to supplement stairs, audible traffic signals for the blind) has become an important aspect of the urban planning process.

Pedestrian studies include: (1) studying pedestrian volumes, speeds, and capacities; (2) establishing needs for traffic controls; (3) surveying pedestrian trip origins, destinations, trip purposes, and walking distances; (4) developing pedestrian trip generation rates; (5) obtaining pedestrian attitudes and perceptions; and (6) analyzing pedestrian behavior and space-use patterns. Detailed study procedures for obtaining and analyzing pedestrian volumes, walking speeds, needed gap sizes, and conflicts are contained in the ITE *Manual on Transportation Engineering Studies* [2010]. Chapter13 also provides more information on nonmotorized transportation.

Pedestrian volume and flow studies may be expressed in terms of volume (persons per hour), flow rate (persons per minute per meter or foot), spacing (square meters or feet per person), or walking speed (meters or feet per minute). Speed, flow rate, and density are interrelated. As flow rates on a sidewalk, crosswalk, passageway, ramp, or stairs increase, walking speed tends to decrease. After the flow rate reaches its maximum, density continues to increase toward a *jam density* or *crush density*, and flow rate and walking speed approach zero.

Most pedestrian counts are made manually. This can be labor-intensive, so the hours of data collection should be chosen carefully. Short-term sample counts may be used and then expanded to provide estimates for the period surveyed. Counts generally should be recorded in 5-minute intervals.

1) *Flow Rates and Capacities*. Pedestrian capacity depends on the effective walkway width. This effective width includes deductions of 6 inches (0.15 meters [m]) or more to account for buildings, curbs, window displays, and other street furniture (poles, parking meters, planters, bicycle racks, newspaper racks, benches, bus shelters). Pedestrian capacity and level of service (LOS) analyses are based on pedestrian spacing, the square footage of effective space per person. This is the reciprocal of density, pedestrians per square feet. LOS standards express spacing in terms of square feet per person per minute.

2) *Walking Speeds*. Pedestrian walking speeds vary by LOS or density by area and by groups of people. Studies have shown walking speeds ranging from about 2.2 feet (0.7 m) per second to more than 5 feet (1.5 m) per second. Many engineers have used 4.0 feet (1.2 m) per second in traffic engineering analyses. However, there is a growing tendency to use 3.3 feet (1.0 m) per second as a general value, and 3.0 feet (0.9 m) per second or 3.25 feet (1.0 m) per second for specific applications such as facilities utilized by elderly or handicapped people. Walking speeds below 3.0 feet (0.9 m) per second should not be used.

3) A special pedestrian walking speed study is sometimes desirable to define an appropriate value to be used in an area under study. Such a study should have a defined distance delimited along the path traveled by the pedestrian population under consideration. Individual pedestrians are timed as they pass through the "trap." A sample of approximately 100 pedestrians is sufficient. The sample should be collected during the timeframe of interest (for example, peak hour, noon, or afternoon). The data are plotted in a cumulative percentage curve. The fifth-percentile value is usually the appropriate value to use for traffic control and safety purposes.

4) *Door Counts*. Counts of people entering and leaving buildings, stores, off-street parking facilities, and transit terminals provide a basis for (1) establishing person-trip generation rates and (2) expanding sample interviews at the same locations. The counts should be made during the a.m. peak, noon time, and p.m. peak periods for developing trip rates. When keyed to interviews, they should normally be conducted from 7:00 a.m. to 6:00 p.m. Trip rates are obtained by relating the pedestrian volumes to the characteristics of the activity surveyed, such as floor space and employment (if only exiting pedestrians are counted, the surveys could be done from 10:00 a.m. to 6:00 p.m.).

## C. Goods Movement Studies

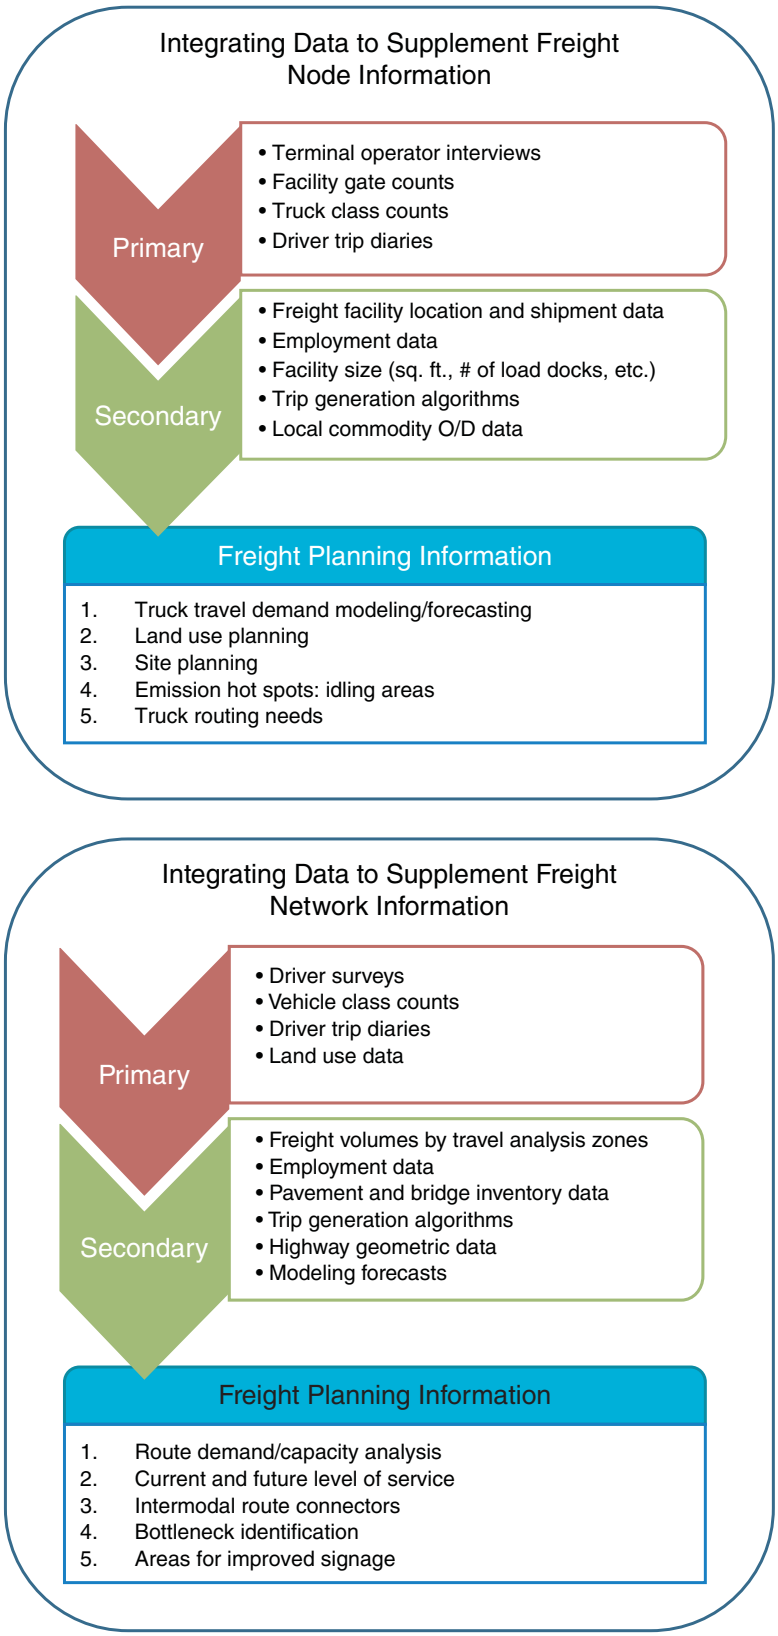
Goods movement involves the collection and distribution of raw materials and finished products. Freight is handled by truck, train, ship, and pipeline with small amounts of high-value cargo going by air. The scale, types, and patterns of goods movement vary widely; studies should be keyed to specific needs. They generally involve obtaining information on (1) types and magnitudes of commodities shipped, (2) modes of conveyance utilized, (3) origins and destinations, (4) shipment and terminal travel times, (5) loading and berthing requirements, (6) daily and hourly variations in shipments, and (7) frequency of shipments. Where trucks are involved, their number, type, weight, commodities carried, and use of roadways are important. Chapter 22 provides more detailed information on freight analysis.

At the local level, goods movement studies are usually undertaken in response to specific problems. Figure 2-28 shows the types of data that are used in transportation planning studies.

### *1. Intercept Surveys*

Truck operators can be interviewed at a cordon line around an urban area, often as part of a comprehensive transportation planning study. The surveys should identify the volumes and types of commodities moving into and through an area, the destinations of these commodities, and the types

**Figure 2-28. Freight Data and Uses for Transportation Planning at Freight Node and Network Levels**



Source: Rhodes et al., 2012. Reproduced with permission of the Transportation Research Board.

of vehicles involved. The Port Authority of New York and New Jersey, for example, conducts commodity surveys of vehicles crossing the Hudson River and Verrazano Narrows Bridge on a periodic basis. Intercept interviews can be conducted at truck weight stations. Where these are located near the cordon line, there is usually space for trucks to pull out for interviews.

The following factors must be considered when conducting intercept surveys:

- *Type of Interview*. These can be conducted as brief one-on-one interviews, or where time is an issue, mail-back postcards can be distributed to willing participants.
- *Traffic control*. When conducted at businesses, data collectors are usually stationed at loading docks to conduct interviews while trucks are being loaded/unloaded to minimize the impact on traffic operations. At weigh stations, truck stops, and rest areas, drivers are directed to a defined area in which all interviews are conducted. Some interviews, however, are conducted at points along a road or at an intersection.
- In these instances, traffic control measures must be put into place to maintain efficient operations for all vehicular traffic. Coordination with law enforcement may be necessary if safety and traffic control assistance is needed. Traffic speeds may need to be reduced to ensure the safety of data collectors. Advanced warning signs also help improve safety for both the motoring public and those involved in the data collection process.
- *Data collection equipment*. Interviews can be conducted using a variety of equipment. The most common data collection tools include paper surveys and handheld computers. The surveys developed for driver interviews are designed to be easily completed in less than three minutes to minimize the impact on the participating commercial vehicle operators.
- *Sampling plan*. Most truck studies do not have the budget available to collect data on every corridor, for all periods of the day, week, and year. Therefore, a sampling plan must be developed to capture an adequate amount of representative data. Goals of the sampling plan should be to provide geographical coverage of the study area, to collect adequate time-of-day and time-of-year data, to capture both intra-regional (internal to internal) and inter-regional (internal to external, external to internal and external to external) trips.
- *Data expansion*. Recognizing that a 100-percent sample cannot realistically be gathered at most locations, it is necessary to expand the records collected to represent the full traffic stream. To represent the total truck traffic, expansion factors can be applied to the survey results. These expansion factors can be established by comparing the number of trucks surveyed during an hour to hourly count data provided by the jurisdiction or collected for the project.

***2. Interviews***

Interviews conducted with shippers, carriers, building owners, and managers/tenants at terminals can provide detailed information of goods movement characteristics and problems.

Building owner/manager/tenant interviews should obtain information pertaining to:

- Building use—floor space by use (for example, retail, warehousing, office), number of tenants, percentage occupied, number of employees, and so on.
- Delivery restrictions—restrictions imposed by the building owner relating to hours of delivery and types of vehicles.
- Delivery reception—location at which delivery and service vehicles park, off-street loading facility availability and utilization, location of freight elevators, and the like.
- Delivery variations—variations in deliveries by hour, day, or month.
- Enforcement—building actions taken to assure proper usage of the available loading space.
- Size and types of shipments.
- Origins and destinations of goods shipped or received.
- Procedures for handling mail and trash.
- Particular problems noted or experienced.
- Reaction to various alternative solutions.

Truck owners and operator interviews can obtain information on trip patterns. A sample could be selected from vehicle registration data; the percentage of total registered truck owners interviewed should range from 1 to 5 percent, depending on the truck classification. Information should be obtained on license owner and location where the vehicle is based, axle arrangement and body style, cargo specialty, commodities carried, trips and stops made, and related travel information.

Questionnaires can be distributed at for-hire truck terminals and followed up with in-depth interviews. The same procedures can be followed for major rail, marine, or air cargo terminals. Interviews could obtain information such as the following:

- A detailed description of the routine operation of the terminal, including hours of operation, workflow, volume fluctuations, and types of commodities carried in the areas served.
- A description of operational characteristics of the terminal, including capacity, number and types of trucks and rail cars served, and special equipment used.
- The types of records maintained at the terminal that might be used in a comprehensive goods movement survey, including shipment patterns and commodity characteristics.
- Particular problems noted or experienced.
- Reaction to various alternative solutions.

Businesses with heavy truck activity can be another great source of information on truck travel characteristics. Information from these establishments regarding the type of services provided, the number of trucks in operation during a typical weekday, and their fleet composition can be used to expand data collected through intercept surveys. These interviews can be conducted in person or via telephone.

By targeting key stakeholders in the trucking industry, planners can capture vital information about the movement of goods through an area. This data collection tool has two major components:

*Defining Stakeholder List*. To best understand how trucks move through an area, the stakeholder interview process must target individuals from a variety of industrial categories, business sizes, and geographic locations.

*Developing Interview Guidelines*. The types of questions asked during this process depend on the purpose of the study and the individual stakeholder being interviewed. The general form of these interviews should be free-flowing, in-person discussions that elicit insight from respondents. Topics of discussion often include supply chain structures, operational information, and the challenges/advantages of operating in and around the study area.

### *3. License Plate Capture*

This method is generally used in combination with the previously described techniques. Video cameras are used to capture license plate information at multiple locations around the perimeter and within a given study area. Information collected at these sites are analyzed and compared against each other to generate travel pattern information. Travel times can be compared to determine whether or not stops were made between detection locations. The following are critical components of any video license plate capture assignment:

*Site Selection*. The purpose of the study usually determines the selection of data collection points. Generally, cameras would be placed at entry/exit points of the study area.

*Camera Placement*. Depending on the company conducting the data collection, video camera placement varies. Some data collectors place their equipment on overpasses, angled down to capture vehicles passing below. Recently, some companies have tried other techniques, such as placing cameras inside traffic barrels on the side of the road.

*Data Processing and Transcription*. The method used to process the license plate data can vary greatly depending on the magnitude of the project and the budget available. License plate collection can be as simple as setting up a camera and manually recording the license plate numbers from the video output at each collection location. The recorded data would then be compared between locations to analyze travel patterns. For larger-scale projects, the data processing can be accomplished by fully automated systems, which collect the license plate data, process it, and store it in a database for analyses.

#### *4. Loading and Unloading Studies*

Studies of loading deck operations are used to determine space requirements and geometric design criteria. These studies investigate occupancy and dwell times often by land use type. The information provides a basis for establishing desirable on-street and off-street loading space.

There is a growing body of information on goods movement at the national, state, and local levels. The reader is referred to the Transportation Research Board's *Guidebook for Understanding Urban Goods Movement*. [Rhodes et al., 2012] Many metropolitan areas have conducted freight or goods movement studies; an Internet search on "urban goods movement" will provide the reader with many examples of how such studies are conducted as well as data on freight flows for individual metropolitan areas.

#### *5. Truck Weight Studies*

Information on truck weights is collected for many purposes, including pavement design, revenue estimates, motor carrier enforcement, highway cost allocation, and other planning and engineering activities. Vehicle weights are reported by motor freight companies as part of their reporting requirements. The recipients of this information vary by state, but the state motor vehicle department is usually the agency that collects this information through the vehicle registration process.

Roadside weight checking is conducted with either permanent or portable scales, usually as part of an enforcement program. Following the changes in trucking regulations in the 1980s and the resulting changes to fleet mixes, truck size and weight studies are often conducted to evaluate the impact on types of trucks being used on pavement performance, geometric requirements, and changes in industry efficiencies. Depending on the analysis to be conducted, the data collection method should consider ADT, percent trucks, percent trucks by type, percent trucks by commodity, interstate versus non interstate trips, site suitability, and nearby alternate routes. Static scales are required to certify truck weights and to establish a legal basis for identifying violators. This requires special truck access to avoid any spillback on the main travel times. Weigh-in-motion (WIM) scales are used to determine if a truck is traveling within a reasonable range of legal weight limits. Information collected may include gross vehicle weight, axle weight, and tandem axle weight. WIM scales are often found at permanent truck weigh station sites, but they are used by some agencies in a roving mode.

#### *6. Global Positioning System (GPS)–Based Data Collection*

Recently, GPS technology has been used to improve the accuracy and amount of data collected in truck studies. In-vehicle devices can accurately combine time-coding and location data with user input about trip characteristics. All data collected by these units can then be easily input into geographic information system (GIS) maps, producing visual displays of route choices and travel patterns. This type of data is increasingly used in statewide and metropolitan freight studies. Chapter 22 on integrating freight concerns into the transportation planning process provides more detail on this new approach toward collecting data on truck movements.

## VI. STATISTICAL CONSIDERATIONS

If cost and time were not important, traffic data collection would likely collect as much data as possible. However, as previously noted, substantial resources are often allocated to collecting the necessary data to conduct a variety of planning studies. Accordingly, data are often collected based on samples that have required levels of precision and error allowance. Statistical analysis methods are essential in this effort. They can address questions such as how to best characterize the distribution of travel times, speeds, or land uses; what sample sizes are needed at a specified level of accuracy to estimate shopper origins at a major activity center; or how to establish predictive relationships between land use and trip generation.

Transportation planners work with data and statistics on a variety of tasks, with the complexity depending on the application. It is beyond the scope of this chapter to present a detailed discussion of the statistical tools used by transportation planners. Interested readers are referred to [Washington et al., 2003; ITE, 2010]. However, statistical sampling is one area where transportation planners use statistics that merits some attention.

### A. Sampling and Inference

Sample procedures make it possible to show inferences about a population. By sampling a small representative fraction of the entire population, it is possible to estimate characteristics that represent the population as a whole with enough

accuracy to base decisions on the result with a reasonable level of confidence. Sampling procedures involve establishing confidence intervals, estimating sample sizes, and comparing various groups. They make it possible to address such questions as the following: How good are the results? What sample sizes are needed? Are the differences between two sample means or variances statistically significant?

The following principal steps in conducting a survey show how sampling is part of the effort.

1) Clearly state the objectives and reasons for the survey.
2) Define the population of interest to be sampled.
3) Identify the data to be collected.
4) Establish the desired degree of precision.
5) Determine the methods of measurement (for example, household telephone survey versus home interview survey).
6) Construct the sampling frame for the population to be sampled. This frame should cover the entire population to be sampled, and each individual element must appear only once on the list.
7) Select the sample design and sampling plan. This includes initial estimates of sample size and precision, as well as time and cost implications.
8) Pretest the survey instrument (questionnaire) and modify it as necessary.
9) Organize the fieldwork and collect the data.
10) Summarize, analyze, and interpret the data. Clearly indicate the amount of error that is expected in the most important elements.
11) Preserve the information assembled for future surveys. Quantifying key parameters, such as the variances, will prove useful in preparing future survey designs.

### *1. Types of Samples*

The common types of probability sampling include: (1) simple random sampling, (2) stratified random sampling, (3) systematic sampling, and (4) cluster sampling.

1) *Simple random sampling*. This is the simplest and most widely used form of sampling. A simple random sample from an infinite population is selected in such a way that all observations chosen are statistically independent. A simple random sample from a finite population involves selecting n units out of the population, N, so that each individual element has an equal chance of being selected. In practice, a sample is drawn unit by unit. A table of random numbers might be utilized. For telephone surveys, random digit dialing procedures can be used.
2) *Stratified random sampling*. A stratified random sample is obtained by dividing the population into classes or strata and then selecting a random sample from each strata. It is useful where there are wide variations among strata and stratification would reduce overall sample size requirements for any given level of precision. It makes it possible to obtain data of known precision for certain subdivisions of the population (for example, travel times on freeways and arterial streets). Stratified random sampling is also commonly used in urban travel behavior studies where it is important to set minimum quotas for subgroups of individuals that appear infrequently in the population, are difficult to interview, and/or are important to model for policy analysis. For example, in urban travel studies, with stratification, it is common to oversample low-income households and current transit users.
3) *Systematic sampling*. A systematic sample draws every *k*th element of the sampling frame beginning with a randomly chosen point. For example, if the first unit is 13 and every 15th unit is chosen, then units 28, 43, 58, and so on would be selected. Systematic samples are easier to obtain than simple random samples in terms of time and cost. If spread more evenly over the population, this approach may be more precise than simple random sampling. However, systematic samples may give poor precision where periodicity in

the data exists. An example of this is the railway bill sampling because sequentially numbered forms are drawn from multiple supplies simultaneously, which increases the likelihood of low numbered forms.

4) *Cluster sampling*. Cluster sampling divides the population into a series of mutually exclusive classes that are usually defined based on convenience. Clusters are then selected for detailed study, usually by some random basis. Either a complete census or a random sample is obtained from each of the selected clusters. Results are then combined. Cluster sampling is useful when there are no reliable lists of elements in the population or because of the ease of constructing lists of sampling units and time-and-cost efficiencies. However, cluster sampling usually results in higher sampling errors than other kinds of surveys. For a given level of precision, stratified samples require the smallest sample and cluster samples require the largest.

### *2. Errors in Sampling*

When estimates are made from a sample, it is not likely that the sample estimate will be exactly the same as that obtained from a complete census. The difference between the two represents the sampling error, if both the sample data and population data are obtained by identical methods. When probability samples are used, the amount of this sampling error can be determined.

Non sampling errors may exceed sampling errors, and they should be minimized by careful survey design and execution. They include errors associated with measuring a unit (for example, trying to estimate standees on a crowded subway train); errors introduced in editing, coding, and tabulating surveys; and failure to measure some units in the sample (for example, nonresponse to the survey).

Nonresponse errors include failure to survey particular units of the sample (that is, people who refuse to be interviewed, are not at home, or are unable to answer). In these cases, there is no assurance that the nonrespondents would respond similarly to those sampled. The nonresponse can be minimized by the method of survey (for example, direct interview versus mail back) and by call back. In estimating sample sizes, it may be desirable to *oversample* various segments of the population surveyed to compensate for nonresponse. While this will address the sampling error, it may not necessarily compensate for nonresponse bias. Table 2-13 shows typical response rates for surveys.

### *3. Household Travel Survey Recruiting and Sample Size Determination*[2]

Since 2010, most regional household travel survey recruiting methods typically use an address-based sampling (ABS) approach. Under this design, the sample frames are selected from the United States Postal Service (USPS) Computerized Delivery Sequence File and are geocoded once the sample frame is generated and invitation letters are mailed. An ABS frame supports both simple and stratified random sampling. The fact that all samples are geocoded makes it possible to obtain surveys that are geographically representative or, through the use of Census geographies, develop targeted strata using data from sources such as the American Community Survey (ACS). Targeted strata include households with possessing certain characteristics of interest such as zero-vehicle, large, or minority households, for example.

**Table 2-13. Response Rate Comparison to Surveys**

| Study | Year | Final Response and Participation Rate |
|---|---|---|
| Massachusetts Travel Survey | 2010–2011 | 34.6% |
| ARC Regional Travel Survey | 2011 | 5.9%–34% |
| CALTRANS HH Travel Survey | 2011 | 5.5% |
| ARC Regional Travel Survey Pre-Test | 2010 | 11%–31% |
| Central Indiana Full Study | 2010 | 41% |
| Oregon Full Study – Region 4 | 2009 | 39% |
| Oregon Full Study – Region 2 | 2009 | 44% |
| Central Indiana Pre-Test | 2008 | 10%–36% |
| Oregon 1-day Pre-Test | 2008 | 15%–46% |
| Chicago Full Study | 2007–2008 | 10%–31% |
| Chicago Pre-Test | 2006 | 9%–29% |

Source: Massachusetts DOT, 2012

[2]This section was written by William Bachman, Westat, Inc.

Households are typically offered the opportunity to self-recruit using a web survey, and conduct a computer-assisted self-interview (CASI), or to call in and complete the survey by phone with a trained survey interviewer/data collector who uses a computer-assisted telephone interview (CATI). Reminder postcards are also sometimes mailed to reiterate the message encouraging participation on the original invitation letter and promote survey response. Once recruited and assigned a travel date, households again have a choice to report their travel (retrieval survey) via CASI, through a mobile device application, or by CATI.

A travel survey for the Massachusetts DOT provides a good example of how a geographically based sampling strategy is required to provide a statistically valid survey result. Figure 2-29 shows the households sampled in the state to obtain survey results. A geographic stratification scheme was used to ensure adequate representation of households by MPO regions and municipal density groups. A demographic stratification was also used to set demographic controls and monitor the performance of the sample against these controls. [MassDOT, 2012]

The determination of survey sample size and demographic stratification is entirely dependent on existing models or the development of more advanced models (for example, activity-based models) and/or other transportation planning activities. Traditional four-step models typically require a representative sample (that is, that closely matches U.S. Census distributions) of socio-demographic categories (household income, household size, vehicle ownership, etc.) as well as an even geographic distribution (see chapter 6 on travel demand modeling). More advanced models require significantly more complex sampling stratification to ensure that certain categories, such as transit riders, are adequately represented. For example, Asheville, North Carolina, conducted a travel survey in 2013 to support a traditional four-step model and the main survey objective was to ensure that enough surveys were completed for households that matched U.S. Census distributions. With those targets in mind, the survey team used U.S. Census data and local demographic information to recruit participants in the Asheville region. Recruiting invitations were

mailed to participants and successful recruiting characteristics were monitored to ensure that adequate samples were collected in all category combinations and in all geographic areas.

In addition to a geographic (for example, by county, jurisdiction, modeling subareas) representation, planners want to have a representative sample relating to socioeconomic characteristics. Table 2-14, for example, illustrates a sampling stratification table for a household travel survey conducted in the Las Vegas region. The highlighted cells were combined, which is typical when the individual targets are small and it would be very difficult to achieve the goals (for example, a three-person household with three workers).

Travel surveys are sometime funded by multiple agencies resulting in more complex sampling requirements. To meet the needs of both the Michigan Department of Transportation (MDOT) and the Southeast Michigan Council of Governments (SEMCOG), a recent statewide survey required a sample plan that met both a statewide geographic distribution among 21 sampling areas as well as a sampling stratification with three variables specific to the SEMCOG region (vehicle ownership, household size, and number of workers). Other variables, such as travel mode, may be monitored to ensure that enough samples are collected to support the development of model algorithms.

## VII. SUMMARY

Transportation planning depends on collecting and analyzing data, both on the transportation system and on system users. Understanding the basic characteristics of urban transportation systems is fundamental to discerning the challenges these systems face today and will likely face in the future. Similarly, knowing the underlying variables that influence urban travel, such as population characteristics and resulting travel patterns, is a basic foundation for analyzing the likely consequences of strategies to influence travel behavior.

This chapter presented an overview of the data collection and analysis procedures that are commonly used in transportation planning. Data are essential to the transportation planning process, and it is, thus, not surprising that a large portion of the budget for transportation planning studies is often devoted to data collection. Given the expense, transportation analysts often adopt different strategies for collecting or updating already collected data for use in a particular study. These procedures are often based on sampling techniques that collect data on representative samples of a target population. This means that the transportation analyst must understand sampling methodology and the appropriate use of different survey techniques.

In addition, both federal and state transportation agencies often have data manuals that guide the collection and analysis of data. It is beneficial to read these manuals for a particular jurisdiction prior to undertaking a data collection effort.

# Land Use and Urban Design[1]

## I. INTRODUCTION

One of the major reasons often stated for investing in the transportation system is to promote economic development. The link between economic development and transportation is founded on the accessibility provided by transportation to the daily social and economic activities in a community. However, this accessibility influences more than just economic development. In a much broader sense, system accessibility influences all forms of interactions. In the context of this chapter, accessibility affects where industries and services locate, where people live, and how easy it is to access all of the supporting activities (for example, health care) associated with a modern community. In other words, a transportation system influences land use.

Over time, the transportation–land-use relationship also defines how a transportation system is used. Areawide, land-use patterns and associated trip-generating activities affect transportation network performance. For example, the concentration of office buildings around a freeway interchange (because of the excellent accessibility afforded by the proximity to the freeway) will likely lead to high levels of congestion on the interchange and adjacent road network. The high concentration of residential, commercial, and office development in downtowns encouraged by rail transit stations also results in heavy station boardings during transit peak periods. For individual land parcels, development characteristics influence how much traffic is generated and attracted to these specific locations. The position of buildings at a site, their relationship to the surrounding community, and the amenities provided to those who use the site (that is, urban design) can influence trip-making behavior.

Although transportation planning has historically viewed land use solely as an exogenous input in travel demand estimation (for example, how many trips are generated given land-use type and intensity of development?), land-use and urban design principles have emerged as effective tools that communities can leverage for improving mobility and accessibility. Transportation planners must be aware of fundamental land-use and urban design concepts, as they serve as the foundation for a comprehensive approach to community-building.

The Federal Highway Administration (FHWA) notes that, "at a minimum, the coordination of land use and transportation requires that those concerned with the well-being of a community (or region, state or nation) assess and evaluate how land-use decisions affect the transportation system and can increase viable options for people to access opportunities, goods, services, and other resources to improve the quality of their lives. In turn, the transportation sector should be aware of the effects the existing and future transportation systems may have on land-use development demand, choices, and patterns." [FHWA, 2013] This chapter is organized to provide the practitioner with the knowledge and tools to contribute such information to the decision-making process.

The following section describes those factors that influence land use and urban form. In particular, three major influences are described: (1) regional planning and the provision of infrastructure, (2) local government planning and development regulation, and (3) land owners, private developers, and financial lenders. The chapter then discusses the role that urban design and access management can play in development and transportation decision making. The following section examines current approaches to land-use modeling and the characteristics associated with both the models and their use in planning. The final section focuses on context-sensitive solutions (CSS) that depend on a combined land-use–transportation perspective for achieving both transportation and community development goals.

## II. WHAT DRIVES DEVELOPMENT AND RESULTING URBAN FORM?[2]

The land-use and development patterns of metropolitan areas and individual communities are influenced by a variety of factors. For example, a study of the key influences that shaped Atlanta's regional development pattern from 1950 to 2000 identified the eight factors shown in Table 3-1. [Meyer, 2001] In some cases, the factors listed in this table are under the control of transportation officials (such as the provision of transportation infrastructure); for others, transportation officials exert little to no influence.

Different groups and individuals participate in or influence development-related decisions. In the private sector, these include developers, contractors, financial lending institutions, and individual and corporate buyers of real estate. In the public sector, the participants include elected and appointed community officials, local agency staff, state and regional transportation planning officials, transit authorities, local zoning and planning commissions, and local school officials, all of whom influence how the community development process occurs.

Many of the institutional and regulatory land-use frameworks found in U.S. communities exhibit common characteristics (such as similar zoning codes). However, in reality, every community is different, and community development patterns evolve under influences that are specific to the regional and market contexts found in a particular community. One must therefore understand not only the ordinances and regulations commonly used to influence the amount and type of community development, but also other factors that can have an impact on development patterns. Three major considerations are important in understanding the institutional and regulatory factors that shape community development: regional planning and provision of public infrastructure, local government planning and development regulations, and the major players in land-use transactions, that is, land owners, private developers, and financial lenders.

### A. Regional Planning and Provision of Public Infrastructure

Although the strongest *governmental* influence on local land use comes from community comprehensive plans and development ordinances, the evolution of a community's development pattern occurs within a much larger economic, social, and political context (see, for example, [Brook, 2013; Congress for the New Urbanism and Talen, 2013; Gallagher, 2013; Katz and Bradley, 2013; and Montgomery, 2013]). Many communities are located in metropolitan areas that are implementing policies intended to influence community development patterns. This regional context for community development takes two major forms—(1) the metropolitan-wide policies or strategies aimed at managing and directing growth, and (2) the metropolitan-wide investment in transportation, sewers, water systems, and other infrastructure/services that are prerequisites for most types of development. Importantly, the metropolitan area planning approach to growth management is strongly influenced by the state and local planning environment, such as the use of impact fees, adequate public facilities ordinances, taxing districts, and other exactions used by local jurisdictions.

Metropolitan planning organizations (MPOs) and regional development agencies often adopt policies intended to influence how growth occurs. These policies focus on directing the shape and character of metropolitan development

[2] Some of the material in this section originated in Meyer and Dumbaugh, 2005.

through actions such as targeting development away from suburban fringe areas, as well as encouraging the more efficient use of existing infrastructure, including roads and sewer systems. The types of policies actually employed vary from region to region, from Portland, Oregon's, growth management boundary and Minneapolis–St. Paul's, Minnesota, infrastructure phasing requirements to more market-oriented approaches, such as the use of impact fees and development exactions. Because such policies have a strong influence on when and if certain lands will be developed, they can be leveraged to encourage desired development outcomes, such as promoting the design of communities that support nonmotorized travel. [Daniels, 1999; Meyer and Dumbaugh, 2005]

Metropolitan transportation planning is just one of the many planning processes that considers development and land-use policies and strategies. As noted in chapter 1, the transportation planning process begins with an articulation of a vision, that is, what characteristics of quality of life, economic vitality, transportation system performance, and societal benefit accruing from public investment are desired by a community or region? The definition of this vision often comes from an extensive public participation process that encourages many different community stakeholders to develop statements regarding a desired future. Not surprisingly, given the importance of the built environment, these vision statements usually emphasize desired development patterns. For example, the following vision statement comes from the Puget Sound Regional Council (PSRC), the MPO for Seattle, Washington.

> *"Our vision for the future advances the ideals of our people, our prosperity, and our planet. As we work toward achieving the region's vision, we must protect the environment, support and create vibrant, livable, and healthy communities, offer economic opportunities for all, provide safe and efficient mobility, and use our resources wisely and efficiently. Land use, economic, and transportation decisions will be integrated in a manner that supports a healthy environment, addresses global climate change, achieves social equity, and is attentive to the needs of future generations."*
>
> *—Puget Sound Regional Council [2009]*

The corresponding transportation goal for this vision included: "The region will have a safe, cleaner, integrated, sustainable, and highly efficient multimodal transportation system that supports the regional growth strategy, promotes economic and environmental vitality, and contributes to better public health." Specific policies adopted to guide transportation investments included:

- Prioritize investments in transportation facilities and services in the urban growth area that support compact, pedestrian- and transit-oriented densities and development.
- Give regional funding priority to transportation improvements that serve regional growth centers, and regional manufacturing and industrial centers.
- Make transportation investments that improve economic and living conditions so that industries and skilled workers continue to be retained and attracted to the region.
- Design, construct, and operate transportation facilities to serve all users safely and conveniently, including motorists, pedestrians, bicyclists, and transit users, while accommodating the movement of freight and goods, as suitable to each facility's function and context as determined by the appropriate jurisdictions.
- Improve local street patterns—including their design and how they are used—for walking, bicycling, and transit use to enhance communities, connectivity, and physical activity.
- Promote and incorporate bicycle and pedestrian travel as important modes of transportation by providing facilities and reliable connections.

Another example of a vision statement comes from the Atlanta Regional Commission (ARC), which produced a policy framework to guide all regional planning efforts, including transportation planning. [ARC, 2015a] As shown in Figure 3-1, ARC's framework has defined three major areas for improving the region: developing and maintaining world class infrastructure, creating healthy livable communities, and supporting a competitive economy.

**Figure 3-1. Policy Framework for Regional Planning by the Atlanta Regional Commission**

Source: ARC, 2015a, Reproduced with permission of the Atlanta Regional Commission.

The policy goal and selected actions most relevant to transportation included: [ARC 2015a]

Goal: Ensure a comprehensive transportation network, incorporating regional transit and 21st century technology

- Promote transit and active transportation modes to improve access.
- Maintain and improve the economic viability and accessibility of key intermodal freight facilities.
- Prioritize data-supported maintenance projects over expansion projects.
- Promote system reliability and resiliency.
- Establish effective transit services that provide regional accessibility.
- Prioritize transit projects in areas with transit-supportive land use, plans, and regulations.
- Promote bicycle transportation by developing safe and connected route options and facilities.
- Promote pedestrian-friendly policies and design.
- Enhance and expand Transportation Demand Management (TDM) programs.
- Prioritize solutions that improve multimodal connectivity.
- Direct federal funding for road capacity expansion to the regional strategic transportation system, including the managed lanes system.
- Road expansion projects in rural areas should support economic competitiveness by improving multi-modal connectivity between centers.
- Implement a complete streets approach on roadway projects that is sensitive to the existing community.
- Promote and enhance safety across all planning and implementation efforts, including support for the state strategic highway safety plan.
- Coordinate security and emergency preparedness programs across transportation modes and jurisdictions.
- Maintain and expand transportation options that serve the region's most vulnerable populations.
- Improve connectivity around transit stations and bus stops for all users.
- Increase funding for Human Services Transportation (HST) and Medicaid transportation services.
- Increase access to areas with essential services, including healthcare, education, recreation, entertainment, and commercial retail.
- Provide safe and reliable access to freight land uses and major intermodal freight facilities.
- Promote the use of information technologies to foster the most efficient movement of freight.
- Preserve industrial land uses in proximity to existing freight corridors.
- Pursue the application and use of advanced technologies.
- Encourage the application of passenger information technologies.
- Encourage development, redevelopment, and transportation improvements to consider impacts on neighborhoods and communities.
- Promote and support urban design standards that enhance elements of accessibility and livability.
- Plan for the impacts of extreme weather events on community services and infrastructure, including system resiliency.
- Foster improved access to cultural assets.

As can be seen in this list, planning concerns span a range of issues that are important to the future of communities. Where transportation investment fits into these larger visions very much influences the types of strategies and actions that will surface at the end of the process.

Unless local communities align their own plans, policies, and regulations to support a regional vision, the vision will not be realized. Portland, Oregon, for example, has established a strong alignment between regional policies and local government actions. In Denver, Colorado, the *Mile High Compact*, a regional policy that encourages nontraditional development patterns, has been adopted by many of the region's communities. In this case, the region's MPO grants extra priority for transportation investment to projects in communities that have adopted this policy.

Although metropolitan plans and policies can provide an overarching context for local decisions, the strongest *regional* influence on land use, and on the decisions leading to development, comes from the actual changes made to those infrastructure systems that provide the basic necessities of modern societies. With urban areas expanding dramatically during the twentieth century, governments at all levels recognized the need for metropolitan-wide efforts to coordinate the provision of critical infrastructure. The federally-mandated metropolitan transportation planning process is an example of such an effort. Others include regional efforts to put in place water systems and waste disposal sites and to handle societal needs that transcend individual community boundaries, such as helping the elderly population. This handbook, in essence, focuses on the how transportation system investment decisions can be informed by the transportation planning process.

## B. Local Governmental Planning and Development Regulation

Local governments are most often the closest service and infrastructure provider to community residents. In the United States and in many other western countries, local comprehensive plans, zoning ordinances, and subdivision regulations are used to guide the levels and types of community development. As per state constitutions, local governments are given the responsibility for establishing the regulations and controls that oversee development decision making within their jurisdictional boundaries. For example, one of the most influential tools for influencing the substance and style of community development (and the one most jealously guarded by local officials) is the local zoning code. It is through this code that the community vision of what it wants in terms of development patterns is expressed in a way that holds the force of law. Table 3-2 shows other types of tools that local officials have at their disposal for influencing community development. In some instances, communities utilize all of the tools shown in the table, whereas in others, only a few are available.

Schools are also an important community investment that influences development patterns, especially in fast-growing communities that attract young families. The planning for school facilities is not often part of the larger community comprehensive planning process, but is an independent activity undertaken by local school boards. In most of these efforts, professionally accepted (and defined) methodologies, analysis tools, and data collection strategies serve as the foundation for the resulting plans and investment programs.

The following sections discuss in more detail some of the land-use planning tools available to communities.

### *1. Comprehensive Plans*

Most local governments and communities produce community-specific comprehensive plans that lay out the desired future for the community along with the infrastructure and policy support needed to achieve it. In many states (for example, California, Florida, Georgia, and Washington), local comprehensive plans are required by state law. Community comprehensive plans often have a high level of detail and focus more on community-specific strategies than regional plans.

Comprehensive plans serve three major functions. First, comprehensive plans reflect what a community desires in terms of future development. In some sense, they thus represent a vision of a desired future. Second, the plan guides public policy and private developer decisions. In other words, what steps must be taken or adopted to assure that the community development plan becomes a reality? Finally, the enabling legislation for most zoning codes and other types of regulatory approaches requires the adoption of a benchmark (a plan) that can be used to judge the desirability and legality of community actions. For example, the standard zoning enabling acts adopted by many states in the early twentieth century often noted that zoning "shall be in accordance with a comprehensive plan." Many of the legal challenges to zoning decisions are often decided on the interpreted consistency between the recommended action and the community's comprehensive plan.

| Table 3-2. Land Regulations and Implied Requirements of Plans | | |
|---|---|---|
| **Regulation Type** | **Regulation Logic** | **Implied Plan Logic** |
| Zoning | Externalities (positive and negative) | Strategy to address interdependence due to irreversibility of investments and indeterminate adjustment process given imperfect foresight |
| | Infrastructure capacity | Strategy for expansion and design of capacity at build-out because of irreversibility and indivisibility |
| | Fiscal objectives | Policy for consistent and fair repeated decisions for the development community |
| | Information costs or errors | Policy to provide information that is a collective good or asymmetric between buyers and sellers |
| | Management of supply | Strategy to reduce infrastructure costs of spatial substitution of uses as technology changes given imperfect foresight |
| | Amenity protection | Strategy to protect scarce natural resources |
| | Development timing | Strategy of zoning for non-urban areas until land use is ready for more intense development |
| Official maps | Project rights-of-ways | Strategy to preserve design decisions by developer that have collective good external effects |
| Subdivision regulations | External effects of design decisions | Policies to achieve design decisions by developer that have collective good external effects |
| Urban service areas | Timing, resource lands protection, "optimal city size," depending on how changes in area are managed over time | Strategy of efficient infrastructure provision and interaction costs over time; policy of consistent and fair resource land protection; target design of city |
| Adequate public facilities ordinances | Timing | Strategy of efficient infrastructure provision and interaction costs over time |
| Development rights (for example, conservation easements, transferable rights) | Permanent allocation of land uses | Target design of pattern of uses, for example, resource lands and urban development |
| Impact fees | Timing, fiscal management, and distribution of costs among current and new residents | Policy for consistency and fairness; strategy for infrastructure financing |

Although the specific requirements of the transportation component of a comprehensive plan will vary by state, the topics most often covered include: (1) an inventory of transportation facilities and services, (2) an assessment of the condition and performance of the current transportation system, (3) the identification of transportation problems or deficiencies with respect to the goals of the comprehensive plan, (4) an analysis and evaluation of prospective solutions to these problems, (5) the development of a recommended investment and operations strategy, and (6) (increasingly) the identification of alternative financing strategies for supporting the recommended strategies.

### *2. Zoning*

Local governments' use of zoning and land-use ordinances to establish the design requirements for, and the physical context of, development projects is perhaps one of the most important influences on community development. [Merriam, 2005] While zoning and land-use ordinances are taken for granted by planners today, a look at the historical impetus for placing restrictions on the use of land provides some insight as to why newer, compact, mixed-use forms of development often come into conflict with locally adopted land-use regulations.

During the Industrial Revolution, millions of Americans flocked to cities in response to a substantial growth in employment opportunities. At the time, local governments did not yet possess a legal means to review the proposed use of a plot of land and effectively guide this population growth. Developers responded to the intense market pressures for new workforce housing by constructing tenements that were as cheap as possible (for example, exhibiting

poor structural supports), having little to no ventilation, water, or sewage facilities. This unregulated development in response to industrialization resulted in myriad negative impacts to the health, safety, and general welfare of local communities. The modern era of land-use zoning in the United States began in the early twentieth century in reaction to deteriorating living conditions brought on by overcrowding in cities.

New York City adopted the first comprehensive zoning ordinance in 1916. The ordinance established three types of districts based on land use (residential, industrial, and commercial) and provided regulations for the physical lay-out of individual structures within a given land-use district. The objective of this ordinance was to create safe and quiet areas for family living, primarily by limiting density. This first zoning ordinance established several elements of zoning that were soon adopted in zoning ordinances in other cities: setback distances from the street, maximum building heights, maximum bulk or what is known today as Floor Area Ratio (FAR, the ratio of a building's total area to its footprint to the area of the entire lot), occupant density, minimum lot size, and permitted and/or allowed uses (residential, commercial and industrial). This ordinance codified two principles of land-use planning that until recently were accepted as characteristics of good practice—limit the intensity of development and separate land uses.

At the federal level, the Standard Zoning Enabling Act (SZEA) of 1924 sought to standardize land-use zoning nation-wide. This act gave President Herbert Hoover the authority to establish an advisory committee to develop a "template" that allowed state governments to enact legislation giving municipalities the authority to zone. The primary tenets of the SZEA were:

1) *Grant of Power*: Promote the health, safety, morals, and general welfare of the community. This included the power to regulate the height, number of stories, size of structure (bulk), percentage of the lot that may be occupied, size of yards, density of population, and the use of buildings.

2) *Districts*: The local legislative body could divide the municipality into districts that were deemed best suited to carry out the act.

3) *Purposes in View*: The regulations were to be made in accordance with the comprehensive plan and designed to lessen congestion in the streets; secure safety from fire, panic, and other dangers; promote health and the general welfare; provide adequate light and air; prevent the overcrowding of land; avoid undue concentration of population; and facilitate the adequate provision of transportation, water, sewage, schools, parks, and other public requirements.

This basic template formed the framework for zoning enabling acts adopted with various modifications in states across the United States.

This initial concept of zoning was legally challenged in a 1926 U.S. Supreme Court case, *City of Euclid, Ohio v. Ambler Realty*. Ambler Realty argued that zoning regulations unconstitutionally diminished the value of its land by imposing use requirements. However, the Supreme Court ruled that zoning did have a "rational relationship to valid governmental interests in preventing congestion and in segregating incompatible uses." [Juergensmeyer and Roberts, 2003] The term "Euclidean Zoning" comes from this case. Ten years after the Euclid case, 1,246 municipalities in the United States had zoning ordinances. [Moore and Thorsnes, 2007]

Another important distinction in zoning is the manner in which states can delegate zoning power to municipalities. The first, commonly referred to as *Dillon's Rule*, prevailed in most communities until the mid-twentieth century. In this concept, local governments have only the powers specifically enumerated by the state. This considerably limited the ability of local governments to act on their own behalf. Today, Dillon's Rule has largely been rejected by most states in favor of *Home Rule*. In Home Rule states, municipalities have all the power necessary to perform their tasks unless that power has been specifically restricted by the state.

A typical zoning designation for different types of land uses in Atlanta, Georgia, is shown in Table 3-3. As indicated, zoning usually identifies the type of land use that can occur on a parcel "by right" and the level of intensity of development. Sometimes specialized zoning is necessary for an area where a large tract of land is involved. Driven by a desire to reverse suburban sprawl and establish more compact patterns of development, many urban areas are now beginning to promote density and the integration of multiple land uses by incentivizing more intense, mixed-use development, which runs contrary to the intent of the earliest zoning ordinances, as well as the content of many approaches to local land-use regulation still in use today. A planned unit development (PUD) designation, for example, allows a mix of land uses, flexibility in the placement of buildings, and the relaxation of development standards.

| Table 3-3. Sample Zoning Codes from City of Atlanta | |
|---|---|
| **Zoning** | **Zoning District Name** |
| **BL** | Beltline overlay district |
| **HBS** | Historic building or site |
| **HD-20G** | West End historic district (example of several) |
| **LBS** | Landmark building or site |
| **LD-20A** | Cabbagetown landmark district (example of several) |
| **LW** | Live-Work |
| **MRC-1** | Mixed residential and commercial, maximum floor area ratio of 1.696 (example of 3 MRC designations) |
| **MR-1** | Multi-family residential, maximum floor area ratio of 0.162 (example of 8 different MR designations) |
| **NC-1** | Little Five Points Neighborhood Commercial (example of 5 different NC designations) |
| **PD-H** | Planned housing development (single-family or multi-family) (example of 3 planned unit designations) |
| **R-1** | Single-family residential, minimum lot size 2 acres (example of 10 single family residential designations, R-1 to R-5) |
| **RG-1** | General (multi-family) residential, maximum floor area ratio of 0.162 (example of 6 such designations) |
| **O-I** | Office-industrial |
| **C-1** | Community business |
| **C-2** | Commercial service |
| **C-3** | Commercial-residential |
| **C-4** | Central area commercial-residential |
| **C-5** | Central business district support |
| **I-1** | Light industrial |
| **I-2** | Heavy industrial |
| **SPI-1** | Special Public Interest District: Central Core (example of 17 special interest districts) |

Source: City of Atlanta, 2015

An approved PUD plan fixes the nature and location of uses and buildings on the entire site. Cluster development is a form of PUD in which buildings, usually residences, are grouped together to preserve open space or environmentally sensitive areas, such as wetlands.

*Overlay districts* are another strategy to provide opportunities for special development or urban design treatments in a particular area (see Beltline overlay designation in Table 3-3). An overlay district keeps the underlying zoning requirements for targeted parcels, but provides owners and developers with the ability to adopt special allowances. A good example of an overlay zone is found in Portland, Oregon, with its "Light Rail Transit Station Zone." [Portland Metro, 2000] This overlay zone "allows for more intense and efficient use of land at increased densities for the mutual reinforcement of public investments and private development. Uses and development are regulated to create a more intense built-up environment, oriented to pedestrians, and ensuring a density and intensity that is transit supportive." Actions include prohibiting parking garages within a specified distance of a station, reducing the minimum number of parking spaces required within 500 feet of a light rail alignment by 50 percent, and requiring streetscape landscaping at a very high level. Such an approach is tailored to foster walkable community environments.

Although zoning has been used extensively in the United States for decades, some argue that current applications of zoning regulations are detrimental to the development patterns best suited for today's market. For example, Levine [2005] argues that land development is one of the most regulated sectors of the U.S. economy, and conventional zoning actually gets in the way of market forces. He notes: "The design template for urban sprawl is written into the land-use regulations of thousands of municipalities nationwide."

Relaxing zoning regulations can facilitate improved mobility in a number of ways. First, allowing mixed residential and commercial uses increases traveler accessibility to a greater number of potential destinations, reducing trip

lengths and increasing the potential for satisfying some of those trips by walking or bicycling rather than by automobile. Second, allowing higher residential densities in transit corridors can support more efficient transit services and reduce automobile mode share. Finally, relaxing minimum off-street parking space requirements can facilitate infill development by both reducing the land area and costs required for a single use. Conversely, other regulations can improve land-use efficiency. For instance, Moderately Priced Dwelling Unit (MPDU) requirements improve equitable access to housing. Transfer of Development Rights (TDR) programs allow by-right zoning on farmland to be transferred to more urban "smarter growth" locations that will have the effect of preserving farmland and reducing sprawl.

*Form-based zoning codes* recognize there is no longer a significant conflict between industrial and residential uses as there was when use-based zoning was originally adopted. As opposed to the Euclidean approach, which first rigidly defines the use of a plot of land and then provides general guidelines as to a building's potential form, a form-based code approach essentially prescribes the style and form of buildings and then allows the use to be flexible. By their very nature, form-based zoning codes facilitate mixed-use development, which is often difficult (and many times illegal) under current zoning laws. Instead of use-based zones, which segregate land uses and often increase the distance required to travel to different types of destinations, form-based zones allow for varying densities and the interspersing of different types of destinations next to (and even on top of) one another. This tends to decrease the distance required to travel to various services.

### *3. Zoning and Parking*

Zoning standards typically establish minimum requirements or formulas for how many parking spaces must be provided for specific types of land uses. The intent of most local governments is to require property owners to provide sufficient off-street parking spaces so as to avoid spillover parking onto public streets or adjacent private property. Parking requirements, however, have come under increasing scrutiny in recent years from many who argue that minimum parking requirements often lead to too much parking. The report, *Recommended Zoning Ordinance Provisions* [Parking Consultants Council, 2007], recommends language to protect the city's interests while allowing flexibility to address the most common circumstances influencing parking demand. Some of the circumstances where flexibility in zoning requirements may be appropriate are:

- *Shared Parking*—In some cases, adjacent land uses generate parking demand at different times of the day, and thus in a shared parking program, parking capacity is shared over the day.
- *Captive Market*—A captive market is an employment location where nearby land uses can be readily accessed by walking or transit (for example, in a central business district). A captive market consideration is a component of shared parking effects; however, it does not require that parking be shared to achieve a reduction in demand.
- *Fees-in-Lieu*—It may be in the best interests of a city to develop public parking in a densely developed activity center, rather than have each property owner provide parking for each building. With the high cost of parking structures and the competing demands on city resources, a number of cities have asked developers to contribute to the costs of developing municipal parking facilities in lieu of providing the totally required amount of parking for their development site.
- *Off-Site Parking*—Many cities have added clauses in their zoning that allow for off-site parking to be substituted for on-site parking under certain conditions.
- *Ridesharing*—Ridesharing generally refers to various forms of carpooling, vanpooling, and subscription bus service associated with employees' trips to and from work. Properly formulated ridesharing programs can reduce both traffic and parking demand. Zoning credits for ridesharing programs are a particularly effective means of achieving transportation management goals. Ridesharing credits are also a means of adjusting parking requirements for any development site that runs a dedicated shuttle. The most common application is hotels that cater to those wanting convenient access to an airport. However, other development sites may also run shuttles and thus merit reduced parking requirements.
- *Transit*—For areas that are well served by public transit, it is reasonable to expect that some reduction in parking demand will occur due to visitors and employees using transit. In some communities, if a development site is within a certain distance of a regularly scheduled transit stop or station, the zoning code allows the developer to reduce the number of parking spaces required on site.

See chapter 11 for additional discussion on the relationship between zoning and parking requirements.

### *4. Subdivision Regulations*

A common development trend that has emerged in urban areas within the United States and many other Western countries over the past 50 years is the division of large plots of land into smaller individual parcels, commonly referred to as "subdividing." Subdivision regulations provide guidance on what a community desires when land is subdivided like this for development purposes. Developers must submit plans to the relevant governmental body (such as a planning board or commission) for approval. This site plan review process covers things such as the size and shape of lots, street design, sewer and water connections, and environmental protection. The most important transportation components of the site plan review process include street layout, provision of sidewalks, access points to the subdivision, and proposed building footprints with respect to regional transit services (if transit services are available).

### *5. Development or Site Plan Review Process*

The development or site plan review process provides an opportunity for communities to make sure development proposals are consistent with the zoning code and the comprehensive plan. This process is often based on checklists reviewed by community planners (and thus developers as well to anticipate what the planners will be looking for) to determine such consistency. Given that differences often occur between development characteristics and zoning requirements, the negotiation on what will be allowed, if anything, usually occurs during this review process. Figure 3-2 presents a typical site plan review process. It is during a process similar to that shown where the determination of what is "good for the community," and the potentially different interpretations from local citizens, is played out.

One of the common debates occurring during this process relates to the perceived value of additional growth in a community. Some view growth as a necessary ingredient to a vibrant and evolving community, whereas others consider such growth as adding additional burdens to community services. This difference of perspective has led to dramatic shifts in the elected representation on community boards and decision-making bodies, depending on which perspective is on the rise at any point in time.

It is important to note that both subdivision regulations and site plan reviews usually require a transportation impact analysis, certainly for larger proposed developments. Traditionally, this analysis focused almost exclusively on automobile access to development sites with little attention to other modes of travel. In many cities, the analysis has shifted to a multimodal accessibility perspective. Whereas road performance levels of service had been consistently applied everywhere in a region (for example, every intersection must operate at least at a level of service C), in many cities today, road performance thresholds can vary depending on the context and availability of alternative modes. Readers are referred to Broward County's (Florida) multimodal concurrency process: (http://www.broward.org/PlanningAndRedevelopment/ComprehensivePlanning/Documents/TransGOPS2014.pdf) and Montgomery

County's (Maryland) development guidelines (http://www.montgomeryplanning.org/transportation/latr_guidelines/latr_guidelines.shtm) as illustrations of how vehicle trip impacts can be exchanged for exactions that lead to more multimodal solutions. ITE's *Recommended Practice on Traffic Impact Analysis for Site Development* is a good reference on different traffic impact analysis approaches. [ITE, 2010a] See also chapter 19 on site planning and impact analysis.

### *6. Growth Management*

Growth management concepts first appeared in the United States in the late 1960s and early 1970s in response to community concerns over human impacts on environmental resources. [Porter, 1997] In 1972, a landmark court case in New York established the legal foundation for communities to manage growth through the comprehensive planning process. In *Golden v. Planning Board of the Town of Ramapo*, the New York Supreme Court (upheld by the U.S. Supreme Court) stated that the uncompensated control of the timing and sequencing of residential subdivision development is legal for a "reasonable period of time" (defined in this case as 18 years or the life of the local comprehensive plan) with such a linkage tied to the provision of capital improvements. As noted by Freilich [1999] "the importance of this law is the recognition of the fundamental constitutional principle that techniques to handle growth over the next 15 to 20 years can be controlled by linking the proposed development with the planned extension of capital improvements over the lifetime of the comprehensive plan."

The following two definitions of *growth management* help identify the key factors that are part of a growth management strategy:

According to the U.S. Environmental Protection Agency (EPA), "growth management is a method of planning new development that serves the economy, the community, and the environment. It changes the terms of the development debate away from the traditional "growth or no growth" to "how and where should new development be accommodated?" [U.S. EPA, 2014] Smart growth answers this question by simultaneously achieving:

- "*Healthy communities* that provide families with a clean environment. Smart growth balances development and environmental protection—accommodating growth while preserving open space and critical habitat, reusing land, and protecting water supplies and air quality.
- *Economic development and jobs* that create business opportunities and improve the local tax base.
- *Strong neighborhoods* that provide a range of housing options, giving people the opportunity to choose housing that best suits them. It maintains and enhances the value of existing neighborhoods and creates a sense of community.
- *Transportation choices* that give people the option to walk, ride a bike, take transit, or drive."

According to ITE's recommended practice on smart growth and transportation guidelines, "smart growth is a complex mix of land use and transportation design" with the following five goals serving as its foundation:

- Pursuing compact, efficient land-use patterns to maximize transportation efficiency and improve the neighborhood environment.
- Providing multimodal mobility within developed areas.
- Providing accessibility within existing built-up areas.
- Making the most efficient use of transportation infrastructure.
- Supporting smart growth through pricing and sustainable funding. [ITE, 2003]

While growth management policies can have a profound effect on encouraging desired development objectives, in many regions, such development policies are not very influential; they simply state desired outcomes or visions of what a metropolitan area wants to look like, with very little policy linkage to individual community decisions on development proposals. A strong "home rule" proviso in many state constitutions that leaves development decisions to local officials is most often the reason for this weak linkage.

Interested readers should refer to ITE's report on growth management for a comprehensive discussion of how transportation actions can reinforce growth management principles. [ITE, 2003]

### *7. Transit-Oriented Development (TOD)*

TOD is a form of managed growth, in this case, offering incentives for development to locate next to transit stops or stations. TODs are usually compact, mixed-use, pedestrian-oriented developments providing greater attention to civic uses of the space and treating the transit facility as the centerpiece of the entire development. According to Reconnecting America, Inc., one of leading nonprofit organizations advocating TOD development, the key characteristics of transit-oriented job sites are:

- Urban densities ranging from mid-rise buildings with 2.0–5.0 FAR to high-rise buildings with 4.0 or higher FAR, with the highest densities located in the closest proximity to transit stations and stops.
- Significant concentrations of workers in order to create the demand that will support convenience, retail, and personal services near the station, and help justify the provision of high-quality transit service.
- A variety of easily accessed transit services to provide a high-level of connectivity in business districts, ranging from local bus or streetcars to enhance local circulation, to light rail or bus to connect to nearby neighborhoods, to express bus and commuter rail to connect to neighborhoods further away.
- Limited parking, or pricing that limits parking demand, ideally in combination with financial incentives from employers to encourage transit ridership.
- A mix of businesses that are "transit-oriented," including shops and restaurants that allow workers to meet their needs without a car. [Reconnecting America, 2008]

Reconnecting America, Inc. notes several observations that make TODs an appealing development concept today and even more so in the future.

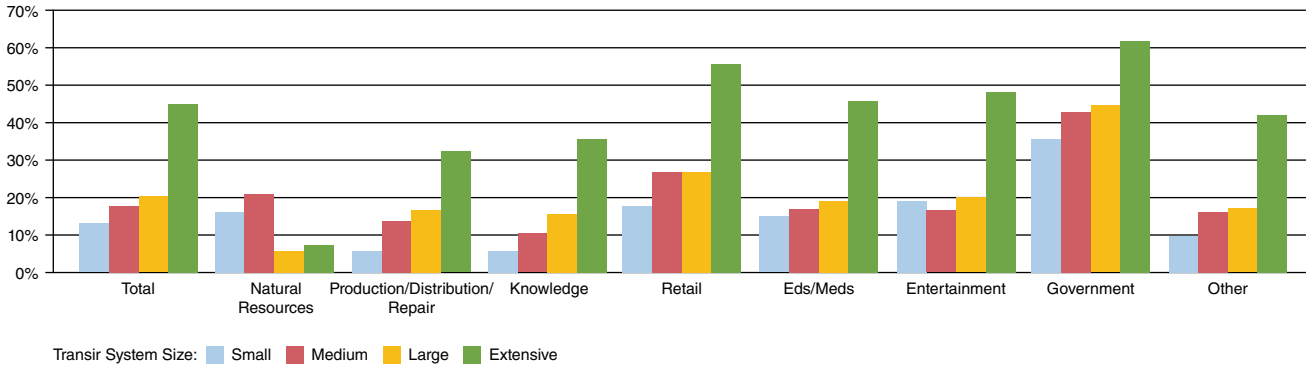
*Demographics are promising for TOD:* Aging Baby Boomers and young urban professionals are population groups attracted to TOD, and both groups are growing in the United States. In particular, these groups tend to desire "walkable" urban lifestyles.

*Corridor-centered growth is increasing, in many cases served by transit:* Corridor-centered growth is a development pattern that is found in many urban areas, often centered around development nodes either at highway interchanges or transit stations. TOD developments are natural elements of a corridor-centered growth pattern.

*TOD-supportive industries are growing:* As shown in Figure 3-3, some types of jobs are more transit-oriented than others, including jobs in the service, financial, and professional sectors. These employment sectors are also some of the fastest growing in the U.S. economy. From a land use and transportation planning perspective, these are the types of jobs (with corresponding firms and companies) that could be targeted for TOD developments.

*TOD needs more than transit:* Real estate development occurs in response to many different market factors, most importantly the monetary value of land parcels to potential buyers and tenants. For example, the economic recession of 2008 to 2010 caused much of the investment in land development to slow down in the United States. With a reviving economy after 2012, development once again began to occur in most major metropolitan areas. Developers began focusing on those parcels that had the greatest level of market attractiveness, with much of this development located in higher density, transit-oriented sections of center cities.

**Figure 3-3. Share of Regional Jobs near Transit by Industry and Transit System Size, 2008**



Source: Center for Transit-oriented Development, 2011

*Active leadership is crucial for success:* Public agencies, most often state governments and transit agencies, can facilitate TOD, using many different policy and financial tools. For example, leveraging other agency resources to improve station locations and working with developers and local governments to provide incentives to develop in these locations have been very successful. In some cases, transit agencies have bought land near transit stations and then worked with developers to build out the station area.

"Mobility hubs" are an emerging concept within TOD research and refer to transit stops or stations with frequent transit service, high development potential, serving as a critical point for trip generation or transfers within the transit system. This concept broadens the mobility emphasis to active transportation modes such as bicycling and walking, and promotes a total mobility perspective for higher density locations. Two examples of guidelines for promoting mobility hubs include:

- Metrolinx in Toronto, http://www.metrolinx.com/en/projectsandprograms/mobilityhubs/mobility_hub_guidelines.aspx.
- Virginia's Multimodal System Design Guidelines http://www.drpt.virginia.gov/activities/MultimodalSystemDesignGuidelines.aspx.

See Reconnecting America, Inc. for a series of reference documents on TODs and the steps necessary to make them happen (Reconnecting America, http://www.reconnectingamerica.org/what-we-do/what-is-tod/).

## C. Private Developers and Financial Lenders

While government has a strong say in determining the policies that shape communities, private companies and investors are probably even more important for private development projects. Both for-profit and nonprofit developers, institutional lenders, and a host of other groups, including contractors, construction professionals, and engineers, are responsible for developing the buildings and neighborhoods that comprise a community.

### *1. Private Developers*

Many landowners do not have the financial resources to develop their land. The individuals or companies having the financial means to do so are called private developers. Developers often buy large tracts of land or multiple parcels so that developments can be of sufficient size to attract clients. Because the attractiveness of a particular development site depends on many factors often outside the control of a developer, private development is a high-risk venture. What developers seek are relatively stable investments that can be relied on to generate a return on their investment.

In many cases, a "safe investment" is one that has been proven to be successful in the local market. Thus, although the site plan review process and the underlying zoning code can become the subject of disagreements over what should be allowed in a development proposal, some have suggested that zoning in fact promotes a market environment that minimizes development risk because all similar types of developments face the same constraints. However, the focus on "what has worked before" can also inhibit innovative land-use strategies and the adoption of new growth management concepts that better meet today's community challenges. For example, many urban communities have encouraged developers to consider higher densities, parking limitations, and a mixing of land uses that are not allowed by the zoning code. When developers generate proposals that attempt to satisfy the latest community desires, they often run into procedural and regulatory barriers designed to "protect" the community from developments that are "different" from the status quo.

When such differences are found in development proposals, the developer must request a variance to existing codes. The public nature of the zoning ordinance and development of the comprehensive plan provides opportunities for community residents to participate in any effort to grant a use variance. The zoning board or commission usually holds a public hearing and all those potentially affected by the change (for example, adjacent land owners) are notified of their opportunity to voice their opinion. This process can take many months.

As noted earlier, the site plan review process is often the step in the process where proposed changes from existing zoning ordinances or regulations are negotiated and accepted or rejected. Complex development projects that could potentially affect many different government agencies, such as transportation departments, school departments, fire and police departments, and so on, are provided the opportunity to comment on the changes, and in cases such as public safety, have the authority to reject the proposal. If the developer still wishes to proceed with the project, the proposal

must be revised to respond to the objection(s) and resubmitted. There have been instances where navigating the site plan review process given agency objections has taken many years.

A study by Inman et al. [2002] surveyed more than 700 developers in the United States about their experience with the development process. Although dated, the survey results are still relevant today. A large majority of the surveyed developers perceived local zoning as the most challenging obstacle in getting approval for non traditional developments. The noted barriers included: local zoning regulations (43 percent), neighborhood opposition (17 percent), lack of market interest (15 percent), and financing (9 percent). Of the developers responding to the survey that had proposed alternative development strategies, but were required to modify their proposals, the following modifications were required: 82 percent had the density reduced by the community planning process, 47 percent had mixed-use characteristics reduced, 29 percent had the housing types changed, 33 percent had the share of mixed use development changed, and 19 percent had changes made in pedestrian or transit orientation. The authors noted the following:

> *"On the whole, the random sample of developers perceives considerable market interest in alternative development; believe that there is inadequate supply of such alternatives; view local government regulation as the primary obstacle to the further development of these alternatives; and indicate interest in developing more densely and mixed use than regulations allow, notably in inner suburban areas. Thus it appears that in the perceptions of developers, at least, it is hardly more planning intervention that would bring about greater alternative development forms in the United States context, but relaxation of restrictive land-use and transportation policies that are excluding these forms to begin with."*
>
> *—Inman, Levine and Werbel, [2002]*

### *2. Financial Lenders*

Most developers rely on institutional lenders to provide the capital funds to support a development project. Thus, for example, if a developer is permitted by a local government to develop a parcel of land that does not meet all of the requirements of the zoning regulations, the institutional lender financing the project must agree to the variations as well. However, financial lenders look at each lending opportunity from the perspective of risk. [Gillham, 2002] Will a loan likely be repaid? Or in development terms, is the proposed development marketable (and thus profitable) given what has happened in the community and the development market in recent years? Most lending institutions rely on a development's consistency with local zoning ordinances as a litmus test for determining financial suitability.

One of the key issues in this regard has been the requirement for a minimum amount of parking at the development site. In some instances, communities and developers that have wanted to reduce the number of parking spaces in order to encourage more transit and nonmotorized transportation travel have run into opposition from lenders who took the position that minimum parking requirements reflect the needed parking capacity to make the development successful. This type of opposition has lessened in recent years as the development and lending communities have become more used to changing transportation requirements, especially in communities that have made a commitment to alternative modes of travel.

In summary, zoning and subdivision ordinances have a very strong influence on community development patterns and on the parcel-specific characteristics of a particular development. One of the implications of this is that nontraditional development proposals desired by community residents might face significant obstacles. Even if such proposals will eventually be approved, the time delay in seeking approvals for variances in existing ordinances could very well cause a developer to seek other alternatives, such as traditional market-tested, large lot, auto-oriented developments. And it is not just the developer that faces risks in additional costs and time delays associated with nontraditional developments. The financial lending institution could also be hesitant to accept a nontraditional development simply because the "community standard" as expressed in the zoning code is not being followed.

## III. URBAN FORM

The previous sections identified the different factors that influence individual development proposals and ultimately the type of development that occurs on individual parcels of land. The cumulative effect of these individual development decisions over time results in a spatial development pattern referred to as urban form. In other words, the development patterns that over time define the physical, economic, and often socio-demographic characteristics of the individual communities are the same elements that, in the aggregate, shape a region. The role of transportation investment in influencing this evolution and vice versa has received a great deal of attention in recent decades. During the 1990s and early 2000s, for example, this attention produced books for the popular market critiquing urban form

and in particular suburbanization (for example, see [Duany and Plater-Zybek, 1991; Hart and Spivak, 1993; Kay, 1997; Kunstler, 1997, 2013; Morris, 2005]).

In addition, more systematic studies of the relationship between land use and transportation have given particular attention to the resulting consequences on such things as air quality and public health. [Whitfield and Wendel, 2015] For example, the Urban Land Institute published *Growing Cooler,* one of the first examinations of the impact of different land-use patterns on the production of greenhouse gases. [Ewing et al., 2007] Specifically, the study tried to answer three policy questions:

1) What reduction in vehicle miles traveled (VMT) is possible in the United States with compact development rather than continuing urban sprawl?
2) What reduction in $CO_2$ emissions will accompany the reduction in VMT caused by more compact development patterns?
3) What policy changes will be required to shift the dominant land development pattern from sprawl to compact development?

Compact development was defined as denser development, enhanced land-use mix, an emphasis on population and job centers, and more pedestrian-friendly design.

The authors estimated that the use of compact development practices at a very high penetration level would result in a 20 to 40 percent reduction in VMT for each increment of new development or redevelopment, depending on the degree to which best practices are adopted. This led to an estimated 7 to 10 percent reduction in total transportation-related $CO_2$ emissions by 2050 relative to continuing sprawl. The authors also suggested that "dramatic" policy changes in land use at the state, regional, and local levels of government would have to occur for this level of $CO_2$ emissions reduction to take place. Indeed, it was the need for such dramatic policy changes that spawned serious critiques of this study. Simply put, many thought the study was misleading because the type of change necessary in land-use policies was unlikely to occur in the foreseeable future.

Soon after, a group of transportation professional organizations sponsored *Moving Cooler*, which was an effort to identify different "bundles of transportation and land-use strategies and their likely impacts on $CO_2$ emissions." [Cambridge Systematics, 2009] The *Moving Cooler* study found, not surprisingly, that more compact development patterns produced less travel and thus fewer $CO_2$ emissions. Transit and nonmotorized transportation improvements were more effective at reducing $CO_2$ emissions in areas with higher population densities. It also concluded that strategies to encourage the use of alternative modes (such as road pricing) would have a greater impact when applied in conditions where better alternatives exist (as would be found with increased transit investment and more compact land-use patterns).

In 2009, the Transportation Research Board published a study on the effects of the built environment on VMT, energy consumption, and greenhouse gas emissions. [TRB, 2009] Given the nature of the work, and the emphasis on facts and science underlying the conclusions, this report was much more circumspect than the two mentioned above. The conclusions included:

1) Developing more compactly, that is, at higher residential and employment densities, is likely to reduce VMT.
2) The literature suggests that doubling residential density across a metropolitan area might lower household VMT by about 5 to 12 percent, and perhaps by as much as 25 percent, if coupled with higher employment concentrations, significant public transit improvements, mixed uses, and other supportive demand management measures.
3) More compact, mixed-use development can produce reductions in energy consumption and $CO_2$ emissions both directly and indirectly.
4) Illustrative scenarios developed by the committee suggest that significant increases in more compact, mixed-use development will result in modest short-term reductions in energy consumption and $CO_2$ emissions, but these reductions will grow over time.

5) Promoting more compact, mixed-use development on a large scale will require overcoming numerous obstacles. These obstacles include the traditional reluctance of many local governments to zone for such development and the lack of either regional governments with effective powers to regulate land use in most metropolitan areas or a strong state role in land-use planning.

6) Changes in development patterns significant enough to substantially alter travel behavior and residential building efficiency entail other benefits and costs that have not been quantified in this study.

Additional studies and research will undoubtedly continue to study the relationship between transportation, land-use patterns, and the resulting impacts. The major conclusion from the three above studies is that transportation behavior and travel patterns can indeed be affected by land use and development patterns. The overall effect, however, will depend on how much the needed development design or strategy (for example, compact development) will penetrate the urban market.

## IV. URBAN DESIGN

Transportation planners and engineers often become involved in another planning effort called urban design. [Montgomery, 2013] Urban design is "concerned with the physical characteristics of the city and the implications of design and planning decisions for the public realm of the city. The urban design strategy must serve as an integrating tool, one that coordinates how various public and private development proposals, including transportation and public infrastructure, will affect the city physically." [City of Pittsburgh, 1998]

Urban design guidance and principles can take many forms. In some cases, communities provide illustrations or concepts of what development characteristics and associated amenities are desired in future development. As an example, Figure 3-4 shows the core development principles adopted as part of a corridor planning study for

**Figure 3-4. Core Development Principles and Means of Applying Them, City of Madison, Wisconsin**

a major urban arterial road in Madison, Wisconsin, and the implementation techniques that could be used to apply them.

Table 3-4 shows the values articulated by a citizens steering committee for urban design concepts relating to the corridor's land use. Urban design standards for the corridor area (that would be incorporated into city development or site plan reviews) were developed simultaneously with the corridor plan.

Figure 3-5 illustrates some of the development and transportation concepts that were recommended for the corridor.

In other cases, urban design guidance takes the form of narrative descriptions of the principles and actions that should guide the "look" and "feel" of community places. [Eitler et al., 2013] For example, the Milwaukee, Wisconsin,

Department of City Development has adopted the following principles for urban design within the city. [City of Milwaukee, undated]

***Principle #1: Neighborhood Compatibility***
New development should be compatible with the pattern of its surrounding context. Development that adheres to this principle will:

- Relate to the physical character and scale of the neighborhood.
- Enhance linkages to surrounding uses, especially public services and amenities (schools, parks, mass transit).

***Principle #2: Pedestrian Friendly Design***
New development should be designed to create attractive, comfortable, and safe walking environments. Development that adheres to this principle will:

- Locate buildings to define street edges and corners.
- Enliven street frontages to enhance the pedestrian experience.
- Create memorable places for people.

***Principle #3: Land-use Diversity***
Diversity uses land efficiently, provides for neighborhood convenience, and contributes to unique urban experiences. Development that adheres to this principle will:

- Encourage a compatible mix of uses at the neighborhood scale.
- Identify opportunities for shared uses.

***Principle #4: Transportation Diversity***
The transportation system should be maintained and improved in ways that accommodate various modes of transportation balanced with needs for pedestrians. Development that adheres to this principle will:

- Create a balanced circulation system that accommodates mobility choice (pedestrians, automobiles, bicycles, and transit).
- Enhance public transportation by making it more comfortable and convenient to use.

As can be seen in these principles, transportation is often a part of urban design policies. The following transportation-related principles from the City of Minneapolis's urban design policy [City of Minneapolis, 2009] provide another example of the mutually reinforcing relationship among development, urban design, and transportation considerations:

**Downtown**

- The ground floor of buildings should be occupied by active uses with direct connections to the sidewalk.
- Integrate components in building designs that offer protection to pedestrians, such as awnings and canopies, as a means to encourage pedestrian activity along the street.
- Locate access to and egress from parking ramps mid-block and at right angles to minimize disruptions to pedestrian flow at the street level.
- Coordinate site designs and public right-of-way improvements to provide adequate sidewalk space for pedestrian movement, street trees, landscaping, street furniture, sidewalk cafes, and other elements of active pedestrian areas.
- Use skyways to connect downtown buildings and that:
  - Provide consistent and uniform directional signage and accessible skyway system maps near skyway entrances, particularly along primary transit and pedestrian routes.
  - Provide convenient and easily accessible vertical connections between the skyway system and the public sidewalks, particularly along primary transit and pedestrian routes.

**Multi-Family Residential**

- Medium-scale, multi-family residential development is more appropriate along Commercial Corridors, Activity Centers, Transit Station Areas, and Growth Centers outside of Downtown Minneapolis.
- Orient buildings and building entrances to the street with pedestrian amenities like wider sidewalks and green spaces.

**Single-Family and Two-Family Residential**

- New driveways should be prohibited on blocks that have alley access and no existing driveways.

**Mixed-Use and Transit-Oriented Development**

- Provide safe, accessible, convenient, and lighted access and way finding to transit stops and transit stations along the Primary Transit Network bus and rail corridors.
- Coordinate site designs and public right-of-way improvements to provide adequate sidewalk space for pedestrian movement, street trees, landscaping, street furniture, sidewalk cafes, and other elements of active pedestrian areas.

**Commercial**

- Enhance pedestrian and transit-oriented commercial districts with street furniture, street plantings, plazas, water features, public art, and improved transit and pedestrian and bicycle amenities.
- Require storefront window transparency to assure both natural surveillance and an inviting pedestrian experience.
- Maximize the year-round potential for public transit, biking, and walking in new developments.

**Industrial**

- Design industrial sites to ensure direct access to major truck routes and freeways as a way to minimize automobile and truck impacts on residential streets and alleys.

**Public Spaces**

- Emphasize improving public access to and movement along the riverfront.
- Develop public plaza standards that give specific guidance on preferred design and maintenance of seating, lighting, landscaping, and other amenities utilizing climate sensitive design principles.

These principles focus on the characteristic of buildings and sites as they relate to transportation options. Streets, sidewalks, and parking facilities are also often part of urban design guidance. Again, from the Minneapolis guidance, the following list presents the urban design-desired actions for streets and sidewalks:

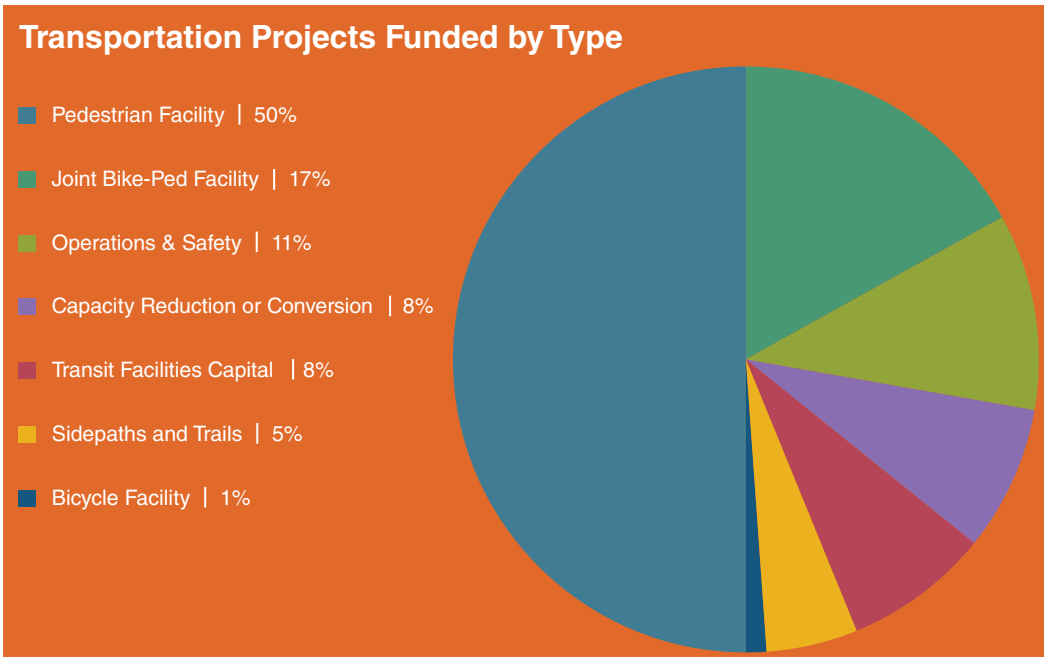
- Consider street variations as a last resort to preserve the network of city streets and arterials.
- Integrate and/or reuse historic pavement materials for streets and sidewalk reconstruction, where appropriate.
- Reduce street widths for safe and convenient pedestrian crossing by adding medians, boulevards, or bump-outs.
- Improve access management and way-finding to and from all streets, sidewalks, and other pedestrian connections.
- Explore options to redesign larger blocks through the reintroduction and extension of the urban street grid.
- Encourage wider sidewalks in commercial nodes, activity centers, along community and commercial corridors, and in growth centers such as Downtown and the University of Minnesota.
- Provide streetscape amenities, including street furniture, trees, and landscaping that buffer pedestrians from auto traffic, parking areas, and winter elements.
- Integrate placement of street furniture and fixtures, including landscaping and lighting, to serve a function and not obstruct pedestrian pathways and pedestrian flows.
- Employ pedestrian-friendly features along streets, including street trees and landscaped boulevards that add interest and beauty while also managing storm water, appropriate lane widths, raised intersections, and high-visibility crosswalks. [City of Minneapolis, 2009]

Urban design also focuses on public spaces. The American Planning Association (APA) defines a public space as "a gathering spot or part of a neighborhood, downtown, special district, waterfront, or other area within the public realm that helps promote social interaction and a sense of community. Possible examples may include such spaces as plazas, town squares, parks, marketplaces, public commons and malls, public greens, piers, special areas within convention centers or grounds, sites within public buildings, lobbies, concourses, or public spaces within private buildings." [APA, 2015] (Note that the importance of public space is recognized as one of the six core principles for roadway systems planning in ITE's *Recommended Practice for Planning Urban Roadway Systems* [2014]).

In the planning and urban design literature, planners often refer to "place-making," which means incorporating urban design concepts into a public (or private) space turning the location into a vibrant and economically sustainable "place to be." Transportation has a critical role in making this happen. For example, the types of transportation strategies as part of a public space include the availability and adequacy of sidewalks; sidewalk buffers, for example street trees, landscaping, on-street parking, and the like; bike lanes where feasible and the addition of bike share stations; urban design guidelines that address streetscape/pedestrian amenities; street trees that provide shade; and other walkability amenities. The concept of Complete Streets is a good example of how publicly provided transportation space can be made more appealing to a range of users (see chapter 9 on road and highway planning).

In recognition of the importance of place making, some MPOs have created funding programs for local cities and towns to develop master plans for targeted community areas where a mix of land uses and appropriate transportation strategies can be combined to create a special place. The Atlanta Regional Commission (ARC), for example, was one of the first MPOs to develop such a program. Called the Livable Centers Initiative (LCI), the program awards funding grants to local communities and nonprofit organizations to develop plans that (1) encourage a diversity of mixed-income residential neighborhoods, employment, shopping, and recreation choices in activity centers, town

**Figure 3-6. Local Project Types Funded for Livable Centers Initiative Funds, Atlanta Regional Commission, 2014**



Source: ARC, 2015b, Reproduced with permission of the Atlanta Regional Commission.

centers, and corridors; (2) provide access to a range of travel modes including transit, roadways, walking, and biking to enable access to all uses within the study area; and (3) develop an outreach process that promotes the involvement of all stakeholders. [ARC, 2015b]

Implementation funds are also available to those recipients where the plans have been formally adopted by the local government as part of comprehensive plans and/or who have taken steps to implement the recommendations, such as creating tax allocation districts or downtown development authorities. Figure 3-6 shows the distribution of ARC's transportation implementation funds with respect to the types of projects funded. It is interesting to note that the majority of funds were spent on pedestrian walkways and other connectivity measures. Given that, as of 2014, the ARC board had committed $500 million through 2040 for projects identified in LCI studies, the program can be considered quite a success. Just over $172 million in federal funds have been spent on LCI construction projects since 2000, with the total investment (including local matches) exceeding $235 million. [ARC, 2015b] Sixty-nine percent of all the new office growth in the region between 2000 and 2014 occurred in LCI-designated centers. The Houston-Galveston Area Council (H-GAC) has a similar "Livable Centers" program. [H-GAC, 2015]

It should be noted that some of the urban design principles listed above could very well conflict with engineering design practice or guidelines (for example, the use of trees to define a street space, or policies on turning lanes or two-way streets). In such cases, transportation officials usually enter into discussions with relevant officials to provide the transportation infrastructure and services that best support adopted urban design principles. This approach is called context sensitive solutions (CSS) and is discussed later in this chapter.

## V. LAND-USE FORECASTING AND TRANSPORTATION PLANNING

For short-term analyses (3 to 5 years), transportation planners can usually take the current activity or land-use system as a given. In such cases, an inventory of the current land-use activity system for the study area is adequate to identify the number of trips to be generated from, or attracted to, a study area. In the long run (5 or more years), however, the urban land-use activity system clearly does change. Neighborhoods gain or lose population or employment of various types. New areas may be developed while older, developed areas may decline in quality, be renovated, or undergo redevelopment. As a result, travel demand patterns and transportation system requirements will also change.

Hence, long-range transportation planning must explicitly consider expected changes in the urban activity system in order to predict future travel demand.

The timeframe for forecasting land-use change varies by the type of planning study. *Comprehensive planning* usually considers "build-out" horizon years, often in the 30- to 50-year time horizon, and is applied area-wide. The *long range transportation planning* process most often uses a 20-year time horizon and is applied at the metropolitan or citywide levels. *Project planning* for the National Environmental Policy Act (NEPA) project development process uses horizon years of 20 to 25 years and is often done at the corridor or site level. *Air quality conformity/programming* focuses on horizon years of 6 to 20 years and occurs usually at the air basin or regional level. The timeframe for *site impact studies*, and the associated traffic impact analysis, will vary depending on local regulations and rules. Usually, the target years for projections include the year of development opening, 5 to 10 years beyond opening date, and full build-out (if the development site is part of a larger activity center).

## A. Population and Employment Forecasting

In most cases, transportation planners are provided a population and employment control value often generated from state-level economic forecasts. In many states, it is expected that the population and employment forecasts will conform to this overall total forecast, although the distribution of such forecasts within the study area is left to the metropolitan or local planning agency.

Approaches for forecasting changes in population include the following:

- The *ratio-trend method*, which relates the population of a study area to the rising or falling ratio of that area's population to the population of a larger area, for which an accepted population forecast exists.
- The *cohort-survival method,* which adds the effects of net natural population increase and net migration to the existing population.
- The *economic-base method,* which gears population growth to a forecast of employment growth.
- The application of a *constant or gradually declining compounded annual rate or percentage increase* in population.
- A *constant absolute rate* of population increase per annum or per 5- or 10-year period.

Employment forecasts, which typically tend to be more difficult to perform, use techniques such as trend extrapolation, input-output analysis, and professional (usually economic) judgment. In the United States, the Federal Reserve Bank system provides employment forecasts for individual metropolitan areas, as does the Bureau of Labor Statistics.

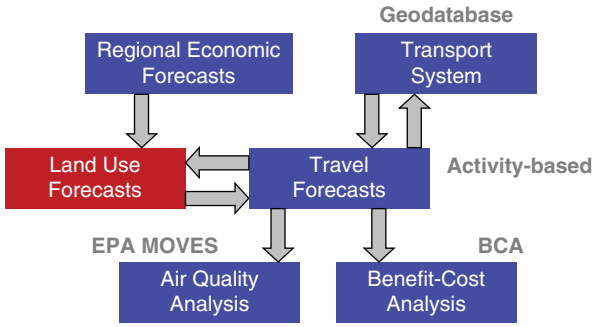
As an example of population forecasts for a large metropolitan area, the ARC notes that its process was "a multi-year effort, benchmarking and culminating into region plan updates. Several forecasting models are used and evaluated. In addition, several advisory meetings are held with local economists, dozens of engagement meetings are held with local governments and constituents over several iterations." [ARC, 2014a] ARC staff used the Regional Economic Models, Inc. (REMI) model to forecast population control totals, and then used another process to distribute the population throughout the region. The types of input data (or assumptions) for the ARC REMI model application included: population survival rates; population characteristics by race; birth rate; labor participation rates; equations that predicted economic output and employment by industry; unemployment rates; special populations such as those living in boarding houses, college dormitories, prisons, and mental institutions; fuel demand; migration; and economic and retired migrants. [ARC, 2014b] The forecasted regional total was then allocated to smaller districts.

## B. Interrelationship between Land-Use Forecasts and Travel Modeling

Land-use forecasts provide two important inputs into predicting future transportation demand: (1) the future levels of population and employment (that is, what will be the future demand?) and (2) the distribution of land uses in the study area (that is, where will trips be coming from and going to?). Figure 3-7 shows the key components of a land-use forecasting model (UrbanSim) and its relationship to a travel demand model as used by the Puget Sound Regional Council (PSRC).

Several observations illustrate what is generally true of all land-use models and their relationship to travel demand modeling. First, accessibility is the major predictor of land use, that is, the more accessible a parcel of land, the more desirable it is for development. This accessibility comes from the travel demand model after it has run through its many steps, shown in Figure 3-7 as a two-way arrow (see chapter 6). There is, thus, a feedback loop from the demand model to the land-use model and, in fact, land-use models are often run through iterations with the updated demand model feedback in order to reach an equilibrium state. In other words, land-use patterns will affect travel times and costs, which in turn could affect land-use patterns, which in turn could affect travel times and costs, and so on.

**Figure 3-7. Land-Use and Travel Modeling, Puget Sound Regional Council**



Source: Puget Sound Regional Council, 2012

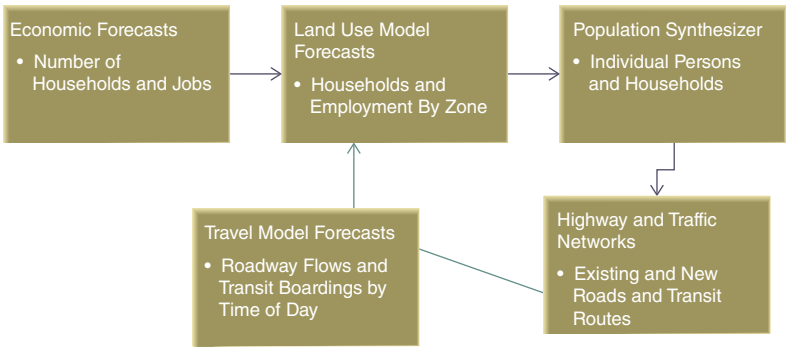
Second, the land-use model has an exogenous input representing regional economic forecasts. In this case, a model other than the land-use model is used to forecast overall population and employment in the study area.

Third, a two-way arrow is also shown between the transportation network and travel forecasts. This represents the identification of projects and strategies as part of the planning process that will not only change the future transportation network but, over time, will affect land use as well.

Finally, the air quality emissions model and the benefit-cost analysis module are simply post-model analyses conducted to assess the air quality implications of the proposed plan and the benefits that will likely accrue.

Figure 3-8 shows another example from Denver, Colorado of the relationship between land-use forecasting and travel modeling. [DRCOG, 2010] In this case, the relationship between the two is simulated using an activity-based travel-demand model (ABM), which is one of the newer forms of travel demand models (see chapter 6). Instead of being based on trips like a traditional four-step model, ABMs represent the actual travel behavior of an individual over a specified period (for example, a day) and use travel tours to reflect the fact that many trips are made as a trip chain, with possibly many different intermediate stops. In this modeling framework, the location of future population is synthesized with a population synthesizer. In the Denver example, a forecast is developed of individual households and persons with detailed demographic characteristics for chosen year. The synthesizer uses two sets of control variables for household characteristics: regional-level controls and zonal-level controls (distributed with a land-use model). The synthesizer then distributes the households randomly within the zone it resides, and assigns socio-demographic characteristics that cumulatively match regional totals.

**Figure 3-8. Activity-Based Modeling and Land Use, Denver Example**



Source: Denver Regional Council of Governments, 2010

With regard to work location, the model takes all workers (as identified from the population synthesizer) and assigns them a regular work location zone and point. Characteristics of the worker and their home zone are used in combination with zonal characteristics to determine the desirability of any zone. For further information on the Denver model, see [DRCOG, 2010].

In sum, no matter what type of travel model is used, a strong linkage exists between land-use forecasts and the travel modeling process. Without having some sense of where households, people, and jobs will be located in the future, it would be very difficult to undertake travel demand modeling in a credible way.

## C. Distributing Population and Employment Among Study Zones

Once the change in overall population and employment has been estimated, the planner next distributes these amounts to the traffic analysis zones in the study area. Transportation planning agencies use different types of land-use models, or in some cases, rely on economic data analysis and local development expertise to forecast future land-use patterns. Some models can be very comprehensive with numerous submodels and mathematical relationships intended to represent the very complex evolution of a community's development patterns. Others rely on simplifications, or simply focus on the most important variables.

At least three generations of land-use modeling efforts can be identified from the practice in Western countries: (1) experimentation in the 1960s with a variety of modeling methods, (2) the emergence of large-scale simulation models in the 1970s, and, (3) currently, operational models that have evolved over the past 20 years and that have built on and extended the earlier models.

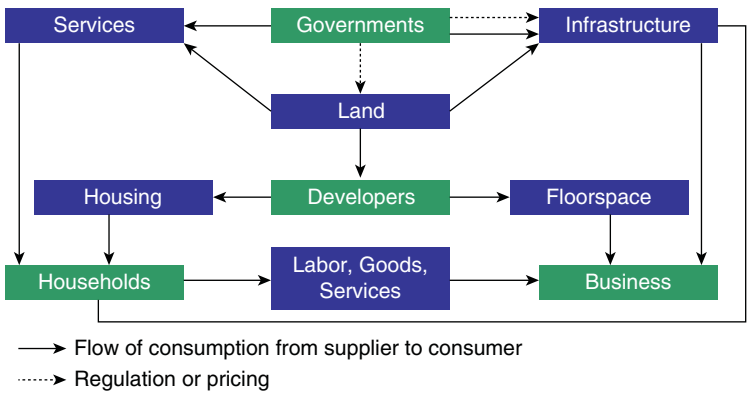
Of the various first generation models, the Lowry model has had by far the most enduring impact on the field. [Lowry, 1964] It is a heuristic model that iteratively allocates households to residential locations and retail or population-serving workers to employment locations, based on an exogenously supplied distribution of basic employment. Lowry models in various forms and of varying levels of complexity have been widely applied, although they are subject to a number of criticisms, including the lack of a dynamic structure and a lack of representation of urban land markets.

The key concept underlying the Lowry model is the definition of two classes of employment: retail and basic. Retail employment arises from all activities that are implicitly related to population and purchasing power. All activities for which a local market or service area can be identified for final products or services are in the category of retail employment. Major shopping centers and office complexes are example sources of retail employment. Basic employment is composed of everything else, that is, all those activities that are site-oriented in that their locations are dependent on factors other than the size and location of residence-oriented local market areas. Thus, for example, heavy industrial locations are considered to be sites of basic employment.

The model assumes that the basic employment in each zone of the urban area is exogenously determined. Given this base employment, the model allocates these workers to residential areas in the urban area using a work-to-residence distribution function. Then, given this residential distribution, the distribution of retail employment serving this population is similarly allocated using a resident-to-shop distribution function. These workers, in turn, must be allocated to residences, which then generate additional retail activity (employment) and so on. Thus, the model incorporates a multiplier effect in which each new employee (basic or retail) generates further retail employment, until the entire process converges to an equilibrium state.

The basic concept in the Lowry model (in a simplistic sense) and in more modern models is that key "agents" are making decisions that together over time result in land-use patterns. Figure 3-9 from the PSRC model, for example, shows four major "agents" that influence future population and employment locations—government, people or households, employers, and developers. In any given year of the land-use simulation model:

**Figure 3-9. Land-Use Modeling, Puget Sound Regional Council**



Source: Puget Sound Regional Council, 2012

- Developers use land to construct housing and nonresidential floor space demanded by households and businesses, which are also interacting in the labor market and in the markets for goods and services.
- Governments provide infrastructure and services, regulate, and, in some cases, alter prices for the use of land and infrastructure.
- Households, individuals, employers, developers, and governments are the key agents that respond to market forces.

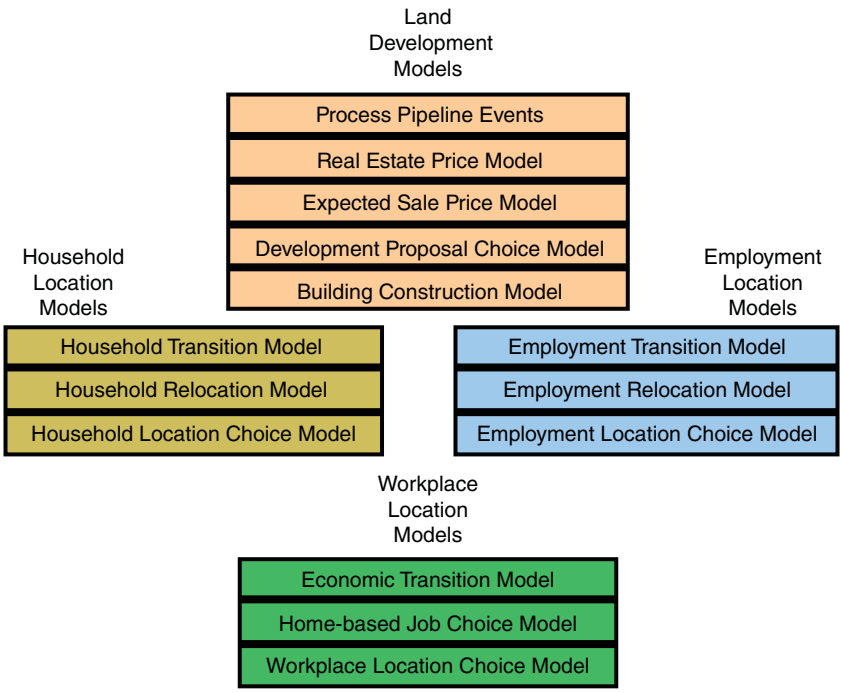
- Households make a cluster of interdependent long-term lifestyle choices, including when to move, neighborhoods to locate within, the type of housing to rent or purchase, and the number of vehicles to own. Individuals within households choose their labor force and educational status, their job mobility and job search, their daily activity schedule, their transportation mode, and route.
- Employers choose to start and close establishments, and choose site locations, size of employment, and types and quantities of real estate to rent or purchase.
- Developers choose to undertake real estate development projects, and the scale and locations of those projects.
- Governments set policies and make investments that affect the choices of other agents, and also make development choices regarding public facilities, including type, location, and scale of development. [PSRC, 2012]

These agents interact in a variety of ways to form future land-use patterns. For example, Figure 3-10 shows four models included within the modeling platform representing the decision process that occurs cumulatively within the overall model. Thus, for example, the model begins with a real estate price model, then proceeds to an expected sale price model, a development proposal choice model, and a building construction model. The intent of these models is to represent the availability of developable land and the corresponding land price. This then feeds into employer and household location decisions.

The basis for distributing population and employment among the zones in the study area—and one mathematically incorporated into land-use models—is the attractiveness of a particular location. The attractiveness of a location for a given activity depends on a wide variety of factors. For example, the attractiveness of a neighborhood as a residential location depends on characteristics such as: (1) the lot or house price, size, type, age, and quality of the available housing; (2) the quality and proximity of schools (if the household contains school-age children); (3) the availability of parks and other recreational facilities; (4) the extent to which the neighborhood is hazard-free (where hazards might include busy streets, noxious factories, and the like); and (5) the social-ethnic-racial composition of the neighborhood (and perceived trends in this composition). Similarly, the attractiveness of a location for a retail store depends on factors such as: (1) the availability of a suitable building for the store, (2) the location of the building relative to the street, (3) pedestrian flows and parking, (4) the rent for the building, (5) the expected market at the location for the goods being sold, and (6) the mix of retail stores currently located in the neighborhood.

In practice, the analysis is limited by the number of attraction attributes that can be specified and observed. The result is that surrogates, generally size variables (for example, total retail floor space in a zone as a measure of retail attractiveness

**Figure 3-10. Models Representing Development Decision Making, Puget Sound Regional Council**



Source: Puget Sound Regional Council, 2012

or total number of single-family housing units in a zone as a measure of residential attractiveness), are used in place of more specific behavioral variables.

Attractiveness is also influenced by *accessibility,* which typically provides the basis for the transportation component of urban activity or land-use modeling. Accessibility is generally defined as some aggregate measure of the size and closeness of activity opportunities of a given type to a particular location. For example, in characterizing the accessibility of a residential zone $i$ to retail shopping opportunities, a common measure used is:

$$A_i = \sum_{j=1}^{n} F_j^{\alpha} e^{-\beta t_{i,j}} \tag{3-1}$$

where,

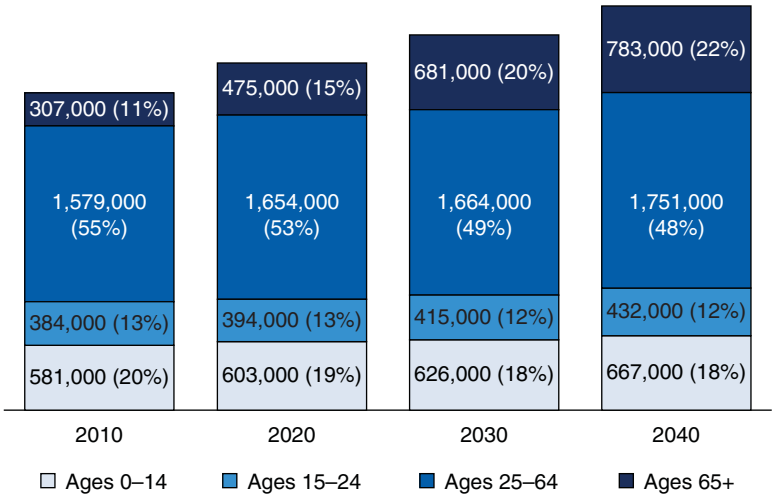
$A_i$ = accessibility of zone $i$ to shopping opportunities
$F_j$ = amount of retail floor space in zone $j$
$t_{ij}$ = travel time from zone $i$ to zone $j$
$n$ = number of zones with retail stores
$\alpha$ = parameter indicating the relative sensitivity of accessibility to store size ($\alpha > 1$)
$\beta$ = parameter indicating the sensitivity of trip-making to travel time (the larger $\beta$ is in magnitude, the less likely people are to travel long distances to shop)

As indicated in equation 3-1, it is assumed that location choice is positively correlated with accessibility. That is, it is assumed people would like to have more accessibility than less to shopping and employment opportunities, retail stores would like to be highly accessible to high-income households, and so on. The negative exponent to the travel time variable in equation 3-1 indicates that as the travel time between residential locations and shopping increases, the level of accessibility decreases. Similarly, the larger the value of $F$ in the equation, the amount of retail space, the more desire there is for residents to travel to that location.

The output of land-use forecasting provides travel models with the expected location of population and employment sites in the study area for the target year, as well as interim years. The following list and Figure 3-11 from the Metropolitan Council (Met Council) in the Twin Cities, Minnesota note the typical information produced by a regional forecast.

- According to the latest regional forecast, the Twin Cities region will gain 783,000 residents over the next 30 years, bringing the total population of the region to 3.6 million in 2040.
- By 2040, the Twin Cities region will experience three major demographic shifts. The population will be, (1) more racially and ethnically diverse, (2) older, and (3) more likely to live alone.

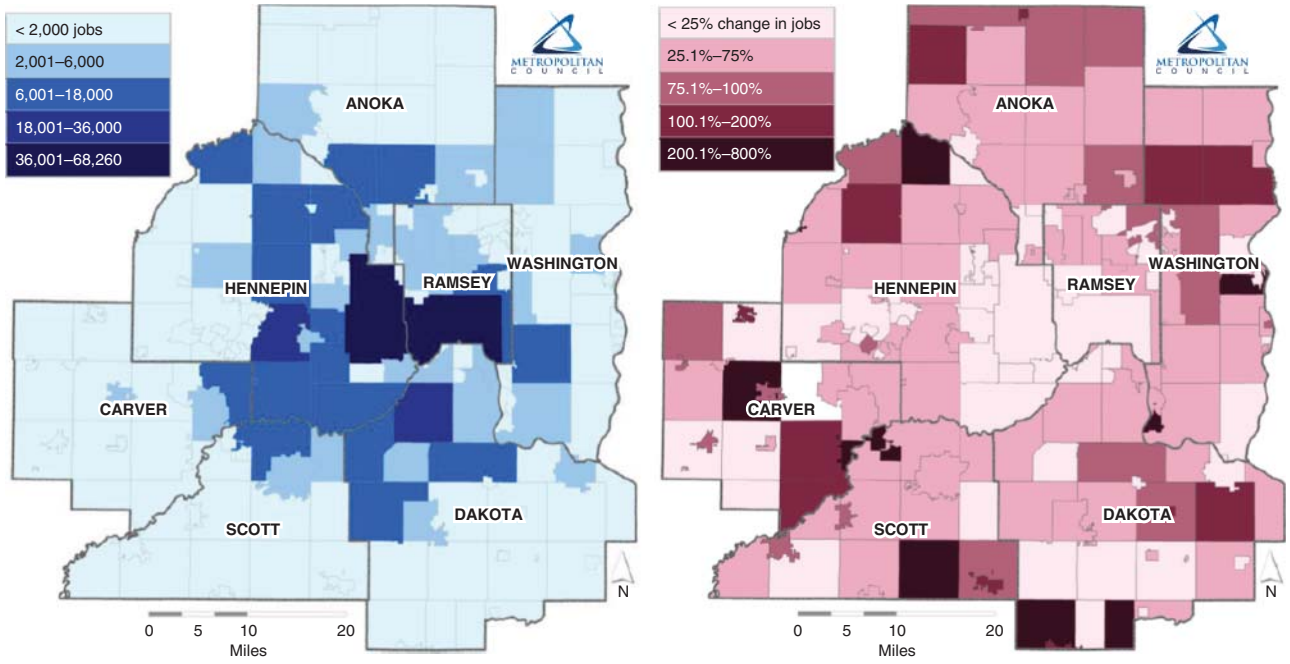
**Figure 3-11. Population by Age Group, 2010–2040, Metropolitan Council, Minneapolis-St. Paul, Minnesota**



Source: Metropolitan Council, 2015a

- Jobs and economic opportunity attract people to the Twin Cities region. The churn of people moving to and from the Twin Cities region is increasing the racial and ethnic diversity of the workforce and schools.
- The housing needs and preferences of older adults—residents over age 65—will significantly reshape the region's housing market.
- The Twin Cities region will add 468,000 jobs, bringing the total number of jobs to over 2 million by 2040. [Met Council, 2015]

**Figure 3-12. Change in Employment, 2010–2040, Metropolitan Council, Minneapolis-St. Paul, Minnesota**



Source: Metropolitan Council, 2015b

Figure 3-12 shows typical results of the distribution phase of land-use modeling, again from the Metropolitan Council. In this case, the figure shows the distribution of new jobs both on an absolute change basis and on a percentage basis.

Figure 3-13 from the Southeastern Wisconsin Regional Planning Commission (SEWRPC), the MPO for the Milwaukee, Wisconsin, metropolitan area, shows another common characteristic of population/employment forecasting and land-use modeling. As shown in the figure, the forecasted employment is viewed from three scenarios, each representing different assumptions as to growth rates, state of the economy, and other variables that might make the Milwaukee area more or less attractive for population and employment. [SEWPRC, 2013] The figure depicts the projected changes in employment under each scenario for both the metropolitan region and one of the MPO member counties. Use of scenarios will be further discussed in the following section.

While it is beyond the scope of this chapter to describe in detail each of the land-use models available in practice today, this section has, nevertheless, provided a very brief overview of the major concepts as to how land-use forecasting is conducted. The transportation planner should be careful when considering a land-use model to understand: (1) the data requirements for each candidate model, (2) the amount of staff resources necessary to calibrate and use the model, (3) the underlying logic of the land development decision-making process embedded in the model, and (4) the level of integration to travel forecasting. In some cases, formal land-use models will make sense; in other situations, scenarios or expert panels might very well suffice to provide the information necessary to conduct transportation planning.

Land-use models are constantly evolving and are continuously being updated by model developers. Several papers and books provide more detailed comparisons of available land-use transport models (see, for example, see [Hunt, Kriger and Miller, 2005; Meyer and Miller, 2014; Waddell, 2011; and Zhao and Chung, 2010]). Thus, planners interested in the latest characteristics of a particular land-use model should examine the most recent documentation for that particular model to see recent enhancements. In particular, most MPOs provide documentation of their land-use forecasting methodology and assumptions. A representative set of documentation includes:

- Atlanta Regional Commission (ARC). 2014a. "Regional Forecasting (Socio-economic Allocation)," http://www.atlantaregional.com/info-center/forecasts/forecast-development.
- Denver Regional Council of Governments (DRCOG). 2010. "Focus Model Overview," https://drcog.org/sites/drcog/files/resources/FocusOverview_WebVersion.docx.
- Metropolitan Council (Met Council, Minneapolis-St. Paul). 2015a. "The Regional Forecast to 2040," http://www.metrocouncil.org/Data-and-Maps/Publications-And-Resources/MetroStats/Census-and-Population/Steady-Growth-and-Big-Changes-Ahead-The-Regional-F.aspx.

**Figure 3-13. Forecasted Employment, Southeastern Wisconsin Region and Kenosha, Wisconsin**

- Southeastern Wisconsin Regional Planning Commission (SEWRPC, Milwaukee). 2013. *The Economy of Southeast Wisconsin*. http://www.sewrpc.org/SEWRPCFiles/Publications/TechRep/tr-010-5th-ed-economy-se-wisc.pdf.
- Southern California Association of Governments (SCAG, Los Angeles). 2010. "Growth Forecast," http://rtpscs.scag.ca.gov/Documents/2012/final/SR/2012fRTP_GrowthForecast.pdf.

In addition, the FHWA manages a website that provides information on the latest developments in land use and transportation planning, which provides a good source of up-to-date information. The website can be found at: http://www.fhwa.dot.gov/planning/processes/land_use/.

## VI. SCENARIO ANALYSIS FOR URBAN FORM

Instead of formal land-use models, many planning agencies use some form of a scenario-based approach or other subjective techniques to predict future land-use patterns. Land-use scenarios can represent different types of desired land-use patterns, for example, more clustering of development around transit stations, encouraging new development to locate in established cities and towns, or expecting infill development in more established communities in the region. Figure 3-14 shows a summary of the process used by a travel modeling effort from Fredericksburg, Virginia, that included land-use scenarios in the methodology.

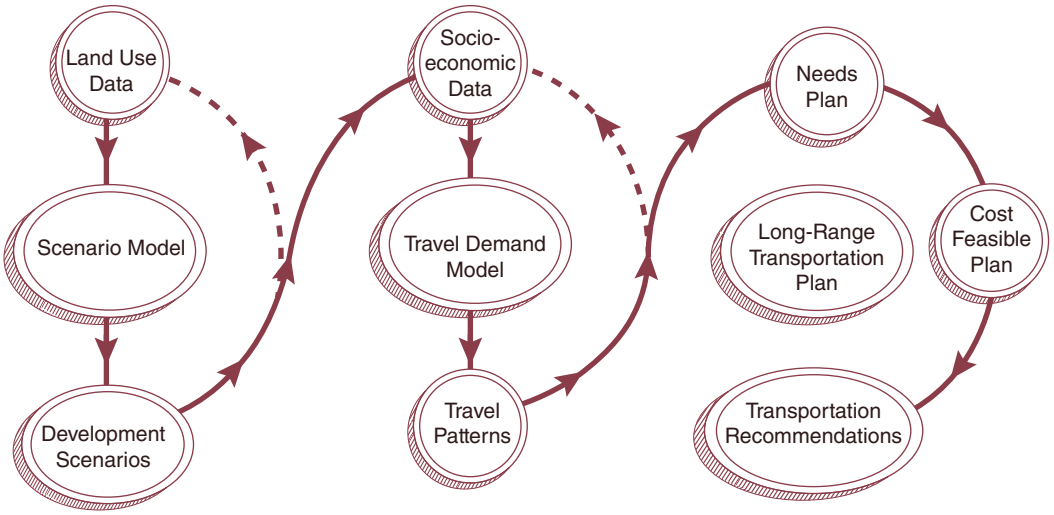
The project team established two focus groups, one with business and development interests (to identify factors that make land more attractive to development) and a second with chief planners and public works officials (to identify the effect of local land development policies and available infrastructure on future development patterns and intensities). Three citizen workshops were held to capture community values and attitudes toward growth in the region. An online survey captured residents' perceptions toward growth and long range planning. A project steering committee was established to provide direct oversight and counsel in the planning process. All of this input led MPO planners to prepare four alternative growth scenarios. Each scenario was sufficiently different to allow for real choices to be made on how the region could develop under one or more planning initiatives (see Figure 3-15). The four growth scenarios were identified as:

- Decentralized Growth
- Compact Centers & Growth Corridors
- Green Print Initiative
- Greater Jobs-Housing Balance

Table 3-5 shows how the different scenarios relate to the 24 performance measures identified by the planning study. As seen in the table, providing incentives for jobs and housing to be located closer together is found to be the most effective in meeting study objectives, a result which has been echoed in many other studies.

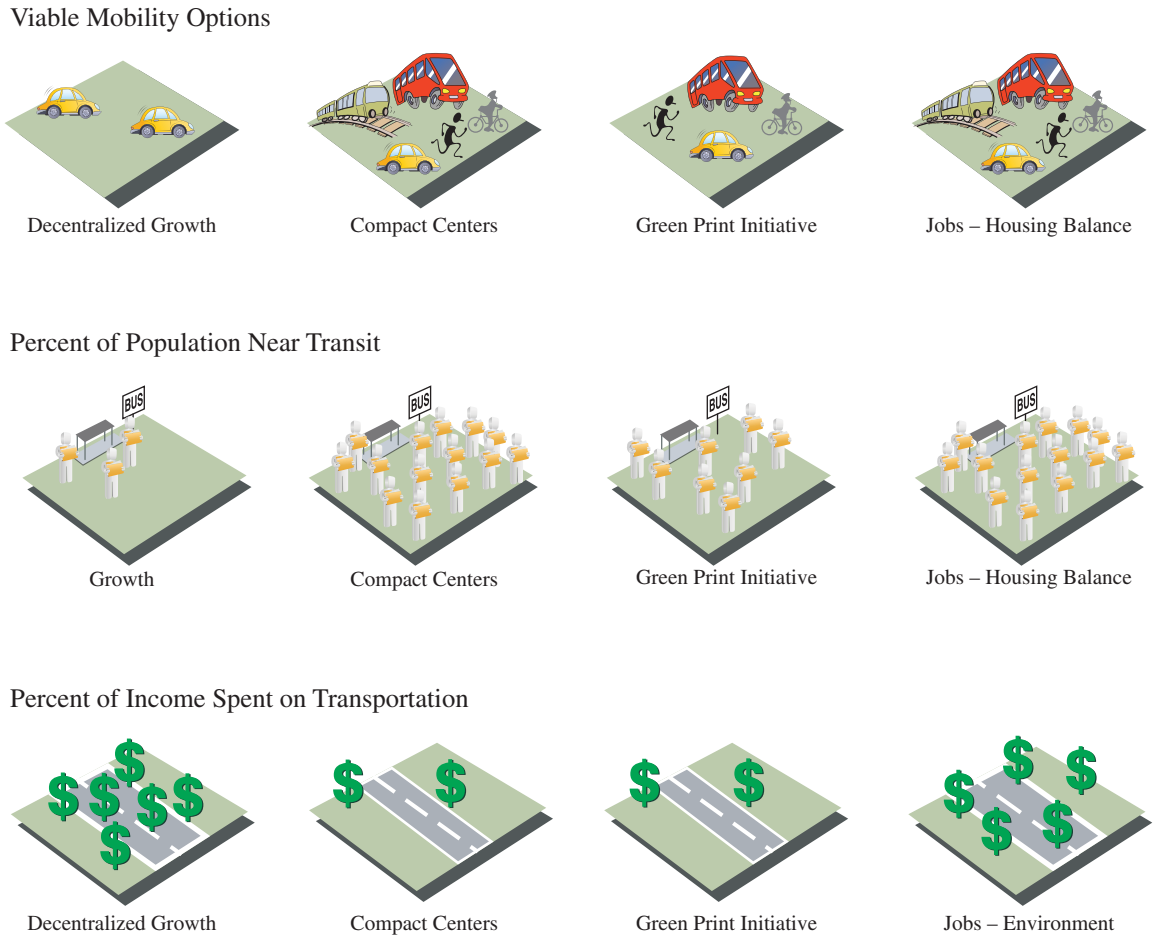
**Figure 3-14. Use of Scenarios in Travel Forecasting, Fredericksburg, Virginia**

General Process Diagram



Source: FAMPO, 2013

**Figure 3-15. Scenario Characteristics, Fredericksburg, Virginia**



Source: FAMPO, 2013

A 2005 review of scenario planning experience in the United States showed its widespread utilization among planning agencies. [Bartholomew, 2005] Tables 3-6 to 3-9 show different characteristics of the scenarios and their evaluation found in this review.

Scenario analysis shows the expected transportation implications for different types of land-use patterns, or of different population characteristics. [Zmud et al., 2014] Decision makers can adopt one scenario or a combination of scenarios as the desired future land-use pattern and can provide investment in transportation facilities and services that would best lead to such a future.

## VII. HIGHWAY FACILITY-RELATED STRATEGIES

At a regional or community scale, land-use strategies can influence the amount of travel occurring in a transportation system and the flows occurring on the network. At the individual facility level, land-use considerations can also have an effect on road performance and safety. Two strategies, in particular, have been used by transportation planners and engineers to improve facility operations and design characteristics: access management and context sensitive solutions (CSS). Both of these strategies are discussed in detail in ITE's *Traffic Engineering Handbook* [Pande and Wolshon, 2016], as well as in chapter 9 of this handbook. The following sections provide an overview of both from the perspective of how land-use considerations are incorporated into project-level planning.

### A. Access Management

Many different types of transportation and land-use strategies can be considered as part of the transportation planning process. It is beyond the scope of this chapter to describe each in detail. However, one strategy clearly links land

use, urban design, and transportation issues at the facility level, this being access management. It is a basic tenet of transportation engineering that site access should maintain the operational integrity of the surrounding road system. This can be best achieved by applying access management principles and designs.

Access management provides or (manages) access to land development while simultaneously preserving the flow of traffic (safety, capacity, and speed) on the surrounding road system. It consists of the systematic control of the location, spacing, design, and operation of driveways; median openings; interchanges; and street connections to a roadway. It also includes applications such as median treatments, auxiliary lanes, and the appropriate spacing of traffic signals. [ITE, 2010a]. An important access management objective is to ensure that the cumulative effects of a series of closely spaced, uncoordinated developments do not deteriorate safety and mobility on the surrounding road system.

Key elements of access management include defining allowable access for various types of roadways, establishing spacing of traffic signals and driveway connections, providing a way to grant variances when reasonable access cannot otherwise be provided, and establishing a means of enforcing standards. The degree of access control and management is determined by statute, deed, zoning, and operational and geometric design standards. Comprehensive statewide access management codes are found in several states including Colorado, Florida, Minnesota, New Jersey, Oregon, and South Dakota. [Committee on Access Management, 2003]

*Access management codes and ordinances* specify when, where, and how access can be provided to developments along a roadway. Access classification systems, an integral part of these programs, give the relevant access with spacing guidelines. They relate the allowable access to each roadway's purpose, importance, and functional characteristics. A functional classification system provides the starting point in assigning highways to access categories. Modifying factors include development density, driveway density, and geometric design features, such as the presence or absence of a median. Additional guidelines for access management are set forth in the *Access Management Manual*. [Committee on Access Management, 2003]

NCHRP Report 548, *A Guidebook for Including Access Management in Transportation Planning*, provides useful recommendations on how access management can be better integrated into the transportation planning process. [Rose et al., 2005] Specifically, this guidebook recommends the following steps for an effective access management program:

- Develop and apply an access classification system that assigns access management standards to roadways in accordance with their level of importance to mobility. This system generally parallels the roadway functional classification system.
- Plan, design, and maintain road systems based on this access classification system and related road geometry.
- Define the level of access permitted to each classification, which includes the following:
  - Permitting or prohibiting direct property access.
  - Allowing for full movement, limited turns, and median.
  - Designating the type of traffic control required such as signal, raised median, or roundabout.
- Establish criteria for the spacing of signalized and nonsignalized access, as well as access setback distances from intersections (corner clearance) and interchanges.
- Apply agreed-upon engineering standards that include appropriate geometric design criteria and traffic engineering measures to each allowable access point or system of access points.
- Establish policies, regulations, and permitting procedures to implement the listed components.
- Ensure coordination with and supportive actions by local jurisdictions exercising their land-use planning authority as well as their development permitting and review authority.

More detailed information on access management from an engineering perspective is found in ITE's *Traffic Engineering Handbook*. [Stover and Williams, 2016]

## B. Context-Sensitive Solutions (CSS)

An important trend in project development in the past decade—and one that links closely to urban design and land-use issues—has been the increasing consideration of the context within which design occurs. [McCann, 2013] Referred to as context-sensitive design (CSD) or CSS (to reflect a broader perspective on potential problem solutions), this approach to design is defined by the FHWA as "a collaborative, interdisciplinary approach that involves all stakeholders to develop a transportation facility that fits its physical setting and preserves scenic, aesthetic, historic, and environmental resources, while maintaining safety and mobility."[FHWA, 2006]

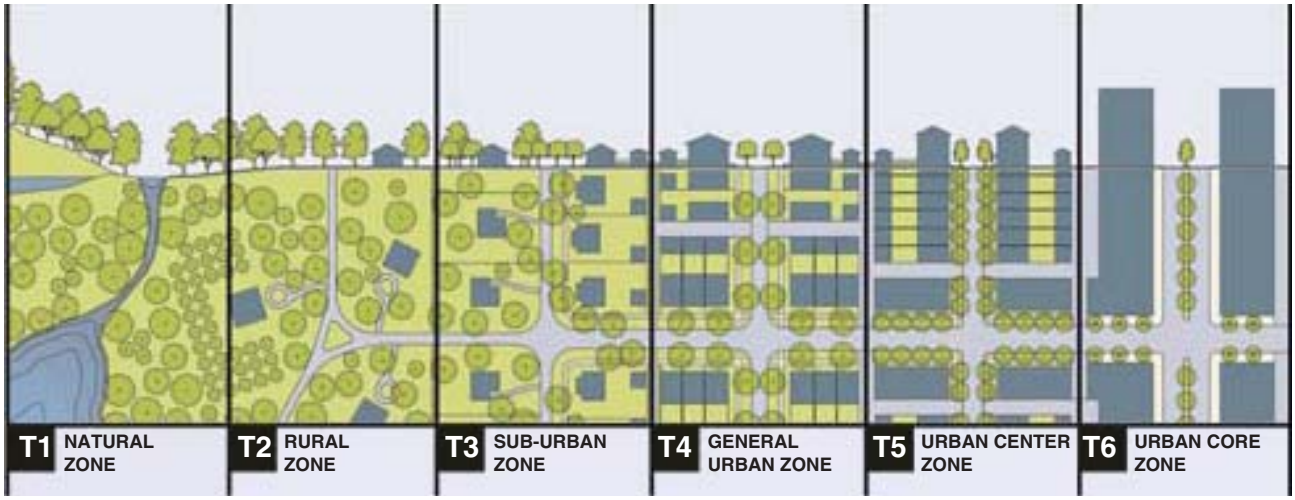
As noted in an NCHRP report, "CSD recognizes that a highway or road itself, by the way it is integrated within the community, can have far-reaching impacts (positive and negative) beyond its traffic or transportation function. The term CSD refers to as much an approach or process as it does to an actual outcome." [Neuman et al., 2002] This chapter uses the term CSS because much of the broad context for transportation facility design in urban areas is defined by the land use and community character surrounding the project. CSS is important to planning practitioners because it describes the best strategies of how to combine the principles or solve the conflicts of urban design and engineering design. Chapter 9 on road and highway planning also presents material on CSS.

Fundamental to CSS approaches is an urban planning concept called the urban-to-rural transect, developed by New Urbanist Andrés Duany. [Duany et al., 2009] As shown in Figure 3-16, the transect represents a transition in development environments ranging from open land to higher density development patterns. Importantly to transportation planners, this transition could also mean a different style of road design, transit service provision, and accommodation of pedestrians and bicyclists. Some communities and professional organizations (such as ITE) have developed guidance based on the transect as it relates to everything from functional classification to geometric design.

The Maryland State Highway Administration outlined the basic characteristics of a highway CSS approach, which included the following: [Maryland State Highway Administration, 1998]

- The project satisfies the purpose and needs as agreed to by a full range of stakeholders. This agreement is forged in the earliest phase of the project and amended as warranted as the project develops.
- The project is a safe facility for both the user and the community.
- The project is in harmony with the community and preserves environmental, scenic, aesthetic, historic, and natural resource values of the area.
- The project exceeds the expectations of both designers and stakeholders and achieves a level of excellence in people's minds.

**Figure 3-16. Rural to Urban Transect and Linkage to Transportation**



Source: Photo courtesy of DuanyPlater-Zyberk & Company via CATS

- The project involves efficient and effective use of resources (time, budget, and community) of all involved parties.
- The project is designed and built with minimal disruption to the community.
- The project is seen as having added lasting value to the community.

According to ITE's Recommended Practice *Designing Walkable Urban Thoroughfares: A Context Sensitive Approach,*

> *"Applying the principle of CSS enhances the planning and design process by addressing objectives and considerations not only for the transportation facility, but also for the surrounding area and its land uses, developments, economic and other activities, and environmental conditions. With a thorough understanding of the CSS principles and design process, the practitioner planning or designing a thoroughfare seeks to integrate community objectives, accommodate all users and make decisions based on an understanding of the trade-offs that frequently accompany multiple or conflicting needs."*
>
> *[ITE, 2010a]*

At the thoroughfare *network planning level*, CSS concepts include:

- Multimodal network planning should be integrated into long-range comprehensive plans that address land use, transportation, and urban form.
- Network planning should address mobility and access needs associated with passenger travel, goods movement, utilities placement, and emergency services.
- Reserving right of way for the ultimate width of thoroughfares should be based on long-term needs defined by objectives for both community character and mobility.

For *street connectivity and spacing*, CSS concepts include:

- Networks should provide a high level of connectivity so that drivers, pedestrians, and transit users can choose the most direct routes and access urban properties. Connectivity should support the desired development patterns. Networks should provide intermodal connectivity to easily transfer between modes.
- Intersperse among arterial thoroughfares a system of intermediate collector thoroughfares serving local trips connecting neighborhood and subregional destinations.
- Expand the typical definition of collectors to recognize their role in connecting local origins and destinations to distribute trips efficiently, keep short local trips off the arterial system, and provide a choice of routes for transit, pedestrians, drivers, and bicyclists.
- Build network capacity and redundancy through a dense, connected network rather than through an emphasis on high levels of vehicle capacity on individual arterial facilities. This approach (having more thoroughfares rather than wider thoroughfares) ensures that the network and thoroughfare facilities can support other objectives, such as pedestrian activity, multimodal safety and support for adjacent development.
- Minimize property access directly onto arterials through design of a connected network of closely spaced arterial and collector thoroughfares and local street connections. With fewer driveway-type interruptions, arterial thoroughfares can perform more efficiently for vehicles and for pedestrians. Thus, network connectivity can provide a foundation for access management strategies to increase corridor capacity and accessibility.

With respect to CSS-related characteristics for choosing *performance measures*:

- Select transportation performance measures that reflect stakeholder objectives and priorities for the system or facility being planned or designed. Some of these might not be strictly transportation measures, but include economic development and other types of measures.
- Use performance measures that recognize all modes.

- Performance goals can vary for different parts of the network as long as direct comparisons are made to the same measures.
- Performance measures could include conventional measures of vehicle congestion, capacity and density, considered at a network-wide or corridor-wide level.
- To reflect walkability and compact development, consider measures such as a connectivity index, intersection density measures, and pedestrian environment measures.
- Selected performance measures should include measures of safety for all users.

For those desiring more information on how CSS principles and approaches can be incorporated into transportation planning and design, the ITE *Recommended Practice* is strongly recommended as an excellent source of information, as is the FHWA CSS toolbox website at http://contextsensitivesolutions.org/content/topics/misc/fhwa-toolbox/. In addition, the reader is referred to chapter 9 on road and highway planning.

For neighborhood street design and CSS principles, the reader is referred to ITE's *Recommended Practice on Neighborhood Street Design, Guidelines*. [ITE, 2010b] Neighborhood-level CSS project descriptions can be found at: www.contextsensitivesolutions.org.

## VIII. SUMMARY

The connection between land use and transportation planning has been a fundamental relationship that has guided both the process of planning as well as the technical tools planners and engineers rely on. For many years, land-use factors were considered by transportation planners only as inputs into the modeling process. In recent years, however, land-use and urban design strategies have become important components of the tools that planners and elected officials can use to enhance community accessibility and mobility. This chapter has provided an overview of the land use–transportation relationship that is so important to the transportation planning process.

Information on future levels of population and employment and their location in a study area is a basic point of departure for conducting most transportation studies. In addition, transportation at the local level will be strongly influenced by the type and magnitude of development that will occur in compliance with local comprehensive plans and zoning ordinances. Given the importance of this land use–transportation relationship to successful transportation planning, it is important that the agencies or units within an agency responsible for land-use forecasting and transportation modeling work closely together to ensure that the transportation planning process has a strong foundation for estimating future travel.

The following lessons learned from a scan of U.S. land use–transportation studies provide some useful guidance on the steps that might be necessary to provide an integrated land use–transportation planning process:

- Individual methods developed for the coordination of transportation planning and land-use policies differ by community. Lessons and best practices can be shared, but ultimately, successful solutions should be the result of local needs and local processes and should respect local values.
- Planning efforts that fail to include sufficient public outreach and participation are unlikely to succeed. Any planning efforts—particularly innovative efforts—that move ahead without sufficient attention to public involvement and concurrence can generate discord and delay implementation.
- Physical design matters as much as good planning. Planning alone is not sufficient to create a successful development that integrates transportation and land use in a way that will attract new users and residents. The aesthetic appearance, the ease of use, and the connectivity of design are all important factors.
- The financial needs of a project and the levels of available funding should be tentatively calculated and then revisited throughout the planning process. Many multimodal transportation and infrastructure projects are completed in stages, with each component planned and financed independently. Such incremental projects lend themselves to the use of multiple sources of funding, each source dedicated to a different aspect of the project.

- The local development climate will strongly influence efforts to coordinate transportation and land-use planning. To be effective, planning should take into account the realities of the private- development environment, including issues of financing, demand, and timing. In these ways, public projects are linked to patterns of private development.
- Ideas should be presented in ways that make sense for a particular community. Creative planning efforts should find ways to present ideas—particularly contentious ideas—in locally acceptable language and context. The political and cultural environment varies by community, and planning projects should use a vocabulary that resonates in the community in which it will be used. [FHWA, 2003]

As noted in the resulting report, "Innovative planning ideas can move beyond established processes and regulations, requiring old policies to be revised and updated. New methods of planning and visioning, particularly those that are grounded in community participation, can present a challenge to established planning regulations. Innovative proposals may be stymied in their efforts to move ahead because of existing zoning and transportation policies, which are often geared toward large-lot, low-density, automobile-oriented development … With time, new and innovative planning processes must be integrated into the existing systems of planning in order to maintain the strength of the established planning processes while allowing for new methods to be explored." [FHWA, 2003]

# Environmental Considerations[1]

## I. INTRODUCTION

It would be hard to find an issue that has engaged transportation planners more during the past 50 years than the potential impacts of transportation system performance and facility construction on the natural and built environment. Since the late 1960s and early 1970s, the transportation planning process at all levels has been guided by laws and regulations governing the impacts that need to be considered as part of decision making, and that often identify the methods of analysis to be used. In addition, the transportation planning process in the United States has been closely tied to the attainment of air quality goals in metropolitan areas whose air quality does not meet national air quality standards.

Many governments throughout the world have passed laws and created regulations to protect and enhance the environment. Specific rules guide their application to the development and operation of infrastructure, including transportation projects. While these laws and regulations vary by country and jurisdiction, this chapter references U.S. environmental laws and regulations to illustrate general principles and practices and to provide a framework for discussion. It also focuses on highway and transit project development processes, with the understanding that other types of transportation facilities, such as airports and maritime and port facilities, follow comparable processes.

Two scales of planning applications merit attention when discussing the relationship between environmental factors and transportation planning. The first is the broader transportation planning occurring at the statewide, metropolitan, or corridor level. This planning is often not project-specific (except for many corridor studies), and thus insufficient engineering is done to identify the types of environmental impacts likely to occur. The second type of planning, which is more closely related to project development, provides a much more detailed analysis of the likely consequences of project alignment and operating decisions. This planning usually includes sufficient conceptual engineering detail to determine the types and magnitudes of environmental impacts likely to be encountered during project construction and operation, as well as what might be needed to mitigate them.

An important policy discussion in recent years has been how to provide a closer linkage between the two scales of analysis, such that information produced in the planning process can be used in project-specific planning to avoid duplication of effort. (This approach is often referred to as environmental streamlining.) Both types of planning will be discussed in this chapter.

This chapter describes the role of environmental impacts and consequences in the transportation planning process. The intent is to discuss ways to incorporate environmental considerations in the planning process so that decisions made early in the process will remain valid for later environmental regulatory reviews and documentation. This chapter also discusses considerations for determining the appropriate level of detail for environmental analysis and documentation during planning. The second section provides an overview of the role environmental considerations play in transportation policy and decision making, followed by general principles that should guide them. The next several sections present more detailed information by impact category, followed by construction-related environmental effects. The final two sections describe how to assess and document mitigation strategies in the systems planning process.

## II. ENVIRONMENTAL CONSIDERATIONS IN TRANSPORTATION PLANNING AND DECISION MAKING

As will be seen in subsequent sections, environmental considerations are found throughout the transportation planning and decision-making processes. The following paragraphs discuss four major concept/linkages that are found in

[1] The original chapter in Volume 3 of this handbook was written by Greg Benz, Senior Vice President, WSP/Parsons Brinckerhoff. Changes made to this updated chapter are solely the responsibility of the editor.

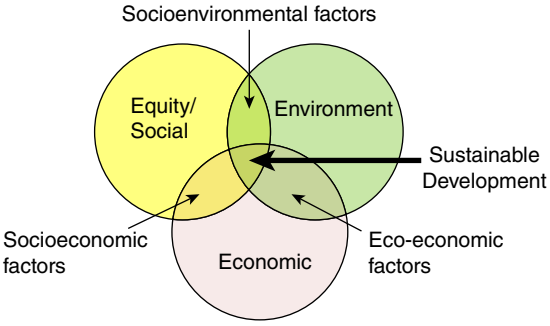
most current practice: sustainability, environmental considerations at the systems level, environmental considerations in project development, and linking the latter two, as one progresses from systems planning to project development.

## A. Sustainability

Sustainability, or sustainable development, has received increasing focus as a desirable societal goal since the mid-1980s, when a United Nations commission defined sustainable development as "meeting the needs of the present without compromising the ability of future generations to meet their own needs." [United Nations World Commission on Environment and Development (Brundtland Commission), 1987] This definition was further refined to include the Triple Bottom Line of economic development, social equity, and environmental quality, defined by the American Association of State Highway and Transportation Officials (AASHTO) as follows and shown in Figure 4-1.

**Figure 4-1. Triple Bottom Line of Sustainability**



- Economy—Support economic vitality while developing infrastructure in a cost-efficient manner. Costs of infrastructure must be within a society's ability and willingness to pay. User costs, including private costs, need to be within the ability of people and households to pay for success.
- Social—Meet social needs by making transportation accessible, safe, and secure; include provision of mobility choices for all people (including people with economic disadvantages); and develop infrastructure that is an asset to communities.
- Environment—Create solutions that are compatible with—and that can be an enhancement to—the natural environment, reduce emissions and pollution from the transportation system, and reduce the material resources required to support transportation. [AASHTO, 2009]

What sustainability means to transportation agencies, and in particular to the transportation planning process, will vary from one jurisdiction to another. [Booz Allen Hamilton, 2014] For example, an AASHTO report on sustainable transportation identified a range of actions shown in Table 4-1 that could provide a more sustainable transportation system.

Many transportation agencies have adopted a variety of policies and tools that support some elements of sustainability, such as context-sensitive solutions (discussed in chapter 3), Complete Streets, asset management, access management, congestion management systems, pavement management systems, environmental analysis for requirements of the National Environmental Policy Act (NEPA), economic analysis of transportation projects and system improvements, and a broadened approach to planning and to project development. Many of the building blocks for Triple Bottom Line sustainability are in place—but they need to be refined, expanded, fully embraced, and integrated.

The performance measures used by states and regions to monitor progress in achieving community goals and objectives can also reflect a sustainability theme. For example, the following transportation system metrics from the Maryland Department of Transportation are good examples of how sustainability can be incorporated into the capital program and operations of a transportation agency. [Maryland DOT, 2013]

**Goals: Quality of Service; Connectivity for Daily Life**

- Percentage of the Maryland State Highway Administration (SHA) network in overall preferred maintenance condition.
- Percent of roadway miles with acceptable ride quality.
- User cost savings for the traveling public due to incident management.
- Percentage of state-owned roadway directional miles within urban areas that have sidewalks and percent of sidewalks that meet Americans with Disabilities Act compliance.

| Table 4-1. Sustainable Objectives and Transportation Options | |
|---|---|
| **Sustainable Objective** | **Examples of Options** |
| Reduce energy consumption | Traffic signal coordination/optimization<br>Low-energy lighting<br>Dedicated transit lanes<br>Bike lanes<br>Transit signal priority |
| Reduce consumption of material resources | Recycled aggregates<br>Narrow traffic lanes<br>Fewer luminaire poles/catenary lighting system<br>Higher-strength concrete pavements<br>Precast or modular construction elements |
| Reduce impacts to environmental resources | Rain gardens for storm water infiltration<br>Diverse plant/tree selections<br>Storm water infiltration basins in planter strips<br>Porous pavement<br>Wildlife crossings |
| Support vibrant urban communities | Noise-reducing pavement materials<br>Public art<br>Pedestrian refuges in medians<br>Emergency vehicle access |
| Support sustainability during implementation | Reclamation of demolition materials<br>Use of renewable fuels for construction equipment<br>Use of locally obtained materials<br>Access to affected businesses<br>Minimize construction "footprint" |

Source: AASHTO, 2009, Reproduced with permission of AASHTO.

- Percentage of state-owned roadway centerline miles with a bicycle level of comfort grade "D" or better and directional mileage of SHA-owned highways with marked bike lanes.
- Travel demand management and transit service quality.

**Goal: System Preservation and Performance**

- Percentage of the SHA network in overall preferred maintenance condition.
- Number of bridges and percent that are structurally deficient.

**Goal: Safety & Security**

- Number of bicycle and pedestrian fatalities and injuries on all Maryland roads.
- Number of high-crash locations.
- Annual number of traffic fatalities and personal injuries on all roads in Maryland.

**Goal: Environmental Stewardship (including climate stewardship)**

- Amount of transportation-related greenhouse gas emissions.

As can be seen in this list, many of the transportation-related sustainability metrics pertain to the natural environment, and do not reflect the other dimensions of sustainability, that is, economic development and societal equity. This is fairly common in the transportation field and is an area where further thought and research are necessary.

Sustainability presents an opportunity for transportation agencies to engage customers and elected officials in crafting management, policy, and public outreach approaches that emphasize triple bottom line (TBL) sustainability values. If done well, and with effective public engagement, sustainability provides an opportunity for increasing transportation agency credibility with the public and elected officials.

Those interested in knowing more about sustainability and transportation are referred to TRB, 2004; USEPA, 2011; FHWA, 2011; ITE, 2013; and the following websites:

- Sustainable Highways Initiative, Federal Highway Administration, http://www.sustainablehighways.dot.gov/.
- Transit's Role in Environmental Sustainability, Federal Transit Administration, http://www.fta.dot.gov/13835_8514.html.
- Sustainability, Center for Transportation Excellence, American Association of State Highway and Transportation Officials, http://environment.transportation.org/environmental_issues/sustainability/recent_dev.aspx.

Later sections discuss so-called "green" analysis tools that can be used to improve the sustainability characteristics of transportation projects.

## B. Environmental Considerations at the Systems Level

Various types and levels of transportation planning support the development of a state's or region's transportation policy and plans. Transportation planning studies help decision makers select the most effective solution to an identified problem in the context of agreed-upon goals and objectives. The planning process should begin by identifying potentially contentious issues and resolving these issues prior to the more detailed project development/preliminary engineering and final design stages, where a major flaw could set back a project several years. A transportation study should examine an appropriate combination of transportation technologies, capacity enhancements, transportation control measures, optional alignments, and transportation system configurations in a given corridor, region, or subarea. The study should then evaluate these strategies in terms of transportation impacts, capital and operating costs, a range of environmental impacts (appropriate to the level of detail to which the strategies are defined), cost-effectiveness or cost benefit, and financial feasibility. The study should yield sufficient information for decision makers to determine which transportation strategies or plan alternatives best meet the goals and objectives. The level of environmental analysis in such planning reflects the scale and level of specificity associated with the study focus.

An example of the types of issues considered in a systems-level planning effort is found in the technical guidance for major capital investments from the Federal Transit Administration (FTA). This guidance notes that systems planning should give adequate consideration to systemwide and regional issues, including the interdependence of corridors in terms of travel demand, system design, and operations; the feasibility of various mode and alignment combinations in each corridor in terms of engineering, cost, operations, and environmental impacts; and the region-wide financial implications of various investment levels in each corridor.

Corridor-level transportation planning studies typically result in a set of strategies or projects in a metropolitan area's transportation plan, and often in a decision to proceed with more detailed project analysis. Such projects should be defined in terms of design concept and scope. There should be sufficient detail to enable the resulting regional plan, composed of many projects and strategies, to meet the requirements of various systems-level environmental analyses, such as regional air quality conformity analyses (see chapter 17 on corridor planning).

Figure 1-1 in chapter 1 offered a framework for transportation planning that represents the major steps in the planning process. Specifically, it suggests that transportation planning include efforts to understand the problems and challenges facing a community or region; establish a future vision; identify desired goals, objectives, and performance measures; conduct technical analysis of different alternatives; evaluate each alternative to develop a sense of which ones were more cost-effective; implement recommended actions; and monitor system performance. These steps are repeated through an iterative process to reflect new transportation challenges facing the jurisdiction. Table 4-2 shows possible linkages between environmental considerations and these major steps in a transportation planning process.

The Metropolitan Transportation Commission (MTC) of the San Francisco Bay Area provides a good example of how environmental considerations can be incorporated into systems planning. By state law, regional plans in California are

| Table 4-2. Environmental Factors in Transportation Planning | |
|---|---|
| **Planning Step** | **Consideration of Environmental Factors** |
| Visioning | A community's vision should include explicit consideration of desired environmental characteristics. This could include targeted resources (for example, air or water quality), geographic areas (for example, wetlands or habitats), or a more general quality of life consideration. Some MPOs that have used scenarios as a means of better defining desired community visions have included "protection of environmental resource areas" as one of the scenarios. In such scenarios, economic development and consequent infrastructure provision for these areas are limited. |
| Goals and Objectives | In most cases environmental factors are found in some form in a planning goals and objectives set. This most often takes the form of a specific statement, such as a goal or objective that expresses the intent of "minimizing the impact on the environment" or a qualifying phrase that modifies a more important goal: "Maximize system performance in a way that minimizes environmental impacts." |
| Performance Measures | This is one of the newest elements of transportation planning; it puts in place a set of measures that is continuously monitored to identify the status of the transportation system and of its linkages to other factors. One type of measure or indicator that could be included in this set is related to environmental quality. For example, several jurisdictions include air-quality measures as part of their system measurement. Other indicators might relate to water quality, wetlands exposure, habitat reduction, historic and cultural resources, and archaeological sites. |
| Data/Analysis Methods | Given the importance of environmental considerations in the evaluation of plans and alternatives, data should be collected on environmental factors that are of concern to decision makers. Analysis capability using such data is needed to provide some sense of the environmental consequence of each alternative. At the systems planning level, the data and analysis methods might be very general, but they would presumably become more specific as the analysis occurs on detailed project or plan alternatives. |
| Alternative Improvement Strategies | The actions adopted as part of the transportation plan could include strategies targeted at enhancing environmental quality. Certainly, the actions that result from programs such as the Congestion Mitigation and Air Quality (CMAQ) initiative would relate to improving air quality. Projects could also relate to transportation enhancements, strategies to reduce single-occupant vehicle use, actions aimed at environmental enhancement (for example, brownfield developments), and water quality. At the systems planning level, where alternative plan configurations are considered, one scenario could be "environmental preservation," which might focus on actions such as minimizing development in river discharge basins. |
| Evaluation | The evaluation process is, in essence, a synthesis that brings together all the information that has been produced as part of the analysis. The evaluation criteria structure how the information is presented to decision makers, and thus are important in raising decision-maker awareness of environmental issues. The evaluation criteria should include measures that relate to the environmental impacts of proposed alternatives. |
| Plan | The transportation plan should reflect the results of the goals setting, analysis, and evaluation. As such, the plan should provide an explicit linkage to the environmental consequences of the proposed set of projects or of the selected alternative, if such was the focus of the study. In those cases where plan alternatives must be analyzed from an environmental perspective, the plan might include a section that shows the results of this analysis. |
| Transportation Improvement Program (TIP) | The transportation improvement program (TIP) reflects the types of projects that are recommended in the transportation plan. Therefore, it is likely that several projects aimed at enhancing environmental quality will be found in the TIP. |
| Implementation of Projects/Strategies | The implementation of projects and strategies will include the project development process as well as the mitigation strategies that are necessary as part of project implementation. Thus, project implementation could very well include, for example, context-sensitive solutions, environmental mitigation, and efforts to minimize or avoid serious environmental impacts. |
| System Operations | The performance of the transportation system, otherwise known as system operations, will naturally include an emphasis on the ability of the transportation system to satisfy demand. However, it is important that the monitoring of system operations should also keep track of the consequences of such operation on the natural and human environment. |

subject to an environmental impact review and a general environmental assessment of the overall program of projects, which are then implemented through a series of later actions. In addition, new performance-based criteria have been introduced into the assessment. Interestingly, the overall evaluation of the region's transportation plan was based on the sustainability framework described in the previous section. [MTC, 2013] Table 4-3 shows the performance goals and the metrics that guided the development of the regional transportation plan. In the environmental impact statement (EIS), each impact area was analyzed according to: (1) environmental setting, (2) criteria of significance, (3) method of analysis, (4) summary of impacts, and (5) impacts and mitigation measures. An assessment of the impacts was then made, with possible findings focusing on:

- Significant unavoidable impacts
- Significant irreversible environmental changes
- Cumulative impacts
- Impacts found to be not significant. [MTC, 2009]

As seen in Table 4-4, it is often difficult to identify mitigation measures at the systems planning level because many of the environmental impacts are project-specific, which is not the level of detail found in systems planning. For a systems-level assessment, the planner should identify the geographic areas of environmental sensitivity (for example, protected populations, wetlands, protected habitats, noise-sensitive receptors, etc.), describe the types of mitigation measures that should be considered, and establish processes ensuring that such mitigation will occur and be monitored. Other chapters in this handbook provide more detailed descriptions of how environmental factors are incorporated into transportation planning (see, for example, chapter 15 on state transportation planning, chapter 16 on metropolitan transportation planning, and chapter 17 on corridor planning).

Amekudzi and Meyer [2005] examined how environmental factors were considered in transportation systems planning by state DOTs and metropolitan planning organizations (MPOs) in the United States. They found:

- The most-considered environmental factors in transportation planning are air quality, land use, socioeconomic considerations, and environmental justice.

**Table 4-4. Example Environmental Noise Assessment of Systems Plan, Metropolitan Transportation Commission, San Francisco Bay Area, California**

| Impact | Mitigation Measure | Significance after Mitigation |
|---|---|---|
| Construction of the proposed Transportation 2035 Plan projects has short-term noise impacts on surrounding areas | None required | Less than significant |
| Transportation 2035 Plan projects could result in noise levels that approach or exceed the FHWA Noise Abatement Criteria or could cause noise levels to increase by 3 dBA or more when compared to existing conditions. | As project sponsors prepare the environmental review document of their individual project pursuant to California Environmental Quality Act (CEQA)/NEPA and prior to environmental certification, project sponsors shall consider adopting appropriate measures that would minimize or eliminate cumulatively considerable environmental impacts pursuant to CEQA/NEPA.<br><br>MTC shall be provided with status reports of compliance with mitigation measures pursuant to MTC Resolution 1481, Revised. Mitigation measures to reduce noise impacts that shall be considered by project sponsors and decision makers may include, but are not limited to, those described below:<br><br>Adjustments to proposed roadway or transit alignments to reduce noise levels in noise sensitive areas. For example, below-grade roadway alignments can effectively reduce noise levels in nearby areas.<br><br>Techniques such as landscaped berms, dense plantings, reduced-noise paving materials, and traffic calming measures in the design of their transportation improvements.<br><br>Contributing to the insulation of buildings or construction of noise barriers around sensitive receptor properties adjacent to the transportation improvement. | Less than significant |
| Implementation of the proposed 2035 Transportation Plan could result in increased noise and ground-borne vibration related to transit operations. | The above mitigation measures are considered appropriate for bus transit noise impacts. In addition to those mitigation measures, the following additional measures are provided to reduce impacts as they relate to rail transit:<br><br>Design approaches to reduce noise and vibration impacts of rail transit, such as vibration isolation of track segments, use of continuously welded track to minimize wheel noise, resilient wheels, vehicle skirts, wheel truing, rail grinding, undercar absorption, or vehicle horn loudness and pitch adjustments.<br><br>Operational changes to reduce noise impacts of rail transit, such as assisting local jurisdictions in pursuing Quiet Zones. | Less than significant |
| The proposed 2035 Transportation Plan, combined with traffic related to projected regional population and employment growth, could result in a cumulatively considerable increase in overall noise levels along some travel corridors. | Mitigation measures listed above could help to reduce this cumulative impact. | Significant cumulative impact |

- The most widely used tools for considering environmental factors in transportation planning were data trend analysis, geographic information systems (GISs), environmental impact–specific models, overlay maps, and focus groups.
- There was general agreement that only part of the data needed for considering environmental factors in transportation planning was currently available.
- The most readily available types of data within agencies relate to air quality, socioeconomics, noise, energy consumption, storm-water runoff, and erosion.
- The most readily available types of data from outside agencies relate to environmental justice, hazardous wastes, historic properties, water quality, biological effects, and climate.
- The majority of states and a minority of MPOs use performance measures that include environmental factors in transportation planning.
- Departments of Transportation (DOTs) and MPOs have a relatively high level of interaction with each other and with environmental resource agencies, the governor's office, environmental advocacy groups, and public interest groups in the transportation planning process.
- Competing priorities and a lack of appropriate planning analysis tools were identified by DOTs, MPOs, and environmental resource agencies as the most significant obstacles to considering environmental factors in transportation planning. Lack of data and lack of regulations were perceived as less important obstacles.
- A majority of DOT and MPO respondents had promoted environmental factors being considered prior to the project development stage.
- The majority of DOTs, MPOs, and environmental resource agencies believed that the most important benefit of considering environmental factors prior to project development is that it results in better decisions. MPOs noted that an equally important benefit was shortening the time to reach project implementation.

This report further noted that issues relating to regional air quality, watersheds, wetlands, wildlife habitat, and environmental justice are often initially considered during system planning in order to determine resource agency requirements and assess cumulative effects. These potential impacts are further considered in project-specific anlayses and refinements.

Another perspective on environmental considerations at a systems level relates to the current focus on measures to monitor transportation systems performance. NCHRP Report 809, *Environmental Performance Measures for State Departments of Transportation,* recommends environmental performance measures for state DOTs. [Crossett et al., 2015] Five categories of such measures were recommended:

*Air Quality*—Change in statewide motor vehicle emissions for nitrous oxides, volatile organic compounds (hydrocarbons), and particulates.

*Energy and Climate*—Statewide on-road gasoline consumption per capita and state DOT fleet alternative fuel use as percent of total fuel use.

*Materials Recycling*—Annual percent by mass of all roadway asphalt pavement materials composed of reclaimed asphalt pavement (RAP) used by the state DOT.

*Storm Water*—Percent of state DOT-owned impervious surface for which storm-water treatment is provided.

*Wildlife and Ecosystems*—Self-administered ecosystems self-assessment tool (ESAT) composed of 41 questions that evaluate performance across all aspects of state DOT programs relevant to wildlife and ecosystems.

## C. Environmental Impacts in Project Development

In systems planning, project priorities are identified in the context of state, regional, or corridor plan goals and policies; the problems being solved; and the relative effectiveness of alternatives or strategies to solve them. Note that although the term "alternative" is used in both transportation planning and the NEPA process, it has somewhat different

meanings in the different contexts. In transportation planning, the term "alternative" is usually applied to various system concepts and strategies to address the needs or problems identified. When used in a NEPA sense, the term "alternative" brings with it the expectation that details are available to allow an assessment of more precise project impacts. This more specific definition is important for environmental resource agencies that are responsible for approving (or not objecting to) the recommended actions from environmental reports. The term "strategy" is used throughout this chapter to distinguish a planning strategy from a NEPA alternative.

For system-level planning, projects are defined with a general design concept (for example, limited-access freeway) and scope strategies—expected transportation mode, project termini, number of lanes or tracks, degree of access control, general alignment, station footprints, and so forth. Project-level planning is much more detailed and refined, focusing on geometric alignment, detailed design concepts and standards, environmental protection, and project phasing. Satisfying federal, state, and local environmental laws and requirements is typically accomplished during the project-level analysis and refinement stage.

Project planning and engineering are typically performed in conjunction with a detailed analysis of environmental impacts, the specification of mitigation measures, and documentation to fulfill jurisdictional (federal, state, and local) environmental protection laws and requirements. It is at this stage, if federal funds or actions are involved, that NEPA becomes an important planning context.

NEPA is arguably the most important U.S. environmental law influencing how transportation projects are planned and designed. Although this law targets project-specific effects, its intent and philosophy on infrastructure make it an important foundation for the consideration of environmental impacts during the transportation planning process as well. Therefore, transportation planners and engineers need to know the important principles and requirements of this law.

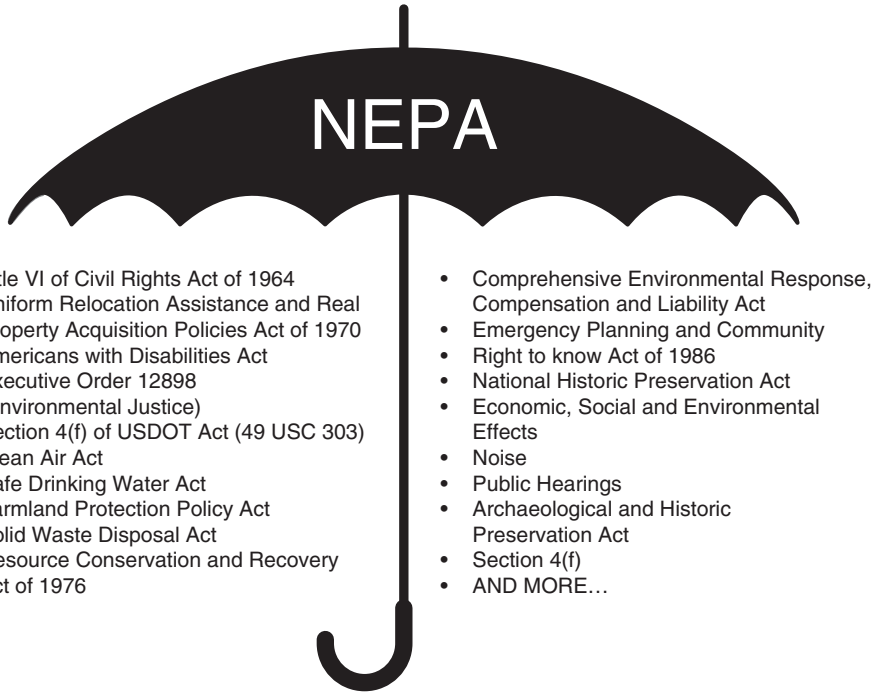
NEPA was enacted to "prevent or eliminate damage to the environment, stimulate the health and welfare of Man, and enrich the understanding of ecological systems and natural resources important to the nation." NEPA mandates that environmental factors be considered when federal actions are involved in a project, such as providing project funding or issuing a permit. The act calls for an assessment of alternatives, opportunities for public involvement, and coordinated agency action. Subsequent legislation and regulations have created a well-established process and standard of practice for fulfilling NEPA requirements, especially for transportation projects. Various other laws and executive orders require consideration of specific natural, cultural, and human resource impacts, and of the policies relating to them, including endangered species, historical and archeological resources, air, water, floodplains, wetlands, parklands, environmental stewardship, and environmental justice. In this context, the terms "environment" and "environmental resources" encompass the natural, cultural, and man-made environments.

NEPA provides an umbrella for addressing all relevant environmental laws and requirements during the development of transportation projects (see Figure 4-2). While the NEPA process provides a means to consider a host of environmental issues, other laws, executive orders, and regulations often have their own requirements and issues that must be addressed during project development. NEPA and other major laws relevant to environmental impacts are discussed in greater detail in chapter 2.

As noted by FTA,

> *"The NEPA process begins far earlier than the design and technical analysis of a particular project. Metropolitan and statewide transportation planning identifies transit needs and mobility problems and proposes solutions that reflect consideration of broad socioeconomic and environmental factors (such as regional air quality). If State or local agencies expect to seek FTA funding assistance for implementation of a resulting project, FTA must gauge the appropriate level of assessment and review of environmental impacts . . . . major proposed actions involving substantial new construction with off-site or long-term impacts usually merit a detailed review that is done with appropriate public involvement and documented in a formal environmental impact statement.*
>
> *The more detailed NEPA reviews are grounded on the notion that alternative solutions are available for meeting identified transportation needs. The formal review process requires the transit agency to develop and evaluate a range of reasonable alternatives, in addition to the proposed project, in order to determine the best option for addressing transportation problems, respecting the community, and protecting the environment."*
>
> *[FTA, 2014]*

**Figure 4-2. The NEPA Umbrella**



Source: *Linking Planning and NEPA: Executive Seminar Course Instructors' Manual*. Washington, DC: National Highway Institute, 2003.

The NEPA process leads to three possible analysis efforts:

- *Environmental Impact Statement (EIS)*—When the proposed action will have a significant impact on the environment, an EIS is required.
- *Environmental Assessment (EA)*—An EA is prepared when there is uncertainty as to the significance of the impacts of the project.
- *Categorical Exclusions (CE)*—Actions that do not individually or cumulatively have a significant social, economic, or environmental effect are excluded from the requirement to prepare an EA or EIS (http://www.environment.fhwa.dot.gov/projdev/tdmpdo.asp).

Which direction a NEPA process takes is dependent upon an initial assessment of the likely significance of expected impacts. Readers are referred to FHWA's *Environmental Guidebook* for further guidance on how NEPA applies to road projects (http://environment.fhwa.dot.gov/guidebook/results.asp?selSub=91). More specific information on project-level environmental impacts as they should be considered during project development is presented in the rest of this chapter.

## D. Linking Environmental Considerations of Systems Planning and Project Development

Success in linking the environmental considerations of systems and project planning depends on several factors: the extent to which collaboration/involvement among the different transportation and environmental agencies has occurred in systems planning, the degree to which planning leads to early consensus on project purpose and need, the complexity of design concepts and scope, and how planning starts to address environmental regulatory requirements. Success can be measured by the extent to which early planning decisions survive in later project development phases where NEPA-related effects are examined in greater detail. The following principles can lead to such success:

*Environmental considerations should inform the transportation decision-making process, while the transportation planning process should inform the environmental compliance process.*

Although decision makers do not necessarily need to know all of the details when making system-level or even project/concept-level decisions, they do need reliable estimates of expected costs, benefits, and environmental impacts. If environmental factors are not considered seriously in the transportation planning process, decisions made at this point in the process may have to be revisited during subsequent project-level planning. For example, problems and needs identified during the planning process can serve as the basis for the purpose and need statement required by NEPA environmental documentation or other environmental processes (see chapter 1). Having an unsupported or poorly defined purpose and need statement is a primary cause of successful legal challenges to transportation projects. A well-supported and documented problem statement emerging from the transportation planning process provides a sound basis for the purpose and need statement that can be used later in the NEPA project development process.

Another important linkage between the planning process and environmental considerations occurs in the development and screening of alternatives and investment strategies. In a typical transportation planning process, a large number of strategies are narrowed to a number of feasible strategies through the analysis and evaluation process. The criteria for screening and refinement should include environmental (for example, socioeconomic, natural, and cultural) considerations along with mobility and other defined transportation-specific concerns, including engineering and operational feasibility, safety, cost, and affordability. The environmental measures are typically defined at a very high level, but with enough information to make decision makers aware of the expected consequences of various investment strategies.

Documenting the methodologies used, the mitigation strategies considered, and the decisions reached in planning can have distinct benefits in later stages of project development and implementation. Environmental or cultural resource agencies may not be part of the early planning process when screening and refinement steps are determined. Clear and reliable documentation can provide a record of considerations and the decisions made for use later in the process. Even if these agencies were involved early in the process, a project developed over a long period may involve different agencies or responsible officials at different points in time, again suggesting the need for good documentation.

*Appropriate parties and stakeholders, especially environmental resource and regulatory agencies and others with environmental interests, should participate in, or at least be aware of, the decisions made.*

An effective planning process involves more than a simple technical consideration of environmental issues. Because of the breadth and diversity of issues typically addressed in a transportation planning process, a wide range of stakeholders should participate when decisions are made. This leads to a broad-based understanding and acceptance of decisions relating to different decision points in the process, from identifying a problem statement to recommending a course of action. These parties could include transportation providers and policy/funding agencies, land use and planning entities, environmental resource and regulatory agencies, community and economic development interests, political bodies, and members of the public. The goal is to have balanced input and a consideration of issues so that decisions are based on the broadest range of perspectives from a community.

Environmental resource and regulatory agencies have statutory roles in reviewing and approving project-level analyses and disclosure documentation for specific resources, and/or issuing permits required for construction and/or operation of a project. Federal, state, and local environmental resource and permit agencies should thus have early involvement in a transportation planning study when some of the most fundamental decisions are being made. They should be an integral part of the cooperative and collaborative process in establishing a problem statement, defining the range of strategies to be studied, identifying the factors to be addressed, and adopting a work program with an agreed-to level of detail for study elements, particularly the environmental analysis. Having environmental resource agencies involved at the beginning of strategy development helps introduce relevant environmental impact avoidance strategies early in the process so that strategy development and screening decisions do not have to be revisited later. This can happen only if the resource agencies are part of the NEPA documentation review and permit processes.

It can be challenging, however, to get environmental resource and permitting agencies to participate in the planning process—particularly in the early stages. These agencies may have limited staff and funding that are fully committed to addressing projects further along in the development process. Nonetheless, it is worth securing the early involvement of these agencies given the benefits described above. One important benefit is that it will make their job—and that of transportation planners and engineers—easier and more effective throughout the rest of the planning process and in later project development stages. Numerous strategies have been used to encourage the early involvement of environmental resource agencies, including having a standard operating procedure for resource agency participation, providing resources for such participation, and initiating the formal environmental impact analysis/documentation process earlier in the planning process, thereby triggering formal resource agency involvement.

### Environmental Stewardship

Environmental stewardship is an emerging concept. At one level it involves protecting the environment through the avoidance, minimization, and mitigation of environmental impacts, or through compliance with environmental laws and regulations. But it also has a larger aim. Environmental stewardship strives to improve environmental conditions and enhance the quality of life wherever possible. It encourages partnerships that promote ecosystem conservation and address public priorities such as mobility and safety.

A transportation project often provides an opportunity to address enhancement opportunities—unrelated to that transportation project—that can be viewed as mitigating or offsetting adverse effects. Incorporating context-sensitive design is one means of accomplishing environmental stewardship. The intent is to develop a project that is in harmony with its surroundings; maintains safety and mobility; and preserves scenic, aesthetic, historic, and environmental resources. Examples might include a recreational trail along a roadway or transit corridor, the restoration of a stream beyond project boundaries, and the use of indigenous materials or architecturally sensitive features in the design of structures or sound barriers. Context-sensitive design goes beyond strict design features and can include the use of materials and construction techniques, operational practices, and maintenance techniques that are environmentally sustainable.

*The rationale or basis for early planning decisions should be well documented to inform later stages of the project development process*.

Even within a highway or transit agency itself, a multidisciplinary, multidepartmental group of stakeholders is often needed throughout the planning and project development process. Typically, different agency units provide leadership at different stages. A planning office may have responsibility for the initial planning work, with a project development office assuming the lead for the preliminary engineering and environmental phase. The project may then pass to a design group at a headquarters location or to a district or regional office, and subsequently to construction and operations and maintenance groups. Because many of these groups often lead later phases of project development, they need to be informed of earlier decisions (and commitments) so they can understand the rationale for project designs and mitigation strategies. This can be done by participating in the planning process, or through formal transmittal documents that accompany a project as it proceeds through project development and that describe agreements and consensus on project characteristics.

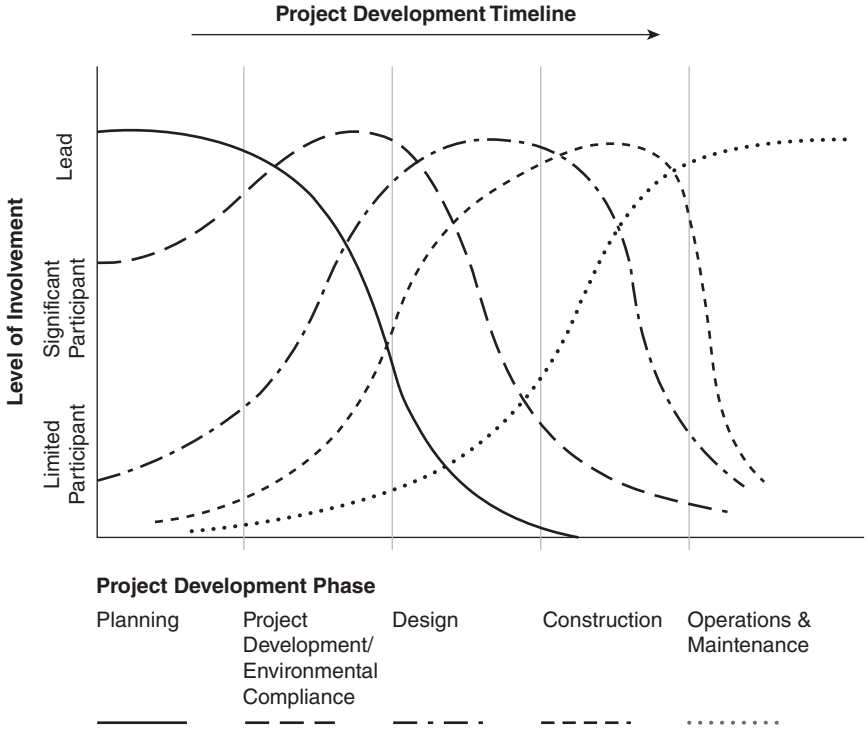
Figure 4-3 illustrates how one transportation agency envisions the involvement of multiple departments. The early planning stages are led and principally staffed by the planning unit, with significant involvement from the project development and environmental groups. The design, construction, operations, and maintenance departments have a limited role in the early stages, primarily informing the process and contributing to decision making from the perspective of designers, builders, operators, and maintainers. As project development progresses, other units assume the lead, and the roles and levels of involvement of the units increase or diminish as appropriate.

Several years can elapse between a decision made during a planning process and subsequent project development and implementation. Agencies and stakeholder participants may change, and different agency units and consultants may be involved in subsequent phases. Federal or local policies and priorities, planning assumptions and forecasts, and existing conditions can and often do change. It is important to remember that an effective planning process cannot rely on institutional memory. It needs solid documentation.

*The planning process should include a public engagement program in which issues identified by the community influence the purpose and need of the project and definitions of prospective strategies*.

It is worth noting that, although study and project participants may change, the affected communities and the issues that matter to them often remain relatively stable. A clear and thorough record of comments received from the public, and the respective responses, shows that issues have been vetted by the responsible authorities. In addition, thorough documentation of the environmental considerations, analysis methods, and results, as well as the development, screening, refinement, and evaluation of strategies, is required to satisfy legal and regulatory obligations. Without documentation, there is a risk that earlier decisions made in the planning phase may have to be revisited or the process repeated due to legal challenges, causing delays, extra costs, and stakeholder frustration.

**Figure 4-3. Roles and Level of Involvement during Project Development Timeline**



Based on unpublished Florida Department of Transportation diagram

Environmental streamlining—that is, using information produced in the planning process for the environmental analysis to minimize repetition and delays—has received a lot of attention from transportation officials in recent years. A Council on Environmental Quality (CEQ) NEPA Effectiveness Study [1997] found that the NEPA process was too long and had high costs; agencies often made decisions before hearing from the public; and the process was initiated too late for it to be fully effective. FHWA [2002] found that it typically took anywhere from 9 to 19 years to complete a federally financed new highway construction project. Five to 10 years were required for planning, preliminary design, and environmental review.

The aim of environmental streamlining is thus to:

- Improve timeliness of the environmental process.
- Improve interagency cooperation.
- Recognize constraints on time and resources (human, financial, etc.).
- Resolve issues early.
- Provide for mediation of process stumbling blocks.
- Improve project management.
- Foster environmental stewardship.

It is implemented by:

- Establishing a coordinated review process between the transportation agency and other involved agencies.
- Emphasizing concurrent reviews to save time and avoid formal dispute-resolution processes.

- Allowing local environmental review processes to be included in the coordinated review process.
- Enabling funding by a nonfederal agency to affected federal agencies to meet expedited time limits.
- Fulfilling responsibilities as trustees of the environment for succeeding generations, moving toward a cost-effective and environmentally sustainable future.
- Integrating environmental values with partners within all transportation work as a core business value.

Streamlining can be implemented via memoranda of understanding (MOU), training, memoranda of agreement (MOA) and programmatic agreements, information sharing, use of delegation authority, and other administrative flexibility actions and initiatives such as pilot programs to demonstrate the feasibility of streamlining strategies.

## III. GENERAL PRINCIPLES REGARDING ENVIRONMENTAL CONTENT AND LEVEL OF DETAIL

The intensity or importance of an adverse or beneficial impact is related to its context. For example, the loss of a few houses or businesses in a small community or neighborhood might be considered more significant than the loss of the same number in a larger community or neighborhood. The small community context makes an impact much more significant than a similar impact in a larger urban area.

Another way to gauge intensity is through social acceptability. An unavoidable loss of several businesses might be considered an acceptable consequence of a project where there are mitigating benefits. On the other hand, impacts to public health and safety or to unique or unusual settings or environments, as well as impacts that generate a high degree of public controversy, might be deemed unacceptable to policy- or decision-making bodies. Unacceptable impacts are sometimes referred to as *fatal flaws*. This means that, notwithstanding the benefits of the project, a particular impact or accumulation of impacts can be so undesirable that it renders a specific strategy or even the overall action unacceptable. In some circumstances, there may be laws or regulations that enforce or set a standard for the acceptability of an impact.

The following paragraphs discuss some important issues to consider when establishing the overall approach to environmental assessment for transportation system and project planning.

### A. Types of Impacts

Transportation systems can affect the environment in many ways. Not only are transportation professionals interested in potential impacts close to or adjacent to a facility, but in a broader sense, they are also interested in the significant effects transportation systems have on the health, economic success, and quality of life of a community. For example, the following vision of a sustainable transportation system, offered by the Oregon DOT, shows the range of impacts and strategy types that might be considered as part of the environmental context for transportation system performance:

> *" By 2030, Oregon's transportation system supports people, places and the economy. We travel easily, safely and securely, and so do goods, services and information. Efficient vehicles powered by renewable fuels move all transportation modes. Community design supports walking, bicycling, travel by car and transit wherever appropriate. Our air and water are dramatically cleaner, and community sensitive and sustainable transportation solutions characterize everything we do.*
>
> *Oregonians and visitors have real transportation choices and transfer easily between air, rail, motor vehicles, bicycles and public transportation; while goods flow just in time through interconnected highway, rail, marine, pipeline and air networks. Our communities and economies—large and small, urban and rural, coastal and mountain, industrial and agricultural—are connected to the rest of Oregon, the Pacific Northwest and the world. Land use, economic activities and transportation support each other in environmentally responsible ways.*
>
> *We excel in using new technologies to improve safety and mobility. We maximize the use of existing facilities across traditional jurisdictions and add capacity strategically. Public/private partnerships respond to Oregonians' needs across all transportation modes. Transportation system benefits and burdens are distributed fairly, and Oregonians are confident transportation dollars are being spent wisely. By 2030, Oregonians fully appreciate the role transportation plays in their daily lives and in the region's economy. Because of this public confidence, Oregonians support innovative, adequate and reliable funding for transportation . . . . "*
>
> *[Oregon DOT, 2008]*

The Oregon DOT produces periodic progress reports indicating the level of achievement ODOT is making with regard to these sustainability goals (see ODOT, 2012).

The environmental consequences of a transportation project can take several forms. Direct impacts are the most obvious and tend to receive the most attention. These occur as the direct result of the *construction of the project* (for example, house or store displacements or loss of habitat) and of *facility operation* (for example, noise or ground vibration). Secondary impacts occur as a consequence of a direct impact. Typically, secondary impacts occur later or at some distance from the project, but they can still be reasonably foreseen. For example, a direct impact of a transportation improvement that improves access to adjacent land is residential or commercial land development. The secondary impact of the transportation investment occurs when this development produces its own set of environmental consequences, such as local road congestion, pollutant emissions, or community disruption. These secondary impacts should be covered in the environmental analysis and in the planning-level evaluation of transportation projects. In recent years, secondary impacts have also been examined in systems-level planning, albeit at a very broad level.

In certain situations, combined or cumulative impacts—those that result from the incremental consequences of an action when added to past occurrences, other actions, or reasonably foreseeable future actions—will generate an overall impact of such magnitude that it should be presented and considered in the evaluation. [CEQ, 1997] For example, the loss of a relatively small amount of wetlands as the result of a single project may in itself appear inconsequential, but the combined effect of a number of seemingly small losses could result in a significant loss and degradation of the wetlands resource (see Figure 4-4). Another way to consider cumulative impacts is to examine the project-related impact in the context of similar impact-generating activities currently occurring. For example, a traffic-generated noise impact on a given neighborhood may not be considered a serious adverse effect by itself, until it is placed in the context of current and expected traffic-related noise generation from other traffic sources. In the larger context, these impacts can have more severe consequences than would appear when they are considered individually. Where appropriate, the environmental analysis and strategies evaluation should include a discussion of cumulative impacts.

Most environmental concerns are limited to the effects of a particular project, such as the noise impacts from an increased number of passing vehicles. However, some impacts may need to be addressed programmatically. For instance, the impacts of a particular project on a watershed or on regional air quality may need to be addressed on a regional or programmatic scale during a regional planning process where the cumulative effects of a number of projects and actions are considered.

**Figure 4-4. Cumulative Impacts**

## B. Appropriate Level of Detail

The purpose of environmental analysis during the planning process is to identify any major environmental or design concerns that are likely to affect the selection of a preferred investment strategy, or that might relate to environmental regulations (such as for air quality) or permitting requirements (such as for wetland permits). This will likely include, at a minimum, the identification of environmentally-sensitive areas within the study boundaries. An initial scoping process should define the appropriate level of social, economic, and environmental analysis for a planning study, along with the approach toward interagency coordination and public engagement.

The level of analysis should be sufficient enough to identify and evaluate all differentiating characteristics of the project concepts and scopes under consideration. As noted previously, it is important to have environmental resource agencies involved at the beginning to help establish the level of detail for the environmental analysis and the strategies to be considered, including avoidance and minimization strategies and future no-build conditions. Resource agencies

would also be valuable participants in screening strategies to make certain that environmental factors are appropriately considered. As will be discussed later, benefits and impacts can be assessed subjectively and/or they can be quantified and monetized (if possible and desired).

Commitments to specific mitigation measures are not usually made at the systems planning level. However, it is important to clarify the degree to which different types of mitigation strategies have been successful in avoiding or minimizing environmental impacts in the state or region. At the systems planning level, it is also desirable to have a sense of the costs associated with environmental mitigation strategies.

The level of detail in environmental analysis should reflect the complexity associated with different types of projects and strategies, with explicit consideration given to the risks and uncertainties related to the likelihood and magnitude of a possible impact. In cases where mitigation strategies would be costly, a more comprehensive study would normally be undertaken. In cases where the strategies and the extent of the impacts are likely to be less costly, a more general approach may be appropriate.

Most importantly, efforts made during a planning study should include close coordination of the inventory, analysis, and findings with agencies having jurisdiction over the various environmental resources. The planning study should document this coordination and should demonstrate the concurrence of the relevant agencies in the early findings.

The approach is very different for environmental analysis at the project planning level. Whereas in systems planning proposed projects are described in general terms, project planning focuses on very specific alignments and design characteristics. Thus, environmental analysis in project planning is much more detailed than that found at the systems level. According to federal transportation law, the appropriate steps for environmental analysis in project planning include:

- Review by a qualified professional of existing environmental resource inventories, supplemented with additional data collection where necessary, and resource planning studies done by/for the resource agencies.
- Preliminary analysis of the nature and severity of likely impacts, with cross references to other sections of the environmental analysis.
- Review of possible changes in the design or alignment of the strategy to avoid the impact (including costs and other implications).
- Identification of potential measures to mitigate the impacts.

Most of the material found in the rest of this chapter provides information on the data and tools that can be used to conduct environmental analysis at the project planning level.

## C. Extent of Impact

Determining the spatial extent of potential impacts, often referred to as the impacted area, is an important part of determining the significance of an impact. For systems planning, the impacted area could be very broad, such as the regional air basin for a metropolitan area; or it might be limited, such as noise impacts to particular land parcels adjacent to busy freeways. The spatial aspect of environmental impacts is reflected in the types of tools used to analyze them. In the preceding illustrations, for example, analysis of regional air quality impacts usually relies on travel network modeling that estimates the flows of traffic in a region, and thus the concentration of motor vehicle–related air pollutants in an air shed that could be hundreds of square miles in area. Noise impacts, on the other hand, can be estimated with facility-specific models that target areas close to high-volume roads.

Impacts of concern should be identified early in the planning process. Several approaches can be helpful in doing this, including looking at prior studies to determine which environmental concerns were studied; consulting relevant agencies and groups; inviting citizen and stakeholder input; and/or actively engaging environmental agencies for their input. Of all the available reports on environmental conditions and impacts for an area, the most useful might be other environmental studies (EISs or environmental assessments) or area planning studies (including resource planning studies).

The process of identifying impact areas should allow the study sponsor to use the knowledge and expertise of the groups most familiar with the study area and those who know the specific laws, regulations, and rules that apply to these impacts. Field reconnaissance, especially in cooperation with other concerned agencies, is usually an excellent method of identifying impact areas. As the planning study progresses, additional areas of concern may be identified through the development and analysis of strategies, additional data gathering, and public and agency involvement.

## D. Role of Travel Demand Forecasting and Traffic Analysis

The analysis of current and future travel behavior and of transportation system performance is at the core of a transportation planning study—especially estimating the effect that various transportation improvements will have on both. Changes in traffic flows and transit operations, in particular, are a key analysis link between the travel forecasting activities of a planning study and many of the social, economic, and environmental analysis topics discussed in the remainder of this chapter. Travel forecasting and system-modeling methods are addressed in chapter 6, and later chapters address methods for evaluating a range of actions and strategies.

Given the link between pollutant emissions, energy consumption, and the use of motor vehicles, air quality impacts are dependent on changes in travel demand and system performance, as is energy consumption. The analysis of noise, safety, and associated neighborhood/community impacts usually requires some level of site-impact analysis. Travel-forecasting results often have to be developed at a level of detail needed for environmental analysis. This is often a challenge. The computer models that serve as the foundation for most statewide and metropolitan transportation planning today were not developed to predict environmental consequences and are often unable to do so reliably. In many cases, post-processing modules have been added to the modeling regimen to accomplish this task. Although these models may not be the best approach for producing good estimates, they are usually the only approach available to transportation planners and engineers for making such assessments, and they are recognized as such in federal planning and environmental regulations.

The following sections describe the scope and appropriate level of detail for the social, economic, and environmental analyses that can be part of a planning study. They also describe the technical tools and methods typically used for such analyses. The list of environmental topics is not meant to be exhaustive, but rather representative of topics addressed in most planning efforts. It is important to note at the outset that many federal, state, provincial, and local planning agencies, as well as environmental resource agencies, publish regulations, rules, and guidance on the legal requirements for conducting an environmental study. The rules and guidance often change to incorporate new laws, or reflect different perspectives from those of new policy makers. At the very beginning of a study, the planner should contact the most relevant environmental resource agencies to obtain the most recent guidance.

# IV. LAND USE AND ECONOMIC DEVELOPMENT IMPACTS

Transportation planning has for decades addressed the interaction between transportation investments and land use and development patterns. This interaction involves both the effect of land use on travel patterns and the influence of transportation investment decisions on land use development (see chapter 3).

Transportation planning takes existing and projected land-use patterns into account in almost every type of planning study. Knowing the future distribution of population and employment is fundamental to predicting future travel demand. At the project level, analyzing the consequences of transportation investment on land use has generally focused on the direct impacts of facility construction, such as land acquisition or the creation or elimination of a particular land-use activity. At the systems level, there is increasing interest in indirect or secondary impacts and/or cumulative impacts on land use that result from changes in accessibility brought about by transportation investments. An example of an indirect or secondary impact would be land development that capitalizes on the improved accessibility of a new highway interchange. A transportation improvement can also bring about an induced change in land-use activity or density, such as joint development around a transit station, that would not have occurred without the investment. Given the strong linkage between land use and transportation investments, land-use implications will likely be a critical topic in many transportation environmental studies.

Many regional land-use policy and planning issues are more appropriately considered at the metropolitan level. Thus, for example, a study that is looking at the implications of alternative future land-use scenarios on both regional environmental indicators and transportation system performance will necessarily have to be conducted at the metropolitan level. In most cases, this will entail using a land-use model or some other analysis tool to assess such consequences. The reader is referred to chapter 3 on land use for a discussion on how planning agencies carry out these types of analyses.

This section focuses instead on the interactions between land use and transportation at the corridor or subarea level. This impact category, required as part of environmental impact statements, is important because of the concerns often raised by local citizens and elected officials about the short- and long-term land-use effects of changing the transportation system.

In many cases, land use is not the purview of the transportation agencies involved in a study. This is true almost everywhere in the United States. For example, state DOTs do not have land-use authority, although through their access-permitting process and role in environmental review, they can certainly exert influence. Local governments are responsible through comprehensive planning and zoning regulations for land-use and development decisions, at least as they concern public authority. Therefore, it may be appropriate to involve as part of the collaborative planning process those agencies or levels of government with responsibility for, or jurisdiction over, land-use and development policies, planning, and decision making. It also may be beneficial to invite input from other stakeholders who have an interest in land use and may be affected by the planning process, such as developers and major landowners.

The following should be taken into account when addressing the land-use and development environmental effects of a transportation strategy:

- Under NEPA and similar environmental regulatory review requirements, federal agencies are required to consider the effects of proposed projects and alternative courses of action when federal action is contemplated. Most federal guidance includes the consideration of impacts on land use and economic development, even though the federal government does not have a role in such local decisions.
- Project sponsors often cite urban development benefits as an important reason for considering a major investment in transportation. In such cases, the magnitude of these benefits may need to be estimated to determine how the expected benefits and other related outcomes compare to the costs and impacts, and whether other strategies might bring about the desired benefits with less cost and/or impact.
- In some cases, cities or community groups may be concerned about the effect a strategy might have on neighborhoods and communities. For example, they may oppose changes in land use that would bring increased activity to quiet neighborhoods or would increase the volume of local traffic. A development impact analysis can help show whether these concerns are valid and, where necessary, foster agreement on appropriate mitigation measures.
- Strategies that have economic development benefits can often be financed, at least in part, through value-capture techniques, or they may be built through public/private partnerships that rely on capturing a strategy's development benefits. Preparing estimates of these future benefits or revenues can be an essential part of the financial planning work done for the planning study. This would include identifying those property owners most likely to benefit from increased property values (note that the dollar increase in property values should not be considered a benefit in the analysis; see chapter 7).

The discussion that follows is meant to provide guidance on the appropriate level of detail for different land-use and economic development impacts. It presents an overview of the linkage between transportation and land development, and identifies a framework and technical approach for assessing the magnitude and incidence of these impacts where appropriate.

## A. Land-Use Impact Analysis

The analysis should separate development that is likely to be induced by a transportation project or strategy from development that would normally occur in the real estate market. Realistically, given the large number of factors that can influence development and the difficulty inherent in forecasting the causal outcomes of these factors, the best the

analyst can often hope to achieve is an informed estimate. The steps for a land-use analysis as part of an environmental study include the following:

### *1. Identify Land-Use Markets*

Land-use impact analysis can occur at different geographic levels, such as a region, corridor, subarea, or specific site. All levels of analysis should be consistent, meaning the sum of all land-use changes predicted at the local level should add up to the regionally defined control total for expected population and employment.

**Impacts on Regional Development.** As discussed earlier, regional land-use and development issues are typically addressed at the metropolitan level and primarily set the land-use planning context for corridor/subarea analyses. In most cases, transportation planning agencies do not have strong influence over local development decisions, although there are some metropolitan areas, such as Portland, Oregon, where regional agencies have been given strong land-use authority. Where corridor/subarea transportation investment strategies affect regional land-use patterns, such as providing increased transportation accessibility to different sectors of the region, such impacts should be considered in the environmental assessment. In addition, in many instances, corridor and subarea studies rely on the regional travel demand model and zonal system established for regional forecasting. Often, the zonal system is too aggregate for smaller-scale analysis, and these zones are then often subdivided to a higher level of detail (see chapter 6 on travel demand forecasting and chapter 17 on corridor planning). This finer level of detail on land-use and development patterns should be shared with the MPO so that its zonal system can be updated.

**Impacts on Corridor or Subarea Development.** Transportation investments are more likely to redistribute regional growth that was going to occur anyway than generate new development in the region. For example, strategies serving a healthy business district may provide the added transportation capacity needed for additional growth to occur at that location rather than in a suburban location. Such distributional effects will likely occur if inferior access conditions currently restrict one part of the region from growing as rapidly as other parts (although location decisions are also influenced by tax policies, access to the labor market, and incentives provided by local governments).

Where new development is anticipated, the analysis should indicate the extent to which the corridor/subarea growth will come from other parts of the region (if possible). It is important that regional decision makers understand that overall corridor/subarea-level impacts tend to be a zero-sum game when looked at from a regional perspective; regional equity and other implications of these impacts should be taken into account.

**Impacts on Local Development.** A transportation investment is likely to have the most noticeable land-use impacts in areas immediately adjacent to stations, interchanges, or other points of new or significantly increased accessibility. Because of the linkage between development and transportation accessibility, standard transportation evaluation or performance measures can be used to compare strategies in terms of their potential to produce local land-use changes. For systems planning, all of the strategies' potential to cause local development might be compared using the following outputs of the travel-forecasting process:

- Percentage of the region's population and/or employment within *x* minutes of the site by automobile and by transit.
- Changes in transit, highway, and other modal travel times, weighted by mode share. For this purpose, the denominator of the logit model can serve as the analysis variable (see chapter 6 on travel demand forecasting).

The methods for evaluating the indirect and induced impacts of transportation investments continue to evolve. These techniques range from those that are largely qualitative in nature, focusing on interviews and expert knowledge, to relatively quantitative approaches, such as linked land-use and transportation-forecasting model systems.

Integration of highly structured transportation and land-use modeling systems represents the most sophisticated means available for understanding or simulating an interaction of transportation and land use. This approach suits metropolitan area studies for the very largest of the major investment strategies. For investment strategies whose scale is less likely to make a measurable impression on overall regional allocations of households and jobs, other techniques can be employed to simulate transportation and land-use interaction (see chapter 3 on land use).

A technique that is well-suited to the latter is conducting a series of highly structured interviews with experts in relevant fields, to elicit their expert opinions on the likely land-use outcome of a major transportation investment. When the interviews are formally structured with a process of feedback to participants through a series of confidential interviews,

the technique is known as a Delphi process. The Delphi process was first applied to land-use forecasting in the 1970s. With the renewed interest in land-use issues, this technique may be appropriate for application in investment studies.

Regardless of the level of sophistication, analyzing the interaction between transportation and land use addresses the same issues and requires systematic data collection and evaluation. Analysts should review all techniques to analyze these relationships and determine which can be used most effectively in their jurisdiction, given available data, resources, and outside recommendations.

***2. Examine Past Land-Use Trends***

The land-use analysis continues with the identification of past land-use trends in the area, defined to include those areas both directly and indirectly affected by a specific strategy. Analysts typically accumulate data on the rates and characteristics of land consumption for a period of 10 to 20 years, or the period that has passed since the last major improvement to the transportation facility. These are defined as the conversion of open or agricultural land to residential, commercial, office, and industrial use. Data on population/households and employment growth for the area can be assembled and evaluated to understand the role that transportation, in general, and current facilities and services, in particular, have played. The analysis would include identifying major development sites and/or employment centers, large-scale residential developments, and other uses that, from a land-use and transportation point of view, are key determinants of travel behavior in the corridor.

It may be prudent to look at nontransportation factors as well, such as regional growth rates, quality of schools, crime, and others. These factors may be the dominant determinants of land-use development, with transportation investment factors playing a relatively minor role. At this point in the analysis, existing and future land-use conditions and trends in the corridor may indicate that land use might not be a major factor in the development and evaluation of the strategies, and thus may not require an in-depth analysis in the transportation study.

***3. Analyze Current Land-Use Conditions***

The next step is to develop an inventory of current land uses in the study corridor, site, or subarea. Depending on the study's resources, this inventory may be based on existing sources, or there may be a need to collect new data. The data will most likely be in a GIS format. Methods for developing a land-use conditions inventory can include the use of aerial photography, records from local tax assessors, purchased data, or reports from commercial and residential real estate brokerage firms and/or other public or private data sources, such as other planning studies and resource agency plans. The inventory should define the amounts and locations of the principal land-use types in the study area.

The analyst should assess the likelihood of existing land uses remaining stable over the timeframe of the study. Evidence of any trends of economic decline or revitalization should be noted. These are easily identified from relative changes in land or real estate values, as compared with those in other similar local areas.

The inventory should also include information about the location of vacant parcels that could now be more desirable given the transportation investment, including underutilized or nonconforming parcels. Underutilized parcels are defined as those that have not yet been developed to the densities permitted by existing zoning or plans. Nonconforming parcels are those that do not conform to existing permitted uses. These may also be underutilized.

An assessment of the effectiveness of existing land-use policies should be undertaken if these policies are included as part of the transportation study. If the study includes an assessment of different land-use scenarios, it is essential to have a good sense of existing land-use conditions.

***4. Evaluate Land Use–Transportation Linkages***

Building on the evaluation of past trends and current conditions, the analyst should next examine the characteristics of proposed transportation strategies as they relate to land use, including an analysis of the likely consequences of increased accessibility and mobility resulting from the strategies. Some investments represent dramatic change in accessibility; others represent only incremental changes. The analyst should evaluate area sites that will be particularly sensitive to such changes.

Accessibility is defined as the extent to which a strategy makes or enhances connections between geographic areas or portions of a region as well as across modes. Mobility is defined as the ease (for example, speed) with which movement can occur. While these two terms are interrelated, it is important to separate them to complete the land-use impact analysis (see chapter 3 on land use).

Finally, the analyst could coordinate this evaluation with the travel forecasting activities and attempt to answer such questions as: To what extent is the strategy largely a peak period facility or service? To what extent does it serve various non-work trip purposes? The answers to these questions may lead to a better understanding of likely land-use impacts.

***5. Estimate and Evaluate Future Land-Use Demand***

The next step in the framework is to evaluate how different strategies will affect the demand for various types of land based on the analysis of changes in accessibility and mobility. This part of the analysis is accomplished by addressing questions such as the following:

- In what parts of the study area will the largest land-use effects occur? In addition to these primary impact areas, where will there be lesser impact? (These secondary areas will tend to be distant from a fixed route or guideway system, or have other constraints in which a change in transportation infrastructure affects land-use demand, for example, zoning or environmental constraints.)
- What types of land uses will be demanded in the market? The study would typically include a traditional taxonomy for land uses in the study area, for example, single/multifamily residential, industrial, or office. Land-use categories are defined by local ordinances and codes; however, the changing needs of residents, employees, and employers are leading to more interest in mixed-use development. In addition, the extent of land consumption (through requirements such as floor area ratios and parking requirements) associated with various land-use categories is only partly determined by market conditions. Land consumption is also a function of local ordinances and permitted densities. Thus, past land consumption trends may not be the only determinant of future demand.
- Are the demands resulting from a change in transportation infrastructure likely to be one-time changes or permanent changes? What is the likely timing of these land-use changes by type?
- Will the changes present net growth in the region, or will the changes cause a redistribution of population that, without the strategy, would have gone to another part of the metropolitan region? The answer to this question depends in part on the extent to which the transportation strategy represents a substantial increase in accessibility to new markets for businesses.
- Will future land-use demands result in the same or a different mix of land uses than currently found in the corridor? For example, will the area be more or less attractive for residential development? Retail development? All types of development?

***6. Evaluate Land Supply***

Because the interaction of land supply, travel demand, and local/regional development policy influences regional growth, it is very useful to evaluate the various determinants of land supply in the study area, as well as how each determinant may be affected by transportation strategies. For example, to what extent will the strategy itself use land that is otherwise developable? To what extent will the right-of-way needed affect the usefulness or marketability of adjacent parcels? These issues are traditionally addressed in a land-use impact analysis; they are considered direct impacts of the strategies.

In addition, the analyst may want to review existing zoning and comprehensive plan designations to understand the opportunities and constraints within which future development will occur. The supply of land affected by the transportation strategy will be shaped by these zoning and planning designations. Traditionally, for example, areas zoned for residential development—even though not yet fully developed—have an established character, which may not be easily changed despite demands for other uses.

***7. Produce Findings and Conclusions***

Comparing and contrasting the way the supply and demand for land and its uses are influenced by transportation strategies allow the analyst to assess direct, indirect, and induced effects of transportation investment, and the supporting data for those conclusions. This final step in the land-use analysis documents the steps taken in the analysis and provides evidence to support any recommendations or conclusions that result. The results are incorporated into the evaluation component of the transportation study (see chapter 7 on evaluation) or as the evaluation results of an environmental study.

In summary, by systematically addressing a series of land use–related issues and questions, the land-use analysis can contribute meaningfully to the strategy evaluation and impact assessment process. The approach described in this

section can be applied to any kind of major transportation investment, both to individual modal elements or to multimodal strategies and plans. The key concepts are the links between changes in accessibility to a site, area, or corridor; the availability and suitability of land and sites in that vicinity; and the potential effects of existing or potential land-use policies, ordinances, or strategies that apply to the affected area.

## B. Consistency with Planning and Zoning

The analysis should examine whether the forecasts for development are consistent with adopted local comprehensive plans and zoning. To the extent that the results of the land-use impact analysis lead to forecasts for levels or types of development inconsistent with current plans, there is an opportunity, or perhaps an imperative, to address and resolve these issues. Although the process for this resolution may evolve beyond the transportation planning study, the issues, opportunities, and conflicts should be clearly identified as part of the study process. Further, the planning process may provide an opportunity to bring about interjurisdictional and interdisciplinary coordinated and collaborative planning.

## C. Impacts on Services and Tax Base

Changes in development can increase the tax base of an affected jurisdiction(s), but may also increase the demand for public services, such as schools and law enforcement. These effects should be explicitly considered in the analysis. Where the fiscal impacts of changes in development are thought to be an issue, local governments should be brought into the study process. Such estimates should take into account the type of development expected to occur, the kinds of public services normally required for such development, and the possible need for new capital facilities to provide these services.

## D. Impacts on Transportation Systems

To the extent that strategies may lead to secondary and cumulative land-use impacts, their effect on transportation system performance should be explicitly considered. If the land-use analysis has identified new development in certain locations, it will be possible to estimate the travel demand and behavior associated with the new developments on these sites. The traditional travel-demand forecasting process can then be employed to determine the effects of this travel behavior on the performance of the transportation system. Where trip generation and distribution lead to the overloading of local street, highway, transit, or nonmotorized system capacity, mitigation measures may be necessary to increase system supply and/or manage travel demand (see chapter 6 on travel demand modeling).

## E. Economic Impacts

Another important impact of the construction and operation of new transportation facilities or services is the effect on employment and local economic activity. Calculating the local employment impact is straightforward and relies on standard factors, which should be readily available from local economic development reports or from the economics or planning departments of local universities. Once a strategy's capital cost has been estimated, the temporary employment due to construction can be calculated using an estimate of person-years of employment per million dollars for this type of construction. In addition, permanent employment opportunities will be created to operate the expanded system. Estimates of permanent employment can be derived from the operating cost developed during the cost analysis. Both the temporary and the permanent effects of this direct employment can then be assumed to multiply the economic impacts as the direct wages and salaries are spent in the local area to generate indirect employment. These multipliers have been calculated for most local areas.

Four types of employment impacts are usually considered in an economic impact study: temporary and permanent direct employment, and temporary and permanent indirect employment. Such employment impacts can be included in the environmental justice analysis that examines social equity consequences of transportation investment (see next section).

The effects of spending large sums of money on the construction and operation of a new transportation facility are not limited to employment, even though most of this money is eventually spent on wages and salaries. Of interest to local governments, some of this money also is spent on local taxes.

## V. SOCIAL AND COMMUNITY IMPACTS

Transportation systems affect the social environment of a community in numerous ways, both during and after construction. Social environment is defined as the surrounding community's interpersonal interactions that are within an impact area of a particular facility or service. Potential adverse social impacts include household or business displacement and relocation, reduced neighborhood cohesion, deterioration in the quality of neighborhoods and lifestyles, and reduced access to vital community facilities and services. Beneficial impacts could include improved access to employment and services, increased economic development, and improved infrastructure. As appropriate, these impacts should be assessed during a planning study. Where adverse impacts are anticipated, possible mitigation measures should be identified, as is required in the United States for highway and transit actions covered by NEPA, the joint FHWA and FTA EIS regulations, and Executive Order 12898 on Environmental Justice.

The lead and collaborating agencies should jointly identify the social issues that need to be considered in the study. The most useful way to identify potential social impact issues is through public outreach. Beginning with the study initiation process and continuing throughout the planning study, a public participation program provides opportunities for interested citizens and groups to express their views on the likely effects of the strategies being considered. This input provides valuable perspectives on potential effects and helps to assess the severity of impacts and possible mitigation measures. Experience reveals that various social indicators, such as neighborhood mobility and stability indices and social interaction analysis, are generally less useful than straightforward public involvement for identifying and assessing realistic social impacts and mitigation options.

Local agencies should avoid making judgments on the significance of social impacts, since this is largely a matter of perception. Instead, impacts should be quantified where possible, identifying the number of displaced households, for example. The planning study should carefully describe the impacts and public views about their significance, while avoiding judgment. The analysis of social impact should also identify groups likely to be affected, as called for in Executive Order 12898 on Environmental Justice. Where social impacts are anticipated, the documentation should use maps displaying neighborhood boundaries, and present a socioeconomic profile of each neighborhood. This information may then be used to assess the distribution of investment benefits and impacts among various jurisdictions, transportation users, and socioeconomic groups.

### A. Community Disruptions

The physical construction of transportation projects frequently requires land, often causing households, businesses, and public facilities to be displaced. These impacts need to be identified and assessed to the degree possible for each strategy. An important measure is the number of individuals, families, businesses, and facilities that would be displaced. The availability of comparable replacement housing—and the significant effects on the neighborhoods the displaced individuals are likely to relocate to—should also be examined. Planning studies often determine the characteristics of the families to be displaced (race, income, tenure, age, family size), as these may have a bearing on the severity of the effects of displacement and the availability of suitable replacement housing. However, data availability and privacy issues may limit this information to what is available from the census data.

The level of displacement is normally determined by using aerial photographs and conceptual engineering drawings. While specific properties (defined by land ownership) to be taken for each alternative may not be known, there should be a fairly accurate estimate of the number of dwellings and businesses that would be displaced. For residential displacements, the community profile provides information on the characteristics of the neighborhood, and thus the likely racial and socioeconomic characteristics of those to be displaced. Where businesses are to be displaced, the study should try to identify the types of jobs likely to be affected and whether these might remain in the community.

Where displacement occurs, families and businesses must be compensated for the cost of the property taken and for relocation costs. Such compensation should be included in the capital cost of each strategy and should include the cost of land and structures, the purchase of business enterprises, relocation expenses, and rent supplements as may be necessary. Guidance on right-of-way acquisition and relocation assistance requirements is given in various federal and local governmental programs.

### B. Noise and Vibration

Many types of transportation investments have the potential to increase noise and vibration levels in a community. Sources of transportation noise include vehicle operating noise, noise caused by diverted or increased traffic due to

a highway or transit improvement, and noise and vibration generated by fixed-guideway transit facilities. (Note that noise and vibration are treated here as part of the social and community effects category, primarily due to their potential disruptive impacts on quality of life and social interaction.)

A major source of vehicle noise is the vehicle itself. This includes exhaust noise from diesel buses or truck engines, the whine of the electric traction motors of rapid transit cars, and the noise from air moving through cooling fans. In addition, tire noise made by rubber-tired vehicles can be substantial at high operating speeds. For rail systems, several types of noise are generated by steel wheels on steel rails, depending on the type and condition of the running surfaces. The guideway structure can also act as a noise source when it vibrates under moving vehicles. Some types of equipment continue to run while the vehicle is stationary (fans, radiators, dynamic brakes, and air-conditioning pumps); thus, the noise persists at traffic signals and in transit stations or storage yards. In transit facilities, noise is generated by ventilation fans (in stations, subway tunnels, and power stations), chiller plants, and maintenance equipment and operations.

Vibrations include those traveling through the ground and those perceived visually, such as by the swaying of signs as trains pass by. For people living near a maintenance facility or a transit or truck route, vibration can be a substantial irritant.

The purpose of a noise impact analysis is to determine and report important changes in noise impact on a community associated with a strategy. The potential for adverse noise impacts is the greatest when noise-sensitive receptors are located in the study area or when the community is located in an environment that is already exposed to high noise levels. Noise-sensitive sites are placed into three categories:

- *Category 1*—Low-density residential areas far from noise sources: buildings and parks where quiet is an important element.
- *Category 2*—Residential buildings, or buildings with overnight sleeping accommodations such as homes, hospitals, hotels, and motels.
- *Category 3*—Institutional land uses with primarily daytime use, including schools, places of worship, libraries, auditoriums, and active parks.

To determine whether a detailed noise analysis is needed, a phased approach is often used, with attention given to the type of strategy, its noise-producing characteristics, and the proximity of noise-sensitive receptors. The level of detail in a noise analysis depends on the level of detail required to evaluate different types of strategies—generally the degree and location of impacts, and the type, effectiveness, and cost of potential mitigation.

The three levels of analysis in this phased approach are described in greater detail in the FTA's *Guidance Manual for Impact Analysis of Transit Noise and Vibration Impact Assessment*. [Hanson et al., 2006] The first phase of all analyses should include a screening to determine whether a noise impact analysis is needed. Noise- and vibration-sensitive land uses, characteristics of strategies that would generate noise, and any potential noise problems should be identified. This can be done by conducting walking or windshield surveys, by reviewing current land-use maps, or by inspecting recent aerial photographs of the study area. If no noise-sensitive land uses are present, no further noise assessment is necessary in the planning study. When noise-sensitive land uses are present, however, this early screening phase can help determine whether further noise analysis is needed. Table 4-5 provides examples based on project type and distance from receptors. The distances noted in the table can be used to locate noise-sensitive land uses in the aforementioned three categories. If none of the listed land uses are found to be within the distances noted in Table 4-5, the proposed alternatives would not substantially increase noise. Therefore, no further analysis would be needed for the planning study.

Another common portrayal of noise standards is shown in Table 4-6 from the Federal Highway Administration. In this case, noise levels are specified for different types of activities, and estimated or measured levels are compared to standards. If noise levels are expected to exceed the standards, some form of abatement will be necessary.

A general assessment analysis provides more detailed information and covers a narrower study area than the screening-level analysis. It is used to examine strategies where environmental evaluation is needed before engineering details are available, as is the case for most planning studies. This phase picks up where the screening-level analysis ends, that is, after sensitive land uses within noise-impact corridors have been identified. During the general assessment phase, existing noise levels at these land uses are estimated. Future noise levels can then be estimated,

| Table 4-5. Screening Distances for Transit Noise Assessments | |
|---|---|
| **Type of Project** | **Screening Distance (ft) from Right-of-Way or Property Line** |
| **Fixed Guideway Systems** | |
| Commuter Rail Mainline | 750 |
| Commuter Rail Station | 300 |
| Rail Transit Guideway | 750 |
| Rail Transit Station | 300 |
| Access Roads | 100 |
| Low and Intermediate Capacity Transit | 100 |
| Steel Wheel | 750 |
| Rubber Tire | 500 |
| Yards and Shops | 2000 |
| Parking Facilities | 250 |
| Access Roads | 100 |
| **Ancillary Facilities** | |
| Ventilation Shafts | 200 |
| Power Substations | 200 |
| **Highway/Roads** | 750 |
| **Bus Systems** | |
| Busway | 750 |
| **Bus Facilities** | |
| Access Roads | 100 |
| Transit Mall | 250 |
| Transit Center | 450 |
| Storage & Maintenance | 500 |
| Park & Ride Lots | 250 |

Source: Hanson et al., 2006

taking into account factors such as vehicle types, speed, traffic volume, and the distance between the noise source and the listener or receiver. This requires the use of travel demand models to estimate future traffic volumes.

Ambient noise levels are compared with projected noise levels to calculate the increase in noise due to a strategy. An inventory of noise-affected receivers within an estimated corridor of the strategies can be prepared. The resulting inventory of affected receivers can also be used for comparing noise impact among strategies. A detailed analysis is used for assessing noise impacts where the formal environmental documents are prepared in conjunction with preliminary engineering. This type of analysis provides much more detail about one or more NEPA alternatives, including site-specific information about noise and vibration impacts on individual receptors, along with prescribed mitigation measures based on the extent to which the criteria are exceeded.

Transportation noise can affect a community in two basic ways. It may be loud and frequent enough to increase the cumulative noise significantly, or it may be objectionable even if it is intermittent or of short duration. Noise-impact assessment involves two components used to determine whether either type of noise impact will occur. An absolute criterion compares the predicted noise from a strategy or an alternative to a standard; it predicts interference from a particular noise source to the exclusion of other sources. The absolute criterion is used for rail rapid transit strategies and bus options on highways. The relative approach involves comparing projected noise levels to existing ambient levels. In this approach transportation noise is not considered in isolation but is integrated with the overall community noise level. The impact is assessed according to the contribution of transportation noise to the overall noise level. The relative approach can always be used. For rail strategies, the absolute criterion is based on the maximum level of a single vehicle pass-by ($L_{max}$), while the relative criterion is based on the change in peak-hour equivalent noise level ($L_{eq}$).

| Table 4-6. Roadway Noise Abatement Criteria (Hourly A-Weighted Sound Level, Decibels) | | | | |
|---|---|---|---|---|
| **Activity Category** | **Activity Criteria** | | **Evaluation Location** | **Activity Description** |
| | $L_{eq}$ | $L_{10}$ (h) | | |
| A | 57 | 60 | Exterior | Land on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose. |
| B | 67 | 70 | Exterior | Residential |
| C | 67 | 70 | Exterior | Active sport areas, amphitheaters, auditoriums, campgrounds, cemeteries, day care centers, hospitals, libraries, medical facilities, parks, picnic areas, places of worship, playgrounds, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, recreation areas, Section 4(f) sites, schools, television studios, trails, and trail crossings. |
| D | 52 | 55 | Interior | Auditoriums, day care centers, hospitals, libraries, medical facilities, places of worship, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, schools, and television studios. |
| E | 72 | 75 | Exterior | Hotels, motels, offices, restaurants/bars, and other developed lands, properties or activities not included in A to D or F. |
| F | No noise analysis required | | | Agriculture, airports, bus yards, emergency services, industrial, logging, maintenance facilities, manufacturing, mining, rail yards, retail facilities, shipyards, utilities (water resources, water treatment, electrical) and warehousing. |
| G | Mitigation is not required, but expected noise levels must be provided to local officials. | | | Undeveloped lands that are not permitted. |

Source: FHWA, 2010a

The assessment of vibration impacts is usually performed in tandem with the noise assessment. At the planning level, this assessment is usually limited to identifying vibration-sensitive buildings. Vibration impacts are assessed on buildings rather than on general categories of land use. Vibration-sensitive buildings, however, may not be evident from land-use surveys. The type of business or industry housed in the structure must be identified to determine if vibration-sensitive processes are in use, such as hospital, laboratory, and recording studio activities. If no vibration-sensitive buildings are identified, no further vibration analysis is needed. If there are such buildings, further analyses may be necessary during preliminary engineering, when data on subsurface conditions are used to assess vibration levels.

When conducting a planning study where different investment strategies are still under consideration, potential mitigation is discussed only in general terms, that is, the possible need for mitigation and the feasibility and cost of various options. Later, when a specific project has been identified, specific mitigation measures should be described and commitments given to implement them, generally during the NEPA/preliminary engineering phase. The final environmental document should contain a complete description of mitigation measures to be implemented as part of the proposed project.

An excellent source of federal and state information on noise analysis is found on AASHTO's Center for Environmental Excellence website: http://www.environment.transportation.org/environmental_issues/noise/docs_reports.aspx.

## C. Neighborhood Cohesion

Neighborhood cohesion refers to a social attribute that indicates a sense of community, shared civic responsibility, social interaction within a limited geographic space, and interdependence that serves an assimilating function for a number of other localized social purposes. The planning study should identify potentially affected neighborhoods that exhibit a strong sense of cohesiveness and that have attributes making the community unique. If cohesiveness is defined explicitly, it may be possible to obtain some empirical evidence to judge the degree of cohesion and thereby gauge the impacts of proposed projects on the neighborhood. Public engagement is likely to prove a good technique

for identifying and assessing potential impacts. Impacts on community cohesion can be mitigated by adopting facility alignments that follow natural neighborhood boundaries or by proposing strategies that enhance the cohesion of the neighborhood.

## D. Neighborhood Quality

Transportation investment strategies could also affect the overall quality of a neighborhood. Such effects may be reflected in changed property values, for example, or in the increased or decreased satisfaction residents derive from living in the neighborhood. Eventually, existing residents might be replaced by new residents with different lifestyles. Such impacts are difficult to predict, let alone quantify, yet they may be of considerable importance to those residing in the community.

Economic and environmental analyses performed as part of the planning study can help reveal the likelihood of any impacts on neighborhood quality and lifestyles. The assessments of noise and aesthetics, for example, should help reveal potential changes in neighborhood quality. Similarly, the economic development analysis may show that a strategy greatly increases a neighborhood's accessibility, and that this could in turn enhance prospects for redevelopment. Such redevelopment may be viewed as a positive impact of the project, but existing residents may prefer that their neighborhood not be changed. The public involvement program should help the study determine the extent to which community residents are concerned about impacts on neighborhood quality and lifestyles.

## E. Access to Community Facilities and Services

Transportation investments may increase or reduce access to community facilities such as hospitals, schools, police and fire stations, shopping, places of worship, and other community-important centers. Access may be reduced if the roadway or guideway facility requires the acquisition of community facilities for right-of-way, or if the roadway/guideway creates a barrier between residents and the facilities. Such impacts should be considered both during the construction stage and for the permanent facility. Potential reductions in such access, particularly for school-age children and the elderly, would be considered a negative impact needing assessment and mitigation.

The impact on access to facilities is normally examined by identifying the location of community facilities and the areas they serve. Roadway/guideway projects that follow service area boundaries tend to have little, if any, impact on access to community facilities; those that create a physical barrier through a service area would have an impact. In such cases, the study should try to determine how many people would be affected by reduced access, and whether this barrier would create special problems for them. Potential mitigation measures might be explored, including changes in alignment, the construction of strategically located pedestrian crossings, or increased transit service by social service agencies. The public engagement program, once again, is the most useful technique for assessing likely impacts and evaluating potential mitigation measures.

## F. Environmental Justice

Executive Order 12898 ("Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations") calls for federal agencies to identify and address "disproportionately high and adverse human health or environmental effects" on low-income and minority populations. The key aspect of this requirement is considering how federal action—or in the case of a planning study, the strategies—will affect low-income and minority groups in the study area and the region. In other words, who benefits? who pays? and who receives adverse or beneficial impacts? According to the FHWA, three major principles guide environmental justice analyses:

- Avoid, minimize, or mitigate disproportionately high and adverse human health and environmental effects, including social and economic effects, on minority and low-income populations.
- Ensure the full and fair participation of all potentially affected communities in the transportation decision-making process.
- Prevent the denial of, reduction in, or significant delay in the receipt of benefits by minority and low-income populations. [FHWA, 2000]

While environmental justice issues are often raised to some extent in planning documents in the United States, project-specific environmental analysis will consider it in more detail. The impacts and benefits accruing to specific low-income and minority populations in neighborhoods and communities should be highlighted. The planning study report's summary of environmental impacts—a cumulative impacts discussion and/or the evaluation chapter and equity discussions—should be compiled and a comparison made between the impacts/costs to identified low-income and minority populations versus the general population.

When a planning study is part of a larger regional planning process, the environmental justice analysis can support a broader system-level assessment of how the investment decisions and priorities will affect low-income and minority populations. GIS tools in particular are very useful in identifying environmental justice impacts in a study area. See chapter 7 on evaluation for more discussion on environmental justice analysis.

## G. Public Health/Active Living

Chapters 1 and 2 describe the important role for transportation in the evolution of communities and in the quality of life of their residents. The physical characteristics of the transportation system are a factor in the health of a community's residents. Over the past 10 years, several agencies and groups have begun to examine this relationship more closely, for example, how can one encourage more exercise through active living? [Raynault and Christopher, 2013] Air quality regulations (see Section VI) have as their major focus the reduction of hazardous pollutants causing serious health issues for those sensitive to different emissions (for example, those with asthma). However, the more recent interest in public health focuses on urban form and how transportation does or does not encourage physical activity.

According to the Centers for Disease Control, a more active lifestyle (for example, exercising) can have the following benefits:

- Control weight.
- Reduce risk of cardiovascular disease.
- Reduce risk for type 2 diabetes and metabolic syndrome.
- Reduce risk of some cancers.
- Strengthen bones and muscles.
- Improve mental health and mood.
- Improve ability to do daily activities and prevent falls, if you're an older adult.
- Increase chances of living longer. [CDC, 2014]

Several transportation planning programs have embraced the concept of active transportation and have integrated such strategies into the transportation planning process. [Dannenberg et al., 2014] The Nashville, Tennessee, MPO, for example, has set aside funding for its active transportation program, with special focus on pedestrian and bicycle facility investments (see http://www.nashvillempo.org/plans_programs/tip/ATP.aspx). Portland, Oregon, has been a national leader in non-motor vehicle transportation for decades and Portland Metro, the region's MPO, has developed a Regional Active Transportation Plan (ATP) that "will make it easier to walk, ride a bike, or take public transportation to your destination. The plan identifies a vision, policies and actions to complete a seamless green network of on- and off-street pathways and districts connecting the region and integrating walking, biking and public transit." [Portland Metro, 2008] In San Francisco, the Metropolitan Transportation Commission (MTC) established the following performance measures for health and equity used in the regional prioritization process: premature deaths from exposure to particulate emissions, injuries and fatalities from collisions, and average daily time per person spent walking or biking for transportation. In addition, the MTC has recognized the important relationship between transportation and land use by trying to promote transit-oriented developments throughout the region. In San Diego, SANDAG, the MPO, awarded local community grants for activities related to pedestrian paths, sidewalks, connections to transit, food access, and urban agriculture. Interestingly, SANDAG also developed a health assessment module for its activity-based travel demand model. [Raynault and Christopher, 2013]

Several chapters in this handbook provide more detailed information on the analysis tools that can be used to assess the effectiveness of active transportation strategies. See, for example, chapter 3 on land use and urban design, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, chapter 14 on travel demand management (TDM), and chapter 19 on site planning and impact analysis. See also NARC [2014].

## H. Historic, Cultural, and Parkland Resources

Transportation investments to be built with federal funding assistance are subject to two legal requirements dealing with potential impacts on historic, cultural, or open-space resources. While the specific provisions of the two laws are somewhat different and are generally treated separately, the work involved in addressing each requirement during a planning study is sufficiently similar to allow combined discussion here.

Section 4(f) of the U.S. Department of Transportation Act requires a finding by the U.S.DOT Secretary of Transportation that no prudent and feasible alternative exists to any federal action that has negative impacts on subject properties, and that all possible planning has been done to minimize harm. Subject properties include significant publicly owned parklands, recreation areas, open spaces, wildlife and waterfowl refuges, and historic sites.

Section 106 of the National Historic Preservation Act requires that federal agencies identify and assess the effects of expenditures of federal funds on historic sites, districts, buildings, and archaeological sites. The provision requires agencies to afford the Advisory Council on Historic Preservation an early opportunity to comment on proposed actions having potential impacts on historic properties and to mitigate these impacts to the extent possible. Subject properties are defined to include those on or eligible for the National Register of Historic Places.

The federal transportation agencies most affected by these laws, FHWA and FTA, must be satisfied that the stipulations are met before any funding assistance is given to transportation projects. As with many other technical areas, it is important to identify the appropriate level of detail required for the planning study, distinguishing it from the level of detail more appropriately done later during project development.

Identifying all potentially affected properties in the corridor or subarea is an important first step in the analysis of possible Section 4(f) and Section 106 impacts. For the diverse types of properties covered by the 4(f) requirement, it is necessary to consult with local, state, and federal agencies having responsibilities for parklands, recreation areas, open spaces, and similar properties. For historic properties, well-developed sources of information often exist. These include the U.S. National Register, state historic registers and other listings, and the files of the State Historic Preservation Officer (SHPO). In most cases, a survey by a historic preservation professional is needed to ensure the inventory is complete and meets Section 106 requirements. This survey uses, at a minimum, the standards of eligibility for the National Register to examine sites not currently listed on the register or those already identified as eligible.

The analysis of potential direct or indirect impacts is the second step in the 4(f) and 106 processes. Direct impacts include the physical taking of the property or parts of the property, while indirect impacts include effects that impair the use of the property for intended purposes. Indirect impacts usually involve noise, visual intrusion, or obstruction of access to the property. Thus, the analysis must consider the current uses of the properties and examine possible constraints on these uses caused by a project. Further, in considering indirect impacts, the scope of the analysis must be broad enough to include not only properties that may be physically taken in whole or in part, but also sites adjacent to and within view of the right-of-way. In some cases, the scope will include sites on access roads to station sites that might experience significant increases in traffic volumes. The processes conclude with determinations by the responsible agencies that proposed actions satisfy statutory requirements.

For the 4(f) requirement, the final NEPA document includes a 4(f) statement that:

- Presents the inventory and description of potentially affected properties.
- Discusses the likely nature of the impacts on these properties.
- Examines alignment variations and other design alternatives for the project that might avoid the impacts.
- Identifies mitigating actions that will be taken to minimize the adverse impacts, where these design avoidance options are not judged prudent and feasible.

Since the FHWA/FTA Administrators have been delegated the authority to verify the Department's finding that the Section 4(f) requirements have been met, this finding is made concurrent with approval of the final NEPA document. The U.S. Department of the Interior reviews and comments on the draft Section 4(f) statement prior to FHWA/FTA approval. See FHWA [2012d] for more detail on how to conduct a Section 4(f) analysis.

Federal legislation in 2005 amended the original law creating Section 4(f) requirements to simplify the processing and approval of projects that have only *de minimis* impacts on lands protected by Section 4(f). A *de minimis* impact is "one that, after taking into account any measures to minimize harm (such as avoidance, minimization, mitigation, or enhancement measures), results in either:

1) A Section 106 finding of no adverse effect or no historic properties affected on a historic property; or
2) A determination that the project would not adversely affect the activities, features, or attributes qualifying a park, recreation area, or refuge for protection under Section 4(f)." [FHWA, 2012d]

A use of Section 4(f) property having a *de minimis* impact can be approved by FHWA without the need to develop and evaluate alternatives avoiding the use of the Section 4(f) property.

For Section 106 requirements, findings of adverse effects must be sent to the Advisory Council on Historic Preservation. Mitigation measures are stipulated in a memorandum of agreement (MOA) among the SHPO, FHWA/FTA, and the grantee and the council, if it chooses to participate in the MOA.

The general recommendation regarding level of effort in this area parallels those of other technical areas. The work during a planning study should be sufficient to identify considerations that may be significant in selecting a preferred strategy. In effect, the purpose is to identify any likely problems in meeting the 4(f) and 106 requirements for each strategy. Thus, actual completion of the requirements is not necessary and, given the number of strategies and degree of uncertainty typical of a planning study, may not even be possible. This general guideline provides substantial latitude for determining the level of effort, depending on the degree of potential impacts in the corridor or subarea, the amount of existing information, and the degree and nature of local concerns.

Most important, efforts during the planning study should include close coordination of the inventory, analysis and findings with the SHPO and other agencies with jurisdiction over subject properties. The planning study should document this coordination and demonstrate the collaboration.

## VI. NATURAL RESOURCE IMPACTS

Transportation projects can have significant impacts on the natural environment, resulting in subsequent impacts on communities and individuals (such as the impacts on air quality and water quality). A planning study should identify the impacts of each strategy as well as their significance. Most planning studies, for example, will consider potential impacts on water quality. Some will also examine impacts on wetlands, floodplains, and aesthetics. Occasionally, detailed studies of endangered species, coastal zones, toxic waste disposal, ocean dumping, navigable waterways, and other factors will be undertaken. Special rules, regulations, and permits apply to many of these impact areas. State and local legislation and ordinances may contain additional requirements. Many of these topics will not apply to a particular strategy or study area and can be eliminated from further consideration after an initial step of determining to what extent such impacts might be relevant to the study.

The requirements for analyzing and dealing with each type of impact are beyond the scope of this overview. However, there are numerous FHWA, FTA, and state/local resource agency documents on assessing impacts of transportation options on the natural environment, which should be consulted.

In cases where the sponsoring agency has identified possible impacts beyond the analysis resources or capabilities of local staff, outside assistance should be obtained. In many cases, specialized consultants are retained. Other governmental, nonprofit, or private organizations and individuals may also be able to provide support. The following federal agencies (and their local and state equivalents) might be useful: Army Corps of Engineers, Environmental

Protection Agency (EPA), Fish and Wildlife Service (FWS), and Coast Guard. Further assistance may be obtained through federally sponsored training courses and manuals.

## A. Air Quality

The EPA has established National Ambient Air Quality Standards (NAAQS) for pollutants considered harmful to human health and public welfare. NAAQS exist for the following pollutants, known as criteria pollutants: carbon monoxide (CO), small particulate matter ($PM_{2.5}$), sulfur dioxide ($SO_2$), nitrogen dioxide ($NO_2$), ozone ($O_3$), and lead (see Table 4-7). Transportation-related pollutant emissions can be of concern primarily at a local level, such as CO emissions at intersections, or at a regional scale, such as ozone levels. Geographic areas that violate one or more of these standards are called nonattainment areas. States, in cooperation with local planning and environmental agencies, produce state implementation plans (SIPs) showing how these standards will be attained and maintained. Transportation control measures (TCMs) can be part of the set of strategies that will help achieve the standards.

Air quality assessments performed during planning address the potential impacts of each strategy from three perspectives: changes in regional pollutant emissions, changes in localized emissions, and the conformity of these changes with adopted air quality implementation plans. Formal conformity determinations will be made later, when the chosen alternative is added to the plan and TIP. For the purposes of a planning study, relative comparisons among the strategies for air quality and conformity impacts are all that is normally needed.

**Table 4-7. National Ambient Air Quality Standards (NAAQS), United States**

| Pollutant | | Primary/Secondary | Averaging Time | Level | Form |
|---|---|---|---|---|---|
| **Carbon Monoxide** | | Primary | 8-hour | 9 parts per million (ppm) | Not to be exceeded more than once per year |
| | | | 1-hour | 35 ppm | |
| **Lead** | | Primary and Secondary | Rolling 3-month average | 0.15 μg/m$^3$ | Not to be exceeded |
| **Nitrogen Dioxide** | | Primary | 1-hour | 100 parts per billion (ppb) | 98$^{th}$ percentile, averaged over 3 years |
| | | Primary and Secondary | Annual | 53 ppb | Annual mean |
| **Ozone** | | Primary and Secondary | 8-hour | 0.075 ppm | Annual fourth highest daily maximum 8-hour concentration, averaged over 3 years |
| **Particle Pollution** | $PM_{2.5}$ | Primary | Annual | 12 μg/m$^3$ | Annual mean, averaged over 3 years |
| | | Secondary | Annual | 15 μg/m$^3$ | Annual mean, averaged over 3 years |
| | | Primary and Secondary | 24-hour | 35 μg/m$^3$ | 98$^{th}$ percentile, averaged over 3 years |
| | $PM_{10}$ | Primary and Secondary | 24-hour | 150 μg/m$^3$ | Not to be exceeded more than once per year on average over 3 years |
| **Sulfur Dioxide** | | Primary | 1-hour | 75 ppb | 99$^{th}$ percentile of 1-hour daily maximum concentrations, averaged over 3 years |
| | | Secondary | 3-hour | 0.5 ppm | Not to be exceeded more than once per year |

Source: Environmental Protection Agency. "National Ambient Air Quality Standards (NAAQS)." Accessed Feb. 24, 2016, from http://www.epa.gov/air/criteria.html.

The level of analysis needed to address air quality impacts and the types of pollutants addressed will depend on the significance of local air pollution problems. A quantitative analysis is needed when a transportation project or strategy is located in a nonattainment area or could cause violations of one or more of the NAAQS. This includes highway investments with added single-occupancy vehicle capacity, transit investments with major parking facilities, downtown bus options (especially in areas where background concentrations are already high), and any proposal where there is the potential for adverse effects on sensitive receptors, including hospitals, parks, convalescent or nursing homes, schools, and residential neighborhoods.

Even though rail projects are electrically powered and the vehicles are nonpolluting, transit stations with parking for a large number of cars can be indirect sources of air pollution. Increased traffic near stations and at parking lots during peak periods may create hot spots or cause local increases in certain air pollutants in much the same way as various types of roadway improvements. Measures such as ramp metering can reduce congestion on major freeways but can create hot spots at the queues at metered ramps. Hot spots can also occur in queues at toll plazas. Tunnel ventilation exhaust facilities also need to be considered. Projects such as bus storage and maintenance facilities, downtown terminals, transit malls, and other projects that concentrate bus activity in populated areas can also negatively affect local air quality.

Comparing estimated air pollution levels with the NAAQS is one of the procedures used to determine whether an investment is likely to have an adverse effect on air quality and, if so, the severity of its effect. In areas that also have state air quality standards, a more restrictive standard may be used. Another procedure is to estimate a potential project's effects on total emissions in an area, known as an emission burden analysis.

Some federal standards are expressed as hourly averages, while others are annual averages. The NAAQS for CO, for example, is expressed as short-term 1-hour and 8-hour standards. The standard for $NO_2$, however, is expressed as an annual arithmetic mean. This makes it more difficult to assess the effects of operations during the short period of greatest use. Although no short-term standard exists at the federal level for $NO_2$, several states have adopted them. These can be used as a basis for gauging the air quality effects of some projects.

The primary criteria pollutants examined for diesel bus and truck activity are nitrous oxides ($NO_x$), which mostly represent the sum of nitric oxide (NO) and nitrogen dioxide ($NO_2$) hydrocarbons (HC), and small particulate matter. The effects of these activities on noncriteria pollutants, such as formaldehyde and benzene, might also be considered.

Ozone is a component of photochemical smog, which is produced by the action of sunlight on a combination of HC and $NO_x$. In metropolitan areas the major mobile-source factors affecting peak ozone concentrations are $NO_x$ and HC emissions from motor vehicles and photochemical production of oxidants. Where gasoline-powered vehicles are the primary concern, the analysis focuses on CO. Most CO pollution and violations of standards are caused by motor vehicle emissions at hot spots or areas of heavy traffic congestion.

One of the most common ways of estimating pollutant emissions from the transportation system (called mobile sources) is to estimate some "activity factor," such as vehicle miles traveled, and multiply that factor by an emissions rate, for example, expressed in grams per mile. At a study level, the network demand model is the tool most often used to estimate this activity factor. For estimating emission rates, the EPA has developed or sponsored several models that can be used to estimate such rates. As listed on the EPA's website, these models include:

- "MOVES (MOtor Vehicle Emission Simulator) is EPA's current official model for estimating air pollution emissions from cars, trucks and motorcycles. In the future the model will also cover non-road emissions.
- NONROAD Model links to information on the NONROAD emission inventory model, which is a software tool for predicting emissions of hydrocarbons, carbon monoxide, oxides of nitrogen, particulate matter, and sulfur dioxides from small and large non-road vehicles, equipment, and engines.
- NMIM, or National Mobile Inventory Model, is a free, desktop computer application developed by EPA to help develop estimates of current and future emission inventories for on-road motor vehicles and non-road equipment. NMIM uses current versions of MOBILE6 and NONROAD to calculate emission inventories, based on multiple input scenarios that you enter into the system. One can use NMIM to calculate national, individual state, or county inventories.

- MOBILE Model links to information on the MOBILE vehicle emission factor model, which was EPA's official model for estimating air pollution emissions from cars, trucks, and motorcycles until it was replaced by MOVES.
- Fuel Effects on Vehicle Emissions links to information on test programs and modeling estimating the emissions impacts of changes in fuel properties and composition. Information on how fuel effects are applied in MOVES and NONROAD is available on the web pages for those models.
- OMEGA, the Optimization Model for Reducing Emissions of Greenhouse gases from Automobiles, estimates the technology cost for automobile manufacturers to achieve variable fleet-wide levels of vehicle greenhouse gas emissions.
- GEM, the Greenhouse gas Emissions Model, estimates the greenhouse gas emissions and fuel efficiency performance of specific aspects of heavy-duty vehicles. This model is a means for determining compliance with EPA's GHG emissions standards and NHTSA's fuel consumption standards . . . ." [U.S. EPA, 2013]

Given the long history and seriousness of the air quality challenge in California, the state's Air Resources Board has developed a menu of models that are used for environmental assessment in the state. For example, the Hotspots Analysis and Reporting Program Version 2 (HARP 2) is a software program consisting of three programs: Emissions Inventory Module (EIM), Air Dispersion Modeling and Risk Tool (ADMRT), and Risk Assessment Standalone Tool (RAST). The focus of this program tool is on emissions hotspots. The EIM allows users to create and manage a facility emission inventory database and calculate facility prioritization scores. The ADMRT performs atmospheric dispersion analyses and can calculate cancer and noncancer (acute and chronic) health impacts. The RAST calculates cancer and non-cancer (acute, 8-hour, and chronic) health impacts using ground level concentrations, uses point estimates or data distributions of exposure to calculate inhalation and multipathway risks, performs spatial averaging on concentrations and risk from various pathways and receptors, calculates population exposure, and calculates cumulative impacts for one or multiple facilities and one or multiple pollutants. [Air Resources Board, 2015]

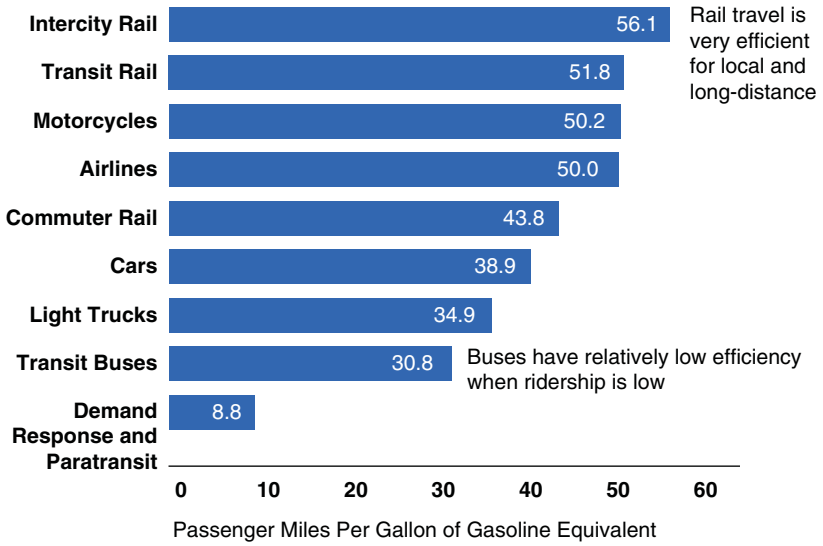
California has developed many other emissions models that are used for California studies and often in other parts of the United States. Interested readers are referred to Air Resource Board, "Modeling Software," http://www.arb.ca.gov/html/soft.htm for a detailed description of the models available.

*Conformity* — Conformity is defined in federal regulations as a transportation plan's, program's, or project's conformity to an SIP's purpose of eliminating or reducing the severity and number of NAAQ violations, and expeditiously meeting its standards. In addition, actions may not cause or contribute to new violations of air-quality standards, exacerbate existing violations, or interfere with timely attainment or required interim emissions reductions toward attainment. A federal conformity rule also establishes how FHWA, FTA, and the local MPO determine the conformance of highway and transit projects.

The MPO must develop tools to identify future investments planned in a nonattainment area and describe how these investments will assist in meeting the SIP's requirements. Transportation planning studies are used to determine transportation investment for corridors or subareas that could become part of an adopted plan and conforming TIP. Two approaches are suggested for evaluating regional conformity:

- A relative comparison of emissions strategies at the corridor level could be included as part of the planning study for NEPA purposes. While a full regional emissions model run would not be conducted for each strategy studied, a regional model run—including design concept and scope strategy—would be made before the plan is amended. The regional model run might cover a package of plan amendments, including not only the project resulting from the planning study but also other plan changes. This is the preferred approach in most planning studies.
- The regional emissions model could be run for each strategy in the study. Once the planning study is completed—and assuming that one of the strategies tested is proposed for inclusion in the plan—the regional emissions analysis would already have been done to support the conformity determination for the plan amendment. This assumes, however, that the project emerging from the planning study is the only amendment being made to the plan at that time.

**Figure 4-5. Average Fuel Economy for Passenger Modes**



Source: U.S. DOT, 2015

Since planning studies do not usually include sufficient information for a detailed hot-spot analysis, it may also be appropriate to conduct a project-level CO impact assessment of projects at typical locations. This will assess whether any of the projects raise serious air emission concerns, such as the existence of current CO problems, or to what degree any of the strategies will add to them. If an apparent problem arises, further analysis might be appropriate.

Planning study reports typically include an air quality section that discusses conformity in general terms and identifies any potential problems with strategies and how to resolve them. Once a project is in development, a supplemental hot-spot analysis is usually needed before completing the formal NEPA environmental analysis report.

*Consultation*—The air quality analysis methodology used in a planning study should be developed in consultation with state and local air pollution control agencies. The consultation process should ascertain which pollutants need to be addressed and the availability of data on existing pollutant concentrations and meteorological conditions. The state and local air pollution control agencies and MPOs should be consulted about the relevance of the SIP to the strategies being analyzed and the criteria for assessing conformity with the SIP.

## B. Energy

Transportation vehicles have different fuel consumption rates, otherwise known as fuel economy. Figure 4-5 shows typical average fuel economy rates for passenger modes. In the past, the energy analysis for proposed transportation investments was typically much less sophisticated than air quality and noise analyses. Energy analyses for fixed guideway transit projects typically reveal no significant difference in operating energy usage among transit strategies, and any differences found appear to have little effect on project decision making. In addition, there are very little data on the energy requirements of transportation facility construction and operations. As a result, comprehensive energy assessments during transit corridor studies were not generally performed.

For highway projects, fuel or energy consumption was simply estimated by determining the average fuel consumed by vehicle type per mile traveled and then multiplying this rate by the number of expected vehicle miles traveled, as determined from the travel-demand model.

However, this lack of sophistication may change with more complex multimodal planning studies being performed and with increasing concerns about the cost, availability, and environmental issues associated with using various energy sources. These concerns may give rise to a consideration of the energy consumption of different fuel types among the strategies. Moreover, each strategy's energy requirements could be calculated if local officials or public involvement were to give transportation energy use high priority in decision making. It also seems likely that carbon-based emissions, those that contribute to global warming, will become increasingly important to many decision makers.

| Table 4-8. Assessment of State DOT Strategic Directions Potentially Reducing Use of Energy: Lead Time and Qualifications | | |
|---|---|---|
| **Strategic Direction** | **Lead Time** | **Qualifications** |
| **Strategies to sustain or increase revenues** | | |
| Tolls or mileage-based user fees | 5–10 years | |
| Fuel taxes | Immediate | |
| Registration fees | Immediate | |
| Beneficiary fees | 5–10 years | Best in states with strong growth |
| General revenue sources | Immediate | |
| Increased use of private capital | 5–10 years | Best in states with strong growth |
| **Strategies to reduce costs** | | |
| Greater efficiency | 5–10 years | |
| Reduced scope of responsibility | 5–10 years | |
| **Strategies to improve auto and truck travel** | | |
| Road expansion | 10–20 years | Best in states with strong growth |
| Goods movement | 10–20 years | Best in states with large ports or trade corridors |
| Congestion pricing | 1–5 years | Best in states with large urban areas |
| ITS | >20 years | |
| Transportation system management | 1–5 years | Best in states with large urban areas |
| Traffic safety | 1-5 years | |
| **Strategies to improve alternative modes** | | |
| Transportation demand management | 1–5 years | |
| Public transportation | 5–10 years | Best in states with large urban areas |
| Land use | >20 years | Best in states with strong growth |
| **Strategies to promote energy efficiency and alternative fuels** | | |
| Vehicle feebates | 1–5 years | |
| Carbon pricing | 1–5 years | |
| Fuel mandates and programs | 1–5 years | Form of mandate varies by state |
| Fuel production and distribution | 5–10 years | Best fuel choice could vary by state |
| Agency energy use | 5–10 years | |

Source: Sorenson et al., 2014

Where energy analyses are performed, they should take into account the energy required to operate and build each investment strategy or alternative. Operating energy consumption is sensitive to many of the same variables as pollutant emissions—vehicle speed, operating mode, cold starts, and vehicle type (fuel, weight). These variables should be taken into account to get an accurate comparison between the options. Previous analyses have also considered the supply of energy in the region, including availability of alternative fuels and other factors, such as whether existing power plants could provide enough electrical power to operate a rail facility. Table 4-8 shows the results of a study, *Preparing State Transportation Agencies for an Uncertain Energy Future,* to gauge the likely timeframe for implementing different types of strategies to reduce energy consumption. [Sorenson et al., 2014]

The results of an energy impact analysis are normally presented in terms of the payback period for each strategy. The payback period is the time required for the operational energy savings, if any, to offset the energy consumed in building the facility. Planning study energy analysis could also be couched in terms of air emissions, particularly in nonattainment areas.

## C. Water Quality

Water quality might be adversely impacted by dredging, discharging fill material or otherwise introducing pollutants into surface bodies of water, increasing runoff or altering surface drainage patterns, and affecting the water table by dewatering or contaminating subsurface waters. Unless projects or alternatives involve any of these activities, a water-quality assessment is not needed.

Wastewater generated by maintenance and storage facilities contains various pollutants, which unless treated and handled properly can be released into city storm-water systems. The environmental analysis should identify activities associated with the strategies that generate wastewater, such as steam cleaning, vehicle washing, and pavement runoff. Typical bus or truck garage effluent, for example, contains concentrations of oil and grease, detergents, chemicals, metals, and solid materials that pass into the sewer system. Storm-water runoff from parking areas and highways may contain harmful pollutants such as lead, zinc, and cadmium as well as de-icing salts. The potential for increasing runoff and corrective measures, such as reducing runoff or preventing pollutants from entering storm-water and groundwater systems, should be considered in the environmental analysis.

A National Pollutant Discharge Elimination System (NPDES) permit, required under Section 402 of the Clean Water Act, may be required if wastewater is discharged directly into the storm-water system. EPA issues NPDES permits and sets their pretreatment effluent limits. States and localities may also have their own limits and identified specific disposal sites. The environmental analysis should determine whether an NPDES permit is required and whether there are other local or state pretreatment requirements and permits.

Any strategy that involves the discharge of dredged or fill materials into U.S. waters must also comply with Section 404 of the Clean Water Act (33 U.S.C. 1344). These waters include:

- All waters that are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters that are subject to the ebb and flow of the tide
- All interstate waters, including interstate wetlands
- All other waters (such as interstate lakes, rivers, and streams) whose use, degradation, or destruction could affect interstate or foreign commerce
- Tributaries of such waters
- The territorial sea
- Wetlands adjacent to U.S. waters.

Generally, under NEPA, the selection and use of the sites, including the criteria for evaluating the impact of the dredged or fill material, are governed by EPA guidelines, but it is the Corps of Engineers' responsibility to ensure compliance with these guidelines and to issue the permits. EPA's guidelines for "Specification of Disposal Sites for Dredged or Fill Material," referred to as the 404(b)(1) guidelines, describe the contents of the permit application and the evaluation criteria (http://www.epa.gov/sites/production/files/2015-03/documents/cwa_section404b1_guidelines_40cfr230_july2010.pdf.

Four conditions must be satisfied before a determination can be made to permit the discharge of dredged or fill material:

- There can be no practicable alternative to the proposed discharge that would have a less adverse impact on the aquatic ecosystem, as long as that alternative does not have other significant adverse impacts.
- The proposed discharge cannot cause or contribute to a violation of any applicable state water-quality standard; any applicable toxic effluent standard or prohibition under Section 307 of the Clean Water Act; the Endangered Species Act of 1973; or Title III of the Marine Protection, Research, and Sanctuaries Act of 1972.
- No discharge of dredged or fill material can cause or contribute to significant degradation of U.S. waters.
- All appropriate and practicable steps must have been taken to minimize potential adverse impacts of the discharge on the aquatic ecosystem.

The District Office of the Corps of Engineers should be consulted as early as possible if it is thought that a permit may be required. This allows the information required for compliance with Section 404 to be integrated into the environmental planning process. Additionally, this information should be taken into account when developing the study work program. The permit itself does not have to be, and generally cannot be, obtained prior to FHWA's/FTA's approval of the formal NEPA environmental document (EA or final EIS). Generally, a planning study should focus on information that helps distinguish among alternatives.

These requirements need to be considered in developing, designing, and assessing the cost of alternative strategies during a planning study. Because water-quality impacts can normally be mitigated, the magnitude of the impacts on water quality is not usually a major factor in selecting a preferred option. The planning study does not normally include calculations to quantify the effects on water quality, only the cost of possible mitigation measures.

## D. Navigable Waterways and Coastal Zones

The Rivers and Harbors Act of 1899 (33 U.S.C. 401 et seq.) requires that the Secretary of the Army issue permits for various activities. Section 9 of the act pertains to the construction of any dam or dike across any navigable waters of the United States, and Section 10 pertains to construction of any structure over, excavation from, or disposal of materials into navigable waters. Navigable waters mean those U.S. waters that are subject to the ebb and flow of the tide shoreward to the mean high watermark and/or those waters that are presently used, have been used in the past, or may be susceptible to use in transport for interstate or foreign commerce. Certain work performed, or structures constructed, in navigable waters require permits pursuant to both Section 9 and Section 10 of the Rivers and Harbors Act. A project involving dredging in navigable waters would require both a Section 10 and a Section 404 permit because Section 404 of the Clean Water Act pertains to U.S. waters, which include more than navigable waters.

During the planning study, the need for such permits should be determined for each option. Initial consultation with permitting agencies should occur to ascertain the specific requirements that must be satisfied if an option requiring a permit is chosen. These requirements should be described in the environmental section of the planning study report.

The U.S. Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.) requires consultation with the Fish and Wildlife Service (FWS) and the appropriate state wildlife agency when a project will impound, divert, channelize, or otherwise control or modify the waters of any stream or other body of water. Generally, if a permit is required under Section 402 or 404 of the Clean Water Act or Section 9 or 10 of the Rivers and Harbors Act of 1899, the consultation requirement will apply. Permit applications will be forwarded to FWS in later project development phases, to be reviewed according to the "Guidelines for the Review of Fish and Wildlife Aspects of Proposals in or Affecting Navigable Waterways" (http://environment.fhwa.dot.gov/guidebook/vol1/doc17g.pdf).

Consideration should be given to preventing wildlife damage or loss, and mitigating any effects caused by a project. If there is particular concern about these resources, it may be appropriate to send the planning study report to FWS for its review and comment, and to include an evaluation of how the actions may affect fish and wildlife resources. The discussion should include potential measures to minimize harm, such as features to reduce turbidity during construction, stabilizing the shoreline with plantings suitable for use by wildlife, or compensation for habitat that may be lost. FWS has issued a mitigation policy, which can be consulted when planning potential mitigating measures (http://training.fws.gov/courses/csp/csp3112/resources/Written_summaries_of_404_program/FWS_Mitigation_Policy.doc). The results of the coordination concerning potential mitigation measures should be included in the formal environmental document during the subsequent project development phase.

If an alternative will result in a project that directly affects the coastal zone of any state with an approved coastal zone management (CZM) program, the environmental analysis must consider whether the alternative will be consistent with the CZM plan. The Coastal Zone Management Act of 1972 (16 U.S.C. 1451 et seq.), as amended, established a voluntary program in which most of the 35 states with coastal zones currently participate. These states have Department of Commerce–approved plans and receive federal money and technical assistance to administer their programs.

The state agency managing the program, called the principal 306 agency, is usually the Department of Natural Resources or its equivalent agency. This agency should be consulted both for state procedures used to determine consistency with the CZM plan and for its opinion on whether proposed strategies under consideration are consistent with the state's program. The final environmental document prepared during subsequent project development should present the applicant's certification that the project is (or is not) consistent with the CZM program and the views of the state agency.

The U.S. Coastal Barrier Resources Act (16 U.S.C. 3501 et seq.) and the Coastal Barrier Improvement Act designate a protected network of undeveloped coastal barriers located on the Atlantic and Gulf coasts, called the coastal barrier resources system. Section 5 of this act prohibits federal expenditure for construction of any facilities, structures, roads, bridges, airports, and the like within the system. Exceptions can be made for some activities, such as the maintenance of

existing channel improvements and related structures and the maintenance, replacement, reconstruction, or repair (not expansion) of publicly operated roads or facilities that are essential links in a larger network or system. Consultation with the Department of the Interior is required.

## E. Climate Change and Extreme Weather

Many scientists estimate that over the next 50 to 80 years, Earth's climate is going to change dramatically due to the increasing levels of greenhouse gases that have entered the atmosphere and will continue to do so in the foreseeable future. This change is expected to occur over the long term (for example, gradual increase in sea levels) and over the shorter term (for example, more frequent and violent storms). Today, the United States has no requirement to include climate change impacts in federally supported environmental analyses (although there are proposals to do so); however, many other countries have such requirements, as do many state environmental laws (for example, California, Massachusetts, and Washington).

An important distinction is made between efforts to reduce greenhouse gases, called mitigation, and efforts to prepare for and respond to changing climatic conditions, called adaptation. As noted in a 2014 NCHRP report on climate change, adaptation can be defined as:

> *"Adaptation consists of actions to reduce the vulnerability of natural and human systems or to increase system resiliency in light of expected climate change or extreme weather events."*
>
> *[Meyer et al., 2014]*

Several guides and research reports are available for analyzing different aspects of both mitigation and adaptation. For mitigation, the most comprehensive guide is Strategic Highway Research Report (SHRP) 2 Report S2-C09-RW-2, *Practitioner's Guide to Incorporating Greenhouse Gas Emissions into the Collaborative Decision-Making Process* [PB Americas et al., 2013]. For adaptation, several national and state guides are available. Some of the more comprehensive include: [PIEVC and Engineers Canada, 2009; U.S. Army Corps of Engineers, 2011; Washington State DOT, 2014; ICF International, 2012; FHWA, 2012a,b,c, 2013; Meyer, Choate, and Rowan, 2012; and Meyer et al., 2014].

Table 4-9 shows the types of impacts that changing climatic conditions could have on roads and highways. Note that the expected impacts are focused not only on infrastructure design, but also on the operations and maintenance of transportation systems. Thus, although the focus of this chapter is on planning in a sense of infrastructure provision, some of the most important consequences of changing climatic conditions will likely be on the maintenance and operations functions of transportation agencies. This is especially true for extreme weather events. [Meyer, Choate, and Rowan, 2012]

It seems likely that interest in, and concern about, the impacts of climate change and weather on transportation systems will continue to grow. Several transportation agencies and organizations are keeping track of developments with respect to analysis tools and strategies that can be used to understand such impacts. Readers are especially referred to the following websites that will likely provide the most up-to-date information on how climate change and extreme weather events can be addressed by the transportation planning process.

- American Association of State Highway and Transportation Officials: "Transportation and Climate Change Resource Center," http://climatechange.transportation.org/.
- Federal Highway Administration: "Climate Change," http://www.fhwa.dot.gov/environment/climate_change/.
- U.S. Global Change Research Program: http://www.globalchange.gov/.

## F. Impacts on the Natural Environment

The effects of major transportation investments on natural areas can be diverse and numerous. They may involve impacts on wetlands, floodplains, ground and surface waters, wildlife, plants, and other natural resources. Federal laws and executive orders prescribe the requirements that apply to each of these impact areas. In addition, specific

| Table 4-9. Potential Impacts of Climate Change and Extreme Weather on Roads and Highways | | | |
|---|---|---|---|
| | **Climatic/ Weather Change** | **Impact to Infrastructure** | **Impact to Operations/ Maintenance** |
| **Temperature** | **Change in extreme maximum temperature** | • Premature deterioration of infrastructure;<br>• Damage to roads from buckling and rutting;<br>• Bridges subject to extra stresses through thermal expansion and increased movement. | • Safety concerns for highway workers limiting construction activities;<br>• Thermal expansion of bridge joints, adversely affecting bridge operations and increasing maintenance costs;<br>• Vehicle overheating and increased risk of tire blow-outs;<br>• Rising transportation costs (increased need for refrigeration);<br>• Materials and load restrictions can limit transportation operations;<br>• Closure of roads because of increased wildfires |
| | **Change in range of maximum and minimum temperatures** | • Fewer days with snow and ice on roadways;<br>• Reduced frost heave and road damage;<br>• Structures will freeze later and thaw earlier with shorter freeze season lengths;<br>• Increased freeze-thaw conditions creating frost heaves and potholes on road and bridge surfaces;<br>• Permafrost thawing leads to increased slope instability, landslides and shoreline erosion damaging roads and bridges due to foundation settlement (bridges and large culverts are particularly sensitive to movement caused by thawing permafrost);<br>• Hotter summers in Alaska lead to increased glacial melting and longer periods of high stream flows, causing both increased sediment in rivers and scouring of bridge supporting piers and abutments. | • Decrease in frozen precipitation would improve mobility and safety of travel through reduced winter hazards, reduce snow and ice removal costs, decrease need for winter road maintenance, result in less pollution from road salt, and decrease corrosion of infrastructure and vehicles;<br>• Longer road construction season in colder locations;<br>• Vehicle load restrictions in place on roads to minimize structural damage due to subsidence and the loss of bearing capacity during spring thaw period (restrictions likely to expand in areas with shorter winters but longer thaw seasons);<br>• Roadways built on permafrost likely to be damaged due to lateral spreading and settlement of road embankments;<br>• Shorter season for ice roads. |
| **Precipitation** | **Greater changes in precipitation levels** | • If more precipitation falls as rain rather than snow in winter and spring, there will be an increased risk of landslides, slope failures, and floods from the runoff, causing road washouts and closures as well as the need for road repair and reconstruction;<br>• Increasing precipitation could lead to soil moisture levels becoming too high (structural integrity of roads, bridges, and tunnels could be compromised leading to accelerated deterioration);<br>• Less rain available to dilute surface salt may cause steel reinforcing in concrete structures to corrode;<br>• Road embankments at risk of subsidence/heave. | • Regions with more precipitation could see increased weather-related accidents, delays, and traffic disruptions (loss of life and property, increased safety risks, increased risks of hazardous cargo accidents);<br>• Closure of roadways and underground tunnels due to flooding and mudslides in areas deforested by wildfires;<br>• Increased wildfires during droughts could threaten roads directly, or cause road closures due to fire threat or reduced visibility. |

(*continued*)

Table 4-9. (*Continued*)

| | Climatic/ Weather Change | Impact to Infrastructure | Impact to Operations/ Maintenance |
|---|---|---|---|
| | **Increased intense precipitation, other changes in storm intensity (except hurricanes)** | • Heavy winter rain with accompanying mudslides can damage roads (washouts and undercutting) which could lead to permanent road closures;<br>• Heavy precipitation and increased runoff are likely to cause significant flood damage to tunnels, culverts, roads in or near flood zones, and coastal highways;<br>• Bridges are more prone to extreme wind events and scouring from higher stream runoff;<br>• Bridges, signs, overhead cables, tall structures at risk from increased wind speeds. | • The number of road closures due to flooding and washouts will rise;<br>• Severe erosion at road construction project sites as heavy rain events take place more frequently; road construction activities will be disrupted;<br>• Increase in weather-related highway accidents, delays, and traffic disruptions;<br>• Increase in landslides, closures or major disruptions of roads, emergency evacuations and travel delays;<br>• Increased wind speeds could result in loss of visibility from drifting snow, loss of vehicle stability/ maneuverability, lane obstruction (debris), and treatment chemical dispersion;<br>• Lightning/electrical disturbance could disrupt transportation electronic infrastructure and signaling, pose risk to personnel, and delay maintenance activity. |
| **Sea-level rise** | **Sea-level rise** | • Higher sea levels and storm surges will erode coastal road base and undermine bridge supports;<br>• Temporary and permanent flooding of roads and tunnels due to rising sea levels;<br>• Encroachment of saltwater leading to accelerated degradation of tunnels (reduced life expectancy, increased maintenance costs and potential for structural failure during extreme events);<br>• Loss of coastal wetlands and barrier islands will lead to further coastal erosion due to the loss of natural protection from wave action. | • Coastal road flooding and damage resulting from sea-level rise and storm surge;<br>• Underground tunnels and other low-lying infrastructure will experience more frequent and severe flooding;<br>• Increase in number of road accidents, evacuation route delays, and stranded motorists. |
| **Hurricanes** | **Increased hurricane intensity** | • Stronger hurricanes with longer periods of intense precipitation, higher wind speeds, and higher storm surge and waves are projected to increase;<br>• Increased infrastructure damage and failure (highway and bridge decks being displaced). | • More frequent flooding of coastal roads;<br>• More transportation interruptions (storm debris on roads can damage infrastructure and interrupt travel and shipments of goods);<br>• More coastal evacuations. |

Source: Meyer et al., 2014

agencies have been given responsibilities for protecting these resources. Analysis and coordination requirements are summarized in this section.

In a planning study, a generic process consisting of four steps is recommended for the analysis of natural areas.

1) Identify the location of natural areas (for example, floodplains, wetlands, wildlife or plant habitat, coastal zone, natural gas field, aquifer recharge areas) that may be affected by one or more of the strategies. In many instances, generalized boundaries of natural areas, particularly in metropolitan areas, have been mapped by responsible state and federal agencies at a level of detail sufficient for a planning study, and it is usually a simple matter to determine if the strategies pass through or close to them.
2) Identify the functions of the potentially affected natural areas. Functions may include flood control, aquifer recharge, species habitat, recreation, spawning areas, pollution abatement, and visual relief.
3) Determine the likely effect of the strategies on the functions of these areas.
4) Evaluate potential mitigation options if substantial effects are expected.

The impacts of transportation strategies on natural areas depend on the ecological functions of those areas. For example, the use of an existing transportation right-of-way through a wetland may not affect its functions. By contrast, filling in a wetland could have a major adverse impact on its ability to support its functions and values.

Wetlands are lowland areas that are inundated or saturated by surface or ground water at a frequency that, under normal circumstances, supports a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs, and similar areas. One of their functions is that they are highly productive areas that provide habitat for many species of plants, fish, and waterfowl. Executive Order 11990, "Protection of Wetlands," requires federal agencies to avoid direct or indirect support of new construction in wetlands wherever there is a practicable alternative.

For any transportation investment that may affect a wetlands area, DOT Order 5660.1A of August 24, 1978, "Preservation of the Nation's Wetlands," requires that an analysis be performed. Activities both upstream and downstream can affect wetland areas and should be studied for possible impacts. FWS, the Army Corps of Engineers, and state natural resources agencies should be contacted as soon as it is suspected that any strategies may affect a wetlands area.

The planning study should include an assessment of the effects on wetlands and associated wildlife resulting from both the construction and operation of the options under the study. It should also include potential measures to minimize possible adverse impacts and avoid, to the fullest extent possible, drainage, filling, or other disturbance of wetlands and the water resources supplying them. The hydrological resources; fish and wildlife; and recreational, scientific, and cultural uses of wetlands should be considered. Strategies that avoid new construction in wetlands should be studied, giving consideration to environmental and economic factors. If the preferred strategy requires new construction in wetlands, the analysis should demonstrate that there are likely no practicable alternatives to the use of the wetlands, and that all practicable measures to minimize harm will be considered. A specific finding attesting to these criteria must be included in a formal NEPA environmental document. This analysis should occur early in the planning process.

U.S. Executive Order 11988, "Floodplain Management," places special importance on preservation of floodplains, directing federal agencies to avoid conducting, allowing, or supporting actions on a floodplain. Maps of the Federal Insurance Administration, a branch of the Federal Emergency Management Agency (FEMA), should be consulted to determine if the proposed strategies are located within the 100-year floodplain. Flood insurance rate maps (FIRMs) are available for review at local zoning or planning commission offices or city halls. Regional FEMA offices can be contacted for assistance, but they do not maintain these maps. If a FIRM is not available for a particular area, a flood-hazard boundary map should be reviewed to get an indication of whether the strategies are clearly out of the floodplain or whether they may be located in a flood-prone area.

If any of the strategies is located within a floodplain, an initial analysis should be included in the planning study. The analysis should discuss any risk to, or resulting from, the strategies; the impacts on natural and beneficial floodplain values; the degree to which the strategies provide direct or indirect support for development in the floodplain; and potential measures to minimize harm or to restore or preserve the natural and beneficial floodplain values likely affected by the strategies.

During the planning study, the floodplain analysis should examine whether any of the strategies entail a significant encroachment. The planning document should explain that a floodplain finding would be required in the NEPA or detailed design processes if any of these strategies are chosen later in the project development process. It should also discuss any potential measures to avoid any significant encroachments or any support of incompatible floodplain development.

### G. Endangered and Threatened Species

Section 7 of the U.S. Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.) requires FHWA/FTA, in consultation with FWS or the National Marine Fisheries Service (NMFS), ensure that projects funded do not jeopardize the continued existence of any listed species or result in the destruction or adverse modification of critical habitat. During study initiation/scoping, FWS or NMFS, and appropriate state agencies, should be contacted for information regarding any species listed (or proposed) as endangered or threatened that may be present in the study area. When a state has a third category of protected species, those that are considered rare, these too must be taken into account. Generally, marine species are under the jurisdiction of NMFS; all other species are under the jurisdiction of FWS. The lists of endangered and threatened wildlife and plants for FWS are contained in 50 CFR 17.11 and 17.12, with the designated critical habitats found in 50 CFR 17.95 and 17.96, and for NMFS, in 50 CFR 222.23(a) and 227.4.

The Section 7 regulation (50 CFR Part 402) sets forth a phased process that may involve early informal or formal consultation, depending on whether a proposed strategy may affect a listed species. Informal consultation includes all contacts between FHWA/FTA, the planning study, and FWS or NMFS that take place prior to formal consultation, including the initial request for information on endangered species in the study area. If it is determined during the planning that no listed species or critical habitat is in the study area, no further consultation is required. If listed or proposed species or critical habitat may occur within the project area, a biological assessment (as defined in the Section 7 regulations) should be conducted during the NEPA process to identify probable locations of listed species and determine the probable impacts of the project on the species and its habitat. [Lederman and Wachs, 2014]

## VII. CONSTRUCTION IMPACTS

Earlier sections of this chapter dealt with the long-term effects of proposed transportation investment strategies and their operation. Construction impacts differ from long-term impacts in duration, type, and level of detail. Further, the intensity of the construction impacts may be at the other end of the spectrum from long-term impacts. For example, the immediate construction impacts of a subway line are usually quite severe, but over the long term, the system's operation usually has negligible adverse impacts and many beneficial effects. During construction, air quality is likely to be degraded because of impaired traffic flows and the operation of construction equipment, which could increase particulates (dust). At the same time, air quality could actually improve in the region during subway system operation because of improved traffic flow and reduced congestion as some travelers choose mass transit instead of driving.

A systems-level planning study will typically discuss the construction impacts in less detail than the long-term impacts. Detailed discussion of the construction impacts is usually contained in the formal NEPA environmental document, which presents the results of subsequent project development work on the preferred alternative.

Construction impacts can be divided into direct and indirect impacts. Direct impacts result from the construction itself and include air and noise pollution and temporary use of land, streets, and sidewalks. Indirect impacts during construction usually result from temporary land takings and include traffic congestion and delays, impaired access to buildings and civic or recreational spaces, and so forth. In many cases, especially when construction requires the closure of major streets, the indirect impacts can be quite substantial, such as reduced access to retail businesses. Although a detailed discussion of the construction impacts is not possible until an alternative is selected during NEPA analysis and preliminary engineering is performed, major impacts for the various strategies can generally be identified and should be noted in the planning study report. The differences among strategies should be highlighted.

The earlier that mitigation of potential construction impacts is considered, the easier it is to incorporate them into the planning and project development process. During the planning study, potential mitigation strategies should be

identified, and all feasible options should be mentioned, at least generally. Although there are usually ways to minimize negative impacts during construction, if the construction impacts are severe, the study should mention the possibility of not building the project. Potential mitigation strategies include alternative construction techniques, use of alternative construction equipment, and scheduling to minimize impacts. This might include considering restrictions on construction activity at certain times of the day or even the year, such as during the Christmas shopping season or fish spawning season.

## VIII. CONSIDERING MITIGATION STRATEGIES DURING THE SYSTEMS PLANNING PROCESS

The various social, economic, and environmental studies conducted during a planning study often reveal potential adverse impacts that will need to be mitigated. However, the analyses performed during a planning study are not normally detailed enough to evaluate fully the various potential mitigation options. It is not advisable, therefore, to make commitments to any specific mitigation measures until more is known about their likely effectiveness. At the systems planning level, it is sufficient simply to identify potential impact areas, potential mitigation options (with order of magnitude costs) for further study during preliminary engineering, and the views of the resource agencies and the public.

The supporting technical document (results report) on social, economic, and environmental impacts, as well as the planning study report, should clearly define those potential impacts that are expected to require mitigation. In addition, they should contain estimates of the range of costs that may be necessary to mitigate them. These costs are then factored into the cost estimate for the strategy. The information developed here will be important to policy makers who will have to make trade-offs in the selection of a preferred alternative during the subsequent NEPA analysis.

### A. Documentation of Environmental Considerations during the Systems Planning Process

Documenting environmental factors considered during systems planning is key to successfully linking systems planning and project development, because documentation of the results is essential to avoid the need to restudy the same issues during subsequent NEPA efforts. While there may be no formal requirements for preparing methodology and technical results reports for social, economic, and environmental impacts during systems planning, such documents are often very useful in preparing the groundwork for subsequent project development efforts. A methodology report provides a means for gaining concurrence among the study participants—particularly the environmental resource agencies—on the key issues to be addressed; the level of detail of the analysis; and the methods, criteria, and data to be used. The results report similarly provides a means to document the details of the analysis beyond the summary level of presentation in the planning study report. The presentation of the methods, data, and criteria used for the planning study, and the actual results and interpretation of the findings, are invaluable for the review agencies in later phases and will greatly aid in the review process and help in streamlining the project development process. [FHWA, 2002]

If a methodology report on social, economic, and environmental impact assessment is being prepared, it should identify the specific impacts to be considered and the particular parts of the study area where these impacts are expected to be of concern. It should also explain the methods and criteria for assessing the impacts. The following could be included, as appropriate, for each area of concern:

- An assessment of data availability and the need for further data collection, such as air quality and noise monitoring.
- A description of the monitoring program, including monitoring sites.
- Models and/or analytic methods to be used to estimate the impacts of each strategy and of each alternative during the NEPA analysis, as well as the variables to be considered in the analysis.
- Key assumptions.
- A list of agencies and outside experts who will be consulted as part of the analysis.

See Amekudzi and Meyer [2005] for information on how environmental issues and factors can be considered more fully during transportation planning.

## IX. SUMMARY

Transportation planners consider many different issues and public concerns in the course of a typical planning study. The impact of transportation on the human and natural environment is one of the most important issues from the perspectives of legal and regulatory responsibility and public interest. Many countries have a long legislative history of environmental protection, and major transportation projects cannot be planned and designed without seriously taking into account likely environmental impacts and how these can be avoided or mitigated. Increasingly, environmental concerns have taken on a broader context, with many groups—including transportation agencies—discussing things such as environmental stewardship and sustainability.

This chapter has provided an overview of the environmental factors that can be considered in the transportation planning process. At the systems planning level, much of this consideration will be at a fairly aggregate level, primarily because many of the specific environmental impacts will not be known until projects are in the preliminary design phase. As a project proceeds into project development, depending on the type of project and funding sponsors, environmental analysis and assessment requirements become much more specific. For example, what are the likely impacts on nearby community facilities, historic properties, wetlands, water quality, noise, and the like? As was described in this chapter, each of these impacts has its own requirements for environmental analysis and mitigation strategies. A primary intent of considering environmental factors in the transportation planning process is to identify what types of impacts might be considered later in the project development process, and what type of planning information would be useful in the project-specific environmental analysis.

Environmental concerns have been part of the transportation planning process for decades. It is highly likely that they will continue to be a major consideration in future transportation planning as well. In addition, new environmentally related issues, such as sustainability or climate change, will likely be added to the many other factors that transportation planners will be considering in decades to come.

# Transportation Finance and Funding[1]

## I. INTRODUCTION

Traditionally, transportation plans did not include a discussion of the financial strategies or funding needed to implement the recommendations resulting from the study—this topic was considered to be outside of the planning process. Beginning in the 1970s, however, and especially with the requirement in the United States for metropolitan planning organizations (MPOs) to produce a transportation improvement program (TIP), transportation plans began to devote more attention to the different sources of funding needed for program implementation. With a declining trend of federal investment in transportation, states and metropolitan areas had to rely more on non-federal sources of funding, including public/private partnerships and contributions from a variety of sources. In addition, as maintenance budgets, which are wholly provided by state and local transportation agencies, increased due to a more extensive and aging infrastructure, state and local dollars were being stretched to meet both the capital and maintenance needs of the transportation system. Today, transportation planning is very much concerned with transportation finance and funding sources. Finding the means to invest in new transportation capacity while operating and maintaining the existing system is arguably the greatest challenge facing the transportation profession.

An important distinction needs to be made between finance and funding. Financial strategies are the mechanisms through which money is made available for transportation investment. Funding is the source of dollars used in the financial strategy. Thus, for example, debt financing or the borrowing of funds from the municipal bond market is a financial strategy. Gas tax revenues or toll receipts are the usual funding sources needed to repay the loan.

For many years, motor vehicle fuel use taxes have been the backbone of highway finance in the United States. For example, federal and state gas taxes were the primary sources of funding for building the interstate highway system and the state road networks. However, the U.S. environment for transportation finance began to change in the 1970s. For highways, transportation officials realized that gas tax revenues would not likely provide the level of funding necessary to expand and maintain the highway network. Many began to explore public/private partnerships, which promoted private investment in transportation projects. Others looked to explore other options for financing capital investment programs that became known as "innovative transportation finance."

For transit, the level of funding needed for the capital expansion of rail facilities was beyond the financial capability of most municipalities, and thus many turned to the federal government for support. In response, the federal government developed the "New Starts" program, whereby funding was provided for a portion of the capital cost of new projects. For the local match of these federal grants and to support locally supported services, transit agencies turned to sales tax revenues and bonding.

Today, states, metropolitan areas, and municipalities use a variety of financing strategies and funding sources to support both the capital investment needs and operations/maintenance costs of their transportation systems.

The next section describes some key finance and funding concepts and terms that are common across most transportation planning efforts. The chapter then introduces both traditional sources of transportation funding and some that are fairly new. This is followed by a discussion of finance strategies and the evolving nature of both public and private investments in the transportation system. An important step in the planning process from a financial strategy perspective is identifying future revenues as part of the capital investment program, as discussed in the following section. The final two sections discuss the importance of environmental justice analysis in developing an investment program, followed by a discussion of the likely finance and funding challenges facing transportation investment in future years.

## II. KEY CONCEPTS AND TERMS

Several key concepts and terms are important in understanding the substance and process of transportation investment programming and financial analysis. In some cases, these terms are specific to transportation, while in others they are generic terms used in all sectors. [BTS, 2014]

- *Capital Expenditure.* Capital expenditures include outlays for new equipment and infrastructure to improve or enhance capacity and quality with improvements lasting more than one year.
- *Discretionary Grants.* Funding grants from a government agency where the selection is at the discretion of the funding agency, usually based on proposals that describe the project's level of impact and benefit.
- *Enabling Legislation.* In the United States, state governments hold constitutional power to create lower forms of government. Every city, town, special-purpose authority, and even the federal government itself, is the creation of the states. For example, if a metropolitan area or state DOT wants to hold a referendum on a sales tax to be dedicated to transportation investment, it must first be "enabled" to do so by a state law.
- *Financial (or Fiscal) Constraint.* Limiting the amount of investment in a long-range plan or transportation improvement program (TIP) to the level of funding reasonably expected over the life of the document, usually 20 to 25 years for plans and 4 years for TIPs.
- *Formula Funds.* Funding allocated to jurisdictions based on a legislatively defined formula. Formula funds can be targeted at capital investment, rehabilitation, and operational needs.
- *Impact Fees.* Fees charged to developers related to the infrastructure improvements necessary for a proposed development and related to the expected trip generation. Such fees are usually defined by local governments, and reflect the number of trips generated per development size (for example, per acre) or density (for example, per dwelling unit).
- *Operation and Maintenance Expenditure*. Recurring payments to cover the cost of administration, operation, and normal maintenance and repair of transportation infrastructure and facilities.
- *Public/Private Partnerships.* Formal or informal relationships among government agencies and private entities that spell out the responsibilities of each in financing a transportation project.
- *Regionally Significant Project.* A project serving regional transportation needs of significant scale to be typically included in transportation demand modeling for air-quality emissions analysis and identified individually in the program document.
- *Risk Analysis.* A systematic process to understand the nature of and deduce the level of risk associated with a project. It provides the basis for risk evaluation and decisions about how risks are treated in a project proposal, and feeds into the determination of value for money on a project being considered as a public/private partnership procurement.
- *Transportation Improvement Program (TIP).* A capital program listing the committed investments in a metropolitan area (or a STIP for a state) over a specified period of time, usually 4 or 5 years. In other countries, this is often called a capital improvement plan or a capital investment plan.
- *TIP Amendment.* Any change to a regionally significant project, including an addition or deletion; major changes to cost, initiation dates, or design concepts or scopes; a major change to a program fund amount; and the addition of a year into the S/TIP.
- *Trust Fund.* An account established by law in a treasury department to hold tax receipts and earmarked for defined projects and/or programs.
- *Unconstrained Needs.* The level of funding needed for transportation improvements and associated operations, maintenance, and rehabilitation that require funding above and beyond assumed revenues. These needs are identified through the planning process.
- *User Charge or Fee.* A cost assigned to users of a good or service reflecting the use of that service. User charges, either direct or indirect, are collected on a periodic or occasional basis in the form of license fees and

excises, and usually paid at the time infrastructure services are consumed, as with the payment of fuel taxes and tolls.

- *Year-of-Expenditure (YOE) Revenues or Costs.* Dollar values that have been escalated to the year that dollars are expended or generated, based on escalation factors appropriate for specific revenue sources. These estimates are needed to make sure that future revenues are adequate to cover expected costs when they occur.

## III. SOURCES OF TRANSPORTATION FUNDING

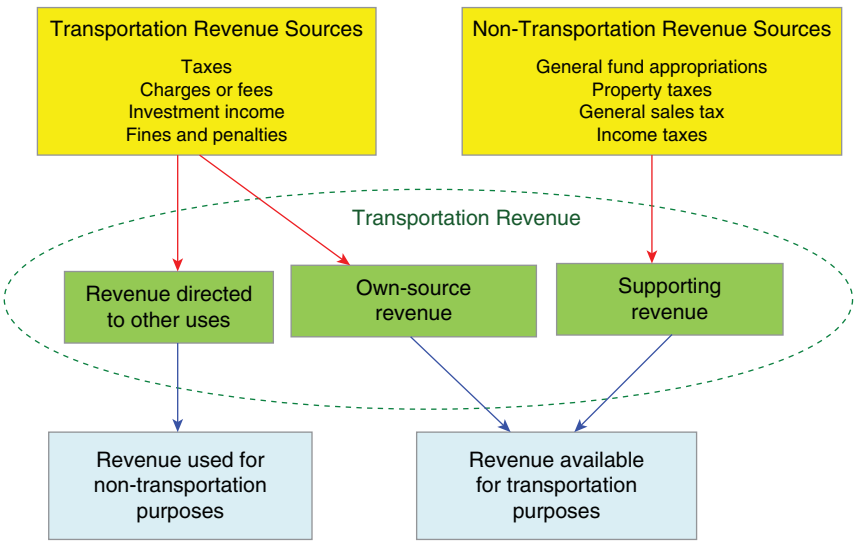
Transportation funding comes from many different sources. Revenues can come from a federal/national government, state/provincial government, local, and municipal governments, private funds, and a whole host of other agencies and organizations that choose to invest in the transportation system. For example, the Puget Sound Regional Council (PSRC), the metropolitan planning organization (MPO) for the Seattle metropolitan area, lists 31 different sources of funding for the region's transportation system. [PSRC, undated] The PSRC's long-range transportation plan also lays out the challenge facing many metropolitan areas today:

> *"It is critically important that the region deliberately moves forward in developing new ways to pay for transportation projects and programs. Limited public financial capacity for transportation infrastructure investment has encouraged transportation professionals and regional policy makers to discuss the potential benefits associated with reforming the way society pays for and finances transportation. The future of the fuel tax as a road finance approach is limited. Advances in vehicle technology and the erosion of purchasing power due to inflation have demonstrated the need to find other ways to pay for transportation investments. Business leaders, national experts, and state legislators are all coming to similar conclusions—traditional tax-based financing measures will not, by themselves, be sufficient to meet the region's transportation investment needs."*
>
> *[PSRC, 2014]*

Figure 5-1 shows in general terms the types of revenue sources available for transportation purposes. As shown, revenue can come from dedicated transportation sources such as gas taxes or fees and nontransportation sources such as property and sales taxes. Figure 5-2 shows typical transportation expenditures.

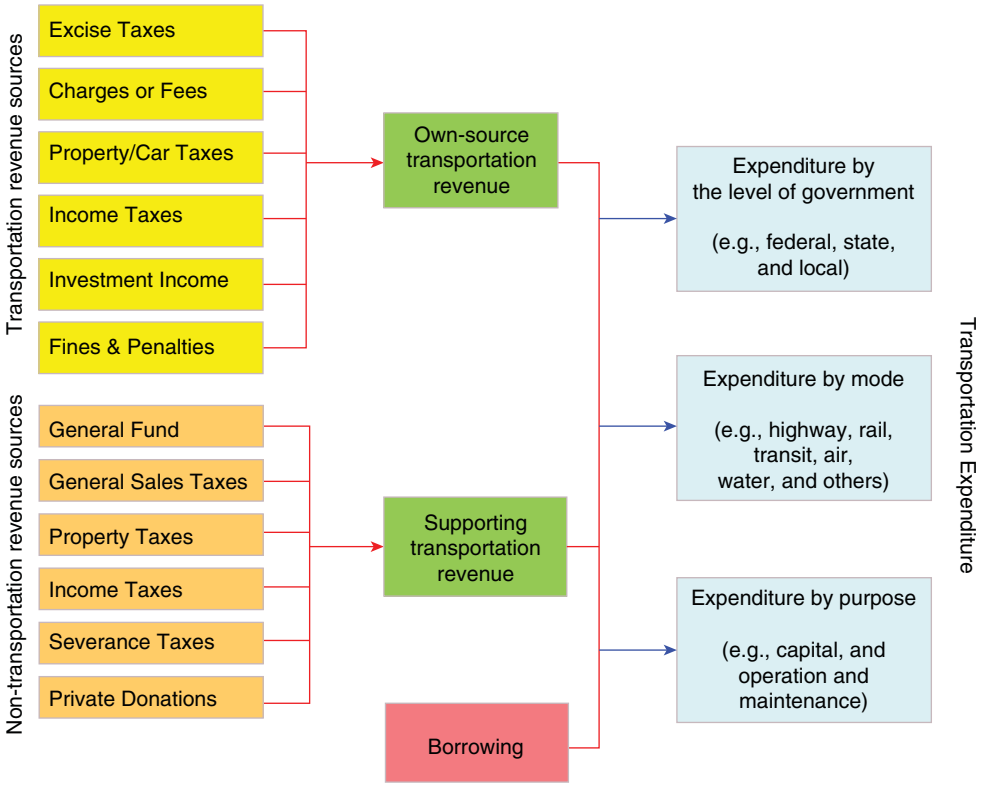
It is noteworthy that the United States is one of the few nations with a revenue source dedicated to transportation in the form of the motor fuel tax. In other countries, transportation investment is part of the general budget for the country, state/province, or municipality and thus competes with other demands for budgetary resources. Experience

**Figure 5-1. Sources of Transportation Revenues, United States**



Source: BTS, 2014

**Figure 5-2. Typical Transportation Expenditures, United States**



Source: BTS, 2014

has shown that transportation investment in such an environment often becomes embroiled in the politics of the budgetary process, more so than usual.

The following paragraphs describe some of the major sources of transportation funds used today in the United States as part of a typical investment program.

## A. Motor Fuel and Excise Taxes

In the United States, motor fuel taxes are the primary source of funds for transportation investment. This falls within a more general category of user fees, in that those who use the system (for example, by using the highway network) pay for its use (for example, through motor fuel taxes). The use of motor fuel taxes began in earnest when the interstate highway system was approved in the mid-1950s. Two federal laws were passed, one to authorize the construction of an interstate highway system and the second to pay a federal share of this system with revenues collected from a federal gas tax. The gas tax receipts were to be deposited in the U.S. Treasury in a special account called the Highway Trust Fund, and these funds were to be dedicated to the construction of the system on a partial state and partial federal cost distribution. The maintenance and operations of that system were the responsibility of the states. Although a few states had used motor fuel taxes for road investment prior to the federal legislation, many more now established their own state highway trust funds for the deposit of their state gas tax receipts. In most cases, the state constitution limited the use of these trust funds to highway construction; the funds could not be used for investment in other modes. Some states have changed these restrictions, and others have developed yet another trust fund for investment in any mode of transportation.

Some states have also established other restrictions on the use of their trust fund dollars. For example, the Michigan Transportation Fund (MTF) is the primary means of distributing state transportation revenues in Michigan, with the two main sources of MTF funding being state motor fuel taxes and vehicle registration fees. [MDOT, 2014] By law, after miscellaneous transfers and deductions of funds, the funds that remain are distributed to the Michigan DOT (39.1 percent), counties (39.1 percent), and cities and villages (21.8 percent). The state constitution also provides that not more than 10 percent of motor fuel taxes and vehicle registration fees may be used for public transportation programs and must be placed in what is called the Comprehensive Transportation Fund (CTF). For the CTF, motor

| Table 5-1. Federal Motor Fuel Tax Rates, 2015, United States | | | |
|---|---|---|---|
| | | Distribution of Tax | |
| **Type of Excise Tax** | **Tax Rate (cents)** | **Highway Account** | **Mass Transit Account** |
| Gasoline[1] | 18.3 per gallon | 84% | 16% |
| Diesel[1] | 24.3 per gallon | 88% | 12% |
| Gasohol[1,2] | 18.3 per gallon | 84% | 16% |
| Liquefied petroleum gas | 13.6 per gallon | 84% | 16% |
| Liquefied natural gas | 11.9 per gallon | 84% | 16% |
| M85 (from natural gas)[1] | 9.15 per gallon | 84% | 16% |
| Compressed natural gas | 48.54 per thousand cubic feet | 80% | 20% |

[1]In addition to these rates, a 0.1-cent per gallon tax is levied and deposited in the Leaking Underground Storage Tank Trust Fund.

[2]Other rates apply to gasohol blends containing less than 10 percent ethanol or blends made with methanol.

Source: AASHTO, 2015c, Reprinted with permission of AASHTO.

vehicle–related sales tax revenue is also deposited in the trust fund, but not more than 25 percent of the state general sales tax on motor vehicle–related products can be used for comprehensive transportation purposes. This is an example of how different sources of funding—for example, motor fuel taxes, registration taxes, and sales taxes—can be combined legislatively into programmatic support for transportation investment with legislatively imposed constraints on their use.

Table 5-1 shows the current federal motor fuel tax structure in the United States for different fuel types. The website of the American Association of State Highway and Transportation Officials (AASHTO) [2015a] lists all of the state gas taxes.

Federal and state gas tax revenues support different funding programs where the funds are dispensed to achieve specific program goals, such as safety, economic development, congestion relief, air quality improvement, and the like. There are too many of these programs to list here, but the U.S. DOT websites and most state transportation improvement programs list the different programs that are supported with motor vehicle–related taxes and fees. See [American Road and Transportation Builders Association, undated; North Central Texas Council of Governments (NCTCOG), 2013; and National Surface Transportation Infrastructure Financing Commission, 2009], for descriptions of federal funding programs.

## B. Vehicle Miles Traveled (VMT) Fees or Mileage-Based User Fees

One of the deficiencies of motor fuel taxes (from a transportation funding perspective) is that as vehicles become more fuel efficient or even operate without petroleum-based fuel (for example, electric vehicles), the consumption of motor fuel will decline, taking motor fuel tax revenue with it. However, at least in the foreseeable future, such vehicles will still need to use the highway infrastructure, thus contributing to the rehabilitation and maintenance needs of the system. One way of ensuring every motorist pays his or her fair share is to charge vehicles for the use of the highway network, most often defined as a VMT fee. As noted by FHWA, "as opposed to tolls, which are facility-specific and not necessarily levied strictly on a per-mile basis, these fees are based on the distance driven on a defined network of roadways." [FHWA, undated] The general idea is that global positioning system (GPS) technology or some other means would be used to identify how far a vehicle has been driven since the last fuel or energy "fill up." The owner of the vehicle would then be charged for the level of use of the road network. This concept has been piloted in Oregon and in other countries, especially for heavy-duty trucks.

One of the key issues with adopting this approach has been the perception by some that it relies too much on technologies that monitor travel, thus potentially infringing on personal freedom. However, with vehicles becoming more fuel efficient while at the same time the demand for transportation funding increases, it seems likely that some form of distance-based tax or fee will be one of the ways of raising the necessary investment dollars. The reader is referred to the FHWA website on innovative finance [FHWA, undated] and the Oregon DOT website ORe*GO*, http://www.myorego.org/. Agrawal et al. [2016] provide a good overview of public perceptions of vehicle miles traveled fees.

## C. Tolls

Tolls are not new to the United States or to other countries. Even in colonial times, toll roads in the now United States were a very common way of supporting the expansion of the road network. In the mid-twentieth century, many states turned to toll roads (turnpikes) to fund the expansion of the long-distance road network in their state. However, with the advent of the interstate highway network in the mid-1950s, interest in toll roads faded. Over the past 20 years, toll roads have made a comeback simply because of the declining level of funding available to state DOTs to expand the highway network. [AASHTO, 2015b] In particular, highway-oriented public/private partnerships, discussed in the next section, depend on a source of funding to pay the concessionaire for the road capital outlays and operations/maintenance costs. In almost every case, the source of funding is toll revenues.

As of 2013, 42 states, the District of Columbia, and Puerto Rico had some form of tolling authorization or facility; 28 states and Puerto Rico had toll facilities operated by statewide entities; 14 states had toll facilities operated by regional entities; 20 states and Puerto Rico had privately operated toll facilities; and 9 states and the District of Columbia authorized tolling, but had no state or regional toll facilities. [FHWA, 2013]

Tolls have been used in many different ways over the past decade. For example, the concept of managed lanes has been implemented in many cities of the world, with the number of projects increasing in recent years, usually with electronic toll collection. The added element to managed lanes is that not only can electronic tolling raise revenues for the transportation agency, but the prices for use of the lane can be varied by time of day and vehicle occupancy to encourage alternative mode use or driving during less congested times. There are several different versions of the managed lane concept:

### *1. High-Occupancy Toll (HOT) Lanes*

In this managed lane concept, single occupant vehicles can use the managed lane during peak periods for a price that often varies by the level of congestion in the lane. The more congested the lane, the higher the price. The driver is thus trading off faster travel times versus higher costs. A major criticism of this concept is that it favors those who can afford to pay the cost of a fast trip, leaving those who cannot relegated to the congested lanes. Studies have shown, however, that in numerous HOT lane operations, many of the users are in fact lower-income drivers who want to arrive at work or some other destination on time. Many metropolitan areas such as Atlanta, Dallas, San Francisco, Seattle, and Washington, DC, are investing heavily in managed lane capacity for their freeway system.

Some examples of HOT lane projects in the United States include:

- SR 91 Express Lanes (Orange County, California).
- I-15 FasTrak (San Diego, California).
- Katy I-10 QuickRide (Houston, Texas).
- I-25 HOT Lanes (Denver, Colorado).
- I-394 MNPASS (Minneapolis, Minnesota).
- I-85 (I-75 under construction) (Atlanta, Georgia).
- SR 167 (Seattle, Washington).

One of the key decisions with high-occupancy toll lanes is whether to use a flat rate for the lane use charge, or a dynamic pricing scheme whereby the price varies by usage. Table 5-2 shows an analysis from Seattle on how revenues and speeds would vary with different pricing schemes. Note that the biggest difference is total revenue and revenue generated per vehicle miles traveled (VMT).

### *2. Express Toll Lanes*

As with HOT lanes, express toll lanes are situated next to regular highway lanes. The difference from the HOT lane concept is that with an express toll lane all personal automobiles using them pay a toll—there are no exceptions made for high-occupancy vehicles (HOV), thus reducing the revenue loss potential due to violations. However, transit vehicles and/or registered vanpools would usually be allowed to operate for free. While these lanes typically represent added highway capacity, existing toll-free lanes also could be converted to toll lanes. Express toll lanes also could be

| Table 5-2. Estimated HOT Lane Performance under Dynamic and Static Pricing Schemes, Seattle | | | | |
|---|---|---|---|---|
| **Scheme** | **Performance Category** | **6:00 A.M.** | **7:00 A.M.** | **8:00 A.M.** |
| **Dynamic** | Total revenue per hour | $1,123,521 | $821,921 | $518,524 |
| | Revenue per VMT | $6.54 | $4.49 | $3.36 |
| | Total travel time cost per hour | $7,255,610 | $5,596,997 | $3,831,644 |
| | Travel time cost per VMT | $3.77 | $2.71 | $1.97 |
| | Average HOT lane speed (mph) | 60.01 | 60.01 | 60.08 |
| | Average general purpose lane speed (mph) | 38.4 | 34.3 | 37.8 |
| **Static** | Total revenue per hour | $368,092 | $503,497 | $311,984 |
| | Revenue per VMT | $2.52 | $3.22 | $2.11 |
| | Travel time cost per hour | $2,993,879 | $3,813,598 | $2,680,838 |
| | Travel time cost per VMT | $1.55 | $1.85 | $1.38 |
| | Average HOT lane speed (mph) | 60.14 | 60.08 | 60.14 |
| | Average general purpose lane speed (mph) | 39.3 | 35.1 | 38.9 |

Source: PSRC, 2014

located adjacent to traditional toll roads, but employ variable pricing (based on time of day and/or congestion levels) to maintain free-flowing traffic.

***3. Truck-Only Toll (TOT) Lanes***

Truck-only toll (TOT) lanes are similar in concept to HOT lanes, but are dedicated to commercial vehicles. Most proposals have the lanes next to regular freeway lanes, but separated with some form of barrier. TOT lanes have been studied in Los Angeles on two freeways heavily utilized by trucks accessing the Ports of Los Angeles and Long Beach. The preliminary Los Angeles region studies found that urban TOT lane facilities might not be desirable because of the predominance of short truck trips, limited travel time savings during off-peak periods, and significant construction costs and geometric constraints related to adding lanes in an urban environment. In addition, one could expect opposition from the trucking industry, whose position is often that they have already paid for the roads through gas taxes (see Table 5-1). The often large costs associated with providing such a lane, especially in an urban environment, are also financially challenging to most DOTs. A public/private financing partnership for such a lane only works if all trucks use the lane, thus possibly encountering industry opposition.

## D. Cordon or Area Pricing, and Parking Charges

Cordon or area pricing is a relatively new concept, although one of the earliest applications in Singapore started in the mid-1970s. The basic concept is that vehicles are charged a fee to enter a highly congested area. The concept was implemented in central London in 2003 where a flat toll of £8 is charged to enter or drive within the tolled area during normal business hours. Tolls could be paid over the phone or via the internet. Enforcement occurs via numerous cameras located throughout the zone. The success of the London scheme has been attributed to improvements made to the public transportation system prior to implementation, where the revenues generated by the pricing scheme have gone to support this new service. In other words, a reasonable alternative to auto use had to be in place before the pricing scheme occurred.

A similar concept was implemented in Stockholm, and smaller implementations have been tried in Durham (UK) and Rome. Cities that are considering some form of pricing to access targeted zones during congested hours include Los Angeles, San Francisco, Bogota (Colombia), and Santiago (Chile). New York City was considering a congestion charging scheme as part of a federal demonstration program, but political considerations stopped the initiative before it could start.

Parking pricing is another policy tool that can help reduce road congestion. It is generally much easier to implement a parking pricing strategy than to apply area-wide toll strategies, but parking pricing faces political challenges common to most proposals that increase the cost of travel. In addition, pricing may only influence the driving behavior of a small group of employees, in that many employers subsidize employee parking. Other aspects that need to be considered

are the likely effects of parking pricing on business attractiveness and the cost equity implications to those using the parking spaces.

Parking pricing strategies have been implemented in the following cities to discourage parking in central business districts (CBDs):

- *Boston*—A parking freeze in downtown Boston and two other neighborhoods limits the growth in the supply of off-street parking. A Resident Permit Parking Program restricts unmetered, on-street parking to CBD residents.
- *California Cities in Air Quality Nonattainment Areas*—A parking "cash out" program provides employees the option of receiving either a free parking space or a cash payment equal to the value of that space.
- *Canada, Sweden, and Australia*—Employer-provided parking is treated as a taxable fringe benefit (this applies to all cities in these countries).
- *San Francisco*—A 25 percent ad valorem tax has been imposed on all commercial, off-street, and nonresidential parking transactions.
- *Washington, DC*—Government employees are required to pay for parking that formerly was free.

See chapter 14 on travel demand management for other examples of programs designed to influence demand, and to raise funds in the process.

## E. Value Capture

This funding mechanism takes advantage of increasing land values that often accompany new transportation accessibility to land, whether highways or transit. In other words, those who benefit from public investment can be charged for these benefits (a similar argument is used for the motor fuel tax). The term "value capture" means recouping some of this value to help pay for the transportation (or other) investments necessary as a precursor to the development. Vadali [2014] examined the effectiveness of many different ways of doing this and began by identifying the following tools.

- *Impact Fees*—One-time charges collected by local governments from developers to finance new infrastructure and services associated with the new development. Usually codified in local ordinances that link the level of development impact (for example, number of dwelling units or square feet) to the size of fee.
- *Special Assessment District*—An additional fee assessed on properties near a new highway or transit facility that is expected to benefit from such proximity. Typically, a vote of the district is needed for fees to be applied to an improvement. In addition, the revenues raised must be targeted to improvements in the district.
- *Sales Tax District*—Similar in concept to a special assessment district, the sales tax district requires those benefiting from a transportation investment to pay a limited sales tax instead of a property tax.
- *Negotiated Exaction*—A negotiated, one-time charge similar to impact fees, but not determined a priori by a formula or impact ratios. Exactions can take the form of in-kind contributions to local road networks, parks, or other public goods as a condition of development approval, or they can be requested in the form of in-lieu fees.
- *Air Rights*—A form of joint development in which development rights above or below highway or transit facilities are used to generate and capture an incremental increase in land value.
- *Joint Development*—Development of a transit facility and adjacent private real estate whereby a private partner either provides the facility or makes a financial contribution to offset its construction costs.
- *Land Value Tax*—A tax imposed on the value of land benefiting from transportation infrastructure.
- *Tax Increment Financing*—A mechanism allocating any increase in total property tax revenues accruing from new access to improvements in a designated district.
- *Transportation Utility Fees*—Utility fees assessed on the basis of characteristics of travel demand, such as traffic volumes.

| Table 5-3. Applicability of Value Capture Mechanisms to Transportation | | |
|---|---|---|
| **Tool** | **Conceptual Basis and Benefit or Levy** | **Basis Applicable Purpose** |
| Impact Fees | • New development to pay for facility use.<br>• One-time developer charges when permits are issued.<br>• Levied before and after an improvement. | Cost recovery |
| Special Assessment District | • Local benefit accruing to all property due to transport access.<br>• Annually levied property owner charges in the service area before and after an improvement. | Capture of project expansion benefits |
| Sales Tax District | • Local benefit accruing to all property due to transport access.<br>• Annually levied sales in the service area before and after an improvement. | Capture of project expansion benefits |
| Negotiated Exaction | • One-time ad hoc developer agreements before or after the improvement (discontinuous spot treatment). | Capturing opportunity for value creation and cost recovery |
| Air Rights | • Air space utilization above, below, under, and nearby/adjacent highway right-of-way for public and private benefit via transfer of rights and joint development.<br>• One-time developer-related opportunity typically after an improvement (on-site developments—discontinuous spot treatment). | Capturing opportunity for value creation and cost sharing and revenue sharing with private sector |
| Joint Development | • Public and private partnership in relation to land (works with air rights or by itself).<br>• One-time developer-related opportunity typically after an improvement (on- and off-site developments). | Capturing opportunity for value creation and cost sharing and revenue sharing with private sector |
| Land Value Tax | • Land value capitalization due to access, incentivize development.<br>• Annually levied property owner changes before and after an improvement—taxes on value of land and a separate tax on value of buildings. | Capture of project expansion benefits |
| Tax Increment Financing | • Increment in property values due to capitalization of access and amenity values. Annually levied property owner charges before and after an improvement. | Capture of project expansion benefits |
| Transportation Utility Fees | • Public good nature of transport. Annually levied property owner charges before and after an improvement. This charge has been used only for defraying operating expenses as opposed to capital costs of projects. | Cost recovery—operating and maintenance costs |

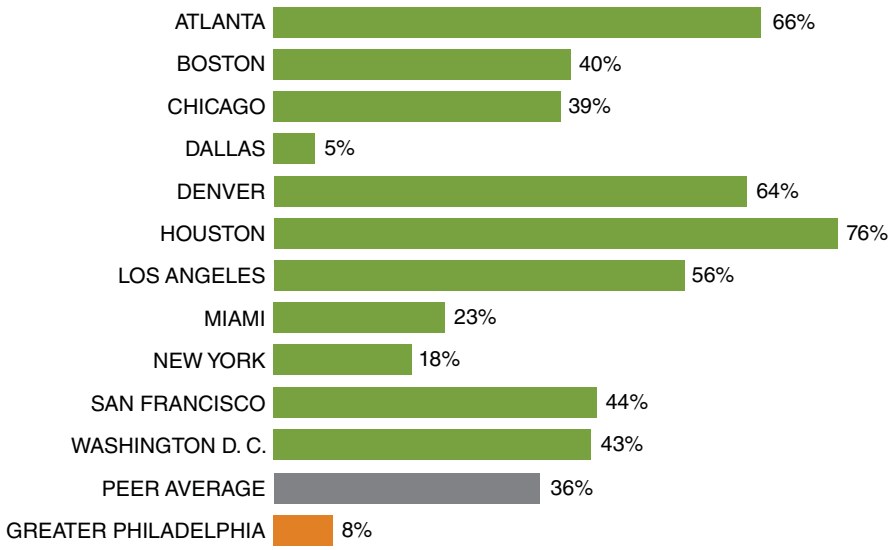
Table 5-3 shows the conceptual basis for each of these tools and the reason for its application.

Each of these tools has received considerable attention in the literature. It is beyond the scope of this chapter to repeat that analysis here. For useful references, see American Planning Association, 2015; Dye and Merriman, 2006; MacCleery and Peterson, 2012; Municipal Services Research Center (MSRC), 2015; Reconnecting America, 2015; Thomas, 2014; and Vadali, 2014.

## F. Other Taxes

A variety of other taxes are used to support transportation investment, especially at the local level. California is using a carbon-based tax to raise revenues for some transportation projects. Other common sources of transportation-related

**Figure 5-3. Percent of Transit Capital Program Coming from Local Sources, Selected U.S. Cities**



Source: DVRPC, 2013

tax revenues include: vehicle license/registration fees, weight fees/taxes, fines and forfeitures, property leases and air rights, advertising (for transit, mainly), and development agreements. Figure 5-3 shows how important local revenues can be for transportation investment. This figure comes from the Delaware Valley Regional Planning Commission (DVRPC), the MPO for the Philadelphia metropolitan area, and was created to illustrate the disparity between Philadelphia's support for transit and peer areas. [DVRPC, 2013] As shown, local support for transit in many U.S. cities varies significantly across the peer systems, but in many it is a significant portion of total investment in the transit system.

Over the past two decades, many metropolitan areas and cities have come to rely on the generation of local tax revenues to support transportation investment. This reliance is a major difference from the 1960s and 1970s where federal and state funding was by far the major contributor to the investment program. [Goldman and Wachs, 2003] The sources for local funding for transportation include: local motor fuel taxes, local motor vehicle registration fees, local option sales taxes, local income/payroll/employer taxes, local severance taxes, value capture, tolls, and fares. [AASHTO, 2015d] Some of these funding sources have been described earlier and thus will not be repeated here. Sales tax revenues, however, deserve some attention.

*Local Option Sales Tax*—This tax has become a common strategy for raising funds for transportation. There are several reasons for this:

- A sales tax produces high revenue for a low marginal tax rate, although it is susceptible to retail sales declines during recessions.
- It has a favorable public perception because individuals of comparable means pay similar amounts of tax—despite its being regressive.
- It is considered fair from a modal perspective whereby, for example, bike/pedestrian and transit projects can be funded by users who pay the sales tax, which is not the case when it is funded with motor fuel tax revenues.
- Sales tax expenditures are a better reflection of ability to pay than is income or wealth.
- A sales tax is an attractive way to exact revenue from nonresident users of local transportation facilities. [Goldman and Wachs, 2003]

The importance of the sales tax for both transit capital and operations/maintenance support is shown in Table 5-4. The data are from the National Transit Database (NTD) and report the funding statistics as of 2009, the last year this type of data was collected by NTD. As shown, the sales tax is by far the largest contributor to transit capital and operations/maintenance revenues.

| Table 5-4. Sales Tax Revenue Contributions to Transit Capital and Operations, United States, 2009 | | |
|---|---|---|
| **Source** | **Amount ($2009)** | |
| **Capital Investments** | | **Percent of Capital** |
| Gas Tax | $38,017,00 | 1.5% |
| Income Tax | $15,775,000 | 0.7% |
| Property Tax | $135,782,000 | 5.9% |
| Sales Tax | $2,009,438,000 | 83.7% |
| Other | $201,796,000 | 8.2% |
| Total | $2,400,808,000 | 100% |
| **Operations/Maintenance** | | **Percent of O&M** |
| Gas Tax | $158,956,000 | 2.4% |
| Income Tax | $81,238,000 | 1.2% |
| Property Tax | $717,386,000 | 10.7% |
| Sales Tax | $5,294,354,000 | 78.8% |
| Other | $463,822,000 | 6.9% |
| Total | $6,715,756,000 | 100% |

Source: Federal Transit Administration (FTA), 2010

Sales taxes, almost always subject to public referenda as enabled by state legislation, will vary from one locale to another. For example, in some cases, the referendum raises revenues for both highway and transit investment. In others, it focuses only on transit projects or only on road projects. In most referenda, a simple majority (50% plus 1) determines the outcome. In California, local tax referenda for specific projects typically require a two-thirds majority. Increases in general taxes, as well as statewide bond measures, require a simple (50%) majority. Yet, even in California, most of the referenda pass. In 2005–2006, the California Legislative Analyst's Office estimated that of the $9.4 billion in local transportation revenue, about one-third, $3.1 billion, came from local option sales taxes. Local revenue was nearly half of the $20 billion spent on transportation in California that year. [AASHTO, 2015d]

It seems likely that with declining federal transportation revenues, metropolitan areas and cities will continue to rely on sales tax revenues for their investment needs.

## IV. TRANSPORTATION FINANCE STRATEGIES

The term "financial strategy" is often used to denote two concepts in transportation. First, it is considered the mechanism by which funds are made available for transportation investment. Second, it is also the term used to describe the combination of different funding sources that together represent the investment strategy for a region or state. Table 5-5 shows a typical representation of the latter. This financial strategy, the level of funding that is expected to be available in the San Diego metropolitan area from 2010 to 2050, includes a wide range of funding sources. [San Diego Association of Governments (SANDAG), 2011] As shown, the funding sources include revenues from local, state, and federal governments. In addition, there are the more traditional sources of funds, such as gas taxes and transit fares. There are funds from local sales tax referenda, called TransNet, as well as San Diego's share of statewide tax referenda (for example, Propositions 1A and 1B). There are funds from nontraditional sources such as impact fees and public/private partnerships. Finally, there are revenues from bonds (for example, TransNet bond proceeds).

The San Diego example is most likely one of the more complex financial strategies found in the United States, given the myriad of funding sources; however, it does illustrate how different sources of funds can be packaged to develop an overall financial strategy for a region. Another unusual aspect of this example is that the financial strategy spans 40 years, a longer time span than most financial plans. More common to other metropolitan areas is that by far the majority of funding comes from local sources (see Figure 5-4).

Most of the innovation in transportation investment planning over the past 20 years has come in the many different financing strategies being used around the world. Usually described under the umbrella of "innovative transportation finance," new mechanisms and tools are now available for investment in the transportation system (see, for example, [Kramer et al., 2015; CPCS et al., 2015; and FHWA, *Project Finance,* undated]. As noted by the FHWA, the innovative nature of today's finance is that it: (1) enables new ways for existing revenue to be used to finance highways and transit,

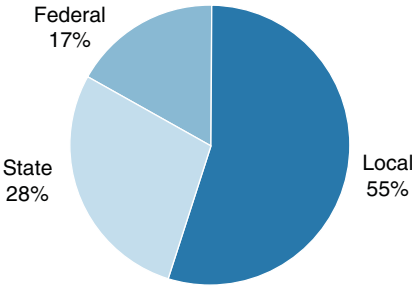
(2) utilizes financing mechanisms such as debt finance, (3) utilizes fund management techniques, and (4) establishes new institutional arrangements. [FHWA, *Project Finance,* undated] Figure 5-5 shows some of the tools that can be used, especially in conjunction with federal funding programs, to capitalize a transportation project. Notice that many of the tools relate to debt financing and public/private partnerships. Public/private partnerships are so important to today's transportation financial picture that they are discussed separately in the section that follows.

Some of the other financing strategies being used more regularly by transportation officials include debt financing and advance construction.

**Figure 5-4. Major Revenue Sources, San Diego Financial Strategy, 2010–2050**



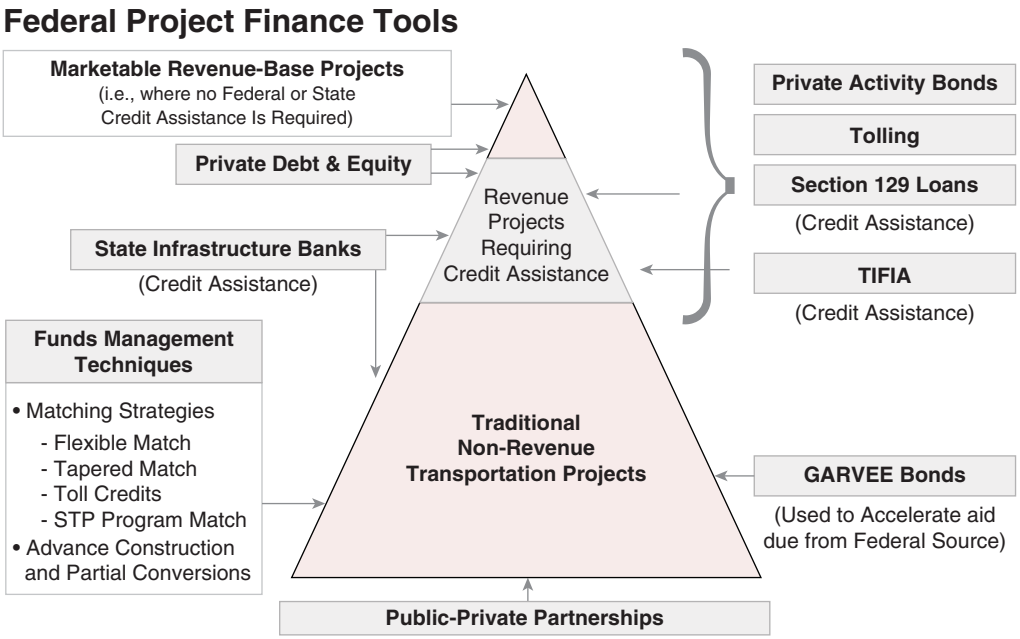
Source: SANDAG, 2011, Reproduced with permission of SANDAG.

Many states use debt financing as a source of funds where the state constitution allows it. Debt financing is very similar to a homeowner's mortgage policy. The government borrows money from the municipal bond market at very low interest rates, and then has to pay back the principal with interest over a set number of years. The advantage of debt financing (sometimes called bonding) is that governments can close large investment gaps with the influx of capital funds, or for similar reasons accelerate the construction of a capital program. In the case of megaprojects, those costing $1 billion or more, debt financing is often the only way a government agency can construct the project, given that there is very little likelihood that $1 billion is available in the short term for the project.

The major disadvantage is that the principal and interest have to be paid back over many years. Some states that have heavily invested in bond financing have found themselves many years later allocating a large percentage of their yearly gas tax revenues to paying off the debt, leaving themselves unable to handle other transportation problems that have occurred since the debt was incurred. Accordingly, governments often establish criteria that dictate how much debt the state or city can sustain. Some of the common benchmarks include:

- Debt per capita.
- Debt as a percent of personal income.
- Debt as a percent of taxable property.
- Ratio of debt service expenditures to total revenues.
- Ratio of debt service expenditures to all expenditures.
- Debt service coverage by pledged revenues. [Henkin, 2009]

**Figure 5-5. Federal Project Finance Tools, United States**



Source: FHWA, *Project Finance*, undated

The key to a successful debt financing strategy is establishing a stable revenue source(s) to pay back the principal and interest. A variety of ways have been developed to do this both for direct borrowing by the government agency and for paying private investors for their borrowing of funds to construct a project. [Henkin, 2009]

- *Availability Payments and Performance Payments*—Public agencies compensating private companies or consortia for their project development and operations activities with annual availability payments that depend on facility performance and availability. Frequently, the public agencies first offer milestone payments when construction is complete and then offer annual payments for each period that the facility is available at a specified performance level.
- *Certificates of Participation (COPs)*—Tax-exempt bonds issued by states usually secured with revenue from an identified source. COPs enable governments to finance capital projects without technically issuing long-term debt.
- *Federal Credit Assistance*—Federal credit, provided through the Transportation Infrastructure Financing and Innovation Act (TIFIA) program and the Railroad Rehabilitation Infrastructure Financing (RRIF) program, providing direct loans (often on a subordinate basis with flexible repayment terms) and other finance assistance to large-scale transportation projects with identified revenue streams.
- *Grant Anticipation Borrowing*—The ability to securitize anticipated federal or state grant proceeds to generate funds for capital outlays. These debt obligations, commonly known as Grant Anticipation Revenue Vehicle (GARVEE) bonds for highways and GANs (grant anticipation notes) for transit, allow debt to be issued without necessarily pledging the credit of the issuer.
- *Private Activity Bonds (PABs)*—Allowing private entities to take advantage of the government ability to issue tax-exempt debt based on the investment purpose of the bond proceeds, but subject to a series of limitations.
- *Shadow Tolls*—Public agencies paying a fee to a private concessionaire for each vehicle that uses a facility. This approach provides incentives to the concessionaire for prompt and on-budget completion and quality performance. Because shadow tolls are not based on user fees, the public agency will need a source of revenue for payments.
- *State Infrastructure Banks (SIBs) and Other Revolving Loan Funds (RLFs)*—A lending organization capitalized (funded initially) with federal grants and state matching funds. Loans from contributed funds can be lent to projects at low interest rates and with favorable terms, with repayments being recycled into subsequent rounds of loans.
- *Tax Anticipation Notes*—Short-term municipal bonds issued in anticipation of future revenues generated from the project. These are sometimes referred to as revenue anticipation notes.

Another strategy being used by state DOTs is advance construction. This allows a state or local agency to initiate a project using nonfederal funds while preserving the eligibility for future federal aid. Eligibility means the FHWA has determined that the project listed in the STIP technically qualifies for federal aid; however, no present or future federal funds are committed to the project. After an advance construction project is authorized, it may be converted to regular federal aid funding, provided that federal funds are available.

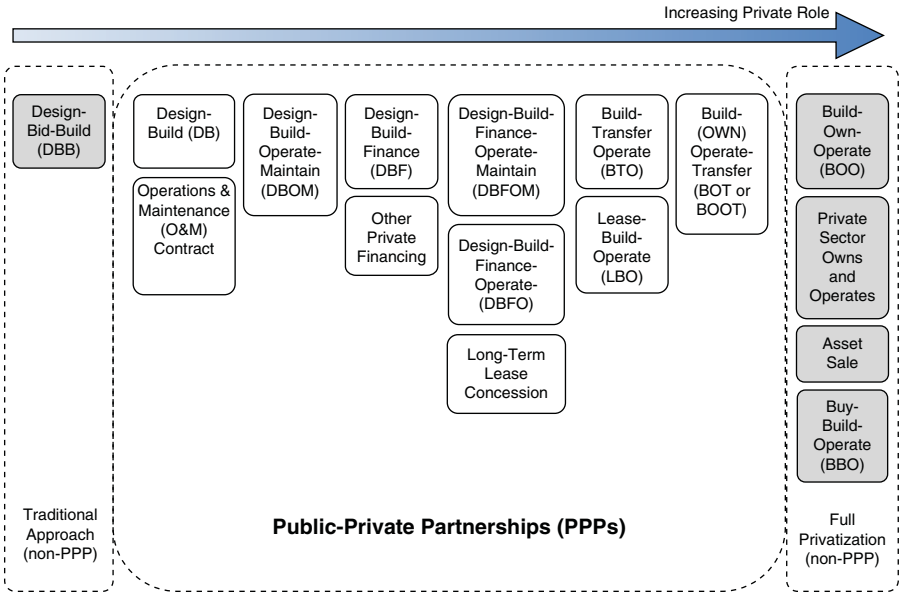
Much of what is considered innovative finance has focused on public/private partnerships, also known as P3s. Because of their importance to innovative finance strategies, the next section focuses on different types of P3 strategies and their potential.

## V. PUBLIC/PRIVATE PARTNERSHIPS

The U.S. DOT defines a public/private partnership in the following manner:

> *"A public-private partnership is a contractual agreement formed between public and private sector partners that allows more private sector participation than is traditional. The agreements usually involve a government agency contracting with a private company to renovate, construct, operate, maintain, and/or manage a facility or system. While the public sector usually retains ownership in the facility or system, the private party will be given additional decision rights in determining how the project or task will be completed."*
>
> *[USDOT, 2004]*

**Figure 5-6. Project Delivery Models along a Continuum of Private Sector Involvement**



Source: Zhao, 2010

P3s differ from traditional public project development in that a private entity or consortium is responsible for more than one phase of the development process. [Gilroy and Poole, 2012] Figure 5-6 shows the many different types of P3 arrangements that could exist. The primary ones include:

> *Design-Build (DB):* The simplest form of P3 is design-build procurement. In this procurement model, a single private contractor is responsible for designing and building a project. The design-builder assumes responsibility for the majority of the design work and all construction activities, together with the risks associated with providing these services, for a fixed fee.
>
> *Design-Build-Finance (DBF):* In a design-build-finance structure, the design-builder takes on the additional responsibility of financing the project. The design-builder arranges financing for the project and is repaid over an agreed upon period, often upon completion of the project.
>
> *Design-Build-Finance-Operate-Maintain (DBFOM):* In this procurement strategy, a private entity (usually a consortium of companies) assumes responsibility for designing, building, financing, operating, and maintaining a project for an agreed upon period. While the public agency retains ownership of the project and must manage the project, the private partner assumes the long-term operations and maintenance risks of the project. The operations and maintenance period of the contract effectively acts as a warranty, enhancing the private partner's incentives to design and construct a quality facility that can be managed efficiently over a long period." [FHWA, 2012a]

Table 5-6 shows the major benefits of P3s as seen from a public sector perspective. The major distinction among the different forms of P3s and thus their benefits is the degree to which risk is transferred to other parties. Risks should be anticipated and should be transferred to those best equipped to manage the risk. Private firms take on the risks of some or all of the financing, designing, constructing, operating, and/or maintaining a transportation facility in exchange for future revenues. The distinguishing characteristic among the different forms of P3s is the degree of responsibility and risk that is transferred to the private sector. [FHWA, 2012a]

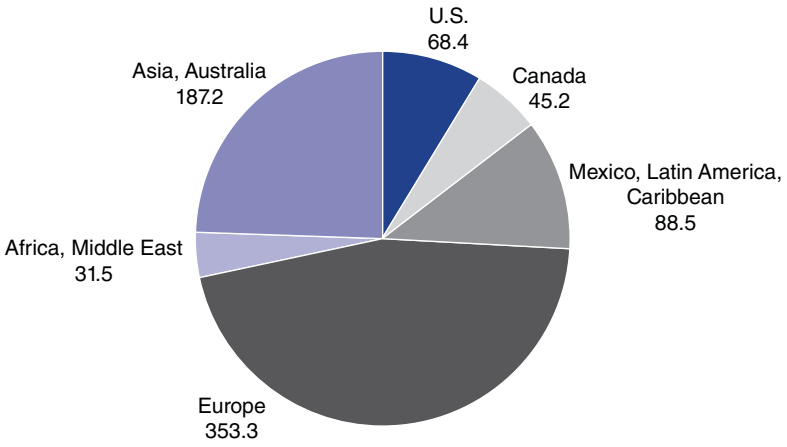
P3s have an important role in the development and delivery of transportation and infrastructure projects in many countries (see Figure 5-7). A Congressional panel examined this experience and made the following observations. [Committee on Transportation and Infrastructure, 2014] The panel found that successful P3s have several common elements, including leveraging the strengths of the public and private sectors, appropriate risk transfer, transparent and flexible contracts, and alignment of policy goals. Unlike most other countries, the United States possesses a robust municipal bond market of approximately $3.7 trillion, of which a significant portion is for infrastructure financing.

| Table 5-6. Benefits from Public/Private Partnerships | |
|---|---|
| **Benefit** | **Description** |
| Increased capacity to finance projects | Using private equity and debt to help finance a project lessens the amount of public funds required in the short term to support a project. In addition, the private partners may be less risk-adverse than the public sector, allowing them to leverage greater upfront capital from anticipated project revenue than the public sector can. By accessing private financial resources, P3s can free up public funds to be used on other worthwhile transportation projects that may not be suitable for P3 delivery. |
| Accelerated infrastructure provision | P3s may provide public agencies access to upfront capital needed to complete major projects that is not subject to annual budget constraints or public debt caps. |
| Improved reliability of project delivery | Many P3s create incentives for the private sector to design and construct a project more efficiently. Several studies have found that P3 projects are more likely to be completed on time and on budget than projects using traditional procurement methods. |
| Improved allocation of resources over the project life cycle | In P3s where the private sector is responsible for operating and maintaining the asset, the private sector has a strong incentive to minimize operations and maintenance costs over the life of the project by improving quality of initial construction. |
| Transfer of selected risks to the private sector | Public sponsors can transfer risks, such as construction and financial risks, to the private sector. |

Source: FHWA, 2012a

The panel found that the existence of a municipal bond market is a major reason why the U.S. P3 market has not grown as quickly as in other countries (which do not offer tax-exempt municipal bonds) and why the potential for P3s in the United States is limited.

**Figure 5-7. Public/Private Partnerships Worldwide, Nominal Total Costs, 1985–2011, $ Billions**



Source: Istrate and Puentes, 2011

The panel's work concluded that, in certain circumstances, "a well-executed P3 can enhance the delivery and management of transportation and infrastructure projects beyond the capabilities of government agencies or the private sector acting independently. The panel's work highlighted that the participation of the private sector in financing a project can bring discipline and efficiency to project delivery, which is too often lacking in the traditional public procurement process." [Committee on Transportation and Infrastructure, 2014]

Many state DOTs have established guidelines or criteria for when a P3 project makes sense for the state. Virginia's guidelines for P3 participation are a good example of such guidelines. The state's P3 policy had the following objectives:

- Create investment opportunities, which increase the quality of transportation services in Virginia.
- Administer a fair and competitive project development and procurement process that encourages innovation, private sector investment and creates long-term value for the Commonwealth.
- Achieve cost efficiencies throughout the life of a project using appropriate transfer of risk.
- Establish reliable and uniform processes and procedures to encourage private sector investment.
- Facilitate timely delivery of P3 projects within established laws and regulations.
- Promote transparency and accountability coupled with informed and timely decision making.
- Foster efficient management of Commonwealth financial and organizational resources. [Commonwealth of Virginia, 2014]

| Table 5-7. Screening Criteria for State DOT Involvement in P3s, Virginia | |
|---|---|
| **Level Project Screening Criteria** | |
| **Project Complexity** | Is the project sufficiently complex in terms of technical and/or financial requirements to effectively leverage private sector innovation and expertise? |
| **Accelerating Project Development** | If the required public funding is not currently available for the project, could using a P3 delivery method accelerate project delivery? |
| **Transportation Priorities** | Is the project consistent with the overall transportation objectives and missions of the Commonwealth and the Agency?<br>Is the project consistent with priorities identified by the appropriate transportation plans and programs, such as SYIP, STIP, and MPO plans and programs?<br>Does the project adequately address transportation needs? |
| **Project Efficiencies** | Would the P3 delivery method help foster efficiencies through the most appropriate transfer of risk over the project lifecycle?<br>Is there an opportunity to bundle projects? |
| **Ability to Transfer Risk** | Would the P3 delivery method help transfer project risks and potential future responsibilities to the private sector on a long-term basis? |
| **Funding Requirement** | Does the project have the revenue generation potential to partially offset the public funding requirement, if necessary?<br>Could a public agency pay for the project over time, such as through an availability payment, as opposed to paying for the entire cost upfront? |
| **Ability to Raise Capital** | Would delivering the project under the PPTA help free up capital from other sources for other transportation priorities within the Commonwealth?<br>Is the project consistent with federal requirements and potential agreements for federal funding and/or approval for P3 projects? |

Source: Commonwealth of Virginia, 2014

Table 5-7 shows the criteria used in Virginia for a high-level scan of the feasibility of a P3 project. [Commonwealth of Virginia, 2014] As seen, the criteria range from how complex the project is to the distribution of risk associated with the project.

P3s can also pose significant legal and practical challenges. Thomas [2014] notes several issues that may arise for transit projects, but in reality are present for all transportation projects:

- *Federal and Local Legal Issues*—P3s currently involve several major exceptions to standard federal laws and regulations. In addition, local laws may restrict or impact P3s. Care must be taken to ensure that the P3 framework complies with FTA requirements and other applicable legal provisions.
- *Insurance Issues*—P3s may involve complex insurance arrangements and project-specific policies.
- *Labor Issues*—If a P3 includes a private entity performing transit operations or other related work, labor issues may need to be addressed by the partners.
- *Performance Metrics*—Most P3 agreements have contractual performance metrics that the concessionaire must satisfy with respect to the service being provided. These criteria are critical for the public partner in that they ensure a desired level of service; they also help define the risks assumed by the private partner in service provision (for which costs are usually assigned in the bid price).
- *Risk Issues*—P3s may involve a private entity serving as a concessionaire, but retain fare-setting power with the public entity. Such arrangements can raise issues regarding revenue risk allocation.
- *Tax and Financing Issues*—To obtain financing and favorable tax treatment, the private entity may need to demonstrate ownership of the asset being developed by the P3, yet the public entity needs to maintain continuing control of the project (among other reasons, to qualify for federal funds).

Excellent examples of how states and other agencies are viewing P3 arrangements can be found in [Rall et al., 2010; Istrate and Puentes, 2011; and Commonwealth of Virginia, 2014]. In addition, many guides are available on the steps that are necessary for developing a successful P3. Those interested are encouraged to visit the FHWA Office of

Innovative Program Delivery, which provides numerous guidelines and tools to assess the benefits and costs of P3 projects (see http://www.fhwa.dot.gov/ipd/).

## VI. INVESTMENT PROGRAMMING AND REVENUE ESTIMATION

The previous sections discussed the different funding sources and financial strategies that are typical in the United States and in many other countries. An important challenge for transportation officials is matching the needs established by the planning process with the level of revenues that are reasonably expected over the lifetime of the transportation plan. The term for this is "programming," which in simple terms, is deciding which projects to fund and when to build them.

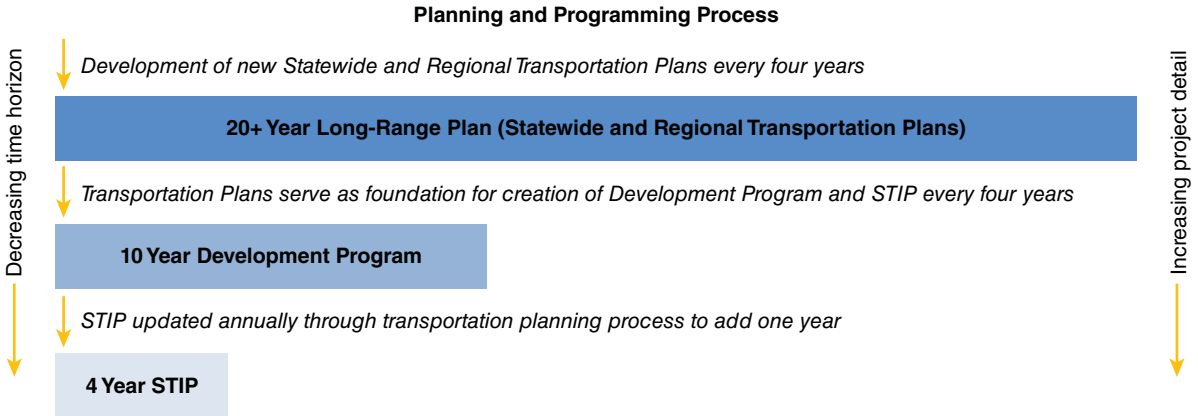
Figure 5-8 shows a typical relationship among the different planning and programming processes as adopted by the Colorado DOT. [Colorado DOT, 2015] The level of detail of projects is much greater during the programming process (the statewide transportation improvement program—STIP), as indicated in the figure.

There is a variety of ways that the programming process can be organized. The Minnesota DOT (MnDOT), for example, has both a decentralized and centralized programming process. A majority of the expected federal highway and transit funds is "targeted" to Area Transportation Partnerships (ATP) for the selection of federally funded projects in the STIP. ATPs are groups established by MnDOT in regions consisting of local officials, freight and passenger interests, MnDOT representatives, and other public representatives. This process is decentralized; ATPs have the responsibility for project selection. Federal funds that are not targeted to the ATPs are used for major statewide bridge and corridor projects that are solicited and awarded centrally. Wholly funded state projects are selected by the eight MnDOT district offices through their district planning processes. [MnDOT, 2015]

As an example of the program development at an MPO level, the Puget Sound Regional Council (PSRC) reviews all projects submitted for inclusion in the capital program to ensure the following:

- Consistency with the region's development and transportation plan.
- Consistency with local comprehensive plans.
- Funds are available or reasonably expected to be available.
- Consistency with the region's air quality conformity determination.
- Consistency with federal and state requirements such as functional classification.
- Consistency with PSRC's project-tracking policies. [PSRC, 2015]

**Figure 5-8. Relationship between Planning and Programming Processes, Colorado**



Source: Colorado DOT, 2015

In addition, PSRC makes sure that the region's financial strategy does the following:

- Reflects the impacts of the economic downturn on transportation finance (both revenues and expenditures).
- Makes the case for the development of new funding over the plan implementation period.
- Adds specificity to the funding assumptions contained in the financial strategy of the previous plan (for example, tolling, regional funding).
- Prioritizes projects using evaluation measures articulated through the VISION 2040 policy.
- Identifies projects that may not be ready for implementation prior to the planning horizon due to financial constraints or other project readiness limitations.
- Develops an illustrative list of projects (unprogrammed) that are not covered by the plan's financial strategy, and are not part of the plan's air quality determination. [PSRC, 2015]

The most important programming documents in the United States for transportation investment are the statewide transportation improvement program (STIP) and the transportation improvement program (TIP) for metropolitan areas (when talking about both generically, this chapter uses the term S/TIP).

## A. State/Transportation Improvement Program (S/TIP)

By federal law, every state and MPO in the United States must produce a state transportation improvement program (STIP) or a metropolitan transportation improvement program (TIP). Although the primary intent of the TIP is to identify project priorities, it can serve other purposes as well. For example, the TIP for the Denver Regional Council of Governments (DRCOG) is intended to achieve the following purposes:

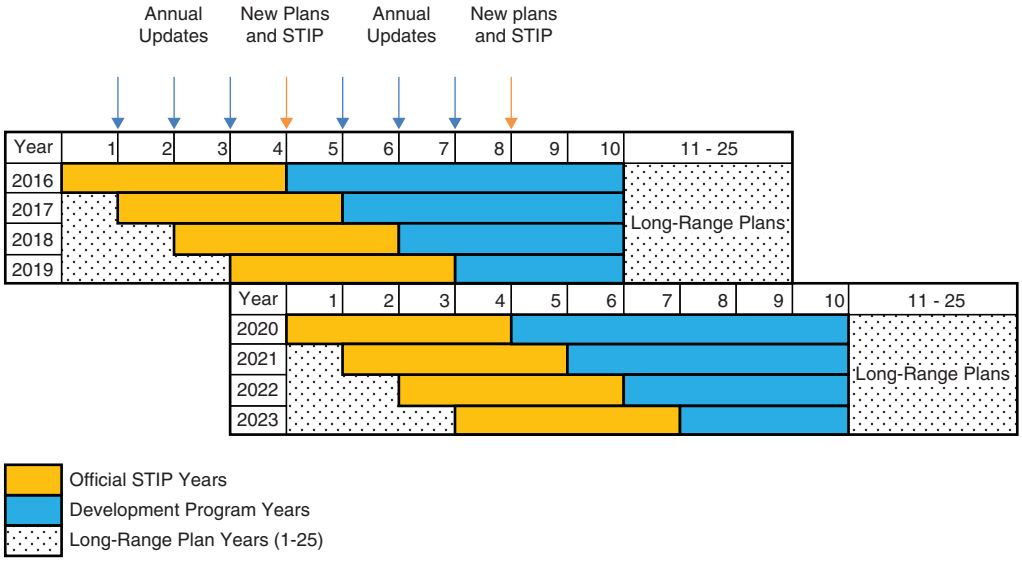
- Serve as a short-range implementation tool to address the goals of the regional long-range transportation plan.
- Provide continuity of current transportation improvement projects with those identified in previous TIPs.
- Identify transportation projects recommended for implementation by transportation mode, type of improvement, funding source(s), and geographic area.
- Estimate the costs of projects proposed for federal funding. The project allocations are to be consistent with the federal funds reasonably anticipated to be available for such projects in the area.
- Establish a prioritization of projects to effectively utilize federal funds as they become available.
- Identify and implement transportation improvements which will maintain the system; improve safety; improve air quality and reduce greenhouse gas emissions; reduce vehicle miles traveled (VMT) and congestion; and enhance the transportation system. [DRCOG, 2015a]

The Metropolitan Transportation Commission (MTC) in the San Francisco Bay area also notes that the TIP is multimodal, covers a four-year period, identifies future commitments of funding and signifies that a project may move ahead to implementation, shows estimated project costs and schedules, must reflect realistic revenue and cost estimates, and can be amended as new projects are added or existing projects are modified. [MTC, 2014a]

Figure 5-9 illustrates the concept of a continual "rolling over" of the S/TIP. Every year or two, depending on when the S/TIP is updated, a new year of investment is added to the capital program to take the place of the year that has just passed.

It is important to note that the S/TIP development process is subject to the same public participation rules as the transportation planning process, and thus requires opportunities for public input and for coordination with Tribal Nations and other transportation agencies (for state DOTs, in particular, there must be close coordination with MPOs). In addition, in those areas subject to Clean Air Act rules concerning nonconformance with air-quality standards,

**Figure 5-9. Rolling Four-Year State Transportation Improvement Program, Colorado**



Source: Colorado DOT, 2015

MPOs are required to show conformity of their TIP with the State Implementation Plan (SIP) for air quality before the TIP can be adopted (see chapter 4 on environmental analysis).

Projects can come from a variety of sources. At the metropolitan level, the rules state that projects programmed in the TIP must come from the long-range transportation plan or other planning products. Thus, a major challenge to MPOs is to prioritize the projects that surface from the planning process for inclusion into the TIP. DVRPC, for example, uses the following screening criteria for choosing road projects for its TIP: [DVRPC, 2013]

- Does the project serve the region's identified population and employment centers?
- Are there significant environmental issues that will be impacted by a project, as measured by DVRPC's Environmental Screening Tool?
- Is the project located in a Congestion Management Process (CMP) Priority Subcorridor?
- What is the reduction in regional vehicle hours of travel (VHT) associated with this project?
- What is the average annual daily traffic multiplied by the peak-period volume-to-capacity (V/C) ratio within the project limits?
- What is the daily truck traffic on the facility?
- How far has the project advanced?

Transit system expansion projects were evaluated with the following criteria:

- Does the project serve areas that will support a high level of transit service, as measured by DVRPC's Transit Score Index?
- Does the project serve environmental justice communities with additional transit needs, as identified by DVRPC's Degrees of Disadvantage (DoD) analysis?
- What is the potential for transit-oriented development?
- What is the status of the project?
- Is the project located in a CMP Priority Subcorridor?
- What is the project's anticipated farebox recovery rate?

System preservation and operational improvement projects were prioritized using asset management system condition data, use (vehicle and truck volumes, or transit ridership), detour length (for bridges), age, TIP status, speed impacts (for pavement), and functional class.

Readers are referred to DRCOG's priority criteria [DRCOG, 2015b] for an example of an extensive numerical approach to project prioritization; see also chapter 7 on evaluation.

At a state level, projects can come from the statewide transportation plan, as well as from many other sources. The following example from the Oregon DOT (ODOT) gives a sense of the breadth of involvement and range of project sources that could characterize a STIP development process.

Oregon categorizes STIP projects into two broad types: "Fix-It" projects, which maintain the existing transportation system, and "Enhance" projects, which improve the system. [ODOT, 2015] State-level plans provide an important source of projects. In ODOT's case, these include:

- *Oregon Transportation Plan (OTP)*—Policy and system investment analysis for the state's transportation infrastructure.
- *Oregon Freight Plan*—Summary of freight conditions and needs related to the state's transportation systems along with goals, policies, and strategies.
- *Oregon Highway Plan*—Policies and performance standards for the state highway system.
- *Oregon Bicycle and Pedestrian Plan*—Analysis of statewide conditions, system and facility standards, and strategies.
- *Oregon Public Transportation Plan*—Goals, policies, and strategies for the state's public transportation system.
- *Oregon Transportation Safety Action Plan*—Strategies for improving the safety of Oregon's transportation system.
- *Oregon Rail Plan*—Goals, objectives, and system needs for freight and passenger rail in Oregon.
- *Oregon Aviation Plan*—Policies and investment strategies for Oregon's public-use aviation system for the next 20 years.
- *Intelligent Transportation Systems Strategic Plan*—Strategies to increase the efficiency of existing transportation infrastructure.
- *Statewide Congestion Overview*—Analysis of congestion problems and recommended solutions.

Other sources for projects originate from a management system database. The Oregon Transportation Management System (OTMS) is used to monitor the condition of transportation assets such as pavement or bridges. Most rehabilitation and reconstruction projects in the STIP are developed from the OTMS. For example, all pavement preservation, bridge, and safety projects are developed using information from the management system. The most important management systems include:

*Bridge Management System (BMS)*—The Bridge Management System for bridges on and off federal-aid highways tracks inspection data and uses mathematical models to forecast future bridge conditions. It helps decision makers identify cost-effective solutions and prioritize investments.

*Intermodal Management System (IMS)*—The Intermodal Management System provides information about intermodal freight and passenger facilities and connections. The focus is intermodal exchanges, such as rail to truck, marine to rail freight movements, or passenger rail to highway exchanges. The system monitors information about general freight traffic on highways, main rail lines, and marine waterways.

*Pavement Management System (PMS)*—The Pavement Management System helps decision makers find cost-effective ways to maintain pavements in a serviceable condition. The PMS includes a pavement database, which contains current and historical information on pavement condition, pavement structure, and traffic. It is a forecast tool that estimates future pavement conditions and helps identify and prioritize pavement preservation projects.

*Public Transportation Management System (PTMS)*—The Public Transportation Management System collects and analyzes information about public transportation operations, facilities, equipment, and rolling stock. The system monitors the condition and cost of transit assets and the cost of transit operations. PTMS identifies needs and helps decision makers select cost-effective strategies for providing operating funds and maintaining transit assets in serviceable condition.

*Safety Management System (SMS)*—The Safety Management System consists of the Information Safety Management System (ISMS) and the Project Safety Management System (PSMS). The ISMS includes sources of data used by the PSMS and the overall monitoring and administration of ODOT's Roadway Safety Program. The PSMS includes processes, procedures, and tools to address critical safety issues for project scoping, design, and construction.

*Traffic Monitoring System for Highways (TMS-H)*—The Traffic Monitoring System for Highways monitors person and vehicular traffic data. It involves a systematic process for the collection, analysis, summary, and retention of highway- and transit-related data over time and is used to forecast future conditions on the highway system. [ODOT, undated]

In addition to ODOT plans and information sources, state projects in urban areas can come from metropolitan area transportation plans and rural transportation plans (including small communities). Outside of metropolitan areas, three planning processes are used to develop the source documents for projects listed in the STIP—ODOT facility plans, local transportation system plans, and local public transportation plans. Facility plans include corridor studies and other facility-specific plans, such as access management plans for interchanges, interchange area management plans, and expressway management plans. Given that Oregon is home to several federal parks and federal facilities, as well as Tribal Nations, the Oregon DOT STIP also includes projects from Federal Land Management agencies (for example, the U.S. Forest Service) and Tribal Area plans.

As can be seen from this description, STIP development relies on a wide range of inputs, not only those from the state DOT's own planning process.

Figure 5-10 shows a typical project description that would be found in an S/TIP, in this case from the DRCOG. The figure shows the expected level of funding over the lifetime of the TIP, the source for that funding, the agency responsible, and an annotated history of the development of the project. Usually, S/TIPs present additional information on the distribution of funds across modes and program types, and often by geographic area. Figures 5-11 and 5-12 illustrate this kind of information.

One of the important inputs into programming is the estimation of future costs and revenues. From earlier sections, one can the large variety of funding sources and financial strategies that can be considered as part of a capital program. For each of these, the state DOT and the MPOs must estimate what level of funding will be generated over the lifetime of the plan or program. This is even more important when one considers the requirement that long-range plans and programs be financially constrained. The next sections discuss ways of doing such estimation.

## B. Estimating Revenues

In order to estimate future revenues, planners must know the underlying funding sources and the factors that influence the amount of revenue generated. Some revenues will relate to future economic activity, largely unrelated to transportation system performance. For example, a sales tax is more affected by the state of the economy than it is by the level of travel. Other revenues are directly related to the use of the transportation system, such as revenues from gas taxes, tolls, or transit fares.

In Seattle, for example, the PSRC had to forecast new transportation revenues for:

- Fuel tax increases.
- Sales tax on fuels.
- Motor vehicle excise tax (percent of value).
- Sales tax increase for local transit.

- Sales tax increase for Sound Transit (the region's transit agency).
- New development or impact fees.
- Road levy (property tax).
- Employee tax.
- Vehicle license fee.
- Street utility fees.

Some of these revenue categories relate to expectations about the future demographics of the region, including population and employment, as well as the value of the vehicle fleet, volume of fuel consumption, the value of retail sales, and others. PSRC uses a regional economic model to forecast future regional economic and demographic

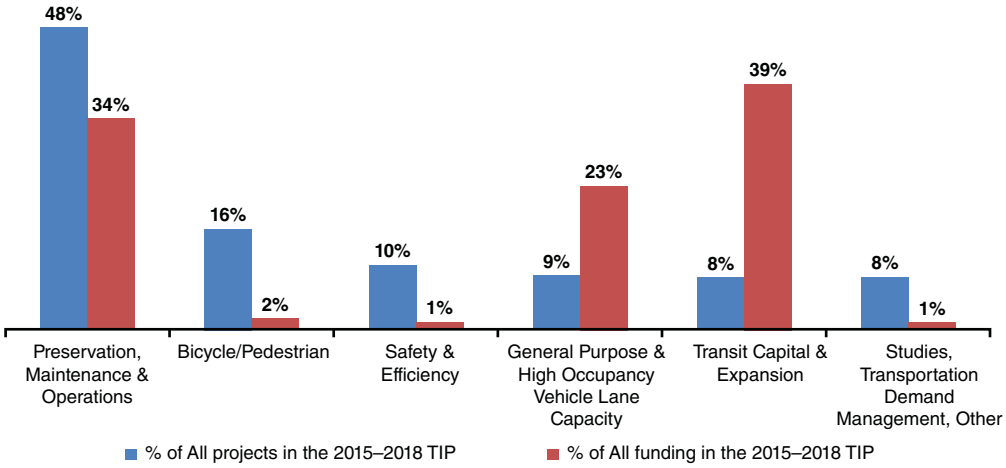
**Figure 5-11. Project Types in the 2015–2018 Regional TIP, Puget Sound Regional Council**



Source: PSRC, 2015

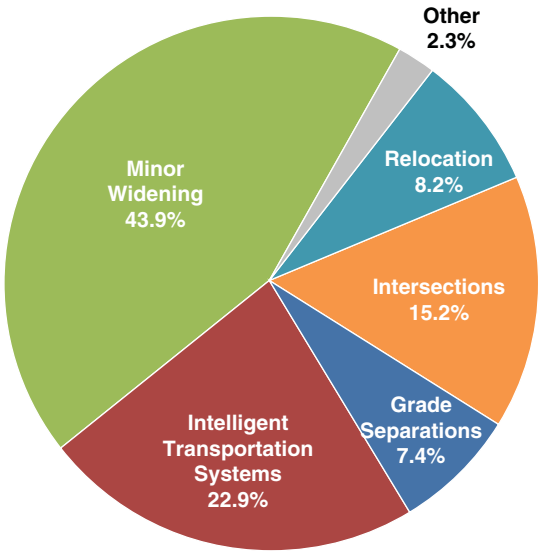
characteristics. These forecasts feed into tax-base forecasts leading to expected revenues (see Figure 5-13). For tolls, fares, and parking charges, PSRC uses its travel demand model to derive the revenue yield from various applications of a toll or fare policy. [PSRC, 2014]

The results of this financial analysis are shown in Tables 5-8 and 5-9 and Figure 5-14. These are typical presentations of revenue forecasting that one would see in MPO and, in some cases, state DOT financial plans. Table 5-8 shows the forecast of revenues related to those sources currently authorized, whereas Table 5-9 shows expected revenues from new sources.

Another example from the North Central Texas Council of Governments (NCTCOG), the MPO for the Dallas-Ft. Worth metropolitan area, again illustrates the assumptions that must be made when forecasting future revenues.

The following financial assumptions were used in the update of NCTCOG's long-range plan: [NCTCOG, 2013]

**Figure 5-12. Project Selection Results for PSRC Funds, Safety and Efficiency Projects, Puget Sound Regional Council**



Source: PSRC, 2015

- Beginning in 2015, the state fuel tax will be indexed (adjusted annually) to fuel efficiency. Because fuel taxes are assessed on a per gallon basis, as vehicles become more efficient they consume less fuel. This decreases the amount of revenue available for transportation improvements. Indexing to fuel efficiency allows existing revenues to be maintained into the future.
- Beginning in 2015, a $10 local option vehicle registration or mobility fee will be assessed within the 12-county Metropolitan Planning Area boundary.
- In 2020, both state and federal fuel taxes will be increased by 5 cents each.
- In 2025, an additional $10 local option vehicle registration or mobility fee will be assessed within the 12-county Metropolitan Planning Area boundary.
- By 2025, the state will have incrementally eliminated 80 percent of the diversions from the State Highway Fund. This does not include the portion of the gas tax that goes to fund education because this is protected by the state constitution.

**Table 5-8. Current Law Transportation Revenues by Source, Puget Sound Regional Council ($2008 millions)**

| Current Law Revenue Sources | 2010–2020 | 2021–2030 | 2031–2040 | 2010–2040 |
|---|---|---|---|---|
| State taxes on motor fuels | $5,260 | $3,420 | $3,040 | $11,720 |
| Registration and license fees (incl. weight) | $800 | $490 | $470 | $1,760 |
| Other state taxes and fees | $380 | $380 | $500 | $1,260 |
| Other taxes and fees for general funds | $6,450 | $6,450 | $6,100 | $18,290 |
| Property taxes (general or restricted) | $2,160 | $2,160 | $1,400 | $5,080 |
| Development and impact fees | $0 | $0 | $100 | $100 |
| Fares and operating revenues | $4,410 | $4,410 | $4,650 | $13,410 |
| Federal—FHWA | $1,860 | $1,860 | $970 | $3,890 |
| Federal—FTA | $2,630 | $2,630 | $1,250 | $5,380 |
| Sales-tax revenue (general) | $12,610 | $12,610 | $19,470 | $46,290 |
| Other transit revenue | $630 | $630 | $660 | $1,610 |
| Parking taxes | $250 | $250 | $140 | $560 |
| Property tax on motor vehicles | $670 | $670 | $0 | $1,160 |
| Port and Tribal contributions | $430 | $430 | $0 | $630 |
| Total Current Revenue | $38,540 | $38,540 | $38,750 | $111,140 |

Source: PSRC, 2014

- In 2030, both state and federal fuel taxes will be increased by 5 cents each.
- Over the life of the MTP, toll roads, managed lanes, comprehensive development agreements, public-private partnerships, and other innovative funding options will be used to implement projects.
- Over the life of the MTP, the state will address pavement conditions, while the MPO will fund bridge replacements.
- Over the life of the MTP, regional transportation partners will continue to implement projects.
- Over the life of the MTP, there will be an increased reliance on local entities to fund projects locally.

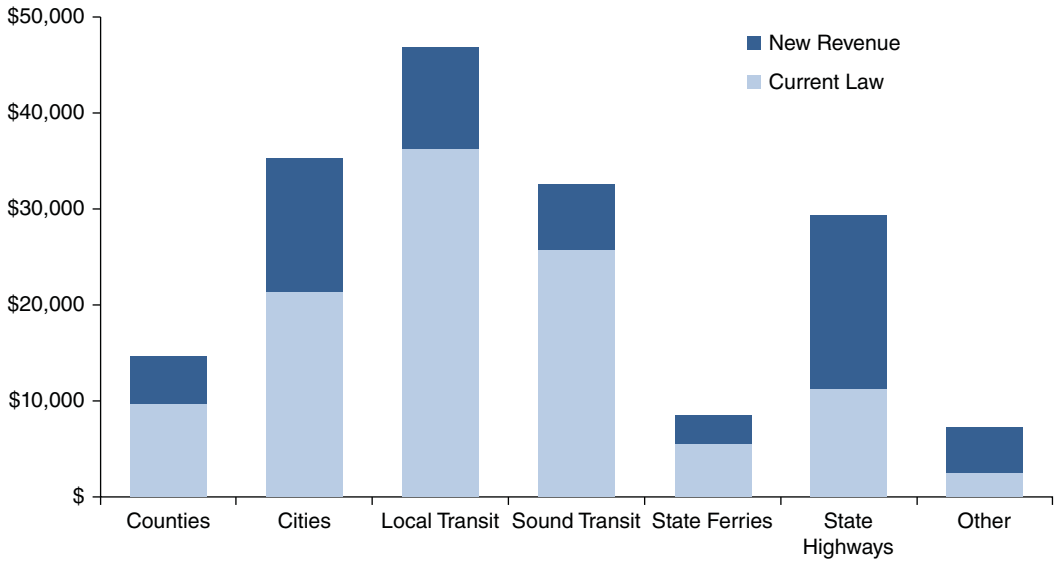
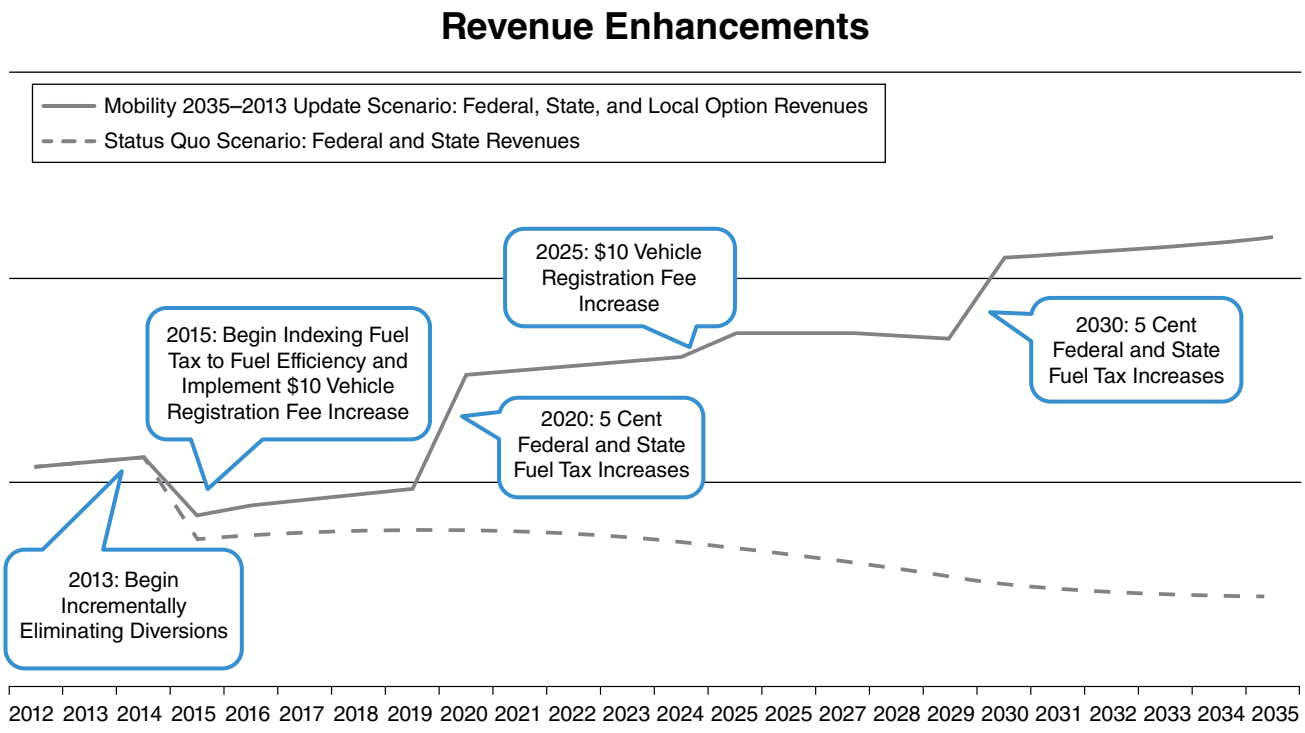
millions of $2008 constant



Source: PSRC, 2014

**Figure 5-15. Impacts of Revenue Enhancements, North Central Texas Council of Governments**



Source: NCTCOG, 2013

Another way of portraying the assumptions of new revenues is shown in Figure 5-15.

A revenue-forecasting model called Transportation Revenue Estimation and Needs Determination System (TRENDS) was used to forecast state and federal funds for the initial regional plan. [Ellis et al., 2011] The financial forecasts also included predicted revenue from the region's toll and managed lane system and local funds, as well as the revenues from the region's three transit systems. Three revenue scenarios were developed that reflected varying possibilities (see Table 5-10):

- *Status Quo*—This scenario represents a minimal level of investment that focuses on traditional transportation revenues as they exist today.
- *Statewide Enhanced*—This scenario represents the financial conditions that would exist if taxes or fees for transportation were increased at the state or federal level.
- *Statewide Enhanced + Local Option*—This scenario represents the most aggressive of the three funding options. In this scenario, the assumptions from the Statewide Enhanced scenario would be used with the addition of several local revenue initiatives. Local initiatives could be project-based (such as implementing a robust toll and managed lane system) and/or they could be tax- or fee-based (for example, an increase in vehicle registration fees). [NCTCOG, 2013]

After evaluating historic trends, the current state of transportation funding, and the plausibility of future funding, the MPO Board selected the $101.1 billion Statewide Enhanced + Local Option scenario to represent the financially constrained revenue forecast for the regional transportation plan.

As can be seen from these two examples, forecasting future revenues is based on historical trends and on reasonable assumptions about future revenue enhancements. The process can combine both economic forecasting and a

| Additional revenue from Status Quo | | +11.5 | +26.2 |

Source: NCTCOG, 2013

travel demand model for estimating future use of the transportation system. Changes that might need to be considered in the analysis include:

- Population change (should be compared with past trends and with statewide demographic control totals).
- Employment change (should be compared with past trends and with statewide economic growth control totals).
- Regional distribution of future population, employment, and land use.
- Demographic change (including automobile ownership, household income, household size, and multiworker households). [Kriger et al., 2006]
- Travel behavior change (including telecommuting, trip chaining, and Internet shopping).

Forecasting future revenues for a state transportation program often includes a similarly wide range of revenue sources. Wachs and Heimsath [2015], for example, surveyed state DOTs and found the following sources of revenue were forecasted by at least one state:

- Oil company gross receipts tax.
- Investment income and small revenue sources.
- Aviation fuel tax.
- Rental car surcharge.
- Off-highway sales tax on dyed diesel.
- Documentary stamp tax.
- Motor carrier surtax.
- Fuel tax transfers and refunds.
- Oversize/overweight permits.
- Damage to state property.

- Toll road lease proceeds.
- Miscellaneous permits and fees.
- Weight distance tax.
- Federal revenue reimbursements.
- 2% Special fuel excise tax on dyed fuel usage.
- Driver's license revenue.
- Truck regulation and enforcement fees.
- Projected unencumbered cash balances.
- Oil company—franchise tax.
- Contribution from Turnpike Commission.
- Vehicle code fines.
- Vehicle sales tax.
- Local participation.
- Interest on cash balances.
- Miscellaneous revenue.
- Dedicated taxes and fees.
- Ferry boat fees.
- Department of Motor Vehicle fees.
- Traffic violation fees.
- Airspace leasing.

They also found that the most common forecasting tools were: simple historical trend extrapolation, expert consensus, and econometric models, including econometric regression analysis.

Good references for revenue forecasting include [FTA, 2000; NCHRP, 2010; CRTPB, 2010; Wachs and Heimsath, 2015; and FDOT, 2013]. Kriger et al. [2009] is a good reference for the estimation of toll revenues.

## C. Estimating Costs of Capital Projects

The project cost estimation responsibilities vary by agency role in project development. For example, state DOTs have primary responsibility for project planning, project development, construction, operations, and maintenance of the state highway system. Thus, highway capital cost estimates included in a regional TIP usually come from the state DOTs; the MPOs usually do not develop the estimates. However, cost estimates for other types of projects such as nonstate highways and pedestrian/bicycle projects are often prepared by MPO staff.

Cost estimates, especially for very large projects, have often been criticized because of "cost creep" once the project is under construction. There are many reasons why final costs might not reflect planning estimates, the most important being that detailed engineering has not yet been done during the planning process, so that specific project costs (such as environmental mitigation) are largely unknown at that point in project development. Anderson et al. [2007] suggest many reasons for discrepancies in project-level cost estimates, including:

**Source Factor**

Bias

Delivery/Procurement Approach

Project Schedule Changes

Engineering and Construction Complexities

Scope Changes

Scope Creep

Poor Estimation

Inconsistent Application of Contingencies

Faulty Execution

Ambiguous Contract Provisions

Contract Document Conflicts

**Internal**

Local Concerns and Requirements

Effects of Inflation

Scope Changes

Scope Creep

Market Conditions

Unforeseen Events

**External**

Unforeseen Conditions

Note that this list is for project-level costs where projects have advanced enough in the project development process to develop the details for more accurate cost estimates. Factors such as scope change and creep are not that relevant to planning level estimates because the specific project scope is not usually developed until after the plan.

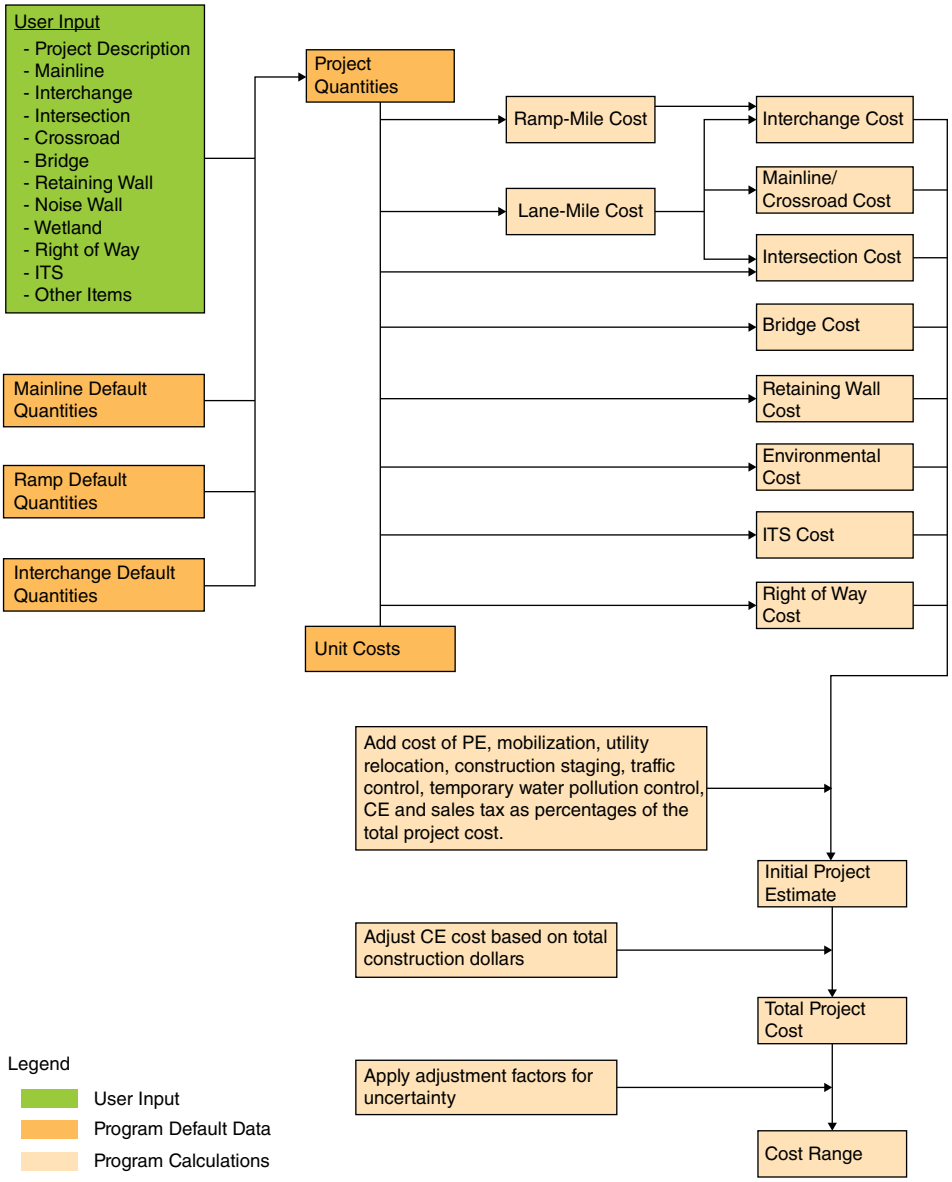
Figure 5-16 shows an approach used by Washington State DOT to develop planning cost estimates. [WSDOT, 2012] The approach simply multiplies unit costs by the expected quantities for a project cost element, and then sums across all component cost estimates to get a total cost. A similar approach is used for project-level cost estimation, but at a much more detailed level. [WSDOT, 2015] Most state DOTs have a cost estimation manual or policy that has been calibrated to the project cost histories in their state. MPOs often use these manuals when developing their own cost estimates.

One of the key characteristics of planning-level cost estimates is that insufficient project design has occurred to allow cost estimators to know with any certainty what the project cost is likely to be. In other words, there is a high level of risk associated with planning-level cost estimates. The way this is usually handled is to apply contingency factors, adding an "uncertainty" cost to the estimate. This contingency factor decreases as the project moves through project development and more detailed engineering is undertaken. Typical contingency ranges by phase are as follows:

- Planning and concept development phase—30 to 40 percent.
- Public involvement phase—25 percent.
- Semifinal phase—15 percent.
- Final review—5 to 10 percent.
- PS&E—0 percent. [Paulsen et al., 2008]

Transit capital cost estimation is similar in some ways to highway cost estimation, in that key standard cost categories are identified for each project, and then unit costs are applied where appropriate to estimate the category

**Figure 5-16. Planning-Level Cost Estimation Procedure for Washington State DOT**



Source: WSDOT, 2012

cost. [TransTech, 2003] The FTA has defined the cost categories for the cost estimation process, and allows two types of cost estimation: the "bottom up (deterministic)" and "top down (stochastic)" approaches. The "bottom up" approach totals the cost of each component of a category. The "top down" approach provides an order of magnitude cost based on data from projects that are similar in nature, where the cost is divided by a unit of measure and applied as a unit cost.

The FTA cost categories include:

Category 10: Guideway and Track Elements

Category 20: Stations, Stops, Terminals, and Intermodal

Category 30: Support Facilities: Yards, Shops, and Administrative Buildings

Category 40: Site Work and Special Conditions

Category 50: Systems

Category 60: Right of Way, Land, and Existing Improvements

Category 70: Vehicles

Category 80: Professional Services

Category 90: Unallocated Contingency

Category 100: Finance Charges

Two methods commonly used for estimating unit prices:

- *The Historical Bid Price Method* uses past unit price bids for similar work adjusted for time and project location and developed as a construction cost index. Bid unit costs are usually available from the state DOT. However, the timing of the bidding vis à vis the economy can also play a significant role in determining whether bids come in above, below, or at an engineer's estimate. External economic factors can cause the cost of constructing a traffic signal—a fairly standardized item—to vary by plus/minus 10 percent. When contractors are looking for work, they will submit lower bids to keep their forces and equipment busy.
- *The Time and Material* (also known as *Crew Price) Method* uses nationally recognized productivity, local labor, and equipment rates from a similar or the same database, and material or subcontract costs from the same database or as obtained by the estimating team for the project. [HDR, Inc. 2013]

As shown in Table 5-11, transit cost estimation also uses contingency factors to take into account the uncertainty of actual costs. Contingencies are allocated to specific project components as well as to the phase of project development.

**Table 5-11. Transit Cost Contingencies**

| FTA Category | Description | Allocated Contingency Percentage |
|---|---|---|
| 10 | *Guideway and Track Elements* | |
| | –Guideway elements (except underground) | 25% |
| | –Guideway elements (underground) | 35% |
| | –Track elements | 20% |
| 20 | *Stations, Stops, Terminals, and Intermodal Connections* | 20% |
| 30 | *Support Facilities: Yard, Shops, and Admin Buildings* | 20% |
| 40 | *Site Work and Special Conditions* | |
| | Demolition, clearing, earthwork | 25% |
| | Site utilities, utility relocation | 30% |
| | Hazardous materials, contaminated soil removal/mitigation, groundwater treatment | 30% |
| | Environmental mitigation, for example wetlands, historic/ archaeological, parks | 30% |
| | Site structures including retaining walls, sound walls | 25% |
| | Pedestrian/bike access and accommodation, landscaping | 25% |
| | Automobile, bus, van access including roads, parking lots | 25% |
| 50 | *Systems* | 20% |
| 60 | *Right of Way, Land, Existing Improvements* | 50% |
| 70 | *Vehicles* | 10% |
| **Unallocated Contingency Factors** | | |
| Planning | System planning | 15% |
| | Alternatives analysis | 10% |
| Design | Preliminary engineering | 20% |
| | Final design | 15% |
| | Construction | 10% |

Source: HDR, Inc. 2013

As the costs of projects continue to rise and the level of funding continues to decline, it will become even more important in the future to have a credible and effective capital cost estimation procedure.

## D. Estimating Costs for Operations and Maintenance

Estimating future operations and maintenance (O&M) costs represents a particular challenge because of both unknown future labor rates and unknown future labor productivity rates. Accordingly, most estimates of future O&M costs are simply escalations of historic trends. For example, the PSRC considered the O&M component of system components as a program cost and assumed cost escalation at historic rates modified to reflect expected changes. City and county maintenance costs were estimated to grow at 2.7 percent in real terms over the 30-year planning period, while nonproject capital requirements were estimated to grow at 2.5 percent in real terms. Local transit operations were estimated to grow at, or slightly above, the rate of inflation, reflecting new cost control policies implemented since an economic downturn. Travel demand management, intelligent transportation systems (ITS), and toll system costs were also estimated programmatically through various detailed methods. [PSRC, 2014]

Transit O&M estimation is a bit different from the simple escalation approach, in that FTA and the transit industry have developed approaches and methodologies for estimating O&M costs, especially for future transit projects. The prerequisite for a transit O&M analysis is an operating plan, which outlines the expected fleet size, headways, and labor requirements. After a major transit facility is constructed, systemwide O&M expenses typically increase, requiring additional subsidies to continue operating and maintaining the transit system. [FTA, 2000] Fixed guideway projects, for example, often result in significant service realignments. The operating plan contains at least 5 years of historical data and 20-year forecasts of O&M expenses for the existing transit system and the proposed project. The O&M expenses are supported by information regarding service characteristics of the transit agency, such as projected vehicle revenue miles, vehicles in service, and directional route miles.

Two major types of models can be used to estimate future O&M costs. A *cost allocation model* assumes that each expense incurred by a transit system is "driven" by a key supply variable such as revenue hours, revenue miles, and peak vehicles. [FTA, undated] A unit cost rate is calculated for each expense line item and an estimated future O&M cost can be calculated by summing the future revenue hours, revenue miles, and peak vehicles multiplied by their respective unit costs. Twelve (12) months of actual transit expense data are preferred, with expenses defined as either fixed or variable.

A *resource build-up model* identifies every factor that contributes to the provision of transit service and the cost of each. As new services are added to the network, the transit agency can then estimate the change in the number of these input factors and the corresponding cost. An example of an operations cost estimation is shown in Table 5-12. As shown, the key variables are annual revenue miles and annual revenue hours.

# VII. ENVIRONMENTAL JUSTICE ANALYSIS

The equitable distribution of funds has been a growing concern among transportation policy makers for many years. [Wachs, 2003; Committee on Equity Implications of Evolving Transportation Finance Mechanisms, 2011] As part of the transportation planning process, the development of the TIP is subject to the requirements that guide the

**Table 5-12. Example Operations Cost Estimation, District of Columbia Streetcar**

| | Annual Revenue Miles | Unit Cost per Revenue Mile | Mileage Based Annual Cost | Annual Revenue Hours | Unit Cost per Revenue Hour | Hourly Based Annual Cost | Total Annual O&M Costs 2009 dollars | Total Annual O&M Costs 2012 dollars | Total Annual O&M Costs 2013 dollars |
|---|---|---|---|---|---|---|---|---|---|
| **Alt. 1 Streetcar** | 263,852 | $5.23 | $1,379,946 | 30,821 | $216.81 | $6,683,013 | $8,062,959 | -- | $9,074,860 |
| **Alt. 2 Streetcar** | 278,554 | $5.23 | $1,456,835 | 37,269 | $216.81 | $8,081,133 | $9,537,968 | -- | $10,734,982 |
| **Alt. 3 Premium Bus** | N/A | N/A | N/A | 33,788 | $95.00 | $3,209,814 | -- | $3,209,814 | $3,306,108 |

Source: District DOT, 2014

process and substance of the planning program. One of these requirements in the United States is that the capital investment program should not unduly burden low-income and minority populations. Those who develop the TIPs must self-certify that such is the case. In some instances, the MPO undertakes a fairly involved analysis of the equity implications of the TIP.

An example of this is the Metropolitan Transportation Commission (MTC) in the San Francisco Bay Area. As part of the 2013 TIP development, the MTC conducted an analysis that specifically addressed the equity implications of the proposed TIP investments. In 2015, the MTC conducted an update of this analysis to reflect the additional TIP investments that had occurred since 2013. The purpose of the analysis was to "understand if low-income and minority populations are sharing equitably in the TIP's financial investments." [MTC, 2014b] The analysis calculated the shares of 2015 TIP investments that affected the identified communities, and compared those shares with the proportional size of this group's population and trip-making relative to that of the general population. The methodology consisted of:

1) The 2015 TIP investments were separated into two modes: transit and road/highway.
2) Investments were allocated in each category to low-income and minority populations, and other populations according to each group's usage share of each mode at the county or transit-operator level.
3) The assignment of investment by usage was performed by multiplying the percent of use of the mode by the investment in that particular mode. This analysis was conducted at the county level for highways and roadways and at the transit-operator level for transit. A similar approach was followed for transit investment allocations.
4) The investments by mode (from county or transit-operator data) were summed for low-income and minority populations and for all other populations based on each group's usage share of each mode. The percent of usage of the system by the target and other populations was then calculated and the percent investment was compared to the percent use of the system by user group.

Tables 5-13 to 5-15 illustrate the information that resulted from this analysis. Based on these results, MTC concluded that there was not disparate impact in the distribution of federal and state funding for public transportation purposes between minority and nonminority populations.

**Table 5-13. Population-based Comparison of TIP Investment by Income Distribution**

| | 2015 TIP Investments | % of Investment | % of Trips |
|---|---|---|---|
| Trips by people living in low-income households (< $50,000/year) | $2,331, 948,851 | 25% | 18% |
| Trips by people living in non-low-income households (> $50,000/year) | $7,176,862,582 | 75% | 82% |
| Total | $9,508,811,413 | 100% | 100% |

## VIII. FUTURE CHALLENGES

This chapter began with the statement that transportation funding and finance constitute perhaps the greatest challenge facing the transportation industry today. This challenge is likely to become even greater in the future. The PSRC identified some crosscutting issues in transportation finance that characterize the ongoing debate about transportation finance. [PSRC, 2014] They are presented here, somewhat modified, to reflect the finance and funding environment of tomorrow.

*The Future of Fuel Taxes.* In the face of inflationary pressures, vehicles with improved fuel mileage, and alternately fueled vehicles, the future of a fuel-tax-based approach to highway finance may be limited. Alternate approaches to collecting user fees have been contemplated for many years. Technical advances have revolutionized road user fee collection approaches and may someday offer a replacement alternative for fuel taxes. As the transportation sector strives to better understand the connection between personal and freight mobility and carbon emissions, taxes on motor fuels will become an even less viable means of funding future investments. One option away from gas taxes is a VMT fee, which would charge a driver per mile traveled. This type of fee would be more attuned to the economic principle of user fees, but several proposals in the United States have been rejected because of the consequences of such a fee structure on those who drive long distances (even though today's gas tax and vehicle fuel economy is doing much the same thing).

*Bond Financing.* Historically, transportation systems in the United States have been financed on a pay-as-you-go basis. However, the pay-as-you-go approach is no longer working well in providing the level of investment dollars needed to enhance the capacity of the transportation system. Many states have turned to debt financing as a way of providing the necessary upfront dollars to implement a capital program. The problem is that, depending on how much is borrowed, the principle and interest payments could well burden future generations with repayment costs that do not allow them to invest in their own transportation strategies.

*Reliance on Non-Transportation-Related Tax Sources*. Increased reliance on non-transportation-related revenue sources, such as the sales taxes and municipal general funds, exposes transportation systems to greater revenue uncertainty. For example, e-commerce has likely eroded the sales-tax base for many communities, given that, in most cases, sales taxes are not charged for Internet purchases. Transit agencies that rely on sales tax revenues will be affected by economic downturns; for example, many had to significantly cut services during the economic recession of 2008–2012 as their sales-tax revenues plummeted.

*Geographic Equity for Statewide and Regional Sources.* Politics lends itself to geographic divides, and these divisions have been a source of debate as to whether transportation dollars are distributed fairly. The issue of "Am I getting my fair share?" is one that will continue to be faced in the future, especially if funding levels decline.

*Cost Burden across User Groups.* The distributional effects of transportation investment—that is, "who wins? and who loses?"—relate to issues of fairness and political viability, but also have implications for efficient transportation system management. Some users of the transportation system impose greater costs than others. Heavy vehicles create more pavement and structural damage; commuters on busy roadways during the peak travel period impose delay on other users. The financial systems that support investments in transportation need to reflect these cost structures.

*Connected and Autonomous Vehicles.* Arguably, the U.S. transportation system is at the cusp of a technology revolution. Connected vehicles, connected vehicle infrastructure, and autonomous vehicles raise important questions on how such vehicle operations can fit into a transportation finance strategy that supports the infrastructure that is still needed for such operations.

## IX. SUMMARY

Transportation finance and funding represent two of the greatest challenges facing the transportation industry. Today, a variety of strategies are used to provide the investment capital needed to expand and maintain the transportation system. New partnerships among public agencies, and between public and private organizations, are using innovative finance strategies to support project implementation. In many ways, the finance and funding analysis process is much more complicated than it was many years ago, when the largest single contributor to state and regional capital programs came from the gas tax. Today, a menu of options is available for transportation officials to choose from.

This chapter has described the current configuration of the transportation finance and funding structure. It seems likely that the way we financially support the transportation system will change a great deal in the future. We are already seeing new institutional arrangements and partnerships that support investment in the system. New technologies are allowing states to capture tolls and fees in a nonintrusive manner, and this capability is only likely to increase in the future.

Although, historically, transportation finance was not part of the transportation planning process, today it is. Very few plans are produced today that do not have a requirement to identify potential financial and funding strategies. Transportation planners thus need to understand the basics of financial analysis as well as the types of strategies that can be considered as part of a state or regional investment program.

# Travel Demand and Network Modeling[1]

## I. INTRODUCTION

Travel demand in the (noncommodity) urban environment refers to the personal travel or passenger trips generated by economic and/or personal needs. Demand for travel is often organized into market segments that reflect a range of factors—including household income, gender, and age of the traveler; auto ownership; and household structure—that influence how many and what kinds of travel activities occur. Transportation supply is represented by the roads, transit facilities and services, information technology, and other infrastructure that enable trips to be made. Transportation supply and travel demand are interdependent—inadequate capacity, which results in congestion, affects travel decisions, and the cumulative effects of individual travelers' decisions affect the performance of the transportation system. Travel demand modeling focuses on this interaction between transportation demand and supply. Given the need for making deliberate, long-term infrastructure investment choices, transportation planners need to know how to model future travel demand and how to interpret the results.

This chapter begins with a brief historical perspective on the evolution of travel demand modeling. The next section discusses some of the key principles and concepts that serve as the foundation of demand modeling, which leads into the next section's description of the major modeling approaches in use today—the four-step model and activity-based modeling. The third section discusses the important relationship between travel demand modeling and air quality analysis, and the final section describes different travel demand software packages available to the transportation community. The reader should note that freight demand modeling is not discussed in this chapter, but is described in chapter 22 on freight transportation.

## II. MODELING TRAVEL DEMAND

### A. Brief Historical Perspective

Prior to the mid-1950s, many urban areas relied on simple uniform growth factors for estimating future travel demand. [Weiner, 1987] In other words, planners simply looked at the historical growth in travel and extrapolated to future years. As transportation became more important to the growing metropolitan areas of the 1950s and 1960s—and especially when a formal transportation planning process was required in federal transportation legislation (see chapter 1)—the need for more formalized forecasting methods became crucial. During the early years of travel demand modeling, demand forecasting was used largely to ensure that sufficient highway capacity was available to meet the growing demand for automobile trips. Very little effort was devoted to predicting the demand for other modes of transportation. Many of the analysis techniques developed during this period became the technical foundation for what is now known as the four-step modeling process.

The 1960s and 1970s saw many important changes in transportation planning. Environmental concerns started to play a small, but more significant role in transportation decision making. Oil embargoes in the 1970s led to a growing concern about the reliance of the U.S. transportation system on imported oil, and models were once again expected to provide information on the likely effects of different transportation strategies in response. Beginning in the mid-1980s, larger urban areas began to look more seriously at ways of providing mobility other than with single-occupant cars, and travel demand models were expected to provide some indication of the most effective types of transit and travel

[1]The original chapter in Volume 3 of this handbook was written by Debbie A. Niemeier, Ph.D., P.E., Professor, and Song Bai, Ph.D., Civil and Environmental Engineering, University of California-Davis. Changes made to this updated chapter are solely the responsibility of the editor.

demand management (TDM) strategies under varying system conditions. During the past 20 years, the emphasis on expanding system capacity to *meet* demand has shifted to a philosophy of *managing* demand. Consider, for example, the application of intelligent transportation system (ITS) technologies to manage system performance and provide better information to travelers (see chapter 10 on transportation system management and operations). To know which investments make sense, travel demand models were called on to determine the effect of these technologies and other operations-oriented strategies on travel decisions. [TRB, 2007]

Today's land-use planning and transportation investment decisions are accompanied by a variety of other considerations unheard of in the 1950s—ranging from air-quality conformity, environmental impacts, and environmental justice issues to informing regulatory processes and addressing reporting requirements associated with government accountability. These context-related changes to planning have also been accompanied by fundamental changes in household factors that often drive demand, resulting in different travel markets today than those of 20 years ago. For example, declining household size and increasing vehicle ownership have had perhaps the greatest impact on travel activity (see chapter 2 on travel statistics). The average household size has dropped by roughly one person in the last 40 years. During the same period, vehicle ownership has continued to rise. As noted by the American Association of State Highway and Transportation Officials (AASHTO), the changes over the past 50 years in auto ownership have been dramatic:

> *"The number of households with one vehicle remained roughly constant for 30 years, but after 1990 it began to increase, perhaps attributable to the influx of immigrant populations and growth in single-adult households. Note that, for the most part, the great changes were in the two-and three-vehicle households. Households with two vehicles increased from about 10 million to more than 40 million in the period, and households with three or more vehicles increased an incredible amount, from 1.3 million to more than 22 million, almost 20 times the 1969 figure."*
>
> *—AASHTO, [2013]*

Household composition and the organization of household activities also continued to evolve. As household structure changed, so did travel patterns, which were also influenced by rapid suburbanization of U.S. metropolitan areas. As the number of single-parent and two-worker households increased, the ways in which individuals arranged their daily travel also became more complicated. Nonwork trips are now often linked to work commute trips, resulting in a linking—or trip chaining—of different types of activities. As early as the mid-1990s, Strathman et al. [1994] found that 31.5 percent of all trip chains were work-related and 68.5 percent were nonwork-related.

Partially in response to these changes, the last two decades of travel demand forecasting have seen significant improvement in tools and methods. The complexity of policy and infrastructure decisions has driven the development of many innovations, which have now made their way into mainstream practice.

## B. Principles and Concepts

Travel demand models are based on several fundamental concepts and principles that have served as the foundation for demand modeling for decades. These concepts range from consumer theory to the idea of travel being considered a derived demand. It is beyond the scope of this chapter to discuss each of these topics in detail. However, transportation planners should understand some of the basic foundations of travel demand modeling in order to understand why models are formulated the way they are.

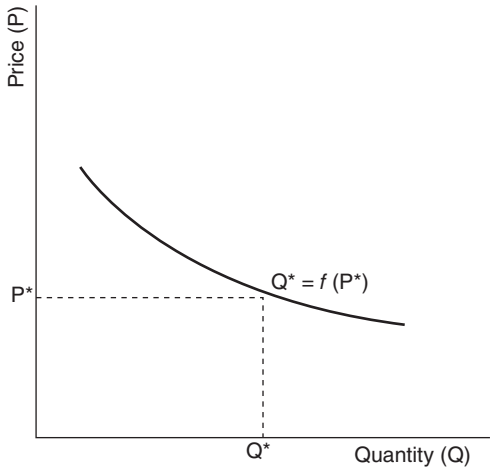
*Travel as a Derived Demand.* Viewing travel as a *derived demand* is perhaps one of the most important concepts in travel demand modeling and has been incorporated into traditional models as well as some of the newer modeling approaches. Put simply, derived demand says that travel occurs because of activities that occur at the destination … travel is simply a means to an end. Demand is derived from the need or satisfaction in arriving at a destination. This has resulted in model variables that describe the attractiveness of destination zones (for example, thousands of square feet of retail space) as well as characteristics of the origin zones (for example, household incomes).

*Travelers as Consumers of Travel.* Consumers of goods usually consider a range of factors when deciding to purchase one product over another. So too in transportation. Travelers are considered to be "purchasing" one mode of travel over another. In travel demand parlance, a mode is considered to have a utility attached to its use (or a disutility, if the characteristic does not lead to higher consumption, for example, cost of travel). The utility of a mode is associated with such things as travel cost, convenience, travel time, availability of the mode, and the like. Travelers are assumed

to weigh the utility of one mode versus another and then choose the one with the greatest utility. Importantly, the choice of one mode versus another is observable, that is, one can develop models based on the observed behavior of individual travelers, aggregated over all travelers in a network.

*Network Flows as Equilibrium Flows*. Figure 6-1 shows a very common representation of the demand for a good and its relationship to price. As shown, the demand curve represents expected quantities consumed at a particular price. For transportation modeling, at an aggregate level, it is assumed that individual travelers cannot increase their utility by choosing another path or another means of arriving at a destination. Using travel cost as a simple representation of utility, this means that a traveler cannot find another least cost travel path different than the one chosen, all things being equal. Thus, the overall trip-making flows on a network for a given price is assumed to be an equilibrium flow. Travel demand modeling must therefore reflect not only the characteristics of travelers, but also the characteristics of network performance. It is the interaction between the demand and supply of transportation that is reflected in demand estimates. Note that the demand curve could shift depending on factors that are outside the control of a transportation planner (for example, the population gradually getting older) and that demand elasticities (change in demand in proportion to change in price) can vary by whether the effect is short term or long term.

**Figure 6-1. Demand Curve**



*Stochastic Behavior.* Although one would expect a "rational" person to always choose the mode of travel that maximizes utility, such is not the case. There are some travelers who will not drive during peak periods, while others will never use a bus. If one believes in the concept of derived demand, a "rational" person would always choose the shortest time path between origins and destinations; however, many choose routes that are longer for no other reason than to "see the sights." Thus, there is some uncertainty associated with trip-making decisions that must be considered as part of travel demand modeling. This is manifested in travel demand models by using the probabilities of certain trips being taken by different modes.

*Trip Purpose and Time of Day.* As noted in chapter 2, trips are made for some purpose (derived demand) and occur at specific times of the day. Thus, travel demand models incorporate trip purpose into the structure and functioning of the models themselves. In traditional models, demand analysis is actually done sequentially by trip purpose. Thus, one would forecast work trips, shopping trips, school trips, and so on individually. These would then be aggregated to obtain a total trip-making "picture." Similarly, time-of-day was handled by forecasting a 24-hour trip table and then reducing it to individual times of the day (for example, peak three hours, peak hour, or off peak hours) using historical percentages of the amount of travel occurring in these time periods. In many recent modeling efforts, trip purpose and time-of-day have been combined by looking at the typical trip-making activities of individuals during the day. For example, a traveler might start from home in the morning, drop off a child at a day care center, drive to work, walk to a nearby coffee shop, walk back to work, walk to a nearby restaurant for lunch, walk back to work, drive to pick up the child at daycare, and drive home in late afternoon. Many of today's demand models are able to represent this trip-making behavior by focusing on a traveler's activities during the day, and thus the term "activity-based models."

*Spatial Distribution of Activities.* Just as trip-making occurs over time, so too do trips occur over spatial areas. Thus, when predicting the demand for travel, transportation planners will want to know where trips are likely coming from and where they are going to. From a modeling perspective, this becomes important for assigning travel flows to transportation networks, such as a highway or transit network. Identifying the spatial nature of trip-making has become more challenging in recent years with employees who work at home, or who work from sites not considered normally as a work location, for example, a coffee shop. As society becomes ever more distributed via the Internet, understanding the spatial distribution of where many of our everyday activities occur could become even more important.

## C. Travel Demand Model Applications

Travel demand estimation occurs in a variety of problem-solving and planning contexts. In each case, the inputs to a model or forecasting tool will vary according to the complexity of the desired outcomes and the scale of demand analysis. Thus, for example, a regional demand forecast will require a representation of the entire region (for example, traffic analysis zones) and of the entire transportation system (for example, transit, highway, and nonmotorized networks). The degree of sophistication and complexity in forecasting future demand for travel can range from the use

| Table 6-1. Typical Output Measures by Road Demand Forecasting Application | | | |
|---|---|---|---|
| **Travel Forecasting Application** | **Typical Volume-based MOEs** | **Typical Time-Based MOEs** | **Accessibility MOEs** |
| Air quality conformity analysis | Area-wide vehicle miles traveled (VMT) | Speeds | |
| Asset management, including bridge and pavement needs | Link-specific volumes | | |
| Capital improvement program, prioritization | Benefit/cost, level of service (LOS) | | |
| Congestion management process | Corridor volumes | Speeds | |
| Corridor mobility studies | Intersection: LOS, Intersection turning movements, travel volumes | | |
| Demand management plans | Number of peak-hour trips, LOS | | |
| Environmental impact statements | VMT, emissions, crashes | Vehicle hours of travel (VHT) | |
| Energy consumption | Fuel consumed (related to miles per gallon) | | |
| Evacuation plans | Hourly travel volumes, throughput | Travel times | |
| Facility design and operations | Design hour travel volumes | | |
| Highway feasibility studies | Benefit/cost, screenline volumes, LOS | VHT | Access to labor market and jobs |
| Interchange justification requests | Travel volumes, LOS | | |
| Roadway (general and freight) long-range planning | VMT, LOS | VHT | Access to labor market and jobs |
| Travel impact studies | Intersection turning movements, LOS, delay per vehicle | | |

of simple growth rates and trend-line analysis to large-scale travel demand and simulation models. Table 6-1 shows different applications for travel demand forecasting and the type of information produced by demand analysis. This information describes the condition and performance of the future transportation system such that investment or operations decisions can be made today in anticipation of future capacity and operational problems. Measures of effectiveness (MOEs) in this table refer to the types of outputs from the forecasting tool. Also note that the focus of the travel demand forecasting tools shown in Table 6-1 is primarily on road demand; forecasts for transit ridership and pedestrian/bicycle use rely on similar, but slightly different approaches.

NCHRP Report 765, *Analytical Travel Forecasting Approaches for Project-level Planning and Design*, [CDM Smith et al., 2014] provides useful insights on the strengths and weaknesses of volume-based, travel-based, and accessibility output measures. Table 6-2 shows this assessment.

NCHRP Report 765 also provides a useful checklist or "rules of thumb" for applying travel forecasting techniques in a transportation analysis, including:

- Every effort should be made to forecast travel on the basis of an analysis of the interaction of transportation demand and supply using well-validated travel demand models. Travel demand forecasts should be based on behavioral/socioeconomic factors, rather than trend-line extrapolations of travel growth whenever possible.
- Additional area detail (additional zones and links) may be created for project-level forecasts.
- Adjustments for over/under forecasting should be conducted at the level of the trip table first, before link-level adjustments are made.
- Link-level adjustments for over/under estimation against base year travel counts should not exceed 15 percent.
- Intersection turning movement forecasts beyond a five-year timeframe are highly susceptible to error and should be avoided.

| Table 6-2. Strengths and Weaknesses of Travel Forecasting Model Outputs | | | |
|---|---|---|---|
| | **Volume-based Measures** | **Time-based Measures** | **Accessibility Measures** |
| **Definition** | Volume-based measures deal with the quantity of use of transportation facilities at a point on a transportation network along several points on a screenline, or between origins and destinations. Demand is associated with specific timeframes. | Travel time measures describe the trip duration of travel by a vehicle between two points or the total effort incurred in travel by a group of travelers between or within regions. | Accessibility measures can be used to assess how environmental justice populations are affected by transportation investments and development and to estimate the proximity of facilities such as ports, airports, warehouses, and distribution facilities to shippers and site retail and other commercial developments, using measures such as the population within a reasonable distance of a development site. |
| **Strengths/Weaknesses** | Travel volumes are the most basic, readily understood, readily accepted, and thus most important output of the travel forecasting process. However, travel volumes do not convey the traveler's experience of congestion or delay. | Travel time-based measures more closely describe a traveler's experience than do volume-based measures. However, most forecasting applications estimate travel time less accurately than travel demand volumes. | Higher levels of accessibility correspond to increased destination choices and modal choices and thus better economic and social outcomes. Basic measures of accessibility are readily understandable when the choices or opportunities available are simply counted.<br>When used at large geographic scales, the measure can be relatively insensitive to small to moderate changes in transportation capacity. Aggregate measures of accessibility that produce unitless results (such as change in utility) can be difficult to explain and understand. |
| **Application/Purpose** | Travel volumes describe the number of vehicles at a point on a roadway. Travel forecasts are often developed for specific travel markets, such as passenger vehicles and trucks. Special-purpose studies may focus on additional vehicle classes, such as buses or combination and single unit trucks. | Travel time information is often compared to some norm or standard to describe performance. The standard or baseline against which travel time performance is being measured should be realistic and clear. When comparing travel times between two points, often the point of comparison is a no-build scenario. A related measure, travel time delay, is expressed as the increment of time incurred in travel, over and above some expected level. Often the expected level is defined as travel in uncongested conditions (free flow times). However, uncongested conditions may be an unrealistic standard in some urbanized areas and during peak periods of travel. This is less of an issue when delay is used as a relative measure, as a way to compare alternatives. | Typical applications include the relationship between a smaller area and a larger region:<br>• Number of households (larger region) within 30/45/60 minutes of an employment or activity center (smaller area), as a measure of access to labor.<br>• Number of jobs (larger region) within 30/45/60 minutes of a residential area (smaller area), as a measure of access to jobs.<br>Researchers and planners have developed more generalized measures of accessibility, suitable for application at a regional level. Such measures rely on formulations similar to the gravity model; the denominator of a destination or mode choice model, the logsum, can also be used as a measure of accessibility across all modes represented. |

Source: CDM Smith et al., 2014, Reproduced with permission of the Transportation Research Board.

- Projected decreases in travel (negative growth rates) volumes in a study area should be examined carefully and explained fully. Possible causes include economic factors; creation of new, parallel routes; shifts in through travel; and forecasting procedures based on unusual and/or unrepresentative travel conditions.
- Benefit/cost analysis should be applied to travel forecasting for investment decision making whenever possible.
- Travel forecasts should be documented in a brief report that includes sufficient information to inform a reader about the purpose of the analysis, the principal finding of the analysis, the rationale or supporting evidence

| Table 6-3. Travel Forecast Precision | |
|---|---|
| **Travel Forecast Prediction** | |
| **Forecast Volume** | **Round to Nearest** |
| <100 | 10 |
| 100 to 999 | 50 |
| 1,000 to 9,999 | 100 |
| 10,000 to 99,999 | 500 |
| >99,999 | 1,000 |

for the finding of the study area's existing conditions, and the approach/methodology used to conduct the analysis.

- Good travel forecasting depends on reliable and timely baseline data. At a minimum, hourly travel counts for automobiles and trucks should be collected at a project site for travel forecasting.
- The assumptions, analysis process, and results of a travel forecasting process should be thoroughly documented and made available for public review.
- Rounding should be done by AADT levels to avoid implied precision, see Table 6-3. [CDM Smith, 2014]

Demand forecasting for transit and nonmotorized travel have some similarities to the road demand forecasting described above. With respect to transit riders, the same basic approach to forecasting is used to forecast future ridership, except that the expected transit riders are assigned to a transit network instead of a road network (of course, for bus planning, the road network is the basic structure of the bus transit network). The outputs for a transit forecasting model are number of riders by trip purpose, time of day, and usually household income.

Walking and bicycle riding are important in many cases not only as a primary mode of travel, but also as a mode for accessing other higher-capacity modes. This is illustrated in Table 6-4 where mode share was estimated in a study in Arlington, Virginia, with different values of pedestrian-conducive environments reflected in a walk score. As shown, as the walkability score increased, the amount of walking and transit ridership increased, while the use of the automobile declined.

For pedestrian and bicycle demand forecasting, greater detail is required on the characteristics of the travelers and of the origins and destinations. Thus, for example, a recent pedestrian forecasting model that is integrated with the

traditional travel demand modeling process uses pedestrian analysis zones (PAZs) that are different from the travel analysis zones utilized for travel demand forecasting. [Singleton et al., 2014] The PAZ's reflect the urban design and land-use characteristics that encourage travelers to walk (known as a pedestrian index of the environment), such as people density, transit access, development density, block size, sidewalk density, and comfortable facilities. The number of travelers walking would then be deducted from the trip-generation estimates (which are usually not mode-specific in the traditional modeling approach), and used to estimate the walking demand for the study area. Figure 6-2 shows the pedestrian index for the environment as estimated for Portland, Oregon. Not surprisingly, the more conducive and more likely areas for walking as a primary mode of travel are in the downtown area.

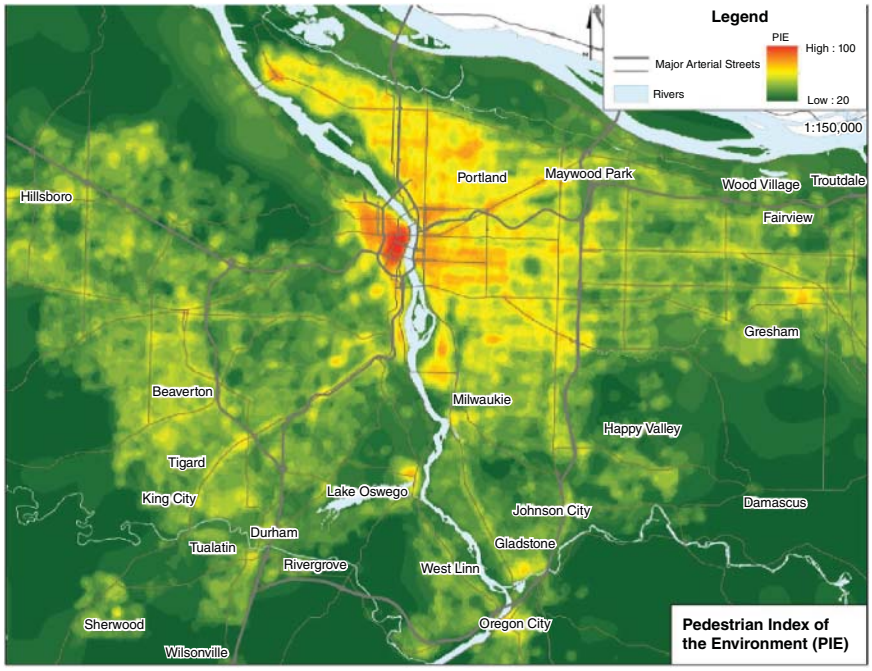
For additional material on demand forecasting for walking and bicycle riding, see chapter 13.

## D. Model Zones and Networks

Travel demand models often depend on a zonal system reflecting the sociodemographic characteristics of the households in the study area (travel analysis zones) and on a coded network. Recent advances in travel demand modeling as reflected in activity-based modeling and microsimulation focus more on individual traveler use of a network, and thus do not rely on travel analysis zones. Chapter 2 and chapter 3 on data collection and land use, respectively, describe the types of data used to populate the zonal systems, and will thus not be repeated here. However, how a transportation network is created and depicted requires some attention.

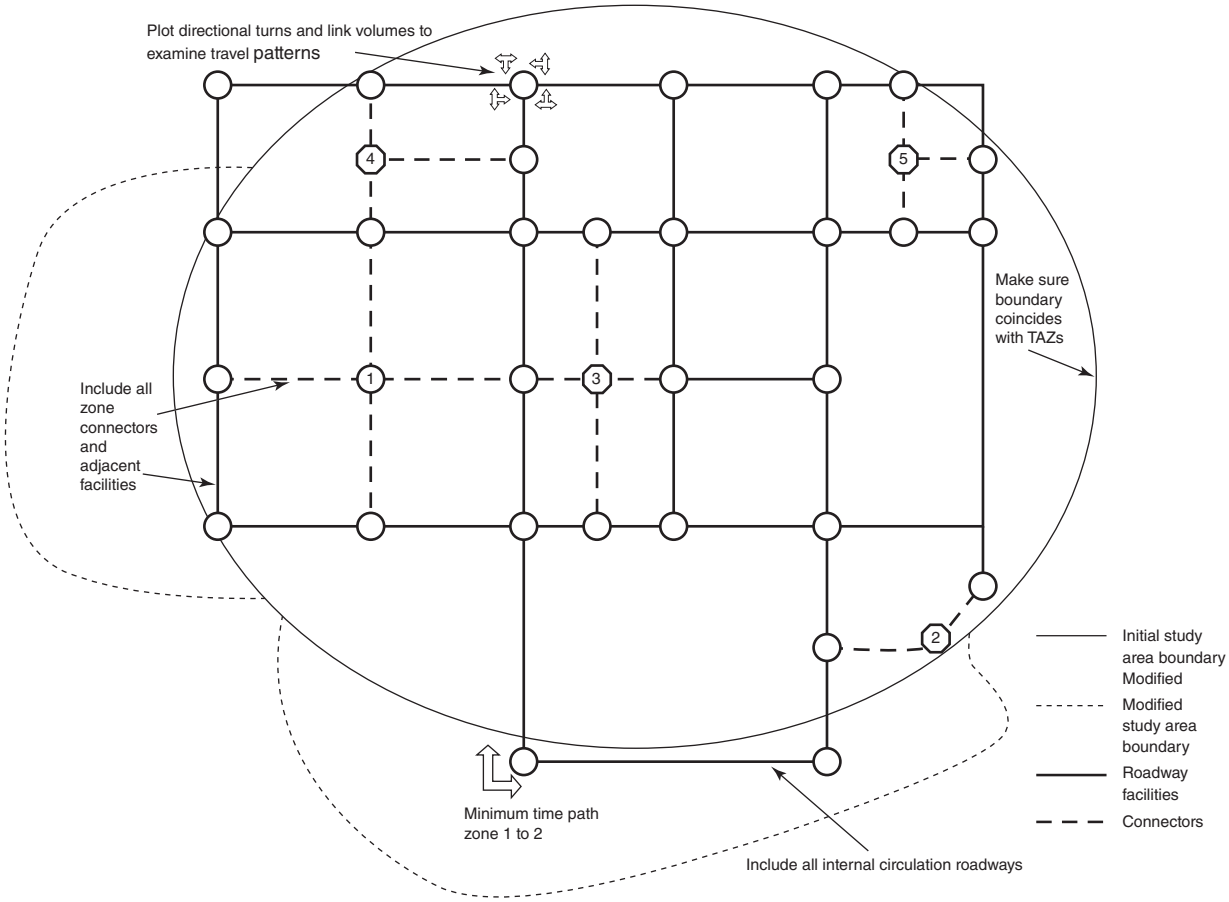
Figure 6-3 shows a typical representation of a network model. As shown, a network consists of two major elements—nodes and links. A node represents any point in the network where a user can enter the network (for example, an intersection or transit station) or where some change in direction occurs (for example, a ramp or access point to a major activity center). Links represent the connections between the nodes, for example, roads, transit lines, bike paths, and the like. Usually, for modeling purposes, each link has a link performance function that defines how that link performs as volume builds (discussed later in the network assignment section). In other words, as more and more volume is assigned to a particular link, the more congested that link becomes and thus the more time it takes to traverse the link. From the perspective of the model algorithms, this link might become so congested that the model

**Figure 6-2. Pedestrian Index of the Environment Estimation for Portland, Oregon**



Source: Singleton et al., 2014

**Figure 6-3. Representation of a Transportation Network**



Source: CDM Smith et al., 2014, Reproduced with permission of the Transportation Research Board.

will look for other paths for users to get to a particular destination. Because the model results depend so much on the valid specification of the network (for example, distance, speed, and location), the modeler needs to be very careful in developing and coding the network. Modern software and GIS packages provide modelers with the capability of building a network fairly easily; however, the modeler must still input the link attribute data.

The following link attributes are most often included in a road network database:

- Node identifiers, usually numeric, and their associated geocoordinates.
- Link identifiers, either numeric, defined by "A" and "B" nodes, or both.
- Locational information (for example, zone, cutline, or screenline location).
- Link length/distance.
- Functional classification/facility type, including the divided or undivided status of the link's cross section.
- Number of lanes.
- Uncongested (free-flow) speed.
- Capacity.
- Controlled or uncontrolled access indicator.
- One-way versus two-way status.
- Area type.
- Travel count volume (where available). [CDM Smith et al., 2014]

Transit link definition is a bit more complicated than that for road networks because riders can access transit services in many different ways, for example, walking, bicycling, auto drop-off, auto parking, other transit services, and so on. Table 6-5 shows some of the transit links that are often used for coding transit service networks.

In most cases, such as regional or community-level modeling, a zonal system and network model already exist, and planners must then ask themselves if the zone system and network are at a level of detail sufficient for the desired analysis. For example, most metropolitan planning organizations (MPOs) have traffic analysis zones (TAZs) based on the latest census information. For large MPOs in particular, these zones have been used in a land-use forecasting model. In addition, census block data are available at the sub-tract level. [Cambridge Systematics and AECOM Consult, 2007] As can be seen in Figure 6-4, the TAZ system for large metropolitan areas (in this case, for the Atlanta, Georgia, metropolitan area) can be extensive.

In many cases, the TAZ boundaries closely replicate census tracts simply to allow the transfer of census data to TAZ databases. Many of these zones, however, might be too large for the study purposes, especially if the study is examining travel flows at a much finer level of detail. For example, a corridor study in Atlanta used the TAZ structure developed by the Atlanta Regional Commission for the analysis of travel flows. The corridor itself was a large regional corridor serving trips throughout the region and thus 1,683 TAZs were included in the analysis. However, because the corridor study was interested in travel flows at key locations included within much larger zones (for example, major development sites near interchanges), 131 new zones were created by subdividing some of the original TAZs into smaller zones. By so doing, the study was able to examine travel flows into and out of key trip generators in the corridor.

## E. Model Calibration and Validation

Two of the most important tasks in developing a credible model are calibrating the demand model with existing data and then validating its results. As will be seen later, many demand models use equations to predict either the demand itself or some aspect of system performance that influences a traveler's decision, such as the level of congestion on the network. These equations often consist of variables such as travel cost, travel time, number of transfers, and so forth, as well as coefficients that reflect the relative magnitude of each variable in the equation. The value of each variable is obtained from existing databases or is measured through data collection efforts. These values are then used

| Table 6-5. Transit Link Characteristics | |
|---|---|
| **Characteristic** | **Description** |
| Drive access link | A link that connects TAZs to a transit network via auto access to a park-and-ride or kiss-and-ride location. |
| *Effective headway* | Time between successive transit vehicles on multiple routes with some or all stops in common. |
| *Headway* | Time between successive arrivals (or departures) of transit vehicles on a given route. |
| *Local transit service* | Transit service with frequent stops within a shared right-of-way with other motorized vehicles. |
| *Mode number* | Code to distinguish local bus routes from express bus, rail, and the like. |
| Park-and-ride-to-stop link | A walk link between a park-and-ride lot and a bus stop, which is used to capture out-of-vehicle time associated with auto access trips, and also for application of penalties associated with transfers. |
| Premium transit service | Transit service (for example, bus rapid transit, light rail transit, heavy rail, commuter rail) with long distances between infrequent stops that may use exclusive right-of-way and travel at speeds much higher than local service. |
| *Route description* | Route name and number/letter. |
| *Run time* | The time in minutes the transit vehicle takes to go from the start to the finish of its route and measure of the average speed of the vehicle on that route. Often estimated by the program based on segment length and speed. |
| Transfer link | A link used to represent the connection between stops on two transit lines that estimates the out-of-vehicle time associated with transfers, and also for application of time penalties associated with transfers. |
| Transfer penalty | Transit riders generally would rather have a longer total trip without transfers than a shorter trip that includes transferring from one vehicle to another; therefore, a penalty is often imposed on transfers to discourage excess transfers during the path-building process. |
| *Walk access link* | A link that connects TAZs to a transit network by walking from one zone to a bus, ferry or rail service; usually no longer than 1/3 mile for local service and 1/2 mile for premium service. |
| Walking link | A link used exclusively for walking from one location to another. These links are used in dense areas with small TAZs to allow trips to walk between locations rather than take short transit trips. |

Note: Italics indicate those characteristics that should be in all transit networks

Source: CDM Smith et al., 2014, Reproduced with permission of the Transportation Research Board.

to estimate coefficients or other parameters of the demand model. Typical approaches for this estimation include regression analysis or maximum likelihood analysis. The intent is to develop the most credible demand model by estimating the variable coefficients based on real-world data. This is called calibrating the model.

Model validation is the process of using the calibrated model and running it against some known values to check if the model is producing valid results. For example, a calibrated demand model could be used to estimate the ridership on existing transit routes and the model results compared to actual ridership for validation. For highways, a typical approach is to estimate travel volumes on specific links on the network, then compare modeled volumes with actual travel counts at those locations. Screenline counts are often used for this purpose. Table 6-6 shows different ways that model results can be validated.

Good practice in model development and use starts with close attention to model calibration and validation.

## III. DEMAND MODELS AND TOOLS

Demand analysis uses many different tools and models, depending on the type of information desired. As mentioned earlier, these tools can be as simple as trend projections based on historical data, or as sophisticated as simulated travel behavior using the aggregate movements of simulated individual travel behavior. The following sections provide an overview of some of the most used analysis tools for demand forecasting. For those interested in participating in on-going discussions relating to travel demand modeling, see http://tfresource.org/Travel_Forecasting_Resource.

**Figure 6-4. Traffic Analysis Zones in the Atlanta Regional Commission Travel Demand Model**

## A. Demand Elasticity Analysis

Demand elasticity is an important tool used by transportation planners for very special types of problems. The analysis approach is based on the economic concept that consumer behavior will respond to changes in the characteristics of the product or service being offered. Thus, the elasticity of demand with respect to price refers to the change in demand when price either goes up or down. In general, as price increases, demand should go down, and vice versa. Demand elasticity analysis is most useful when one is dealing with transportation services or products where a relationship between service characteristic and travel demand is clear, such as, what happens to transit ridership when fares are raised? Or what happens to transit ridership when more frequent service is provided? Or what happens to parking demand when parking fees are applied?

Some important terms for demand elasticity analysis include: [Meyer and Miller, 2014]

*Direct Elasticity*. Direct demand elasticities are those that involve variable relationships relating "directly" to the demand in question. In other words, there is assumed to be a direct causal relationship between the two. If the price of parking goes up, parking demand goes down … a direct linkage between cause and effect. The elasticity of transit demand with respect to transit fare, transit travel time, transit service headway, and so on, would all be direct elasticities. The demand elasticity is considered *elastic* if a 1 percent change in any variable produces more than a 1 percent change in demand. The demand elasticity is considered *inelastic* if a 1 percent change in any variable produces a less than 1 percent change in demand. A demand elasticity is considered *unit elastic* if a 1 percent change in any variable produces a 1 percent change in demand.

**Table 6-6. Examples of Primary and Secondary Model Validation Tests**

| Component | Primary Tests | Secondary Tests | Potential Validation Data Sources |
|---|---|---|---|
| **Networks/Zones** | • Correct distance and speeds on links<br>• Network topology, including balance between roadway network detail and zone detail<br>• Appropriateness of zone size given spatial distribution of population and employment<br>• Network attributes (managed lanes, area types, speeds, capacities)<br>• Network connectivity<br>• Transit run times | • Intrazonal travel distances (model design issue)<br>• Zone structure compatibility with transit analysis needs (model design issue)<br>• Final quality control checks based on review by end users<br>• Transit paths by mode on selected interchanges | • GIS centerline files<br>• Transit on-board or household survey data |
| **Socio- economic Data/Models** | • Locations of special generators<br>• Qualitative logic test on growth<br>• Population by geographic area<br>• Types and locations of group quarters<br>• Frequency distribution of households and jobs (or household and job densities) by TAZ | • Households by income or auto ownership<br>• Jobs by employment sector by geographic location<br>• Dwelling units by geographic location or jurisdiction<br>• Households and population by land-use type and land-use density categories<br>• Historical zonal data trends and projections to identify "large" changes (for example, in autos/household from 1995 to 2005) | • Census data<br>• Quarterly Census of Employment and Wages<br>• Private sources, such as Dun & Bradstreet |
| **Trip Generation** | • Reasonableness check of trip rates versus other areas<br>• Logic check of trip rate relationships | • Checks on proportions or rates of nonmotorized trips<br>• Reasonableness check of tour rates<br>• Cordon lines by homogeneous land-use type | • NCHRP 716<br>• Travel counts (or intercept survey data) for cordon lines<br>• Historic household survey data for region<br>• National travel surveys |
| **Trip Distribution** | • Trip length frequency distributions (time and distance) by market segments<br>• Worker flows by district<br>• District-to-district flows/desire lines<br>• Intrazonal trips<br>• External station volumes by vehicle class | • Area biases (psychological barrier, for example, river)<br>• Use of k-factors (design issue)<br>• Comparison to roadside intercept origin destination surveys<br>• Small market movements<br>• Special groups/markets<br>• Balancing methods | • National freight flow data<br>• NCHRP 716<br>• Travel counts (or intercept survey data) for screenlines<br>• Historic household survey data for region<br>• National travel surveys |

Table 6-6. (*Continued*)

| Component | Primary Tests | Secondary Tests | Potential Validation Data Sources |
|---|---|---|---|
| **Time of Day of Travel** | • Time of day versus volume peaking<br>• Speeds by time of day | • Cordon counts<br>• Market segments by time of day | • Permanent travel recorder data<br>• National travel surveys<br>• Historic household survey data for region<br>• Transit boarding count data |
| **Mode Choice** | • Mode shares (geographic level/ market segments)<br>• Check magnitude of constants and reasonableness of parameters<br>• District-level flows<br>• Sensitivity of parameters to LOS variables/elasticities | • Input variables<br>• Mode split by screenlines<br>• Frequency distributions of key variables<br>• Reasonableness of structure<br>• Market segments by transit service<br>• Existence of "cliffs" (cutoffs on continuous variables)<br>• Disaggregate validation comparing modeled choice to observed choice for individual observations | • Travel counts and transit (or intercept survey data) for screenlines<br>• National Census data<br>• NCHRP 716<br>• Transit on-board survey data<br>• National travel surveys<br>• Household survey data (separate from data used for model estimation) |
| **Transit Assignment** | • Major station boardings<br>• Bus line, transit corridor, screenline volumes<br>• Park-and-ride lot vehicle demand<br>• Transfer rates<br>• Transit run times | • Kiss-and-ride demand<br>• Transfer volumes at specific points<br>• Load factors (peak points) | • Transit boarding counts<br>• Transit on-board survey data<br>• Special surveys (such as parking lot counts)<br>• Transit schedules and schedule adherence checks |
| **Travel Assignment** | • Assigned versus observed vehicles by screenline or cutline<br>• Assigned versus observed vehicles speeds/times (or vehicle hours traveled)<br>• Assigned versus observed vehicles (or vehicle miles traveled) by direction by time of day<br>• Assigned versus observed vehicles (or vehicle miles traveled) by functional class<br>• Assigned versus observed vehicles by vehicle class (for example, passenger cars, single-unit trucks, combination trucks) | • Sub-hour volumes<br>• Cordon line volumes<br>• Reasonable bounds on assignment parameters<br>• Available assignment parameters versus required assignment parameters for policy analysis<br>• Modeled versus observed route choice (based on data collected using GPS equipped vehicles) | • Permanent travel recorders<br>• Travel count files<br>• HPMS data<br>• Special speed surveys (possibly collected using GPS-equipped vehicles) |

Source: As reported in CDM Smith et al., 2014, Reproduced with permission of the Transportation Research Board.

*Indirect or Cross Elasticity*. Indirect or cross elasticity typically relates to the effect on the demand for other modes of travel when some characteristic of the target mode is changed. The elasticity of transit demand with respect to changes in automobile parking prices or road tolls would be an example of a cross elasticity. In other words, if parking prices go up, parking demand will go down (the direct relationship). However, some of the former parkers will now use transit (the secondary relationship).

*Short-Term Elasticity*. The change in demand over the short term (usually defined as two years) reflects the immediate response to changes in price and does not take into account longer-term decisions (such as auto ownership) that might be taken by a household in response to a price change.

*Long-Term Elasticity*. The change in demand over the long term (usually defined as 5 years or more) reflects the longer-term decisions that households might make in response to a price change (such as ownership or vehicle technology choice, house location and/or lifestyle changes). Long-term elasticity might be influenced by a threshold level, that is, price elasticity may not be the same for large as compared to small changes in underlying price.

*Shrinkage Ratio.* If one assumes a linear demand function, one can easily estimate the change in demand by applying the slope (or elasticity) of the demand curve. This is called a shrinkage ratio. For example, assuming an elasticity of $-0.50$ and a 10 percent increase in price, one would expect a $(-0.5 \times 0.1 = -0.05)$ or 5 percent reduction in demand.

*Arc Elasticity.* In reality, most demand curves are not linear (see Figure 6-1), and a price elasticity represents the percent change in demand with respect to a 1 percent change in price. So using the preceding example, a 10 percent increase in price really represents ten 0.5 percent reductions. For those familiar with engineering economy, this can be denoted as an effective interest rate over 10 interest periods of $(1 + 0.005)^{10} = 1.0511$, or a reduction from an original amount of $1/(1.0511) = 0.9514$, or a 4.86 reduction, which is smaller than the 5 percent estimate obtained with the shrinkage ratio. Given the variation in the demand curve at the ends of the function, the change in quantity should be approximated by a midpoint formulation based on the average value of each independent variable.

Assuming an arc elasticity midpoint formulation, the following equations can be used to determine either quantity or price given a change in the other variable and an estimated arc elasticity $\bar{e}$.

$$\bar{e} = \frac{(Q_2 - Q_1)\,(P_1 + P_2)}{(P_2 - P_1)(Q_1 + Q_2)} \tag{6-1}$$

$$P_2 = P_1 \frac{Q_1(\bar{e} - 1) + Q_2(\bar{e} + 1)}{Q_2(\bar{e} - 1) + Q_1(\bar{e} + 1)} \tag{6-2}$$

$$Q_2 = Q_1 \frac{P_1(\bar{e} - 1) - P_2(\bar{e} + 1)}{P_2(\bar{e} - 1) - P_1(\bar{e} + 1)} \tag{6-3}$$

Litman [2013] notes several studies that have produced demand elasticities. Table 6-7, for example, shows a range of elasticities of vehicle travel with respect to fuel price. In addition, he makes the following general observations concerning travel demand elasticity:

- Higher-value travel, such as business and commute travel, tends to be less price sensitive than lower-value travel.
- Wealthy people tend to be less sensitive to pricing and more sensitive to service quality than lower-income people.
- Prices tend to affect consumption in proportion to their share of household budgets.
- When there are good or easy substitutes available for a good/service, the elasticity is likely to be greater (in absolute terms).
- Consumers tend to be more responsive to price changes they consider durable, such as fuel tax increases, compared with oil market fluctuations perceived as temporary.
- Pricing impacts tend to increase over time. Short-run (first year) effects are typically a third of long-run (more than five years) effects.
- Travel tends to be more price sensitive if travelers have better options, including different routes, modes, and destinations.

| Table 6-7. Examples of the Range of Elasticities of Vehicle Travel with Respect to Fuel Price, Various Studies | | | |
|---|---|---|---|
| Johannson and Schipper | Summary of various previous studies | International | −0.2 long run |

- Travelers tend to be particularly sensitive to visible and frequent prices, such as road tolls, parking fees, and public transit fares.
- How fees are promoted, structured, and collected can affect their impacts.

Table 6-8 shows some typical elasticity values for changes in transit service characteristics.

See Litman [2013] and FHWA, https://www.fhwa.dot.gov/asset/hersst/pubs/tech/tech11.cfm, for a good overview of elasticity analysis.

## B. Travel Demand Models

Travel demand models can generally be divided into two categories. The first includes models using a four-step analysis process, which is perhaps the most commonly used approach. The second category includes techniques used to model individual trip makers' activities during a given travel time period; these are referred to as activity-based models. Over the years, the techniques associated with four-step models have dramatically improved, yet there remains a fundamental limitation—the decision-making process associated with individual travel behavior is not well-represented in the structured approach to trip-making found in four-step models. The need to better reflect the range of individual travel decisions and intrahousehold interactions has motivated the development of activity-based modeling. Activity-based models estimate travel demand based on a basic premise—the demand to accomplish personal activities during the day (for example, work, school, personal business, on so forth) produces a demand for travel that is often connected (for example, trip chaining).

The transition from conventional four-step models to activity-based models is occurring in many of the larger metropolitan areas in the United States, although the transition has faced some challenges. The data requirements for both model types are very different. New models usually require the collection of new data to develop and validate the model against existing travel volumes. Data collection is always a large budget item and thus many agencies hesitate to embark upon a new modeling regime. This is an important issue for activity-based modeling. In contrast to the four-step data collection methods, such as household travel surveys and use of census data, activity-based models require detailed information on the daily activities of representative travelers. This type of information is often collected with trip diaries, which is a much more involved method of data collection than traditionally required in the four-step process (see chapter 2 on data collection).

The following sections describe the four-step modeling approach, followed by tour-based models (a transition model form to activity-based models), and activity-based models. Space does not allow a detailed discussion of the theory and mathematical foundations of travel demand modeling. For more information on these concepts, refer to [Goulias, 2003; Ortuzar and Willumsen, 2011; and Meyer and Miller, 2014]. In addition, most MPOs have placed on their agency websites background and explanatory information on the demand models used to forecast travel in their study area. Readers are encouraged to examine such information for more detailed information regarding demand modeling applications.

### *1. Four-Step Models*

Traditional travel demand modeling consists of four sequential steps: trip generation, trip distribution, mode choice, and trip assignment. These four-step models answer the questions: How many people travel? What are the travel patterns for the study area? What travel modes are used? What trip paths will be followed through the transportation network? Figure 6-5 shows the general framework for a four-step modeling system. Although the four steps have remained the major structural form for modeling since the 1950s, the methods and approaches used to perform each of the steps have matured through the years. However, model sophistication varies by region size, budget constraints, and the knowledge and depth of technical staff.

**Figure 6-5. The Four Steps in Traditional Travel Demand Modeling**

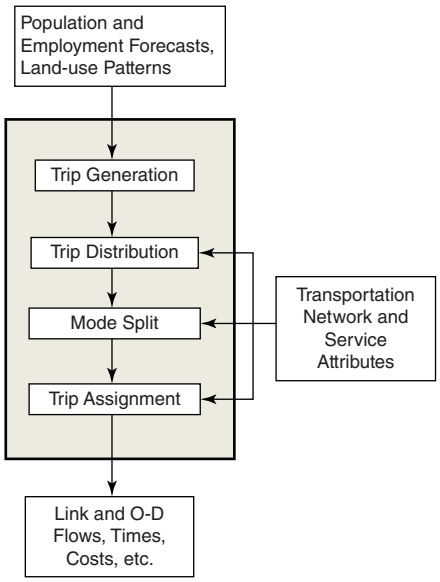

Figure 6-5 begins with population, employment, and land-use forecasts, which are often provided by other agencies or staff within a planning agency. Chapter 3 describes typical approaches for providing this input into the transportation planning process. The box "Transportation Network and Service Attributes" relates to the discussion earlier on network representation.

**Trip Generation.** The generation of trips, either from a point of origin or attracted to a destination, is one of the most important components of travel demand modeling (see chapter 3 on land use and urban design and chapter 19 on site planning and traffic impact analysis). The number of trips generated by each unit of land or type of activity varies according to social, economic, geographic, and land-use factors. Comprehensive studies include estimating both trip productions and trip attractions. Trip productions relate to the home end of the trip, while trip attractions relate to employment or other non-home ends of the trip. Normally, trip productions serve as the control total to which aggregate trip attractions are adjusted.

State, regional, and local transportation agencies often compile their own trip generation rates used in their study areas. Some of these rates are based on local surveys of different types of land use. Many of these analyses have focused on vehicle-related person trips (vehicle driver, vehicle passenger, transit passenger). However, more recent analyses have also included pedestrian and bicycle trips. Thus, a clear definition of the specific trips included in the trip generation analysis is essential.

Trip generation relationships to land-use characteristics are established either by regression techniques or through cross-classification (or category) analysis. Household trip generation is usually a function of median income per family, household size as well as automobile ownership and availability. Other factors may include net residential density and distance from the city center. Rates (or relationships) are normally derived for total trips and for key trip purposes such as home-to-work. They are computed for a 24-hour period or for peak hours. A typical trip generation rate analysis such as that shown in Table 6-9 gives daily person-trips per household as a function of auto ownership and family

| Table 6-9. Illustrative Trip Generation Rate Analysis | | | | |
|---|---|---|---|---|
| | Trip Generation Rates | | | |
| | Person Trips per Household per Day | | | |
| | Autos per Dwelling Unit | | | |
| **Persons per Dwelling Unit** | **0** | **1** | **2** | **3+** |
| 1 | 2.8 | 3.1 | 3.6 | - |

size (income could be used as an alternate to car ownership). As shown in Table 6-9, two-person households with two cars would generate on average 7.9 person trips per day.

Typical trip attraction rates are shown in Table 6-10, summarized from a study of travel forecasting techniques in National Cooperative Highway Research Program (NCHRP) Report 716*: Travel Demand Forecasting: Parameters and Techniques.* [Cambridge Systematics, Inc. et al., 2012] Trip attractions are keyed to factors such as floor space, hospital beds, employees, and stadium seats. In comprehensive studies, various types of employment are commonly used to obtain trip attraction rates. From Table 6-10, the number of nonhome-based person trips attracted to a zone using model 1 would be 0.6 × number of households in the zone + 0.5 × basic employment + 4.7 × retail employment + 1.4 x service employment.

Most trip generation models use cross-classification or linear regression to estimate the number of productions (trips produced by a zone) and attractions (trips attracted to a zone). Trip productions are typically expressed in units of trips per household or zone, while attractions usually relate to variables associated with employment or commercial activities (for example, the number of employees or retail square footage). Whether trip attraction model parameters are estimated from local data or are transferred from another study area, they are usually derived from household survey data. Commonly, linear regression equations are used to estimate the parameters, such as the coefficients in linear regression equations at an aggregate level such as districts (groups of zones).

Both productions and attractions are estimated for different trip types. The most common trip types are home-based work (home to work or work to home), nonhome-based (for example, work to/from shopping) and home-based other (for example, home to/from shopping). This latter category is often defined for special trip generators. In Atlanta and Dallas-Ft. Worth, for example, the travel demand model has a special trip generation module for trips to the airport.

Defining a larger number of trip purposes and types for trip generation is one of the major changes in trip generation modeling over the past several years, which also reflects a more complex travel behavior of today's travelers compared to those of 30 years ago. With greater definition or segmentation of trip types, presumably better trip generation rates can be estimated. In Chicago, for example, the planning agency has developed an expansive list of trip purposes with trip generation rates produced for 11 different purposes, and separate trip generation rates estimated for adult workers and nonworkers for home-based shop and home-based other trips. Thus, for each trip purpose, trip rates for key market segments are usually estimated separately. Market segments for productions are usually defined by variables such as the number of autos per household, household income, and/or household size.

Person and vehicular trip rates for specific activities can be obtained by drawing a cordon around the activity under consideration and then counting the number of people entering and leaving by time of day and by mode of travel. In urban settings, people counts are essential in transportation studies, especially in the city center. For free-standing suburban developments, vehicle trip rates will usually be sufficient (see chapter 2 on data collection).

Other chapters in this handbook provide more detail on how trip generation data are used in different types of transportation studies. In addition, the Institute of Transportation Engineers sponsors a trip generation website with up-to-date information (see http://www.ite.org/tripgeneration/otherresources.asp).

**Trip Distribution.** Trip distribution translates the zonal productions and attractions derived during the trip generation step into origins and destinations, and identifies the impedance (for example, travel time or travel cost) for each origin-destination pair for all zones in the study area. The output of the trip distribution step is an origin-destination (O-D) trip table for all trips by trip purpose.

The gravity model or variants of it are still the most widely used technique for trip distribution. It assumes that the number of trips from zone *i* to zone *j* is directly proportional to the product of trip productions in zone *i* and trip attractions in zone *j,* and inversely proportional to a friction factor (a function of impedance) between the two zones (which is the basic concept of the Law of Gravity, hence the name). Impedance captures elements of the spatial separation for two zones and can be represented as travel time, cost, distance, or some composite (referred to as a generalized cost function). It is also common to estimate a gravity model for each travel purpose because trip distribution characteristics can vary by purpose of travel. Socioeconomic adjustment factors (or K-factors) are sometimes specified as adjustments to impedances. In general, it is difficult to justify the use of K-factors, yet MPOs have continued to rely on them as a way of improving model fit.

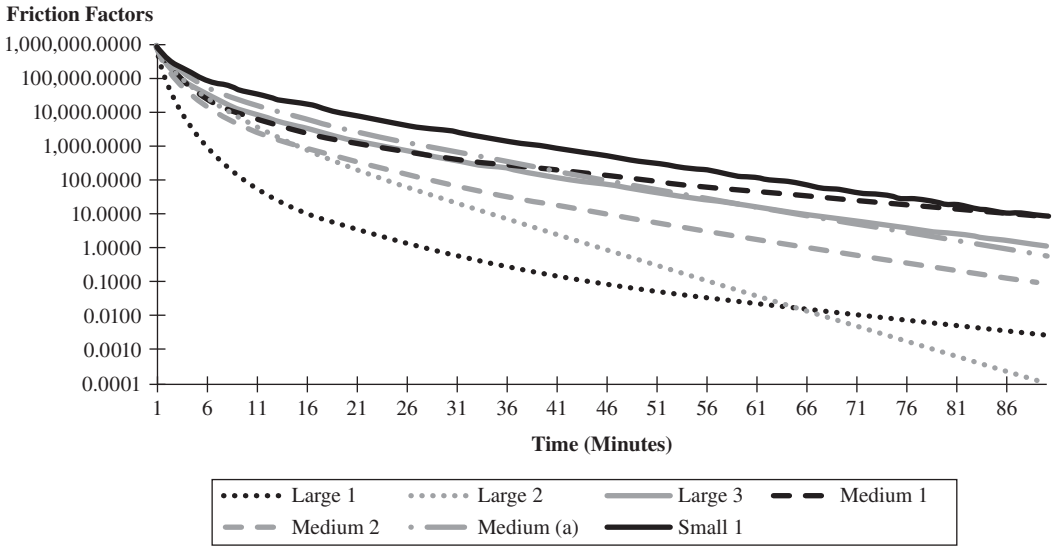
Equation 6-4 shows the mathematical formulation of the gravity model.

$$T_{ij}^{P} = P_{i}^{P} \frac{A_{j}^{P} x\, f(t_{ij}) x\, K_{ij}}{\sum_{j'} A_{j'}^{P}\, x\, f(t_{ij'}) x\, K_{ij'}} \tag{6-4}$$

Where:

$T_{ij}^{P}$ = Trips produced in zone *i* and attracted to zone *j*
$P_{i}^{P}$ = Production of trip ends for purpose *p* in zone *i*
$A_{j}^{P}$ = Attraction of trip ends for purpose *p* in zone *j*
$f_{t_{ij}}$ = Friction factor, a function of the travel impedance between zone *i* and zone *j*
$K_{ij}$ = Optional adjustment factor used to account for factors other than travel impedance

**Figure 6-6. Home-based, Nonwork Trip Distribution Gamma Functions, by Metropolitan Area Size**



Source: Cambridge Systematics, Inc. et al., 2012, Reproduced with permission of the Transportation Research Board.

In some recent models, trip distribution uses a multinomial logit choice model of the attraction location (for a description of logit models, see the following section on mode choice). In this case, the alternatives among which a traveler chooses are the attraction zones themselves, and the utility functions that define the level of attractiveness for each zone include travel impedance and the number of attractions in the zone.

Formulating the friction factors, or the travel impedance between every zone, is an important step in the use of the gravity model. Three major approaches are used in practice. The first simply assumes that the friction factor is a measure of travel time between the zones usually with an exponent. The second adopts an exponential formulation where the friction factor is $1/\exp^{(m \times t_{ij})}$. A third formulation assumes a Gamma distribution with scaling factors used to provide the best fit for the distribution (see Cambridge Systematics, Inc. et al., 2012). Such friction factors are usually formulated by trip purpose as shown in Figure 6-6. Readers are referred to [Cambridge Systematics, Inc. et al., 2012] for more detail on the trip distribution model step.

**Mode Choice.** Mode choice models are used to predict the number of trips that will use each of the available modes for origin-destination pairs. Modes can include, for example, auto, premium transit, local transit, ridesharing, and walking. Discrete choice models, such as multinomial logit and nested logit models, are the predominant modeling approach used in practice. The most widely used discrete-outcome modeling approach is the multinomial logit model, which is based on the concept of utility. This approach assumes that individual travelers assign a utility to each of the available modes, where utility is defined as: $U = V + e$, where $V$ is the systematic utility (that is, an equation consisting of known variables and their values) and $e$ is an error term. The error term represents those variables that are not in the data set or that are perhaps unknown to the planner, but that affect an individual's choice among alternatives. For example, some drivers avoid a short path to their destination simply because they do not want to drive on freeways, which are perceived as being unsafe. This type of behavioral factor is not likely found in any database, but could affect the probability that some travelers will not follow the least-time path.

The systematic utility, that is, the value of V, is most often represented as a linear equation. Some examples include:

$$V = -0.030 \times (\text{In-vehicle time}) - 0.075 \times (\text{Out-of-vehicle time}) - 0.0043 \times (\text{Travel cost})$$

$$V = -0.019 \times (\text{In-vehicle time}) - 0.058 \times (\text{Walk time}) - 0.081 \times (\text{First wait time}) - 0.040 \times (\text{Transfer time}) - 0.0072 \times (\text{Travel cost})$$

Each mode alternative would have its own systematic utility function that has been estimated based on the trip characteristics faced by travelers that have actually made trips. If actual trip data are unavailable, the utility model

coefficients can be estimated from surveys. Depending on the number of mode alternatives available to trip makers, there would be a utility function for auto, shared ride auto, different types of transit and pedestrian/bicycle trips, and any other mode that is considered an option for an individual traveler.

The systematic or measurable utility, *V*, does not take into account the randomness often associated with individual travel decisions (the "*e*" value in the systematic utility equation). If "*e*" is treated as a random variable, one can then develop an equation assuming an underlying distribution for this random variable that predicts the mode an individual will choose among a set of modes that are available for the trip. Research has shown that a Type II Gumbel distribution for this variable provides the most usable form of an equation (called a logit equation) that predicts mode choice, as formulated in Eq. 6-5.

$$P_n = \frac{e^{V_n}}{\sum_{for\ all\ alternatives} e^{V_{n'}}} \tag{6-5}$$

Where:

$P_n$ = Probability of choosing mode $n$
$V_n$ = Measurable utility of mode $n$
$n'$ = number of alternatives available for the trip
$e$ = base logarithmic $e$

As an example, suppose the systematic utility function has the following form, with the definition of each variable and the respective values for both auto and bus shown in the table:

$$V_{\text{mode}} = a_{\text{mode}} - a_1X_1 - a_2X_2 - a_3X_3 - a_4X_4$$

| | $X_1$ = Access time | $X_2$ = Transfer time | $X_3$ = Travel time | $X_4$ = Cost (cents) |
|---|---|---|---|---|
| Auto | 5 | 0 | 20 | 250 |
| Bus | 15 | 10 | 35 | 75 |

The utility function values for both auto and bus, where the coefficients have been provided, are as follows:

$$V_{\text{auto}} = -0.02 - 0.025(5) - 0.05(0) - 0.15(20) - 0.016(250) = -7.145$$
$$V_{\text{bus}} = -0.90 - 0.025(15) - 0.05(10) - 0.15(35) - 0.016(75) = -8.225$$

Assume as well that there are 15,000 trips between zone *i* and zone *j*. Using Eq. 6-5, the probabilities of an individual choosing auto or bus, and the estimated number of auto and bus trips, are:

$$\text{Probability Auto} = \frac{e^{-7.145}}{e^{-7.145} + e^{-8.225}}$$
Probability Auto = 0.75
# of Auto Trips = 0.75 × 15,000
Auto Trips = 11,250 Trips

$$\text{Probability Bus} = \frac{e^{-8.225}}{e^{-7.145} + e^{-8.225}}$$
Probability Bus = 0.25
# of Bus Trips = 0.25 × 15,000
Bus Trips = 3,750 Trips

In practice, the use of discrete choice models has revolutionized the way user choices can be modeled. Perhaps the most significant development has been the expansion of the mode types now included in the choice set of most MPO models, and the variables used as measurable characteristics of a household's and individual's satisfaction with the available mode choice set.

A typical mode choice model is estimated for different trip purposes, at a minimum home-based work, home-based nonwork and nonhome-based, with available modes defined by trip purpose. For example, the Denver Regional Council of Governments assumes five modes are available for home-based work: drive alone, shared ride 2, shared ride 3+, transit walk access, and transit drive access. For home-based, nonwork trip purposes, the available modes are auto, transit walk access, and transit drive access. Usually, home-based work models are estimated separately for different market segments as well, such as low-, middle- and high-income groups. Sometimes, models provide geographic segmentation with alternative-specific constants for different geographic markets.

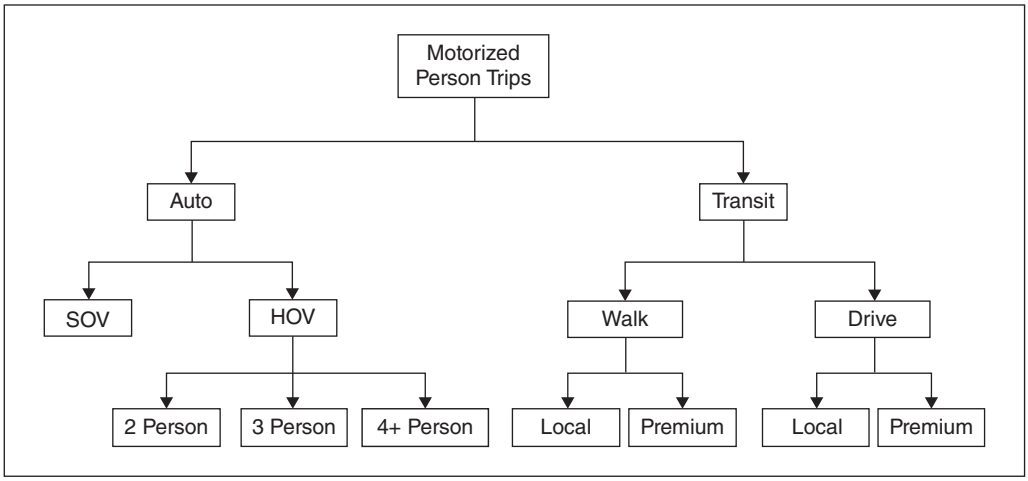
The multinomial logit model described earlier assumes that each of the alternatives available to a traveler can be defined with alternative-specific characteristics. Research has shown, however, that many of these alternatives are perceived by the travelers as having similar characteristics and that instead of being viewed as independent alternatives they are bundled into different categories of alternatives. The logic is that a traveler's first decision is between high-level characteristics, for example, travel time or perceived comfort, and that subsequent mode choice decisions then lead to a more specific choice on how to travel. This research has led to nested logit models. Figure 6-7 illustrates the concept of nested logit models. As shown, the model assumes that a traveler choosing to use a motorized mode of transportation will first decide to use either auto or transit. Once that choice is made, the traveler can then decide which form of auto or transit mode will be selected. For the auto choice, the traveler can choose single-occupant vehicle (SOV) or high-occupancy vehicle (HOV). If the HOV mode is chosen, the traveler then has the choice of 2 persons, 3 persons, or 4+ persons in a rideshare vehicle. For transit, the traveler has a choice of accessing transit by walking or driving, and the walk or drive access mode is also differentiated by whether the transit service being accessed is a local or premium service. Each of these "modal" decisions has associated with it utility functions describing the alternatives available to the traveler.

Another major reason for using nested choice models is to help overcome the irrelevance of independent alternatives (IIA) concept found in logit mode choice models, which can potentially cause erroneous results when new modes are introduced into the choice set (say, a new transit mode). In essence, this result says that this new transit mode would be treated as another new mode (and thus attract trips from the existing modes) even though it might have similar characteristics to modes already available, which in reality would not make it as attractive as a stand-alone mode. By putting the new mode in the first tier of a nested model, this effect is reduced.

A nested logit model is often used to better represent substitution patterns. For example, an improvement in the level of service of one alternative will proportionally draw more share from alternatives in that nest than from alternatives not in the nest. As shown in Figure 6-7, an improvement in the drive access time for premium transit is expected to proportionally draw more riders from those driving to use local transit (as these alternatives are in the same lower-level nest). In addition, greater substitution will be observed among the other transit modes (walking to local and premium transit) than auto modes.

Finally, it is worth noting that there are a few MPOs that have a combined mode-destination choice model, which combines mode choice and trip distribution decisions into one discrete choice model.

**Figure 6-7. Illustrative Nested Mode Choice Model**



**Trip Assignment (Route Choice).** Trip assignment results in an estimated demand on each of the network links. Link attributes (for example, road or transit line capacity, link length, speed limits, turning restrictions, and travel signals) are represented in the network database and are used to calculate the "cost" of using the link. In its simplest form, this can be measured using the average travel time to traverse the link, or in more sophisticated network models, a generalized cost function is used. In both cases the network assignment models assign trips through the network to minimize the time or cost of travel.

Generally, the process is done separately for highway and transit network assignment. The two networks are related in that congested highway travel times should be used to estimate bus performance, assuming that buses are not provided with preferential treatment on the road network. Highway network assignment focuses on auto vehicle trips and can model trip makers' network paths using approaches such as all-or-nothing, incremental, capacity-restrained, user equilibrium, and system optimum assignment. In current practice, almost all large MPOs use the user equilibrium method in highway network assignment. This method is based on the behavioral assumption that users will choose routes that minimize their own generalized travel cost. Equilibrium occurs when no users can reduce their travel costs by switching routes. Transit assignment uses variables specific to transit link performance such as transit fare, stop or station transfers, waiting times, and trip times.

Most contemporary trip assignment models use similar approaches: (1) a static user-equilibrium assignment algorithm; (2) a multiple-time-period assignment for multiple classes (for example, drive-alone, rideshare, and bike/walk); (3) an iterative feedback loop mechanism between, at a minimum, the network assignment step and the trip distribution step; (4) separate specification of facilities like HOV and high-occupancy toll (HOT) lanes; and (5) independent transit assignment using congested highway travel times to estimate a bus ridership assignment.

One of the most important elements of the assignment process is the construction of link performance functions. This is often where models begin to distinguish themselves. A link performance function (often a volume-delay function for roads) defines the relationship between speed and travel flow on a roadway segment and is used to estimate travel time or cost in the trip assignment procedure. The function can be linear, polynomial, exponential, hyperbolic, or a conical specification. For many years, the most commonly used function was the Bureau of Public Roads (BPR) equation—or a simple modification of it—that represented generalized travel costs. This equation estimated travel time on a link as being the free-flow travel time (no congestion) plus a factor that represented an increase in travel time as the link became more congested, usually represented by the link volume/capacity ratio raised to some exponent. However, as more experience with network operations and traffic flows occurred, planners found out that much of the delay in urban road networks occurred at intersections with conflicting and opposing traffic flows causing much of the delay. Volume-delay functions did not easily capture this phenomenon, and thus many of today's trip-assignment models incorporate delay relationships that have been developed from research and practical experience, with the basic concepts coming from the *Highway Capacity Manual.*

**Time-of-Day Factors.** As a final note in this section, the traditional four-step modeling process divides the day into modeling periods to better reflect capacity constraints likely to occur during peak travel periods, such as a.m. peak or p.m. peak periods. The factor defined for each modeling period is usually referred to as a time-of-day factor and is used to determine the proportion of total daily trips occurring in a specified hour or modeling period. Such factors are usually estimated separately by trip purpose.

Time-of-day factors should be independently derived and a variety of sources can be used, depending on where in the four-step process the time-of-day factors are applied. If the time-of-day factors are applied after network assignment, travel data (for example, volume counts) can be used to develop the hourly or period proportions. Alternately, if the time-of-day factors are applied prior to network assignment, household surveys can be used to derive the appropriate proportions. There are also a number of emerging techniques, such as departure choice models, that provide a more sophisticated approach toward time-of-day modeling (for a good discussion of time-of-day factor methods, see [Cambridge Systematics, 1997]).

### *2. Activity-Based Models*

Four-step models have a number of limitations, most notably the lack of a strong behavioral framework that consistently represents human decision making throughout the modeling process, and a reliance on zonal averages for many key variables. Activity-based models overcome many of the theoretical deficiencies associated with the conventional four-step models. By directly considering the linkages among different trip purposes that a traveler might accomplish during a typical trip-making time period, an activity-based model can provide a greater sensitivity to transportation policies relating to travel behavior. Activity-based models provide good approaches for estimating the effect on travel

behavior of policies relating to land use, congestion pricing, parking costs, travel subsidies, and travel demand management strategies. [TMIP, 2012] Davidson et al. [2007] identified three key components of any activity-based approach, including: (1) an activity-based foundation with household activities as the starting platform, (2) a tour-based structure that retains associations between individual household activities, and (3) the use of micro-simulation tools to preserve a disaggregate modeling approach. As they note, a model can have one or all of these features at any given time in its evolution, that is, the components are relatively independent of one another.

The Strategic Highway Research Program (SHRP), Phase 2 primer on activity-based models is an excellent source of information on this type of modeling. [Castiglione et al., 2015] This material will not be repeated here. However, there are several observations in the primer that warrant some attention. Table 6-11, for example, shows the major differences between four-step and activity-based models in the form of questions that the planner must ask as part of the analysis. Table 6-12 indicates the differences in detail and the level of policy sensitivity of model results. As seen, activity-based model results provide a much higher level of detail spatially and temporally, as well as at the person and household levels.

Activity-based models are usually part of a much larger integrated modeling system that includes the following components:

- Population synthesis models create detailed, synthetic representations of populations of individuals within households (agents) whose choices are simulated in activity-based models.
- Activity-based travel demand models predict the long-term choices (such as work location and automobile ownership) and the daily activity patterns of a given synthetic population, including activity purposes, locations, timing, and modes of access.
- Auxiliary models provide information about truck and commercial travel, as well as special purpose travel such as trips to and from airports or travel made by visitors.
- Network supply models are tightly linked with activity-based demand models. The flows of travel by time of day and mode predicted by activity-based travel demand models and auxiliary models are assigned to roadway, transit, and other networks to generate estimates of volumes and travel times. Measures of impedance output from network supply models are usually used as input to activity-based models and other integrated model components. [Castiglione et al., 2015]

In some of the early applications of activity-based models it was found that the data requirements are much greater for such models than the traditional trip-based models. Figure 6-8 shows the basic structure of the model components. Table 6-13 shows the types of data input for activity-based models, the use of that data, and typical sources. As seen,

**Table 6-11. Travel Questions and How They Are Handled in Demand Models**

| Key Travel Questions | Trip-Based Model Components | Activity-Based Model Components |
|---|---|---|
| What activities do people want to participate in? | Trip generation | Activity generation and scheduling |
| Where are these activities? | Trip distribution | Tour and trip destination choice |
| When are these activities? | None | Tour and trip time of day |
| What travel mode is used? | Trip mode choice | Tour and trip mode choice |
| What route is used? | Network assignment | Network assignment |

many of the data uses described earlier in this chapter for four-step models are found in activity-based models as well. A number of activity-based models have been developed since the 1990s that address a range of specific travel-related issues, but it is really in the last decade that implementation of activity-based models for travel forecasting has accelerated markedly. Among the U.S. regions using some form of activity-based travel demand modeling are Atlanta; Columbus, Ohio; New York; Portland, Oregon; and San Francisco.

Unlike a four-step model that estimates individual trips, an activity-based model uses "tours" as a way of estimating trip-making. Castiglione et al. [2015] define a tour as a "series of trips beginning and ending at home or work anchor location. By modeling decisions on a tour basis, there is an enforced consistency between the outbound and return portions of the tour, so that a mode chosen to go to work conditions the mode available for the return home." The types of activities that constitute a tour can vary widely, and most activity-based models examine one or more of the following activities: at home, work at home, work (at workplace), school (K–12), university/college, personal business/medical, shopping, eat meal, social/recreational, and escort passenger. An example of two tours (the work to lunch to work tour is considered a subtour) is shown in Figure 6-9. Note that in a four-step model, the trips shown in this figure would have been modeled as one home-based-work trip, two nonhome-based other trips, one nonhome-based shopping trip, and one home-based shopping trip.

**Figure 6-8. Integrated Model Structure with Activity-Based Modeling Component**

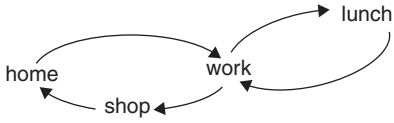
**Figure 6-9. Illustration of Trip Tours as Used in Activity-based Models**



Source: Castiglione et al., 2015, Reproduced with permission of the Transportation Research Board.

The output of most activity-based models is an origin-destination matrix, which is then provided as input to a trip assignment model.

**Atlanta Regional Commission (ARC) Activity-Based Model Example.** The ARC decided to develop an activity-based model in order to provide an analysis capability that better reflected travel behavior in the region. [ARC, 2014] Key characteristics of the ARC approach include:

1) The model's zonal system consisted of 2,027 zones, which were subdivided into three categories of transit access: 7 minutes or less walking to transit, 13 minutes or less walking to transit, and no walking to transit. This resulted in 6,081 subzones.

2) Trip decision makers in the model system included both persons and households. These decision makers are created (synthesized) for each simulation year based on tables of households and persons from 2,000 pieces of census data and forecasted TAZ-level distributions of households and persons by key socioeconomic categories.

3) Eight person-types were used, with each person-type mutually exclusive with respect to age, work status, and school status. The person-types were based on the results of a household survey.

4) Households were segmented by four income ranges—<$20,000, $20,000 to $50,000, $50,000 to $100,000, and >$100,000.

5) Ten activity types, also defined as being mandatory, maintenance, or discretionary, were identified. The classification of each activity type reflected the relative importance or natural hierarchy of the activity; for example, work and school activities are most inflexible in terms of generation, scheduling, and location. Typical activity types included:

**Mandatory**

a. Work—Working at regular workplace or work-related activities outside the home.

b. University—College +

c. High School—Grades 9–12

d. Grade School—Grades K–8

**Maintenance**

e. Escorting—Pick up/drop off passengers (auto trips only).

f. Shopping—Shopping away from home.

g. Other Maintenance—Personal business/services and medical appointments.

**Discretionary**

h. Social/Recreational—Recreation, visiting friends/family.

i. Eat Out—Eating outside of home.

j. Other Discretionary—Volunteer work, religious activities.

6) One hour increments, beginning at 3 a.m. and ending with 3 a.m., were used for the activity-based tours.

7) Thirteen modes were available for modeled trips.

Figure 6-10 shows the different submodels that were part of this new modeling approach. The approach reflected a sequence of "choices" made by the model leading to predicted travel volumes on the transportation system. The results of each submodel become input into the submodel that follows it. This sequence included:

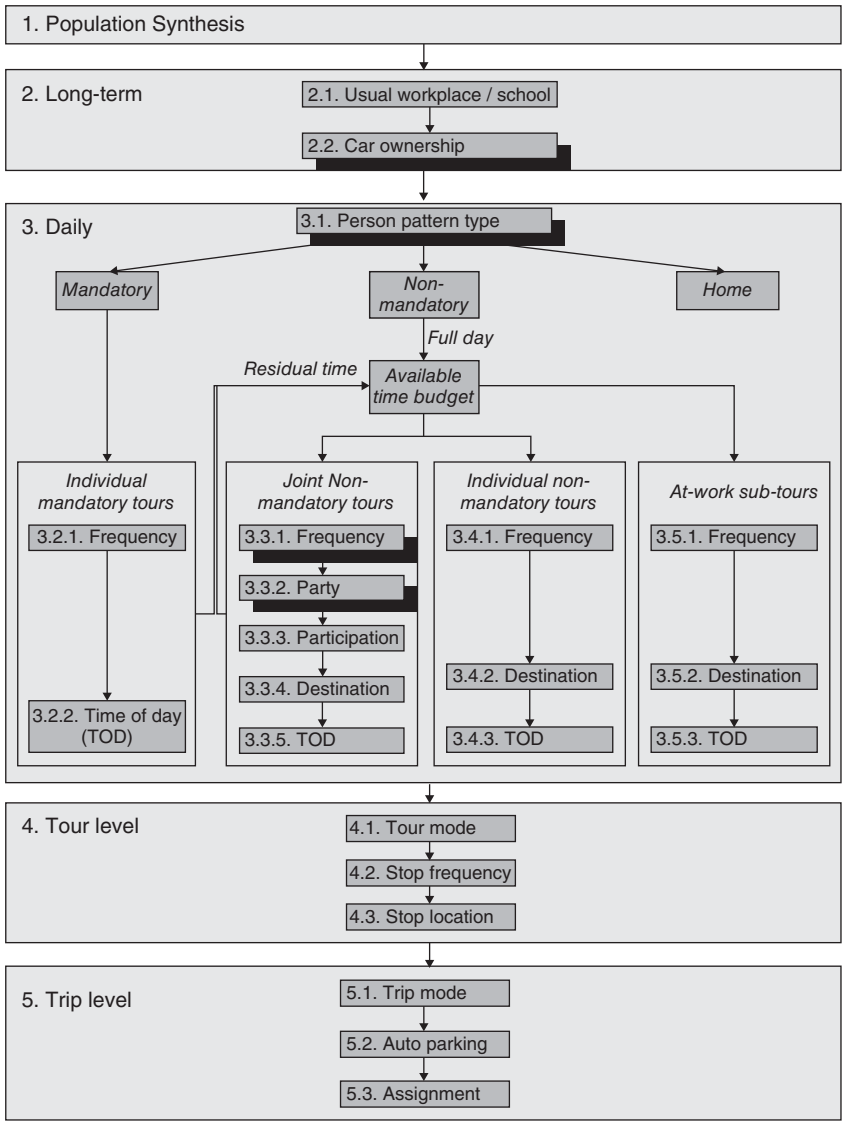
*Synthetic population*

- Zonal distributions of population by controlled variables.
- Household residential location choice (allocation to zones).

*Long-term level*

- Usual location for each mandatory activity for each relevant household member (workplace/university/school).
- Household car ownership.

**Figure 6-10. Illustration of Trip Tours as Used in Activity-Based Models, Atlanta Regional Commission**



Source: ARC, 2014, Reproduced with permission of the Atlanta Regional Commission.

*Daily pattern/schedule level*

- Daily pattern type for each household member (main activity combination, at home versus on tour) with a linkage of choices across various person categories.
- Individual mandatory activities/tours for each household member (note that locations of mandatory tours have already been determined in long-term choice model).
  - Frequency of mandatory tours.
  - Mandatory tour time of day (departure/arrival time combination).
- Joint travel tours (conditional upon the available time window left for each person after the scheduling of mandatory activities).
  - Joint tour frequency.
  - Travel party composition (adults, children, mixed).
  - Person participation in each joint tour.

- Primary destination for each joint tour.
- Joint tour time of day (departure/arrival time combination).

- Individual nonmandatory activities/tours (conditional upon the available time window left for each person after the scheduling of mandatory and joint nonmandatory activities).
  - Person frequency of maintenance/discretionary tours.
  - Primary destination for each individual maintenance/discretionary tour.
  - Individual maintenance/discretionary tour departure/arrival time.
  - Individual at-work subtours (conditional upon the available time window within the work tour duration).
  - Person frequency of at-work subtours.
  - Primary destination for each at-work subtour.
  - At-work subtour departure/arrival time.

*Tour level*

- Tour mode.
- Frequency of secondary stops.
- Location of secondary stops.

*Trip level*

- Trip depart time model.
- Trip mode choice conditional upon the tour mode.
- Auto trip parking location choice.
- Trip assignment.

As can be seen in this list of submodel choices, the activity-based model reflects many of the travel choices facing trip makers on a daily basis. Each submodel must be based on a credible and defensible logic and, as with all models, has to be calibrated and validated against real trip data (or with survey results).

In summary, activity-based modeling uses a variety of approaches ranging from decision trees, Monte Carlo simulation, and neural networks to utility maximizing and discrete choice models (logit or nested logit models). Like the four-step models, these approaches can require a fairly large database of detailed surveys of activities. In contrast to the traditional four-step software packages, however, there are few commercially available software packages that include activity-based models. See the following references for more detailed description of activity-based model applications: [Donnelly et al., 2010; Vanasse, Hangen, and Brustlin, 2011; Ferdous et al., 2011; Resource Systems Group, 2012]

## C. Linkage to Air Quality Modeling

For metropolitan areas that are in nonattainment or maintenance of air quality standards, estimated future mobile source emissions must not exceed the emission limits (called budgets) established in the state implementation plans (SIPs). With the exception of California, states estimate their mobile source emissions by combining travel model outputs, volumes, and travel times/speeds with emissions factors derived using the Environmental Protection Agency's (EPA) MOtor Vehicle Emissions Simulator (MOVES) emissions model. [FHWA, 2014] However, transportation modeling and air quality modeling have not been integrated consistently. The travel activity data—particularly link speed data from travel demand models—are rarely resolved as finely as needed to estimate mobile source emissions. Consequently, additional post-processing of travel model output is often required. The post-processing procedures employed will differ by region, but in general can have a significant effect on subsequent emissions estimates.

The EPA specifies six criteria that travel models must meet to be acceptable for air quality conformity analysis: (1) models must be validated against observed travel, and future travel estimates must be reasonable given past trends; (2) land use, population, and employment estimates and projections must be based on the latest planning assumptions; (3) projected trends in land development should be consistent with future transportation system alternatives; (4) a capacity-sensitive assignment method must be used, and peak- and off-peak link volumes must be estimated; (5) a feedback mechanism must be used; and (6) the model should be reasonably sensitive to changes in travel times and costs.

Using sensitivity analyses, the EPA has identified two input parameters to which MOVES emissions factors are particularly sensitive: speed and time-of-day distributions of travel activity. There are two major difficulties with how speeds are estimated. First, speed estimates used in the travel models are rarely validated on a wide-scale basis because of high data collection costs and very limited available data. Second, a variety of link performance functions can be used in trip assignment models, producing substantial variations in post-processed speed estimates. The effect of using different performance function forms for assigning travel volume is not usually a major concern for travel demand modelers since results can be validated against travel counts. However, the impact on post-processed speeds and on subsequent emissions modeling may not be trivial. Research suggests that using different speed-flow functions or post-processing methods may result in significantly different emissions estimates. Little research has been done to identify how an MPO should select a speed-flow function both for the assignment step and for any post-processing that is performed. Attention to the selection and effect of post-processing techniques will be required as legislative mandates and/or policy initiatives related to air quality become more stringent.

With respect to time-of-day distributions, roadway (or link) travel volumes are estimated per modeling period (for example, a.m. or p.m. peak), where periods typically embrace two to four hours. Conversely, photochemical air quality models, such as EPA's urban air shed model (UAM), require hourly volumes. A variety of post-processing strategies can and have been used to address this particular problem including, among others, categorizing roadway segments by peaking characteristics and applying specific hourly proportions based on observed travel for selected roadway facilities or by applying various probabilistic strategies. Although the need for increasing the time resolution of travel models is more often linked to improving our understanding of operational effects (for example, peak spreading), it is also a critical ingredient in assessing air quality.

For a good overview of air quality modeling and its relationship to transportation demand modeling, see [PB Americas et al., 2013].

## D. Software

The four-step modeling structure has evolved slowly over a lengthy period of time. Various planning agencies have used a similar structure throughout the modeling process—a sequential model application with feedback loops and aggregate-level calibrations/validations. Most MPOs use advanced commercial travel demand modeling software packages, such as TransCAD®, EMME/2, and CUBE. These packages are professionally designed and are generally well maintained. This has substantially reduced the computational burden with modeling applications and made many advanced techniques more routine. The recent development of many four-step models suggests significant improvements related to algorithmic or technical details, including increased spatial precision (for example, adding new zones/links), better temporal resolution (increased time of day slices) and the use of additional modeling steps (for example, the addition of vehicle ownership models and greater segregation of trip types).

Menu-driven software (for example, TransCAD®, EMME/2) generally incorporates a wide variety of modeling approaches in the form of menu options. These packages are somewhat easier to use and allow less experienced modelers to access more advanced techniques, and the embedded GIS tools are slightly easier to learn in the integrated environment for scenario runs. Many of the menu-driven software packages also allow for scripts. Regardless of the software chosen, each individual region must develop its own model specific for that region. Many of the menu approaches allow a user to accept default national or regional averages for some variables.

Current software development trends suggest that most developers are moving toward the integration of different modeling processes into a suite or a family of packages to improve modeling efficiency. One example is the CUBE System developed by Citilabs, which is built on an interface with ArcGIS and incorporates four different modules as a family of software products: (1) Cube Voyager, which performs travel forecasting based on the four-step approach and provides some advanced techniques; (2) Cube Dynasim, which performs dynamic multimodal microsimulations for

intersection design and analysis; (3) Cube Cargo, which performs freight forecasting and facility analysis; and (4) Cube Me, which performs statistically optimized trip matrix estimation. Another example is the PTV Vision Suite developed by PTV America, Inc., which integrates a travel demand-forecasting model, VISUM; a travel/transit simulation model, VISSIM; a transit planning and optimization model, VISUM PuT; a real-time travel management model, VISUM On-Line; and a travel conditions displaying model, TML. The trend seems to be oriented toward developing computer-based packages that include both travel demand-forecasting models and travel simulation models that require greater technical expertise.

## IV. SUMMARY

One of transportation planning's most important roles is to provide information to decision makers on the potential consequences of investments in the transportation system—and the consequences of not investing in the system. Modeling travel demand and assessing the performance of the transportation system are fundamental to this role. Travel demand modeling has been an important element of transportation planning for many decades and to this day remains the foundational approach for producing estimates of future travel demand. Every metropolitan planning organization uses some degree of travel demand modeling, often with substantial portions of the budget allocated to data collection, model calibration, and forecasting activities.

Travel demand models have been used for nearly 50 years, but in the last 20 years, significant policy demands have pushed the limits of what can be reasonably achieved with the standard four-step models. Although numerous federal agencies provide a wealth of guidance on travel modeling for various policy issues, accepted practices vary widely throughout the U.S. In fact, model performance standards are often determined and evaluated unique to the policy application. In spite of this, the development of travel models has continued at a rapid rate. As our understanding of travel behavior has improved, researchers and practitioners have continued to extend and refine the functional performance of the models. In many cases, practitioners have been innovative and have accommodated a variety of different contemporary policy issues using the standard four-step model.

The four-step models that continue to be used, at least in the short-term, will place greater focus on implementing best practices, such as those identified by Davidson et al. [2007]: (1) using disaggregated modeling; (2) considering within-household relationships and their impact on travel decisions; (3) evaluating individual characteristics in addition to household variables; (4) considering household aging and how it affects future travel decisions; (5) defining feasible choice sets; (6) using accessibility measures; and (7) developing realistic estimates of performance characteristics, such as travel time.

However, the next decade of modeling will likely see continued shifts from the four-step models to activity-based and simulation models and continued increases in data collection and computational costs. Many MPOs are considering the development of tour-based models, with a number already in practice. As modeling practices continue to become more complex and software evolves to accommodate this complexity, transportation analysts will need greater technical expertise, whether in-house or through the use of consultants. Balancing resources between the maintenance of current models and the migration to new models will be difficult, but it is important that larger MPOs begin the migration to models that will allow them successfully to meet new and expanding regulatory and policy needs.

# Evaluation and Prioritization Methods[1]

## I. INTRODUCTION

Prudent management of public investment in the transportation system requires transportation planners and engineers to identify cost-effective investment strategies and actions. Evaluation is the process of synthesizing the results of an analysis of alternatives and comparing the alternatives to identify the relative value of one alternative over another. Evaluation is one of the most important components of transportation planning because it provides the information needed to make decisions. Evaluation can also influence the definition of alternatives as well as the credibility of the planning process itself.

Although evaluation provides a structured set of information for decisions, transportation planning lies at a unique intersection of technical analysis and political prerogative. The goal of the evaluation process is to provide information to help decision makers reach informed decisions that provide the greatest public good. Certainly, the technical information on the system performance of different alternatives is a critical underpinning of such decision making. However, depending on the size, nature, and complexity of a problem, it is also important to have participation throughout the process by citizens, other stakeholders, and elected officials who finally adopt a plan.

Figure 7-1 presents an overall framework for evaluation. The shaded area indicates the scope of this chapter. The following section considers the basic concepts that are part of every evaluation process. These include relating the alternatives to goals, objectives, and performance measures and basic economic analysis concepts such as inflation, defining costs and benefits, and identifying equity impacts. Next, various evaluation techniques are examined, including the selection of the appropriate evaluation methods. The following section describes how uncertainty and risk should be incorporated into the evaluation process. The chapter continues with an examination of some of the mistakes that commonly occur in evaluation, and a description of different approaches to project prioritization and programming. The remainder of the chapter presents examples of evaluation efforts that have been undertaken by public agencies.

The chapter identifies important references for those interested in the evaluation process. A number of websites are also available on benefit/cost analysis, including some free spreadsheet models, such as: http://bca.transportationeconomics.org/home and http://www.dot.ca.gov/hq/tpp/offices/eab/benefit_files/Cal-BCv4-1.xls.

## II. CHARACTERISTICS OF THE EVALUATION PROCESS

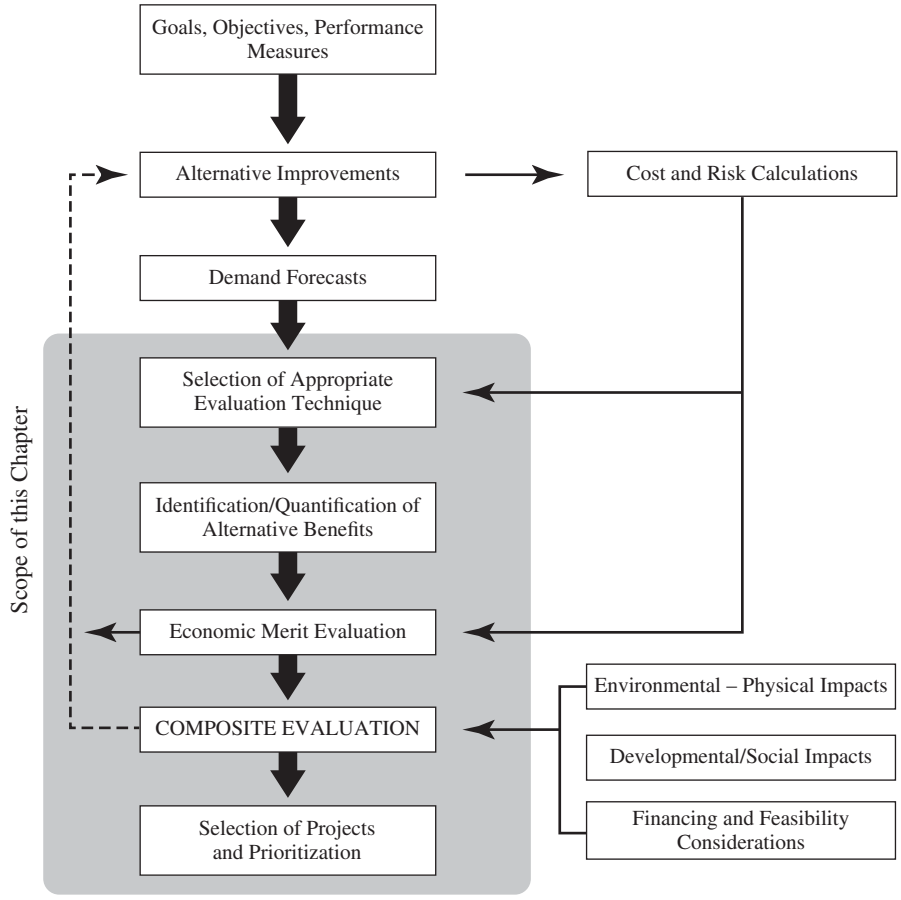
The following characteristics of the evaluation process are important for planners to know:

- Most transportation studies examine several alternative courses of action. At the plan level, these alternatives might be a small number of different investment strategies, such as focusing on a different modal emphasis or on different investment levels. At the corridor or site level, these alternatives are usually more numerous and are described in more detail. In environmental analyses, one of these alternatives is the *do-nothing* alternative.
- Ideally, but not always in practice, evaluating all relevant factors (called the composite evaluation) may lead to improved definitions of alternatives (shown as the dashed feedback line in Figure 7-1). If a preliminary evaluation shows the need to modify the scope and/or scale of an alternative, this can be used to define a modified alternative, which then proceeds to a more detailed assessment.

[1]The original chapter in Volume 3 of this handbook was written by Steven B. Colman, Principal, Dowling Associates Inc. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer
© 2016 by by John Wiley & Sons, Inc. Published by John Wiley & Sons, Inc.

**Figure 7-1. Overall Evaluation Framework**



- Most alternatives include projects having different life spans, with benefits and costs occurring at different points in time. Thus, evaluation must provide a way to meaningfully compare projects with different costs and benefits over the study timeframe.
- Transportation projects and programs typically involve an initial expenditure of funds (called capital costs), followed by a period of ongoing costs, such as operations, maintenance, and eventual rehabilitation and reconstruction costs. These costs may vary from year to year. The discounted costs over the life of a project are called its *life-cycle costs*.
- Many project costs and benefits can be measured in monetary terms because there are market costs associated with them (for example, the cost per ton of concrete or per transit bus). Frequently, however, there are costs and benefits for which no market values are readily available (for example, the community disruption caused by construction activities or the aesthetic value of a project design, among others). In such cases, the evaluation process needs to incorporate this information into the assessment in creative ways.
- Because the primary purpose of evaluation is to provide decision makers with information on the relative merits of one alternative versus others, evaluation criteria should relate directly to the information needed and desired by decision makers. Specifically, the criteria should reflect closely the goals and objectives defined earlier in the planning process. Criteria used that result in the selection of the "correct" alternative (from the viewpoint of the decision makers), but that do not reflect the goals and objectives of the process, could indicate a breakdown in the overall evaluation process.

Generally, this chapter considers only the direct (or primary) effects of transportation projects. Examples include changes in travel time, operating costs, and safety outcomes. Indirect (or secondary) effects or nonquantifiable

costs—such as economic development impacts that occur after a project has been constructed or an alternative implemented—are outside the scope of this chapter. Of course, transportation planners and engineers should be aware that the potential for such impacts exists (see [Berger & Assocs., 1998; Economic Development Research Group et al., 2012; FTA, 2013; Forkenbrock and Weisbrod, 2001; Lakshmanan and Chatterjee, 2005; Weisbrod et al., 2001]; and the website *Transportation Project Impact Case Studies*, http://tpics.us/, for a review of social and economic development impacts of transportation improvements). Those interested in land-use and development impacts of transportation investment are referred to chapter 3 on land use and urban design.

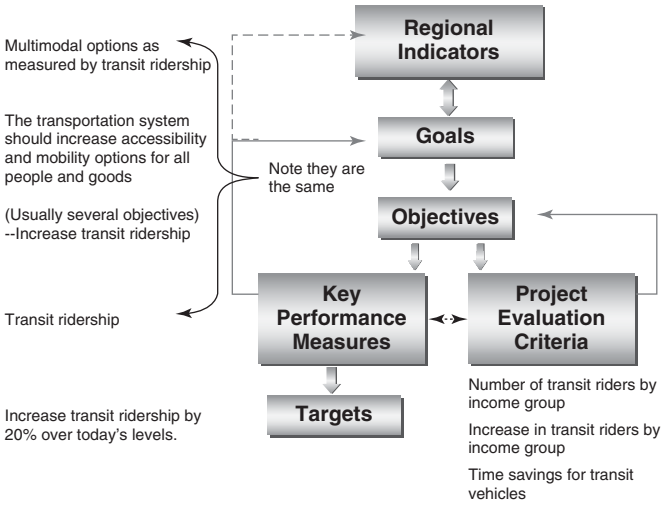
## A. Basic Concepts

### *1. Goals, Objectives, Evaluation Criteria, and Performance Measures*

The relationship between goals and objectives and the evaluation process is an important, but often overlooked characteristic of effective planning. A clear and comprehensive statement of the goals and objectives of a project or plan is critical to developing and evaluating plan alternatives. All studies can benefit from using available goals and objectives from other planning documents (for example, a regional or long-range transportation plan). Smaller and simple projects may require only very brief statements of the goals and objectives, or a purpose and needs statement.

Goals are statements of broadly expressed desired end states. Objectives provide more specifics on how the goals can be accomplished. One of the most common mistakes in developing goals and objectives is confusing *means* and *ends*. For example, "adding capacity to a presently congested highway" is not a valid goal statement in that it is a strategy for accomplishing a related goal. In this instance, a possible goal might be to improve mobility. The following are definitions (illustrated in Figure 7-2) of terms often found in planning practice:

**Figure 7-2. Performance Measurement Hierarchy**



Source: Meyer, M. 2006. "Performance Measures for Regional Transportation Planning," Memorandum prepared for the Atlanta Regional Commission. Atlanta, GA: Atlanta Regional Commission.

- *Regional Indicator*. This high-level indicator reflects a characteristic of a region or its transportation system and presents an indication of what is happening to the region over time. In Figure 7-2, the indicator is the level of multimodal options available in the region, with the surrogate being overall transit ridership. Often, but not always, a regional indicator might not be under the control or direct influence of transportation agencies. For example, air quality is a regional indicator in many areas, for which transportation is only one contributor.
- *Goals*. Goals are generalized statements that indicate a desired end state or characteristic of a system. Thus, in Figure 7-2, the goal is to have a transportation system that increases mobility and accessibility for people and goods, but it does not say how this should be done.
- *Objectives*. Objectives are more specific statements of how a plan will achieve the goal. In Figure 7-2, one way of improving mobility and accessibility is to increase transit ridership. Usually, there are several objectives associated with a goal. A key difference between goals and objectives is that objectives are typically measurable (quantifiable), but goals are not.
- *Key Performance Measures*. These are a small set of measures that indicate how the transportation system is performing. This core group of perhaps 10 to 12 performance measures reflects critical success factors and measures progress toward organizational goals. Thus, they are critically important to decision makers

and for public dissemination. In Figure 7-2, the system performance measure is "aggregate transit ridership." This measure allows decision makers to determine the effectiveness of a system plan in the context of this objective.

- *Project Evaluation Criteria/Measures of Effectiveness*. Evaluation criteria relate directly to the evaluation of alternatives and scenarios and to a variety of issues that might be relevant to a particular alternative. Thus, in Figure 7-2, several criteria are shown that are not exactly the same as the system performance measures, but that feed directly into understanding the effects of alternatives and/or scenarios. They are called criteria because they help guide the decision as to which alternative under consideration is best.
- *Targets*. In some instances, it is desirable to establish a standard or desired outcome to focus attention on what is considered to be success. In Figure 7-2, the target is "increase ridership by 20 percent over current levels by the year 2020." Not only does this provide a more specific focus on achieving the goal, but it also allows planners and decision makers to monitor system performance over time to determine if it is at least heading in the right direction. [Meyer and Miller, 2014]

Clearly, the criteria used in evaluating a scenario or alternative should relate directly to important system performance measures. Thus, for every key performance measure, one or more similar project evaluation criteria are used to allow a direct connection to system performance, as indicated with a two-headed arrow in Figure 7-2.

The set of evaluation criteria should be comprehensive, but not duplicative, nor too lengthy. The criteria should be transparent (that is, readily understood by decision makers and the public), and the costs of data collection when using these criteria should be commensurate with the size of the project or plan and its complexity (see [Cambridge Systematics, 1996; Meyer and Miller, 2014; and Rothblatt and Colman,1996] for a more detailed discussion on goals, objectives, evaluation criteria, and performance measures). Table 7-1 presents a list of typical evaluation criteria for different performance measure categories.

### *2. Importance of Project or Alternative Definition*

Most transportation plans recommend a set of cost-effective projects for implementation. For metropolitan plans, the number can reach thousands over the lifetime of the plan itself. For an individual project, improvements could take place over time as a series of one or more related construction phases. Depending on the scale of the planning effort, project definition can be an important input into the evaluation process. Project definition reflects the level of funding that will be necessary through cost estimation, likely environmental impacts, and the place of the project in the overall transportation system.

A transportation project is usually defined by its:

- Project identity and location (at the plan level, this is often described in very general terms).
- Project type.
- Length.
- Capacity (for example, number of lanes, degree of grade separation, or additional transit vehicles).
- Access points (stations, interchanges).
- Degree of grade separation and vertical alignment.
- Average and maximum operating speed.
- Horizontal and vertical alignment (including tunnels, cuts).

Transportation plans usually deal with broader categories to test the effects of different long-range policies, such as the number and type of community groups affected, proximity to important land uses, and the role transportation investment plays in the broader transportation network (for example, part of an evacuation route). Table 7-2 shows some of the factors that might be considered as part of a transportation plan.

Another method of incorporating the different dimensions shown in Table 7-2 into the planning and evaluation process is through scenario planning. In essence, scenarios examine different land use and transportation investment

| Table 7-1. Sample Criteria for Evaluating Major Urban Transportation Alternatives | |
|---|---|
| **Performance Categories** | **Evaluation Criteria** |
| **System Performance Criteria** | |
| Mobility | • Sum of travel times (peak/off-peak) to selected points<br>• Travel time index (ratio of congested travel times to free flow travel times)<br>• Average speed weighted by travel flows<br>• Congestion cost per person<br>• Commercial vehicle delay per mile |
| Accessibility | • Number of areas or major activity centers served by a project<br>• Availability of service to transportation-disadvantaged groups<br>• Accessibility index from a gravity model<br>• Percent of all jobs within 30-minute commute time<br>• Percent of dwellings within 1/4 mile walking distance of transit |
| Traffic Relief | • Number of intersections and miles of street where level of service is below standard<br>• Average speed by facility type (or classification)<br>• Vehicle-miles or hours of travel by level of service |
| Safety | • Number or cost of collisions, injuries, and fatalities |
| Modal Balance | • Percent trips by transit, carpool, etc.<br>• Mode share to regionally significant activity centers |
| System Efficiency | • Gallons of fuel consumed<br>• User cost (vehicle operating cost plus time cost) |
| **Impact Criteria** | |
| Regional Development | • Consistency with adopted land-development goals/policies |
| Neighborhood Disruption | • Number of dwelling units, and businesses displaced or impacted<br>• Number of defined neighborhoods or homes encroached upon<br>• Acres of existing developed land affected<br>• Net dwelling units within unacceptable noise contours |
| Air Quality | • Tons of emissions, by type<br>• Exceedance days of national or state standards<br>• Conformity to National Ambient Air Quality Standards |
| Special Land Use Impacts | • Acres of parks, recreational lands, or schools affected<br>• Acres of prime farmland affected<br>• Acres of wetlands affected<br>• Number and significance of historical sites, archaeological districts, etc. |

(*continued*)

| Table 7-1. (*Continued*) | |
|---|---|
| **Performance Categories** | **Evaluation Criteria** |
| **Implementation Criteria** | |
| Cost | • Capital, maintenance, and operating costs<br>• Probability of funding availability<br>• Percentage of funding from nonlocal sources |
| Attitudes and Equity | • Degree of acceptance by elected officials and citizens<br>• Amount of tax base shift from one jurisdiction to another<br>• Impact on low-income neighborhoods and groups |

Source: Adapted and expanded from Maricopa Association of Governments, Transportation and Planning Office, 2010, Phoenix, Arizona

| Table 7-2. Possible Scenario Factors for Long-Range Transportation Planning | |
|---|---|
| Modal Emphasis | • Transit versus auto emphasis (could also affect land use)<br>• Freeway versus surface street improvements |
| Funding Levels Available | • Low<br>• Medium<br>• High |
| Geographic Emphasis | • Change/growth areas versus maintenance/slow growth areas |
| Type of Growth | • Compact/infill versus sprawl<br>• Transit-oriented development/pedestrian development versus existing trends for the past 20 years<br>• Industry-type emphasis (e.g., emphasis on encouraging service industry growth, telecom, manufacturing, tourism, and so on)<br>• Balanced versus imbalanced jobs/housing growth (e.g., jobs grow faster than the number of employed residents)<br>• High versus low countywide/regional growth rate |
| Pricing | • Stable gas prices versus increasing real gas prices<br>• Free parking (existing) versus paid parking<br>• Reduced real transit fares versus higher real transit fares |

packages to determine which scenario provides the best outcome from a transportation system performance perspective. For example, a study in Atlanta, Georgia, that focused on approximately 1,000 square miles of the area's fastest rates of development growth examined the following scenarios as part of the analysis and evaluation process:

- *Current Atlanta Regional Commission (ARC) Forecast*—What happens if development is spread throughout the study area with the greatest concentrations in the southern half of the study area?
- *Existing Communities*—What happens if development is largely concentrated in and around existing communities and activity centers in the study area?
- *Transit-Oriented Development*—What happens if a grid network of radial and east-west transit is developed and future land use concentrates along these lines?
- *Equity (East-West Corridor)*—What happens if development is further concentrated along east-west corridors and transit is enhanced?

- *Managed Growth*—What happens if much of the new growth is distributed in "hamlets" of balanced residential and commercial development in the north?
- *Local Plans*—What happens if development occurs as anticipated in the plans of the local jurisdictions, and total development is higher than projected by ARC?
- *Less Growth*—What happens if roughly half of the development projected by ARC occurs, and there is little new highway capacity added? [GRTA, 2004]

By examining the implications of these different scenarios, transportation planners were able to identify the key factors driving transportation demands in the study area; identify the likely consequences of different land use and transportation strategies; and, perhaps most importantly, inform local officials regarding the strong linkage between land-use decisions and resulting transportation system performance.

### *3. Defining Costs and Benefits*

The choice of which costs and benefits to include in an evaluation can strongly influence the ultimate outcome of the evaluation process. [AASHTO, 2010; Cambridge Systematics, 1996; ECONorthwest et al., 2002; European Conference of Ministers of Transport, 2001; and VTPI, 2009] Defining costs and benefits in public sector evaluations is often more complicated than for those in the private sector, simply because public choice needs to include the societal costs of resource consumption that do not normally have a market price. The rest of this section will take the viewpoint of public sector decisions, with the understanding that a subset of the tools presented also could be used to evaluate a private investment decision.

Costs and benefits can affect three major groups: (1) suppliers or owners of transportation facilities or services, usually public agencies, (2) users of the transportation facility or service, and (3) everyone else (nonusers, society at large). Noise, air and water pollution, aesthetics, and neighborhood/social cohesion impacts, among others, are considered nonuser costs or costs to society, although in many instances such costs are faced by users as well. These are felt by groups other than suppliers and users, although clearly overlaps are possible (for example, drivers may also be subject to unhealthy air quality and traffic noise).

Costs and benefits are sometimes mirror images of each other. For example, an environmental mitigation (a noise barrier) may be a cost to the owner agency, but a benefit to the surrounding neighborhood. The choice of whether to consider an impact a cost or benefit can affect the results of an evaluation, such as in a benefit/cost analysis. As an example, consider a project where, without taking into account the value of the noise effects of the project, the costs and benefits are both equal to $1,000. The project will result in a reduction in noise exposure, which is valued at $150. If reduced noise is treated as a negative cost, the benefit/cost (B/C) ratio is $(\$1{,}000/(\$1{,}000 - 150)) = 1.18$. On the other hand, if the reduced noise is considered a project benefit, the B/C ratio will be $((\$1{,}000 + 150)/(\$1000)) = 1.15$. Most engineering economy texts recommend the *modified benefit/ cost analysis method*, which treats the reduction of costs as a positive benefit, in this case resulting in a B/C ratio of 1.15.

Classifying an item as a cost or benefit becomes particularly difficult when secondary or indirect impacts of a project are considered. For example, a large transit project might reduce the number of second (or third) cars owned by households, which would be considered a benefit in most evaluations. However, to auto dealers, mechanics, and banks making auto loans, this would actually be a cost—or at least a reduction in revenue. Similarly, projects intended to stimulate new job creation may in fact merely attract jobs away from other locations. For this reason, as well as the possibility of double-counting benefits, it is usually best to focus the evaluation on the primary—or direct—impacts of a plan or project, and consider the secondary effects separately.

### *4. Costs Included in Evaluation*

Costs are usually divided into two categories: *capital* and *operating and maintenance* (O&M) costs, although, as will be seen, the division is not always simple. *Capital costs* are defined as those costs needed to implement an alternative or start a project. Thus, they include the costs of construction and initial vehicle procurement (for transit projects), associated allowances for contingencies, and administration. They also include the costs of planning, environmental studies, project design, and engineering, and any other *one-time* costs. Excluded from this definition is the out-year reconstruction or replacement of facilities and components, including the replacement of vehicles acquired as part of the implementation of an alternative. Costs of reconstruction and replacement are treated as part of the life-cycle cost analysis and are not included specifically in the capital costs, so as to avoid double-counting. Capital costs thus typically include items such as: (1) right-of-way acquisition and relocation costs, (2) construction costs, (3) vehicle acquisition costs (for transit), and (4) engineering and design costs.

From an accounting perspective, capital costs relate to assets that have a useful life of at least 1 year. O&M costs are recurring costs, or costs that last less than a year and may include: maintenance, operation, and administration costs; insurance and collision/mishaps; user travel costs; and taxes (typically for private sector only).

Because prices of goods and services tend to rise over time, it is important to distinguish between *real* dollars (also called *constant*, *inflation-adjusted*, or *base-year dollars*) and *nominal*, *current*, or *data-year* dollars, which are not adjusted for inflation.

Because planning studies often derive unit costs from historic data, it is necessary to convert historic costs to current values. This conversion is generally done with a factor called a construction cost index (CCI) number. The Federal Highway Administration (FHWA), trade publications (such as *Engineering News-Record*), and some state departments of transportation (DOTs) provide such information. An example of the national highway CCI as disseminated by the Federal Highway Administration is shown in Table 7-3. An index number of 100 represents the average prices in a given month, quarter, or year; thus, for example, if transportation agencies use March 2003, shown in Table 7-3, as the *base year*, the index number is equal to 100 for that quarter. CCIs for individual contract items can also be easily found; these standard items and their units are typically expressed in dollars per some unit quantity.

### *5. Cost Estimation for Transit Projects*

Although the names and definitions are somewhat arbitrary, the procedural phases in the development of a major transit project can be divided into system planning, project development (including environmental review of alternatives), engineering, and final design/construction. These steps are structured around the major choices that must be made as a project emerges from broad regional planning efforts and proceeds toward implementation, such as: Which corridor(s) has/have the greatest needs? What kind of improvement is appropriate? Which design standards should be used? For transit projects, the first substantial engineering efforts usually occur in the project development process and alternatives analysis, with progressively more detailed engineering work as a project development process is completed and enters into the engineering phase.

**Table 7-3. National Highway Construction Cost Index (NHCCI)**

| Year | Quarter | NHCCI Index |
|---|---|---|
| 2003 | March | 1.0000 |
| | June | 1.0156 |
| | September | 1.0038 |
| | December | 0.9929 |
| 2004 | March | 1.0260 |
| | June | 1.0638 |
| | September | 1.0849 |
| | December | 1.0910 |

System planning typically includes general concepts and options for technology, alignments, engineering feasibility, priorities, and costs. Cost in this phase of work is preliminary and is often expressed in ranges. In the alternatives analysis phases, conceptual engineering is performed, prototype design standards are developed, preferred modes are selected, and a financial plan is developed. In this stage, cost ranges are significantly narrowed.

As part of the project development process, design standards are developed along with proposed alignments and financial commitments. Approximately 30 percent of the total engineering effort is performed during project development, in most cases to satisfy environmental analysis needs. In final engineering, construction drawings are prepared, including specifications and other construction documents.

A clear understanding of the context of each project phase is crucial because it provides a guide for identifying the appropriate level of effort and detail for the engineering and cost-estimating work. Although the varying contexts make it impossible to specify a particular level of effort that is correct for every project planning effort, it is important to remember that project planning is used to select the best alternative, not to accomplish all the steps necessary to its implementation.

During project planning, two levels of engineering effort are often applied: one for typical facilities and the other, much more detailed, for special situations. For segments of alternatives that can be analyzed at a fairly aggregate level, a typical cross section for the segment is defined. Detailed unit costs are used with quantities (such as square yards, pounds, person-hours) taken from the typical sections to derive costs per linear foot (LF) for each section. A similar approach is used to derive per-facility composite costs for various facility types: interchanges, transit stations, park-and-ride lots, and the like. Plan and profile drawings are prepared for each alternative, and quantities—lengths, number of grade separations, special features—are taken from these estimates. Segment costs are computed to represent the capital costs of each identified segment, exclusive of systemwide elements and add-on items.

Segments that cannot be handled with the typical section approach are those where special conditions exist—typically a major structure or an uncertain alignment in areas with major existing structures or difficult terrain. These segments are costed in detail, with drawings, detailed quantities, and detailed unit costs. Additional specialized investigations may be carried out in these areas, for example, of soil conditions, archaeological constraints, hazardous materials, and the like.

For a major transit investment, systemwide elements include (as applicable) vehicles, electrification, signal/central control systems, and similar items, because these items are not related to individual segments. As such, they are estimated with unit costs applied to systemwide quantities. Add-on items of contingency allowances, costs of engineering and construction management services, and design are then added. These items are usually estimated through multipliers that express the add-on costs as percentages of the estimated baseline capital costs.

### *6. Measuring Societal Costs and Externalities*

Externalities, also known as spillover or third-party effects, are impacts that are not captured by the free exchange of money (that is, by markets). A project can impose externalities on others (in which case they are known as negative externalities), or can confer benefits (positive externalities). Motor vehicle air pollutants are an example of externalities. It might cost $30 to fill the gas tank of an automobile, for which there is an active market price. However, those who breathe the pollutants emitted by burning the gasoline are not voluntary parties to this transaction and are not compensated for it. Economists estimate this cost to society by examining the health-related costs associated with air pollutant–related illnesses.

Societal costs are similar and have been defined as the disutility that accrues to society as a result of a particular act, such as the production or consumption of a commodity. [Greene, Jones, and Delucchi, 1997] Societal benefits involve the added utility resulting from the production or consumption of a good or service. Economists have long known that private markets do not always capture all of the costs or benefits of certain actions. Excluding externalities in the evaluation process can lead to the wrong choices being made. This points out an important distinction between private and public decision making—private firm decisions will generally include only actual internal costs.

The difficulty with including externalities in an analysis is that it is often difficult to give them a monetary value because, by definition, there are few active economic markets for trading them (the only two major ones are in California and Europe, where greenhouse gas emission markets have been established). This has led to a number of attempts to provide values for external costs based on indirect methods (see [Freeman, 1993; and Greene, Jones, and Delucchi, 1997]).

One practical approach is cost of avoidance. Cost of avoidance places a value on the attempt to avoid or prevent the impact. For example, road alignment A subjects 250 more homes to noise exposure above the state's 70-dB standard than does alignment B. Clearly, this makes alignment A less desirable than B, all else being equal. How do we evaluate the additional noise externality associated with alignment A? The avoidance approach asks: How much would it cost to avert the impact—say, through double-glazing windows, insulation, air conditioning, construction of noise barriers—on the 250 homes to bring their noise exposure to within the 70-dB standard? This cost is then added to the other costs of alignment A.

An obvious problem with this approach is that it may not always be possible to avoid all of the related impacts of alignment A. The interior noise levels may be comparable, but exterior levels will be higher for the 250 homes affected. Placing a value on the additional irritation of higher noise levels in outdoor activities is more difficult, as there is no effective way to avert that impact, although it could be mitigated by a noise barrier or alignment change. Nevertheless, various measures related to environmental mitigations often take this approach; for example, the addition of pollution-control equipment to cars or the reformulation of gasoline to reduce air pollution, among others.

### *7. Benefits Included in Evaluation*

Economic benefits associated with capital investments in transportation facilities are usually measured in terms of user benefits. User benefits for each alternative are determined by calculating the values of anticipated reductions in negative effects compared to the no-build alternative. The type of benefits will relate closely to the purpose and need for the project. For most large projects, travel time savings will be the largest source of benefits, followed by savings from reductions in collisions and from reductions in user or vehicle costs. Direct and quantifiable economic benefits to transportation facility users from a major capital investment usually relate to the following:

Savings to users of the project, in terms of:

- Travel time savings (or increases) to private vehicles, both those using the facility and those using other facilities that are substitutes.
- Travel time savings (or increases) to public transit passengers and vehicles.
- Travel time savings to commercial vehicles.
- Out-of-pocket vehicle operating costs (for example, fuel, wear-and-tear).
- Collision costs (improved safety).
- Savings to users diverted from one facility (or route)/mode to another.
- Constant auto and transit user travel time savings (congestion relief on existing parallel routes and such). "Constant" refers to (1) those users not changing their route or mode, (2) constant transit users (those who continue to use transit), and (3) constant auto users (those who continue to drive).

**Travel Time Savings.** Travel time savings is the largest single benefit category in most major road projects, often accounting for 60 percent or more of the total benefits. Major transit projects often will have time savings for existing transit users, and will also shift some trips from highway to transit. The shifted auto user will, on average, spend *more* time per trip using transit than driving, for most types of trips. However, positive travel time benefits will accrue to all remaining auto users (constant auto users), including both those diverted to a new road and those continuing to use existing facilities (as a result of congestion relief). Some transit users (constant transit users) also will benefit from the provision of improved transit services, even though they do not change mode.

The overall amount of travel time savings can be estimated from network models. However, in order to attach a monetary value to this amount, one must know the economic value of an hour of travel time. The approach used in most studies is to estimate the value of time as one-third to one-half the pre-tax wage rate of the users. The U.S. Office of Management and Budget (OMB) recommends using 50 percent of the average *work* wage rate, before taxes. The U.S. DOT recommends using 50 percent of the average wage rate in the region. [AASHTO, 2010] The approach used for estimating the value of travel time for a particular study will depend on the accepted practice in that study area.

A few caveats should be noted when applying a single value of time to travel time savings. First, small blocks of travel time (say, 2 minutes) may be valued at less (per minute) than large blocks (say, 15 minutes), because the small blocks

do not present usable or perhaps even noticeable changes for the user. AASHTO suggests that individual travel time savings of less than 5 or 10 minutes per trip are of relatively little value, although AASHTO eliminated this distinction in 2003. [AASHTO, 2010] The travel time value reflects the fact that time saved does *not* usually result in increased earnings for the user, but does have some real value as reflected in observed traveler behavior. In fact, studies have generally shown that people do not place value on travel time savings of 2 minutes or less.

It should be acknowledged that there is some controversy on the nonlinear valuation of time value. Small [1999], for example, offers arguments contrary to the AASHTO approach.

Second, value of time will depend on trip purpose. A driver who is late to work might be willing to spend quite a bit to save a few minutes, but the weekend driver out for sightseeing might not. Indeed, current interest in pricing managed lanes on urban freeways focuses on congested periods during the day, usually during peak commute times when the work trip is most prevalent. In such a case, the value of time, and thus commuter willingness to pay, is much higher than at other times of the day or of the week.

Third, many regions derive values of travel time from the *mode choice* module of the regional travel demand model. Although this model is theoretically acceptable, in practice, transportation planners must be careful that misspecification of the mode choice model does not lead to an undervaluation of travel time.

Many commercial vehicle operators also will realize economic benefits from time savings due to reduced congestion. Such savings result in greater productivity and/or reduced labor costs. Where such benefits do occur, they reflect the drivers' wage rate and fringe benefits, plus certain other values related to the ownership and operation of the vehicle. Appropriate values of freight value of time for economic analysis range between $50 and $80 per vehicle-hour and sometimes higher. The estimated value often depends on the size of the truck, the goods being moved, and the distance over which the goods are being transported. Intercity trips tend to have higher time values than shorter trips.

**Out-of-Pocket Auto-Operating Cost Savings.** Variable (avoidable) motor vehicle–operating costs for auto users diverted to transit, carpools, or another facility represent an important source of potential project benefits. Fuel-, oil-, and mileage-related vehicle maintenance costs typically average 13 to 20 cents per mile. Assuming a vehicle left at home is not used by others during the day, the reduction in O&M costs are a net benefit to the driver.

For auto users diverted to transit modes, a factor must be applied to account for the fact that an auto typically can carry more than one person in the peak and off-peak periods. To get a reduction in the vehicle miles of travel, the number of auto person trips is typically divided by 1.15 to 1.2 for peak-period trips, and 1.25 to 1.4 for off-peak trips. Benefits in this category also include reductions in operating costs due to reductions in stop-and-go operation on free-flow facilities and a reduced number of stops on interrupted-flow facilities.

Operating cost savings to the owner of the facility would be considered benefits in the calculation.

**Savings Due to Reduced Injuries and Fatalities.** One of the major benefits associated with transportation investment is the reduction in the number and severity of crashes. These include crashes with other motor vehicles as well as crashes between motor vehicles and pedestrians or bicyclists. Estimating the safety benefits of a specific alternative requires one to identify the reduction in safety-related societal costs. One widely used source from the U.S. DOT suggests that the appropriate costs (in 2012 dollars) for crash categories for a single person injured is:

- Fatality: $9,100,000
- Critical injury: $5,396,300
- Severe injury: $2,420,600
- Serious: $955,500
- Moderate injury: $427,700
- Minor injury: $27,300 [USDOT, 2013]

The U.S. DOT also strongly encourages any safety analysis to use both a 3 percent and 7 percent discount rate in the analysis to assess the sensitivity of the analysis results to the choice of discount rate.

If these costs are to be used, they should be inflated to the study year. They represent comprehensive costs, including a measure of the value of lost life, obtained through empirical studies of what people would actually pay to reduce their safety and health risks. Even this raises some controversy because the actual economic costs—such as lost income, medical expenses, and the like—are generally much lower (for example, $1.1 million per fatality). Further confusion over the value of human life occurs given that several U.S. government agencies use different values for a single life.

**Estimating Costs and Benefits by Measuring Individual Preferences.** Two major approaches have been used to value benefits through the actual prices that consumers are willing to pay for them, or through some estimate of what they would be willing to pay. [Meyer and Miller, 2014] For example, on the presumption that consumers prefer houses on quiet streets to those on noisy ones, and are therefore willing to pay higher prices for them, transportation planners might compare the sales price paid for houses on streets with differing noise levels. In economic terms, consumers should be willing to bid up the prices of houses on quiet streets relative to noisy streets. This approach to valuing such benefits or costs is called revealed preferences (RP).

The disadvantage of this approach is that there are many factors that determine house prices in a neighborhood, not just noise levels. Of course, the size, quality, and sale date of the house must be considered and standardized by statistical techniques. But many other factors can come into play. Houses on noisy streets may be considered to be less safe (for example, higher traffic volumes may make it less safe for children); they may be closer to other noise generators (schools, commercial buildings); they may be considered dirtier (because of more vehicular and pedestrian traffic); and so on. In practice, it takes a very large amount of sales data to assess the impact accurately. See Diaz [undated] for additional literature and discussion. Nevertheless, through statistical techniques, this method has gained some currency, particularly for valuing environmental impacts, such as noise and air pollution.

RP data have also been used to estimate values of travel time when there is a tolled and untolled facility in proximity to one another, and data exists on which facility drivers use. Drivers who willingly pay a $2 toll to save 15 minutes of travel time must be valuing their time for that trip at a rate of *at least* $8 per hour (although we do not know how much more). This is one of the inherent limitations of RP methods. They tell us only about people's behavior given an observable choice set. If there is little variation across the attribute (for example, all houses in a city are exposed to an equal amount of traffic noise), there will be no way to determine the actual value placed on the attribute. Also, co-linearity between variables (variables where two or more attributes tend to be associated with each other) often exists, which makes the disentanglement of values placed on a single attribute extremely difficult.

Because of the problems inherent in RP methods, stated preference (SP) methods have been developed in an attempt to derive estimated values from hypothetical comparisons. Many of the same problems occur with RP and SP surveys, such as sample and response bias. SP methods have unique problems, including the wording and presentation of trade-offs (which is key to obtaining accurate values), and also the way the project impacts are presented to respondents for comparison (asking respondents how much they would be willing to pay for noise reductions in decibels will not elicit good responses). Questions presented without trade-offs ("Would you use … ?" or "How much would it be worth to you … ?") are likely to elicit invalid information. However, SP surveys do have the potential to examine a much wider range of conditions than exist at the time of the survey. SP surveys have been used successfully in studies to assess the value of travel time and in aesthetic/visual preference issues.

Good SP questions need to be counter-posed with the trade-offs involved. Asking people if they would use transit if it were available in their neighborhood is not likely to elicit as accurate a response as asking them if they would use transit if they had to walk two blocks and wait an average of 10 minutes for the bus to arrive, and if the overall trip would take 50 percent more time than by automobile.

**Distributional Impacts and Equity.** Equity addresses the question of who pays and who benefits from the expenditures of resources. An equity analysis is not required in every evaluation; in fact, it is probably appropriate only for very large projects, where potential costs (and benefits) are large, and the distributional impacts are uneven.

Even when projects have large net benefits, the distribution of costs and benefits can be uneven geographically among different income groups and between neighborhoods. For example, the construction of interstate highways in U.S. metropolitan areas unquestionably increased mobility; however, because of the nature of the highways, the relative gain in mobility was much greater for suburbs and outlying cities than it was for those in inner cities and near downtowns. In some cases, the interstates divided existing neighborhoods and, because of the closure of local streets, actually made some trips more circuitous. These impacts were generally ignored at the time much of the interstate was planned (the late 1950s and 1960s). In fact, some of the environmental legislation in the late 1960s in the United States relating to

road planning and construction originated because of egregious decisions on the part of transportation agencies (for example, aligning new freeways in parks, cemeteries, and low income neighborhoods because the land was cheap).

Equity is essentially a normative issue—that is, it concerns what ought to be. There is no completely objective way to assess what is an equitable impact and what is not. Facts can inform that decision. In the end, disagreements over normative statements cannot be settled solely by an appeal to facts. It is the public will, as expressed through elected officials in a democratic society, that determines what is equitable and what is not.

Assessment of equity impacts should generally begin at the stage of developing goals and objectives. For example, Table 7-1 indicated consideration of two potential equity impacts: (1) amount of tax base shifted from one jurisdiction to another and (2) impact on low-income neighborhoods and groups. These evaluation criteria illustrate common ways of looking at equity—spatially and modally—among income groups and for identifiable groups of people.

**Spatial Impacts.** Travel forecasting models and geographic information system (GIS) techniques have made it much easier to assess the spatial impacts of projects. For example, choropleth maps can be created fairly easily at the census geography or travel zone level, illustrating things such as auto availability, travel time accessibility by different modes, pollution impacts, and so on. Imagine a range of transit improvements in a city. The changes in travel times (positive or negative) could be examined at the traffic analysis zone (TAZ) level, with shades representing less than a 5-minute change in travel time due to an alternative, warm colors representing various levels of increases in travel time, and cool colors representing travel time decreases. The overall spatial impact on different areas and neighborhoods can become readily apparent from such a map. It is important to note that any project can have both positive and negative impacts; for example, a rail alternative might assume that parallel bus services are eliminated or redirected as feeders to rail stations. This may actually cause in-vehicle or overall travel times to increase for certain users.

**Modal Impacts.** These occur as the generalized cost of one (or more) mode(s) improves relative to that of other modes. High-occupancy vehicle (HOV) lanes might improve travel times for carpools and transit users but not for single-occupant vehicle users, which is a distributional impact. General capacity increases may reduce the use of transit in a corridor. These impacts are readily determined from the outputs of a multimodal travel model, although the state-of-the-art in predicting nonmotorized trips is such that, in most areas, only qualitative effects can be assessed for pedestrian and bicycle travel.

**Income Impacts.** Transportation impacts sometimes distribute costs and benefits unevenly because of the manner in which transportation projects are paid for. Transportation projects in the United States are most commonly funded through consumption taxes, such as taxes on gasoline or general retail sales. Such taxes have a tendency to be regressive; that is, they tend to take a higher share of income from poorer households than from richer ones. In 2011, the bottom 20 percent of U.S. household incomes spent an average 5.6 percent of their income on gasoline and oil, whereas the top 20 percent of household incomes spent just 4.3 percent. However, when one excludes gasoline from the expenditures, the bottom 20 percent spent 9.2 percent of their income on transportation, whereas the top 20 percent of household incomes spent 11.8 percent, likely reflecting the cost of vehicles. [AASHTO, 2013] Thus, even an apparently fair method of raising revenue, such as a tax on gasoline, disproportionately affects lower-income groups. If proportionality is a goal (that is, treating all income groups equally), the use of consumption-based taxes is not the best strategy.

Information on personal income can be obtained from the U.S. Bureau of the Census and the U.S. Department of Labor. There are other proxies that can be used for income that may be more current, if currency is important: (1) unemployment rates in an areas, and (2) areas experiencing job losses (or gains) in prior years.

**Impacts on Identifiable Groups.** Impacts also may occur disproportionately to ethnic minority populations, the elderly, or those with transportation disabilities, who are often geographically concentrated. For example, in many U.S. cities, ethnic minorities and immigrant populations are concentrated in parts of the region (most often in the center city or in dense, radial corridors) that do not benefit directly from investments in suburban transportation systems. In some cases, the courts have had to decide whether the investment using federal funds did or did not cause disproportionate hardship to such populations. These issues are addressed partly through the Executive Order on Environmental Justice (see chapter 1).

**Least-Cost Planning.** Another approach toward planning that has important implications for evaluation is least-cost planning, also known as integrated resource planning. Least-cost planning had, as its genesis, the energy planning efforts of the 1970s. It was found that under certain conditions, it might be less costly to promote energy conservation programs (for example, more energy-efficient appliances) than to build new energy-generating capacity. Utility

planners had traditionally only looked at the expansion of supply, rather than both the supply and demand for electricity. In some areas, least-cost planning led to laws requiring more energy efficiency in new appliances, additional insulation in buildings, and rebates to consumers for the purchase of energy-efficient appliances. This concept has been expanded to water conservation and other areas.

From an evaluation perspective, least-cost planning places great weight on the definition and valuation of all possible effects of a project and the determination of the least-cost approach, where costs include all societal costs. In addition, acknowledging and estimating uncertainty in the results of evaluation become an inherent part of the planning process.

## B. Evaluation Techniques

Many useful and valid methods can be used in transportation planning to evaluate the relative effectiveness of different alternatives. If a travel forecasting model is available, it can often provide many of the inputs necessary for a good evaluation (see chapter 6 on travel demand modeling). In fact, the problem may be that too much information is available, and the analyst's major challenge becomes choosing data that are key to the evaluation. There is also a danger that when much time and effort has been expended in developing a complex travel forecasting model, there will be a temptation to put too much faith in its results. Particularly with respect to long-range forecasts, the analyst should always be aware that many of the assumptions implicit in any forecast of conditions several decades from now may be subject to considerable uncertainty.

### *1. Selecting the Appropriate Analysis Method*

Two basic requirements of an appropriate evaluation procedure are that: (1) it should produce understandable results to those who make the final decisions, and (2) it should be appropriate for the range of alternatives under consideration and the complexity of decisions being made. Descriptions of four basic evaluation techniques are found in Meyer and Miller [2014].

**Effectiveness Matrix.** An effectiveness matrix is the simplest of all the evaluation techniques. A measure for each criterion and alternative is inserted into the cells of a matrix, where the columns represent the different alternatives under consideration, and the rows represent the different evaluation criteria. The value entered in the matrix may be an actual measured value, a ranking, or a normalized value (that is, adjusted to make the total of all the scores add up to one, or some other arbitrary number, such as 10 or 100). This matrix enables stakeholders and decision makers to see the effectiveness of each alternative compared to all the other alternatives. This technique is useful if the number of alternatives and evaluation criteria is reasonably small, and the costs and benefits are difficult to measure. Cell entries may be, for example, best or worst, may rank the alternatives from one through $N$ alternatives, or may consist of judgments as good, poor, or average. Effectiveness matrices are often used in environmental analyses.

**Aggregate Ranking.** If an effectiveness matrix becomes too large and unwieldy to assist in making a decision, bottom-line scores may be derived through some form of aggregation. Use of normalized values provides a good method of aggregating measures with different units or dimensions. A second method of aggregation involves summing the scores associated with the criteria for each alternative. The aggregation may be made for each category of criteria (performance, impact, and implementation) and/or for all criteria together. Evaluation scores must be made at the ordinal level of data measurement, such as best (first) to worst (last). Alternatively, ratio-level scores may be developed for each alternative (for example, Plan A has 92 percent of the ridership of Plan B).

Careful attention should be given to selecting the appropriate evaluation criteria (this is true of most evaluation techniques, but particularly for aggregation approaches). Unless criteria are weighted, the selection of less important criteria can bias the selection toward a less desirable alternative. Alternatively, bias can be introduced with weights if they do not reflect local values as expressed by the goals and objectives defined outside of the evaluation process. Weights may sometimes be developed as part of the development of the goals and objectives in the public participation process, with a technical advisory committee, or both.

Final selection of an alternative often requires the weighting of criteria to reflect the varying importance of the objectives being measured. Input from citizens and elected officials is essential in determining proper weighting so that the complete range of differing viewpoints and interests will be represented in the final analysis. A case study applying aggregate ranking to conversion of one-way streets to two-way operation is provided later in this chapter.

**Cost-Effectiveness.** This evaluation method can be used as an independent technique or in combination with the two above. This procedure involves the direct comparison of two related criteria or groups of criteria. Usually, the monetary cost of each alternative is compared to some performance measure of the plan or project. Alternative improvements may then be compared based on their efficiency in meeting common objectives. For example, cost-effectiveness methods have been used to assess noise reduction strategies (dollars per decibel reduction), water-quality improvements (dollars per salt concentration reduction) and transit investments (annualized dollars per new rider). The method is particularly useful when plans are being measured against benefits for which it is difficult to assign a dollar value.

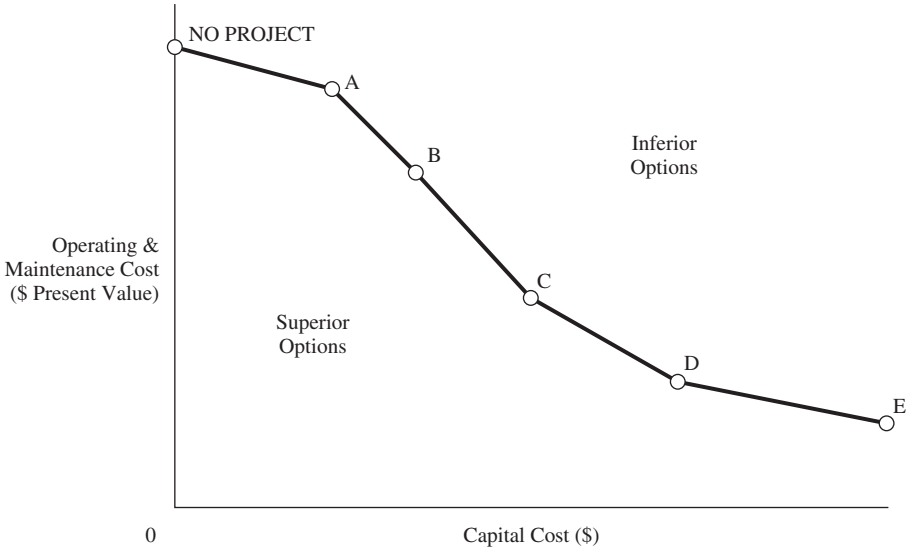
A common example in transportation safety is the proper value to place on a fatality. Rather than attempting to make such a valuation, which inevitably will be subjective and controversial, the planner can merely keep the original units in the comparison. For example, during a 20-year period, Plan A might eliminate 40 injuries (compared to some baseline) at a total cost of $50,000, while Plan B saves 55 injuries at a cost of $65,000. Thus, comparing plans, B costs $15,000 more than A, but results in 15 fewer injuries. The relevant question to ask is, "Is each injury reduction worth at least $1,000?" If it is, then Plan B dominates; if not, then Plan A is preferred. This gives decision makers the opportunity to subjectively evaluate the costs and benefits (or output measures) of the plans. The planner is not required to determine the exact value of a prevented injury. The key in cost-effectiveness analysis is to look at differences between the results of alternatives, divided by the difference in cost. This is illustrated in Figure 7-3.

One approach, perhaps not entirely satisfactory, is to evaluate the project with ranges of costs associated with the difficult-to-quantify factors. If there is a positive net benefit even with high values placed upon the nonmonetary costs, it is likely that the project is desirable. On the other hand, if even low values placed on nonmonetary costs result in low, or negative, net benefits, transportation planners may conclude that the alternative is not desirable. In most cases, however, many project alternatives are likely to fall between these two extremes.

**Benefit/Cost Analysis and Net Present Value (or Net Benefit).** These related measures (sometimes also called cost/benefit analysis) involve measuring as many criteria as possible in terms of monetary units (dollars). The performance criteria represent the benefits, while the impact and implementation criteria represent the costs. Costs are usually easier to estimate than benefits simply because they are already expressed in dollar terms. Because many costs usually occur in the early stages of a project, and benefits are spread out over a number of years (see Figure 7-4), discounting is used to bring all monetary streams (both costs and benefits) back to a current year (usually the year in which the analysis is being done). That way, the costs and benefits can be put in equivalent year values. Discounting is discussed in greater detail later in this chapter.

The alternative with the largest net benefit (present value of discounted benefits minus present value of discounted costs) is the best alternative. Net benefit must exceed zero to justify the plan/alternative, and typically it must do so by a considerable margin.

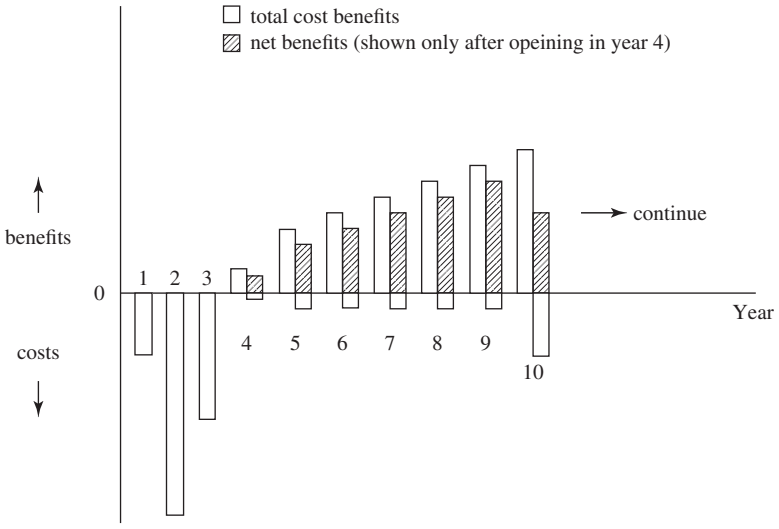
**Figure 7-3. Illustration of Cost-Effectiveness Evaluation**



Benefit/cost (B/C) ratios should be used with great care because of the misleading results they can produce. Small projects often have very high B/C ratios, but are not necessarily the only project that should be undertaken. Large projects may include components with poor B/C ratios, and the ineffectiveness of these components may be masked by averaging them with other components with high B/C ratios. Both B/C and net benefit evaluations suffer from the limitation that they require dollar values for all benefits.

Another important point to recognize with B/C analysis is that when multiple projects are being compared, the incremental B/C of one project over another is the key to best project selection, not just the overall B/C ratio. The incremental B/C ratio of project *j* compared to project *k* would then be:

**Figure 7-4. Illustration of Costs and Benefits for a Major Transportation Investment**



$$\text{Incremental B/C of project } j \text{ over } k = (B_j - B_k)/(C_j - C_k)$$

Remember, this incremental approach was also true for cost-effectiveness analysis.

A simple example illustrates the concept of incremental B/C ratios, as well as the mistake of simply accepting the first B/C ratios as the criterion for selecting the best project. Assume that a planner has estimated the present value of costs and benefits as shown in Table 7-4 for five projects. As can be seen from this table, project A has the largest B/C ratio, and thus one might be tempted to choose this project. However, one must first conduct an incremental B/C analysis to make such a determination.

First note that the B/C ratio for project C is less than 1.0, so this means that project C is no longer in consideration. Comparing the lowest cost alternative with the next highest alternative, we look at the value of A compared to B.

$$\text{Incremental B/C Comparing B to A} = \frac{PVB_B - PVB_A}{PVC_B - PVC_A} = \$\frac{460{,}000 - \$375{,}000}{\$200{,}000 - \$150{,}000} = 1.7$$

Given that the incremental B/C ratio is greater than 1.0, the higher cost alternative (B) dominates the lower cost alternative (A). In plain English, what the 1.7 means is that for every $1 of additional cost to construct project A, one would get $1.70 in additional benefit. In the absence of any extenuating circumstances, this would be a logical action to take.

We now conduct the next incremental B/C analysis by comparing project D to project B, remembering that project C is no longer in the mix.

$$\text{Incremental B/C Comparing D to B} = \frac{PVB_D - PVB_B}{PVC_D - PVC_B} = \frac{\$500{,}000 - \$460{,}000}{\$250{,}000 - \$200{,}000} = 0.8$$

**Table 7-4. Example Benefit/Cost Analysis**

| Discounted Benefits and Costs | | | | |
|---|---|---|---|---|
| | **A** | **B** | **C** | **D** |
| *PVB* | $375,000 | $460,000 | $500,000 | $500,000 |
| *PVC* | $150,000 | $200,000 | $550,000 | $250,000 |
| *B/C* | 2.5 | 2.3 | < 1.0 | 2.0 |

Given that the incremental B/C ratio is less than 1.0, the lower cost alternative (B) dominates the higher cost alternative (D). Or in plain English, spending an extra $1 to construct project D will earn you $0.80, not a good return on your investment. Thus, alternative B is the recommended project.

Note in this case that the initial B/C ratios of each project gave project A the highest initial value, and yet project B was the recommended choice. This is one of the mistakes often made by engineers—choosing the highest B/C ratio after the initial comparison. In other words, we want to find the project alternative with the highest marginal benefit per additional unit cost which may not necessarily be the project with the highest overall benefit/cost ratio. Also note that by simply finding the net annual worth, we would have chosen project B immediately because it has the highest NPV ($460,000 − $200,000 = $260,000).

B/C analysis and net present value work best when there are active markets for goods and services that can be used to provide prices for the additional expenditure or savings. An alternative that reduces fuel consumption by 30,000 gallons per year can be said to save $90,000 a year if fuel is valued at $3 per gallon. However, not all items have active markets. Most environmental costs do not, nor do health effects. A shortcoming of B/C analysis is that it cannot assess the large number of social, environmental, and political effects that often must be considered in evaluating large projects. Various attempts have been made to place monetary values on factors such as noise, air pollution, aesthetics, displacement, safety, and so on, that are intrinsically difficult to value. Generally, there has been a tendency to ignore these nonmonetary costs in B/C analysis because they are difficult to value, and this can result in a biased selection of alternatives.

For an overview of benefit/cost techniques for evaluating highway investments, see FHWA's *Economic Analysis Primer* at http://www.fhwa.dot.gov/infrastructure/asstmgmt/primer05.cfm.

**Return on Investment.** Return on investment (ROI, or rate of return) is another technique applicable to analyses in which cost and benefits can be measured in dollar terms. The rate of return is the interest rate that makes the costs equivalent to the income stream. For example, a $300,000 investment will result in new operating revenue of $50,000 per year, and annual operating costs of $20,000 per year. It is estimated that the salvage (resale) price of the investment will be $150,000 in 10 years. The rate of return on this investment would be approximately 6.2 percent per year.

An obvious limitation of the ROI method is that although it tells us the rate of return on the investment, it says nothing about the overall benefit achieved. A very small project might have a very high rate of return, whereas a large project might have a lower but still substantial rate of return. This does not mean that the very small project should be chosen over the large project. Rate of return has mostly found favor in the private sector, where it is sometimes used to guide management investments and evaluation of performance. The popularity of ROI has caused some confusion, however, in public-sector evaluation. The interest rate charged (effectively a discount rate for the project) in the private sector will almost always include the risk associated with borrowing the capital funds to build the project; firms teetering on bankruptcy can only sell bonds at interest rates much higher than those of a stable, profitable company. This is known as a risk premium.

In public-sector economics, it is better to consider risk through an explicit evaluation of different outcomes, rather than through a higher discount rate. Private-sector risk often includes the possibility of default—that is, the bonds (or other financial instruments) have zero value. In the public sector, the risk is generally that costs will be greater, or benefits lower, than forecast (or both). This is discussed in the section on risk and uncertainty.

**Project Evaluation Period, Useful Life, and Salvage Values.** Costs and benefits are usually accumulated over a project period that represents some reasonable planning horizon. The planning horizon will depend on the nature of the project and the technology employed. Ten to 30 years is most common, although occasionally analyses are done for 40- or 50-year periods. Long evaluation periods are problematic because the accuracy of the projections of demand and usefulness of the improvement becomes increasingly less certain as the project time horizon is extended into the future. Technology—along with public attitudes and values—may change in unpredictable ways. A reasonable rule of thumb for defining a planning horizon is to use the service life of the alternative with the longest service life under consideration. This is usually not more than 40 years.

Different components of a transportation system have differing service or useful lives. Some commonly used values are shown in Table 7-5. Those with an asterisk are ones specifically recommended by the Federal Transit Administration (FTA).

| Table 7-5. Typical Service Lives of Transportation Assets | |
|---|---|
| Diesel bus (urban standard) | 12 years* |
| Mid-size bus (medium duty) | 10 years |
| Van (9–15 passengers) | 4 years |
| Rail vehicles | 25 years* |
| Fixed guideway trolleys | 25+ years* |
| Parking lot | 20 years* |
| Parking structure | 25 to 50* years |
| Fixed facilities (stations, structures) | 50+ years* |
| Land (including clearance and relocation) | 100* years to Infinite |
| Pavement (asphalt) | 20 years |
| Train control systems | 30 years* |

Source: FTA, 2008

These estimated service lives assume a relatively high level of maintenance (both corrective and preventive); thus, the service life is a function of technological obsolescence, rather than of the physical deterioration of the subsystem itself. Technical obsolescence can be due to a number of factors, including better ways of doing something, maintenance costs growing relative to the replacement costs, and better uses for the asset. As an example, high fuel prices can make a serviceable transit fleet obsolete because of the availability of newer, more fuel-efficient vehicles.

The useful lives noted above assume that there will be periodic major maintenance and overhaul activities, which must be included in the cost analysis. These occur at various intervals throughout the study period. For example, a study period of 25 years may require that a bus fleet be replaced twice—once at year 12 and again at year 24. A capital recovery factor (annualized cost) can be used to avoid the problem of the leftover or residual values of the vehicles in the 25th year. Because land is technically not "worn out," it typically has an infinite life. (The difference between the assumption of 100 years and infinite is virtually nil in the discount tables.)

Longer useful lives, all other things being equal, will tend to reduce the annualized cost of an asset. Because of discounting, the analysis will not be very sensitive to errors made in the far "out" years; for example, there is a relatively small difference between the annualized cost of an asset lasting 30 years and one lasting 35 years. However, the error can be substantial with mis-estimation in the early years. For example, the difference in annual cost for an asset lasting 5 years is very different from one lasting 10 years.

Salvage values represent the value of a project or project component at the end of the study period. Just like an old car being turned in for a new model, most of the components noted have some remaining value at the end of their service life. However, because many of the subsystems have long service lives, the salvage value is typically not realized until some distant out-year. Thus, it is often more convenient to ignore them as part of the economic analysis. In addition, the values are often insignificant because they are so small at the end of a long project evaluation period, and their present worth often turns out to be less than 1 percent of the cumulative project cost. With increased emphasis on recycling building materials, however, this could change for certain physical assets.

### *2. Definition and Use of Discount Rates*

Because projected costs and benefits occur at different times, a present-value analysis needs to be employed to account for the *time value of money*. A discount must be applied to future values because a dollar received today is not the same as a dollar received in the future—even after making allowance for inflation and the risk of not being paid. The present value (or present worth) of net project costs is the basic cost measure used in comparing costs and the cost-effectiveness of alternatives. A discount factor is used to convert future costs and benefits to a present-year value. Thus, the annual estimates of future benefits and costs are discounted to present values using a discount factor that acknowledges the potential rate of return from an alternative investment of the same amount of money.

Given a discount rate of $r$, an interest rate of $i$ and costs (or benefits) occurring $t$ years from now, the equation that relates future values to current values is given as:

$$F = P(1 + i)^t \text{ or } P = F/(1 + r)^t$$

where:

$P$ = Present value of an amount
$F$ = Equivalent future value of the amount (nominal dollars)
$i$ = interest rate per annum
$r$ = discount rate per annum

In this equation, estimating the future value of a present sum uses an *interest rate* similar to the interest rate provided by lending institutions. However, if you want to estimate the present value, $P$, of a future sum, $F$, then you discount the future sum to the present time with a *discount rate*. The discount or interest rate is expressed as a decimal value. For example, a 7 percent discount rate would be 0.07. If a cost (or benefit) accrues 5 years from now, with an interest rate of 5 percent, the interest rate factor applied to it should be $(1 + .05)^5 \approx 1.28$. In other words, $1.00 in current costs (or benefits) is equivalent to $1.28 five years from now assuming an interest rate of 5 percent. Or alternatively, a future value of $1.28 is equivalent to $1.00 in current costs (or benefits) discounted over 5 years at a 5 percent discount rate.

As can be seen above, strictly speaking, a discount rate is not identical to an interest rate. In public sector economics, a discount rate actually represents society's preference between the value of consumption today and consumption in the future—in other words, a social time preference rate. Most practicing planners and engineers will not have to deal with this distinction, but should be aware it exists. There are many readings on engineering economy for those interested in pursuing this topic in greater depth (see, for example, [Berechman, 2009; Sinha and Labi, 2007; and Markow, 2012]).

Choice of the appropriate discount rate can often be a controversial decision. Discount rates in the range of 5 to 10 percent are most commonly used. For a U.S. federally funded project, at least one analysis must be done with a 7 percent discount rate, as mandated by the U.S. Office of Management and Budget (OMB) in Circular A-94. As noted by OMB, "The 7 percent rate is an estimate of the average before-tax rate of return to private capital in the U.S. economy. It is a broad measure that reflects the returns to real estate and small business capital as well as corporate capital" (see [OMB, 1992] for further discussion). Interestingly, the FTA recommends a discount rate of 2 percent for major transit investment analysis.

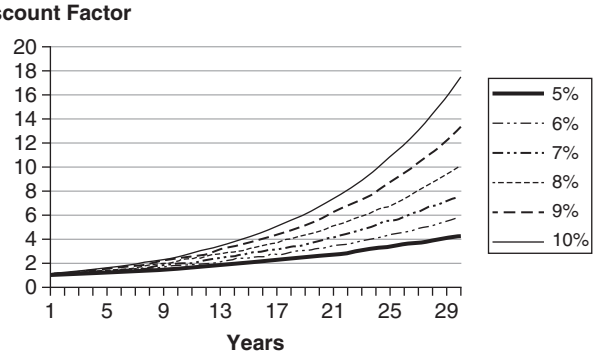
Many agencies prefer to use as their discount rate the interest rate at which they can normally borrow funds. For example, at the time of this writing, most U.S. state and local public agencies can issue long-term bonds at an interest rate of 2.5 to 5 percent per annum that are exempt from state and federal taxation.

One approach to defining a discount rate is based on the concept that the no-build alternative, which by definition assumes little or no investment, leaves money available in the lending market for private sector investment. Thus, the discount rate could be estimated as the assumed rate of return on an alternative private investment with the amount of money needed for a build project, before taxes and excluding inflation.

The higher the discount rate, the greater the comparative effect on the economic efficiency of costs incurred during the early years of the project period, and the lower the comparative effect of costs incurred in later years. Thus, low discount rates will favor large, capital-intensive projects with long lives, whereas high interest rates will favor projects with lower capital, greater operating and maintenance costs, and shorter useful lives. This is why capital-intensive projects in countries with very high interest rates (for example, much of the developing world) do not make as much sense to investors as in countries with relatively low costs of capital, all things being equal.

Figure 7-5 graphically shows the effect on present worth of discount rates between 5 and 10 percent over a period of 30 years. Note that after 30 years (the far right of the graph), $4 at a 5 percent discount rate and $17 at a 10 percent discount rate are both equivalent to $1 in current dollars. The analyst can either program the formula noted earlier for discount factors, use several widely available software packages, or use tables available in most textbooks dealing with engineering economy or economic evaluation.

**Figure 7-5. Effect of Discount Rate on Present Worth**



**Capital Recovery Factor.** Once a useful life and discount rate have been selected, it is possible to define an annual capital recovery factor (CRF) for an asset. The CRF is merely a combination of the cost of funds tied up in an investment, plus an annual amount to recover the asset's depreciation and replacement costs. More formally, it is the future series of end-of-period payments that will just cover a present sum ($P$) over $t$ periods, with compound interest $r$. The CRF is estimated as:

$$CRF = \frac{r(1+r)^t}{(1+r)^t - 1}$$

Tables are widely available in engineering economy textbooks for different interest or discount rates, and number of time periods (usually in years). Notice that over a long period ($t$ is very large), the CRF will approach $r$ as a limit. Here is an example:

What is the CRF and annualized cost of a $300,000 bus, assuming no salvage value and a 7 percent discount rate? The useful life of a bus, as previously noted, is 12 years. Thus, the CRF will be:

$$CRF = \frac{0.07(1+0.07)^{12}}{(1+0.07)^{12} - 1} = \frac{0.15765}{1.2522} = 0.1259$$

Of this amount, one-twelfth (or 0.08333) will be for depreciation of the asset (assuming the bus depreciates uniformly over 12 years), and the remainder (0.04257) for the average payment on the remaining balance. The annualized cost will be:

$$\$300{,}000 \times 0.1259 = \$37{,}770 \text{ per year}$$

The example includes some rounding. In most cases, it is not necessary to carry out the results to more than four or five decimal places unless a very large sum is involved. CRFs can also be extremely useful in thinking about renting an asset at a given rate of return (the discount rate). They can also be used to determine the equivalent annual cost of assets with varying service lives.

**Effects of Inflation.** Annual costs and benefits are usually measured in constant (for example, 2016) dollars, thereby excluding the effects of inflation. Adjustments are sometimes made to base unit costs to account for net or real changes in the economic values for costs expected to change at rates higher or lower than the average inflation rate in the economy. Although some cost items at one time rose faster than inflation, historically, future extrapolations of such differences have not been very accurate. Some forecasts have been spectacularly wrong, especially because sharp price spikes sometimes turn out to be relatively short-lived.

The important thing to understand is that inflation will have no effect on determining present values for the economic efficiency analysis. Inflation will, however, be a major consideration in the financial feasibility analysis for which projections of future capital and operating needs will have to be expressed in inflated dollars. Basic financial comparisons are usually performed using an assumed inflation rate, or better yet, a range representing the most reasonable optimistic (lower) and pessimistic (higher) rate range. A "real" discount rate is the discount rate net of inflation and is used to estimate constant dollar amounts. A "nominal' discount rate includes the rate of inflation and is used to estimate current or end-of-year dollar amounts.

An oft-heard complaint is: "If we don't build this now, the cost will keep going up due to inflation!" The economic cost of the project is determined by real resources that must be invested in the project: hours of labor, pounds of steel, cubic yards of earth moved, and so forth. If correctly estimated, these quantities should change little over time. On the other hand, financial costs—wage rates, unit prices for materials—mostly increase over time due to inflation. Thus, from a financial perspective, that is, the amount of money that will be necessary to build the project in the future, the complaint is correct.

Take an example of a project estimated to cost $30 million if built today. Waiting until next year, with inflation at 5 percent per year, the project will cost $31.5 million. If project funds were placed in an investment earning 5 percent per year, there would be $31.5 million next year to build it. Of course, the problem with this illustration is that most government budgeting works with a fixed dollar amount without regard to inflation. If the funding agency has set aside a fixed amount (such as $30 million) for the project, then someone will have to come up with the additional $1.5 million at the actual time of construction next year, to cover inflation. However, this problem

is due to governmental budgeting practices, not due to inflation. The more important issue is that whatever benefits the project would have produced in the year's delay are lost. The lost travel time, cost of crashes, and so forth, cannot be regained.

### *3. Treatment of Risk and Uncertainty in Project Evaluation*

Inadequate treatment of uncertainty (risk) and potential error in cost estimates has been a recurring problem for major transportation projects (both highway and transit). Generally, the tendency at the planning stage has been to underestimate costs and overestimate benefits (see, for example, [Button, 2009; Danata et al., 2006; and Flyvbjerg et al., 2002]). Defining error as the difference between the planning estimates and the actual cost to build the project, it is possible to identify four potential sources of error:

1) Changes in the scope of the project
2) Changes in the design standards used to build the project
3) Incorrect unit cost assumptions in the planning estimates
4) Unforeseen problems in implementing the project (including delays)

Each of these is briefly covered below:

*Changes in Scope*—In the project planning phase, planners often face a wide variety of options: alignments, degree or type of grade separation, length and location of the facility, design speed, quality of service, and so forth. The design speed and quality of service overlap with changes in design standards. Citizen participation in the project development process may result in scope changes at a later phase of development, which is one reason for incorporating stakeholder participation early in the planning process. For example, citizen protests regarding an elevated freeway might require it to be placed below grade in a cut. Another example is costing a bus tunnel and then later deciding to add tracks to accommodate a future light-rail system. Unforeseen environmental mitigations are also incorporated, including remediation of toxic substances.

*Changes in Design Standards*—These are similar to the broader uncertainties about scope, but are more specific in nature. Design standards cover the entire range of the physical characteristics of the project, including vertical and horizontal clearances, seismic standards, materials, upgrading amenities, environmental mitigations, and so forth. Examples include: (1) requirements for higher vertical clearances for all new interchanges after the cost estimates had been prepared, (2) changes in accessibility requirements for the disabled/handicapped, (3) revisions to flood maps requiring higher elevations, and (4) discovery of endangered species, requiring additional study (time delays) and project mitigation.

*Errors in Unit Cost Assumptions*—A variety of potential errors exist in the unit cost assumptions used in project planning. Unit costs are generally derived from actual (submitted) bids from other similar projects. These costs are averaged from several projects. Their transfer to the current situation is often uncertain in terms of the commonality of definitions used for both the historic data and the unit costs defined for the project planning effort. The use of cost averages from comparable projects can also introduce errors because of cost differences due to time of construction, region of construction (costs can vary widely even county to county), incomplete understanding of all elements of "comparable" projects, and the like. Additional uncertainty in unit costs includes the availability of appropriate construction firms and skilled labor, the bid climate during the construction period, the actual quantities supplied, and fluctuations in basic materials prices.

*Difficulties in Implementation*—Perhaps the largest source of uncertainty in costs during the planning stage is the inability to anticipate difficulties that will be uncovered in later stages of project development. These uncertainties often come with right-of-way acquisition, utility relocations, soil conditions, lawsuits, and discovery of historically significant artifacts during excavation. Delays in implementation generally raise costs because of inflation and because of the costs of stopping and then remobilizing labor. Contractors may be owed special payments for such stopping and restarting, and scope changes during construction (*extra work orders*) can prove costly because there is relatively little bargaining power with the contractor who is already contracted to do the work. Encountering the unexpected during construction is not unusual; archaeological finds, toxic wastes, flammable or poisonous gases, water intrusion, and unforeseen damage to nearby buildings have all been factors raising the cost of major transportation projects in recent years. Wilson discusses the role of value engineering (VE) and risk management in controlling such costs. [Wilson, 2005]

The problem of cost mis-estimation is international in scope, with many high-profile megaprojects going over budget by significant amounts. Flyvbyerg et al. [2003] found numerous examples of cost overruns on large projects, including

the Boston, Massachusetts, Central Artery (actual cost was three times the estimate); the Humber Bridge in England (actual cost was 2.75 times the estimate); the Washington, DC Metro (actual cost was 1.85 times the estimate), and the Channel Tunnel rail project (actual cost was 1.8 times the estimate). Their other significant conclusions about large infrastructure projects included:

- Ninety percent of very large infrastructure projects had underestimated costs.
- Rail projects had the worst cost accuracy, costing on average 45 percent more than the estimates.
- Tunnels and bridges cost 34 percent more on average than estimated.
- Roads were 20 percent more costly on average than estimated.
- Over all, transportation projects were 28 percent more costly than estimated.
- Cost underestimation has not decreased over time; no learning seems to be taking place.

One way of dealing with uncertainty, especially for cost estimates, is to assign contingency factors to cost estimates during the planning stage. The net effect of this approach is to increase project cost estimates (especially for cost estimation during project planning stages) to take uncertainties or risks into account. For example, Table 7-6 shows contingency percentages (of the estimated project costs) associated with different components of a planned streetcar line in Washington, DC. Allocated contingency is used for projects where the engineering design level is determined to be less than preliminary engineering completed. Because project information is incomplete for individual components of the project, and the risk associated with this lack of information is potentially large, a contingency allowance is added to the planning cost estimate. Unallocated contingency is primarily an allowance for unknowns and risk related to the level of engineering design completed. As a project or alternative goes through more detailed engineering, the uncertainties should decrease, and thus the contingency percentages as well.

Another way of treating uncertainty is to assign probabilities to specific outcomes. For example, consider Table 7-7, showing the net present value of benefits for three projects. The rankings of the three projects will depend on the ultimate outcome. Under the most optimistic or most likely outcome, Project A is superior to the others, but under worst-case conditions, it is far worse. Let's say that there is a 10 percent probability that either the best or worst case will occur, and an 80 percent probability that the most likely outcome will occur. Expected values can be associated with each project:

$$E(\mathrm{A}) = (0.1)500 + (0.8)(100) + (0.1)(-500) = +80$$

$$E(\mathrm{B}) = (0.1)(400) + (0.8)(50) + (0.1)(0) = +80$$

$$E(\mathrm{C}) = (0.1)(80) + (0.8)(80) + (0.1)(80\ ) = +80$$

In this example, all three projects have an equal expected value. If there is no good reason to alter either the probabilities or the net benefit estimates, risk aversion may be a tie-breaker. Project C, although it has the poorest payoff under either the best or most likely case, is a "sure thing." Project A offers the highest potential payoff under the most optimistic set of assumptions, but also has a very large downside risk. It may wind up having substantial negative net benefits. Other factors that might be considered include: (1) equity impacts of the various projects and (2) support among the public or decision makers for specific projects (including level of controversy).

An obvious limitation on the expected value technique is that it may be difficult to assign reliable numbers to the probabilities of outcomes. Some ways of doing so might be through Delphi planning techniques, with simulation techniques for inputs and assumptions, or by looking at the outcomes of other projects of a similar size and nature. [Small, 1999] For example, if a third of similar projects ran 50 percent over budget, a worst-case analysis might include a scenario in which costs actually turn out 50 percent greater than assumed for the analysis.

**Risk Assessment in Climate Change Adaptation Planning.** The transportation planning profession has begun to consider the potential effects of a changing climate on the performance of the transportation system. Such a consideration takes uncertainty to a new level in transportation planning—what will a change in climate 50 years from now mean to transportation systems, and what should we be doing now in terms of facility design or land-use plans to reduce such impacts?

| Table 7-6. Contingency Percentages for Planning Estimates, Anacostia Streetcar Project, Washington, DC | | |
|---|---|---|
| **FTA Category No.** | **Description** | **Allocated Contingency Percentage** |
| **Allocated Contingency** | | |
| 10 | Guideway and Track Elements | |
| | • Guideway elements (except underground) | 25% |
| | • Guideway elements (underground) | 35% |
| | • Track elements | 20% |
| 20 | Stations, Stops, Terminals, and Intermodal | 20% |
| 30 | Support Facilities: Yard, Shops, and Admin Buildings | 20% |

According to FHWA, "A risk assessment integrates the severity or consequence of an impact with the probability or likelihood that an asset will experience a particular impact. To determine consequence, transportation agencies may wish to consider the level of use of an asset, the degree of redundancy in the system, or the value of an asset (in terms of cost of replacement, economic loss, environmental impacts, cultural value, or loss of life)." [Federal Highway Administration, 2012] Table 7-8 shows some of the evaluation techniques that could be used to assess the risks associated with climate change adaptation projects.

Source: Wall and Meyer, 2013 adapted from Willows and Connell, 2003

One of the approaches suggested by those who have examined this issue is a risk-based planning approach (see [Meyer et al., 2014; Wall and Meyer, 2013] for an overview of risk in climate adaptation planning).

### *4. Typical Problems, Issues, and Errors in Project Evaluation*

This section reviews some common errors and misunderstandings that occur in evaluating transportation projects. It is intended to illustrate frequently found errors, rather than an exhaustive review of all possible problems.

**External Funds (Grants) Are Subtracted from the Capital or Operating Costs of the Project.** External grants (for example, from a state or federal agency) represent real resources and as such must be counted in the cost calculation for the project. Although external grants may provide local economic benefits, their application to a specific project means that resources have been diverted from other uses or other entities paying taxes. Therefore, external grant sources should never be subtracted from costs.

This problem can also lead to selection of capital-intensive projects because external funding programs will often pay for capital but not operating or maintenance expenses. Although this problem can be noted in the analysis, a fair analysis should still consider all real resources used. External grants (or any other matching funding, for that matter) may be legitimately considered at the prioritization stage of project development.

**All Costs of the Project Are Not Included (Construction Period Delays, Energy Use).** This problem frequently occurs in highway construction projects, where the cost of traffic delays during construction is omitted. Including such costs gives a truer picture of the benefits of an improvement and may also lead to better traffic-control plans during construction to minimize construction delay. Another example is in the analysis of the net energy payback from transit projects. In some cases, the considerable energy used in constructing a subway has been ignored, and only the operating and maintenance energy consumption of the subway versus autos is used. Ignoring the energy used during a construction project will bias the result toward a lower operational energy cost.

**Some Benefits Are Double-Counted.** This occurs very often in analyses that consider both user and supplier impacts. For example, in one study of the social costs of automotive use, the authors calculated the total cost of crashes, then added in auto insurance premiums to get a total cost of crashes. In reality, of course, insurance offsets some of the cost of crashes; only the amount not compensated by insurance should appropriately be considered in such a calculation. Another example includes travel time savings from a new rail system and increases in property values near stations. In fact, this is a double-counting because the increase in property value is merely a way that property owners reap a benefit from reductions in user travel time; one is a function of the other, and adding the benefits together results in double-counting.

**Average Rather Than Marginal Costs/Benefits Are Used in the Analysis.** In economic decision theory, it is the *differences* between alternative choices that count, not the average value. As economists say, all decisions are at the margin. What counts is how much additional benefit can be achieved for how much additional cost. The average cost is not the relevant consideration. Average costs (or benefits) are often used to mask politically motivated decisions.

**Differences between Market and Societal Costs (Prices) Are Ignored.** Ignoring societal costs of inputs or byproducts of a project can again lead to less than optimal decisions and overconsumption of a good. One such case is that of a city considering electric trolley buses to replace diesel services. One of the major operating costs of the system was electrical power. The city also owned a hydroelectric-power system, which would sell excess power to other departments at a cost based on the historical investment cost of the system, which was about 2.5 cents/kilowatt-hour, a price well below the market rate. This energy price was used in the economic assessment of the replacement service.

The economic evaluation should have used the going market rate. The opportunity cost of the power was the price at which it could be sold to willing buyers (for example, a local private utility). That cost was easily determined because such a market existed; the lower price reflected a bias among the evaluators to promote electric trolley bus services.

**An Inappropriate Discount Rate Is Chosen.** Excessively low discount rates will artificially favor projects that are capital-intensive and have a very long life. Many water projects in the United States have been historically based on 3 percent discount rates and 100-year service lives—assumptions that tended to strongly favor major capital investments. Any analysis using a discount rate less than the agency's cost of capital—currently at least 4.5 percent—should be suspect. At least one analysis should be done using a 7 percent rate. In less developed countries, higher discount rates may be appropriate to reflect the scarcity of capital available for investments.

**Network and Other Important Effects Are Ignored.** Examining a significant improvement in isolation from the rest of the transportation network is likely to give misleading results, especially when it is part of a congested network. For example, if only the travel time benefits to a single route are examined, the benefit to parallel facilities (in terms of reduced delay, collisions, and the like) will be improperly ignored. These effects can only be estimated when a network travel model is available. The author's experience has been that in certain instances, the travel time savings to other nonimproved facilities is as great, or greater, than the benefit to the improved facility when the network is highly congested.

Similarly, the analyst should be careful that when estimating travel time savings due to new capacity, the impact of travel time shifting is accounted for. This effect has been shown in a number of empirical studies: When new capacity is available, drivers may shift their travel time closer to the peak hour, negating some of the benefits of the capacity increase. Naturally, there is some benefit to drivers who can time their trips closer to the time they would prefer to make them, but the point is that the benefit analysis, which is based on travel time savings, may overestimate the improved travel speeds. Similarly, if the project will save a considerable amount of driver time, it may draw some passengers from parallel transit routes or, if high-occupancy vehicle (HOV) lanes are to be implemented, some transit riders may switch to carpools.

## C. Prioritization and Programming of Projects

Once a set of desirable projects has been developed, it is necessary to identify which projects are better than others, and also to establish the timing for project implementation. This timing will need to consider budget constraints (not all projects can be done at once) and also the precedence and interdependencies between projects (Project B may require that Project A be completed first in order to be effective).

Project prioritization is inherently normative, with the usual objective being "given a budget constraint of *x* dollars over *y* years, what combination of projects will maximize the benefits achieved?" For example, a metropolitan planning organization (MPO) might have discretion over $20 billion in capital investments over 20 years (not all available equally each year). The budget constraint is assumed to be exogenously determined (that is, taken as a given), although information on project benefits might be used to persuade decision makers to increase the budget, if justified.

A peer review of state department of transportation (DOT) and metropolitan planning organization (MPO) efforts at multimodal project prioritization made the following recommendations in developing prioritization criteria.

- Criteria should be simple and articulated at a high level to keep decision making transparent.
- Prioritization criteria should calculate the benefits of proposed projects, and not simply assess the existing conditions.
- The content of long-range transportation plans and other multimodal plans should support an agency's choice of prioritization criteria.
- Agencies should choose a manageable number of criteria (i.e., five or six) to focus on meaningful and comprehensible outcomes.
- Criteria should focus on impacts to the traveling public rather than on impacts to infrastructure itself (e.g., amount of traffic crossing deficient bridges rather than the number of deficient bridges).
- Criteria should consider the context of each project (e.g., a rural project should not necessarily lose points for not including sidewalks).
- Where possible, criteria should rate projects based on mode-neutral characteristics, such as "asset condition" rather than "pavement condition."
- Criteria should focus on outcomes rather than outputs. [Middleton, 2014]

A recommended best practice not identified in this list, but mentioned in earlier sections, is that prioritization criteria need to reflect the goals and objectives of the planning study. For example, Table 7-9 from the Delaware DOT shows how the criteria used in the project prioritization process relate to the mission, vision, and goals established for the state's transportation program.

The prioritization process is easier where both costs and benefits are quantifiable. AASHTO recommends ranking projects in descending order of B/C ratios (where available), independent of their net present values (NPVs), and then selecting projects for construction until the budget is exhausted. [AASHTO, 2010] The process is easiest when projects are mutually exclusive—one, and only one, project will be picked. Where projects are interdependent, it may be best to try to group together projects that require a second project to be fully usable. If possible, the NPV of the first-phase project or project segment should be estimated. In most cases, the first-phase project should have some independent utility, even if it must precede another project to obtain its full benefit.

A further complication in government finance is that some projects will be eligible for matching or restricted funds from an external funding source (typically the federal or state government). In that case, some agencies' program projects maximize the capture of external funds, until the maximum available in any fiscal year is reached. This is often done at state DOTs to maximize the use of federal highway funds. Projects that exceed external funding eligibility are then moved to a second tier of competition with projects not eligible for external aid. Another consideration may be that states or counties are statutorily entitled to minimum budget allocations (a normative form of geographic equity). Regardless of these special provisions, it is critical that all projects should have positive NPVs.

Programming is a different process than prioritization. Programming is simply matching the projects that have been selected to the cash flow and investment timeframes that characterize a particular study time horizon. Programming

| Table 7-9. Delaware DOT's Prioritization Criteria in Relation to Agency's Mission, Vision, and Goals | | | |
|---|---|---|---|
| **Mission** | **Vision** | **Goals** | **Prioritization Criteria** |
| Every Trip | We strive to make every trip taken in Delaware safe, reliable, and convenient for people and commerce. | Minimize the number of fatalities and injuries on our system.<br>Build and maintain a nationally recognized system benefiting travelers and commerce. | Safety<br>System Operating Effectiveness<br>System Preservation |
| Every Mode | We provide safe choices for travelers in Delaware to access roads, rails, buses, airways, waterways, bike trails, and walking paths. | Provide every traveler with access and choices to our transportation system. | Multimodal<br>Mobility/Flexibility/Access |
| Every Dollar | We seek the best value for every dollar spent for the benefit of all. | Minimize the environmental impact of the state's transportation system.<br>Achieve financial sustainability through accuracy, transparency, and accountability. | Environmental Impact/Stewardship<br>Revenue Generation and Economic Development |
| Everyone | We engage and communicate with our customers and employees openly and respectfully as we deliver our services. | Develop and maintain a place where talented and motivated employees love to work and can be national leaders in transportation. | Impact on the Public/Social Disruption/Environmental Justice |

Source: Middleton, 2014

can also take into account other difficult-to-quantify factors, such as equity, level of project controversy, environmental impacts, statutory requirements, and project readiness. These factors may be overlapping. For example, a controversial project may also have undesirable equity or environmental impacts.

The evaluation techniques discussed earlier—effectiveness matrix, aggregate ranking, and cost-effectiveness— can also be used to establish priorities and timing of projects. Typically, prioritizing projects will involve a wider range of issues, including project financing. For example, a large, expensive project may require an agency to borrow funds for its construction; the resulting debt service payments on the borrowed funds will reduce the amount available for other projects later on.

An example of a prioritization scheme from Vancouver, Washington, is summarized in Table 7-10. Notice that this prioritization scheme is based on assigning points to individual projects, summing the total points by "Needs" categories, and then multiplying by defined weights. Projects with the highest scores have greater priority over those with smaller scores.

The peer review of cross-modal project prioritization mentioned earlier provided some useful observations of the feasibility and ease of use of many of the more common prioritization criteria.

- *Congestion*. Measuring congestion provides transportation agencies with a good sense of system operating effectiveness and a general assessment of the health of a transportation system. Several of the peers indicated that congestion relief was one of the most easily quantifiable prioritization criteria.
- *Economic Development/Competitiveness*. Economic development and economic competitiveness are key considerations for any transportation project; however, defining, estimating, and quantifying the economic impacts of any given project can be a challenging and multifaceted task. Observations included: (1) estimates of economic impacts might account for a wide range of factors, including: access to jobs, job creation, job retention, port connectivity, freight mobility, attractiveness to new/existing businesses, access to shopping, and even impacts to regional food systems, (2) job creation estimates often favor the selection of highway construction projects, which tend to require higher labor costs over projects from other modes, and (3) access to key job centers may be a more useful criterion for cross-modal project prioritization.

**Table 7-10. Example Selection Criteria, Transportation Improvement Program, Vancouver, Washington**

***Summary of Needs Criteria***

| Evaluation Criteria | Maximum Weight |
|---|---|
| Mobility | 20 |
| Multimodal/Operations | 15 |
| Safety | 20 |
| Economic Development | 20 |
| Financial/Implementation | 15 |
| Sustainability/Air Quality | 10 |
| Total Weight | 100 |

**Example Assignment of Points**

**Mobility, 20 Maximum Points**

**Existing Peak Hour Condition, 0–8 points**

- V/C Ratio 0.9 or greater/Less than 60% of Posted Speed — 8 points
- V/C Ratio 0.8 to 0.89/60–64% of Posted Speed — 6
- V/C Ratio 0.7 to 0.79/65–69% of Posted Speed — 4
- V/C Ratio 0.5 to 0.69/70–74% of Posted Speed — 2
- Transit (Unless corridor can be identified) — 5

**Network Development, 0-4 points**

- Extends Improvements — 1–2 points
- Completes Gap — 2–3
- Completes Corridor — 3–4
- New Network Connection — 0–4
- Improves Parallel Corridor — 0–2

**Multimodal/Operations, 15 Maximum Points**

**Multimodal, 0–10 points**

- Transit Expansion — 0–8 points
- Peak Hour Transit Buses (1 point per 2 Buses) — 0–5
- Transit Replacement — 0–3
- Exclusive Transit Lanes (Transit Only, BAT Lanes, etc.) — 2–8
- Transit Amenities (Shelter, Bus-Pullout) — 0–2
- Park and Ride Construction — 5–8
- Carpool/Vanpool — 1–3
- Improve Non-Motorized Access to Park and Ride/Transit — 1–2
- Extends or Completes Gap in Bicycle Route — 1–3
- Construct 10-foot separated path or two 5-foot striped bicycle lanes — 2
- Sidewalks (Both Sides) — 1–2
- Sidewalks wider than 5′ and/or Planter Strip (3′ minimum) — 1–3
- Improves Transit Speed/Reliability — 1–3
- Transportation Demand Management — 1–3
- Contact C-TRAN's Capital Project Manager (10+ days) — 1
- Adopted Complete Street Policy — 1

**Safety, 20 Maximum Points**

**Existing Conditions, 0-6 points**

- Pavement Widths (Deviation from standards) — 0–2 points
- Shoulder Widths (1 pt. per 2 feet less than 6′) — 0–3
- No Center Turn lane/Pocket (Project must correct) — 1

Table 7-10. (*Continued*)

**Provides Access Management, 0–6 points**

| | |
|---|---|
| • Add Non-Traversable Median greater than 50% of Project Length | 3 |
| • Add C-Curb at Intersections or less than 50% of Project Length | 2 |
| • Close Minor Intersections | 1 |
| • Reduce Access Points | 2 |
| • Eliminate Existing At-Grade Crossing | 5 |

**Economic Development, 20 Maximum Points**

**Employment Growth 0-12 points**

| | |
|---|---|
| • Retail Employment Growth (Regional Model-Select Link) | 0–5 points |
| • Other Employment Growth (Regional Model-Select Link) | 0–7 |

**Financial/Implementation, 15 Maximum Points**

**Previously Completed Work (Prior to application deadline), 0–6 points**

| | |
|---|---|
| • Environmental Permits Submitted/Approved | 1–2 points |
| • Plans, Specs, and Estimate Completed | 2 |
| • Right of Way Acquisition Complete | 2 |
| • No Sensitive Areas or Issues Pending | 2 |

**Sustainability/Air Quality, 10 Maximum Points**

**Sustainability Measures, 0–10 points**

| | |
|---|---|
| • Enhanced Treatment Stormwater Control | 2 points |
| • Hardscaping or Native Planting (no permanent irrigation) | 1 |
| • Correction of Fish Barrier | 0–3 |
| • Enhances Stream Bank Conditions | 1 |
| • Corrects Existing Sensitive Area Impacts | 2 |
| • Appropriate Reduction in Existing Pavement Width | 0–3 |
| • Replace or Install Low-Energy Street Lighting | 3 |
| • Reuse/Recycling of Materials | 2 |
| • In-Place Pavement Reconstruction or Structural Retrofit | 2 |

Source: Southwest Washington Regional Transportation Commission (RTC). 2015. *Selection Criteria Transportation Improvement Program*. Vancouver, WA: RTC. Accessed August 7, 2015, from http://www.rtc.wa.gov/programs/tip/docs/tipcrit15.pdf

- *Public Health*. Transportation agencies are increasingly considering the impact of transportation projects on public health in their planning and project development processes. Some agencies are developing metrics for the impacts of transportation projects on physical activity, particularly with regard to bicycle and pedestrian facilities.
- *Revenue Generation*. Apart from economic impacts, some transportation agencies score projects based on a revenue-generation criterion. This criterion refers to both project funding from partner agencies and the potential for continual revenue generation through tolling or other means.
- *Safety*. Meeting participants observed that comparing the safety impacts of projects across modes is a major challenge. In developing a truly cross-modal project prioritization process, the peers noted that agencies must develop a strategy for valuing lives equally across all modes of travel. [Middleton, 2014]

The following case studies illustrate many of the characteristics of evaluation and prioritization that have been discussed in this chapter.

# III. CASE STUDIES

## A. MPO Regional Transportation Plan (RTP)

The Metropolitan Transportation Commission (MTC) is the federally designated MPO for the nine-county San Francisco Bay Area. Its jurisdiction encompasses approximately 7 million people, and it is one of the larger MPOs in the United States. MTC is responsible under both federal and state law for programming billions of dollars of transportation funds (capital and operating) each year.

Like all MPOs, MTC is responsible for maintaining the Regional Transportation Plan (RTP). The 2013 transportation plan was one of the first in the United States to use a performance measure structure to assess the effectiveness of proposed strategies and projects. In addition, the transportation plan was integrated with a proposed land-use/development plan that promoted strong interaction between transportation investment and community development. As noted in the plan:

> *"The Plan Bay Area will address new requirements flowing from California's 2008 Senate Bill 375, which calls on each of the state's 18 metropolitan areas to reduce greenhouse gas (GHG) emissions from cars and light trucks. . . . The mechanism for achieving these reductions will be a Sustainable Communities Strategy that promotes compact, mixed-use commercial and residential development that is walkable and bikeable and close to mass transit, jobs, schools, shopping, parks, recreation and other amenities. If successful, Plan Bay Area will give people more transportation choices, create more livable communities and reduce the pollution that causes climate change." [MTC, 2013]*

Table 7-11 shows the relative impacts of the proposed plan on the performance measures identified as part of the transportation planning process. Note in the figure the use of an arrow to indicate the extent to which a particular performance target is met. Table 7-12 shows the equity assessment for the transportation plan. MTC also performed a project performance assessment to identify the highest-performing investments. Each major project was evaluated based on two criteria: benefit/cost ratio and a "target" score (which measures the contribution the project makes toward achieving Plan Bay Area's 10 adopted performance targets). Figure 7-6 shows the results of the project level assessment. By using such a formulation, MTC was able to show decision makers what types of projects were most cost-effective.

## B. Corridor Plan

The Texas DOT conducted a corridor study of a major interstate highway in the Dallas-Ft. Worth metropolitan area. Proposed improvements at different locations along the corridor included highway expansion with frontage roads; managed lanes that utilize strategies for managing hours of operation, auto occupancy, and value/toll pricing; travel demand management and transportation systems management (TDM/TSM) actions; and bicycle and pedestrian measures designed to decrease and manage demand on the transportation system. These elements include employer trip generation programs, telecommuting options, traveler information, special event options, and signal and intersection improvements.

The following goals and objectives were identified to guide the study. [Texas DOT, 2015]

*Goal 1: Transportation Mobility and Efficiency:* Provide transportation facilities and services in the corridor that improve mobility, circulation, connectivity, and efficiency, reduce congestion, and effectively carry increased local, regional and interstate traffic.

- Objective 1.1: Reduce traffic congestion and travel time on the facility for the safe, efficient, and effective movement of people and goods.
- Objective 1.2: Plan transportation improvements in the corridor that provide sufficient accessibility to facilities, including the appropriate design of highway main lanes, high-occupancy vehicle lanes, interchanges, frontage roads, and bus transit facilities, and park-and-ride facilities, as needed.
- Objective 1.3: Verify that proposed corridor improvements are consistent with existing transportation plans and coordinated with local and regional planning organizations.

| Table 7-11. Performance Assessment of Regional Transportation Plan, MTC, San Francisco Bay Area | | | |
|---|---|---|---|
| **Plan Meets or Exceeds Target** | | | |
| **Climate Protection** | **Target #1:** Reduce per-capita $CO_2$ emissions from cars and light-duty trucks by 15 percent. | Plan meets and exceeds target; reduces per-capita emissions of $CO_2$ by 18 percent (by 2040). | |
| **Adequate Housing** | **Target #2:** House 100 percent of the region's projected growth by income level (very-low, low, moderate, above-moderate) without displacing current low-income residents. | Plan meets target; houses 100 percent of population growth. | |
| **Healthy and Safe Communities Reduce Particulate Matter** | **Target #3a:** Reduce premature deaths from exposure to fine particulates ($PM_{2.5}$) by 10 percent. | Plan meets and exceeds target; reduces premature deaths from exposure to fine particulates by 71 percent. | |
| **Open Space and Agricultural Land** | **Target #6:** Direct all non-agricultural development within the year 2010 urban footprint (existing urban development and urban growth boundaries). | Plan meets target; directs all non-agricultural development within the existing urban footprint. | |
| **Economic Vitality** | **Target #8:** Increase gross regional product (GRP) by 110 percent—an average annual growth rate of approximately 2 percent (in current dollars). | Plan meets and exceeds the economic growth target; 119 percent increase in GRP is forecasted over the life of the plan. | |
| **Plan Makes Progress Toward Target** | | | |
| **Healthy and Safe Communities Reduce Particulate Matter** | **Target #3b:** Reduce coarse particulate emissions ($PM_{10}$) by 30 percent. | Plan reduces coarse particulate emissions by 17 percent, but falls short of target. | |
| **Active Transport** | **Target #5:** Increase the average daily time walking or biking per person for transportation by 70 percent (for an average of 15 minutes per person per day). | Plan boosts per-person active transportation by 17 percent, but falls short of target. | |
| **Transportation System Effectiveness** | | | |
| **Increase Non-Auto Mode Share** | **Target #9a:** Increase non-auto mode share by 10 percentage points (to 26 percent of trips). | Plan boosts non-auto mode share to 20 percent of trips, but falls short of target. | |
| **Reduce VMT per Capita** | **Target #9b:** Decrease automobile vehicle miles traveled (VMT) per capita by 10 percent. | Plan reduces VMT per capita by 9 percent, but falls short of target. | |
| **Local Road Maintenance** | **Target #10a:** Increase local road pavement condition index (PCI) to 75 or better. | Plan improves pavement condition of local roads to a PCI of 68, but falls short of target. | |
| **Plan Moves in Opposite Direction From Target** | | | |
| **Reduce Injuries and Fatalities from Collisions** | **Target #4:** Reduce by 50 percent the number of injuries and fatalities from all collisions (including bike and pedestrian). | Plan moves in opposite direction from target; injury and fatality collisions are projected to increase during plan period by 18 percent. | |
| **Equitable Access** | **Target #7:** Decrease by 10 percentage points (to 56 percent from 66 percent) the share of low-income and lower-middle income residents' household income consumed by transportation and housing. | Plan moves in wrong direction; the share of household income needed to cover transportation and housing costs is projected to rise to 69 percent for low-income and lower-middle income residents during the Plan Bay Area period. | |

(*continued*)

| Table 7-11. (*Continued*) | | | |
|---|---|---|---|
| **Transportation System Effectiveness** | | | |
| Highway Maintenance | **Target #10b:** Decrease distressed lane-miles of state highways to less than 10 percent of total lane-miles. | Plan moves in opposite direction from target; the percentage of distressed state highway lane-miles in the region will rise to 44 percent of the regional highway system by year 2040. | |
| Transit Maintenance | **Target #10c:** Reduce the share of transit assets past their useful life to 0 percent. | Plan moves in opposite direction from target; the share of transit assets past their useful life is projected to increase to 24 percent of all assets during the Plan Bay Area period. | |

**Table 7-12. Results of Plan Bay Area Equity Analysis, 2010–2040, San Francisco Bay Area**

| Performance Measure | Target Population | 2010 | 2040 (Baseline Forecast) | 2040 (Plan Bay Area) |
|---|---|---|---|---|
| Housing and Transportation Affordability<br>*Percentage of income spent on housing and transportation by low-income households* | Low-Income Households | 72% | 80% | 74% |
| | All Other Households | 41% | 44% | 43% |
| Potential for Displacement<br>*Percentage of rent-burdened households in high-growth areas* | Communities of Concern | n/a | 21% | 36% |
| | Remainder of Region | n/a | 5% | 8% |
| Healthy Communities<br>*Average daily vehicle miles traveled per populated square mile within 1,000 feet of heavily used roadways* | Communities of Concern | 9,737 | 11,447 | 11,693 |
| | Remainder of Region | 9,861 | 11,717 | 11,895 |
| Access to Jobs<br>*Average travel time in minutes for commute trips* | Communities of Concern | 25 | 26 | 26 |
| | Remainder of Region | 27 | 29 | 27 |
| Equitable Mobility<br>*Average travel time in minutes for nonwork-based trips* | Communities of Concern | 12 | 13 | 13 |
| | Remainder of Region | 13 | 13 | 13 |

Source: MTC, 2013, Reproduced with permission of the Metropolitan Transportation Commission.

- Objective 1.4: Use cost-effective, innovative strategies that may include (but are not limited to) travel demand management (TDM), transportation systems management (TSM), and intelligent transportation systems (ITS).
- Objective 1.5: Schedule planned corridor improvements to maintain traffic flow during construction.

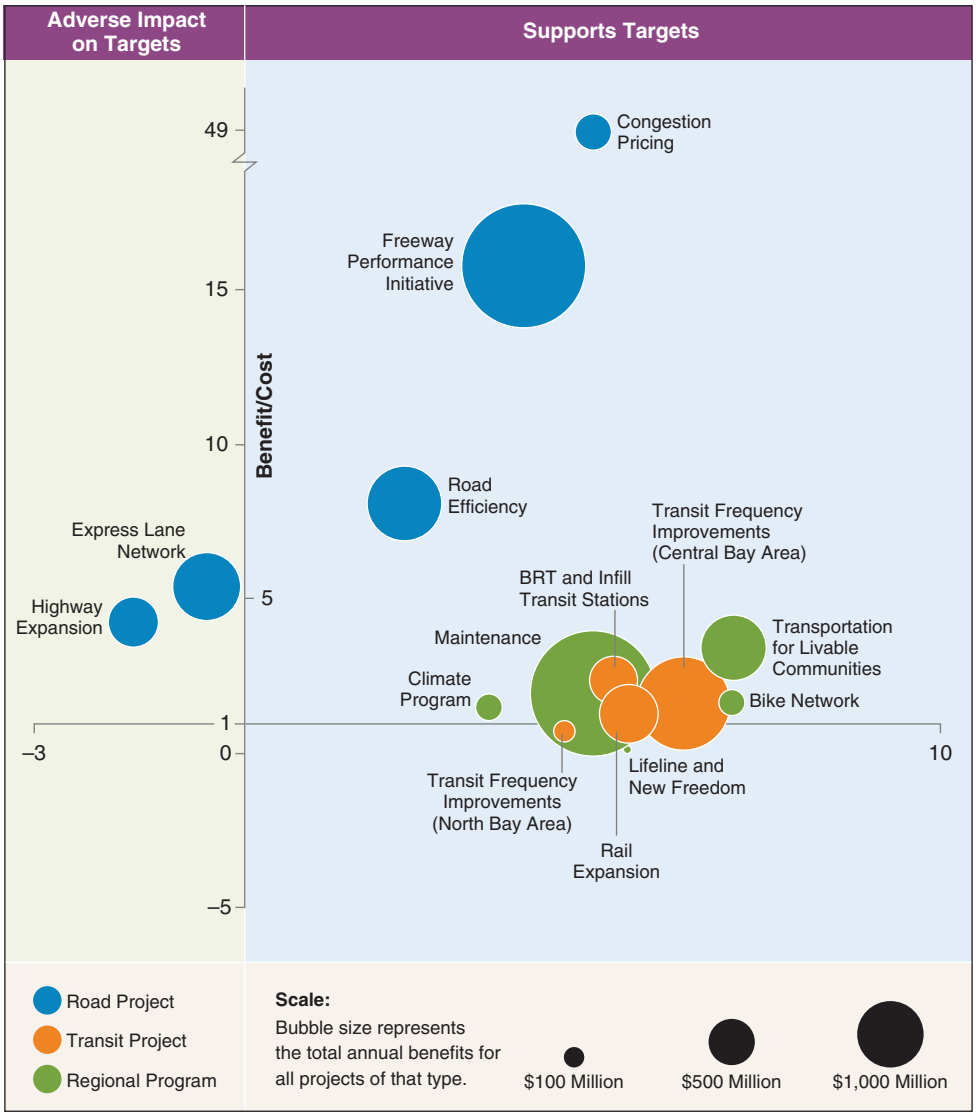
*Goal 2: Safety:* Enhance safety on transportation facilities for all travel modes in the corridor.

- Objective 2.1: Reduce the rate of accidents on transportation facilities in the corridor.

*Goal 3: Multiple Travel Modes:* Provide a balanced corridor transportation system with multiple travel modes that provides adequate capacity for and convenient access to high-occupancy vehicle (HOV) facilities, bus and rail transit, and bicycle/pedestrian travel modes within the study area.

- Objective 3.1: Provide transportation improvements in the corridor that combine multiple motorized travel modes, including bus transit services (e.g., express lanes), high-occupancy vehicle (HOV) facilities, and rail transit facilities, as needed.

**Figure 7-6. Project-Level Assessment for Project Types by Benefit/Cost and Project Scores, Metropolitan Transportation Commission**



Source: MTC, 2013, Reproduced with permission of the Metropolitan Transportation Commission.

- Objective 3.2: Provide transportation improvements that promote bus and rail transit services in the corridor, facilitating connections to neighborhoods and downtown areas of Fort Worth and Arlington, and other local and regional activity centers.
- Objective 3.3: Improve and extend bicycle and pedestrian facilities in the corridor in coordination with improvements to motorized transportation.

*Goal 4: Environmental Quality:* Provide a corridor transportation system that protects and enhances air quality; has minimal negative impact on the natural and social environment; protects ecological, cultural, and historic resources; and adheres to environmental justice.

- Objective 4.1: Provide transportation improvements in the corridor that improve regional air quality, minimize noise impacts, and conserve energy.
- Objective 4.2: Provide transportation improvements in the corridor compatible with conservation of natural resources, preservation of open space, parklands, and ecologically significant areas, and mitigate where necessary.

- Objective 4.3: Provide transportation improvements in the corridor compatible with the preservation and protection of historic, archeological, and cultural resources.
- Objective 4.4: Minimize neighborhood and community disruption and dislocation of residences and businesses resulting from corridor transportation improvements, as well as disproportionate adverse impacts on minority and low-income populations.

*Goal 5: Quality of Life:* Provide transportation improvements in the corridor that will enhance and not detract from neighborhood, community, and regional quality of life.

- Objective 5.1: Improve access to existing and emerging residential and employment centers in the corridor to encourage economic development and employment opportunities.
- Objective 5.2: Provide transportation improvements that encourage mixed land use development, transit- and pedestrian-friendly urban design, and compatibility with existing adjacent land uses and community land use plans.
- Objective 5.3: Provide equity in access to all travel modes to the traditionally underserved.
- Objective 5.4: Reduce adverse impacts of corridor transportation improvements on aesthetics and visual quality.

*Goal 6: Financial Feasibility:* Provide transportation facilities and services in the corridor that are fiscally responsible and economically feasible.

- Objective 6.1: Provide cost-effective and financially feasible transportation facilities in the corridor that are affordable to users, transportation providers, the region's communities, and participating agencies, and where the costs and benefits of the system are fairly distributed.

In order to narrow the number of alternatives considered by the study, a set of criteria was defined that met four requirements:

- *Effectiveness and Comprehensiveness in Measuring Goal Attainment*—The screening and evaluation measures were selected to reflect and measure the extent to which the alternative strategies contribute to the achievement of accepted transportation-related goals and objectives. Similarly, they were proposed to conform to federal guidelines governing the evaluation of major transportation investments.
- *Ability to Reflect the Specific Nature of the Alternatives*—The recommended screening and evaluation measures are relevant to the need to evaluate alternative transportation strategies in isolation, as well as in combination. These measures are capable of reflecting interactions between transportation and other factors, such as land use and the environment, and among travel modes.
- *Realistic in Terms of Technical and Resource Requirements*—The computation of measures should allow for efficient use of available data and provide comparable levels of detail, both among different screening and evaluation categories and across alternative strategies.
- *Relevance for Policy Evaluation*—The total number of screening and evaluation measures is reasonable and allows for thorough coverage of key goals and issues. Where possible, quantitative as opposed to qualitative methods are employed to depict potential effects in an objective manner.

The criteria have been grouped into five categories to facilitate analysis. These include:

- **Mobility Effects:** travel demand, roadway capacity, level of service, travel time, circulation, access, truck movement, safety, and access to multiple travel modes.
- **Social and Economic Effects:** socioeconomic and cultural environment (historic, cultural, and archaeological resources; residential and business displacement/dislocation; socioeconomics and equity; neighborhood integrity and cohesion).
- **Environmental Effects:** natural environment (air quality, noise, energy consumption, water quality and quantity, vegetation, wildlife, soils, open space, parklands, ecologically significant areas, drainage/flooding,

aesthetics, and visual quality); land use (residential patterns, compatible uses, development suitability according to community values).

- **Cost-effectiveness and Affordability:** capital costs, operations and maintenance costs, achievement of benefits commensurate with resource commitment, sources and sufficiency of revenues.
- **Other Factors:** compatibility with local and regional plans and policies, constructability, and construction effects.

Finally, Table 7-13 shows the evaluation criteria used to assess the alternatives that resulted in a preferred alternative for the corridor.

## C. Small Bus Life-Cycle Cost Analysis

Life-cycle analysis of a small bus is an excellent example of economic evaluation in action. [KFH Group et al., 2000] Life-cycle costing (LCC) is a technique for estimating the total cost of owning and operating an asset over the economic life of that asset. The predicted LCC provides a basis for planning decisions, for comparing different equipment or different design features, and for the awarding of bids for the provision of equipment and/or services. The U.S. Office of Management and Budget (OMB) defines LCC as:

> *"The sum total of the direct, indirect, recurring, non-recurring and other related costs incurred, or estimated to be incurred, in the design, development, production, operation, maintenance and support of a major system over its anticipated useful life."*

The lowest bid procurement process has been commonly used in public sector acquisitions of capital goods and is sometimes required by statute. This procedure has been used for many years for purchasing conventional urban transit buses (typically 35–40 ft long and seating 40–55 passengers). These buses are produced by a limited number of manufacturers and are designed for an urban environment. Changes in vehicle design have occurred at a gradual pace, and most operators are experienced in maintaining and operating such equipment. Most transit properties are prepared to write specifications and to evaluate proposals.

A different situation exists for small transit buses. These buses vary from vehicles resembling vans to coaches less than 35 feet long. Small buses are classified as light-, medium-, or heavy-duty, depending upon their size, cost, and anticipated service life, and the type of service for which they are appropriate. Although many of these vehicles are owned by urban transit properties, they are also used in private businesses and by cities, suburban and rural communities, and social service agencies.

Service requirements range from fixed-route, fixed-schedule center-city operations to demand-responsive operations involving long distances in rural areas. The vehicle market is served by many manufacturers offering vehicle components, stock vehicles, and a wide spectrum of modifications. In many cases, the bus is not specifically designed for the type of service it will enter. The result is that, in purchasing small buses, the operator is offered a multitude of possible choices. These vehicles vary greatly in initial cost.

LCC offers certain advantages over low-bid procedures. LCC permits the operator to rely on a broad performance specification, and to make a selection based on the predicted total cost of owning and operating the vehicle or equipment. Unlike low-bid procurement, LCC does not limit the bidder to the specific vehicle design features. LCC ensures, ideally, that all aspects of maintenance and operation are considered in making the final selection.

One of the dangers of LCC is that it entails estimates of future repair frequency, future usage rates, useful life, and rates for future inflation. Some of these factors, such as usage rates and inflation rates, are applied similarly to all vehicles being compared. But others, such as useful life, repair frequency, or fuel consumption rates, are estimated for each vehicle using similar operating experience data as a basis for the estimate, unless actual on-property test rates are available. The accuracy of the estimates depends on how nearly the assumed future conditions (for example, price inflation, fuel costs, vehicle usage rates) approach the conditions that will actually prevail. Another factor is how representative the operating experience is of the future performance of new vehicles. The estimates of useful life, condition and mileage at retirement, price of fuel, and similar factors are critical.

| Table 7-13. Criteria for Detailed Evaluation of Corridor Alternatives |

Source: Texas DOT, 2015

**Table 7-14. Comparison of LCC for Three Small Transit Vehicles**

| Cost Category | Units | Vehicle 1 | Vehicle 2 | Vehicle 3 |
|---|---|---|---|---|
| **Maintenance** | | | | |
| **—Labor** | $/mile | 0.0831 | 0.0336 | 0.1638 |
| **—Parts** | $/mile | 0.0459 | 0.0753 | 0.0963 |
| **Commodities** | | | | |
| **—Fuel** | $/mile | 0.3000 | 0.3429 | 0.2400 |
| **—Oil** | $/mile | 0.0018 | 0.0015 | 0.0024 |
| **Total Maintenance Cost** | $/mile<br>$ present value | 0.4308<br>258,480/year | 0.4533<br>271,980/year | 0.5025<br>301,500/year |
| **Present Value of Total Maintenance Cost for 6 Years @ 7%** | Total fleet | $1,318,299 | $1,387,152 | $1,537,710 |
| **Salvage Value (after 6 years, in discounted dollars)** | Per bus<br>Total fleet | $36,500<br>$438,000 | $23,000<br>$276,000 | $43,000<br>$516,000 |
| **Net cost after salvage** | Total fleet | $880,299 | $1,111,152 | $1,021,710 |

The basic LCC analysis consists of four major steps: (1) compilation of vehicle operating cost data and projection of future costs, (2) estimation of salvage (resale) value, (3) adjustment for time-value of money (discount rate), and (4) determination of total life-cycle cost. As an example, consider three different vehicles that will be operated an average of 50,000 miles per year during a 6-year period. Twelve vehicles will be required, with 10 vehicles in service and two spare. The fleet will operate 600,000 miles per year, or 3.6 million miles during the fleet's 6-year life.

The data shown in Table 7-14 are derived from tests and operating experience and related to the number of miles operated. In this case, Vehicle 1 proves to be the least costly to operate. However, Vehicle 3 is ranked second, despite its operating cost being higher than Vehicle 2's (primarily because its salvage value is higher). If the unit price of Vehicle 1 were $12,000 more than Vehicle 3's, then Vehicle 3 could actually be more economical. For 12 buses, the $12,000 price difference would be $144,000, which is more than the LCC difference between Vehicles 3 and 1 (See KFH Group, Inc. et al., TCRP Report 61, for further detail on this analysis approach).

## D. One-Way Street Conversion in a Central Business District

The purpose of this evaluation was to consider the potential for converting certain existing one-way streets to two-way operation in the central business district of Oakland, California, a city of approximately 400,000. Although one-way streets have many advantages, the identified benefits of conversion to two-way operation were:

- A decrease in travel speeds to benefit pedestrians and reduce noise.
- Reduction in vehicle miles of travel (VMT) because fewer "around the block" movements would be required.

- Decrease in turning movements at intersections.
- Consolidation of transit stops to a single street, which had been split in two due to the use of couplets in the central business district (CBD), resulting in less confusion to transit passengers.
- Less confusion to visitors unfamiliar with the street system, especially where there is a lack of uniformity in the street grid.
- Promoting CBD retailing (businesses generally dislike one-way streets, on the assumption that it reduces visibility and makes it less convenient to shop).
- Ability to include raised-median pedestrian refuge islands on some two-way streets.

A ring of three freeways was completed around Oakland's CBD between the mid-1950s and 1982. During this period, virtually every street in the CBD was made one-way (the primary exception being the major shopping and transit artery, Broadway, which remained two-way).

While the noted benefits seemed reasonably certain, the costs seemed less certain or quantifiable; therefore, an aggregate ranking was selected for the evaluation. Scoring criteria were developed, shown in the following paragraphs. This resulted in candidate locations for further investigation. These were field-checked then readjusted as needed, and the recommendations made.

Because the impact of two-way operation could be both good and bad, the scoring system used a range of –5 to 5. A score of 0 was used to indicate no benefit or impact. For example, the effect on transit operations for a street with no transit would be given a 0. The extreme scores (−5 or 5) were assigned if the conversion would have a highly adverse impact (−5) or a highly favorable impact (5). The scores were then summed for a total value assigned to each street.

The eight criteria used for evaluation were:

- *Peak Traffic Volume*. Streets with high existing traffic volumes were given scores close to −5, whereas very low volume streets were given scores closer to 5. This evaluation was somewhat qualitative, because traffic volumes were not available on every street segment.
- *Primary Connection to a Freeway*. Certain streets operate as major freeway connectors and, thus, would require a major reconfiguration or reconstruction of freeway ramps if converted to two-way, so they were given low scores. The latest freeway incorporates several ramps, which would be particularly difficult to make compatible with two-way operation on intersecting streets. The actual costs were not developed for this first-cut evaluation. Only some streets have bridges or freeway underpasses; changing them could involve costly new construction.
- *Land-Use Compatibility*. Streets with residential or retail frontage (especially small shops) were given higher scores than streets with offices, off-street parking, or other uses.
- *Availability of Parallel Routes*. A high score (4 or 5) was given to a street that had a nearby street with sufficient capacity to accommodate traffic diverted from the converted street.
- *Transit Benefits*. Transit benefits were assigned if there was bus service on the street. In addition, points were given if ridership was likely to increase if two-way service were instituted.
- *Suitable Street Width*. If reconfigured to two-way operation, can a suitable number of lanes (including turning lanes) be provided with parking? Generally, streets with a greater curb-to-curb width were given higher scores, whereas narrower streets were given lower scores.
- *Network Connectivity*. Will two-way traffic confer network connectivity benefits by allowing for improved circulation and fewer turning movements? Is the street a discontinuous, isolated segment, or part of a larger grid? Short, disconnected segments can probably be changed to two-way without adverse impacts, and so were given higher scores.

- *Signal Coordination*. Signals are far easier to coordinate (synchronize) on one-way than two-way streets. Unless there is optimal signal spacing, effective vehicle progression cannot be provided in *both* directions. This usually requires favoring one direction of traffic over another (this in fact is done on Broadway today). Depending on the controller, the favored movement can be adjusted by time of day to serve the greatest traffic flow (for example, inbound in the morning peak, outbound in the evening, and balanced during the rest of the day).

Low scores were given if signals were well-coordinated on the street; high scores were given if there was no coordination. Higher scores were also given if there was (approximate) uniformity of block length, which can be used to provide two-way traffic signal coordination.

The final ranking of 29 streets led to scores ranging from −18 to 26. A phased implementation program was recommended, with streets scoring more than 13 included in the first phase.

## E. Rail Transit Projects

Facing a need to prioritize funding for as many as 69 competing rail projects, the California State Senate passed a concurrent resolution requesting that the California Transportation Commission (CTC) submit a listing of high-priority rail projects that could be implemented within 5 years. The criteria for determining which projects qualified for the high-priority designation were:

- *Project Readiness*—A measure of the status of the project planning that helps determine if a project can be implemented in 5 years.
- *Local Support*—The degree of local support for a project, as reflected in local funding commitments, actual levels of transit ridership in the area, and formal actions by local authorities.
- *Local Priority*—The priority ranking a project has been given by local agencies among its competitors within a particularly urban region or system.
- *Project Worth*—Measures of the worthiness of the project in terms of relationships between costs and potential ridership and/or other anticipated project benefits. Environmental consequences: each project's major impacts representing consideration in priority determination.
- *Need for State Funding*—The amount of state funding required, the project's ability to capture federal funds for the state, potential private-sector involvement, and other indications of the need for and desirability of state funding assistance.
- *Other Considerations*—Any unique circumstances or conditions that affected the appropriate timing or justification of a particular project.

# IV. SUMMARY

The development of transportation alternatives and the fair presentation of competing choices are among the key activities transportation planners engage in. Because transportation problems and deficiencies will almost always exceed the resources available to solve them, it is important that transportation planners be able to recommend the best choices available, or, in the case of decisions that involve changes to current public policy, make the fairest presentation to those entrusted with decision-making authority. This chapter discussed how alternative solutions to transportation problems can be evaluated and compared so that the best course of action can be taken. Evaluating and prioritizing transportation projects are usually the last steps in the transportation planning process, but they are some of the most important. All of the other information developed—planning goals, objectives, measures, information alternatives—is brought together in this step to select the best actions for the agency.

Transportation alternatives are a natural outgrowth of the goals and objectives developed as part of the transportation planning process. Good goal definition can help generate a wider range of potential problem solutions than narrowly focused goals. If a goal automatically suggests a single appropriate solution, it is probably too narrowly conceived.

The next step is to enumerate and, to the extent possible, quantify all of the potential costs and benefits of a project or plan. This is a valuable exercise even when all of the costs and benefits may not be known or quantifiable. The analyst should be careful that benefits are not double-counted. It is during this phase that it begins to become clear where project risks—in terms of both costs and benefits—may lie.

After costs and benefits are quantified, the appropriate evaluation technique may be selected. This selection usually will be based on the size and complexity of the project, the stage of project planning, the degree to which project costs and benefits can be quantified, and the amount of time available to perform the evaluation. This chapter suggests a number of techniques ranging from the very simple to more complex net present-value computations.

Comparative estimates of system (alternative) costs and benefits should be developed in terms of constant dollars, usually dollars in the year in which the analysis is performed, excluding the effects of inflation. The costs should include capital outlay, operations, and maintenance cost elements. The cost analysis should consist of the following steps:

- Determine the present value of the cumulative costs of the base plan over the project period (could be the "do-nothing" or "null" alternative).
- Determine the present value of each alternative system, using the same basic assumptions as applied to the base alternative.
- Calculate the incremental cumulative cost of each alternative, compared to the base alternative, subtracting residual land values.

Cumulative costs are determined by annualizing total estimated capital costs and then summing for the number of years under consideration. These annual costs are then discounted at a selected discount rate to a present value. Unit-cost assumptions to be made in developing these cost estimates are usually documented in a report. Historical cost data can be adjusted to current values with a construction cost index (CCI).

Economic benefits are usually calculated for each alternative at weekday usage levels based on available projections of the out-year (horizon year) usage (demand), which may be in terms of vehicles or passenger trips per day. Annual demand levels and project benefits for each year between the base year and the horizon (out) year are typically approximated by straight-line interpolation. Most travel models will only provide forecasts for base year and one or two out-year conditions, although occasionally more data points are available. These estimates of future benefits are then discounted to determine their present worth, using the discount rate.

The discount rate in most evaluations will be specified by an external source, such as the analyst or an external funding agency. Discount rates can significantly affect the results of the analysis, so they should be chosen carefully to be consistent with the nature of other types of projects undertaken by the agency. A sensitivity analysis may be desirable to show the potential difference in outcomes if different discount rates are assumed. This can be easily done in a spreadsheet and in most commercially available benefit/cost programs. Risk factors should be considered explicitly, not by using varying discount rates for different alternatives.

Travel-time savings probably should be given the greatest amount of attention by the analyst because, for large projects, they will frequently be more than half of the total project's benefit. Some standards have been presented for determining the value of travel time for different classes of users. Once again, a sensitivity analysis using different values of time may be desirable. Consistency between project evaluations is also important, as differences in the value of travel time could lead to misleading conclusions. Cost-effectiveness analysis can also be used to rank projects according to the least cost per travel minute saved.

The analyst should be aware that transportation decisions can have important equity and distributional impacts with respect to both costs and benefits. There are traditionally several dimensions used to measure distributional impacts, including spatial, modal, income, and demographic groups. Census data and a travel-demand forecasting model can provide much of the information needed for this assessment.

Prioritization and evaluation share a number of key characteristics. They both seek to select the best projects from a field of contenders based on several factors. The major difference is that evaluation seeks to determine whether, and by how much, a plan or project is worthy of investment of public (or public/private) funds, given other, alternative ways of using the money. Once this is accomplished, prioritization seeks to determine the best order in which to sequence

or program funds, which may include nontechnical considerations. Those factors might include project readiness, degree of consensus, equity considerations, availability of external funds, and other similar factors.

Risk and uncertainty are inherent in any public (or private) investment, especially as there has been a bias toward underestimating costs and overstating benefits. Recent megaprojects have had a history of going significantly over budget. In general, the larger the project and the more novel the technology and conditions, the greater the risk. Several techniques for attempting to control risk and uncertainty were noted in this chapter, including value engineering (VE), scenario planning with expected values, and peer review by outside experts (often part of the VE process). In the end, the analyst needs to be frank about appraising some of the project risks in the evaluation analysis.

Frequently made errors in project evaluation include the following:

- External funds (such as grants) are used to reduce costs.
- Some project costs are overlooked.
- Benefits are double-counted.
- Average (rather than marginal) costs or benefits are used.
- Differences between market and social costs are ignored.
- An inappropriate discount rate is used (usually, one that is too low).
- Network or other important effects are ignored.

In summary, a good evaluation should: (1) account for the cumulative cost of all alternatives over the total project period, recognizing that some alternatives may have a shorter useful life than others, (2) use demand projections for an appropriate horizon year (usually from 10 to 30 years from the year in which the analysis is done), (3) recognize the effects of differing service lives of alternative capital (or major maintenance) investments, (4) eliminate the effects of inflation because inflated benefits or costs do not represent increases in *real* economic values, (5) account for the time value of money, by employing a present-value economic analysis, using a discount factor that accounts for the potential rate of return of alternative investments, and (6) apply appropriate unit values for benefits.

# Asset Management[1]

## I. INTRODUCTION

Transportation infrastructure in the United States is valued in the trillions of dollars. Much of this infrastructure, such as many portions of the interstate highway system, was constructed in the late 1950s and early 1960s and is in need of renewal. Similarly, transit infrastructure such as rail track and maintenance facilities are in need of repair or reconstruction (known in the transit industry as maintaining a state of good repair). Just as much as this infrastructure reaches the end of its useful life, additional network capacity is needed to handle growing travel demands and to provide improved levels of service, particularly in those areas experiencing high congestion levels. It is not surprising, therefore, that federal, state, and local governments face a challenging task in allocating finite resources to address various community needs for infrastructure capital expansion, renewal, and preservation. Asset management is one of the tools that can be used in support of such decisions.

There are several reasons why asset management as a topic is being presented in a handbook on transportation planning. The first reflects the types of projects and investments that many states/provinces, metropolitan areas, and cities/towns are facing. As indicated in the previous paragraph, much of the transportation investment focuses on renewal, rehabilitation, and reconstruction of the infrastructure. The priorities for this type of investment most often comes from asset management systems. Second, the tools and techniques for asset management inherently deal in uncertainty and risk, two concepts that are rapidly being integrated into the transportation planning process. Finally, the new focus on system performance and condition necessarily leads to a discussion of how asset management systems can provide input into the performance measurement program implemented by a state transportation agency or a metropolitan planning organization (MPO).

The benefits of an asset management system are many. For example, the Organization for Economic Cooperation and Development (OECD) notes benefits of better internal and external communications; improved asset inventory, condition, and level of use; enhanced network performance; increased use of asset management tools; better information for the budget process; and professional development of staff members. [OECD, 2001]

With respect to transit, the Federal Transit Administration (FTA) has defined the benefits of asset management as:

- Improved customer service—improves on-time performance and service operations, vehicle, and facility cleanliness; reduces missed trips, slow orders, and station shutdowns; and focuses investments around customer centered goals and metrics.
- Improved productivity and reduced costs—maintains assets more effectively, using condition-based approaches and using predictive and preventive maintenance strategies (where these can be employed) to reduce costs while improving service delivery.
- Optimized resource allocation—better aligns spending with an agency's goals and objectives to obtain the greatest return from limited funds and incorporates lifecycle cost, risk, and performance trade-offs into capital programming and operations & maintenance budgeting.
- Improved stakeholder communications—provides stakeholders with more accurate and timely customer-centered performance indicators, and provides tools to communicate forecasted performance metrics (including level of service) based on different levels of funding. [FTA, 2012]

[1]The original chapter in Volume 3 of this handbook was written by Professor Adjo Amekudzi-Kennedy, Georgia Institute of Technology. Changes made to this updated chapter are solely the responsibility of the editor.

As identified by the American Association of State Highway and Transportation Officials (AASHTO), asset management can lead to continuous improvement in the following areas:

- Lower long-term costs for infrastructure preservation.
- Improved performance and service to customers.
- Improved cost-effectiveness and use of available resources.
- Focus on performance and outcomes.
- Improved credibility and accountability for decisions and expenditures.
- Improved stewardship capacity.
- Development of stronger stakeholder relationships, transparency, and accountability.
- Planning for growth. [AASHTO, 2002, 2011]

These characteristics of asset management are relevant to transportation planners by their focus on improving transportation system performance in the most cost-effective manner possible. In other words, transportation asset management (TAM) represents good planning and decision-making practice. The last characteristic mentioned, planning for growth, is an important consideration in the adoption of many TAM programs around the world—and this accountability often begins in the transportation planning process.

The next section defines transportation asset management, followed by a description of how to adopt an asset management approach in an organizational context. The next section provides a brief history of the evolution of transportation asset management in the United States. The following section describes the role of transportation asset management and transportation planning, including its relationship to goals and objectives, performance measures, data collection, analysis tools, and evaluation. The final section discusses the challenges in adopting an asset management approach.

## II. WHAT IS TRANSPORTATION ASSET MANAGEMENT?

Transportation asset management is a "strategic and systematic process of operating, maintaining, upgrading, and expanding physical assets effectively throughout their lifecycle. It focuses on business and engineering practices for resource allocation and utilization, with the objective of better decision making based upon quality information and well-defined objectives." [AASHTO, 2014] A similar definition is found in the U.S. federal transportation legislation, Moving Ahead for Progress in the 21st Century (MAP-21), which defines asset management as a "strategic and systematic process of operating, maintaining, and improving physical assets, with a focus on engineering and economic analysis based upon quality information, to identify a structured sequence of maintenance, preservation, repair, rehabilitation, and replacement actions that will achieve and sustain a desired state of good repair over the lifecycle of the assets at minimum practicable cost." [23 U.S.C. 101(a)(2), MAP-21 § 1103] With respect to transit assets, a guide from the Federal Transit Administration (FTA) defined asset management as "a strategic and systematic process through which an organization procures, operates, maintains, rehabilitates, and replaces transit assets to manage their performance, risks, and costs over their lifecycle to provide safe, cost effective, reliable service to current and future customers." [FTA, 2012]

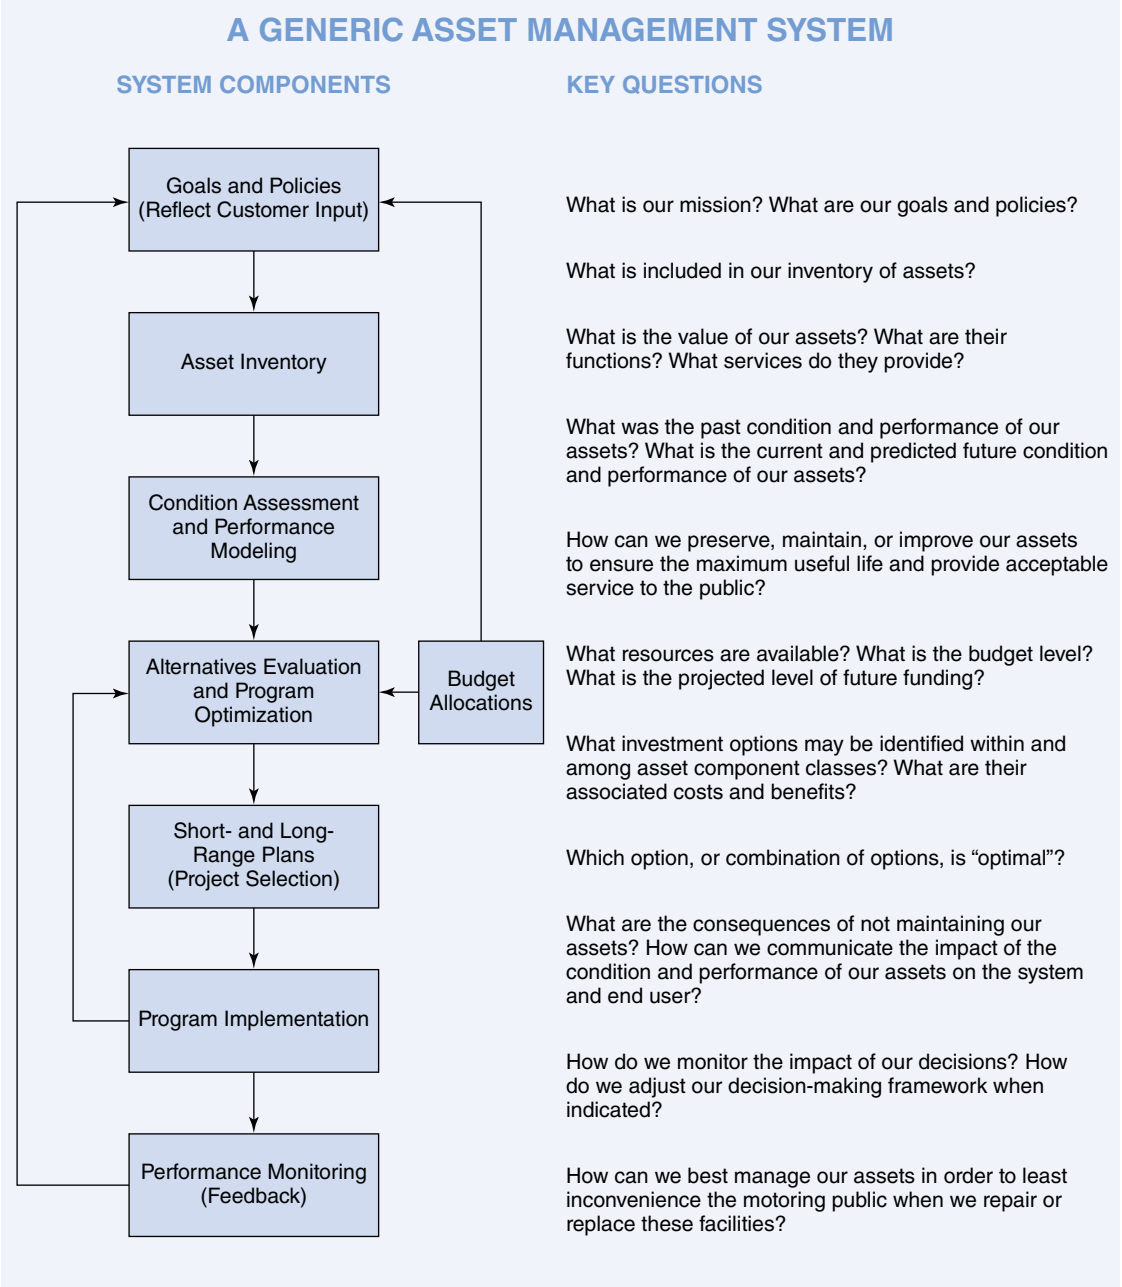
Asset management is a value- and performance-oriented approach to system visioning, goal setting, alternatives development, identifying the preferred alternatives, programming and implementing projects, monitoring performance, and defining community and agency vision. It includes the planning, design, construction, operations, maintenance, and rehabilitation and renewal of facilities, in other words, the entire life cycle of a project. Although some of the original applications of asset management focused simply on the condition of the asset, more recent approaches have taken many different factors into consideration in a more comprehensive way, such as traveler data, customer opinions, and risk analysis. More and more, asset management is being embraced as a business process for delivering agency strategic goals [AASHTO, 2011a]—meaning it becomes a comprehensive approach to delivering system and organizational performance.

In essence, five core questions constitute the key aspects of an asset management program: (1) What is the current state of my assets? (2) What are the required levels of service and performance delivery? (3) Which assets are critical to

sustained performance delivery? (4) What are the best investment strategies for operations, maintenance, replacements, and improvement? and (5) What is the best long-term funding strategy? [FHWA, 2009]

A generic TAM framework introduced by the Federal Highway Administration (FHWA) highlights the integral role of performance monitoring in asset management (see Figure 8-1). [FHWA, 2007a] Such monitoring provides a feedback loop between how the transportation system is actually performing and the early steps in transportation planning—visioning and setting goals and objectives. TAM expands on infrastructure monitoring to apply it to the decision-making process. The framework shown in Figure 8-1 depicts TAM as a systematic, fact-based, and reproducible decision-making approach that can be used to analyze trade-offs to determine the most desirable alternatives when allocating resources for system expansion, preservation, and renewal. Figure 8-2 shows a similar framework developed for transit asset management systems. In particular, this framework shows the relationship between asset management actions and the decisions that need to be made by transit agency decision makers.

**Figure 8-1. A Generic Asset Management System**



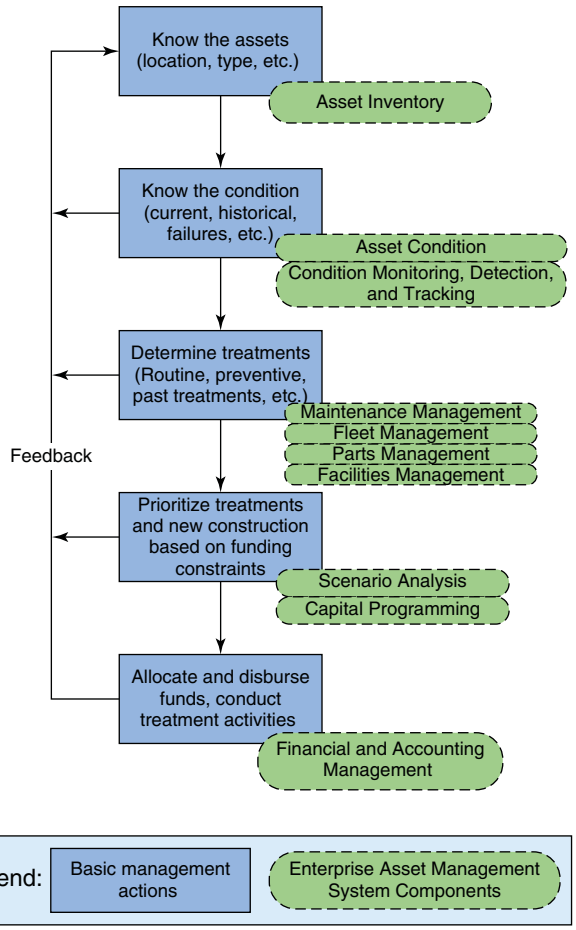
Source: FHWA, 2007a

A long-term commitment to asset management may involve incremental changes to an agency's policies, business processes, and information technology (IT) capabilities. Some agencies have taken a comprehensive look at their investment decision-making processes and developed an asset management plan to address gaps in their policies, planning procedures, and IT systems. Application of asset management in an agency setting can help to build a common vision for all management and staff both horizontally and vertically in the agency by helping all involved to speak the same language regarding near-term or longer-term expectations.

A self-assessment tool in the AASHTO *Transportation Asset Management Guide* offers a means for taking stock of the overall investment decision-making apparatus as it relates to asset management. [AASHTO, 2011a] Tailored to help agencies identify areas for improvement, the guide prompts agencies to answer the following questions:

- How can your agency improve the way it currently manages assets?
- Are current and planned initiatives sufficient, or do they require modification, addition, or redirection?
- What approaches may work well in your agency or have worked well in other agencies similar to yours?

**Figure 8-2. Transit Asset Management Framework**



Source: FTA, 2012

The self-assessment tool is organized around four key areas of asset management: (1) policy goals and objectives, (2) planning and programming, (3) program delivery, and (4) information analysis. Table 8-1 shows the policy goals and objectives module, and Table 8-2 shows the information systems and analysis module of the tool. The tool asks targeted questions to help agency officials determine their strengths and gaps in the four areas and assigns an overall score at the end of the survey. Because the tool is tailored for a wide range of employees, it can help agency officials to reach consensus on what areas need work, and thus position the overall agency strategically to develop an effective asset management plan that places priorities on addressing existing deficiencies and opportunities.

Many state DOTs have conducted self-assessments and developed blueprints to move toward an asset management-oriented approach to transportation planning.

## III. RECENT U.S. HISTORY OF TRANSPORTATION ASSET MANAGEMENT

Asset management is not a new concept; it has been used in the private sector for many years. [AASHTO, 1997] For several decades, many transportation agencies in the public sector used some aspect of asset management to support transportation investment decision making. In a well-recognized effort during the late 1950s and early 1960s, the American Association of State Highway Officials (AASHO), as it was then called, collected data on surface roadway condition and ride quality. Empirical models were developed to link pavement condition with serviceability, thus enabling officials to estimate pavement ride quality from pavement distress data. The AASHO road tests are considered seminal work in the development of performance prediction models for transportation facilities and have served as an important foundation for pavement management systems. [Carey and Irick, 1960] Many advances were made since these original tests, particularly in the development of new performance prediction models that link the causes and effects of facility deterioration.

A recent Transportation Research Board (TRB) synthesis on asset management in state DOTs showed over 70 percent of the responding agencies (43 state DOTs) noted that using asset management principles made their decisions more

data-driven, defensible, and performance-based. [Hawkins and Smadi, 2013] Sixty percent of the agencies claimed to be balancing preservation and capital improvement needs with their asset management program, and 50 percent of the agencies had developed a process to share asset management information with elected and appointed officials, which is helpful for communicating investment needs, trade-offs, and adding transparency to the decision-making process. More than 90 percent of the agencies used asset management information to select bridge and pavement projects; however, for other asset decisions (e.g., maintenance, operations, and safety) this number dropped to below 40 percent, indicating a need for looking at how ancillary assets could be incorporated into transportation asset management plans. A number of agencies are making significant efforts to management ancillary assets with a range of asset management policies, system/program integration approaches, data collection methods and costs, benefit qualification, and asset category prioritization approaches. [Akofio-Sowah et al., 2014]

Asset management techniques in transportation investment decisions began with bridges. In 1967, the Silver Bridge in West Virginia collapsed, killing 46 people. This disaster shocked the nation and raised public awareness of the importance of systematic monitoring of the condition of built facilities in general. As a result, a National Bridge Program was authorized by Congress in the Federal Aid Highway Act of 1970. This program initiated a nationwide system for monitoring and tracking the condition of bridges. As part of the program, periodic collection of data on both the inventory and the condition of bridges was required. The goal of the bridge monitoring system was to provide decision-support information for evaluating the relative needs for bridge maintenance, repair, and rehabilitation (MR&R), and for prioritizing projects. Bridge condition assessment in the United States has been formally required on a regular basis ever since. Attention on this requirement was renewed by the 2007 collapse of a highway bridge in Minneapolis, Minnesota, that killed 13 people.

By the 1980s, several state and local agencies had developed capabilities for periodic inventory and condition assessment as well as for performance prediction for pavements and bridges. By the 1990s, several agencies had also developed economic analysis tools for evaluating and prioritizing project alternatives. [McNeil et al., 2000] However, in the United States, one of the most important motivations for asset management among state transportation agencies has been federal transportation legislation, described in the next section.

## A. Early Asset Management-Related Legislation

In 1991, the Intermodal Surface Transportation Efficiency Act (ISTEA) required state departments of transportation (DOTs) and MPOs to develop six infrastructure management/monitoring systems as part of the planning requirements of the act. These management systems focused on pavements, bridges, highway safety, traffic congestion, public transportation facilities, equipment, and intermodal transportation facilities and systems. These requirements were motivated by a desire to foster a more systematic and systemic consideration of the functional capability and conditions of transportation assets on the nation's transportation system. Whereas pavement and bridge management

systems were fairly common to transportation engineering practice and highway safety management systems had been developed in many states, the congestion management systems, intermodal management systems, and public transportation facilities and equipment management systems were relatively new to most agencies.

In 1995, partly in response to state DOT pressure to remove unfunded mandates, Congress removed the requirement for these systems (except for congestion management systems in air quality nonattainment areas). The brief consideration of these management systems, however, left a legacy in many transportation agencies, and many continued developing and using them for infrastructure management.

Many state DOTs, MPOs, and local agencies incorporated some level of asset management into their transportation planning, programming, and project development processes because of state law. For example, the Virginia legislature passed the nation's first public/private partnership law in 1995, allowing Virginia DOT to contract out roadway maintenance to the private sector while retaining management functions for quality control/quality assurance. The Vermont (2001) and Michigan (2002) legislatures both passed asset management laws for transportation that required the consideration of asset management principles in investment decision making. In Michigan, for example, the state's Asset Management Law (Public Act 499 of 2002) established an 11-member Transportation Asset Management Council to provide input for the development of a statewide asset management strategy. Because of this law, there are several examples of Michigan counties at various stages in the adoption and use of asset management in their business processes. The council adopted the following program activities as a primary means of accomplishing its goal:

- Survey and report on the condition of roads and bridges by functional classification categories for the state and regional planning areas.
- Assess completed and planned investments in roads and bridges by the various transportation agencies of the state.
- Support the development of appropriate asset management tools and procedures.
- Provide education and training on the benefits of developing road improvement programs through the use of asset management principles and procedures. [Michigan Asset Management Council, 2011a]

In an initiative to promote asset management in local agencies, the council developed agency guidebooks (see [Michigan Transportation Asset Management Council, 2011a, b]). Experiences in Michigan demonstrate that funded mandates can be used as an effective means to implement asset management widely.

## B. Governmental Accounting Standards Board (GASB) 34

The Governmental Accounting Standards Board (GASB) in 1999 issued recommendations for state and local government agencies to report financial information on their assets, including civil infrastructure facilities, based on accounting standards contained in GASB Statement 34. [GASB, 1999] GASB recommends agencies report on their civil infrastructure assets using the book value method (historical costs less depreciation over their life cycles); otherwise, they must demonstrate that their assets are being maintained above a certain minimum condition level using an asset management system (AMS).

GASB 34 resulted in a surge of interest in asset valuation both in practice and academia and led to a distinction between depreciation-based and condition-based methods for infrastructure reporting. Depreciation-based methods simply depreciate the value of an asset using a depreciation schedule (usually a straight-line depreciation). A condition-based method takes into account, based on asset management systems, the current condition of the asset given the demands that have been placed on it and determines the value associated with its replacement.

## C. International Asset Management Scanning Tour

In April 2005, the U.S. DOT, AASHTO and NCHRP sponsored an international scanning study to investigate best practices in asset management in the world. The team, made up of local, state, federal transportation officials, and professors, visited national, provincial/state, and regional-level transportation agencies in Australia, Canada, England,

and New Zealand. The study identified the following important characteristics for agencies that were successful in adopting asset management:

- Top-level management commitment (at the very highest levels) was apparent.
- A dramatic change had occurred in viewing asset management as a key business area of the agency.
- A position or office had been created with responsibility for asset management.
- Asset management was fully integrated into several agency planning and policy documents.
- Life-cycle costing and risk assessment were used when establishing investment priorities.
- Facility valuation was used in infrastructure reporting.
- Asset management was used for developing a program of investment and capital renewal.
- The concept of a *gap analysis* was used to identify asset management needs.
- Asset management training for all levels of officials was important for fostering a change in the organizational culture. [FHWA, 2005]

The team also found asset management practices and processes were used successfully to obtain funding for transportation infrastructure, even when governmental budgets were being cut. Importantly, asset management practices were also found to be essential when entering into public-private partnerships for the provision of transportation infrastructure.

## D. Domestic Asset Management Scanning Tour

One of the recommendations of the international scanning tour was to conduct a similar fact-finding exercise among U.S. transportation agencies. Such a tour occurred in 2006. The scan team met with a range of organizations representing state transportation agencies (Florida, Michigan, Minnesota, Ohio, Oregon, and Utah), a city transportation department (Portland, Oregon), metropolitan planning organizations (SEMCOG in Detroit, Michigan, and Grand Valley Metropolitan Council in Grand Rapids, Michigan), two county transportation departments (Hillsborough County, Florida, and Kent County, Michigan), a tollway authority (Florida Turnpike Enterprise), and a statewide asset management association in Michigan. The major observations from this scan included the following:

- The agencies visited had all adopted a *preservation-first* strategy for their investment priorities. However, in many cases, this strategy ran up against concerns for reducing congestion on existing roads as well as dealing with the need for new road capacity to handle population and employment growth.
- In each case, the success of the asset management process was directly linked to the actions of an asset management champion or champions within the organization. Until asset management became institutionalized within the agency's standard operating procedures, the role of the champion was especially critical.
- In several cases, the existence of an asset management process, and more importantly, of the information that justifies a transportation investment in a road system, was instrumental in securing additional dollars from the legislature. The use of an asset management approach was critical for providing officials with the needs and consequences of investing (or not investing) in highway infrastructure.
- The most successful asset management processes moved away from a *worst-first* investment strategy. Instead they adopted investment principles based on life-cycle costing and result in the most cost-effective preservation and maintenance strategies.
- The most successful asset management processes had performance measures that guided investment decisions throughout the organization. These performance measures became important indicators for system monitoring and were used in one case for annual personnel evaluations. A performance-based asset management approach became the normal way of doing business in many of the sites visited.

- Scenario analysis showing the consequences on performance measures was one of the most effective methods of convincing decision makers of the need for investment in the transportation system. This capability was instrumental in supporting political discussions on the needs for infrastructure investment.
- There was no one organizational model for successful asset management. Many different successful organizational models of asset management were found during the scan. Perhaps the most important organizational characteristic found was the use of a team approach in defining and implementing an asset management process.
- The growing pains of an asset management process in almost all cases fostered enhanced communications among many different organizational units. Many of the participants agreed the need to promote cross-organizational coordination in an asset management process led to more effective planning and decision making in the agency.
- One of the most important starting points for implementing an asset management process was to conduct an organizational self-assessment.
- There was little evidence of the application of risk analysis techniques in the asset management processes observed. The concept of risk assessment allows transportation officials to determine the economic costs associated with infrastructure failure and to incorporate these costs into the analysis process.
- In several cases, agencies viewed data as an asset and the data collection process as an important decision-support function. Effective communication tools were needed to leverage the information and value derived from data collection efforts and the strategy of "*collect once, use often*."
- Customer input had been adopted as part of the asset management process in several cases. Surveys were used to determine those aspects of the infrastructure maintenance and condition that were most important to the users of the road system. Some performance measures were selected (for example, ride quality) because of their impact on public perceptions of the agency's performance.
- New technologies have the potential to make data collection for asset management activities more cost effective and efficient. For example, laptop computers or tablets combined with global positioning systems (GPS) powerful tools can be used to collect condition data on the road network. [Cambridge Systematics and Meyer, 2007]

## E. TAM Asset Management Guide

A *Transportation Asset Management Guide* was published in 2002. [AASHTO, 2002] The guide offered a useful framework for agencies to assess how well their current business processes and operations were tailored to deliver the best value with existing resources and to identify opportunities to improve existing procedures and capabilities. An agency exerts varying influence on the factors controlling facility expenditures over the facility life cycle. Hence, the nature and timing of decisions are critical and have a measurable impact on the cost-effectiveness of infrastructure service delivery (this is discussed later).

In 2011, AASHTO produced volume 2 of the *Asset Management Guide*, titled *Asset Management Guide: A Focus on Implementation* [AASHTO, 2011a]. Volume 2 focused on the characteristics of successfully implementing asset management within transportation agencies. It explicitly recognized that the exact nature and substance of the material included in a transportation asset management plan (TAMP) would vary by the level of maturity of the agency's TAM process and its impact on decision making. For example, the content of an initial TAMP might simply be a diagnostic document intended to understand the strengths and weaknesses of TAM practices, and may include asset management objectives and measures, performance gap identification, life-cycle cost and risk management analysis, and a financial plan, all to establish the directions and steps necessary to reach a higher level of TAM maturity. It would "record current policies, standards, lifecycle tactics, levels of service, information systems, critical assets, knowledge of assets, and work programs." [AASHTO, 2011a]

Meeting the requirements of an initial and core TAMP for pavements and bridges would rely on the existence of information and data that could be input into each section of the TAMP above. For example, with respect to performance measures (found in the levels of service section), action would relate to the existence of performance measures relating to condition preservation for both pavements and bridges; this could be expanded to include the degree to

which stakeholders are involved in the definition of performance measures, including the linkage to federally defined performance measures. One could also focus on the co-benefits of asset investments on goals relating to such things as safety, mobility, environmental quality, and financial sustainability.

## F. MAP-21 and Asset Management Regulations

The 2012 U.S. surface transportation legislation, MAP-21, has been the most specific legislation with respect to transportation asset management requirements. The law required every state to develop and implement a "risk-based State Asset Management Plan" for the National Highway System (NHS), including data collection, maintenance and integration, software costs, and equipment costs [FHWA, 2012a]. Subsequent to the law, FHWA issued a Notice of Proposed Rulemaking relating to the required asset management systems. The proposed rule establishes the basic structure of a risk-based transportation asset management plan. The minimum topics to be included in a TAMP and the process for developing the plan are identified, as are the timeframes for plan development. The following highlights some of the key requirements:

- State DOTs are required to develop and implement asset management plans for the National Highway System (NHS) to improve or preserve the condition of the assets and the performance of the NHS relating to physical assets (although state DOTs are encouraged to include all highway infrastructure assets within the right-of-way).
- State asset management plans must include strategies leading to a program of projects that would: (1) make progress toward achievement of the state targets for asset condition and performance of the NHS, and (2) support progress toward the achievement of the national goals.
- With respect to required processes, each state DOT must establish a process for:
  - Conducting a performance-gap analysis and identifying strategies to close gaps.
  - Conducting life-cycle cost analysis for an asset class or asset subgroups at the network level.
  - Undertaking a risk-management analysis for assets in the plan. As part of this process, state DOTs would identify and assess risks (e.g., extreme weather) that can affect asset condition or the effectiveness of the NHS as it relates to physical assets.
  - Addressing the risks to assets and to the highway system associated with current and future environmental conditions, including extreme weather events, climate change, and seismic activity, in order to provide information for decisions about how to minimize their impacts and increase asset and system resiliency. A mitigation plan for addressing the top priority risks must also be described.
  - Evaluating roads, highways, and bridges that have repeatedly required repair or reconstruction due to emergency events. For assets in the asset management plan, state DOTs are required to develop an approach to address and monitor high-priority risks to assets and the performance of the system.
  - Developing a financial plan covering a 10-year period.
  - Developing investment strategies to improve or preserve the condition of the assets and the performance of the NHS.
  - Using pavement and bridge management systems to analyze the condition of interstate highway pavements, non-interstate NHS pavements, and NHS bridges, and to determine optimal management and investment strategies.
- A TAMP should include, at a minimum, (1) asset management objectives, which should align with the agency's mission; (2) measures and targets designed to achieve and sustain a desired state of good repair over the life cycle of the assets at minimum practicable cost; (3) summary listing of the pavement and bridge assets on the NHS, including at a minimum a description of the condition of those assets for: interstate pavement, non-interstate NHS pavement, and NHS bridge assets; (4) performance gap identification; (5) life-cycle cost analysis; and (6) risk management analysis for assets and the highway network included in the plan, and including for those assets a summary of the statewide periodic evaluations, financial plan, and investment strategies.
- The TAMP must discuss a set of investment strategies leading to an immediate program of projects.

One of the key characteristics of the MAP-21-required asset management approach is the emphasis on risk and risk management. As noted by FHWA, "risk is the positive or negative effects of uncertainty or variability upon agency objectives. Risk management generally consists of the cultures, processes, and structures that are directed toward the effective management of potential opportunities and threats." FHWA sponsored pilot studies in three states in 2012 (Louisiana, Minnesota, and New York) to outline what a risk-based asset management approach and a risk-based transportation asset management plan looks like.

The most recent federal transportation legislation, Fixing America's Surface Transportation (FAST) Act, reaffirms the MAP-21 requirements for asset management plans and the reporting of performance and condition metrics. The act states that if a state DOT does not achieve or make significant progress toward achieving targets in any performance measurement area after one reporting cycle, the state must submit a report describing the actions they will undertake to achieve the targets in the future. The penalty for falling below the minimum condition levels for pavements on the Interstate system is also imposed after the first reporting cycle.

Those interested in asset management should stay abreast of FHWA-sponsored studies and pilot programs on asset management at https://www.fhwa.dot.gov/asset.

## IV. ASSET MANAGEMENT AND TRANSPORTATION PLANNING

As noted by the FHWA, "several key planning functions and activities where asset management principles are likely to have the most impact and where the current state of practice could be strengthened significantly" include:

*Long-Range Plan Development and Updates*—The development and updating of long-range plans offer an opportunity to develop clear policy goals for executive management and key stakeholders; establish system performance measures; broaden the range of investments and actions included in the planning effort, including freight, safety, preventive maintenance, operations, and intermodal and multimodal options as appropriate; and broaden the range and level of integration of the data and analysis tools used to support the planning and programming process.

*Performance Measurement*—Whether established as part of a long-range plan update or as a stand-alone initiative, defining a set of system performance measures is a prerequisite to good asset management. Because they focus on system performance, these measures can help encourage the culture change required for asset management, which is a "systems view" not a project view. Such measures should be tied to the policy goals and objectives of the planning process.

*Strategic Resource Allocation and Trade-Offs*—The planning process examines strategic resource allocation issues and trade-offs. Most agencies do not have the full set of tools, data, or organizational structure and roles to really examine expenditures in all key areas in a consistent manner and consider options and trade-offs. Broadening the role and focus of planning can incrementally broaden the type of trade-offs considered and that move an agency toward a more integrated decision-making model.

*Linkage to Programming and Budgeting*—The extent to which plans and planning activities influence program and budget decisions varies widely. Unless this linkage is clear and strong the value of planning can be questioned—the ability to directly impact programming and budgeting decisions is often viewed as the single most important criterion for judging the effectiveness of transportation planning. Thus, planning can utilize data produced by the asset management system to establish priorities for infrastructure renewal that are part of the transportation plan.

*Data and Analytic Tool Development and Support*—In many agencies, the planning function is the "owner" of some of the data and tools required to support a variety of planning activities. However, as the range of issues and investment trade-offs considered in planning increases, many key databases and tools will be maintained by other functional units (for example, system physical conditions, real-time operations data, crash statistics, pavement and bridge management systems). Shared access to, and common definition of, data and joint use and understanding of analysis tools is important. As noted by FHWA, "The planning function provides a platform for a more integrated agency-wide data collection and management strategy and the development of new, or enhanced, analytic tools to support a broader and more integrated set of tradeoff analyses."

The rest of this section describes how asset management can provide important information to the transportation planning process. (See chapter 1 for more detailed discussion on the different components of the transportation planning process).

## A. Vision, Goals and Objectives

An effective asset management approach will align an agency's vision, goals, and objectives with a set of performance measures and targets at various levels of decision making (for example, network-level [strategic], operations, and project development). Experience suggests that successfully achieving this alignment makes the decision-making process more effective in achieving desired outcomes. For example, if one goal of a state DOT is to provide the state's citizens with a road network that meets the needs of both personal and freight travel, then one objective might be to maintain the road network in good condition. A possible performance measure connected to this objective might be *the number of lane-miles of road maintained at a specified condition level*. This measure provides direct feedback to decision makers on the extent to which the identified goal is being achieved.

Most asset management programs have a set of defined goals and/or objectives to guide rehabilitation and maintenance decisions. The linkage between asset management activities and transportation planning with respect to more general vision, goals, and objectives statements is most often found in the types of goal statements that guide statewide and metropolitan transportation planning studies. Figure 8-3, for example, shows the logic underlying the development of the metropolitan transportation plan in Dallas–Fort Worth, Texas. As shown, the first priority for the region's transportation investment is infrastructure maintenance, followed by other initiatives that are important to the region.

A local asset management example comes from Portland, Oregon, where the vision statement of the city transportation department states the transportation system will be "maintained and preserved" to support the many different uses streets serve in an urban environment. According to the city, the asset management program "provides a targeted level of service and performance for various assets within the transportation network, in a cost-effective manner, by making the right amount of investment for the right asset in the right location at the right time." [City of Portland, 2014] Figure 8-4 shows a typical reporting of the condition of the city's assets.

**Figure 8-3. Priority Consideration of Investment Factors, Dallas–Ft. Worth, Texas**

**Figure 8-4. Example of Infrastructure Report Card, Portland, Oregon**

CITY OF PORTLAND BUREAU OF TRANSPORTATION

## Infrastructure Asset Report Card – FY 11-12

Met or exceeding target | within 80% of meeting target | Not meeting target | Target — Results

| BRIDGES | Rating | Target | Result | | |
|---|---|---|---|---|---|
| Bridge condition – % of bridges requiring critical and urgent maintenance | | 5% | 4% |  | Addressing critical maintenance needs will prevent bridges from falling into worse condition. Inspection is done every two years. |
| Bridge condition – % of bridges that are weight restricted | | 5% | 16% |  | A bridge's structural integrity is key to movement of freight and transit. |
| **PAVEMENT:** Arterial/Collector | Rating | Target | Result | | |
| Pavement condition – % of arterial/collector streets that are in fair or better condition | | 80% | 60% |  | Streets in fair or better condition are likely to need preventive maintenance fixes to keep them from falling into poor or very poor condition. |
| Pavement condition – % of arterial/collector streets in very poor condition | | 2% | 8.3% |  | Pavement that is in very poor condition most likely requires a rebuild and is much costlier to fix. The target was changed to 2% this year. |
| **Pavement: Local** | Rating | Target | Result | | |
| Local Pavement condition – % in fair or better condition | | 70% | 53% |  | * New Measure* Local streets deteriorate slower than arterial roads partly because they do not carry the same loads as the busier streets. |

Source: City of Portland, 2012

The Ohio Department of Transportation (ODOT) is another example of an integrated approach to asset management. Asset management is considered a core value and function of the organization. ODOT's asset management plan goals that relate to planning include:

1) Adopt a Transportation Asset Management policy as the Department's business process for managing critical assets and making capital investment decisions.

2) Establish an Asset Management oversight group to direct the respective Central Office Divisions to establish and lead Asset Task Committees to determine statewide standards, procedures, and formats for a centralized asset inventory database.

3) Develop a centralized Asset Management platform for integration of all asset inventory databases to reside in a geo-Spatial environment tied to the Base Transportation Referencing System.

4) Mandate the collection of asset data directly related to supporting a "Safety First" philosophy in all aspects of transportation system development and operation. Leverage existing resources and new innovative technologies to enhance asset inventory collection with improved safety, efficiency, and data quality.

5) Implement management systems around critical assets, with a focus on developing an integrated asset management process.

6) Require as-built plans for all future projects and establish a work order based asset inventory updating process to ensure that the centralized asset database remains updated.

7) Utilize the Department's Research and Development Program to support Transportation Asset Management activities.

ODOT decisions are guided by a set of principles and strategic goals that link to performance measures found at all levels of organizational decision making. ODOT has adopted goals in five major strategic decision-making areas: transportation safety, economic development and quality of life, efficient and reliable traffic flow, system preservation, and resource management. The system preservation goal is defined as "achieving a steady-state condition for pavement and bridges, that is, a state of relatively low and stable level of deficiencies, small enough that a predictable rate of preventative maintenance and regular repairs can sustain that level of acceptable conditions." Condition and performance measures are integrated within all departmental functions and are not really identified as asset management measures as such. Annual pavement and bridge inspections are conducted. Overall condition targets have been established for the different road systems. The DOT uses a "mix of fixes" to provide as close to a steady state in condition as possible.

It is important to note that, although this section has focused on asset management applications in planning, the asset management concept can be applied throughout the entire life cycle of facilities and systems. Operations asset management, for example, focuses on analytical procedures for managing the assets used to support facility operations. Similar to the approach used for planning, asset management includes consideration of the following:

- Associated goals and objectives (for the operation of the system).
- Linkages between goals, objectives, and performance.
- Trade-offs between alternative improvements.
- Engineering and economic evaluation results.
- Impacts of varying asset life-cycle and investment-cycle time horizons. [FHWA, 2004]

More detailed treatments of asset management for system operations may be found elsewhere (see, for example, [TRB, 2005]). While the applications are different, the overarching asset management concepts remain the same. As asset management implementation advances in the different stages of the life cycle of facilities and systems, it is expected that these asset management procedures and activities will be progressively integrated.

## B. Performance Measures

Although visions, goals, and objectives are important points of departure for a planning process, they often do not provide enough detail on how progress or relative performance of different plan alternatives will be measured. Performance measures provide this greater level of detail. MAP-21 established a national policy in support of performance measurement: "Performance management will transform the Federal-aid highway program and provide a means to the most efficient investment of Federal transportation funds by refocusing on national transportation goals, increasing the accountability and transparency of the Federal-aid highway program, and improving project decision making."[§1203; 23 USC 150(a)] National performance goals were identified in seven areas:

safety, infrastructure condition, congestion reduction, system reliability, freight movement and economic vitality, environmental sustainability, and reduced project delivery delays.

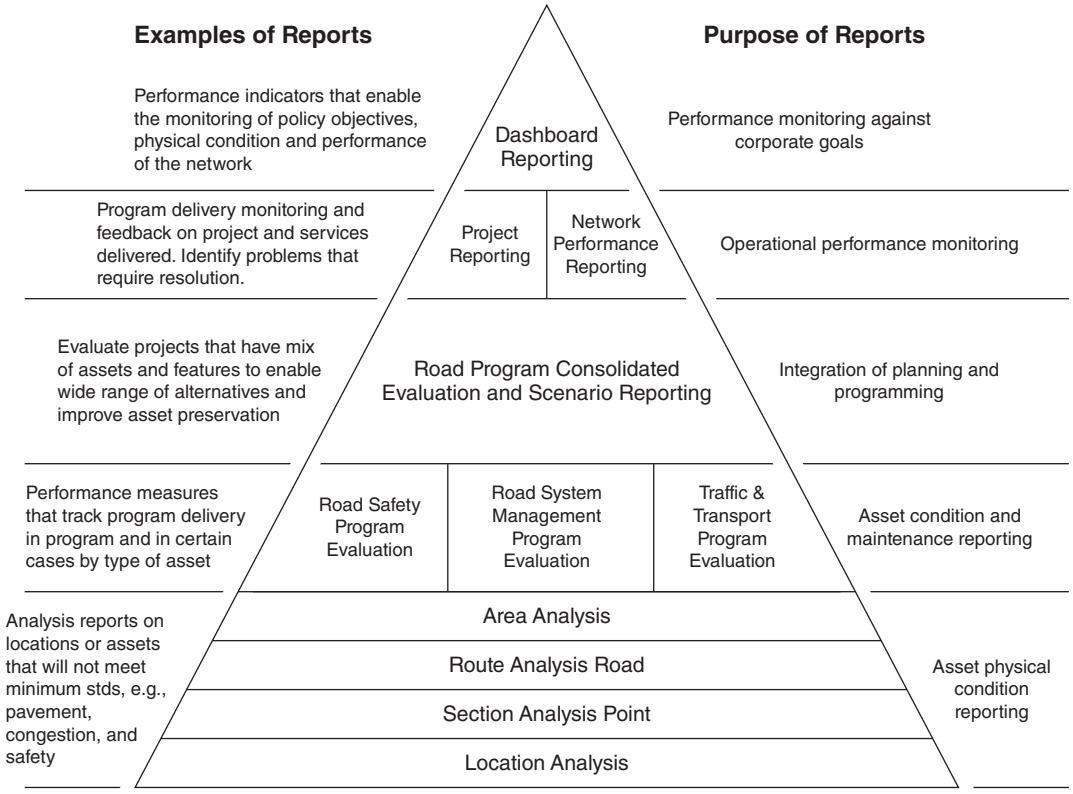
Effective performance measurement is an integral part of an asset management approach in transportation planning, programming, and project development. Well-defined policies that achieve the overall agency vision and goals must be related to clear measures of performance (measurable quantities that indicate level of achievement of objectives) with targets (target outcomes with time deadlines). Continuous performance monitoring is then required to close the loop between the planning objectives and actual system outcomes.

The report *Performance Measures and Targets for Transportation Asset Management* [AASHTO, 2011a] outlines critical considerations for developing performance measures for TAM. It emphasizes the following as important attributes for performance measures to support effective asset management: They must be policy-driven, embrace a strategic perspective, consider options and trade-offs, be supported by credible information, provide effective feedback relative to system goals and objectives, and be useful across various organizational units and levels.

The international scanning tour described earlier found a common framework for performance measurement in all the best practice case studies. Each country's effort was related to a broad set of goals and objectives defined either by a legislative body or through a public visioning process. These goals and objectives led to the identification of system-specific performance measures, often tied to target values to be achieved in a future year. Performance measurement was applied at several different levels of planning and decision making; for example, measures were targeted at longer-term strategic investment decisions and shorter-term network operations functions.

Figure 8-5 shows the performance reporting hierarchy used by VicRoads (the state's transportation agency) in Victoria, Australia. In some cases, these performance categories could provide the basis for cross-asset evaluation and investment prioritization. NCHRP Report 446, *A Guidebook for Performance-Based Transportation Planning,* provides a useful library of performance measures for all types of transportation goals and objectives. [Cambridge Systematics, 2000] For the system preservation goal, Table 8-3 presents some of the measures that are used more often than others.

**Figure 8-5. Information Reporting Hierarchy at VicRoads, Victoria, Australia**



Source: FHWA, 2005

| Table 8-3. Typical Performance Measures for System Preservation | |
|---|---|
| **System Preservation Category** | **Common Measures** |
| System condition—Roadway, General | Percentage of roadway/bridge system below standard condition<br>Age distribution |
| System condition—Roadway, Pavement | Percentage of highway mainline pavement or bridges rated good or better |
| System condition—Roadway, Bridge | Percentage of highway mainline bridges rated good or better |
| System condition—Roadway, Freight facilities | Pavement condition on links to intermodal facilities |
| System condition—Bicycle facilities | Miles of highway rated good or fair for bicycle travel |
| System condition—Rail | Miles of track in operation |
| System condition—Transit vehicle | Miles between road calls for transit vehicles<br>Age distribution |
| System condition—Other modes | Miles to be dredged<br>Runway surfacing frequency |
| System condition—Multimodal | Hours or days out of service (roads, bridges, transit equipment or airports) |
| Program delivery—Time-related | Number of lane-miles let to contract for resurfacing<br>Number of bridges let to contract for repair or replacement |
| Program delivery—Cost-related | Percentage of budget allocated to system preservation<br>Average maintenance costs |

## C. Data Needs

Data needs for asset management relate directly to an agency's responsibilities and its goals concerning infrastructure condition and performance. Guidance for data collection for various infrastructure and asset management systems is available in standard references such as [AASHTO, 1996; 2011a; 2011b; AASHTO et al., 1996; Pierce et al., 2013; and FHWA, 2012c, 2013a,b] Several of the early asset management applications typically categorized data into inventory and attribute data. This categorization still characterizes many of the infrastructure management systems used today for all aspects of asset management.

Inventory data are critical. They provide a current description of an agency's assets (what the agency owns, where it is located and such). Attribute data, on the other hand, refer to characteristics of facilities/systems that are subject to change, such as facility demand, the condition of the facility, and so forth. Table 8-4 shows the type of data typically collected for pavement management for decisions at the network and project levels. [Pierce et al., 2013]

Classification of data needs at different levels of detail (for planning, programming, and project development) is important because data collection can be very expensive and time-consuming. An adequate level of data detail must be available for project selection and programming as well as planning at the network level. In addition, some of the needed data may be used in more than one unit within an agency. Agency-wide data management is thus necessary to ensure the data themselves are being treated as an asset and managed most cost-effectively to provide up-to-date information.

Several agencies (for example, Colorado DOT, Arizona DOT, Virginia DOT, and Pennsylvania DOT) continue to modernize their legacy databases and applications, some of which were developed for very specific functional responsibilities within the organization (for example, one database format for pavements, another for bridges). The goal is to integrate their databases into a comprehensive system that can be accessed and used effectively by multiple business units. In many cases, geographic information systems (GIS) are used as the common platform for data integration. Quality assurance and quality control for data collection are critical elements in these efforts for modernization. Additionally, ensuring that data are up to date is particularly important for generating useful information for decision making and earning or increasing credibility with the legislature and public.

A good example of a strategic approach toward asset data management comes from the Pennsylvania DOT (PennDOT). Responsible for the fifth-largest highway system in the United States, PennDOT has an annual budget

| Table 8-4. Network- and Project-Level Data Collection | | |
|---|---|---|
| **Aspect** | **Network-level** | **Project-level** |
| Uses | Planning<br>Programming<br>Budgeting<br>Pavement management system treatment triggers, identification of candidate projects, life-cycle cost analysis<br>Network-level condition reporting<br>*Mechanistic-Empirical Pavement Design Guide* (MEPDG) calibration | Project scope<br>Refine pavement management system treatment recommendations<br>MEPDG calibration |
| Data Items Typically Collected | International Roughness Index<br>Rut depth<br>Faulting<br>Cracking<br>Punchouts<br>Patching<br>Joint condition<br>Raveling<br>Bleeding<br>Surface texture | Detailed crack mapping and other distresses<br>Structural capacity (e.g., falling weight deflectometer)<br>Joint load transfer<br>Base/soils characterization (e.g., ground penetrating radar, cores, trenches) |
| Other Items Collected Concurrently | Video<br>GPS coordinates<br>Geometrics (e.g., curve, grade, elevation, cross slope)<br>Other assets (e.g., bridges, signals)<br>Events (e.g., construction zones, railroad crossings) | Drainage conditions<br>Appurtenances (e.g., sign and guardrail location and condition)<br>Geometrics (e.g., curve, grade, elevation and cross slope) |
| Speed | Typically highway speeds | Walking or slower speeds |

Source: Flintsch and McGhee, 2009, as reported in Pierce et al., 2013

of more than $4 billion. During the past 20 years, PennDOT made significant investments in the following suite of management systems designed to support its business operations:

- Roadway Management System (RMS).
- Bridge Management System (BMS).
- Maintenance Operations Reporting Information System (MORIS).
- Engineering Construction Management System (ECMS).
- Multimodal Project Management System (MPMS).
- Automated Permit Routing/Analysis System (APRAS).
- Electronic Document Management System (EDMS).
- Financial Management Information System (FMIS).

Developed in-house, these mainframe applications evolved over time in reaction to the changing needs of the agency and provided a wealth of standard inventory and condition data for the last 15 to 20 years. In the 1990s, PennDOT undertook an extensive evaluation of its business operations to integrate its information systems and strategic business planning. The process was designed to ensure that the management systems were compatible with one another from a business process point of view. Simultaneously, it worked on technically integrating individual data systems so that they could combine data and analysis results from the updated management systems and provide integrated information to decision makers across the agency.

## D. Analysis Methods and Tools

This section discusses several asset management methods and tools that are being used to determine the most cost-effective approach toward enhancing infrastructure performance. Some of these methods are more appropriately used within an agency's asset management program, while others could possibly be applied within a transportation planning context. It should be noted that several asset management software programs have been developed for both highway and transit assets. The intent of these programs is to automate the analysis of asset condition, ultimately resulting in investment priorities. Readers are encouraged to search the Internet to identify available asset management programs.

### *1. Infrastructure Condition Assessment Methods*

An objective and repeatable rating system must be used to evaluate facility condition. Various types of condition indices have been developed, including the Army Corps of Engineers' (ACOE) pavement condition index (PCI), FHWA's bridge sufficiency index, and Caltrans' bridge health index. Other indices exist for pavements, bridges, signs, and other appurtenances (see [Patidar et al., 2007; Pierce et al., 2013]).

The American Society for Testing and Materials' (ASTM) standard for the condition evaluation of airport and roadway pavements and parking lots is the ACOE's Pavement Condition Survey and Rating Procedure, which results in the PCI. The condition assessment procedure is based on visual assessment of the type, quantity, and severity levels of pavement distresses and provides a methodology for converting the data to a single value on a scale of 0 (failed pavement) to 100 (excellent pavement). [Shahin, 1994] The bridge health index relates the physical condition of bridges to the overall asset value of the bridge, capturing losses in bridge condition as reductions in the replacement value of the facility. [Shephard and Johnson, 2001]

State DOTs have adopted their own set of pavement condition measures that are provided to agency leadership as well as disseminated in annual reports. The Minnesota DOT (MnDOT), for example, reports on four measures: the Ride Quality Index (RQI), the Surface Rating (SR), the Pavement Quality Index (PQI), and Remaining Service Life (RSL). As noted in the annual report, "each index captures a different aspect of the pavement's health and can be used to rank pavement sections and predict the need for future maintenance and rehabilitation." [MnDOT, 2015] The definition of these measures are:

*RQI: Ride Quality Index*—The RQI is MnDOT's ride, or smoothness, index. It uses a zero to five rating scale, rounded to the nearest tenth. The higher the RQI, the smoother the road is. The RQI is intended to represent the rating that a typical road user would give to the pavement's smoothness as felt while driving his/her vehicle.

*SR: Surface Rating*—Pavement distresses are those defects visible on the pavement surface, symptoms indicating some problem or phenomenon of pavement deterioration such as cracks, patches, and ruts. MnDOT uses the SR to quantify pavement distress. The distress identification is done by viewing digital images of the pavement captured by a van that rides along the state highway collecting different types of pavement data. The percentage of each distress in the 500-foot sample is determined and multiplied by a weighting factor to get a weighted distress value.

*PQI: Pavement Quality Index*—The PQI is a composite index, equal to the square root of the product of RQI and SR. It gives an overall indication of the condition of the pavement, taking into account both the pavement smoothness and cracking. The PQI is the index used to determine if the state highway system is meeting performance thresholds established for the Government Accounting Standards Board, Standard 34 (GASB 34).

*RSL: Remaining Service Life*—The RSL is an estimate, in years, until the RQI will reach a value of 2.5, which is generally considered the end of a pavement's design life. The RSL is determined from pavement deterioration curves. A regression curve is fit through the historical RQI data for each pavement section and the year the RQI will reach 2.5 is estimated.

Table 8-5 shows how the measures relate to standard condition values, in this case for the RQI measure. Table 8-6 shows how MnDOT has defined ride quality index.

### *2. Deterioration Modeling for Performance Prediction*

Infrastructure deterioration models describe infrastructure condition or performance in terms of factors that cause deterioration in facilities, such as usage, loads, climatic factors, construction quality, and maintenance activities. These

| Table 8-5. Ride Quality Index (RQI) Performance Categories, Minnesota DOT | | |
|---|---|---|
| **Descriptive Category** | **RQI Range** | **Performance Measure Category** |
| Very Good | 5.0–4.1 | Good |
| Good | 4.0–3.1 | |
| Fair | 3.0–2.1 | Fair |
| Poor | 2.0–1.1 | Poor |
| Very Poor | 1.0–0.0 | |

| **System** | **"Good" RQI Target** | **"Poor" RQI Target** |
| Interstate | 70% or more | 2% or less |
| Other-NHS | 65% or more | 4% or less |
| Non-NHS | 60% or more | 10% or less |

Source: Minnesota DOT, 2015

types of models can help agencies allocate their budgets more effectively when planning for preservation, maintenance, and renewal of the highway network and bridge inventory.

Several types of models have been developed for pavement and bridge management systems. Such models may be classified based on their mechanical properties (mechanistic) or statistical data relationships (empirical) and whether they capture uncertainty (probabilistic or stochastic) or not (deterministic). They may be developed for network-level decision making (with aggregate properties) or project-level decision making (using more detailed data). Empirical models include statistical regression models, fuzzy sets, artificial neural networks, fuzzy neural networks, and genetic algorithms. They are more common than mechanistic models, which predict future changes based on expected physical response (such as material strain, stress, or deflection) as a function of known factors that cause changes in these responses (such as load on the facility). Empirical models must be validated periodically for accuracy.

Figure 8-6 shows the difference between probabilistic and deterministic models. In the probabilistic formulation, the probability of going from one pavement condition state to another is found through analysis of historical data and the application of statistical analysis techniques. Thus, in the example, the probability of going from an initial state of "very good" to "good" using the life frequency data was 0.09, or 9 percent. The deterministic model uses historical data to plot the condition of different pavements with different service lives over time.

Markov models, semi-Markov models, and survivor curves are examples of probabilistic models commonly used in the development of performance prediction models. Markov models use transition matrices to describe the probability that a facility in a known condition state at a known time will change to some other condition state in the next time period.

Regression models are another model form often used to predict future pavement condition. Regression models are simple to use. However, developing and validating them usually requires a database with many years of data from which to discern cause-and-effect relationships. Hence, they must be recalibrated periodically for quality assurance. They are also not readily transferable from one site to another. An example of the use of regression models to predict pavement condition is found in [Chou, Pulugurta, and Datta, 2008]. The following is a sample regression model for of a strategy for pavement overlay with repairs for one district.

$$PCR_P = 98.401 - 6.142 \times [(Age + 1)^{0.728} - 1]$$

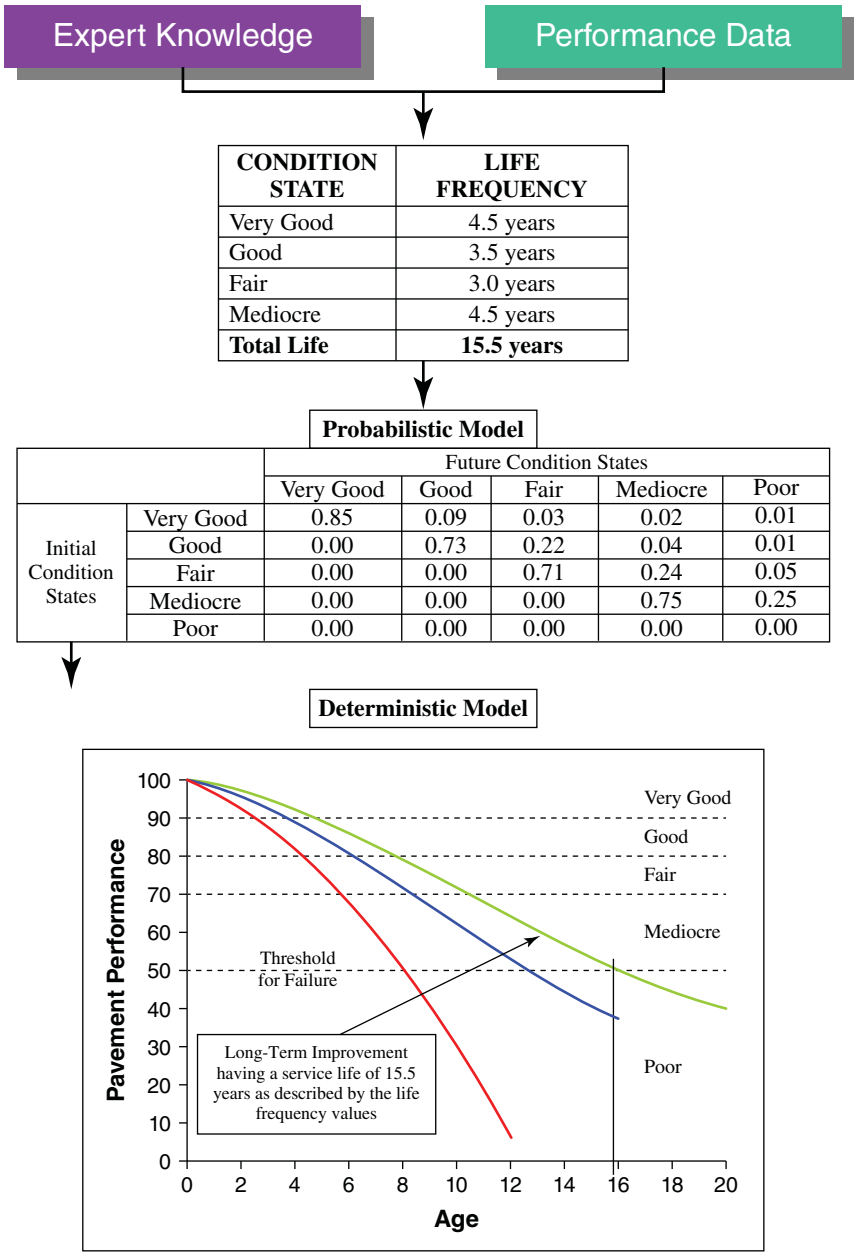
$$n = 1523,\ R^2 = 0.74$$

where

$PCR_P$ is the pavement condition measure for pavement strategy.

*Age* is the age of the pavement since treatment.

**Figure 8-6. Example of Probabilistic and Deterministic Pavement Condition Models**



Source: Hedfi and Stephanos, 2001

Interestingly, the authors compared two types of regression models and a Markov model and determined that the Markov model was a better model form for prediction purposes in this case.

The RQI deterioration in the Minnesota DOT example used regression curves that were based on section-specific historical data or statewide data. If adequate historical data exists since the last rehabilitation on a section, a regression curve is fit through the data and used to predict the RQI. If there is inadequate historical data for the section, or if the regression through the historical data results in an unrealistic curve, a default curve is used to predict the future RQI. Table 8-7 shows a comparison between the RQI as predicted with the deterioration curves and actual measurements.

As shown in the table, the difference between the predicted 2014 condition and the actual 2014 condition was not that great. MnDOT attributed differences to one, or more, of the following: (1) timing of the construction work was different than expected (versus our van schedule), (2) districts were tested in a different order than originally expected, (3) construction projects were advanced, reducing "Poor" and increasing "Good," (4) construction projects

| Table 8-7. Comparison of Predicted 2014 RQI versus Actual 2014 RQI, Minnesota DOT | | | | |
|---|---|---|---|---|
| **Interstate System RQI Category** | **Actual 2013 Data** | **Predicted 2014 Data** | **Actual 2014 Data** | **Difference Actual vs. Predicted** |
| Good RQI (RQI > 3.0) | 75.2% | 77.3% | 75.9% | (1.4%) |
| Poor RQI (RQI <= 2.0) | 2.4% | 1.5% | 1.9% | 0.4% |
| **Other NHS System RQI Category** | **Actual 2013 Data** | **Predicted 2014 Data** | **Actual 2014 Data** | **Difference Actual vs. Predicted** |
| Good RQI (RQI > 3.0) | 71.0% | 68.9% | 70.9% | 2.0% |
| Poor RQI (RQI <= 2.0) | 2.9% | 3.3% | 3.0% | (0.3%) |
| **Non-NHS System RQI Category** | **Actual 2013 Data** | **Predicted 2014 Data** | **Actual 2014 Data** | **Difference Actual vs. Predicted** |
| Good RQI (RQI > 3.0) | 62.5% | 63.1% | 67.2% | 4.1% |
| Poor RQI (RQI <= 2.0) | 6.8% | 6.2% | 4.4% | (1.8%) |

were incomplete, keeping "Poor" from becoming "Good," (5) maintenance work kept roads from falling into "Poor" or out of "Good," (6) a change in a road's rate of deterioration (either faster or slower), and (7) unforeseen funding or projects improving the road. [MnDOT, 2015]

### *3. Valuation*

Many asset management approaches used throughout the world rely on asset valuation. To evaluate or place a value on something is to determine its significance, worth, or condition. Several methods exist for valuing physical assets (see Table 8-8). GASB 34 allows governments to report either a depreciation expense or to apply an alternative modified/preservation approach. Government agencies may use the modified approach in lieu of depreciating their assets if they have a systematic approach to managing their assets that, at a minimum, meets the following four requirements: (1) have a current inventory of eligible assets, (2) document the condition of those assets via a reproducible assessment procedure, (3) demonstrate that assets are being preserved at a level predetermined by the government, and (4) estimate the actual cost to maintain and preserve the assets. [MnDOT, 2015]

The GASB 34 Statement, which requires state and local agencies to report on their infrastructure value, has renewed broad interest in valuation methods, both in practice and in academia. As noted earlier, one of the key distinctions in valuation methods is between traditional accounting-based methods (for example, book value) and condition-based methods (for example, replacement cost value).

| Table 8-8. Description of Valuation Approaches | |
|---|---|
| **Valuation Approach** | **Description** |
| Book Value | Present worth of capital and subsequent costs of asset depreciated to the present |
| Equivalent Present Worth in Place | Represents worth "as is." Based on historic costs adjusted for inflation, depreciation, depletion, and wear |
| Productivity Realized Value | Represents value of asset in use. Present worth of future benefits for the remaining service life of the facility |
| Written-Down Replacement Costs | Uses current market prices to determine costs to rebuild or replace facility in its current condition |
| Market Value | Price that the buyer is willing to pay |
| Net Liquidation Value | Present worth of amount obtainable from selling off the components of an asset over a reasonable period of time |
| Salvage Value | Present worth of the amount obtainable disposing or recycling a facility |
| Option Value | Value of asset in specific circumstances |

Source: Adapted from Haas, R. and C. Raymond. S. "Appraising a Transportation Corridor." *Right of Way* (November/December 1998); and Damodaran, A. *Investment Valuation: Tools and Techniques for Determining the Value of Any Asset*. Hoboken, NJ, USA: John Wiley and Sons Inc., 1996.

### *4. Economic Analyses*

Many transportation agencies use economic analysis methods to determine the best economic decision with respect to return on investment. In most cases, the economic test that is applied to different asset management strategies is benefit-cost analysis. A good example of this approach is found in the New York State DOT (NYSDOT). [FHWA, 2012d]

Basic network-level transportation management systems were established at NYSDOT as early as the 1960s. Over time, these systems were continuously improved by the use of more sophisticated database management technology and the addition of economic analysis methods for project-level evaluation of investment candidates for different classes of assets. NYSDOT's pavement management system, bridge management system, safety management system, and congestion needs assessment model employ life-cycle cost analysis (LCCA), least-cost analysis, benefit-cost analysis, and user cost analysis, respectively, for alternatives analysis. The agency developed a prototype of a TAM trade-off model that draws available economic and performance data from almost 2,000 investment candidates identified by the separate management systems. The TAM trade-off model ranks these projects both within and among program areas based on benefit/cost ratios.

One of the strengths of the TAM trade-off model is its ability to assess the cost-effectiveness of grouping assets together, such as facilities in a corridor. The model is designed to provide a network-level or program-level assessment of investment priorities, cutting across asset-specific system results. The TAM trade-off model is used as a first cut in program development.

### *5. Risk Analysis and Management*

Conducting risk analysis and management is an important element of asset management programs. Risks arise because of uncertainty; they represent the probability of loss. Although relatively little analysis has been incorporated into the planning process to address risks, a range of planning and project development risks are associated with a typical transportation plan's recommendations, including possible inadequate funding, long-term political risk associated with changing societal values and their impacts on transportation, local opposition to a plan or project, technological obsolescence, and the risks of a changing market. [Meyer and Miller, 2014; Mehndiratta, Brand, and Parody, 2000]

Approaches to address risk identify the sources of uncertainty and take measures to avoid, reduce, mitigate, or otherwise manage them. Several risk management approaches have been developed to address these uncertainties, for example, incremental planning, coalition building and staged implementations, sensitivity analysis for forecasting risks, legislation to limit or clarify liability, transparency in the bidding process, and turnkey contracts. [Brand, Mehndiratta and Parody, 2000; Mehndiratta, Brand, and Parody, 2000] Risks may be addressed at any stage of the planning and project development process. However, success in managing risks is related to the stage of the infrastructure life cycle where risks are addressed. For example, some environmental risks are managed more effectively at the earlier planning stages than at the project development stage. [Lytton, 1987] Thus, risk treatments can occur at the visioning stages when planning alternatives are being considered all the way through the project development stage. The following examples depict the types of risk treatments used at various agencies. Risk analysis can be a highly effective asset management tool. Identifying and planning for risks at the outset of planning and project development, when done appropriately, will promote decisions with more robust outcomes.

Probabilistic models address risk by considering uncertainty or variability in the analysis. Markov models, discussed earlier, used for deterioration modeling of pavements, bridges, and other facilities, capture the uncertainties associated with varying demand for different facilities in the network and other sources of variation such as the characteristics of the vehicle fleets, using the facilities, maintenance histories of facilities, and the like.

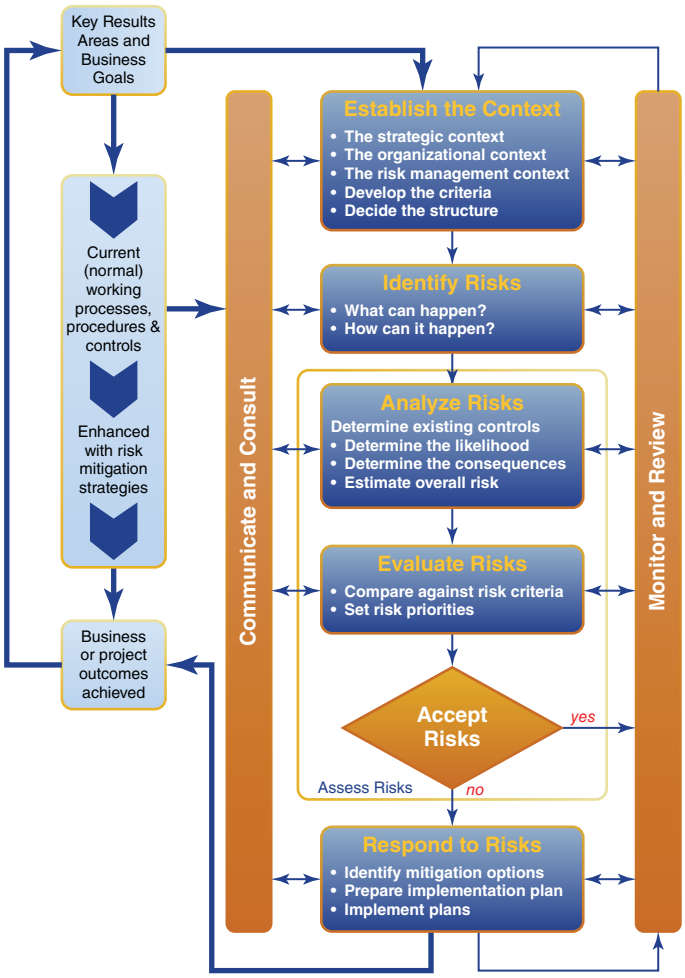
Models such as the Surface Transportation Efficiency Analysis Model (STEAM) developed by the FHWA take into account uncertainty by modeling demand probabilistically and applying Monte Carlo simulation to generate several probable levels of travel demand. Thus, the model outputs are generated as a range of values with associated probabilities rather than a single value with 100 percent certainty. This provides decision support information that reflects the underlying uncertainty for those inputs with a strong potential to affect the outputs of the model most significantly, for example, facility demand. [FHWA, 2007b]

Real options models are a relatively new approach toward considering risk in transportation decision making (see, for example, [Gavin and Cheah, 2004; Brand et al., 2000]). The real options approach differs from the traditional investment paradigm in a number of ways:

- While transportation investment opportunities have potential benefits, there is a risk of unintended negative outcomes, which are difficult to reverse once the investment decision is made.
- It recognizes that there may be value in deferring an investment decision and wait for new information because such information could lower risks. Thus, the value of the decision to wait for new information is an opportunity cost whose lost value should be included as a cost in the net present value formulation.
- Because the optimal timing of transportation investments could be to defer investments, alternatives should include flexible options that can be staged over time and have the potential to capitalize on more favorable future conditions.

MnDOT has one of the most advanced risk-based asset management plans in the United States. To a large extent the development of the asset management plan benefitted from the adoption years before of an Enterprise Risk Management Framework for agency decision making (see Figure 8-7). This framework, "establishes the standards, processes and accountability structure used to identify, assess, prioritize and manage key risk exposures across the agency." [MnDOT, 2014] A risk-based approach was used to develop the Statewide Highway Systems Operation Plan (HSOP), as well as the Statewide Long-range Transportation Plan. Developing a risk-based asset management plan thus was part of the culture in the agency. Because many of the risks associated with the general threats to agency operations and budgets had been dealt with in other plans and programs, the asset management plan strategy was to focus on assessing and developing mitigation strategies for "underman-aged" risks, where opportunities existed for improving the asset management process.

**Figure 8-7. Enterprise Risk Management Approach in Minnesota DOT**



Source: Minnesota DOT, 2014

The following were identified as the major transportation-related risks:

- Natural events (for example, floods, storms, earth movement).
- Operational hazards (for example, vehicle and vessel collisions, failure or inadequacy of safety features, and construction incidents).
- Asset aging effects (for example, steel fatigue or corrosion, advanced deterioration due to insufficient preservation or maintenance).
- Adverse conditions in the economy (for example, shortage of labor or materials, recession).
- Staff errors or omissions in facility design, operations, or provision of services.
- Defective materials or equipment.
- Lack of up-to-date information about defects or deterioration.
- Insufficient understanding of deterioration processes and cost drivers.

The process followed in identifying risks and risk mitigation strategies is shown in Figure 8-8. MnDOT began by looking at the "global" risks such as natural events, operational hazards, and so on, and the potential impacts on the asset, the public, and the agency. Work groups of technical experts were formed to describe and rate the major risks related to each asset category that used a rating scale shown in Figure 8-9. Each work group developed a series of

**Figure 8-8. Risk Identification Process, Minnesota DOT**

**Figure 8-9. Risk Rating Matrix, Minnesota DOT**

| CONSEQUENCE RATINGS | LIKELIHOOD RATINGS AND RISK LEVELS | | | | |
|---|---|---|---|---|---|
| | RATE | UNLIKELY | POSSIBLE | LIKELY | ALMOST CERTAIN |
| CATASTROPHIC | Medium | Medium | High | Extreme | Extreme |
| MAJOR | Low | Medium | Medium | High | High |
| MODERATE | Low | Medium | Medium | Medium | High |
| MINOR | Low | Low | Low | Medium | Medium |
| INSIGNIFICANT | Low | Low | Low | Low | Medium |

Source: Minnesota DOT, 2014

risk statements and risk ratings, identified risk mitigation strategies, and estimated mitigation costs. This process was iterative, extending over three workshops. The work groups ended up identifying the risks by asset type shown in Figure 8-10. The risks in italics were considered to be those that were undermanaged by MnDOT and became the focus of the TAMP risk management strategy.

Risk management strategies were identified in a seven-step process.

- *Step 1*: Define preferred mitigation strategy for addressing the risk identified.
- *Step 2*: Identify data, resources, tools, and/or training required to enact the strategy.
- *Step 3*: Describe whether the strategy will reduce the likelihood of another identified risk.
- *Step 4*: Estimate the approximate cost of implementing the preferred mitigation strategy.
- *Step 5*: Identify whether an alternate strategy might be available that does not fully mitigate the risk but lowers the overall likelihood or consequence associated with the risk.

**Figure 8-10. Identified Asset Risks, Minnesota DOT**

| PAVEMENTS | BRIDGES |
|---|---|
| • *Not meeting public expectations for pavement quality/condition at the state/district/local levels*<br>• *Inappropriately managing or not managing pavements such as frontage roads, ramps, and auxiliary lanes*<br>• Inability to meet federal requirements (such as MAP-21, GASB, etc.)<br>• Inability to appropriately manage to lowest life-cycle cost<br>• Premature deterioration of pavements<br>• Significant reduction in funding<br>• Occurrence of an unanticipated event such as a natural disaster | • *Lack of or deferred funding*<br>• *Inability to manage to lowest life-cycle cost*<br>• Occurrence of an unanticipated natural event<br>• Catastrophic failure of the asset<br>• Significant damage to the asset through manmade events<br>• *Premature deterioration of the asset*<br>• Shortage of workforce |

| • *Failure/collapse of tunnel/culvert*<br>• *Flooding and deterioration due lack of tunnel capacity*<br>• *Lack of culvert capacity*<br>• *Inability to appropriately manage culverts*<br>• Inability to appropriately manage tunnels<br>• Inappropriately distributing funds or inconsistency in culvert investments<br>• Significant damage to culverts through manmade events | • Lack of having a mandated process for inspection<br>• *Poor contract execution*<br>• *Inability to manage to lowest life-cycle cost*<br>• Significant damage to asset through manmade events<br>• Premature deterioration of the asset<br>• Unforeseen changes in regulatory requirements, travel demands, or technology<br>• *Shortage of workforce* |

Source: Minnesota DOT, 2014

- *Step 6*: Estimate the cost associated with the alternate strategy.
- *Step 7*: For both strategies developed, identify the impact on likelihood and consequence of the original risk should either of the strategies be adopted.

The process resulted in the following priority investments highlighted in the TAMP.

**Priority Level 1: High Priority, Address Immediately**

- *Pavements*—Annually track, monitor, and identify road segments that have been in poor condition for more than 5 years, and consistently consider them when programming.
- *Deep Stormwater Tunnels*—Address the repairs needed on the existing South I-35W tunnel system.
- *Deep Stormwater Tunnels*—Investigate the likelihood and impact of deep stormwater tunnel system failure.
- *Highway Culverts*—Develop a thorough methodology for monitoring highway culvert performance.
- *Overhead Sign Structures and High-Mast Light Tower Structures*—Develop and adequately communicate construction specifications for overhead sign structures and high-mast light tower structures.
- *Overhead Sign Structures and High-Mast Light Tower Structures*—Track overhead sign structures and high-mast light tower structures in a Transportation Asset Management System (TAMS).

**Priority Level 2: Address Based on Established Priorities**

- *Pavements*—Collect and evaluate performance data on ramps, auxiliary lanes, and frontage road pavements for the highway system in the Twin Cities Metro Area.
- *Bridges*—Augment investment in bridge maintenance modules and develop related measures and tools for reporting and analysis.

- *Highway Culverts*—Include highway culverts in MnDOT's TAMS.
- *Deep Stormwater Tunnels*—Place pressure transducers in deep stormwater tunnels with capacity issues.
- *Deep Stormwater Tunnels*—Incorporate the deep stormwater tunnel system into the bridge inventory.
- *Overhead Sign Structures*—Develop a policy requiring a 5-year inspection frequency for overhead sign structures, as well as related inspection training programs and forms.

**Priority Level 3: Revisit When Additional Funding Becomes Available**

- *Highway Culverts*—Repair or replace highway culverts in accordance with recommendations from the TAMS.

The Minnesota DOT case study presents a good model for considering asset risks in the development of a TAMP. The use of such an approach was most likely easier in MnDOT than it might be in another state DOT's simply because MnDOT had already progressed along the learning curve on how risks can be incorporated into agency planning and decision making. Nonetheless, the use of internal asset experts and facilitated meetings, along with a data-driven analysis process, were shown to be successful in developing a TAMP that is a national model.

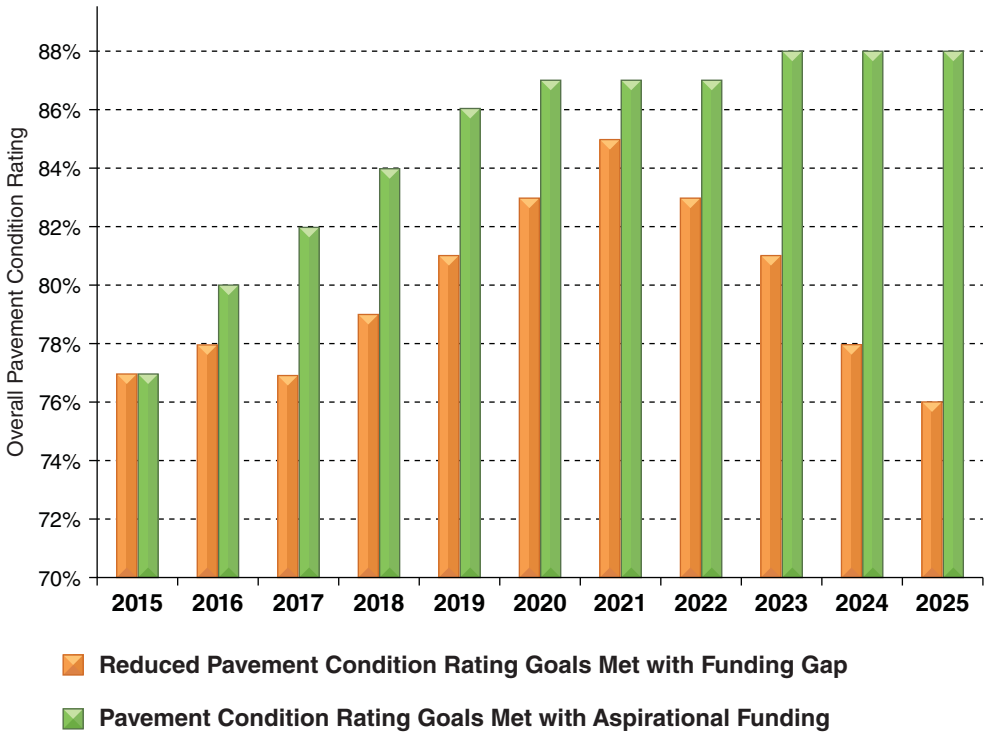
### *6. Scenario Planning Methods*

Scenario planning is used in asset management in two major ways. Primarily, different budget scenarios are assumed for estimating the impact of limited resources on pavement condition. Typical scenarios in this case might be: "Maintain historical levels of pavement restoration/rehabilitation budget levels," "Reduce restoration/rehabilitation budget levels by *x* percent each year," or "Increase restoration/rehabilitation budget levels by *y* percent each year." Figures 8-11 and 8-12 show what the results of a scenario analysis might look like. In Figure 8-12, the following two financial scenarios were assumed. [FHWA, 2015]

Scenario 1—Bridge the Gap with Increased Funding

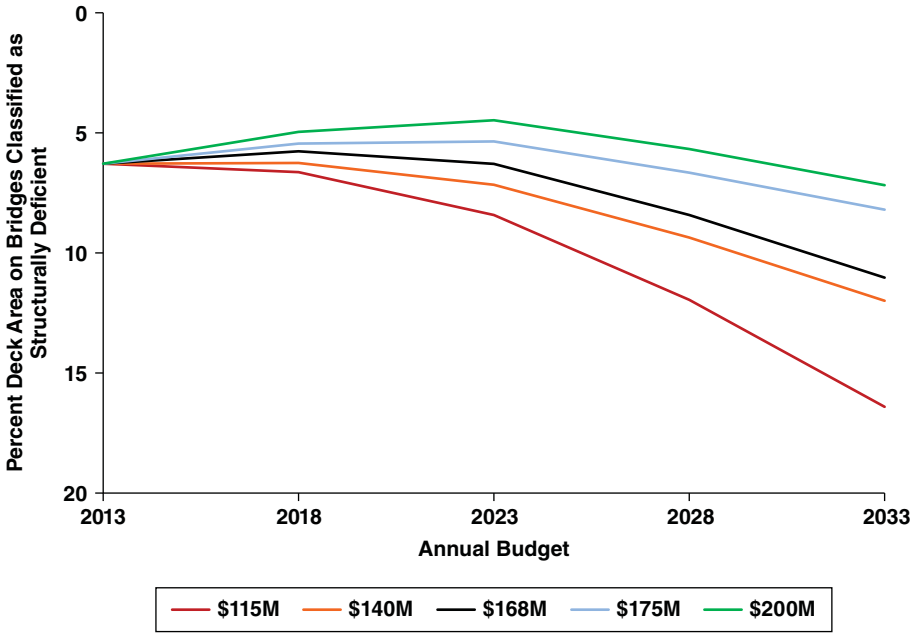
Scenario 2—Targets Reduced to Align Uses with Projected Funding

**Figure 8-11. Illustrative Example of Percent Pavement Condition Rating with Two Assumed Levels of Investment**



Source: FHWA, 2015

**Figure 8-12. Impact on Bridge Condition with Varying Budget Levels, Colorado DOT**



Source: Colorado DOT, 2013

Examples of risk treatment in asset management can also be seen in the use of scenario methodologies to address uncertainties in the visioning stage of planning (for example, Cape Cod and Portland). [Zegras et al., 2004] Systematic consideration of several plausible scenarios in planning allows the agency to address possible variation in the dominant factors influencing planning outcomes (such as actual versus forecasted growth, or the impacts of different policies on congestion, air quality and economic development, among others).

Scenario planning is particularly useful when planning for capital investments, especially when examining the impact of plan alternatives in an uncertain future. Rather than forecasting conditions given certain assumptions about the future, plausible future scenarios are considered, and the robustness of decisions under these scenarios is evaluated. The scenario approach enables planning agencies to assess the added value that could be derived from various types of planned investments and to use these as inputs in selecting the final recommended plan. Clearly, the extent of new infrastructure added to an area's transportation network will affect the necessary budget to support the transportation system. Thus, the use of scenarios can very clearly be linked to the asset management strategy that should be in place to handle the demands of the existing network as well as those of network additions. [Amekudzi and Meyer, 2006]

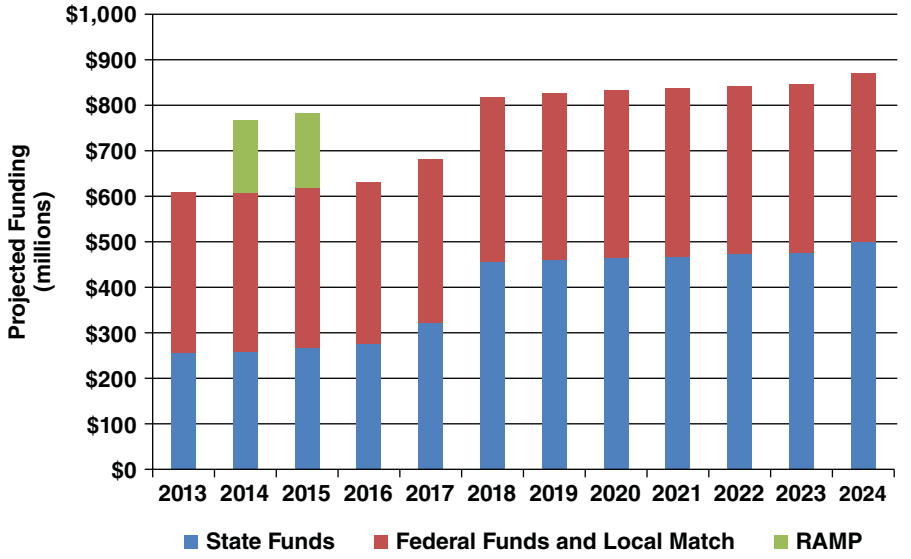
## E. Evaluation and Prioritization

The overall level of funding expected by year, and the corresponding level of condition that can be achieved with such funding, are two important products of an asset management program. Figure 8-13 illustrates a typical outcome of an asset management planning process, in this case from the Colorado DOT. These results can provide some indication of the overall program investment that will occur over the next 10 to 15 years. Transportation agencies, however, must still identify specific projects within a given budget, and this means that some form of evaluation and prioritization will be necessary.

Priority programming and optimization methods are used by agencies to evaluate and prioritize improvement alternatives. They may be used at the network or project levels, that is, for planning, priority programming, or project selection. The primary intent of this step in the planning process is to determine which combination of strategies and projects provides the most cost effective approach to investment.

Priority programming methods for maintenance, repair and rehabilitation are fairly well developed and widely used in transportation operating agencies. Such decisions rest with implementing and operating agencies, although funding

**Figure 8-13. Projected Funding Potentially Available for Asset Management, Colorado DOT**



Note: Responsible Acceleration of Maintenance and Partnerships (RAMP) funding in 2014 and 2015 is a one-time infusion of capital funds resulting from restructuring cash flow in the agency.

Source: Colorado DOT, 2013

requests for certain types of infrastructure preservation strategies are often represented in the transportation plan. Prioritizing for maintenance activities should answer the following questions:

1) What projects or sections of a facility should be maintained, repaired, or rehabilitated (selection of candidates)?
2) How should they be built or maintained (selection of project-specific alternatives or maintenance-treatment alternatives)?
3) When should they be built or maintained (selection of timing)?

Modeling these questions simultaneously, that is, considering and evaluating all possible combinations and trade-offs, is not simple. Consequently, several agencies have models that deal with either of the first two questions. For an investment to be truly optimal, however, all three questions must be evaluated.

Several methods may be used to determine priorities ranging from simple subjective ranking to mathematical optimization techniques. Table 8-9 shows different classes of priority programming methods with their advantages and

**Table 8-9. Different Classes of Priority Programming Methods**

| Class Method | Advantages and Disadvantages |
|---|---|
| Simple subjective ranking of projects based on judgment. | Quick, simple; subject to bias and inconsistency; could be far from optimal. |
| Ranking based on parameters, such as serviceability, deflection, etc. | Simple and easy to use; could be far from optimal. |
| Ranking based on parameters with economic analysis. | Reasonably simple; should be closer to optimal. |
| Optimization by mathematical programming model for year-by-year basis. | Less simple; may be close to optimal; effects of timing not considered. |
| Near optimization using heuristics and marginal cost-effectiveness. | Reasonably simple; can be used in a microcomputer environment; close to optimal. |
| Comprehensive optimization by mathematical programming model taking into account the effects. | Most complex; can give optimal program (max. of benefits). |

Source: Adapted from Haas, R. and C. Raymond. "Asset Management for Roads and other Infrastructure." Presented at the 8th Annual Fall Asphalt Seminar, Ontario Hot Mix Producers Association, Toronto, Ontario, Canada, December 1, 1999.

disadvantages. [Haas and Raymond, 1999] Priority programming and optimization methods are essentially means of conducting trade-off analysis. Trade-off analysis seeks to move beyond the analysis of alternative treatments and timing of treatments for a single type of infrastructure to a more comprehensive evaluation of the multiple assets for which an agency is responsible. Effective trade-off analysis will help agencies determine the marginal benefits of expending the next additional dollar for a range of assets in order to accomplish various outcomes (for example, capital improvement, preservation, safety improvement, reliability risk reduction and such).

Some efforts have been made to develop more comprehensive asset management systems based on trade-off analysis. Developed through the NCHRP, the Asset Manager Network Tool (AssetManager NT) is designed to assist transportation executives and program managers in understanding how different patterns of investment will affect the overall performance of the transportation network over the long term and the trade-offs that result from different levels of investments in different categories. AssetManager NT enables users to explore systemwide performance implications of different budget levels for selected investment categories that can be defined based on asset types (for example, pavement versus bridge), geographic areas (for example, districts or regions), or system subnetworks (for example, National Highway System, trunk line system, priority truck networks and primary corridors). Assessing trade-offs for competing investments, if incorporated in decision making, will represent a departure from traditional methods of allocating resources for competing needs, particularly across different physical facilities (roadways versus bridges) and functions (for example, capital investment versus preservation).

Not surprisingly, given what was said in the previous section about risk, many of the evaluation and prioritization methods used in asset management incorporate risk assessment in their overall approach. For example, the international scan on asset management found that all of the agencies visited used some form of risk analysis in assigning priorities for investment. Experiences in England, Australia and Canada are described below.

*England: Risk Analysis for Project Prioritization*. The Department for Transport, England's transportation agency, uses a risk matrix in which project values are assigned a score that relates to the probability of failure associated with a specific component. The higher the likelihood of failure, the greater the attention received in the investment program. Table 8-10 shows the agency's values for calculating the likelihood of risk events.

The likelihood of a risk event is calculated as follows:

$$L(\text{Risk Event}) = L(\text{Cause}) * L(\text{Defect}) * L(\text{Exposure}) * L(\text{Effect})$$

where $L$ stands for likelihood

As an example, suppose that for a particular project, it has been determined that the likelihood of the cause is high (0.85); there is a medium likelihood of the defect occurring (0.50), a low likelihood of exposure (0.15), and a high likelihood of the effect occurring (0.85).

The risk associated with the project is estimated as follows:

$$L(\text{Risk Event}) = 0.85 * 0.50 * 0.15 * 0.85 = 0.054$$

Similar assessments can be made of all projects being considered and ranked according to the level of risk associated with each. This type of analysis can be conducted to identify the projects that pose the highest risk of failure and allocate funds to solve the most serious problems.

**Table 8-10. Values for Calculating Likelihood of Risk Events (England)**

| Likelihood Rating | Description | Range of Likelihood Values | Expected Value |
|---|---|---|---|
| Certain | Certainty | 1.0 | – |
| High | Highly Likely | 0.7–0.99 | 0.85 |
| Medium | Likely | 0.3–0.69 | 0.50 |
| Low | Possible, but not likely | 0.0–0.29 | 0.15 |

Source: FHWA, 2005

*Queensland: Risk Analysis for Bridge Prioritization*. Queensland, a state in Australia, has developed a program called *Whichbridge*, which assigns a numerical score to each bridge based on the risks attached to the condition of the bridge. Factors considered in this assessment include the condition of bridge components, effect of multiple defective components, significance of members to load-carrying capacity, global and local environmental impacts, component materials, currency of inspection data, obsolete design standards, and traffic volumes. System reports rank structures based on risk exposure and safety considerations using a relative rather than absolute ranking. The risk is determined as a product of the probability of failure and the consequence of failure. Consequence is used as a surrogate for the costs of failure, which relate to things such as human factors, environmental factors, traffic access, economic significance, and industry access consequences. [FHWA, 2005]

*Edmonton: Risk Analysis for Asset Prioritization*. Edmonton, Alberta, Canada, uses a formal risk assessment process to evaluate the impact of failure for a given component of infrastructure. The first step in the risk analysis is to segment infrastructure assets into logical groupings based on common characteristics. For each segment (for example, one kilometer of road), data are collected describing the inventory, state and condition and the 10-year rehabilitation financial estimates for that asset. The condition of the asset is then categorized using Edmonton's standardized rating system and conditions assessed by reviewing the assets within a given department through a combination of workshops and independent analysis. To examine the state and condition of the city's assets, each asset is rated on the five-point ranking system (very good, good, fair, poor, and very poor) according to its physical condition, demand/capacity, and functionality. Failure is assumed to occur in two ways, either suddenly and unexpectedly, or gradually and expectedly. The approach uses 155 different deterioration curves and probabilities to determine expected failure.

Level of risk is measured using numerous indicators, for example:

- *Portion of an Asset Deemed to Be Critical (Expected to Fail)*—Represented by those assets that have deteriorated past the expected service life and are considered unacceptable.
- *Impact of Failure of an Asset*—Impacts of assessed failure are measured according to the social (health and safety of citizens), environmental (impact on the environment), and economic (cost of failure) indicators, factoring the city's objectives into the decision-making process.
- *Overall Condition*—Categorized by A (very good), B (good), C (fair), D (poor), or E (very poor), using the standardized rating system.
- *Severity*—Reflects the overall likelihood of asset failure, the expected amount of failure and the impact of the failure on the city. An analytical combination of expected assets in critical condition and the impacts of failure of those assets help to analyze infrastructure deterioration levels at a large-scale level. [City of Edmonton, 2015]

Another common approach to risk management is to assign project contingency funds to the cost estimates that are used in transportation plans and programs. These contingencies represent costs for unexpected occurrences during the construction period. A recent development in financial management is the use of shared-risk contingency funds. In the $715-million, 11.9-mile (19.2-km) Hiawatha light rail transit project in Minneapolis/St. Paul, MN, for example, a $5.5-million shared-risk contingency fund was established based on 19 risk items. The contractor was to keep 91 percent of whatever was left in the fund after project completion, thus creating incentives for the contractor to manage risks wisely and ensure that adverse events were minimized.

The use of contingencies in cost estimates can have a substantial effect on the estimation of fiscally constrained budgets that, by federal law, must be part of transportation plans and transportation improvement programs (TIPs). If the contingencies turn out to be insufficient to cover cost overruns, the TIP budget estimate must be adjusted to reallocate funds to the project from other project(s) or delay the project until enough funding is available (see chapter 5 on transportation finance and funding for further discussion on contingencies).

## F. Monitoring System Condition and Performance

The final component of a transportation planning process—monitoring system condition and performance—is very much in line with asset management practices. A formal performance monitoring system is an integral component of an effective asset management system because it closes the loop between planning goals and objectives and actual system outcomes, and enables agency officials to regularly adjust or readjust their strategies to achieve desired outcomes.

It also provides a means for identifying unexpected performance gaps and addressing risks proactively rather than reactively. The previous sections have examined the different means of monitoring system performance and condition (for example, infrastructure management systems), and thus this information will not be repeated here.

## V. ASSET MANAGEMENT CHALLENGES AND OPPORTUNITIES

As the nation's infrastructure continues to age and new infrastructure is added each year, asset management will likely become even more important in the future than it is today. The following asset management-related topics are likely to be included among what the transportation profession will be focusing on in coming years.

### A. Expanding Information Management Capabilities

Most states have some legacy management systems from the ISTEA era that could serve as a foundation for the development of integrated asset management systems. Some state agencies have begun to integrate their data across various business units (for example, Pennsylvania, Michigan, Colorado, Arizona, and Virginia) to develop common platforms that support more comprehensive investment analysis (see, for example, [ADOT, 2006]). Other state agencies (for example, New York and Oregon) have invested in developing improved economic analysis capabilities for alternatives analysis. Both PENNDOT's data integration activities and NYSDOT's economic analysis tools initiatives highlight the potential for modernizing legacy systems to form the basis of an integrated asset management system.

It seems likely that more effective and efficient utilization of data to produce the information needed for decision making will continue to be a major focus of asset management development activities. Monitoring system performance is key for successful asset management efforts.

### B. Public-Private Partnerships

Public-private partnerships in infrastructure provision are an increasingly common strategy both internationally and in the United States. These partnerships usually entail private consortia building, operating and maintaining transportation facilities under an agreement with a government agency. The government is still the owner of the facility and will in fact assume responsibility for the facility once the terms of the partnership agreement have been met (anywhere from 40 to 100 years). A comprehensive asset management effort needs to be part of any agreement to deliver good service to users during the life of the contract as well as to ensure that the asset is returned to the owner in good condition.

### C. Outsourcing Contracts

Many transportation agencies contract out some portion of their operations and/or maintenance activities for limited time periods. Outsourcing per se is not necessarily asset management, but it uses asset management techniques to the extent that both the owner and the contractor adopt and use such methods. In fact, experience with alternative delivery systems both internationally and in the United States has shown that an asset management system is essential for overseeing the outsourcing of infrastructure services. As more government agencies consider outsourcing some of their operational functions, we will see a corresponding increase in the use of asset management within these agencies.

### D. Funding Constraints and Pressures for New Infrastructure Capacity

Despite an overall growth of infrastructure expenditures in several sectors during the past several decades, funding constraints in various agencies are a major driver in the search for improved ways to obtain better levels of service with fewer funds. These constraints are the result of several factors, key among them are rapid urbanization and the resulting growth in demands for infrastructure services, and the need to renew significant portions of infrastructure networks and facilities as they near the end of their useful lives. Rapid urbanization is expected to continue over the next half-century simultaneous with an increasingly older population as life expectancies rise. These factors will further accentuate pressures to provide infrastructure services with fewer resources (given the dwindling tax base) and heighten the need for infrastructure finance reforms. They will also highlight the need for adopting better methods to maximize the effect of limited budgets, namely the adoption of asset management as a fundamental way of doing business.

## E. Multimodal Trade-Offs

The transportation profession has been interested in multimodal trade-offs for many years, but there are very few examples where such an assessment actually occurred. However, identifying the most cost-effective alternatives that cut across multiple modes is increasingly important to ensure that the best solutions are found. We can thus expect to see further development of analytical capabilities in this area that evaluate trade-offs and co-benefits among such alternatives fairly confidently. The benefits to be gained are potentially tremendous particularly with respect to Development of Regional Impacts (DRIs) and megaprojects, which are becoming increasingly common—especially in cities with large-scale facilities that are at or nearing the end of their useful lives (for example, the Boston Central Artery Tunnel or New York's subway). We would also expect to see increased flexibility in the mechanisms used to fund such projects, allowing agencies to fund solutions involving multiple modes.

## F. Infrastructure Renewal

Significant investments in transportation infrastructure were made over several decades, and a growing number of these assets are coming to the end of their useful lives either because of natural obsolescence or because of growing demands from rapid urbanization outpacing their ability to function effectively. The twenty-first century will thus be marked with the challenge of renewing existing infrastructure, including addressing obsolescence, which is usually under continuing heavy demand. Because of the demands placed on these systems, they cannot be conveniently shut down while they are being rehabilitated, reconstructed or renewed. The asset management approaches discussed in this chapter represent important opportunities to manage the risks associated with the renewal of substantial portions of the overall asset base. In particular, asset management offers a practical platform and business process to consider infrastructure renewal proactively to step up the resiliency of transportation systems to extreme weather events and other hazards.

# VI. SUMMARY

The United States has made significant investments in transportation infrastructure during the past 60 years, estimated at more than $1.75 trillion. Large portions of this infrastructure are reaching the end of their useful lives and require renewal. While at the same time, there is a need to expand the capacity of existing transportation systems to accommodate rapidly growing urban populations, and these pressures will continue. Thus, trade-offs between investments for renewal and preservation versus capital expansion will likely be important decisions for the foreseeable future.

Asset management offers organizational resources, planning methodologies, and information technology capabilities to: (1) increase the value obtained from infrastructure expenditures, (2) demonstrate accountability more clearly, and (3) earn increased credibility with elected officials and their constituencies, while (4) achieving a progressively higher quality of infrastructure services for communities. This chapter explained how an asset management paradigm and tool kit can be used to enhance the transportation planning, programming and project development processes. The underlying concept is the efficient use of resources for the systematic delivery of best-value infrastructure for transportation system users, while demonstrating these values to political decision makers and the general public.

Readers are encouraged to check the FHWA website on transportation asset management for the latest information and regulations concerning asset management (https://www.fhwa.dot.gov/asset)

# Road and Highway Planning[1]

## I. INTRODUCTION

Systems of interconnected, well-designed, and well-maintained streets and highways are critical to the economic well-being and quality of life of nations and their citizens. Such systems also represent a massive public investment in infrastructure. In 2013, there were 8,656,000 lane-miles of roadway in the United States, with just over 6 million in rural areas and 2.6 million in urban areas (a lane-mile is a one-mile length of one road lane). Although the post–World War II era of massive highway capacity expansion has ended, system growth (largely by rebuilding and expanding existing highways) indeed continues, albeit at a more modest pace. From 2012 to 2013, approximately 4,000 lane-miles of urban interstate highways and approximately 13,000 lane-miles of major urban arterial highways were added to the U.S. highway network. [BTS, 2015]

Most importantly, it is what the highway network enables that is critical to a nation, state, or community. In a study of the economic impact of the highway network in the United States, Shatz et al. [2011] observed that the highway network:

> *Enables producers to reach markets more cheaply, to increase the size of their market area, and to have a broader choice of input suppliers. It can increase the speed with which producers can reach markets or inputs, allowing them to hold lower inventories and carry out just-in-time production. Highway infrastructure can enable workers to choose among a wider array of employment opportunities and to live farther from their workplaces. It can enable consumers to have a more varied choice of goods, services, and prices.*

From a transportation planning perspective, the road network becomes not only a major means of providing mobility and accessibility, in so doing it supports other transportation modes in their use of the roadway right-of-way, such as sidewalks, bicycle lanes, and bus operations, as well as in providing access to transportation terminals and stations. Anecdotally, it seems likely that the vast majority of transportation planning in the United States focuses attention on roads, albeit in a multimodal context. Road and highway planning are an integral part of transportation planning in most countries and thus become an important part of the transportation planner's skills and knowledge base.

Every chapter in this handbook presents some topic that is tied to road and highway planning. Gaining a complete understanding of road and highway planning is difficult without an appreciation for how demographics, land use, travel demand, alternative modes, environmental considerations, stakeholders' concerns, and funding are all essential to the planning process. For example, chapter 10 on network and facility operations, examines how the road network can be better managed, and how new technologies can be applied to provide more productive network operations and more efficient trip-making by travelers. The Highway Trust Fund, discussed in chapter 5 on transportation finance and funding, depends on the motor fuel tax, and with more efficient vehicles and the likely transition to hybrid or electronic vehicles in the future, a major policy question becomes how will improvements to the road network be funded? Chapter 4 on environment and the community discusses many of the negative impacts associated with the construction of the road network and the vehicle operations on it. This chapter cannot possibly cover all of these aspects of road and highway planning. Where appropriate, the text indicates other chapters in the handbook for relevant information.

The next section presents urban roadway principles that should guide roadway and highway planning. It discusses some of the performance and capacity relationships used for determining "need" in highway planning, and this is followed by a discussion of infrastructure condition measures. This is followed by a discussion of context-sensitive solutions (CSS), traffic calming, Green Roads, and Complete Streets, four concepts that many transportation planners are involved in today. Finally, the last two sections present examples of highway system planning leading to a highway investment program.

## II. BEST PRACTICE FOR URBAN ROADWAY SYSTEMS

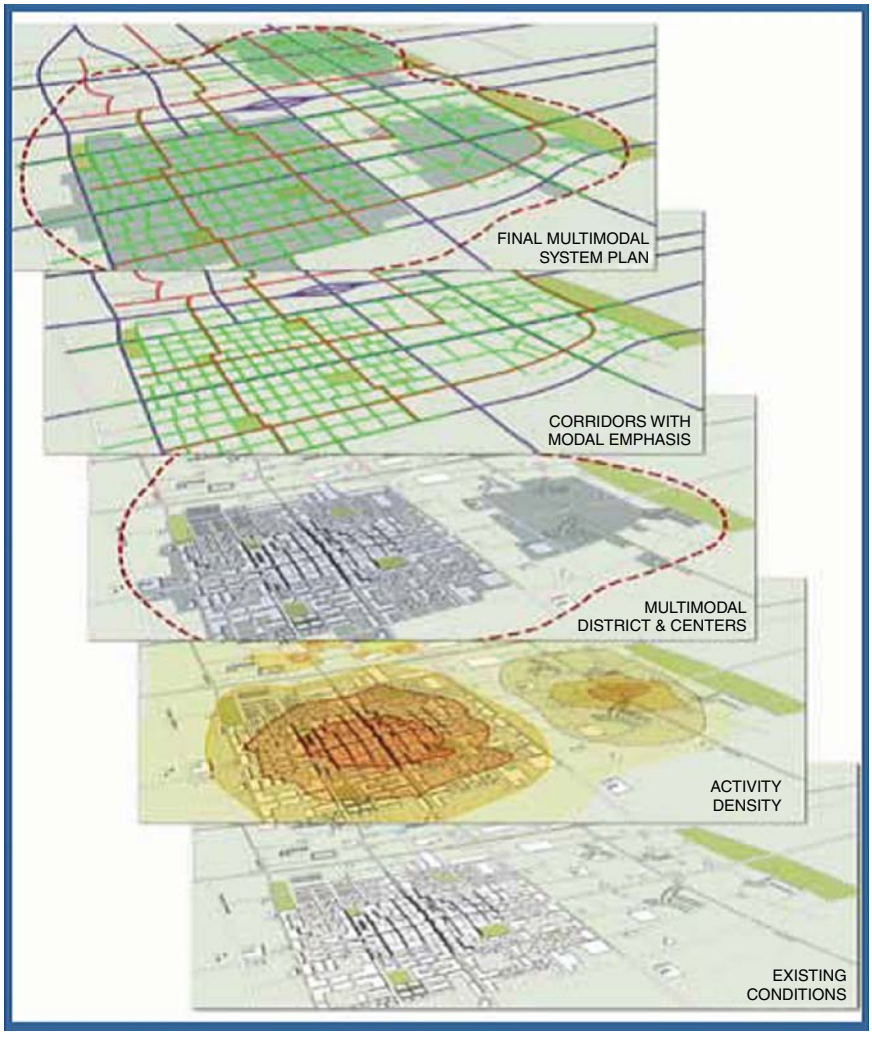
Planning best practice views transportation systems from a multimodal perspective, that is, transportation is a connected system providing modal options to travelers. Figure 9-1 represents this concept well. As shown, the system consists of different networks and activities that together constitute a transportation system. One of these layers is the road network, or in the figure's terms, "corridors with modal emphasis."

The Institute of Transportation Engineers (ITE)'s *Recommended Practice on Planning Urban Roadway Systems* identifies some of the key characteristics of planning an urban roadway network. [ITE, 2011] It is important to note that except for systems in newly developing areas or where new highway systems are being superimposed on existing development, much of the activity in planning urban roadway systems involves modifying existing facilities, or on occasions adding a major new facility. The best practices include:

**Urban roadway systems should consist of a multimodal network of streets and highways that serves automobiles, trucks, transit, bicyclists, and pedestrians.**

- Define the roadway network to handle traffic volumes safely and efficiently—providing convenient routes around the area for through traffic and routes within the area for traffic moving between major land uses.
- Define vehicular mobility appropriately in dense urban areas where multiple modes of transportation are served, to ensure that the plan will not result in speeds that threaten the safety of pedestrians or have negative environmental and aesthetic impacts from noise. For example, appropriate speeds on streets and highways in

**Figure 9-1. Multimodal Transportation Systems**



Source: VDOT, 2013

an urban setting should be driven by the functionality, the degree of access control, and the context of the street or highway. A freeway loop around a downtown might work well at 55 miles per hour, but if that same traffic must navigate surface streets, speed limits of 25 miles per hour or less may be more appropriate. The key is to design the physical form of the road (geometry, lane width, etc.) within the context of the road's surroundings.

- Develop the roadway system in such a manner that there are sufficient interconnections and a degree of redundancy, meaning that no single roadway has an overwhelming volume of traffic and most roadways can maintain a smaller scale and therefore provide a multimodal environment for pedestrians, bicyclists, and transit users. For example, transportation planners and urban planners agree that a functional grid, a network with a high degree of interconnectivity, is superior to urban/suburban networks where residential streets are discontinuous.
- Provide reasonably direct access for emergency and service vehicles.
- Arrange parking facilities, vehicular and pedestrian circulation routes, bicycle routes, and buildings to minimize conflicts between nonmotorized and vehicular movements.
- Provide direct routes for truck movements between freight generators and major roadway facilities.
- Provide a system of bicycle facilities and routes. Consider the most likely bicycle users, which may include commuters, students, or recreational bicyclists.
- Integrate transit service efficiently within the roadway network; ensure easy access for pedestrians, cyclists, and motorists accessing bus stops, terminals, or train stations.
- Consider direct connections to activity centers by transit and high-occupancy vehicles (HOV) during the planning stage of freeways to ensure good access by these modes.
- Develop a hierarchy of transit services that includes primary transit access on exclusive bus lanes or HOV lanes, secondary transit access on other major roadways in mixed traffic, and a feeder transit network on collector and local streets.
- Encourage coordination of the full hierarchy of transit services including the integration of public rapid transit with intercity passenger transportation, with suburban commuter railroads and feeder buses, and with park-and-ride facilities. City feeder bus routes should focus on either the central area or on high accessibility corridors.
- Consider traffic management techniques (including HOV and managed lanes, reversible lanes, and congestion pricing strategies) that can be employed to achieve more efficient use of roadway networks during peak hours.

**Urban roadway systems should be planned such that individual roads and streets serve different functions within the network (functional classification), serving all modes of passenger and freight/goods movement.**

- Balance the roadway system plan to meet the need for all modes of transportation, including private vehicles, commercial vehicles, transit, bicycles, and pedestrians. While each facility will not need to serve every mode, the system as a whole should provide a good level of service for each mode. Some individual roadways may have priority for specific modes.
- Consider the land-use context and urban form in determining the relative importance of each mode on various streets in the network. Areas that are intended to be walkable and transit-oriented should have street networks that will support these modes.

**Urban roadway systems should have a high degree of connectivity to help provide multiple routing options for all user groups.**

- Move toward a roadway system that includes redundancy in the roadway network to offer more than one direct route between points in the area.
- Identify layered and of necessity, overlapping, networks for pedestrians, bicyclists, transit, autos, and trucks so that each network has an appropriate level of connectivity and redundancy.

- Move toward networks with more frequently spaced roadways, as opposed to sparse networks of wide arterials.
- Consider emergency vehicle access as part of the network planning. Emergency vehicles will often operate more effectively within a dense network, where alternative routes are available in the case of severe accidents or emergency roadway closures.
- Provide direct access to the regional transportation system for industrial sites.
- Avoid having a concentration of vehicular traffic at bottleneck intersections and rely on connectivity improvements to reduce congestion.
- Provide high levels of roadway connectivity to afford more options for local trips and less dependence on arterials for short trips.
- Provide multiple roadway connections throughout neighborhoods to provide alternative routing, improve emergency response times, reduce travel costs for school buses and snowplows/street sweepers, and reduce the demand on the arterial system. Where vehicle connections are hindered by a natural feature or other obstacle, consider at least a pedestrian/bicycle link.

**Urban roadway systems should have a network density appropriate to the land-use patterns and urban form that are served.**

- Size the roadway network to complement the design and character of the surrounding community.
- Integrate the planned roadway system with the area's land-use plan so that it serves as a total and integrated multimodal system rather than as a series of loosely related roadway improvements.
- Provide high-density, walkable, mixed-use development along major transit corridors to maximize the opportunity for transit.
- Provide a roadway network conducive to pedestrians by planning small block sizes, high roadway connectivity (especially for local streets), and complete sidewalk systems. Pedestrian crossings are safer in a denser network of two- to four-lane roadways as opposed to a sparser network of six-lane roadways.

**Urban roadway systems should recognize the role of roadways as public spaces and in shaping urban environments.**

- Recognize the multiple roles of major urban roadways in access, place making, and economic development.
- Include an assessment of the context zones within the planning area. Plan the roadway system to be compatible with the appropriate context zones such a modal balance, connectivity, and scale of roadways.
- Plan the transportation facilities to be aesthetically attractive and, to the extent possible, to blend in with or highlight the surroundings and topographic features through which they pass.

**Urban roadway systems should be planned with consideration of environmental, social, economic, and financial issues.**

- Plan the roadway system to be sufficiently flexible so that it can be adapted over time to meet future challenges in travel patterns not foreseen at the time of the plan's formulation. Examples include preservation of corridor rights of way to facilitate network expansion as growth occurs or designation of flexible roadway cross sections to accommodate dedicated transit lanes or wider sidewalks.
- Plan for a roadway network that minimizes the length of vehicle trips to reduce vehicle miles traveled (VMT).
- Plan the roadway system to encourage development that reduces average trip lengths and is conducive to travel by transit, bicycle, or foot.
- Bring origins and destinations closer together through higher densities and appropriately mixed land use.
- Develop a financing plan over the long term to ensure implementation of the urban roadway system.

- Plan the roadway system to consider the safety of all users and seek to minimize conflicts.
- Plan the roadway system to be within the reasonable financial capabilities of the community.
- Consider incompatibilities in providing major goods movement mobility with other uses. For example, major truck routes should not cross major pedestrian corridors.

The application of these principles in transportation planning is described throughout this handbook such as in chapters that deal with land use; statewide, regional, and local planning; transit; pedestrian and bicycle planning; freight movement; and parking management.

One of the key themes running through these principles is the concept of "context." The relationship between road systems and land use has been a foundation of transportation planning since the very first studies were conducted in the 1950s. This relationship, however, was primarily focused on how many trips would be generated from, and attracted to, land parcels. The trip generation-land-use linkage was simply one of relating land-use characteristics to aggregate trip-making. Road design was based on widely accepted design standards reflecting the design volumes that were forecasted from the planning models. The role the road played in the network was directly related to the expected volumes it was to carry, not the land-use context.

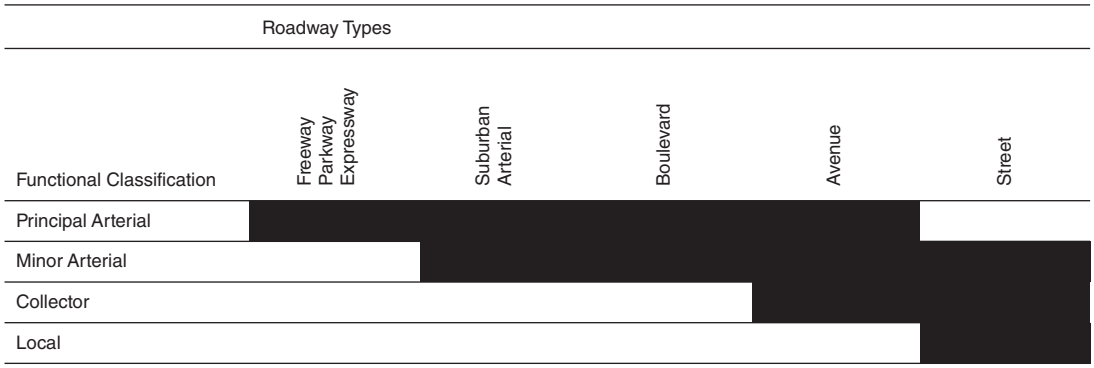
This relationship was the basis for the concept of a functional classification system where roads were classified (and design standards stipulated) for the function and role they played in the network. The most common classification scheme identified arterials, collectors, and local roads as the primary components of a functional classification for network planning (see chapter 2 on travel characteristics and data and [AASHTO, 2011]). However, many communities today have adopted a different approach, one that looks at roads for the role they play in the road network, and how they relate to land use and the urban context. Depending on the community, this typology can include many different road types (as will be seen below, New York City has defined 13). Table 9-1 shows some of the elements of this road typology, and Figure 9-2 shows the relationship to the more traditional functional classification system.

**Table 9-1. Roadway Classification Descriptions**

| Typology | Description |
|---|---|
| Freeway/Parkway/Expressway | Freeways are high-speed (55+ mph), controlled-access roadways with grade-separated interchanges and no pedestrian access. They include tollways. Expressways and parkways are high- to medium-speed (45 mph) limited-access roadways with some at-grade intersections. |
| Suburban Arterial | High-speed (40 to 45 mph) divided arterial in suburban environments designed to carry primarily higher-speed, longer-distance traffic and serve large tracts of separated single land uses (e.g., residential subdivisions, shopping centers). |
| Boulevard | Walkable, low-speed (35 mph or less) divided arterial in urban environments designed to carry both through and local traffic, pedestrians, and bicyclists. Boulevards may be long corridors and be high transit ridership routes. Boulevards are primary goods movement and emergency response routes and use vehicular and pedestrian access management techniques. A multiway boulevard is a variation of a boulevard characterized by a central roadway for through traffic and parallel access lanes accessing abutting property, parking, and pedestrian and bicycle facilities. |
| Avenue | Walkable, low-speed (35 mph or less) urban arterial or collector roadways, generally shorter in length than boulevards, serving access to abutting land. Avenues serve as primary pedestrian and bicycle routes and may serve local transit routes. Goods movement is typically limited to local routes and deliveries. Avenues may serve commercial or mixed-use sectors and usually provide curb parking. |
| Street | Walkable, low-speed (25 mph) roadway in urban area, primarily serving abutting property and local traffic. A street is designed to (1) connect residential neighborhoods with each other, (2) connect neighborhoods with commercial and other districts, or (3) connect local streets to major roadways. |

Source: ITE, 2011

**Figure 9-2. Relationship of Functional Classification to Roadway Types**



Source: ITE, 2010

While it is desirable from a pure mobility perspective to have high volumes of through-traffic circumvent an area on a controlled-access arterial, it is not always possible or even feasible. In fact, by far most arterials are surface streets, and therefore the presence and needs of transit, pedestrians, and cyclists must be considered in shaping the physical form even of arterials. Functional classification is one of the factors to drive physical form—the other being context. While streets have many nonvehicular functions, carrying vehicular through-traffic and providing access to adjacent land for vehicular traffic will remain the primary functions of roads and highways.

Figure 3-16 showed one of the more well-known context zone concepts from Andres Duany, one of the leading urbanists in the United States. The "transect" illustrates the idea that road function and design will most likely change as the urban environment changes. These context zones are not only useful for determining the physical form of appropriate transportation solutions, but they help the public understand how urban design and transportation strategies need to be considered together.

This contextual relationship has also been articulated in so-called "smart growth" policies and plans. According to an ITE *Recommended Practice on Smart Growth*, the transportation-related goals for smart growth include:

- Pursuing compact, efficient land-use patterns to maximize transportation efficiency and improve neighborhood environment.
- Providing multimodal mobility within developed areas.
- Providing accessibility within existing built-up areas.
- Making the most efficient use of transportation infrastructure.
- Supporting smart growth through pricing and sustainable funding. [ITE, 2011b]

In addition, the *Recommended Practice* noted that the principles of smart growth include "transportation system efficiency, preservation of transportation resources, maximum effectiveness of transportation investment, reduced urban sprawl, and reduced vehicle pollutant emissions."

Table 9-2 from the *Recommended Practice* shows the relationship between desired smart growth land-use characteristics (and policy decisions) and transportation. As noted, "urban form influences how people choose to travel . . . . pedestrian-friendly, mixed-use communities that emphasize and create environments for walking, bicycling, and transit use can help achieve the balance of modes that many areas seek." [ITE, 2011b]

Public and professional interest in roads that are more sensitive to their surroundings has led to the emergence of new ways of thinking about road planning of which the four most prominent are: context-sensitive solutions (CSS), traffic calming, Green Roads, and Complete Streets.

## III. CONTEXT-SENSITIVE SOLUTIONS (CSS)

The FHWA defines context-sensitive solutions (CSS) as "a collaborative, interdisciplinary approach that involves all stakeholders in providing a transportation facility that fits its setting. It is an approach that leads to preserving and enhancing scenic, aesthetic, historic, community, and environmental resources, while improving or maintaining safety, mobility, and infrastructure conditions." [FHWA, 2015a] CSS emphasizes "one size does not fit all" and is dependent upon the context of a community, its supporting infrastructure, as well as the vision of its leaders and stakeholders, community values, historical relationships, culture, financial constraints, environmental justice issues, and even political realities.

Whereas conventional road planning and design relies on traffic demand and level of service (LOS) metrics, CSS identifies critical contextual factors and uses this information to establish a more flexible framework for project development. For example, ITE's *Recommended Practice on Designing Walkable Urban Thoroughfares: A Context Sensitive Approach* uses the concept of context zones and a set of thoroughfare types consistent with the diverse characteristics found within urban areas as a guide to road design. [ITE, 2010] The more traditional functional classification of roads (that is, principal and minor arterials, collectors, and local roads) is tempered by the design criteria relating to thoroughfare types, which in turn reflect contextual factors. Context is defined both by the design of the thoroughfare itself and the adjacent buildings, land-use types, and surrounding district. The collaborative approach toward project planning and design flexibility uses multidisciplinary teams to reach a balance between safety, mobility, community, and environmental goals within the context of transportation goals and community needs.

FHWA [2007] has identified how the CSS process can relate to both transportation planning and project development. Table 9-3 shows those elements common to both and those that relate directly to planning.

A recent ITE *Recommended Practice on the Integration of Safety in the Project Development Process and Beyond: A Context Sensitive Approach* takes what it calls "the logical next step" in the evolution of the CSS process, which is to integrate safety into the project development process. By considering safety consequences as an important and integral part of the overall context, and applying context-sensitive and flexible design principles, the highway designer, safety engineer, planning team, and the general public can make more informed decisions with respect to community benefits. The *Recommended Practice* notes that new safety analysis tools have been developed in recent years providing planners with analysis capability to quantify safety benefits in project development to a level of detail not possible in the past (for example, using the *Highway Safety Manual*). The *Recommended Practice* provides information on how to use these tools and illustrates best practice applications. The intent is to achieve quantifiable safety impacts, similar to what has been done in the areas of traffic operations, economics, cost estimation, and environmental impacts (see chapter 23 on incorporating safety into the transportation planning process).

| Table 9-3. The CSS Process and its Relationship to Transportation Planning and Project Development | |
|---|---|
| **Transportation Planning** | **Project Development** |
| **Communication** | |
| Communication with all stakeholders is open, honest, early, and continuous. | Communication with all stakeholders is open, honest, early, and continuous. |
| A full range of user-friendly tools for communicating transportation plan options are used to effectively present information and proactively solicit feedback. | A full range of tools for communication about project alternatives is used (for example, visualization). |
| **Representative Disciplines** | |
| The multidisciplinary team(s) is (are) fully representative of the human and natural environment as well as the communities' perspectives of a good quality of life and important issues. | A multidisciplinary team is established early, with disciplines based on the needs of the specific project, and with the inclusion of the public. |
| **Consideration of Community and Natural Resources** | |
| The landscape, community, and valued resources are understood before analysis of the transportation system begins or potential transportation solutions are explored. | The landscape, the community, and valued resources are understood before engineering design is started. |
| **Process** | |
| The transportation plan includes an upfront preplanning process that allows all formal partners, including, but not limited to, environmental agencies and community representatives, to participate in the early identification of issues that should be considered during the transportation planning process. | A full range of stakeholders is involved with transportation officials in the scoping phase. The purposes of the project are clearly defined, and consensus on the scope is forged before proceeding. |
| **Evaluation** | |
| The transportation plan evaluates multimodal, operational, and innovative strategies, and the recommended plan addresses all transportation needs, including, but not limited to, safety, access/mobility, and air-quality issues. | The highway development process is tailored to meet the circumstances. This process should examine multiple alternatives that will result in a consensus of approach methods. |
| **Treatment of Context-Sensitive Solutions (CSS)** | |
| The adopted transportation plan is a clear reflection of contextual factors and includes explicit support for CSS in all follow-on project development phases. | A commitment to the process from top agency officials and local leaders is secured. |
| **Public Involvement** | |
| The transportation planning process is based on a comprehensive public involvement/ participation plan that is based on meaningful opportunities for input. | The public involvement process, which includes informal meetings, is tailored to the project. |
| **Communication Strategy** | |
| A full range of user-friendly tools for communicating transportation plan options are used to effectively present information. | A full range of tools for communication about project alternatives is used (for example, visualization). |

Readers are referred to ITE's context-sensitive website (http://ite.org/css), FHWA's website (http://www.fhwa.dot.gov/planning/csstp) and the Context Sensitive Solutions website (http://www.contextsensitivesolutions.org for the most up-to-date information on the latest guidance and research on CSS. Chapter 3 on land use and urban design also discusses CSS from the perspective of land use.

## IV. TRAFFIC CALMING

A frequent mindset of traditional highway planners and engineers was that wider and straighter streets promoted safety, and that a minimum of two travel lanes, in addition to two parking lanes, was a reasonable minimum cross section to accommodate traffic in an unimpeded way. The unintended consequences of this approach, particularly on local

residential streets, included various combinations of undesirable "cut-through" traffic and higher speeds that threatened vehicular and pedestrian safety. [Lockwood, 1997; Ewing, 1999] Traffic calming is a form of context-sensitive solutions. It is now widely accepted as a way of retrofitting "overdesigned" streets whose vehicular function is primarily to serve local access. Besides slowing vehicle speeds, traffic calming also serves to modify driver behavior.

Typical traffic calming measures include: speed humps, diverters/closures, roundabouts, chokers, and other engineering measures designed to slow vehicle speeds. The city of Chicago's *Tools for Safer Streets* provides a good example of the variety of traffic calming actions a community can consider. [Chicago Department of Transportation, 2013a] The city's guide includes:

**Intersections and Corridors**

- Marked crosswalks
- In-road "State Law Stop for Pedestrians" signs
- Pedestrian refuge islands
- Signals and beacons
- Accessible pedestrian signals
- Pedestrian countdown timers
- Leading pedestrian intervals
- Lagging left turns
- Road diets
- Speed feedback signs
- Roundabouts

**Neighborhood Streets**

- Chicanes
- Speed bumps
- Narrow street lanes
- Bumpouts
- Neighborhood traffic roundabouts

It is beyond the scope of this chapter to describe each of these in great detail. Such information is found in other publications and websites (see, for example, ITE, http://www.ite.org/traffic/tcdevices.asp; FHWA, http://safety.fhwa.dot.gov/speedmgt/traffic_calm.cfm; Project for Public Spaces http://www.pps.org/reference/livememtraffic/; and the traffic calming chapter in ITE's *Traffic Engineering Handbook*). [Gulden and De La Garza, 2016] However, to give some sense of the characteristics of traffic calming measures, two are highlighted here—roundabouts and road diets.

*Roundabouts* are large, raised, circular islands in the middle of intersections primarily aimed at slowing traffic while at the same time making the intersection work more efficiently. The benefits of roundabouts include:

- Creating a steady flow of traffic.
- Reducing conflict points, thus reducing crashes.
- Reducing vehicular speeds, which reduce the severity of crashes.
- Reducing the number of traffic signals required.

- Narrowing entrance streets allows safer pedestrian crossing.
- Providing streetscaping opportunities that enhance aesthetic appeal.
- Designing a sloping ramp around the perimeter of the raised island allows larger vehicle to navigate the intersection without mounting the curb. [PPS, 2015]

A great deal has been written on roundabouts, especially over the past 10 years. The reader is referred to the FHWA website on roundabouts as a good resource for the latest information http://safety.fhwa.dot.gov/intersection/roundabouts.

*Road diets* reallocate the cross-sectional space (travel lanes and shoulders) by restriping the road to provide more space to bicyclists and pedestrians by reducing the amount of road space for motor vehicles. To some, this is a controversial decision because it often entails removing through travel lanes in order to add space for walking and cycling, and removing left turns from through lanes (quite often with a two-way left turn lane); to others it provides a better context for the road itself and the function it is supposed to serve in the community. The benefits of road diets include:

- Narrowing lanes and widening sidewalks to provide safer walking space for pedestrians.
- Removing through lanes and adding bicycle lanes and turning lanes to provide safer and more convenient riding space to bicyclists and left turns.
- Narrowing street lanes to discourage speeding. [PPS, 2015]

As seen in these points, enhanced safety is one of the major benefits of road diets. A study of 14 road diets in Iowa found a 45 percent reduction in head-on crashes, 30 percent reduction in rear-end crashes, 74 percent reduction in angle/oncoming left-turn crashes, 41 percent reduction in broadside crashes, and 45 percent reduction in sideswipe-same direction crashes. [Stout, 2005] In Seattle, the overall change in crashes at 10 road diet locations ranged from 0 percent to a 60 percent reduction. [Lagerwey, 2005] Although the majority of before-and-after studies show a reduction in crashes, road diets are sometimes difficult to implement, primarily because of drivers who feel the road is becoming more difficult to drive on. Accordingly, implementing road diets requires a very careful and well-thought-out project planning process.

According to Rosales [2007], some guidelines for considering road diets in road planning include:

1) Consider road diet projects when a pavement reconstruction project or jurisdictional roadway transfer and other supporting conditions are present, such as the existences of an adjacent parallel route.
2) Consider community requests to evaluate and implement road diet projects. With technical evaluation and community involvement with stakeholder groups, road diet projects are more likely to be successful.
3) By implementing a road diet as a pilot project study, the effects on safety and operations can be measured before deciding to keep it permanently and/or to fund enhanced design features and a more permanent solution. However, a temporary solution may not provide all of the benefits of a permanent solution (this should be acknowledged and made clear to stakeholders upon implementation).
4) Coordinate with other corridor improvements.
5) Coordinate road diet projects with concurrent pavement overlay projects, if possible. A road diet striping plan on new pavement results in less driver confusion.

Figure 9-3 shows road diet project design options from Tulsa, Oklahoma.

The most up-to-date information on road diets can be found at the FHWA website http://www.fhwa.dot.gov/everydaycounts/edc-3/reconfiguration.cfm.

## V. GREEN ROADS

As noted in chapter 1 and chapter 7 on evaluation, the concept of sustainability is one of the important societal trends influencing not only the transportation profession, but many other fields as well. With increasing consideration of the triple bottom line (TBL) of economic development, societal equity, and environmental quality (sometimes referred to as the "Three Pillars of Sustainability"), several project sustainability rating systems have been developed to rate individual projects on the degree to which they meet sustainability criteria. Five prominent rating systems in the United States include: FHWA's Infrastructure Voluntary Evaluation Sustainability Tool (INVEST), the Institute for Sustainable Infrastructure's Envision®, the Sustainable Transportation and Access Rating System (STARS), Greenroads™, and GreenLITES. Table 9-4 outlines high-level information on the development and structure of these systems.

Two of these rating systems, INVEST and Envision™, will be briefly discussed below to provide some sense of how they work, particularly in terms of road and highway planning.

*Infrastructure Voluntary Evaluation Sustainability Tool (INVEST 1.1)*. INVEST is a voluntary, self-evaluation rating tool developed by the FHWA to measure the level of sustainability on roadway projects. The tool was developed with input from state and local transportation agency officials and staff, including those from the American Association of State Highway and Transportation Officials (AASHTO) and the American Society of Civil Engineers (ASCE).

INVEST includes three different evaluation systems: (1) system planning, (2) project development, and (3) operations and maintenance. System planning (SP) constitutes 17 potential credits. It is focused on agency-wide practices such as integrating long-range transportation plans (LRTPs) with economic, environmental, and community goals; linking planning with the environmental process; ensuring financial sustainability of the transportation system; and so on. The system planning criteria include:

SP-01: Integrated Planning: Economic Development and Land Use

SP-02: Integrated Planning: Natural Environment

SP-03: Integrated Planning: Social

SP-04: Integrated Planning: Bonus

SP-05: Access & Affordability

SP-06: Safety Planning

SP-07: Multimodal Transportation and Public Health

SP-08: Freight and Goods Movement

SP-09: Travel Demand Management

SP-10: Air Quality

SP-11: Energy and Fuels

SP-12: Financial Sustainability

SP-13: Analysis Methods

SP-14: Transportation Systems Management & Operations

SP-15: Linking Asset Management and Planning

SP-16: Infrastructure Resiliency

SP-17: Linking Planning and NEPA

| Table 9-4. Green Project Rating Systems in the United States | | | | | |
|---|---|---|---|---|---|
| **System** | **Sponsor** | **Scope** | **Organization** | **Review/ Certification** | **Construction-Related Factors** |
| **Envision® Version 2.0** | Institute for Sustainable Infrastructure | Infrastructure | 60 credits in five categories (Quality of Life, Leadership, Resource Allocation, Natural World, and Climate and Risk); bonus point opportunity | Stage 1: Self-assessment and Stage 2: Fee-based review | 13 credits focused on materials, energy, and water under Resource & Allocation Category |
| **GreenLITES** | New York State DOT | Highways | Design/Construction checklist includes 180 criteria, and other modules cover planning through operations and maintenance | Self-assessment | Credits interspersed throughout the checklist; focused within Water Quality, Materials and Resources, and Energy and Atmosphere |
| **Greenroads™** | Greenroads Foundation | Highways | 11 Project Requirements; 37 Voluntary Credits; focused on design and construction | Fee-based review | 8 credits in Construction Activities; 6 credits in Materials and Resources; 5 credits in Pavement Technologies |
| **INVEST 1.1** | FHWA | Highways | 3 Checklists: System Planning (17 criteria), Project Development (29 criteria), and Operations and Maintenance (14 criteria) | Self-Assessment | Factors within Project Development scorecard include emission reduction, noise mitigation, quality control, warranties, etc. |
| **STARS** | North American Sustainable Transportation Council (STC) | Multimodal Transportation | STARS Project: 29 credits organized in 6 categories: Integrated Process, Access, Climate and Energy, Ecological Function, Cost Effectiveness Analysis, and Innovation.<br>STARS Plan: 8 credits<br>STARS Employer Programs: not yet developed | Fee-based review | 2 credits in Climate and Energy and 3 credits in Ecological Function |

Source: Parsons Brinckerhoff, 2014

As noted by the FHWA, INVEST can be used to evaluate and enhance transportation plans and programs, including:

- Retrospectively evaluating the sustainability of a completed program (or part of a program).
- Proactively setting goals, providing guidance, and measuring the sustainability of a developing program. INVEST can be used as a tool at this point to encourage broad participation, evaluate sustainability trade-offs, communicate benefits and goals, and reward excellence. Users can choose to what extent to measure success against the absolute scale of how many overall points are achieved by a given program or set an achievement level they would like to reach and use this tool to meet those goals.
- Assisting owners, stakeholders, and program teams with understanding new technologies and best practices in sustainability and helping them anticipate new, related requirements that may emerge.
- Estimating the sustainability of a System Planning program (including processes, procedures, policies, and practices) at a statewide, regional, or local level to facilitate the decision-making process. [FHWA, 2015b]

The operations and maintenance (OM) scorecard includes 14 potential credits with a focus on maintenance programs for bridges, pavement, traffic control, and infrastructure, among others. There is one scorecard each for the SP and OM modules. The project development (PD) scorecard includes a potential 29 credits and is focused on project-level sustainability decisions such as multimodal accommodations, life-cycle cost analyses, recycled materials, and construction practices, among others. The PD module includes six scorecard options, which vary based on project context and type (categories include paving, basic rural, basic urban, extended rural, extended urban, and custom).

*Envision*®. Envision was developed to be a sustainability-rating system for a wide range of infrastructure. According to the Envision website, it "offers a way of assessing the sustainability of infrastructure projects, not simply in individual improvements, but in terms of their overall contribution to the communities they serve." [Institute for Sustainable Development, 2015] Figure 9-4 shows the criteria that can be assigned to individual projects.

Although each project rating system has its unique characteristics, all focus on life cycle analysis, and rewarding project sponsors for making a project more sustainable by targeting project characteristics on the TBL goals.

## VI. COMPLETE STREETS

Complete Streets are designed and operated to provide the safest achievable access for all users, including motorists, bicyclists, pedestrians, and transit riders. [ITE, 2010; Los Angeles County Metro, 2014] The concept of Complete Streets to some extent evolved from the context-sensitive solutions (CSS) approach to road planning and design, as well as experience in some communities that had adopted a more flexible approach to road design in the early 2000s. In addition, the urban planning profession during this time was championing the idea that streets were public spaces as well as a means for moving vehicles. The best example of this concept is the *Urban Street Design Guide* published by the National Association of City and Transportation Officials. [NACTO, 2013] As noted in the *Guide,* "Growing urban populations will demand that their streets serve not only as corridors for the conveyance of people, goods, and services, but as front yards, parks, playgrounds, and public spaces. Streets must accommodate an ever-expanding set of needs. They must be safe, sustainable, resilient, multimodal, and economically beneficial, all while accommodating traffic."

Similar in concept to context-sensitive solutions, the *Guide* states that street design depends on context, and defines 13 such contexts likely found in urban areas: downtown one-way street, downtown two-way street, downtown thoroughfare, neighborhood main street, neighborhood street, yield street, boulevard, residential boulevard, transit corridor, green alley, commercial alley, residential shared street, and a commercial shared street. Thus, for example, for a transit corridor, the *Guide* recommends:

- Transit corridor retrofits should be coordinated with land-use changes to maximize a corridor's potential for economic growth and transformation.
- A pedestrian-scale environment should be provided.

**Figure 9-4. Envision® Sustainability Project Criteria**

Source: Institute for Sustainable Development, https://www.sustainableinfrastructure.org/downloads/Envision_Credit_List.pdf

- A raised cycle track on either side of the corridor promotes bicycle and transit use.
- If local transit service is obstructed by double parking and local traffic congestion, a BRT, streetcar, or light rail transit service should be considered if transit ridership supports it.
- Consider the trade-offs between shortening a traffic signal cycle length and providing sufficient time for pedestrians to cross the road.
- Consider off-board fare collection to improve transit speed.
- Design transit stops to reinforce the desired operation of the transit service.

Many state DOTs, MPOs, and cities have adopted Complete Streets principles as part of their planning and design guides. For example,

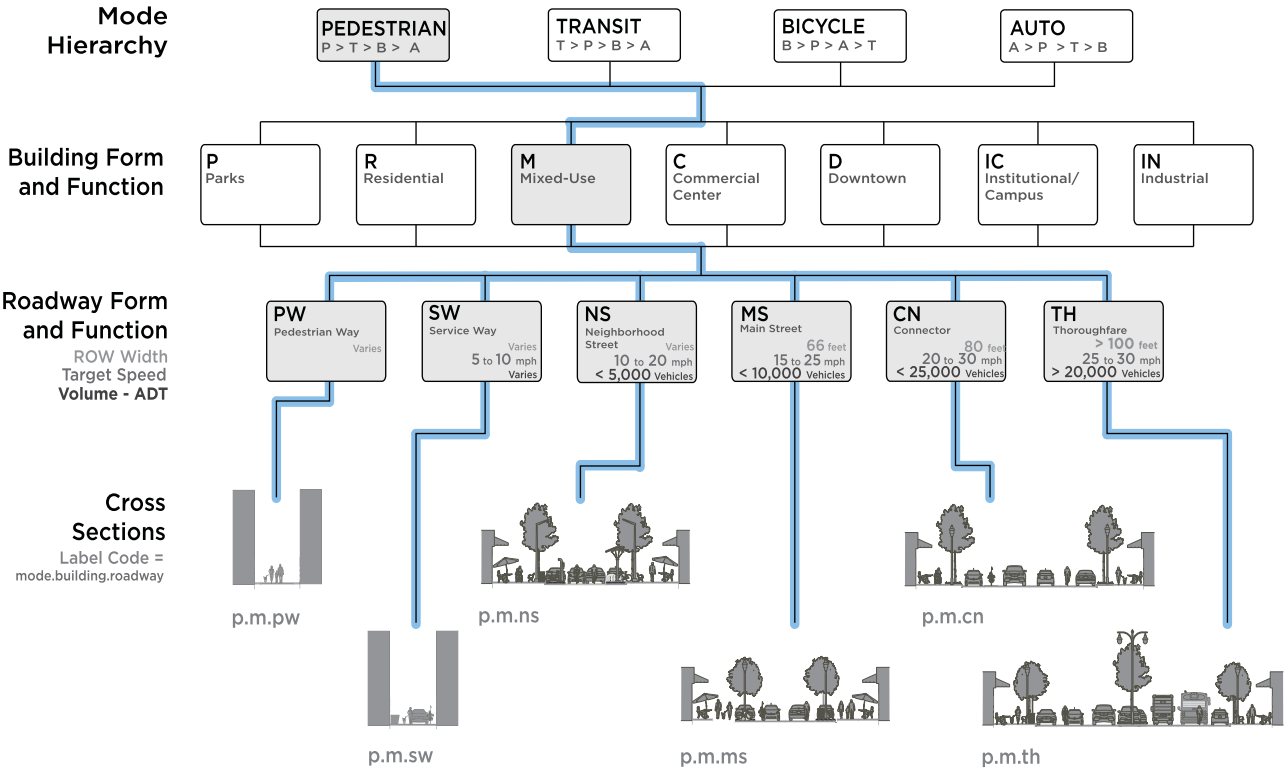
**Chicago Department of Transportation [CDOT, 2013]**

CDOT has adopted modal hierarchies to inform design and operation decisions. The default hierarchy is: Pedestrian > Transit > Bicycle > Automobile. These hierarchies not only inform street design, but they also provide planners with some sense of what type of road is appropriate in different contexts. For example, one could envision in a downtown transit corridor environment where Transit > Pedestrian > Bicycle > Automobile. On a parkway with no bus service, one might consider an Automobile > Pedestrian > Bicycle > Transit hierarchy. Figure 9-5 shows how many different combinations of mode hierarchy and building form and function could combine to end up with typical cross sections. Target speed in this case refers to the speed range that is desired after the street is constructed.

**Minnesota DOT [MnDOT, 2014a]**

In implementing its Complete Streets policy, MnDOT realized that road design standards could potentially be one of the key obstacles to flexible design. Accordingly, MnDOT revised its guidance on design elements to provide more flexible design opportunities. The design guidance for the following elements was revised: traveled lane width standards for state highways, bridge width standards for state highways, design speed guidance for state highways,

**Figure 9-5. Modal Hierarchies as Part of a Complete Streets Policy, Chicago DOT**



Source: Chicago DOT, 2013

superelevation and horizontal alignment design, maximum roadway design grades, vertical clearance requirements for new construction, traveled-way pavement cross slopes, and lateral offset to obstruction.

**City of Decatur, Georgia**

Decatur was one of the first cities to adopt a Complete Streets philosophy in its comprehensive transportation plan. A new street typology that looked at city streets by land-use context was used to identify key multimodal and economic development opportunities. As in other studies, level of service (LOS) measures were tied to the ability of facilities to handle current and expected demand. However, both the pedestrian and bicycle LOS measures included other factors relating to the quality of the travel experience, such as sidewalk width, pavement condition, and buffers between pedestrians/bicyclists and moving vehicles (a methodology found in the *Highway Capacity Manual* and described in chapter 13 on pedestrian and bicycle planning and chapter19 on site plan review and traffic impact analysis). Latent demand scores were used to account for the demand for bicycle and pedestrian travel to destinations (schools, retail stores, employment centers) that would likely increase with safer and more convenient ways of reaching the destination. Finally, the plan was one of the first in the United States to undergo a Health Impact Assessment (HIA) that examined how development patterns and transportation projects could affect public health. The concept of Complete Streets was one of the recommendations for improving community health.

Complete Streets as a policy or design guide will likely be an important characteristic of future transportation project development. It is important to transportation planners because the context of road development broadens the perspective of road design, feeding into planning concerns for land use, urban design, and sustainability. For updates on Complete Streets see National Complete Streets Coalition, http://www.smartgrowthamerica.org/complete-streets/changing-policy/model-policy.

# VII. SYSTEM PERFORMANCE AND CAPACITY MEASURES

## A. Traditional Measures

Of all the modes of transportation, roads and highways have been studied the most, and thus have the most well-developed concepts and relationships that define system and facility performance. This body of knowledge has been the basis for many of the manuals and technical guides directing road planning today (see [AASHTO, 2010, 2011, 2014] and [TRB, 2010, 2013, 2015]). Also, in many ways it has been the conflict between desired performance/capacity and community context that has led to the programs and initiatives described in the previous sections.

It is important to begin the discussion of performance and capacity with some understanding of what type of information and/or data are used in road and highway planning and roadway design. The following traffic characteristics are important inputs into the types of decisions that have to be made regarding roadway design and often in determining the priorities among different projects (see chapter 2 on travel characteristics and data provides a more detailed discussion of how traffic data are collected).

*Average Daily Traffic*—This is the most basic measure of traffic demand for a highway, and is estimated as the total volume during a given time period divided by the number of days in the time period. Although useful as an indicator of roadway use, ADT does not provide any indication of variation in demand by hour, day, week, or season, and is *not* an indicator of congestion.

*Peak-Hour Traffic*—In order to reflect better the operating conditions of a road or intersection during a day, planners collect information on peak hours and peak periods. Peak-hour counts provide input into performance assessments (when compared to capacity), and when further disaggregated into smaller time units, for example, 10- or 15-minute periods, are important inputs into traffic control strategies. Most highway agencies use the $30^{th}$ highest hourly volume of the year as the design control for a road.

*Directional Distribution*—The distribution of traffic by direction is important for road design (e.g., the number of lanes needed) and is used in transportation planning as input into modeled trip distributions and network assignments. For example, this information is a critical part of traffic impact studies (see chapter 19 on site planning and impact analysis).

*Vehicle Classification*—The vehicle fleet using the road system on a daily basis is quite diverse, especially for goods movement. Two general classes are used to group vehicles by operating characteristics: passenger cars (including automobiles, vans, pick-up trucks, and sport utility vehicles) and trucks (including single-unit and combination trucks, and recreational vehicles). The type of vehicle using a road or entering an intersection will have an effect on performance (for example, the more trucks, the more congestion). See chapter 2 on travel characteristics and data.

*Speed*—Speed is an important system characteristic to those who use the system. For transportation designers, it is a critical input into geometric design characteristics for roads and intersections. In recent years, the use of design speeds to justify design standards has been critiqued as resulting in unnecessarily wide and fast facilities. Two design concepts that have become of interest to planners and discussed earlier, traffic calming and road diets, are mostly intended to reduce the speed of vehicles on the road.

*Vehicle (Person) Miles Traveled*—The measure of network use is usually defined as either person or vehicle miles traveled (one person or vehicle traveling one mile). These measures result from travel demand models that predict the number of vehicles or persons using a road network, the trip lengths, and mode choice. VMT is an important variable for estimating motor vehicle-related pollutant emissions as well.

*Volume/Capacity*—This is a traditional measure that compares current or predicted volumes to the capacity of a facility to handle traffic. The closer this ratio gets to 1.0 (and in many modeling efforts, the ratio is much greater than 1.0), the more congested the road segment.

The Transportation Research Board's *Highway Capacity Manual* is the most widely used reference in determining the performance of existing roads and intersections, and for providing input into estimating future performance. [TRB, 2010] The *Manual* examines the performance characteristics of individual components of the highway network, with the logic being that the performance of the overall facility will vary dramatically depending on how each component operates. For example, freeway segments are different from intersections, which are different from an urban street, and so on. The *Manual's* procedures determine service measures that describe the performance of each system component. Table 9-5 shows the service measures that can be used for different facilities and system components. For example, signalized intersection performance can be assessed using vehicle delay (seconds/vehicle),

**Table 9-5. Service Measures by System Element**

| System Element | Service Measures | | | | Systems Analysis |
|---|---|---|---|---|---|
| | Auto | Pedestrian | Bicycle | Transit | |
| Freeway facility | Density | - | - | - | Speed |
| Basic freeway segment | Density | - | - | - | Speed |
| Freeway weaving segment | Density | - | - | - | Speed |
| Freeway merge/diverge segment | Density | - | - | - | Speed |
| Multilane highway | Density | - | LOS Score | - | Speed |
| Two-lane highway | % time spent following | - | LOS Score | - | Speed |
| Urban street facility | Speed | LOS Score | LOS Score | LOS Score | Speed |
| Urban street segment | Speed | LOS Score | LOS Score | LOS Score | Speed |
| Signalized intersection | Delay | LOS Score | LOS Score | - | Delay |
| Two-way stop | Delay | Delay | - | - | Delay |
| All-way stop | Delay | - | - | - | Delay |
| Roundabout | Delay | - | - | - | Delay |
| Interchange ramp terminal | Delay | - | - | - | Delay |
| Off-street pedestrian-bike facility | - | Space<br>Bike/Ped Meeting Events | LOS Score | - | Speed |

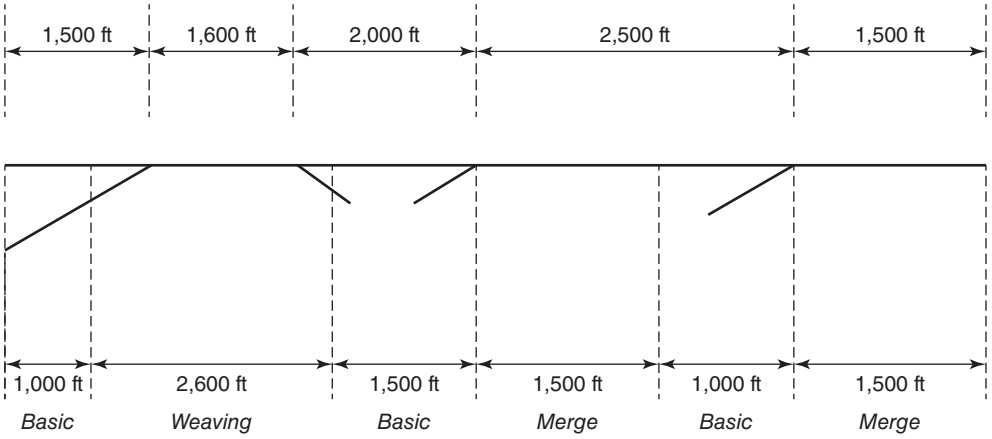
**Figure 9-6. Freeway Segments for Assessment of Performance**

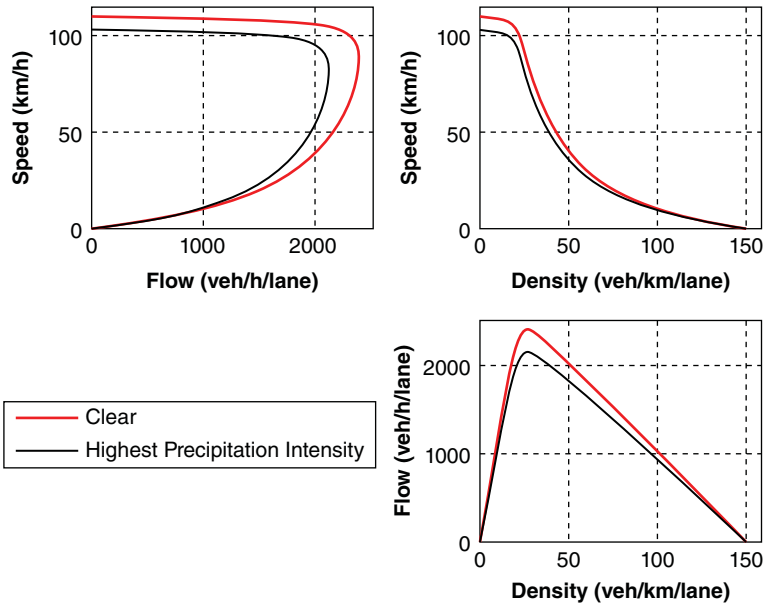


Source: TRB, 2010, Reproduced with permission of the Transportation Research Board.

whereas the assessment of the level of service for pedestrian and bicyclists at the same location would rely on level of service (LOS) scores. Another example is shown in Figure 9-6 where a freeway is divided into three segments—a basic segment and segments relating to weaving and ramp entrances. The methods for estimating performance are different for each segment (with the one having the least performance being the one that controls overall performance of the freeway).

The methods for estimating performance, in most cases defined as level of service, are fairly involved and readers are referred to the source documents for a detailed description of the recommended methods. However, some basic concepts need to be understood to place these methods in context. Figure 9-7 shows the fundamental relationships among traffic flow, density, and speed. These relationships are important because they define traffic-flow regimes where facility capacity is reached, that is, they define critical density ($D_{cap}$), maximum flow ($V_m$), and critical speed ($S_{cap}$). These relationships have been turned into levels of service metrics representing different facility operations levels. Figure 9-8, for example, shows the level-of-service thresholds for a flow versus speed comparison for a freeway. As levels of service progress from LOS A to LOS F, freeway users experience progressively worse conditions. One can see that speeds are quite low in the LOS F region.

**Figure 9-7. Relationship among Traffic Flow, Density, Speed, and Impacts of Rain**

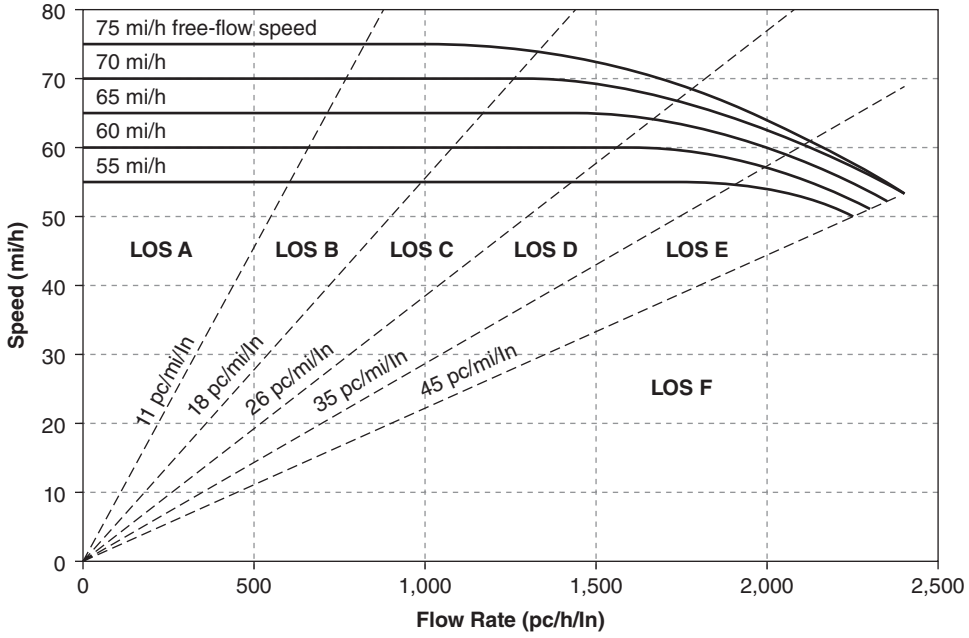


Source: Hranac et al., 2006

Table 9-6 shows the metrics that are used to define levels of service for a freeway. Transportation agencies often define their own threshold levels for determining unacceptable performance. In most cases, LOS E and F are considered to be heavily congested conditions. In more rural areas or smaller communities, the threshold might be higher (that is, LOS C or D) simply because the experience of exposing travelers to any level of congestion is considered to be an unacceptable deterioration of service. Similar concepts of level of service exist for pedestrian walkways and bicycle paths (see chapter 13).

In estimating level of service, most procedures start with an unadjusted estimate of speed assuming there are no factors that might cause speed to decline other than the amount of traffic on the road. In reality, of course, many different

**Figure 9-8. Level of Service and Traffic Flow and Speed, Freeways**



Source: TRB, 2010, Reproduced with permission of the Transportation Research Board.

**Table 9-6. Level of Service for Freeways**

| Level of Service | Density (passenger cars/mile/lane) |
|---|---|
| A | ≤ 11 |
| B | > 11 – 18 |
| C | > 18 – 26 |
| D | > 26 – 35 |
| E | > 35 – 45 |
| F | > 45 |

Source: TRB, 2010, Reproduced with permission of the Transportation Research Board.

factors can affect vehicle speeds. Figure 9-9 shows how one starts with an estimated free-flow speed for a freeway, and then adjustments are made based on empirically established reductions in flow rates due to identified factors. For example, for intersections, saturation flow rates are adjusted based on different lane widths, number of heavy trucks in the traffic stream, approach grade, existence of a parking lane and parking activity adjacent to a lane group, local bus blocking potential, lane utilization, area type, left-turning and right-turning vehicles, pedestrians facing left-turning vehicles, and a pedestrian-bicycle adjustment for right-turning vehicles.

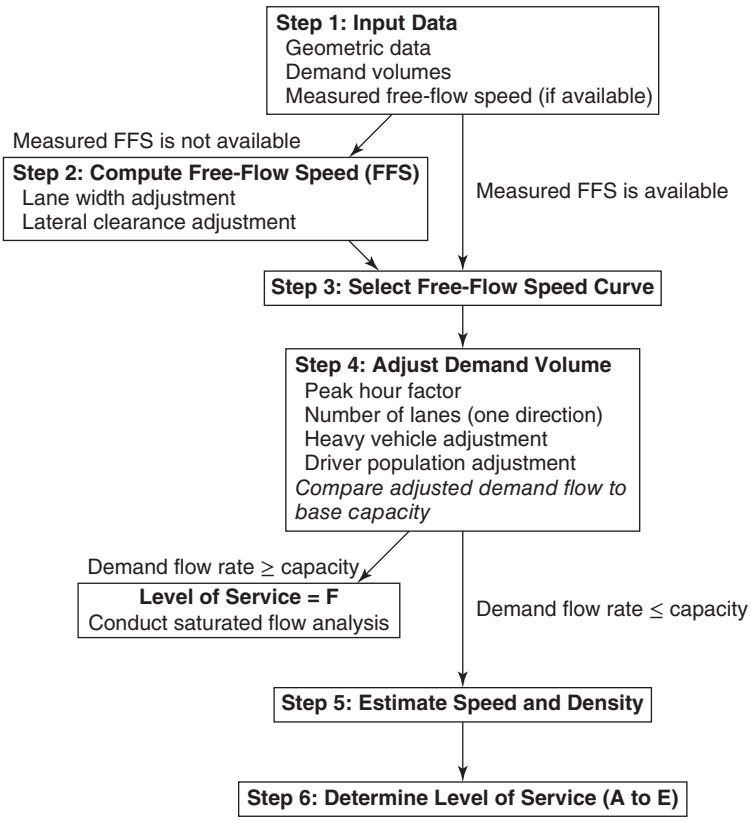
Given the legislative requirement to include performance measures in the transportation planning process in the United States (see chapter 1), transportation planners need to be aware of the latest methods and approaches for determining facility and system performance. For example, current federal legislation requires states and MPOs to report on a series of performance measures for the National Highway System (NHS), as well as condition measures (that will be discussed in the next section). These measures include:

- Performance of the interstate system and the remainder of the NHS
- Fatalities and serious injuries—both number and rate per vehicle mile traveled—on all public roads
- Traffic congestion
- On-road mobile source emissions

## B. Multimodal Performance Measures

In keeping with the philosophy of Complete Streets, there has been a growing interest in the profession in defining performance measures that reflect the multimodal performance of a facility. In other words, planners should not just focus on the individual levels of service of a highway or a transit line or a pedestrian/bicycle facility, but rather what is the composite level of service for transportation using the facility? This is more difficult than it sounds. The major reason for this is the fundamentally different performance characteristics of the "vehicle" involved (in quotes because for walking the vehicle is the pedestrian). Attempting to integrate or link the performance of automobile flows with pedestrian flows in a road corridor, for example, raises questions on how the two can be compared fairly, and what type of measure(s) best reflect the experience of *all* users in the transportation corridor?

**Figure 9-9. Level of Service Determination for Freeways with Adjustments**



Source: TRB, 2010, Reproduced with permission of the Transportation Research Board.

The Florida DOT has developed multimodal planning software for both arterials and freeways that rely on the concepts in the *Highway Capacity Manual* (HCM) as well as the *Transit Capacity and Quality of Service Manual* (TCQSM). For example, ARTPLAN, FDOT's multimodal conceptual planning software for arterial facilities utilizes average travel speed solely as the service measure. [FDOT, 2013] For bicycles and pedestrians, ARTPLAN uses the planning application of the bicycle LOS methodology and the pedestrian methodologies in the HCM. For bus, ARTPLAN uses the conceptual planning application of the TCQSM methodology applied to bus route segments and roadway facilities. The multimodal level of service for a road segment is then presented as the individual LOS estimates for each individual mode—no attempt is made to combine or integrate the different measures. This is very similar to the urban streets multimodal measure of performance proposed in NCHRP Report 616. [Dowling et al., 2008] Other than these two efforts, very little has been done in developing a true multimodal system performance measure.

A recent study on multimodal performance measures at intersections adds caution on which approach is used and how the results are interpreted. Brozen, Black, and Liggett [2014] examined the use of three different approaches to assess the multimodal performance of an intersection: the HCM 2010 level of service analysis, a LOS protocol developed by the city of Charlotte, North Carolina, and a Bicycle Environmental Quality Index (BEQI) and Pedestrian Environmental Quality Index (PEQI) developed by the Department of Public Health in San Francisco. As noted in the paper, for bicycles, "the metrics were in complete disagreement in scoring intersections," and for pedestrians "despite grading on a completely different set of variables, the PEQI intersection grades were still reasonably close to grades assigned by the Charlotte LOS and HCM 2010 LOS approaches." The major differences in outcomes were explained by the different component variables constituting each method. As noted by the authors, the choice of method really depends on the goals of the study, "if the goal is to improve traveler satisfaction across all modes, the HCM 2010 LOS approach would be the best choice; improved safety or geometric design would be better evaluated through the Charlotte LOS approach; and the BEQI includes additional variables such as the availability of bicycle parking and presence of bicycle signage." [Brozen, Black, and Liggett, 2014]

In addition, it is important to note that some communities and the state of California have begun to remove LOS from consideration in traffic impact studies and replace it with VMT as the measure of record. The logic of doing so is that LOS is not conducive to transit and active transportation modes as solutions to mobility problems. It really

focuses on reducing local congestion, but ignores the impacts of development-generated travel on the larger network. Given the range of values for each LOS level, even though a development is adding traffic to the network, the LOS might not change (and thus technically little mitigation is necessary). This issue is one that will likely receive more attention in the future.

As of the date of this handbook, the specific performance measures to be use by state DOTs and MPOs in transportation planning as per the U.S. DOT have not yet been chosen. However, it seems likely that the performance measures will clearly relate to the types of service measures described above. On-road mobile emissions, for example, are estimated from network models that produce VMT estimates as well as average vehicle speed. Traffic fatalities and serious injuries are also of great concern to transportation agencies and will be part of every performance measure reporting scheme (see chapter 23 on integrating safety into transportation planning).

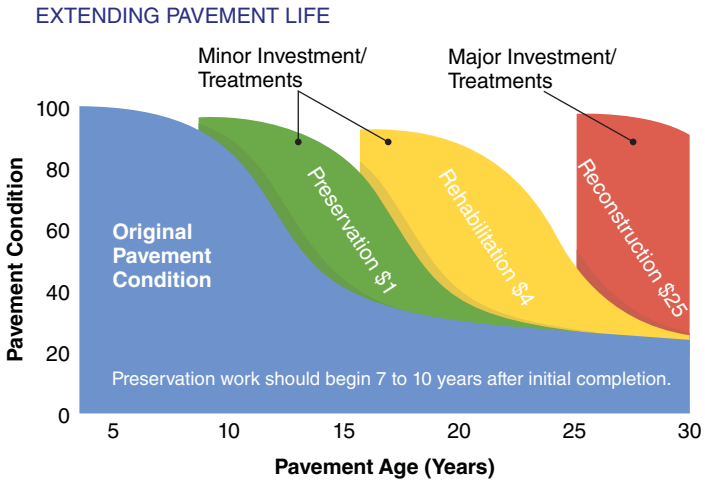
## VIII. CONDITION MEASURES AND MANAGEMENT SYSTEMS

As noted above, federal transportation law in the United States requires state DOTs and MPOs to report on the condition of the National Highway System (NHS). Two condition measures were required as part of this legislation: (1) pavement condition on the interstate system and on the remainder of the NHS, and (2) bridge condition on the NHS. Both of these condition measures have been part of state DOTs' system management structure for years. In particular, all state DOTs have management systems capable of monitoring system condition and in most cases forecasting future asset conditions assuming investment levels. The most available management systems include pavement management, bridge management, road or inventory management, maintenance management, and asset management systems. Asset management systems are described in chapter 8 and thus are not repeated here.

### A. Pavement Management Systems

A pavement management system is a "set of tools or methods that can assist decision makers in finding cost effective strategies for providing, evaluating, and maintaining pavements in a serviceable condition. It provides the information necessary to make these decisions." [Oregon DOT, 2015a] Figure 9-10 represents the Utah DOT's philosophy on pavement management systems. The basic approach is that by keeping the pavement at a reasonable state of condition through preservation or minor reinvestment, the state DOT can avoid much more costly reconstruction in later years. As noted by the Utah DOT, "regular upkeep to prevent deterioration provides the best value at the lowest life-cycle cost. This preservation philosophy not only provides the best value for physical assets, it also provides additional safety benefits by ensuring that signs are well maintained, pavement striping is visible, and pavement provides adequate friction." [Utah DOT, 2014]

**Figure 9-10. Extending Pavement Life, Utah DOT**

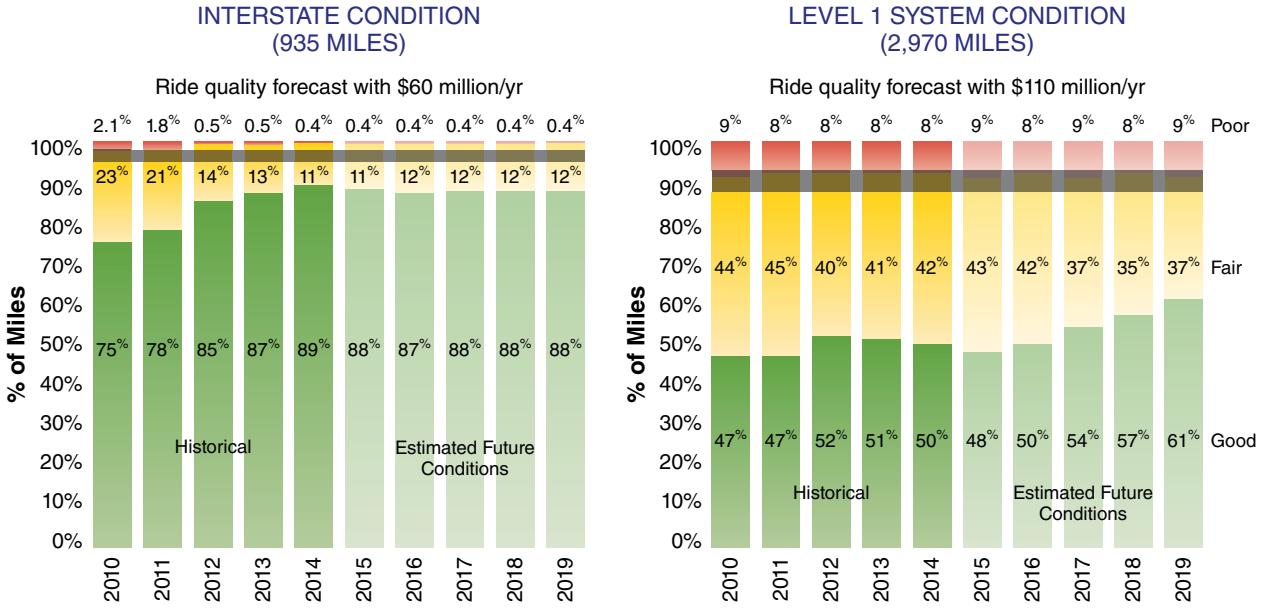


Source: Utah DOT, 2014

UDOT uses distress surveys and modeling techniques to forecast pavement conditions. Forecasting is conducted and reported by type of facility (for example, interstate, national highway system, urban, and rural), material (for example, concrete and asphalt), region, and available budget. Figure 9-11 shows how the pavement management system can be used to forecast future conditions by making assumptions on future traffic growth and the amount of funding available for pavement preservation.

Another example from the Oregon DOT is shown in Table 9-7. The table shows what is considered an "idealized" annual investment in pavement that will allow network pavement condition to reach a steady state. This is done by investing in an appropriate mix of preventive pavement maintenance, preservation, and rehabilitation projects.

**Figure 9-11. Estimated Pavement Conditions, Interstate, and Other State Roads, Utah DOT**



Source: Utah DOT, 2014

**Table 9-7. Idealized Annual Pavement Investment Program, Oregon DOT**

| Pavement Condition | Activity | Annual Need (lane-miles) | Service Life (years) | Lane-Mile-Years* | Annual Need |
|---|---|---|---|---|---|
| Failed | *Reconstruction* | | | | |
| | Concrete | 20 | 40 | 800 | $45 million |
| | Asphalt | 25 | 20 | 500 | |
| Poor | Structural Paving (multilayers) | 250 | 20 | 5,000 | $68 million |
| Fair | Nonstructural (thin paving) | 400 | 10 to 15 | 5,000 | $70 million |
| Good/Fair | Chip Seals | 650 | 8 | 5,200 | $17 million |
| All | Routine & Stop Gap Maintenance | 500 | 2 to 5 | 1,500 | Included in Maintenance Budget |
| Total | | | | | |
| Reconstruct | | 45 | | 18,000 | $200 million |
| Paving | | 650 | | | |
| Seals | | 650 | | | |

*A lane-mile-year is one year's worth of deterioration for one mile of road lane

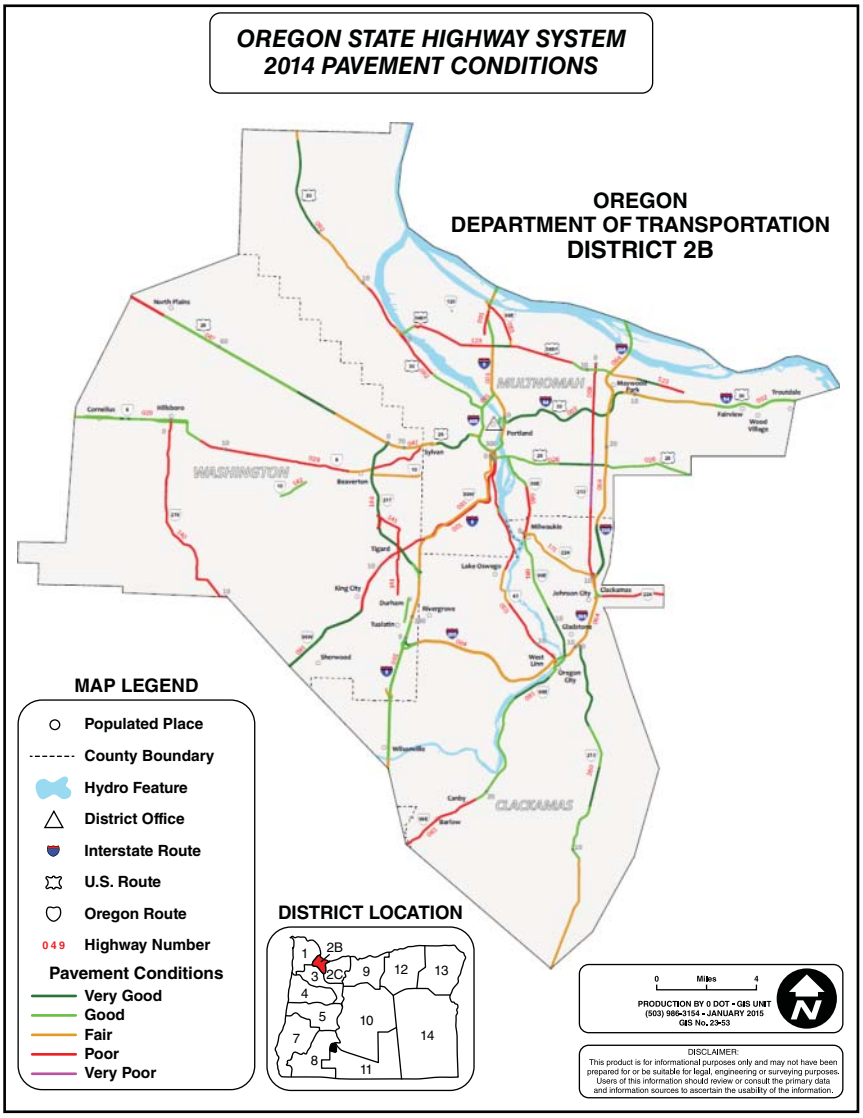
Source: Oregon DOT, 2015b

Annual rehabilitation and resurfacing mileage needs for the state highway network were approximated by pavement type by dividing the number of lane-miles by the typical life span of resurfacing and rehabilitation treatments. In theory, if Oregon DOT can keep up with this treatment cycle, pavement conditions would be in a sustainable "steady state," where each year the roads coming due for treatment would be programmed and there would be no backlog.

Pavement management systems not only provide an overall programmatic sense of investment needs, but they can also indicate where on the state highway system the needs are greatest. For example, Figure 9-12 shows a typical map for the Oregon DOT illustrating current pavement conditions on the state highway system for one district office.

Both the Utah DOT and Oregon DOT examples show how pavement management systems can be used for forecasting future needs with respect to pavement projects in a state or region. The outputs from such systems typically feed into the resource allocation and planning programs of state DOTs.

**Figure 9-12. Pavement Condition Map, Oregon DOT**



Source: Oregon DOT, 2015b

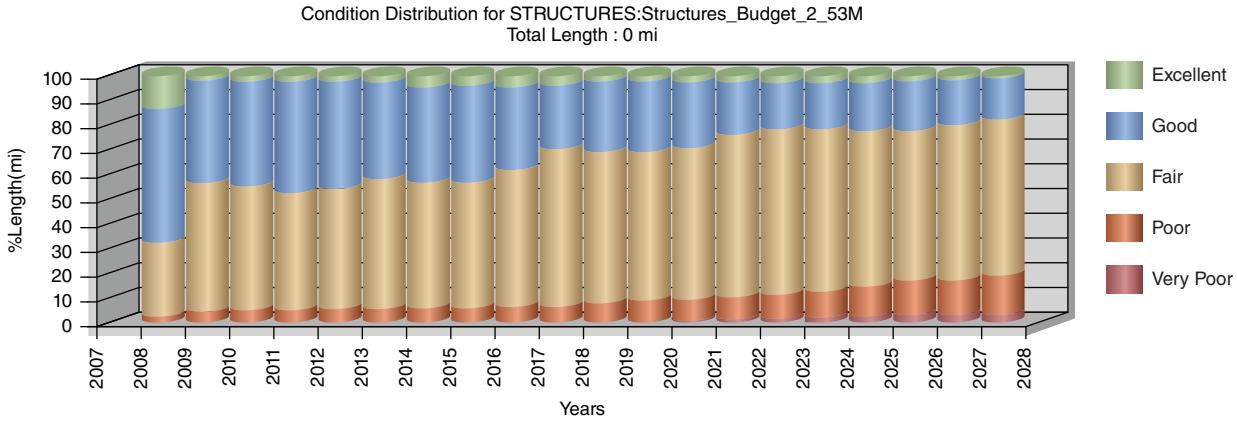
## B. Bridge Management Systems

Bridge management systems for states are required by federal law. The outputs of these systems are placed into the National Bridge Inventory, a database supported by the FHWA. [Markow and Hyman, 2009] The key output of these systems is a sufficiency rating, which evaluates highway bridge data by calculating four separate factors, resulting in a numeric value of a bridge's condition to remain in service. The result is denoted in percentages, where 100 percent represents an entirely sufficient bridge and zero percent represents an entirely insufficient or deficient bridge. The input data describe a bridge's structural evaluation, functional obsolescence, and its essentiality to the public. A low sufficiency rating could thus be caused by structural defects, narrow lanes, low vertical clearance, or other possible issues.

Structural evaluation describes an overall rating of the condition of the bridge structure, which is a sum of separately rated conditions of the structural components of the bridge. Scores are given for bridge decks, superstructure, and substructure. The ratings are on a 1 to 9 scale where a 9 means excellent condition and a 1 means imminent failure. Commonly reported conditions include:

*Functionally Obsolete*—Functionally obsolete means a bridge is no longer by design functionally adequate for its task. Reasons could include not having enough lanes to accommodate traffic flow or having inadequate

**Figure 9-13. Use of Bridge Management System to Forecast Future Bridge Conditions, Utah DOT**



Source: Utah DOT, 2015b

emergency shoulders. A functionally obsolete bridge may be perfectly safe and structurally sound, but may be the source of traffic jams or may not have a high enough clearance to allow an oversized vehicle.

*Structurally Deficient*—Structurally deficient means a bridge has one or more structural defects that require attention.

Most state DOTs and many agencies in other countries use a bridge management software called AASHTOWare™, which is a product in AASHTO's BRIDGEWare™ suite of programs (previously referred to as Pontis). The program can be used for bridge inventories, managing inspections, conducting a needs assessment, and supporting project and program development.

Bridge management systems produce information very similar to that produced by pavement management systems. This includes the current condition status of a state's bridges. A bridge deterioration function allows state transportation officials to project into the future and estimate the status of the state's bridges given different levels of investment. Figure 9-13 shows the expected future conditions of bridges in Utah given current expected bridge investment revenues. In this figure, the percent length of bridges (in miles) in various levels of condition are projected to the year 2028 with currently budgeted investments. As shown, percent mileage in excellent or good condition declines over time, while the corresponding mileage in poor or fair condition increases. Similar figures can be created that show the expected improvement in bridge condition if extra investment occurs.

## C. Road or Road Inventory Management System

Most states and many city/local government agencies have a road inventory or road management system that provides the base layer for all the other management systems used in the agency. For example, the Pennsylvania DOT (PennDOT) has a roadway management system (RMS) that defines and monitors the state-owned highway network. It represents an inventory of roadway features, conditions and characteristics, and provides decision makers with the information necessary for funding, business planning, project design, and maintenance programming. [PennDOT, 2015] Given that it serves as the geospatial reference for other management systems, there is a location reference system (LRS) tying data to roadway locations. Data stored and managed in the RMS includes roadway geometry information, traffic information, pavement and shoulder history, maintenance history, municipal and legislative boundaries, intersections, roadside features, structure locations, railroad crossings information, pavement testing, condition survey information (including guide rail and drainage features), and posting/bonding information.

As an indication of its importance to the agency, other users of the RMS include PennDOT units responsible for Automated Highway Occupancy Permits, Automated Permit Routing & Analysis, Bridge Management, Crash Recording, Engineering & Construction Management, Maintenance Operations & Resources Information, Multi-modal Project Management, Municipal Services Information Center, and Sign Inventory Management & Ordering.

Another example comes from Massachusetts where a road inventory file contains the spatial coordinates for all public, and a good portion of the private, roadways in Massachusetts. In addition, the file contains roadway attributes

covering the roadway classification, ownership, physical conditions, traffic volumes, pavement conditions, highway performance monitoring information, and more. [MassDOT 2015] The other layers in the MassDOT's GIS platform include a rail inventory, bicycle inventory, boundaries for the highway districts, interchanges, traffic count locations, rest areas, park and ride lots, toll booths, pipe outfalls, transit parking lots, train stations, freight rail yards, ferry routes, seaports, water taxi stops, airports, and National Highway System (NHS) terminals.

## D. Maintenance Management Systems

State DOTs spend considerable dollars maintaining the state road system. In order to develop more productive maintenance programs, many state DOTs have adopted a maintenance management program usually supported with a maintenance management system.

Washington State DOT (WSDOT) provides a good example of a systematic and performance-driven approach to maintenance management. WSDOT developed a maintenance accountability program (MAP) with tools to link strategic planning, the budget, and maintenance service delivery. As noted in the maintenance plan, "the MAP, through its component pieces, provides WSDOT the means to clearly communicate to its key customers, the Legislature, the Governor, the Transportation Commission, and ultimately the tax paying public, the impact of policy and budget decisions on program service delivery." [WSDOT, 2012a]

The MAP uses outcome-based performance measures with a rating scale of A (best) to F (worst) for reporting the level of service provided. A performance measure is made up of a condition indicator (deficiency or condition to be measured), outcome measure (unit of measure), and thresholds for the five service levels for each MAP activity. A threshold is the range of allowable deficiencies or conditions for each service level. Figure 9-14 illustrates the type of data that is collected for each asset and the different gradations in service levels. These data are input into a management system, resulting in the outputs shown in Figure 9-15. This information has been influential in explaining the benefits of a maintenance program to legislators, and to show how a state DOT can be proactive in managing its maintenance program.

# IX. STATE HIGHWAY PLANS AND CITY THOROUGHFARE PLANS

Notwithstanding the desire for roadway system planning to be multimodal and emphasizing context as discussed earlier, many transportation agencies develop highway system plans focusing exclusively on highway capital needs. In many cases, these agencies have also developed modal plans for aviation, rail, pedestrian/bicycles, and transit. The primary reasons for developing a highway-oriented plan are: (1) funding categories are often programmatically restricted to single modes, and thus it makes little sense developing a plan with elements that cannot be funded, (2) most transportation modes are very different in character, spatial extent, and overall impact (e.g., transit services

are primarily in urban areas versus a state highway network that covers the entire state), and (3) it is often legislatively required.

This section provides two examples of highway plans—a statewide highway system plan for Minnesota, and a thoroughfare plan developed by the Atlanta Regional Commission (ARC). The approaches and methods used in these studies are very similar to those described in other chapters, especially chapter 6 on travel demand modeling, chapter 10 on network and facility operations planning, chapter 15 on statewide transportation planning, chapter 16 on metropolitan transportation planning, chapter 17 on corridor planning, and chapter 18 on local and activity center planning. These methods and approaches will not be repeated in the following sections. The examples that follow will simply highlight some of the key aspects of each planning study.

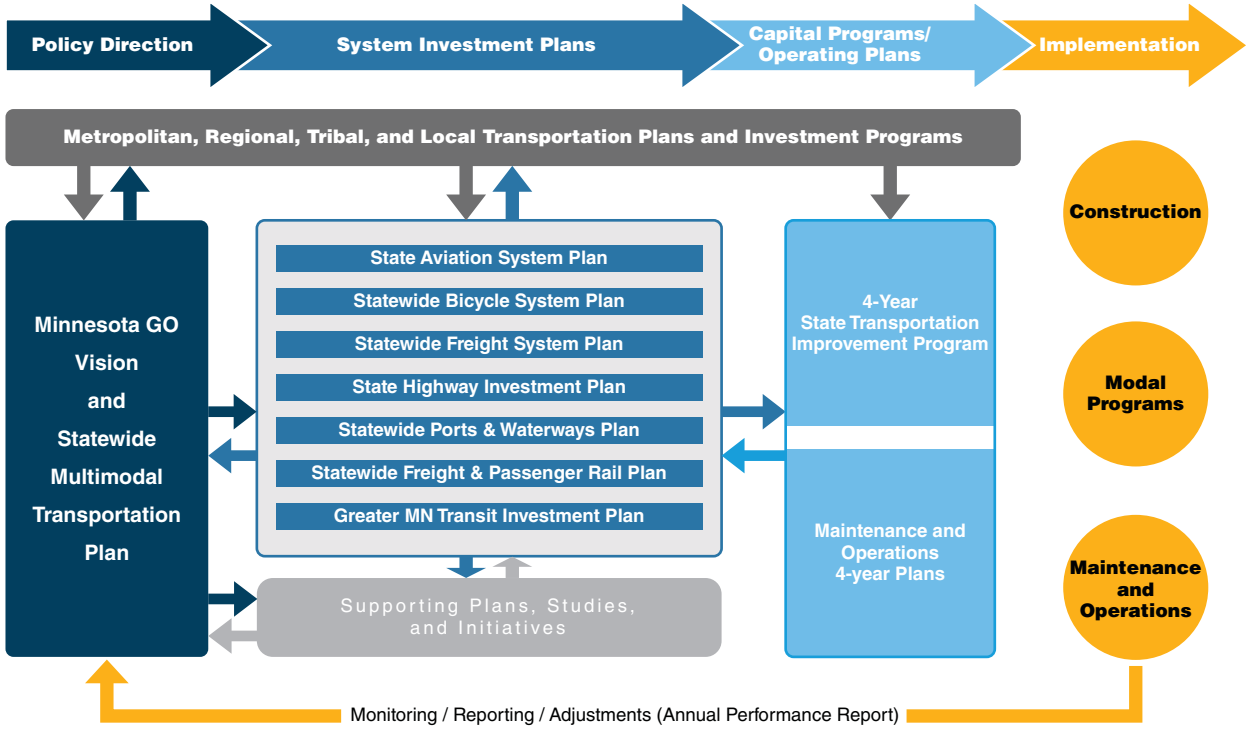
## A. Minnesota DOT State Highway Investment Plan

The Minnesota 20-Year State Highway Investment Plan (MnSHIP) is "MnDOT's vehicle for deciding and communicating capital investment priorities for the system for the next 20 years." [MnDOT, 2013] The overall recommended investment budget in the plan was $18 billion (the so-called "constrained" budget), although the needs assessment identified a total of $30 billion in needed projects. MnDOT does have a statewide multimodal transportation plan that lays out the policy principles and guidelines for the modal plans that follow. Thus, the highway systems plan was developed within a multimodal transportation policy context (see chapter 15 on statewide transportation planning). Figure 9-16 shows the relationship among all of the plans prepared by Minnesota DOT.

The highway plan began by noting the trends likely affecting the future use of the state's transportation system, including:

- *An Aging Population*—Over the next 20 years, the peak of the baby boom generation will move past the age of 65. Although many will continue to drive personal vehicles, the frequency and destinations of their travel will likely change.
- *More Minnesotans Living in Urban Settings*—A greater percentage of Minnesota's population is living in urban areas. According to the 2010 U.S. Census, 70 percent of Minnesotans lived in towns and cities, with more than 50 percent of the state's population living in the Twin Cities metropolitan area.

**Figure 9-16. Minnesota DOT's Statewide Planning Process**



Source: MnDOT, 2013

- *Energy Shifts*—Due in large part to global demand, the price of gasoline in Minnesota has more than doubled since 2002, while the stability of supply and prices has become increasingly erratic. Drivers have adapted by driving less, switching to more efficient vehicles, or using different fuels.
- *Transportation Technology*—Technology for vehicles, traffic signals, transit systems, and other areas of transportation is improving and becoming more integrated. These improvements increase efficiency, improve safety, and reduce emissions.
- *Persistent Budget Challenges*—In the face of transportation funding challenges, MnDOT and its partners are placing more focus on innovative design, shared services, and other collaborative solutions to address and prioritize transportation needs.
- *Health Impacts*—Transportation choices, such as bicycling and walking, bring health benefits and are seeing increased popularity. Along with more Minnesotans living in urban settings, a focus on higher density, mixed-use development and changing travel demand are creating new opportunities to design for and encourage healthier transportation options.
- *Increased Global Competition*—An efficient transportation system enables Minnesota to support a diversified economy that offers the opportunity to compete globally, attract human capital, and maintain innovation and competitiveness.
- *Changing Work Environments, Telecommunications, and Access to Services*—Businesses are taking advantage of options for telecommuting and flexibility in work arrangements for employees.
- *Floods and Water Quality*—Flooding can dramatically damage roads and other transportation facilities, which, in turn, can result in costly detours and delays for users. During the past decade, Minnesota spent an average of almost $2 million a year fixing flood-damaged roads.

MnDOT identified five investment areas and categories of investment that were central to the plan's recommended investment strategy (see Table 9-8). Note that the asset management category depended primarily on pavement management and bridge management systems inputs.

| Table 9-8. Minnesota DOT Investment Areas and Categories | | | | |

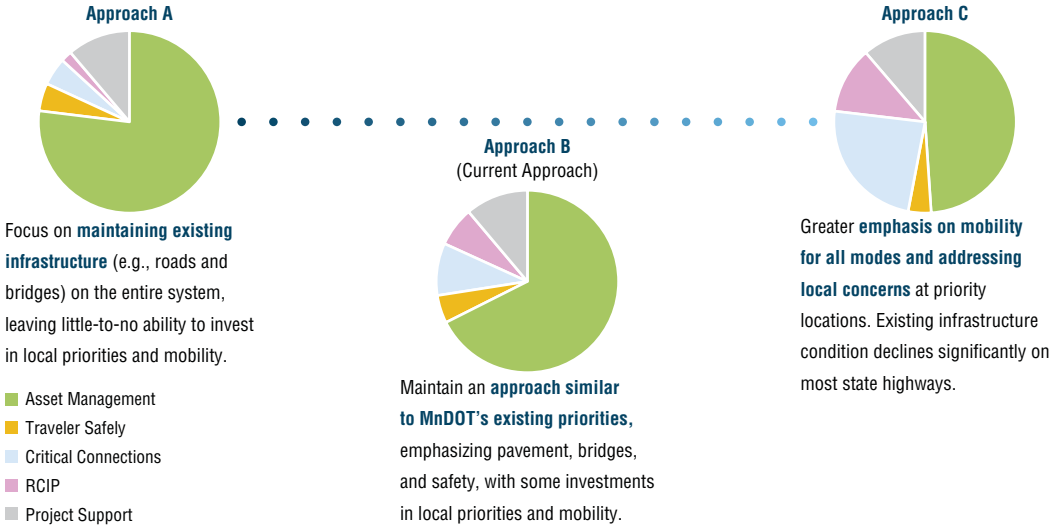
Source: MnDOT, 2013

**Figure 9-17. Scenarios Used in MnDOT's Highway Planning Process**



Source: MnDOT, 2013

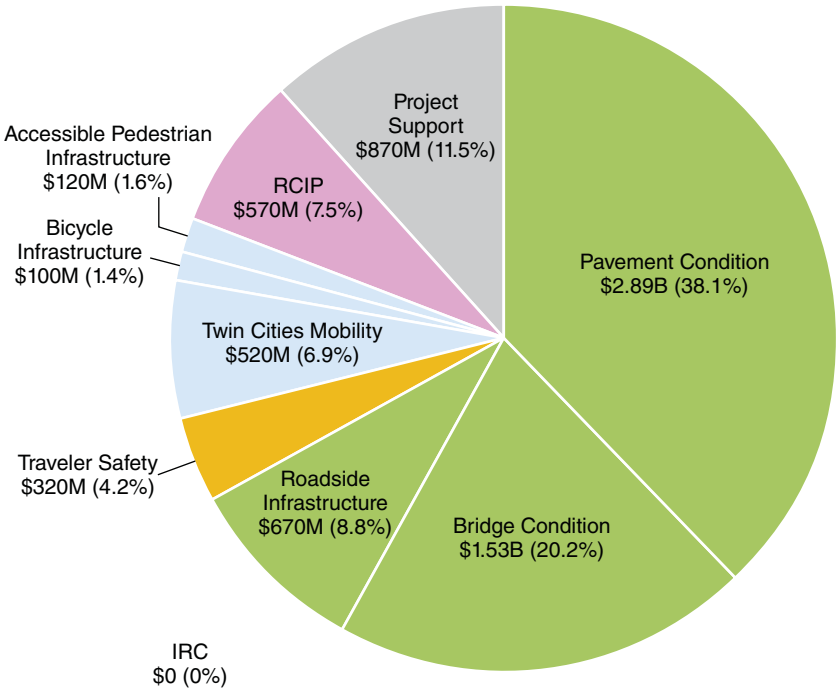
To illustrate the trade-offs associated with different ways of investing the expected $18 billion in the state highway system, MnDOT developed performance levels for each investment category and then packaged different performance levels from each category into three scenarios or "approaches." A two-month public outreach process including nine stakeholder engagement meetings and an online interactive scenario tool, and a one-and-a-half day internal workshop involving key MnDOT staff was used to assess the different scenarios. The online tool enabled participants to select their preferred scenario (Approach A, B, or C) and rank categories for increased or decreased investment. The scenarios used for this analysis are shown in Figure 9-17.

Based on the input from the public and stakeholders, and from its own management systems and other sources of data, MnDOT developed its $18 billion, 20-year plan. Figure 9-18 shows the distribution of the funds for the first 10 years of the plan. Of note in this planning process is the conscious identification of risks to the transportation program and to some of the investment priorities, and the mitigation of those risks by recommended actions in the plan (see Figure 9-19). This plan (and the planning process) is an excellent example of the state-of-practice highway system planning.

## B. Atlanta Regional Commission (ARC) Strategic Thoroughfare Plan

The ARC's *Strategic Thoroughfare Plan* was intended to: (1) identify and classify a prioritized roadway component of the Regional Strategic Transportation System, (2) develop guidelines on the management and design of these roadways in relationship to area context and multimodal needs, and (3) create a geo-referenced dataset of roadway attributes,

**Figure 9-18. Distribution of Investment Dollars for First 10 Years, Minnesota DOT**



Source: MnDOT, 2013

including real-time truck movement data that would establish the overall framework for a future data clearinghouse. [ARC, 2011] The following criteria were used to screen potential thoroughfare candidates:

- *National Highway System designation*—Roadways important to the nation's economy, defense, and mobility.
- *Principal Arterial Designation*—Facilities that carry a large number of trips for long distances.
- *Regional Mobility Corridor Designation*: Corridors that demonstrate regional mobility based on the qualitative analysis. These facilities averaged over 10,000 trips per day (AADT) with an average trip length of 20 miles or more.
- *Regional Truck Route Designation*—Roadway segments designated as Regional Truck Routes on the Atlanta Strategic Truck Route Master Plan.
- *Premium Transit Roadway Alignment*—Roadway facilities identified for premium transit enhancements such as Bus Rapid Transit (BRT), Arterial Rapid Bus, etc.
- *Regional Traffic Operations Program (RTOP) Corridor Designation*—Cross-jurisdictional regional corridors identified by the state DOT for performance monitoring activities and prioritization of operational and maintenance improvements.

Table 9-9 shows the criteria that were then used to identify a more carefully defined set of thoroughfare candidates.

The regional travel demand model, which provided information for many of the mobility performance measures, the regional land-use database, the roadway crash database, the GIS bike/pedestrian network, and the truck route GIS network were used to identify performance measures and targets for the thoroughfare network (for more detail on the data sources used, see [ARC, 2010]). These are shown in Table 9-10.

The final recommended thoroughfare plan is shown in Figure 9-20. Note that the recommendations are organized in different "levels" to reflect the significance of the road to the region's road network.

**Figure 9-19. Identification of Risk in Minnesota DOT's State Highway Plan**

| Key Capital Investment Risks | Mitigated Risk Through Year 10 (of 3 ✓) | Mitigated Risk Through Year 20 (of 3 ✓) |
|---|---|---|
| **GASB 34:** pavement and bridge conditions deteriorate, jeopardizing state bond rating | ✓ ✓ | ✓ |
| **Federal policy:** failure to achieve MAP-21 performance targets on NHS reduces funding flexibility | ✓ ✓ ✓ | ✓ |
| **MnDOT policy:** misalignment with Vision and Statewide Multimodal Transportation Plan results in loss of public trust | ✓ ✓ | ✓ |
| **Bridges:** deferring bridge investments viewed as an unwise/unsafe strategy | ✓ ✓ ✓ | ✓ ✓ |
| **Responsiveness:** rigid investment priorities limits ability to support local economic development and quality of life opportunities | ✓ ✓ | — |
| **Operations budget:** untimely or reduced capital investment leads to unsustainable maintenance costs | ✓ ✓ | ✓ |
| **Public outreach:** investment inconsistent with MnSHIP public outreach results in loss of public trust | ✓ ✓ | — |

| | |
|---|---|
| ✓ ✓ ✓ | *Adequately mitigated*<br>MnDOT mitigates most or all of the risk through its investment priorities |
| ✓ ✓ | *Partially mitigated*<br>MnDOT mitigates most of the risk through its investment priorities, but must accept some risk |
| ✓ or — | *Unmanaged or inadequately mitigated*<br>MnDOT is unable to mitigate the risk well, and must accept much of the risk or transfer it to another agency |

## X. ROAD INVESTMENT PROGRAMS AND PERFORMANCE MONITORING

The product of road and highway planning is almost always a capital program that prioritizes road projects over a specified number of years. For state DOTs, this capital program is the primary section of the statewide transportation improvement program (STIP). The STIP presents the prioritized list of road projects for an entire state and often then provides the list for individual DOT districts or regional offices. For city and municipal road planning, the list of projects is included in a capital investment plan or program (CIP). In both the statewide and local case, the list has to be approved by either the agency board of directors or a legislative body, and sometimes by both. Chapter 5 on transportation finance and funding presents more detail on the STIP and other program documents. The reader is referred to this chapter for further information.

| **Twin Cities Urban Freeway Congestion:** % of metro-area freeway miles below 45 mph in AM or PM peak | Tracking Indicator | 21.4% (2012) | N/A | Stable ('10-'12)<br>17.3 18.2 21.5 21.0 21.4<br>2008 2012<br>Better | After falling during the recession, the extent of congestion has been near its historic peak each of the last three years.<br>**Outlook —** Congestion is expected to worsen as economic activity increases and the region continues to grow. |
| **Interregional Corridor (IRC) Travel Speed:** % of system miles performing more than 2 mph below corridor-level speed targets | ≤ 5% | 2% (2011) | ● | Meeting target<br>2.0 2.0 2.0 2.0 2.0<br>2008 2012<br>Better | 98 percent of IRC system miles have performed at or above targeted speed each of the last 10 years.<br>**Outlook —** Result expected to remain stable through 2023. |
| **Snow and Ice Control:** Frequency of achieving bare lanes within targeted number of hours | ≥ 70% | 82% (2012) | ● | Meeting target<br>68 79 79 88 82<br>2008-9 2012-13<br>Better | MnDOT has achieved its statewide snow and ice control target nine out of the last 10 winter seasons. |

Source: MnDOT, 2014b

With today's emphasis on monitoring system performance many jurisdictions have developed a process for monitoring the achievement of transportation plans and programs. In Texas, for example, the legislature requires the Texas DOT to develop a 24-year long-range plan and the DOT must submit an annual report on the progress being made in achieving the plan's goals and targets. [Texas DOT, 2015] Minnesota DOT provides another example of the progress reporting that can occur for a state DOT. As seen in Figure 9-21, the performance measure values over the past five years are presented along with an indication of the trend in those statistics. This information provides state DOT officials with an indication of where extra effort might be necessary to achieve the goals of the plan.

## XI. SUMMARY

Roads and highways are the backbone of a transportation system, and thus an important focus of the transportation planning process. Many of today's planning approaches and tools were in fact originally developed for highway planning. Historically, road and highway planning focused on the road itself: Whether and where should it be built? How much and what kind of traffic will it carry? How many lanes and access points should it have? And what are the environmental impacts on the adjacent community and natural resources? Much of the data collected as part of transportation data collection efforts are used by transportation planners in a wide range of multimodal planning applications. In fact, long-range highway planning at a systems level is almost always folded into a multimodal approach that emphasizes the right mix of modal alternatives.

Today, highway planning is evolving to reflect growing concerns for the context within which roads and highways are provided. Context-sensitive solutions, traffic calming, green roads, and Complete Streets policies that consider transit, pedestrian, and bicycle needs along with those of people in cars and goods in trucks exemplify road planning efforts that seek outcomes extending well beyond the movement of motor vehicles on roadways. In addition, with the emphasis on system performance, many of the traditional road performance measures that focus on congestion, delay, and asset condition are now being used as part of broader, multimodal system monitoring programs for states and metropolitan areas.

This chapter described the important role that road and highway planning have in a nation's, state's, or city's transportation system. The context within which roads are planned and designed has become a very important factor in decisions relating to both project plans and design concepts. In particular, the relationship between the urban context and the role of a road has been incorporated into many design guides, especially at the local community level. Principles of roadway systems planning include a concern for such a context and for multimodal integration at the network and site levels. In transportation, more states and cities are adopting a context-sensitive solutions, traffic calming, green roads, and Complete Streets approach to planning and design.

Even though these approaches are more sensitive to the context within which roads are planned, constructed, and operated, most road planning still relies on the performance and capacity measures that have been used for years in the profession. In addition, measures that reflect the condition of pavements, bridges, and other assets provide important input into the transportation investment decision-making process. Finally, the actual planning for roadway systems is very similar to other planning contexts, with an articulation of goals and objectives, the use of traffic and land-use data, the use of travel demand models and other means of forecasting future impacts, and finally a concern for the funding resources that will be necessary to implement the plan.

# Transportation System Management and Operations[1]

## I. INTRODUCTION

Transportation planning and operating the transportation system have historically been two relatively detached sets of activities with different requirements and varied agency responsibilities and cultures. Transportation planning, for example, has traditionally focused on creating the physical infrastructure and services needed to meet future travel demand. There was often very little consideration for short-term and ongoing operational issues. Conversely, the management and operation of the transportation system has typically involved a different set of practitioners often having a short-term or real-time focus on today's system operations, and giving little consideration to how their activities relate to regional transportation system goals and objectives. However, a safe, reliable, and secure transportation system requires more than just providing the highway and transit infrastructure to move people and freight. In the twenty-first century, it also requires efficient and coordinated operations to meet the public's performance expectations and those of elected and appointed decision makers. Transportation system management and operations (TSM&O) is a concept that allows this to happen.

The U.S. federal transportation legislation, Moving Ahead for Progress in the 21st Century Act (MAP-21), defined transportation systems management and operations (TSM&O) as "integrated strategies to optimize the performance of existing infrastructure through the implementation of multimodal and intermodal, cross-jurisdictional systems, services and projects." The most recent version of the Federal Highway Administration's (FHWA's) *Freeway Management and Operations Handbook* defines TSM&O as "a set of strategies to anticipate and manage traffic congestion, and minimize the other unpredictable causes of service disruption, delay, and crashes." [Noblis et al, 2015] For purposes of this chapter, the term "TSM&O" will be used as an overarching strategy or program of strategies having the intent as described in these definitions. The term "management and operations (M&O)" will be used to describe the types of strategies that are part of such a program.

Both of the above definitions relate to transportation planning in several ways. First, M&O strategies should be considered by planners as important strategies for improving transportation system performance (for example, many states and metropolitan areas are implementing a regional managed lanes strategy as the core investment strategy for future system performance). Many M&O strategies are also being viewed as viable options for state and metropolitan investment primarily because there is little likelihood of finding the dollars or public support for widening major highways, and thus some other means of enhancing system capacity is necessary.

Second, many M&O strategies have a regional focus and thus require cross-jurisdictional collaboration. The metropolitan planning organization (MPO) was created to provide such a forum for regional collaboration (see chapter 1). It should come as no surprise that metropolitan transportation plans produced by MPOs in Atlanta, Dallas–Ft. Worth, Los Angeles, San Francisco, Seattle, and Washington, DC have M&O strategies as one of the core investment strategies for improving transportation system performance in their regions.

Third, the transportation planning process is inclusive and open to the public, important stakeholders, and governmental agencies having some responsibility for actions that could influence, or be influenced by,

[1] The original chapter in Volume 3 of this handbook was written by Wayne Berman, Federal Highway Administration. Changes made to this updated chapter are solely the responsibility of the editor.

*Transportation Planning Handbook: Institute of Transportation Engineers, Fourth Edition*, Michael D. Meyer

transportation investment. Greater coordination and collaboration among planners and system operators could help focus attention on those investments that more effectively and efficiently address short-term and long-term system performance needs. Stronger coordination, therefore, helps both planners and operators do their jobs better.

Finally, given the focus of transportation planning on system performance (see chapter 1), M&O strategies can provide system-level benefits that relate to some of the most used performance measures, including:

*Improved Travel-Time Reliability*. Travelers and freight shippers are increasingly sensitive to unanticipated disruptions to tightly scheduled personal activities and manufacturing supply-chain processes. Travel times have become increasingly unpredictable due to the growth in nonrecurring congestion, such as unexpected or unusual delays caused by crashes, inclement weather, special events, or project construction. Growth in overall traffic volumes often means that even small disruptions can have a significant ripple effect on transportation system performance over a broad geographic area. Stronger connections between planners and operators help planners consider programs and strategies to address reliability, such as deploying technologies to rapidly detect incidents; utilizing variable message signs and other approaches for providing quick, reliable traffic information to the public and media outlets; and using roving incident response teams to quickly clear crash sites.

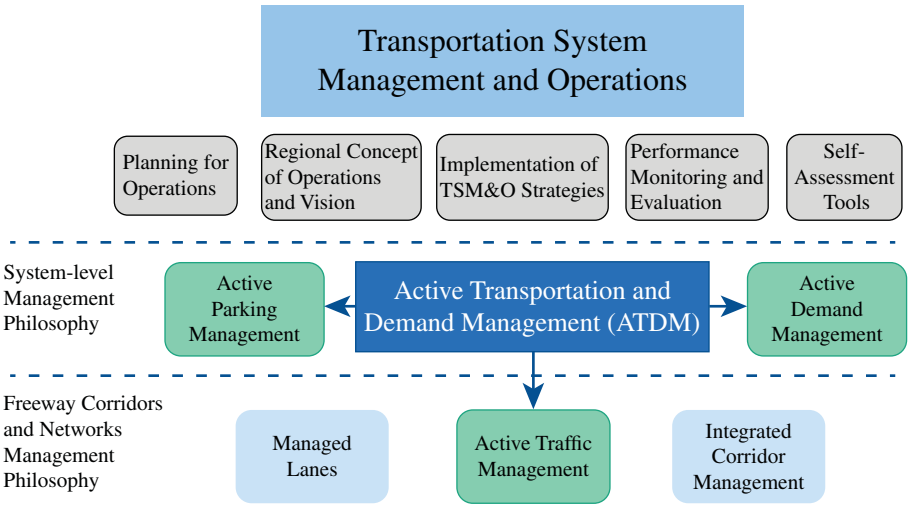
*Improved System Resiliency*. System operations is also an important focus for a resilient transportation system. States and regions that advance operational flexibility in their planning and investment prioritization are building capacity to address a myriad of emergency and security situations. In addition, sources of funding may be available specifically for activities that support transportation security and emergency preparedness, which can be used to support transportation TSM&O objectives.

*Improved Environmental Quality*. The FHWA has developed a self-assessment tool for transportation professionals to gauge the level to which actions they are undertaking help sustainability goals. The Infrastructure Voluntary Evaluation Sustainability Tool (INVEST) is a web-based collection of voluntary best practices designed to help transportation agencies integrate sustainability into their programs (policies, processes, procedures, and practices) and projects. [FHWA, undated] Agency efforts are assigned points based on the practices currently undertaken. TSM&O is an area where points can be assigned. As noted by FHWA, "Improving the efficiency of the existing transportation system supports all of the Triple Bottom Line principles by improving mobility and reducing funding needs, congestion, and resource consumption." [FHWA, undated] Points can be scored if a TSM&O policy or plan exists, whether TSM&O performance measures are used for decision making, and the degree to which M&O strategies are being implemented.

A discussion of TSM&O necessarily entails an introduction to several other system operations concepts that are important activities in developing an effective transportation system. Figure 10-1, for example, shows how TSM&O as an overarching framework consists of several different efforts. For example, planning for operations and a regional concept of operations that includes system-level, real-time system management (for example, active parking management and active demand management), as well as targeted actions and approaches for different parts of the transportation system, in this case, for freeways are important processes that have a strong relationship to transportation planning. Figure 10-1 is used to structure much of this chapter.

In appreciating the benefits of TSM&O strategies, one must first understand transportation network and facility performance. The next section examines two characteristics of network and facility performance—road congestion and travel time reliability—that are often the focus of M&O strategies. The following section focuses on planning for operations and organizing for TSM&O in the context of agency capabilities. Following the framework laid out in Figure 10-1, the next section discusses active transportation and demand management, and how it helps meet TSM&O objectives. A description of M&O strategies for improving transportation system performance is presented in the next section. The following section then describes the opportunities for improving connections between the planning process and operations. It highlights how existing relationships can be strengthened, new ones developed, and how opportunities for greater coordination and collaboration can be exploited. It emphasizes the important role that both planners and operators can play in building stronger connections and the benefits of these relationships. The final section discusses emerging technologies—autonomous vehicles and connected vehicles (both vehicle-to-vehicle and vehicle-to-infrastructure technologies)—that are likely to have significant impacts on transportation system management and operations.

**Figure 10-1. Transportation Systems Management and Operations Framework for Freeway Management**



Source: Noblis et al., 2015

It is important to point out that many M&O strategies and actions happen outside of a statewide or metropolitan transportation planning process. For example, traffic incident management, road weather management, construction work zone management, and planned special events can happen anywhere in a state, and often do not include the participation of transportation planners. This chapter will focus on M&O strategies that have some link to transportation planning.

## II. UNDERSTANDING NETWORK AND FACILITY PERFORMANCE

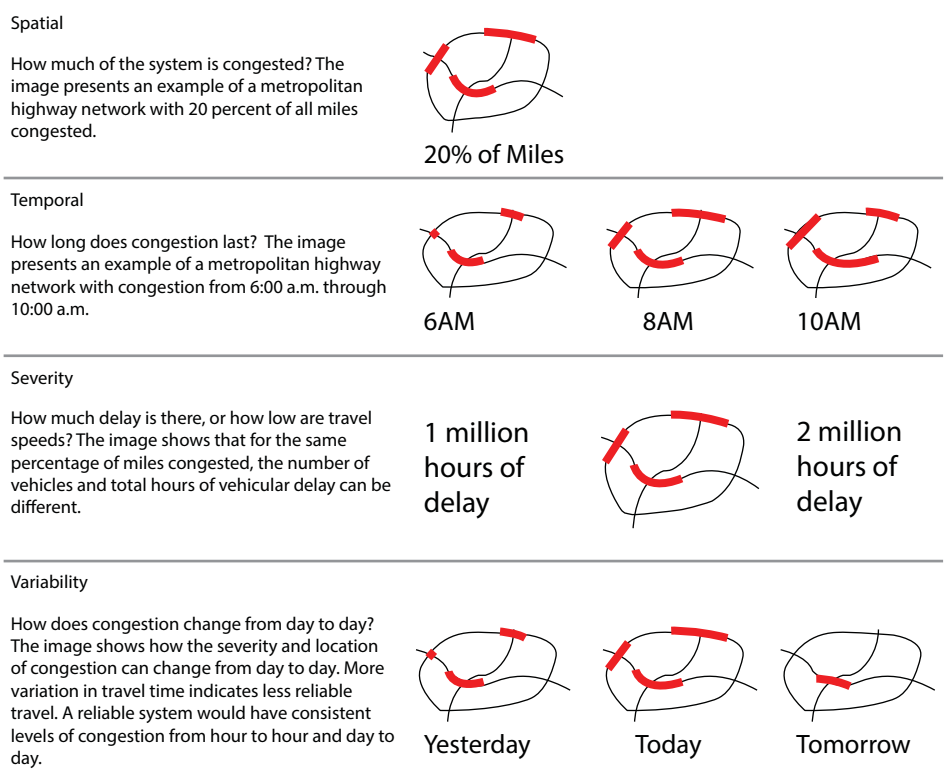
For a variety of reasons, the operational performance of the transportation system is of growing concern to transportation officials. For example, chapters 15, 16, and 17 describe current efforts to incorporate performance measures into the statewide, metropolitan, and corridor transportation planning processes. Two performance characteristics in particular—congestion and travel time reliability—are often at the top of the list when system performance is discussed, and thus transportation planners should understand some of the key issues associated with each. Note that the following sections focus on road performance; transit operations and bicycle/pedestrian operational issues are discussed in chapters 12 and 13, respectively. In addition, this chapter will not discuss some of the fundamental relationships among key variables such as traffic flow, speed, and density that in many ways define levels of service for road performance. Such information is presented in chapter 9 on road and highway planning.

### A. Road Congestion

Road congestion is one of the most important characteristics associated with the performance of the transportation system, second only to safety. As discussed in chapters 2 and 9, congestion can be defined in several different ways, 1) spatially (how much of the system is congested?), 2) temporally (how long does congestion last?), 3) severity (how much delay is there or what are the average travel speeds?), and 4) variability (how does congestion change hour-by-hour and day-to-day?) (see Figure 10-2). The latter characteristic relates to travel time reliability, which is discussed in the next section.

The focus of many M&O strategies is on reducing the incidence and/or associated delay of congestion-causing elements of the transportation system. Road congestion results when there is inadequate capacity to handle traffic demand at a particular location and at a particular time. This can occur on a daily basis at the same location because the road design and resulting capacity are unable to handle demand. This is referred to as *recurring congestion*. Congestion can also occur due to crashes, other incidents, work zones, and weather. This is called *nonrecurring congestion*. Figure 10-3 shows an estimate of the incidence of different types of delay on the U.S. road network. As shown, an estimated 60 percent of delay is caused by events occurring on a nonrecurring basis.

**Figure 10-2. Different Dimensions of Congestion**

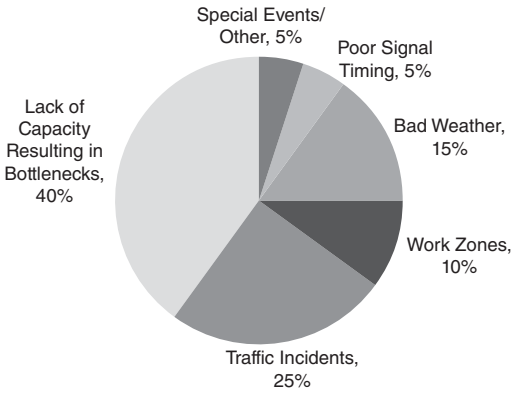


Source: Cambridge Systematics et al., 2013a

Figure 10-4 shows a typical map for the Atlanta strategic highway network that indicates key bottlenecks and congested routes in the study area. Note in this case that the different dimensions of congestion described earlier were used to identify congested locations.

A range of strategies can be used to reduce congestion levels, from long-term land-use policies to shorter-term improvements to road geometry. Table 10-1 shows the many types of strategies that could be considered as part of a congestion management process (CMP). The CMP, required of every metropolitan area over 200,000 population (called transportation management areas (TMAs)), focuses on congestion relief and is designed to be "flexible to allow MPOs to progress and adjust over time as goals and objectives change, new congestion issues arise, new information sources become available, and new strategies are identified and evaluated." [Grant et al, 2011] Note that M&O strategies are part of the strategy list in Table 10-1. Many of these strategies are discussed in other chapters of this handbook (chapter 3 on land use and urban design, chapter 11 on parking, chapter 12 on transit planning, chapter 13 on pedestrian and bicycle planning, and chapter 14 on travel demand management).

**Figure 10-3. Causes of Delay on the U.S. Highway Network**

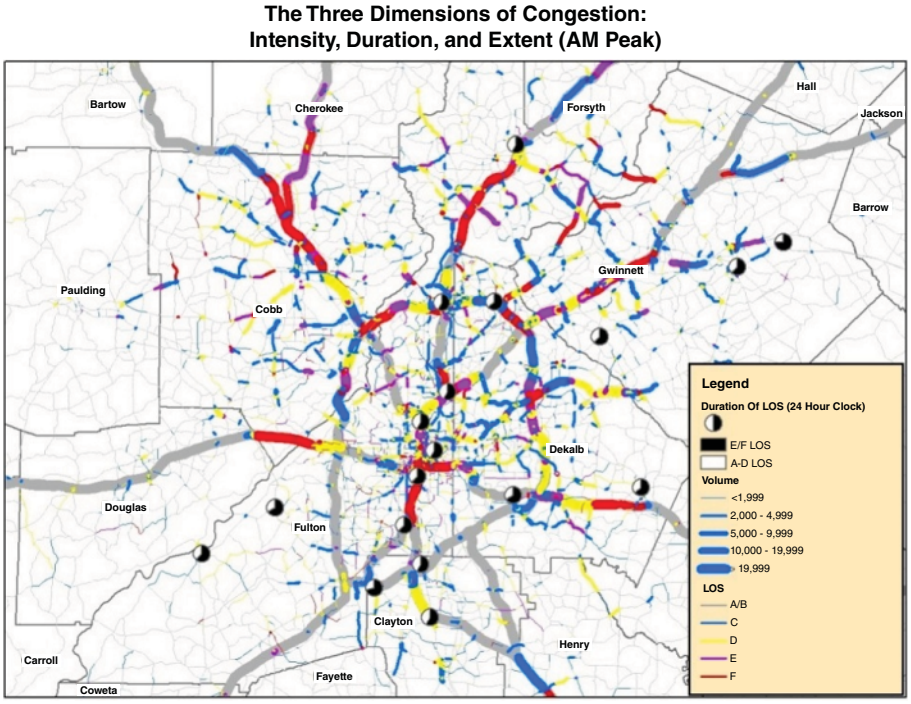


Source: Cambridge Systematics, 2014

## B. Travel Time Reliability

Transportation system reliability has been a growing concern of transportation officials over the past decade. Simply put, reliability is a measure of the stability of system performance over time. Thus, if a trip takes 45 minutes on a particular day, a traveler would expect the same trip to take close to 45 minutes during the same time period the next day, all things being equal. Figure 10-5 shows this concept from the perspective of how one can measure performance of a single road link. The question arising from Figure 10-5 is which statistical measure for reliability makes most sense from a performance metric perspective?

**Figure 10-4. Congestion Locations on the Atlanta Strategic Highway Network**



Source: ARC, 2015

**Table 10-1. Types of Projects for Congestion Management Programs**

| Major Categories | Benefits | Costs | Examples |
|---|---|---|---|
| Access Management | Increase capacity, efficiency, and mobility; reduce travel time | Vary from low to high and include design, implementation, and maintenance costs | Turn restrictions, turn lanes, frontage roads, roundabout intersections |
| Active Transportation | Decrease auto mode share; reduce VMT; provide air quality benefits | Low to moderate | New sidewalks and bike lanes, improved facilities near transit stations, bike sharing; and exclusive rights of way |
| Highway | Increase capacity, mobility, and traffic flow | Vary from low to high depending on strategy; constructing new ROW results in higher cost than design improvements | High-occupancy vehicle (HOV) lanes, super street arterials, highway widening, acceleration and deceleration lanes, design improvements |
| Land Use | Decrease single occupant vehicle (SOV) trips; increase walk trips; increase transit mode share; air quality benefits | Low to moderate and involve establishing ordinances and may require economic incentives to encourage developer buy-in | Infill, transit oriented development (TOD), densification |
| Parking | Increase transit use; reduce VMT; generate revenue | Low to moderate, but require economic incentives to encourage developer buy-in | Preferential parking for HOVs, park and ride lots, advanced parking systems |
| Regulatory | Decrease VMT; air quality benefits; increase safety; generate revenue | Vary | Carbon pricing, VMT fee, pay-as-you-drive insurance, auto restriction zones, truck restrictions |
| Travel Demand Management | Reduce peak period travel; reduce SOV VMT | Low to moderate | Alternative work hours, telecommuting, road pricing, toll roads |
| Transit | Shift mode share; increase transit ridership; reduce VMT; provide air quality benefits | Vary from low to high depending on strategy; constructing new transit travel ways is higher cost than improving service frequencies | Increasing coverages and frequencies, new fixed guideway travel ways, employer incentive programs, signal priority, intelligent transit stops |
| TSM&O | Reduce travel time; reduce stops; reduce delays; increase safety; improve reliability | Vary, but tend to be low to moderate; large-scale projects involving new infrastructure and devices higher cost | Signal coordination, ramp metering, highway information systems, service patrols, incident management |

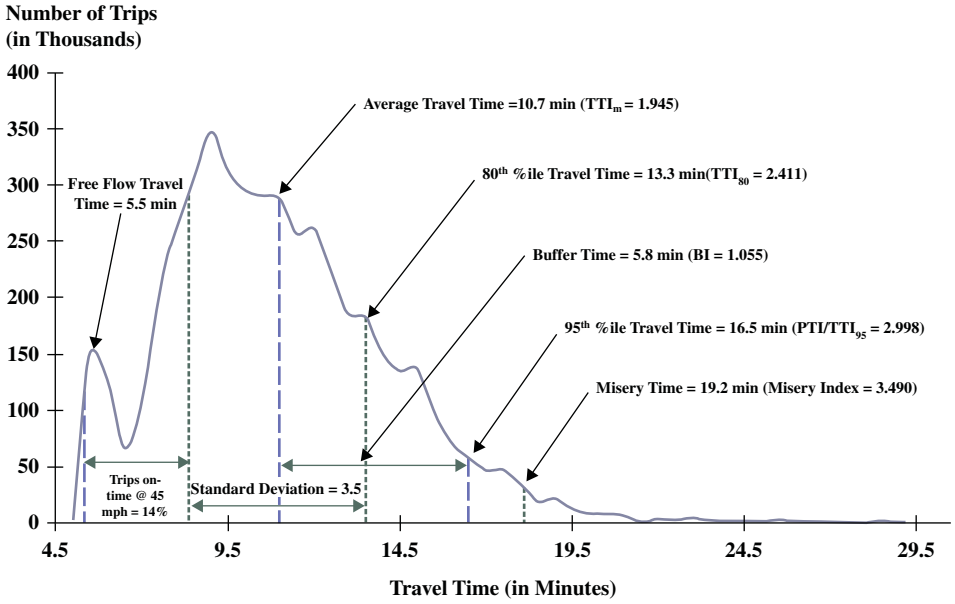
**Figure 10-5. Reliability Metrics for a Road Segment Travel Time Distribution**



Source: Cambridge Systematics et al, 2014

Table 10-2 shows different types of measures that can be used to measure system reliability. As part of its national reporting on congestion conditions, the Texas A&M Transportation Institute (TTI) has developed a series of measures relating to Figure 10-5 (see chapter 2 and the following section on performance measures). These measures are reported biennially and often generate interest on travel reliability in different metropolitan areas.

M&O strategies can play a major role in improving travel time reliability by reducing the number of incidents that cause disruption to the system (for example, ramp metering), and by reducing the level of delay when such incidents occur (for example, incident management). The Strategic Highway Research Program, Phase 2 of the Transportation Research Board targeted travel time reliability as one of the key system characteristics whose improvement would have notable impact on system performance. Numerous research reports and practitioner guidance can be found at http://shrp2.transportation.org/Pages/Reliability.aspx.

**Table 10-2. Definitions of Reliability Measures**

| Reliability Performance Metric | Definition | Units |
|---|---|---|
| Buffer Index | • The difference between the 95th percentile travel time and the average travel time normalized by the average travel time<br>• The difference between the 95th percentile travel time and the median travel time, normalized by the median travel time | Percent |
| Planning Time Index | • 95th percentile travel time index (95th percentile travel time divided by the free-flow travel time) | None |
| Failure/On-Time Measures | • Percent of trips with travel time less than 1.1 × median travel time or 1.25 × median travel time<br>• Percent of trips with space mean speed less than 50 mph, 45 mph, or 30 mph | Percent |
| 80th Percentile Travel Time Index | • 80th percentile travel time divided by the free-flow travel time | None |
| Misery Index | • The average of the highest 5 percent of travel times divided by the free-flow travel time | None |
| Skew Statistic | • The ratio of (90th percentile travel time minus the median) divided by (the median minus the 10th percentile) | None |
| Standard Deviation | • Usual statistical definition | None |

## III. PLANNING AND ORGANIZING FOR TSM&O

The TSM&O framework in Figure 10-1 shows a level of planning and organizing activities that often precede the implementation of M&O strategies, and that are used to provide feedback to existing programs so as to improve overall performance. Three efforts, in particular, merit some discussion—planning for operations, a regional concept for operations, and organizational capability (which includes the performance monitoring and self-assessment topics shown in the figure).

### A. Planning for Operations

Planning for operations is defined by the FHWA as "a joint effort between planners and operators to support improved regional transportation system management and operations." [Grant et al., 2010] The concept includes a variety of activities to improve transportation system operations and hence transportation system performance. Included is the consideration of M&O strategies in the transportation planning process, as well as the need for collaboration among transportation system operators, transit agencies, highway agencies, toll authorities, local governments, and others to facilitate improved transportation system operations.

Planning for operations has a strong linkage to key components of the transportation planning process. For example, it means identifying goals, objectives, and performance measures that are system operations-focused; it means including management and operations strategies in the mix of projects and actions considered in the planning process; and it means using prioritization criteria that reflect the types of benefits that would occur with M&O strategies.

As noted earlier, U.S. federal law requires urbanized areas over 200,000 population to have a congestion management process (CMP) as part of their transportation planning process. The CMP, as defined in federal regulation, is intended to serve as "a systematic process that provides for safe and effective integrated management and operation of the multimodal transportation system." [Grant et al., 2011] Generally, the process includes:

- Developing congestion management objectives.
- Establishing measures of multimodal transportation system performance.
- Collecting data and using system performance monitoring to define the extent and duration of congestion, and determine the causes of congestion.
- Identifying congestion management strategies.
- Implementing activities, including developing an implementation schedule and identifying possible funding sources for each strategy.
- Evaluating the effectiveness of implemented strategies.

Because the CMP is a federal metropolitan planning requirement that emphasizes M&O strategies, it can serve as a strong foundation for integrated planning and operations. A CMP can take a variety of forms. At its core, a CMP should include a system for data collection and performance monitoring, a range of strategies for addressing congestion, performance measures or criteria for identifying when action is needed, and a system for prioritizing which congestion management strategies would be most effective.

A CMP can help raise awareness among the planning community of the system efficiencies that are possible with operational strategies. A CMP becomes an integral component of the planning and programming process when CMP performance measures and strategy evaluations are fully utilized in the development of the long-range plan and the transportation improvement program (TIP).

A CMP can expose MPOs to a broader range of strategies for addressing congestion. Federal regulations require that, through the CMP, planners give serious consideration to strategies that have a demonstrable impact on congestion and that CMPs include an assessment of the cost effectiveness of proposed strategies. Additionally, CMPs must consider strategies that "improve existing transportation system efficiency." M&O strategies are more likely to be included in a transportation plan if they are put forth as part of the CMP.

When a CMP is explicitly driven by regional goals and objectives and when operations managers are involved in the CMP development and implementation, it affords an opportunity for operations managers to recognize how their transportation strategies support the underlying objectives of the region's transportation planning and programming. In addition, the CMP can serve as a forum for interjurisdictional discussions on which strategies are most effective.

The CMP provides a good foundation for planning for operations. However, it tends to focus on congestion reduction, and there are many other objectives that M&O strategies can address, such as accessibility and travel time reliability. Including TSM&O considerations in the transportation planning process is discussed in more detail in a later section.

## B. Regional Concept for Operations

A Regional Concept for Transportation Operations (RCTO) assists in the planning and implementing of M&O strategies in a collaborative and continuous manner. An RCTO should lead to a consensus of partner agencies on short-term TSM&O goals and how they are going to achieve them. [FHWA, 2015a]

The six key elements of an RCTO are:

- *Motivation ("Why")*—Reasons for developing an RCTO based on regional needs, goals, or operational concerns.
- *Operations Objective ("What")*—Desired near term outcome(s) in terms of transportation system performance and related performance measures.
- *Approach ("How")*—Overall description of how the operations objective will be achieved.
- *Relationships and Procedures*—Institutional arrangements, memoranda of understanding (MOUs), protocols, information sharing, and so on.
- *Physical Improvements*—Facilities, equipment, systems, and the like.
- *Resource Arrangements*—Sources and use of funding, staff, equipment, and so forth. [FHWA, 2015a]

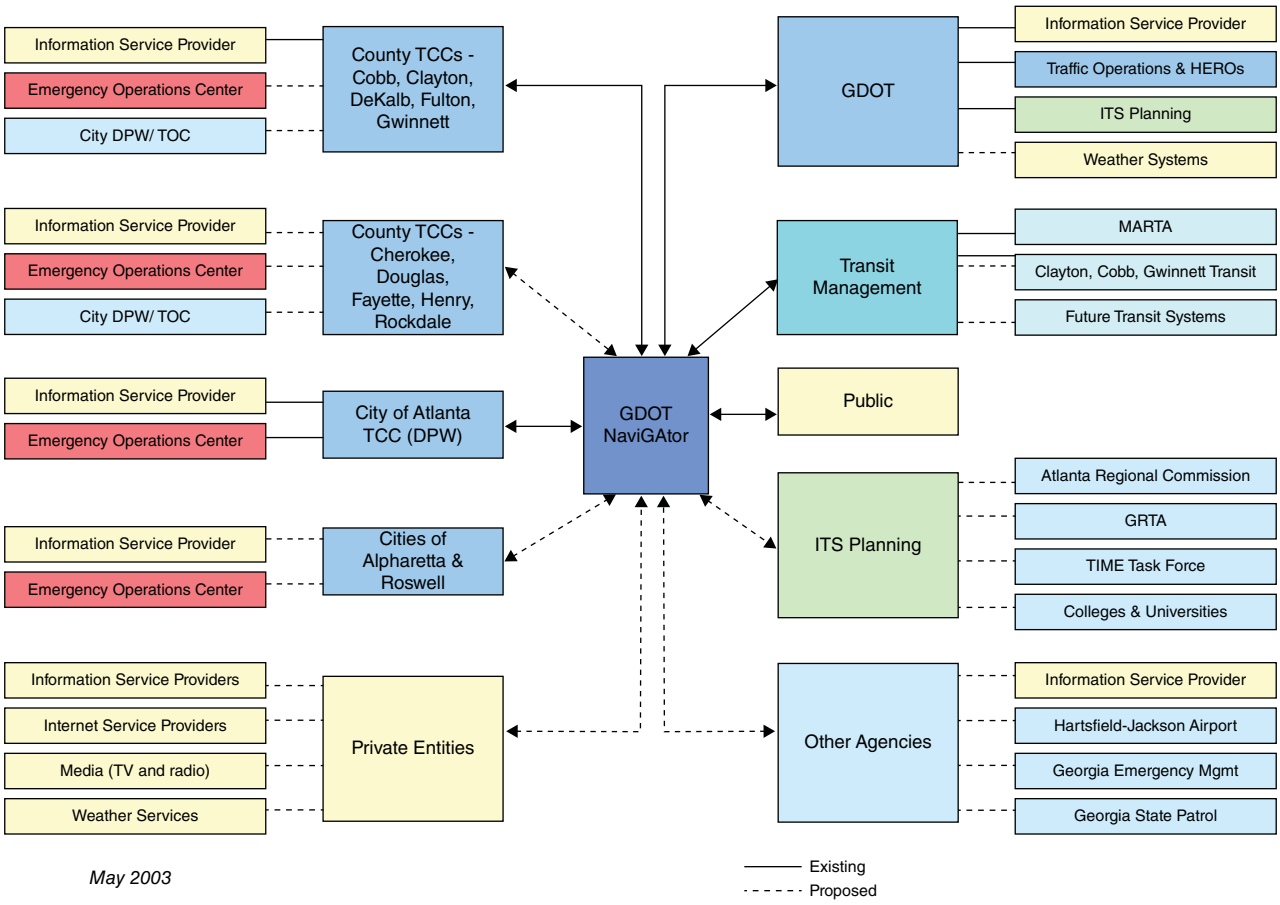
An example of a regional concept for operations comes from the Atlanta Regional Commission (ARC) in its development of the intelligent transportation system (ITS) architecture for the region (see below for more discussion on ITS). ARC formed an ITS Subcommittee with members from federal, state, and local agencies involved in ITS technology planning and deployment in the region. This subcommittee later became the Regional Management and Operations Subcommittee, which currently provides input into the development of the transportation plan and the Transportation Improvement Program (TIP), and provides a forum for information exchange relating to system operations.

The effort to develop an ITS strategy for the region began with a vision of what an ITS strategy could do for the region's transportation system. It was envisioned that the strategy would consist of:

- An extensive communications network that will provide direct, real–time information to any local and state transportation and incident response agency that participates in transportation operations within the 10-county Atlanta region.
- Real-time traveler information through various media to the public.
- An institutional environment that emphasizes efficient operations of the transportation system and that provides technological tools to enhance the operations of all transportation and incident response agencies.
- A process that monitors system performance and allows for system growth and enhancement.

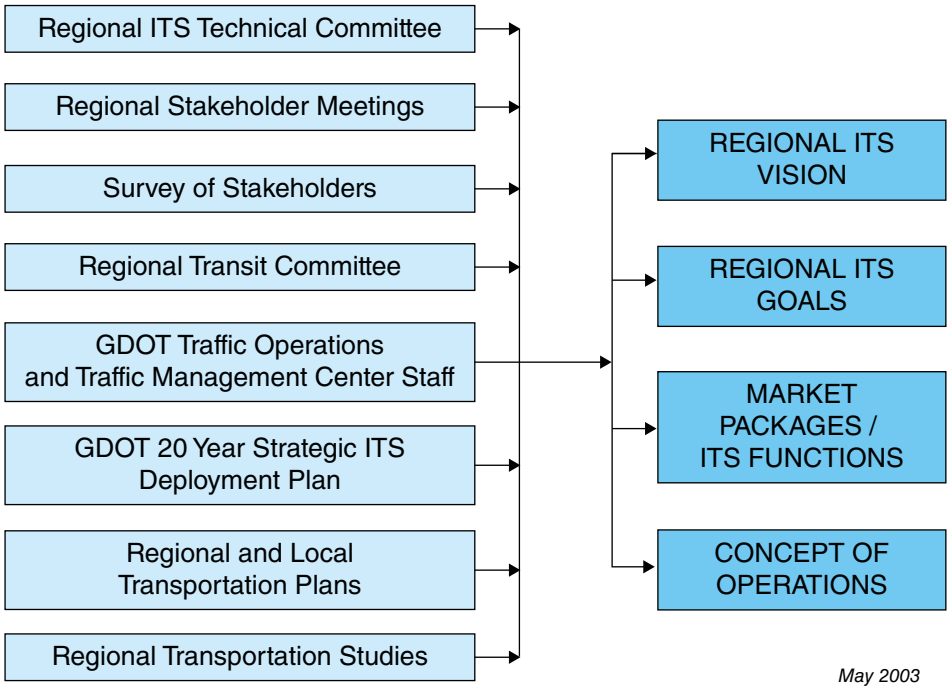
Figure 10-6 shows the ITS concept of operations developed to guide the development of an implementation plan. Georgia NaviGator is a regional traffic management center that disseminates information on real-time system performance. Note the large number of participants involved with the ITS strategy, which suggests the need for coordination and collaboration. Figure 10-7 shows the sources of input that contributed to the ITS strategy.

**Figure 10-6. Atlanta's ITS Concept of Operations**



Source: ARC, 2006 TOC = Traffic operations center TCC = Traffic control center

**Figure 10-7. Sources of Input into ITS Strategy, Atlanta**



Source: ARC, 2006

The regional ITS architecture includes an operational concept that defines the institutional relationships among the organizations involved in the deployment and operation of regionally integrated ITS systems. This operational concept serves as a starting place for linking planning and operations more broadly. Given that a region's ITS priorities and organizational approach need to evolve along with its travel patterns, available funding, and technological capabilities, the architecture was expected to mature in response to changes in the region's long-term goals and objectives.

## C. Organizational Capacity

Developing the organizational capacity for creating and managing a TSM&O program is a key challenge to agencies responsible for system operations. A report by the Transportation Research Board's Strategic Highway Research Program (SHRP), *Guide to Improving Capability for Systems Operations and Management*, describes the steps to increase state DOT capability in managing a variety of M&O strategies, such as incident management in response to crashes, breakdowns, hazardous material spills, and other emergencies; integrated corridor management; road weather management; and work zone traffic management. [Parsons Brinckerhoff et al., 2011] This report is a good guide for those wanting to incorporate M&O strategies into their agency's activities.

The study concluded that the agencies with the most effective TSM&O activities were differentiated not by budgets or technical skills, but by the existence of critical processes and institutional arrangements tailored to the unique features of TSM&O applications.[FHWA, 2015b] In particular, six dimensions of the most successful efforts were considered critical for success: business processes, systems and technology, performance measurement; agency culture; organization and staffing; and collaboration. Three of the dimensions were process-oriented:

- Business processes, including planning, programming, and budgeting (resources).
- Systems and technology, including use of systems engineering, systems architecture standards, interoperability, and standardization.
- Performance measurement, including measures definition, data acquisition, and utilization.

Three dimensions were institutional:

- Culture, including technical understanding, leadership, outreach, and program legal authority.
- Organization and staffing, including programmatic status, organizational structure, staff development, and recruitment and retention.
- Collaboration, including relationships with public safety agencies, local governments, MPOs, and the private sector.

The study offered a "maturity" model that allows officials to first understand where their organization is with respect to TSM&O program characteristics, and to then identify what steps are necessary to advance to higher levels of "maturity." The American Association of State Highway and Transportation Officials (AASHTO) used the results of this study to develop a self-assessment tool that would identify types of actions for enhancing the TSM&O program. The levels of TSM&O maturity in this tool included:

- *Level 1*—Activities and relationships largely ad hoc, informal, and champion-driven, substantially outside the mainstream of other DOT activities.
- *Level 2*—Basic strategy applications understood; key processes support requirements identified and key technology and core capacities under development, but limited internal accountability and uneven alignment with external partners.
- *Level 3*—Standardized strategy applications implemented in priority contexts and managed for performance; TSM&O technical and business processes developed, documented, and integrated into DOT; partnerships aligned.
- *Level 4*—TSM&O as full, integrated, and sustainable core DOT program priority, established on the basis of continuous improvement with top-level management status and formal partnerships. [AASHTO, 2015a]

| Table 10-3. TSM&O Capability Levels and Business Processes | | |
|---|---|---|
| | **Level of Capability Maturity** | |
| **Business Process** | **Level 1: Ad Hoc** | **Level 4: Integrated** |
| Program Scoping | • Narrow and optimistic<br>• Mission vague—ad hoc operations, activities based on regional initiatives, with limited central office support<br>• Narrow/ITS-project based, low-hanging fruit<br>• Absence of statewide service standards | • Full-range core program<br>• Full-staged program of synergizing functionalities<br>• Operations as key trade-off investment with other improvements in terms of mobility management<br>• Program extended to lower jurisdictions |
| Technical Processes | • Informal, undocumented<br>• Projects/issues handled on firefight basis with only modest formal regional/district planning (but no standard template)<br>• Minimal concepts of operations and architecture, procedures ad hoc/no consistency<br>• National Incident Management procedures compliance<br>• No/limited documentation | • Integrated and documented<br>• Integrated operations-related planning, budgeting, staffing, deployment, and maintenance both within operations and with statewide and metropolitan area planning<br>• Full documentation of key concepts of operations, procedures, and protocols |
| Technology and Systems Development | • Qualitative, opportunistic<br>• Technologies selected at project level ("big bang")<br>• Limited understanding of operating platform needs<br>• Mixed data items<br>• Lack of appropriate procurement process | • Standardized, interoperable<br>• Systematic evaluation/application of best available technology/procedure combinations with evolution<br>• Standard technology platforms developed/maintained<br>• Assets inventoried |
| Performance Measurement | • Outputs reported<br>• Concept of continuous improvement absent<br>• Projects lack objectives: measurement of outputs only with limited analysis/remediation<br>• Output measures reported<br>• Limited after-action analysis | • Performance accountability<br>• Continuous improvement perspective adopted (requires intra- and interagency after-action analysis)<br>• Accountability and benchmarking at unit and agency level via regular outcome performance reporting—internal and public |

Source: Parsons Brinckerhoff et al, 2012. Permission granted by the Transportation Research Board.

Table 10-3 shows what different levels of maturity mean in terms of agency actions. In this case, only the first and fourth levels of maturity are shown simply to give a sense of the range of capability that might be found in TSM&O programs.

Providing a focus on M&O strategies in transportation planning and decision making can occur via the leadership of the MPO or state DOT, or it can evolve gradually as more agencies and stakeholders begin to realize the advantages of coordinated action. Several handbooks and guides have been developed to help transportation officials develop a comprehensive and collaborative TSM&O program in their state or region. Parsons Brinckerhoff et al. [2011] is the most comprehensive examination of the steps that can be taken to improve such programs, and as such is a good reference for those interested in enhancing their program.

The AASHTO self-assessment checklist mentioned above allows officials to determine not only the current position of their TSM&O program with respect to effectiveness, but shows possible directions for the program based on self-assessment questions. Five categories of questions relate to the organizational structure of the program, the process

of making decisions, the products of the program, the allocation and utilization of resources, and the reporting of inputs to performance measurements. For those interested, the AASHTO self-assessment tool is found at: http://www.transportationops.org/tools/aashto-tsmo-guidance.

## IV. ACTIVE TRANSPORTATION AND DEMAND MANAGEMENT

Figure 10-1 showed three system management "philosophies" under the topic of Active Transportation Demand Management (ATDM). ATDM is defined by FHWA as "the dynamic management, control, and influence of travel demand, traffic demand, and traffic flow of transportation facilities." [FHWA, 2012b] ATDM in turn consists of three major components—active traffic management, active demand management, and active parking management.

*Active traffic management* is "the ability to dynamically manage recurrent and nonrecurrent congestion based on prevailing and predicted traffic conditions. Focusing on trip reliability, it maximizes the effectiveness and efficiency of the facility." [FHWA, 2012b] Continuous monitoring of the transportation system is the foundation of active traffic management. Using archived data and or/predictive methods, an agency can make real-time changes to achieve or maintain system performance.

**Typical Strategies**

- *Dynamic Lane Use/Shoulder Control*—The dynamic opening of a shoulder lane to traffic or dynamic closure of travel lanes on a temporary basis in response to increasing congestion or incidents.
- *Dynamic Speed Limits*—The dynamic change in speed limits based on road, traffic, and weather conditions.
- *Queue Warning*—The dynamic display of warning signs to alert drivers that congestion and queues are ahead.
- *Adaptive Ramp Metering*—The dynamic adjustment of traffic signals at ramp entrances to proactively manage vehicle flow from local access roads.
- *Dynamic Rerouting*—The dynamic provision of alternate route information in response to increasing congestion at bottlenecks/incidents.
- *Dynamic Junction Control*—The provision of lane access based on highway traffic present and merging/diverging traffic to give priority to the facility higher volume to minimize the impact of the merging/diverging movement.
- *Adaptive Traffic Signal Control*—The optimization of signal timing plans based on prevailing conditions to increase throughput along an arterial. [FHWA, 2012b]

**Typical Benefits**

- Increase in throughput of 3 to 7 percent.
- Increase in overall capacity of 3 to 22 percent.
- Decrease in primary motor vehicle incidents of 3 to 30 percent.
- Decrease in secondary motor vehicle incidents of 40 to 50 percent.
- Overall harmonization of speeds.
- Increase in trip reliability. [FHWA, 2011]

*Active demand management (ADM)* uses "information and technology to dynamically manage demand, which could include redistributing travel to less congested times of the day or routes, or reducing overall vehicle trips by influencing a mode choice." [FHWA, 2012c]

**Typical Strategies**

- *Dynamic Fare Reduction*—The reduction in the fare for use of the transit system in a particular corridor as congestion or delay on that corridor increases. Fare changes are communicated in real-time to the traveling

public, through general dissemination channels such as the transit website, as well as personalized messages to subscribers.

- *Dynamic High-Occupancy Vehicle (HOV)/Managed Lanes*—The dynamic change in the qualifications for driving in a high-occupancy vehicle (HOV) lane(s). The HOV lane qualifications are dynamically changed based on real-time or anticipated conditions on both the HOV and general-purpose lanes.
- *Dynamic Ridesharing*—The use of advanced technologies, such as smart phones and social networks, to arrange a short-notice, one-time, shared ride. This facilitates real-time and dynamic carpooling to reduce the number of auto trips/vehicles trying to use already congested roadways.
- *Dynamic Routing*—The use of variable destination messaging to disseminate information to make better use of roadway capacity by directing motorists to less congested facilities. Real-time and anticipated conditions can be used to provide route guidance and distribute the traffic spatially to improve overall system performance.
- *Dynamic Transit Capacity Assignment*—The restructuring of schedules and adjusting assignments of assets (for example, buses) based on real-time demand and patterns, to cover the most overcrowded sections of network. Real-time and predicted travel conditions can be used to determine the changes needed to the planned transit operations, thereby potentially reducing traffic demand and subsequent delays on roadway facilities.
- *On-Demand transit*—The traveler making real-time trip requests for services with flexible routes and schedules. This allows users to request a specific transit trip based on their individual trip origin/destination and desired departure or arrival time.
- *Predictive Traveler Information*—The use of a combination of real-time and historical transportation data to predict upcoming travel conditions and convey that information to travelers pre-trip and en route (such as in advance of strategic route choice locations) in an effort to influence travel behavior. Predictive traveler information is incorporated into a variety of traveler information mechanisms (for example, multimodal trip planning systems, 511 systems, dynamic message signs) to allow travelers to make better informed choices.
- *Transfer Connection Protection*—The improvement in the reliability of transfers from a high frequency transit service (for example, a train) to a low frequency transit service (for example, a bus) by dynamic management of operations. [FHWA, 2015c]

**Typical Benefits**

- Little evidence is reported in the literature relating to the quantifiable benefits of these strategies. However, they can contribute to the effectiveness of comprehensive travel demand management (TDM) programs (see chapter 14 on travel demand management).

*Active parking management (APM)* is "the dynamic management of parking facilities in a region to optimize performance and utilization of those facilities while influencing travel behavior at various stages along the trip making process, that is, from origin to destination." [FHWA, 2015d]

**Typical Strategies**

- *Dynamic Overflow Transit Parking*—The dynamic use of overflow parking facilities in the vicinity of transit stations and/or park-and-ride facilities when the existing parking facilities are at or near capacity. Parking demand and availability is continuously monitored and real-time determinations are made if overflow parking is needed, and accompanying dynamic routing information would be provided to travelers.
- *Dynamic Parking Reservation*—The use of technology to reserve a parking space at a destination facility on demand to ensure availability.
- *Dynamic Wayfinding*—The provision of real-time parking-related information to travelers associated with space availability and location so as to optimize the use of parking facilities and minimize the time spent searching for available parking. Parking availability is continuously monitored and routing information to the parking space is provided to the user.
- *Dynamically Priced Parking*—The use of parking fees that are dynamically varied based on demand and availability to influence trip timing choice and parking facility or location choice to more efficiently balance

parking supply and demand. Parking availability is continuously monitored and parking pricing is used as a means to influence travel and parking choices and dynamically manage the traffic demand. [FHWA, 2015d]

**Typical Benefits**

- *Travelers*—Easier access, reduced time spent looking for parking, and reduced frustration.
- *Venue Operators*—Increased accessibility and associated increase in patronage and customer satisfaction.
- *Parking Operators*—Increased space occupancy and associated increase in revenue.
- *The Jurisdiction and Nearby Neighborhoods*—Reduction in the number of patrons circulating through the street network looking for a parking space. [FHWA, 2007]

See chapter 11 on parking for further information on parking management strategies.

## V. EXAMPLES OF MANAGEMENT AND OPERATIONS (M&O) STRATEGIES

The FHWA has created a reference library for M&O actions that provides the latest information on the following topics. See http://www.ops.fhwa.dot.gov/publications/publications.htm#eto.

- Active transportation and demand management
- Arterial management
- Congestion mitigation
- Corridor traffic management
- Emergency transportation operations
- Facilitating integrated ITS deployment
- Freeway management
- Freight operations and technology
- Freight vehicle size and weight
- Localized bottleneck reduction
- Operations asset management
- Planned special events traffic management
- Planning for operations
- Real-time system management information
- Real-time traveler information
- Road weather management
- Special events
- Tolling and pricing program
- Traffic incident management
- Travel demand management
- Work zone management

The following examples from this list are described in more detail to illustrate the potential of M&O strategies to enhance transportation system performance.

## A. Emergency Transportation Operations

Agencies involved in M&O strategies are increasingly concerned with disaster preparedness planning and the coordination of regional emergency response. A number of regions have established an M&O committee focusing on day-to-day operations activities, with a transportation emergency preparedness subcommittee that focuses on longer-range planning and training programs related to emergency management. Arrangements such as these facilitate better coordination between planning and operations.

Extreme weather events have affected nearly every state in the United States, particularly in recent years. In 2012, a total of 133 disaster events occurred, resulting in $881 billion in damages. Events included hurricanes, droughts, heat waves, severe local storms, nontropical floods, winter storms, wildfires, and major dust storms. Transportation system managers and operators are often at the front line preparing for and managing the impacts of these events. In areas where natural disasters tend to occur, for example, hurricanes, earthquakes, and major floods, transportation agencies provide evacuation routes out of potentially affected areas, as well as access routes needed for emergency response.

AASHTO has developed guidance for transportation system managers in anticipating and handling system disruptions. [AASHTO, 2014] A "Top 10" list of suggestions for TSM&O managers and staff to better prepare for extreme weather included:

- *Contingency Plans*—Have contingency plans for power outages, detours, debris clearance, and routing for overweight or disabled trucks—to include preapproved contractors and funds.
- *Evacuation and Emergency Routes*—Operate effective evacuation routes in high-risk areas.
- *Traveler Information*—Develop effective public and traveler information systems/services to inform travelers of travel options (including social media tools, mobile apps, and collecting real time conditions through vehicle technology).
- *Drill and Test*—Use response to "routine emergencies" to test staffing, deployment, and communications. Also, coordinate in advance with partners at the local, state, and federal level in the event response is required.
- *Pre-Positioning Materials and Equipment*—Develop strategies for responding to transportation system disruptions due to weather-related events, including pre-positioning replacement materials (culverts, etc.) in vulnerable areas.
- *Backup Communications*—Prepare backup communications such as satellite phones, portable highway advisory radios, truck radios, and alternative networks.
- *Risk Reduction Strategies*—Identify facility locations vulnerable to risks (flooding, landslides, etc.), and develop appropriate strategies to minimize such risk.
- *Early Warning Indicators*—Incorporate "early warning indicators" for potential extreme weather-related risks into asset and maintenance management systems.
- *Harden the System*—Prepare for events with backup power generators, "hardened" — Sign structures and traffic signal wires, pre-positioned variable message sign boards and support vehicles trucks.
- *Workforce Protection*—Protect workers from extreme temperatures and weather during day-to-day and response activities. [AASHTO, 2014]

Several different kinds of M&O strategies can be used to handle emergencies. For example, Advanced Traveler Information Systems (ATIS) are important in conveying to the traveling public the conditions of the transportation system and the recommended routes to safety. In recent disasters, the means of communication have included toll-free telephone lines, websites, variable message signs, fixed portable highway advisory radio, and automatic messaging apps that provide warnings to travelers as conditions change. [Zimmerman et al, 2007]

The FHWA has conducted evacuation studies in many major U.S. metropolitan areas to identify the readiness and impediments for mass evacuations. These studies are good descriptions of the challenges metropolitan areas face in evacuations (see FHWA [2015e]). Table 10-4 shows the types of impediments facing successful evacuation efforts. [Vásconez and Kehrli. 2010] Notice that many of these impediments are the types of strategies and issues MPOs

| Table 10-4. Perceived Impediments to Effective Evacuations in Selected U.S. Cities | |
|---|---|
| **City** | **Identified Evacuation Impediments** |
| Atlanta | Contraflow Constraints; Infrastructure Limitations; Arterial Road Systems with Overpasses Cannot Accommodate Trailer Heights; Bridge Weight Restrictions Impede Movements; and Traffic Data Is Scattered Throughout the Region |
| Baltimore | Evacuation Plan Needs Updating; Infrastructure Impediments-Roadways; and Region Lacks a Coordinated Signal Timing System |
| Boston | Contraflow Constraints; Shoulders May Not Be Able to Support Additional Evacuation Traffic; and No Place for Sheltering |
| Charleston | Infrastructure Constraint I-26; East-West Evacuation Routes; Lane Restrictions; ITS Capabilities along Evacuation Routes; and Incident Responder Coverage Along I-26, Charleston to Columbia |
| Chicago | Traffic Congestion; Emergency Vehicle Access; Railroad Crossing/Street Blockage; Contraflow Operations Would Impede Evacuations; and Real-Time Highway Information for Responders and Public |
| Dallas/Ft. Worth | Infrastructure Limitations; Lack of Cameras along Key Routes; and Evacuation Plans Do Not Exist |
| Denver | No Evacuation Plan; No Evacuation Routes Identified; No Lane Assignments for Emergency Services; Infrastructure Limitations; Traffic Flow Analysis on Evacuation Routes; and Weather Hindrances |
| Detroit | Infrastructure Conditions Impede Responder Operations; Congestion; and Bottlenecks on Freeways, including Narrow Freeway Lanes and Limited Shoulders |
| Hampton Roads | Traffic Signal Timing; Number of Water Crossings; Limited ITS Deployment Along Key Evacuation Routes; Flood-Prone Infrastructure; and Human Resources to Manage Evacuation Operations and Tools |
| Houston | Bottlenecks; Communications with the Public; Number/Type of Resources to Deploy; More CCTV Cameras; and Modeling Timeliness |
| Jacksonville | Work Zones; Limited Fueling Stations; No DMSs on Westbound I-10; and No ITS Deployment on Key Interstates |
| Las Vegas | Insufficient Lanes and Daily Congestion; Coordination with Other States on Evacuation Routes; Communications Systems Would Not Support Evacuation Operations; Deployable Traffic Signs and Evacuation Route Signage; and Traffic Flow Monitoring |
| Los Angeles | Congestion and Evacuation Route Capacity; Communications Capabilities; and Public Outreach and Understanding Evacuation Process |
| Miami | Insufficient Road Capacity; Damage to Critical Infrastructure; Work Zones on Major Routes; Traffic Signal Timing; and Lack of ITS Devices on Major Arterial Roads |
| Minneapolis-St. Paul | Infrastructure Capacity and Congestion; Lack of Coordinated Plan and Universal Agreement on the Benefits of Evacuation; Disconnected Transportation and Emergency Operations Centers; Need for More Signage and Public Education; Coordination of Signal Timing Plans; Address Equipment Gaps for Pedestrian Movements; and Develop Multiple Options for River Crossing |
| National Capital Region (DC, MD & northern VA) | Regional GIS Database; Traffic Signal Coordination on Arterials; Limited Roadway Capacity; Institutional Coordination; Communication Interoperability and Protocols; and VIP Movements and Security |
| New Orleans | Highway Flooding; Additional ITS Capacity; Insufficient Capacity; and Lack of Emergency Lanes |
| New York City | Infrastructure Condition and Limitations; Need Improved Coordination between State/Local Transportation Officials and Responders; Limited Deployment of ITS Impact on Sharing Situational Awareness Data; Weather Impacts; and Need for Public Information Campaign |
| Philadelphia | Expressway Congestion; Need for Situational Awareness; Emergency Signal Timing Coordination; Operational Coordination; and Toll Waivers |
| Phoenix | Communication Capabilities; Community Outreach and Education Program; Rural Evacuation Route Signing and Information (public outreach) Strategy; Mass Evacuation Regional Command and Control Center; and Evacuation Route Signing |
| Portland, OR | Bridge Vulnerability; Capacity and Infrastructure Limitations; Communications and Coordination with Neighboring Jurisdictions and the Public; Communications and ITS Technology for Incident Operations; Improved Traffic Management and Safety; More Robust Planning for Evacuation Operations; and Identification and Use of Resources |
| San Diego | Communication Capabilities; Evacuation Route Capacity; and Need Public Outreach Campaign |
| San Francisco | Communication Capabilities if Damaged; and Infrastructure (Roads, Bridges and Overpasses) along Evacuation Routes |
| Seattle | Congestion; Limited Infrastructure; and Insufficient Responder Resources to Manage an Evacuation |
| St. Louis | Limited Capacity; and Highway Capacity and Bridges |
| Tampa-St. Petersburg | Highway Infrastructure Capacity; Bridge Infrastructure Capacity; Bridge Vulnerability to Damage; Highway Vulnerability to Damage; and Limited Evacuation Routes due to Geographic Limitations |

Source: Vásconez and Kehrli. 2010

consider as part of the planning process, for example, limited infrastructure, contraflow lane strategies, coordinated data collection and integration, congestion levels, and the like.

From an operations perspective, the major participants in anticipating and responding to disasters will be those who own and manage transportation systems. MPOs, as a region's leading convener of other agencies, can provide an important forum for discussions and collaboration to make sure the region is prepared.

Those interested in system disruptions are referred to [Meyer et al., 2014; AASHTO, 2013, 2014; Baglin, 2014]. Readers interested in evacuation planning are referred to FHWA's emergency operations website: http://www.ops.fhwa.dot.gov/publications/publications.htm#eto.

## B. Facilitating Integrated ITS Deployment

ITS technology is defined as "the application of information technology to surface transportation in order to achieve enhanced safety and mobility while reducing the environmental impact of transportation." [USDOT, 2011] The U.S. DOT vision for a future transportation system includes one where:

- A fully connected, information-rich environment where travelers, freight managers, system operators, and other users are fully aware of all aspects of the transportation system's performance across all relevant modes.
- A cooperative system in which highway crashes and their tragic consequences are rare because vehicles of all types and roadside systems work together to:
  - Communicate the events and hazards happening around them.
  - Coordinate action and response among vehicles and their operators to avoid collisions.
- Travelers who have comprehensive and accurate information on travel options—transit travel times, schedules, cost, and real-time locations; driving travel times, routes, and travel costs; parking costs, availability, and ability to reserve a space; and the environmental footprint of each trip.
- System operators have full knowledge on the status of every transportation asset.
- Vehicles of all types that can communicate with traffic signals to eliminate unnecessary stops and help people drive in a more fuel-efficient manner.
- Vehicles that can communicate the status of on-board systems and provide information that can be used by travelers and system operators to mitigate the vehicle's impact on the environment and/or make more informed choices about travel modes. [USDOT, 2011]

ITS first began in the United States in the early 1990s, primarily in recognition of the rapid advance in technologies that could provide useful capabilities to managing transportation systems. In the United States, the federal government requires that regions have a regional ITS architecture, defined as, "a specific, tailored framework for ensuring institutional agreement and technical integration for the implementation of ITS projects or groups of projects in a particular region. It functionally defines what pieces of the system are linked to others and what information is exchanged between them." [FHWA, 2006] The linkage to long-range transportation planning as noted by FHWA includes:

- The services described in the Regional ITS Architecture can provide the basis for operational strategies to improve the transportation system to meet the region's vision and goals.
- The Regional ITS architecture can be used to support evaluation and prioritization of strategies in two ways. The first is through the definition in the architecture of archiving and data collection systems that support collecting the data needed for evaluation. The second is through the detailed definition of ITS projects and their sequencing that can be used to establish a long-range strategy of investment in a technology-focused system.
- The definition of an integrated transportation system described by the Regional ITS Architecture can support a key element of the transportation plan, for example, the element "operations and management of the transportation system."

- The process of developing and maintaining a Regional ITS Architecture can help to enhance the linkage between operations and planning through closer involvement of a wider array of stakeholders from both of these areas of transportation. [FHWA, 2006]

## C. Freeway Management

Freeway traffic management and operations is the "set of activities that transportation agencies conduct to plan, design, develop, implement, operate, and maintain transportation infrastructure or assets on or near controlled-access freeways in order to best utilize the available freeway system capacity in cooperation with other regional transportation stakeholders and consistent with the region's vision and goals."[Noblis et al, 2015] Freeway M&O utilizes such strategies as ramp metering, traveler information systems, managed lanes, lane variable speed limits, pricing, and incident management programs to enhance the operational capacity of freeways and freeway corridors. The FHWA has developed the *Freeway Management and Operations Handbook* (FMOH) providing useful information on the many different types of M&O strategies that are part of freeway management. As of the writing of this transportation planning handbook, the FHWA in collaboration with the Transportation Research Board Committee on Freeway Operations was updating the FMOH. [Noblis et al., 2015] Interested readers should access the FHWA website on freeway management to review the latest version of the FMOH (http://ops.fhwa.dot.gov/freewaymgmt/frwy_ops.htm).

One freeway M&O strategy, in particular, has received much attention over the past 10 years and is being implemented in many U.S. metropolitan areas. Managed lanes are defined as highway facilities or a set of lanes where operational strategies are proactively implemented and managed in response to changing conditions. [FHWA, 2008a]. For example, high-occupancy vehicle (HOV) lanes have been used for decades in major freeways to encourage the use of transit and ridesharing. This early form of lane management was static, that is, the rules for using the HOV lanes were rigidly structured .... you either had two or more persons in the car (and thus could use the lane) or you did not. Several agencies realized that HOV lanes were often not used to their highest potential and that single occupant vehicles might be allowed in the underutilized lanes for a price. This price could change in real time depending on the volume in the HOV lane. For example, if an HOV lane was approaching capacity, allowing a single occupant vehicle into the lane could cause notable delays, and hence the price was high. If ample capacity was available, very little delay would result and the price was lowered (the term for such lanes was high-occupancy toll (HOT) lanes, now largely called managed lanes).

The concept of managed lanes and the use of pricing to provide enhanced freeway operations also became an important approach to financing freeways. Public/private partnerships for financing new freeway capacity rely on some source of funding for payments to the private entity willing to build and operate such a facility. In some cases, these facilities have been entire roads, while in others the concept was to use this financing strategy to build and operate managed lanes (see chapter 5 on transportation finance and funding as well as [FHWA, 2012d]). A good overview of managed lane projects can be found at Texas A&M Transportation Institute (http://managed-lanes.tamu.edu/projects).

Table 10-5 shows the range in system performance benefits for freeway management strategies. Although listed individually, most freeway management programs include a combination of many of the strategies listed in the table.

## D. Regional Signal Coordination and Management

Traffic signal management is defined as "the planning, design, integration, maintenance, and proactive management of a traffic signal system in order to achieve policy based objectives to improve the efficiency, consistency, safety, and reliability of the traffic signal system." [Koonce et al., 2009] In particular, given the number of jurisdictions in a typical metropolitan area having responsibilities for signal design, operations, and maintenance, a regional signal management program often focuses on cross-jurisdictional collaboration and coordination. As noted in a FHWA study of coordinated traffic programs, the "regional" nature of such efforts can take many forms (and thus potential coordinating roles for state DOTs and/or MPOs):

- Establish different objectives and policies for varying arterial types, such as arterials within central business district or downtown, suburban, and rural areas. Objectives may vary depending on the type of land uses, travel patterns, travel speeds, and vehicle characteristics. An operations program should address these variations to maintain regional consistency.

| Table 10-5. Benefits from Freeway Management and Operations (FMO) Strategies | |
|---|---|
| **FMO Strategy Type** | **Selected Findings** |
| Managed Lanes/Variable Speed Limit (VSL) | Field data collected over the last two decades show variable speed limit (VSL) systems can reduce crash potential by 8 to 30 percent. |
| Managed Lanes/VSL | A VSL system used to regulate traffic flow through work zones on a 7.5-mile section of I-495 saved motorists approximately 267 vehicle-hours of delay each day. |
| Managed Lanes/VSL | A VSL system on the I-270/I-255 loop around St. Louis reduced the crash rate by 4.5 to 8 percent, due to more homogenous traffic speed in congested areas and slower traffic speed upstream. |
| Active Traffic Management | Collisions on I-5 in Washington State have been reduced by 65–75 percent in a 7.5-mile corridor where an active traffic management system was deployed. |
| Integrated Corridor Management (ICM) | Decision support system scenarios modeled on the ICM Corridor in Dallas Texas show travel time savings of 9 percent on arterials when vehicles divert from the freeway. |
| Integrated Corridor Management | Transportation researchers have used analysis, modeling, and simulation (AMS) methodologies to estimate the impacts of proposed ICM solutions. Projected benefit-cost ratios for four cities range from 10:1 to 25:1 over a 10-year period, which include significant fuel savings and emissions reductions. |
| Ramp Metering | The Kansas City Scout program used ramp meters to improve safety on a 7-mile section of I-435; before and after data indicated that ramp meters decreased crashes by 64 percent. |
| Ramp Metering | The implementation of ramp metering in Kansas City increased corridor throughput by as much as 20 percent and improved incident clearance by an average of four minutes, with these benefits remaining consistent in the long term. |
| Traffic Incident Management | Northern Virginia's freeway safety service patrol assessment estimated an annual savings of $6.49 million in motorist delay and fuel consumption, resulting in a benefit-cost ratio estimate of 5.4:1. |
| Traffic Incident Management | Benefit-cost ratio for Georgia's HERO motorist assistance patrol program and NaviGAtor incident management activities estimated at 4.4:1. |
| Information Dissemination—Dynamic Message Signs (DMS) | Ninety-four percent of travelers took the action indicated by the DMSs in rural Missouri and drivers were very satisfied by the accuracy of the information provided. |
| Surveillance | NY State DOT TMC operators and NY State Thruway Authority staff were able to reduce traffic queues by 50 percent using vehicle probe data available through the I-95 Corridor Coalition. |

Source: Noblis et al., 2015

- Establish a regional working group comprised of key stakeholders and a champion to lead the group in being responsible for traffic signal management and maintenance within the region.
- Develop the vision, goals, objectives, and performance measures for traffic signal management and operations in the region.
- Develop a regional traffic signal management concept of operations to identify high-level policies and plans needed to support plans and procedures for individual arterials. Such high-level policies should include:
  - Balancing major street throughput and average network/intersection delay.
  - Vehicle clearance times (yellow and all red).
  - Left-turn movement treatments (leading, lead-lag, lagging).
  - Pedestrian treatments (rest in walk, leading walk, recall, clearance times, etc.).
  - Signal timing monitoring and plan updates.
  - Intersection hardware maintenance.
- Identify information and resource sharing needs on a regional level (for example, identifying whether local agencies need to access and view freeway detector and closed circuit television [CCTV] cameras) for the purpose of traffic signal management and maintenance.

- Propose technology and ITS needs to support corridor traffic signal management and maintenance at a regional level.
- Assess and establish engineering and maintenance staffing needs and qualifications. [Koonce et al., 2009]

A good example of a regionally coordinated traffic signal program comes from Denver, where the MPO has established a traffic signal system improvement program. This program has two major components:

- A capital improvement program, providing equipment and installing communications links to improve system capabilities.
- A traffic signal timing improvement program, providing new traffic signal timing and coordination plans to demonstrate the benefits of the capital improvements. [DRCOG, 2014]

The focus of the program is on the following goal and objectives: [DRCOG, 2013]

Goal: The region's traffic signals systems will operate in a safe manner, making most efficient use of arterial street capacity.

Objective 1: Minimize arterial traveler stops.

Objective 2: Minimize traveler stop time at intersections.

Objective 3: Maximize traffic signal system equipment reliability.

The types of projects to accomplish this goal include: (1) upgrade and replace insufficient/unreliable communications for highway corridors/areas, (2) expand system control to key signals not on system, (3) improve the signal system efficiency, control, and the ability to monitor system operations performance, and (4) pilot advanced functions such as traffic adaptive control and advanced functions to support transit, bicycles, and pedestrians.

## E. Traffic Incident Management

In many metropolitan areas, state DOTs and MPOs have taken the lead role in advancing coordinated incident response and freeway service patrol programs, collectively called traffic incident management (TIM). The primary goals of TIM programs are to: (1) reduce the duration and impacts of traffic incidents and (2) improve the safety of motorists, crash victims, and emergency responders. [Bauer et al., 2013] Because traffic incidents are responsible for such a large portion of regional congestion, many MPOs have coordinated the multijurisdictional challenges of putting such programs in place.

TIM activities are typically categorized into the following five functional areas:

- Detection and verification
- Traveler information
- Response
- Incident scene management and traffic control
- Quick clearance and recovery

Regional traffic management centers (TMCs) play an important role in each of these activities. In many cases, traffic incident management was the major motivation for the development of TMCs. They now serve as a foundation for broader cooperation in regional TSM&O efforts. TMCs, for example, provide a critical capability in monitoring managed lanes operations and of responding quickly to incidents. [Tantillo et al., 2014] Table 10-6 shows the different TIM roles that TMCs play in eight managed lanes projects in the United States. As shown, TMCs have an important

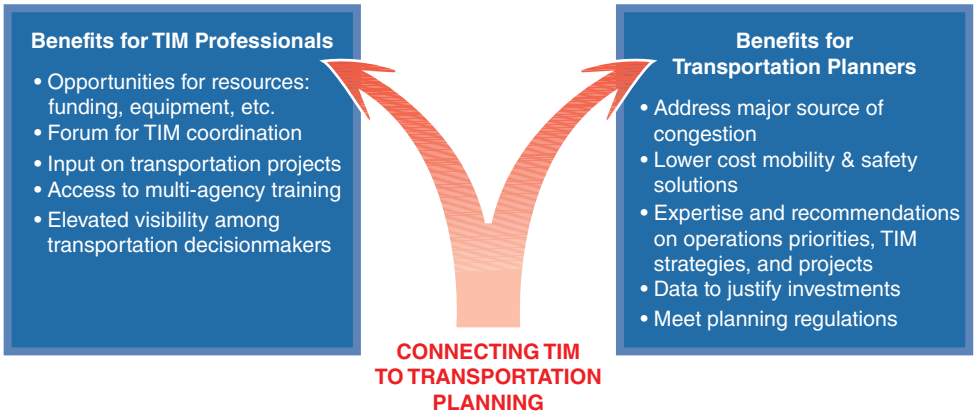
role to play in all aspects of managing an incident on the road system. Figure 10-8 also shows the benefits to both TIM professionals and transportation planners of having a strong linkage between the two.

Transportation planners should also be aware that a group of organizations have created the National Traffic Incident Management Coalition (NTIMC) whose intent is to encourage safe and efficient management of incidents. A National Uniform Goal (NUG) has been adopted for TIM that relates to the following 18 different strategies.

- TIM Partnerships and Programs
- Multidisciplinary NIMS and TIM Training

**Figure 10-8. Traffic Incident Management (TIM) Linkages to Transportation Planning**



Source: Bauer et al., 2013

- Goals for Performance and Progress
- TIM Technology
- Effective TIM Policies
- Awareness and Education Partnerships
- Recommended Practices for Responder Safety
- Move Over/Slow Down Laws
- Driver Training and Awareness
- Multidisciplinary TIM Procedures
- Response and Clearance Time Goals
- 24/7 Availability
- Multidisciplinary Communications Practices and Procedures
- Prompt, Reliable Responder Notification
- Interoperable Voice and Data Networks
- Broadband Emergency Communications Systems
- Prompt, Reliable Traveler Information Systems
- Partnerships with News Media and Information Providers

Readers are encouraged to access the NTIMC website for the latest information on TIM strategies (http://ntimc.transportation.org/Pages/default.aspx).

## F. Special Events

Cities of all sizes often host special events that could temporarily overwhelm the local transportation system. A FHWA study of special events planning and the potential role of ITS strategies concluded, "When planning is characterized by communication and active participation of stakeholders, the value of ITS tends to increase because there are more people who benefit from the wider access to timely and accurate information that ITS make possible. As a result, most of the lessons that successful planners have taken from their experiences with planned special events focus not so much on the technologies that work best for them, but the aspects of coordinating, planning, and implementing a transportation plan that lends value and usefulness to the information the technologies provide." [FHWA, 2008b] With respect to transportation planning issues, the report recommended:

- Coordinate with construction programs at the state, county, and local levels to ensure that there are no planned construction projects scheduled to occur on the day of event.

- When planning, remember the needs of local citizens as well as event attendees.
- When developing a traffic plan, consider establishing detours for commercial vehicles and other non-event-related vehicles around the area of the event venue.
- Put portable dynamic message signs in place several days prior to the start of a planned special event to inform motorists of the event and give them sufficient time to find and become familiar with alternate routes.
- While the event is actually underway and plans are being executed, have the same core members of the planning group available to modify the plan as necessary.
- Use state or regional motorist assistance vehicles to patrol the roadways around events, borrowing from other agencies if necessary.
- Develop an after-action review of each special event, both to identify shortcomings as well as to determine what worked well so successful practices can be expanded or used for other events. [FHWA, 2008b]

A special event can serve as a catalyst for the development of a new model for planning and operations coordination—a model that can potentially continue to function long after the event has occurred. To sustain and build upon the collaborative efforts common during special events, it is important that stakeholders consider in advance how to build from these events. Planners and operations representatives can work together to discuss opportunities to build from successful event coordination.

Readers interested in special events planning are referred to FHWA's emergency operations website: http://www.ops.fhwa.dot.gov/publications/publications.htm#eto. A useful handbook is found in [Latoski et al, 2003].

## G. Some TSM&O Program Examples

**State DOTs.** Being the owner and operator of a state's major highway system, state DOTs are heavily engaged in M&O strategies. The Florida DOT (FDOT) provides a good example of a state's TSM&O effort. FDOT has used the following guiding principles as the foundation for its TSM&O strategy.

- *Definition of TSM&O*—TSM&O is an integrated program to optimize the performance of existing multimodal infrastructure through the implementation of systems, services, and projects to preserve capacity and improve the security, safety, and reliability of the transportation system.
- *System Vision*—To operate the transportation system at the highest level of cost-effective performance.
- *Expanded Vision for Arterial and Freeway Operations*—To operate the transportation system at the highest level of cost-effective performance, resulting in reduced excess delay on arterials and freeways, real-time management and traveler information for all modes, and seamless coordination with all operating agencies.
- *Agency Mission*—To deploy a customer-driven TSM&O program focused on mobility outcomes through real-time and effective management of the existing transportation system toward its maximum efficiency. [Florida DOT, 2013]

The different types of strategies, or as defined by FDOT, "focus areas," in the TSM&O strategic plan, include:

- *Ramp Signals*—Regulates the flow of traffic entering freeways.
- *Advanced Traffic Management System (ATMS)*—Enhances signal coordination.
- *Severe-Incident Response Vehicles*—Act as a central point of contact at major incidents.
- *Managed Lanes*—Manages roads in response to changing conditions, creating a more effective and efficient freeway.
- *Incident Management*—Improves safety for motorists and responders, reduces congestion, and improves safety.
- *Rapid Incident Scene Clearance*—Responds to major incidents using heavy wrecker performance-based contracts.
- *Traveler Information*—Improves traveler decision making in response to changing conditions.

- *Arterial Management*—Manages traffic on arterial roadways more effectively.
- *Work Zone Traffic Management*—Improves safety and enhanced traffic management in work zones.
- *Weather Information*—Provides advanced information for significant weather events and changing conditions.
- *Variable Speed Limits*—Promotes uniform traffic flows.
- *Hard Shoulder Running*—Increases corridor capacity.

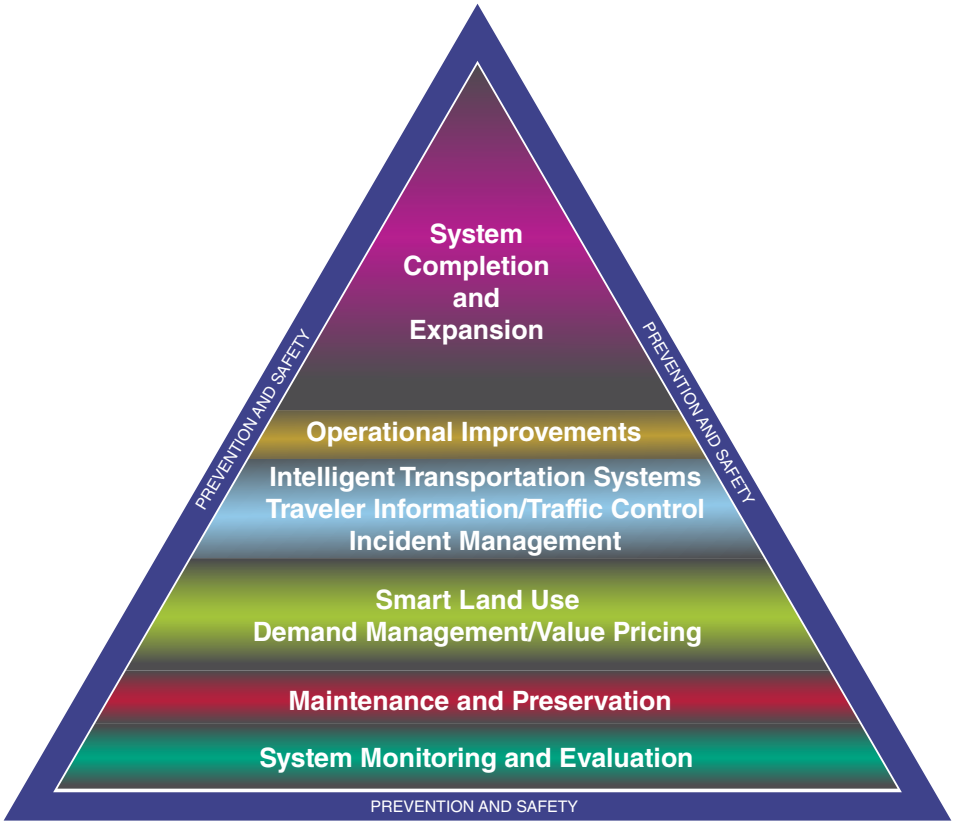
Because planning for operations means coordinating activities among transportation planners and managers having responsibility for day-to-day transportation operations, FDOT's strategic plan also lays out the organizational and management decisions to create TSM&O institutional capability within the agency.

Another state DOT example comes from California. Caltrans, California's state transportation agency, has been a national leader in TSM&O operations for decades, especially in the application of new technologies for system management. Figure 10-9 shows the types of efforts and actions that Caltrans is involved in, and illustrates the important foundation that operations provides to the agency's overall activities. [Bowen and Zhagari, 2015] One of the major reasons why Caltrans has placed emphasis on system management and operations is that the return on investment has been estimated to be much greater for these types of strategies than for others such as system expansion.

Another Caltrans initiative that illustrates well the application of advanced technology for system management is called "connected corridors," a program developed in collaboration with the University of California, Berkeley. The concept is to develop a coordinated system management approach of freeways, ramps, arterials, and other local roadways in a corridor to provide safe, reliable travel for all users in all modes, using: [Kuhl, 2014]

- Traffic management systems.
- Well-maintained infrastructure.

**Figure 10-9. Caltrans' Mobility Pyramid**



Source: Bowen and Zhagari, 2015

- Managed/priced lanes.
- Advanced ramp meter operations.
- Enhanced communication networks.
- Freeway service patrol and incident management strategies.
- Enhanced traveler information.
- Decision support systems.
- Approved concepts of operations with local and regional partners.

The goal is ultimately to "enable the coordination of existing transportation infrastructure and vehicles, deliver improved corridor performance, improve accountability, evolve Caltrans to real-time operations and management, and enhance regional, local, and private sector partnerships." [Kuhl, 2014]

**MPOs.** The types of TSM&O strategies and decisions facing transportation officials will vary by size of region, agency responsibilities, and transportation system components. Table 10-1, for example, showed the types of projects that a large MPO might consider as part of its congestion management process. A smaller MPO might have a very different perspective in terms of the types of projects or actions that would be considered. For example, Table 10-7 shows an assessment from Lawrence, Kansas, of the types of strategies that might be appropriate today and in the future.

The Pikes Peak Area Council of Governments (PPACOG), the MPO for the Colorado Springs, Colorado, metropolitan area and a medium-sized MPO, considers the following TSM&O strategies as most appropriate for its region: regional signalization; roadway channelization; intersection improvements; incident management; ramp metering; and an Intelligent Transportation System (ITS) program consisting of computerized signal systems, traffic control and surveillance equipment, and motorist information systems. [PPACOG, 2012]

FHWA [2012a], Baird and Noyes [2014], and AASHTO [2015b] provide a good description of state DOT TSM&O programs. A good overview of the types of TSM&O strategy candidates for MPOs is found in [IBI Group, 2009] and useful information is also provided in [Bauer et al., 2011].

**Table 10-7. Operations and Management Strategies for a Small MPO: What's Right for Lawrence?**

## VI. LINKING TRANSPORTATION PLANNING AND PLANNING FOR OPERATIONS

Many opportunities exist to foster collaboration between planners and operators and to incorporate M&O strategies into the transportation planning and decision-making process. FHWA calls for the development of an "objectives-driven, performance-based approach" for such collaboration. [Grant et al., 2010] The planning for operations discussion earlier provides a good framework for establishing linkages between operations and planning. In particular, there are seven areas where TSM&O concepts and M&O strategies can be incorporated into the transportation planning process:

- Incorporating system operations stakeholders into the transportation planning structure
- Establishing system operations goals and objectives
- Defining operations performance measures for the transportation planning process
- Using ITS technologies for data collection and sharing
- Using operations-oriented analysis tools
- Identifying TSM&O strategies to be included in the plan and TIP
- Sharing funding and resources

These are discussed in the following sections.

### A. System Operations Stakeholders and Institutional Structures

The MPO serves as the regional agency coordinating transportation planning and programming among state and local agencies. For TSM&O, it can provide regional leadership by bringing operations managers in the region together to establish a decision-making framework for regional operations policies, plans, and programs. The inclusiveness of the planning process makes it a valuable tool for building regional collaboration for operations among a broader range of transportation managers. Because interagency and interjurisdictional collaboration is critical for effective regional transportation management, the regional planning process can be an important forum for addressing regional operations concerns.

A major event (hosting a national or global event or responding to a major natural disaster) could motivate planning and operating agencies to coordinate more effectively. Hosting the Olympics, for example, has been the focus of many studies on how federal, state, and local operating agencies can focus their collective resources on managing the host city's transportation system. New institutional arrangements might be created to oversee new programs (for example, ITS), to respond to new state or federal mandates, or to take advantage of new funding sources. Moreover, arrangements are often formed to focus on regional operations objectives, such as regional management of work zones, coordinated incident management, or ITS deployment. It is not uncommon for an initial committee or task force that is focused on a particular topic to broaden its mandate over time to include coordination among a range of regional M&O strategies. Some institutional arrangements are created to link planning and operations for a specific process (such as an interagency committee that oversees the development of performance measures). Many regions have other types of institutional arrangements that focus on TSM&O more broadly and can serve as a link to regional planning activities.

The circumstances that lead to institutional innovation may differ across regions. In Philadelphia, for example, an MPO Transportations Operations Task Force consists of the technical staff representatives from over 35 regional stakeholders and acts as a forum for agencies to share information on ITS deployments and incident management programs and develop a consensus on regional ITS issues. In Orlando, the Transportation Systems Management and Operations Committee can have up to 23 representatives from the three counties and the 16 cities in the MPO planning area, and eight representatives from regional transportation agencies. The Florida DOT is a nonvoting advisor. The Committee acts as an advisory group to the MPO policy board, and recommends TSM&O projects. In Atlanta, the Atlanta Regional Commission has formed the Regional Transit Committee to focus on regional transit planning, funding, and governance. This committee consists of 12 members representing political jurisdictions and transit operators in the MPO planning area. The committee often discusses issues concerning coordinated transit operations.

At the state level, most DOTs do not have advisory committees for TSM&O efforts, although they often have task forces or committees for specific topics such as work zone safety, ITS implementation, and the like.

The following recommendations highlight opportunities to better coordinate planning and operations and could help prompt agency managers to consider where new institutional arrangements might be needed:

*Designate an MPO Stakeholder Committee or Task Force on Regional TSM&O*. An increasing number of MPOs support interagency committees that deal directly and regularly with the management and operations of regional transportation systems. In hosting such committees, the MPO facilitates discussions on interjurisdictional coordination, funding strategies, and data sharing.

*Include Stakeholders with Specific Concerns or Expertise on Regional Operations Programs*. One way to achieve greater stakeholder participation in stakeholder forums is to focus the forum's discussions on issues of greatest concern to important stakeholders. For example, someone who manages first responders is more likely to attend a committee dealing with regional incident management than a committee dealing with the broad topic of regional TSM&O coordination. Freight transportation planning is an area where focused forums have also been successful. Such committees have managed to bring freight needs and perspectives to the planning process, helping promote a regional perspective on operations challenges (see chapter 22 on freight transportation).

*Encourage Multi-Jurisdictional and Public/Private Sector Involvement in Regional Operations Strategies*. Many states and regions have developed system operations capabilities, such as traffic management centers (TMCs), that offer opportunities for integrated operations independent of other regional bodies. These organizations may have specific mandates, such as running a regional incident management program, providing real-time traffic information, or coordinating emergency management plans. They often provide a unique opportunity to bring together the public safety and operations management communities and thus are well positioned to address broader operations issues. Regional transportation operations collaborations and TMCs can provide valuable input to the planning process. At the same time, state, and regional planners should ensure that these organizations are aware of the planning cycle and planning decisions that could influence regional initiatives.

*Define an Organizational Structure for the MPO That Reflects the Importance of Regional Operations*. MPOs have historically been organized around long-range planning and programming of capital projects. In recent years, many MPOs have expanded their role to include greater involvement in regional systems management issues. Some agencies have chosen to restructure to reflect a growing responsibility for regional system operations. MPOs should consider the potential benefits of an institutional structure that reflects a heightened focus on managing the regional network.

For those interested, the following references provide good examples of different institutional arrangements for TSM&O programs as well as guidance on how to organize such an effort. [FHWA, 2005; Grant et al., 2010; Balke and Vogt. 2011]

## B. Goals and Objectives

The framing of a regional transportation vision and goals affords an opportunity to integrate operations agencies into processes that shape future transportation systems. Near-term goals and visions, important for engaging businesses and members of the public in setting priorities, should involve TSM&O practitioners. The region's or state's vision should emphasize efficient operations, as well as needed physical infrastructure investments. Figure 10-10 shows the relationship among vision, goals, and objectives as it relates to incorporating system reliability concerns into transportation decision making. Figure 10-11 shows a typical hierarchy of objectives as it relates to system reliability.

Some examples from state DOTs and MPOs are presented here.

### *1. State DOTs*

**Washington State DOT [2007]**

*20-Year Transportation Vision*—Washington's transportation system should serve citizens' safety and mobility, the state's economic productivity, communities' livability, and the ecosystem's viability.

**Figure 10-10. Incorporating Reliability into Various Levels of Policy Statements**

| DESCRIPTION | ELEMENT | APPROACH TO INCORPORATING RELIABILITY |
|---|---|---|
| Broadest statement. Identifies the purpose of the organization | *Vision* | Reliability included only if it is a top agency priority |
| Broad statement that identifies how an agency delivers the vision | *Mission* | Reliability may be included if it is a major issue impeding the agency |
| Short statements describing a small set of the most critical issues that an agency is addressing | *Goals* | Reliability included if a significant issue |
| Additional specificity for the goals | *Objectives* | Reliability commonly addressed |
| Steps to implement the goals and objectives | *Policies, Strategies, Actions* | Actions to address reliability included |

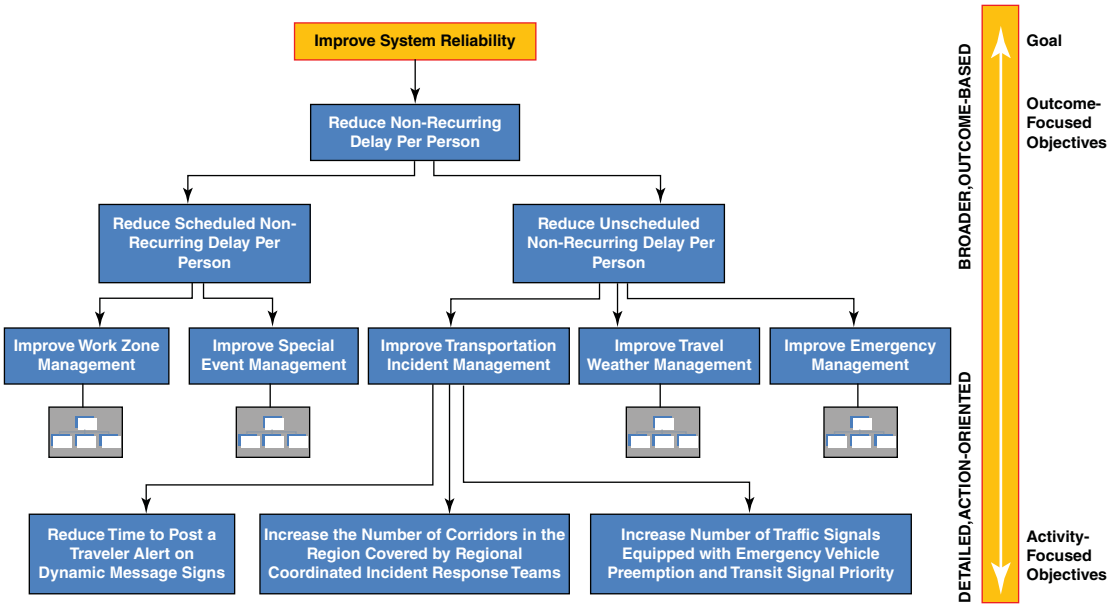
**Figure 10-11. Objectives Hierarchy for Improving System Reliability**



Source: Grant et al., 2013

## Investment Guidelines

- *Preservation*—Preserve and extend prior investments in existing transportation facilities and the services they provide to people and commerce.
- *Safety*—Target construction projects, enforcement, and education to save lives, reduce injuries, and protect property.
- *Economic Vitality*—Improve freight movement and support economic sectors that rely on the transportation system, such as agriculture, tourism, and manufacturing.

- *Mobility*—Facilitate movement of people and goods to contribute to a strong economy and a better quality of life for citizens.
- *Environmental Quality and Health*—Bring benefits to the environment and our citizens' health by improving the existing transportation infrastructure.

**South Carolina DOT [2014]**

*Vision*—Provide safe, reliable surface transportation systems and infrastructure, and effective support for a healthy South Carolina economy through smart stewardship of all available resources.

Goals

- *Mobility and System Reliability*—Provide surface transportation infrastructure and services that will advance the efficient and reliable movement of people and goods throughout the state.
- *Safety and Security*—Improve the safety and security of the transportation system by implementing transportation improvements that reduce fatalities and serious injuries as well as enabling effective emergency management operations.
- *Infrastructure Condition*—Maintain surface transportation infrastructure assets in a state of good repair.
- *Economic and Community Vitality*—Provide an efficient and effective interconnected transportation system coordinated with state and local planning efforts to support thriving communities and South Carolina's economic competitiveness in global markets.
- *Environment*—Partner to sustain South Carolina's natural and cultural resources by minimizing and mitigating the impacts of state transportation improvements.
- *Equity*—Manage a transportation system that recognizes the diversity of the state and strives to accommodate the mobility needs of all of South Carolina's citizens.

### *2. MPOs*

**San Diego Association of Governments (SANDAG) [2011]**

*Vision:* A transportation system that:

- Supports a prosperous economy; promotes a healthy and safe environment, including climate change protection; and provides a higher quality of life for all San Diego County residents.
- Better links jobs, homes, and major activity centers by enabling more people to use transit and to walk and bike; efficiently transports goods; and provides fast, convenient, and effective transportation options for all people.

Goals:

- *Mobility*—The transportation system should provide the general public and those who move goods with convenient travel options. The system also should operate in a way that maximizes productivity. It should reduce the time it takes to travel and the costs associated with travel.
- *Reliability*—The transportation system should be reliable. Travelers should expect relatively consistent travel times, from day to day, for the same trip and mode of transportation.
- *System Preservation and Safety*—The transportation system should be well-maintained to protect the public's investments in transportation. It is also critical to ensure a safe regional transportation system.

**Charlotte Regional Transportation Planning Organization (CRTPO, Charlotte, North Carolina) [2014].** The following goals and objectives from Charlotte regional transportation plan are those relating mainly to system management and operations (a complete list is found in [CRTPO, 2014]).

*Goal:* Provide, manage, and maintain a safe, efficient and sustainable transportation system for all modes, intended to serve all segments of the population.

*Objectives:*

- Designate resources to maintain the existing transportation system.
- Minimize congestion within the existing transportation system.
- Develop an efficient street and highway network capable of providing an appropriate level of service for a variety of transportation modes.
- Encourage design features that minimize crash potential, severity, and frequency.
- Enable all users to choose a convenient and comfortable way to reach their destination, regardless of location, personal mobility level, age, or economic status.
- Promote future opportunities for interregional mobility through enhancements to intercity rail service and the provision of high-speed rail service.

*Goal:* Encourage walking, bicycling, and transit options, integrated with motor vehicle transportation, by providing a transportation system that serves the public with mobility choices.

*Objectives:*

- Increase the connectivity of the existing street network, including minimizing barriers and disconnections of the existing roadways, and improving access to activity centers.
- Improve the transportation system by developing streets and highways that are accessible to, or compatible with, multiple modes of transportation by utilizing design standards consistent with NCDOT's Complete Streets policy.
- Include sidewalks and bicycle facilities in the design of roadways to accommodate and encourage pedestrian and bicycle travel, and maximize linkages to off-road facilities and transit services.
- Support the operation of safe and efficient scheduled transit services that minimize travel times and distances.

*Goal:* Maximize travel and transportation opportunities for the movement of people and goods.

*Objectives:*

- Develop regionally significant streets and highways in a manner that manages congestion and minimizes travel times and distances.
- Promote the integration of, or coordination among, different transportation modes by supporting intermodal terminals that facilitate the movement of goods.
- Establish measures to enhance the intercity, interregional, and intraregional capacities of major transportation corridors.

Optimally, as regions strive to improve the efficiency, reliability, and safety of transportation systems, strategies that transcend jurisdictional boundaries will need to be developed and evaluated early in the planning process. In this manner, *solutions packages* that combine operations, infrastructure, and land-use strategies and projects can be formulated. Such a *transportation-as-a-system* perspective can help improve the quality and timeliness of transportation decisions because it inherently integrates operations into the planning process.

For further information on goals and objectives, see chapter 15 on state transportation planning and chapter 16 on metropolitan transportation planning.

## C. Performance Measures

"What gets measured gets managed." This often-repeated maxim recognizes that performance measurement can focus the attention of decision makers, practitioners, and the public. Because they focus attention on the operating performance of the transportation system, performance measures are an important mechanism for increasing awareness of TSM&O approaches within the planning process. Performance measures provide a means of linking

a transportation agency's perspective with the experience of those who use the transportation system. Defining performance measures and tracking performance often requires communication and coordination among those managing the operations of the transportation system (who often have data and expertise on real-time system performance), and those involved with planning and policy development (who can use this information to set goals, track progress, and make investment decisions).

Significant ways in which performance measures strengthen the planning-operations collaboration are:

*Performance measures bring focus to customer-oriented outcomes*. Performance measurement has traditionally been the realm of planners and policy analysts as part of the planning and investment prioritization process. Metrics tended to be those that could be modeled and used for long-term investment decision making, such as average travel times and miles of congested roadways. Examples of performance measures that focus on TSM&O included:

- Total or average hours of incident-related delay.
- Consistency of peak and off-peak travel times (that is, reliability).
- Average travel time by mode to designated regional centers.
- Commercial vehicle delay per mile.
- Extent of real-time information provision (for example, lane-miles or intersections for which information is available, number of ways to access such information, and so forth).
- Transit on-time performance.

*Performance measures elevate the status of TSM&O approaches*. Efforts to focus on system performance often result in better recognition of the value associated with TSM&O approaches. Use of performance measures and measuring the benefits of M&O strategies, such as traffic incident management and traveler information services, can help decision makers appreciate the value of such approaches for meeting both short- and long-term goals.

*Performance measures help inform policy decisions*. By focusing attention on system characteristics important to the traveling public, performance measures can help planners focus on the day-to-day experience of transportation system users. This provides important balance in settings where planners have been exclusively focused on very long-term development of the network. With greater focus on the day-to-day characteristics of the system, the issues faced by operators (such as incident response, work zone management, and provision of traveler information) take on greater importance. As a consequence, mid- and long-term planning can reflect greater consideration of TSM&O planning and investment needs. A greater understanding of operations issues by planning staff can also help in setting transportation policies.

A number of opportunities exist to use performance measurement to build stronger linkages between planning and operations. These include:

- Involve operations managers in the process of developing performance measures.
- Incorporate operational performance measures into strategic and long-range transportation plans.
- Use operations data for tracking performance in annual or quarterly reports.
- Use performance measures to motivate data and tool development.

Some examples of operations-oriented performance measures for different-sized jurisdictions include:

**Florida DOT**

- Percent travel in generally acceptable operating conditions during peak hour
- Hours of delay (passenger and trucks)
- Travel time reliability (passenger and trucks)
- Percent miles severely congested (passenger and trucks)

- Number of serious injuries and fatalities in motor vehicle crashes
- Fixed route transit incidents

**Fredericksburg MPO, Virginia**

- Annual hours of delay per peak period traveler
- Number of highway fatalities and fatality rate
- Number of highway crashes and crash rate
- Number of transit crashes, injuries and fatalities
- Number of aviation crashes and fatalities
- Mean travel time to work

**Hampton Roads MPO, Virginia**

- Annual delay, hours per peak auto commuter
- INRIX Index (extra time during peak period)
- Annual roadway fatalities, injuries and crashes and corresponding rates
- Annual transit fatalities, injuries and crashes and corresponding rates
- Annual highway-rail crossing crashes and rate (per million population)
- Annual aviation accidents
- On-time performance, Amtrak

**Madison MPO, Wisconsin**

- Miles of congested roadways (based on level of service)
- Freeway congestion duration
- Travel time to work (by mode)
- Miles of congestion on truck routes
- Total vehicle crashes by severity vs. VMT
- Metro transit bus crashes per 100,000 VMT
- Total bicycle and pedestrian crashes and fatalities
- Transit system on-time performance

**Minnesota DOT**

- Total number of fatalities resulting from crashes involving a motor vehicle
- Twin Cities urban freeway congestion: % of metro-area freeway miles below 45 mph in a.m. or p.m. peak periods
- Inter-Regional Corridor (IRC) travel speed: % of system miles performing more than 2 mph below corridor-level speed targets

**Missouri DOT**

- Average travel time and 95 percentile trip planning time for major metropolitan areas
- Miles of freeways in categories of percentile speed compared to free flow speed (for example, miles with 10 percent above free flow speed)

- Cost of congestion
- Average time to clear traffic incident
- Average time to meet winter storm performance requirements
- Work zone impact measure on traveling public

Performance measures should be periodically reexamined to make sure they are providing the information desired and needed by decision makers. The Minnesota DOT, for example, provided the following guidance on updating performance measures for its maintenance and asset management activities:

> *Continually improve reliability and credibility of performance measures*. The credibility of the measures is important in managing the asset and communicating the needs to the public and policy makers. It is imperative that good, reliable measures are developed and that data is tracked over time to establish historic patterns. This data can be used to evaluate current practices as well as predict impacts of changing investment levels or resources. Suggested actions include:
>
> - Continually improve data collection and methodology for performance measures (for example, pavement patching, guardrail, signing, and preventive bridge maintenance). As part of this process, consider independent review and verification of data.
> - Track historic data trends and report measures over time. Build trend-line data sets.
> - Forecast future performance and budget needs based on historic data.
> - Work to better define "winter severity" index and relationship of index to overall snow and ice removal cost. Track information over time to better compare snow and ice cost changes.
> - Compare standards and/or performance targets with applicable national standards from other available operations and maintenance plans.
> - Establish periodic audits of Highway System Operations Plan performance measures encompassing both performance and financial data. [MnDOT, 2005]

TSM&O professionals contribute a unique perspective on how to measure performance and can therefore add a great deal to the regional discussion about performance measurement at the system, corridor, or facility levels. Performance measures help determine whether resources are being prioritized properly to meet goals and objectives. Performance measurement can dramatically influence which regional needs are highlighted within the planning process and which are downplayed or ignored.

Good examples of performance measures that reflect system and facility operations are found in [Cambridge Systematics et al., 2008; Cambridge Systematics et al., 2010; Grant et al., 2013; and Cambridge Systematics et al., 2014].

## D. Data Collection and Sharing

Data collection and interpretation have experienced significant changes over the past 10 years, and will likely see more in the future. With vehicle-to-vehicle and vehicle-to-infrastructure technologies becoming more commonplace, the data generated by travelers on an average day will far surpass data that was available to transportation planners in recent years (see later section on connected technologies). Much of this data will be useful for transportation planning. According to the FHWA, "the use of operations data is vital to the advancement of transportation planning as MPOs and state DOTs shift to a more performance-based planning process that requires system performance data to guide decision making." (http://www.ops.fhwa.dot.gov/plan4ops/focus_areas/analysis_p_measure/data_for_planning.htm).

The availability of data also has a great deal to do with the types of performance measures that can be adopted. Operations data address real-time performance of the transportation system, allowing for the development of measures that can better capture the experiences of users (such as travel time and travel time reliability). However, to access and

properly apply real-time data, the planning process needs the resources and expertise of operations practitioners. [Shaw, 2003]

Using advanced technologies, it is now possible to collect and store vast amounts of data to support the planning and operation of transportation systems. Roadway loop detectors, for example, can provide real-time information about traffic volumes and speeds. Global positioning systems and radio/cellular phone triangulation can determine vehicle location and speed. Electronic fare collection and automatic vehicle location systems can record detailed information on transit service and use. These rich data sources may not only replace many more expensive, traditional data collection methods, such as manual traffic counts, surveys, and floating car studies, but they may also allow data to be combined across modes and operational environments in new ways. In doing so, they can create a more complete picture of how policy, infrastructure and service changes affect the reliability and performance of transportation systems.

Data sharing refers to a broad range of activities that support the full use of readily available transportation information. [Kittelson and Assocs. 2013; Pack and Ivanov, 2014] Many government and private organizations collect data that can inform the design and operation of transportation facilities and systems. First and foremost, data sharing implies awareness about such data sources and a fresh perspective in considering their potential value in new uses. Data sharing typically requires that organizations store data and make them available in usable formats. It may also involve a forum to coordinate with other organizations about potential data exchange opportunities. Table 10-8 shows different types of information technology strategies and typical applications.

**Table 10-8. Information Technology and Data-Sharing Strategies**

| Strategy | Description or Application | Modes Affected | Impact on Reliability |
|---|---|---|---|
| Advanced automatic collision notification (AACN) systems in all vehicles | Crash notification within 1 min for all crashes; network of sensors in infrastructure to detect imminent or actual events or hazards | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Bus rapid transit and signal preemption | Vastly improved transit as a serious option | Transit | High |
| Combined sensors–computer–wireless link | Multiple information fusion methods combining data from multiple sensors and databases; data fusion nodes communicating on ad hoc wireless network | n.a. | Medium |
| Comprehensive real-time information | Real-time information available to all modes in an integrated fashion; pedestrians, bikes, and vehicles will have relevant information and options on how to proceed with trips | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Customized real-time routing | Tuned to driver preferences and driven by real-time congestion and reliability data, with predictive capability; what conditions will be at arrival | Passenger vehicles, freight, transit | High |
| Video coverage of networks | Can see picture of the road ahead in car, on phone, in TMC | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Rapid incident clearance | Automated scene assessment, damage assessment through total stations and digital imaging, rapid removal of damaged vehicles; ability to do on-scene accident investigation in minutes, not hours, with automated imaging technology | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Real-time condition monitoring to predict long-term infrastructure performance | Major elements self-monitoring on real-time basis; reports problems in advance | All (infrastructure) | High |

(*continued*)

Table 10-8. (*Continued*)

| Strategy | Description or Application | Modes Affected | Impact on Reliability |
|---|---|---|---|
| Real-time information on parking availability, roadway conditions, routing, rerouting | Time spent on parking significantly reduced; drivers will know parking availability ahead of time | Passenger vehicles | High |
| Reliance on roadside signs for driver information | Real-time messages directly to vehicles for information, routing, traffic management, incident management, etc. | Passenger vehicles, freight, transit | Medium |
| Universal fare instruments for transit and road pricing | Highly controlled to minimize transfer and waiting time; elimination of dwell times caused by fare collection | Passenger vehicles, freight, transit | High |
| Weather detection and response systems | Snow and ice management through chemical and nanotechnology applications; reduce reliability problems due to weather despite increasing extreme events | All (infrastructure) | Medium |
| Data from vehicle traces (for example, GPS tracking of trucks and containers) | Powerful source of reliability data; vastly improved ability to measure reliability makes it feasible to manage for reliability, to guard against performance degradation, to guarantee performance, etc. | Passenger vehicles, freight, transit | Medium |
| Data sharing | Barriers overcome through creative confidentiality agreements, technologies, and algorithms | n.a. | Medium |
| Fully implemented NG9-1-1 | Full AACN telemetry data in actionable form pushed into NG9-1-1 system; image from inside vehicle automatically received at public-safety answering point after crash | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Hybrid wireless mesh networks | Mesh networks facilitating communication of VII and improving mobile interconnection; vehicle-to-vehicle and vehicle-to-infrastructure networks a reality | All (passenger vehicles, freight, transit, bikes, pedestrians) | High |
| Latest onboard technology | Fleet turnover inertia overcome with software upgrades rather than new vehicle purchases | Passenger vehicles, freight, transit | Medium |
| Multimodal routing, schedules, trip planning | Gives people travel options; same for freight (though to a large degree, this exists for freight through 3PL) | All (passenger vehicles, freight, transit, bikes, pedestrians) | Medium |
| Predictive models for real-time systems operation | Forecasting models supporting real-time systems operations and preventing possible breakdowns on the network | n.a. | Medium |

Note: 3PL = third-party logistics; BRT = bus rapid transit; na = not applicable; AACN = advanced automated crash notification; NG9-1-1 = Next Generation 9-1-1.

Source: Kittelson and Assocs., 2013. Reproduced with permission of the Transportation Research Board.

Interest in data sharing is prompted in part by growing concern about the performance of transportation systems as well as the performance of individual facilities, and by the increased focus on M&O strategies to enhance transportation system performance. Efforts to improve travel time reliability and predictability require more detailed data than have traditionally been analyzed by planners. The system focus means that data on conditions are needed virtually everywhere in the transportation system across jurisdictions and modes. This contrasts with the typical hot-spot approach that has governed data collection and transportation management in the past.

The ITS architecture, that is, the strategy established to provide a coordinated approach to the application of advanced technologies to transportation system management, also encourages the identification of new data sharing opportunities. Information flow analysis is an important element of the national ITS architecture (and regional ITS architectures). An information flow analysis is typically diagramed in a way that illustrates the appropriate

information flows between each major component of the transportation system, thereby highlighting potential data sharing options. A related element of the recommended national ITS architecture—the Archive Data User Service—was designed to facilitate alternative uses of ITS data, including use of data for transportation planning. The Archive Data User Service helps promote a regional data sharing approach consistent with current and anticipated technological capacity.

Organizations that receive data benefit from valuable information on transportation system demand and performance, often at little or no cost. Sharing data can benefit the organization providing data by building awareness of the agency's programs and creating a check on data accuracy. Data sharing may necessitate changes within the agencies receiving data, including a willingness to evaluate planning practices and operations strategies in light of more complete information.

Data sharing is often a first step toward broader coordination between planning and operations. Sharing data requires establishing new relationships with other agencies and building mechanisms to support sustained data exchange and storage. Data formats, accuracy, consistency, and appropriate use can complicate the process of establishing inter- and intra-agency data sharing programs, but there are many examples where such challenges have been met.

Data sharing can be used as a mechanism to link planning and operations in several ways:

- *Develop a regional data clearinghouse*. A central data clearinghouse can help facilitate access to the region's full range of transportation data for both planning and operating agencies.
- *Coordinate data resources with transit agencies*. As a result of ITS deployments, transit agencies are becoming more valuable data-sharing partners, enabling them to participate in regional planning activities in new ways.
- *Use special events to initiate new data partnerships*. Coordinating special events creates an opportunity to develop awareness of data that are available from other organizations.
- *Use operations data to develop more effective performance measures*. Operational data are also essential for the development of many performance measures.
- *Use operations data to improve planning analysis tools*. Data gathered through transportation systems operations activities can be valuable to transportation planners for improving travel demand models and developing other analytical tools. The availability of more detailed operations data can lead to better travel demand forecasting models, including models that are more sensitive to the effects of operations strategies.
- *Use archived data to inform TSM&O planning*. While archived data can be useful to transportation planning agencies, it can also help those responsible for M&O to internally plan and coordinate their activities for the most effective results.

Another type of data collection important in planning for operations focuses on evaluating strategies and actions that have been already been implemented to gauge their overall success and appropriateness for future application. In this case, the types of data collected would reflect the different possible outcomes of an implemented strategy. For example, Table 10-9 shows the types of data collection tools that would be considered in the evaluation of the strategies or actions listed. Chapter 7 on evaluation provides more information on ex post facto evaluation of projects.

## E. Operations-Oriented Analysis Tools

Determining where transportation improvements are most needed is an important component of regional planning processes. Planning needs assessment traditionally has focused on additional roadway or transit capacity to improve mobility in particular corridors. As the focus of planning efforts extends beyond mobility to also address travel time reliability and accessibility, M&O strategies grow in importance, especially in light of environmental, community, and funding constraints on new physical infrastructure projects. The needs assessment phase, therefore, provides an important opportunity to more effectively engage TSM&O in the decision-making process. The need to better integrate TSM&O into regional needs assessment is heightened further by the increased focus on transportation security, which relies on effective operations planning and response to prepare for and respond to system disruptions.

| Table 10-9. Data Collection Methods for Evaluating Transportation Strategies | | |
|---|---|---|
| **Strategies Being Evaluated** | **Performance Measures** | **Data Collection Methods** |
| Incident management | • Average incident duration<br>• Occurrence of secondary accidents<br>• Incidence response time | • Log of incident duration (from dispatcher records)<br>• Measurement of speeds from surveillance system |
| Traffic management | • Average speeds<br>• Intersection delay | • Traffic volume counts<br>• Moving car runs<br>• Measurement of speeds from surveillance system |
| Traveler information | • Door-to-door trip time<br>• Transit ridership<br>• Mode share<br>• On-time arrivals | • Trip logs (by regular commuters), for roads and/or transit<br>• Traffic counts<br>• Transit ridership counts<br>• Mode shift survey |
| Transit operations | • Transit travel times<br>• Transit ridership<br>• Peak load factor<br>• Schedule reliability<br>• Transfer time/station delay or waiting time<br>• Transit travel time<br>• Roadway impacts (for example, vehicle delay, speeds)<br>• Mode share | • Mean incidence clearance time |
| Travel demand management | • Mode share<br>• VMT reduced | • Mode share survey<br>• Traffic counts |

### *1. Analysis Tools and Methods*

A variety of analysis tools and approaches are used to predict the effectiveness of M&O strategies. Figure 10-12 shows a typical range of analysis approaches and the level of precision associated with key characteristics. In many state DOTs and MPOs, network simulation is an important analysis tool for understanding network performance.

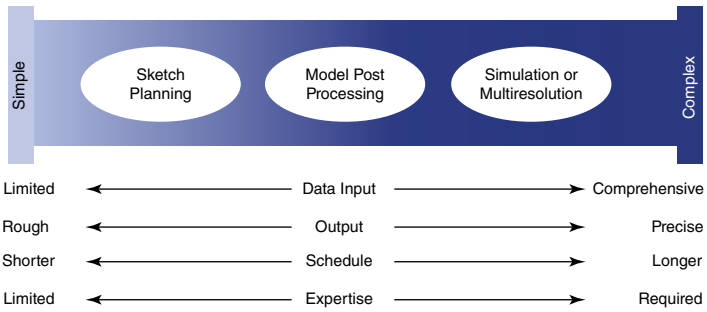
The different types of analysis tools that fit into this spectrum were defined by Cambridge Systematics et al., [2014] as:

*Sketch-Planning Methods*. Analysis methods intended to provide quick assessment of reliability (and the impacts of projects affecting reliability) using generally available data as inputs to the analysis. These are the least resource-intensive of the analysis methods and produce order-of-magnitude results that are often used in early planning stages.

*Model Post-Processing Methods*. Analysis methods focus on applying customized analysis routines to data from a regional travel demand model to generate more specific estimations of travel time reliability measurements. They benefit from the travel demand model's robust network and supply-and-demand conditions. The most common of these methods is based on analysis from the ITS Deployment Analysis System (IDAS) tool, developed by FHWA, which estimates incident-related congestion (a major component contributing to travel time variability).

*Simulation or Multiresolution Methods*. Methods that use an advanced traffic simulation model's ability to test and assess the driver's behavior and reactions to nonrecurring events. Multiresolution methods often take advantage of the integration of several standard modeling tools (for example, microsimulation and travel demand models) to combine different tools' abilities to assess shorter-range and longer-range impacts of various congestion mitigation strategies. For reliability assessments, these simulation and multiresolution methods are often combined with multi-scenario analysis, whereby models are run with several alternative conditions that represent logical variations in travel demand, weather conditions, incident occurrence, presence of work zones, or other factors influencing nonrecurring congestion.

**Figure 10-12. Spectrum of Reliability Analysis Tools and Methods**



Source: Cambridge Systematics et al., 2014. Reproduced with permission of the Transportation Research Board.

*Monitoring and Management Tools and Methods*. Tools and methods intended to provide analysis of real-time and archived traffic data. They differ from the aforementioned methods as they primarily target assessing past conditions rather than forecasting future conditions; however, these tools and methods may play a significant role in providing data for forecasting methods.

Table 10-10 identifies potential applications of different types of analysis tools and methods for different transportation planning needs. As shown in the table, performance metrics themselves are considered an analysis tool to understand system performance.

**Table 10-10. Transportation Planning Needs and Operational Analysis Tools**

| | Operational Analysis Tools and Methods | | | | | | |
|---|---|---|---|---|---|---|---|
| **Transportation Planning Needs** | **Sketch Planning Tools** | **Deterministic Models** | **Travel Demand Forecasting Models** | **Simulation** | **Archived Operations Data** | **Operations-oriented Performance Metrics** | **Traffic Signal Optimization Tools** |
| Needs Assessment/Deficiency Analysis | | X | X | X | X | X | X |
| Preliminary Screening Assessments | X | | | | | X | |
| Alternatives Analysis | X | | X | X | | X | |
| Strategic ITS Planning | X | | X | | | X | |

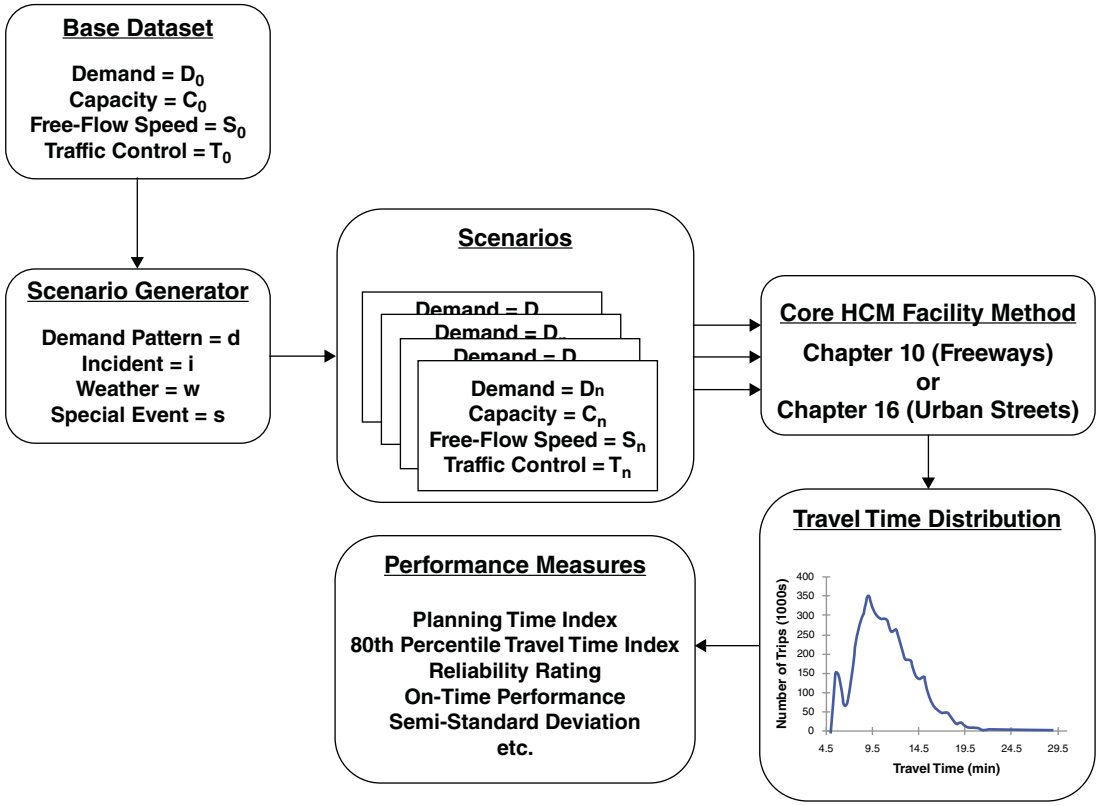
### *2. Scenarios*

Many analysis efforts include two or more scenarios, often relating to particular themes. For example, a region may define one analysis scenario as all desired capital investments, while another scenario consists of whatever investment is needed simply to maintain the existing system. Or, alternatively, a scenario might be implementing what is already in the investment program, but putting all additional resources into M&O strategies. Developing an integrated M&O-focused alternative is an excellent opportunity for involving operations practitioners in the planning process. This is a chance to see how regional or state coordination of TSM&O efforts can address short- and midterm needs. Moreover, incorporating M&O strategies into all types of capacity enhancement projects is important for ensuring that the effective capacity of the system is achieved.

As of the publication of this handbook, there is a proposal to include in the *Highway Capacity Manual* two chapters that focus on nonrecurring congestion impacts on freeways and urban streets. The basis for the proposed methodology is the development of analysis scenarios reflecting different factors that could affect system or facility reliability, such as work zones, weather, incidents, and infrastructure design characteristics. Figure 10-13 shows the general concept of how scenarios are used to estimate the impact of nonrecurring events on facility reliability. In general, the scenario generation process includes the following steps:

- Adjusting the base demand to reflect day-of-week and month-of-year variations associated with a given scenario.
- Generating severe weather events based on their probability of occurrence in a given time of year, and adjusting capacities and free-flow speeds to reflect the effects of the weather events.
- Generating various types of incidents based on their probability of occurrence and adjusting capacities to reflect their effects.
- Incorporating user-supplied information about when and where work zones and special events occur, along with any corresponding changes to the base demand or geometry.

**Figure 10-13. Proposed Process for Use of Scenarios in Estimating Impact on Freeway and Urban Street Reliability**



Source: Ryus et al., 2013, Reproduced with permission of the Transportation Research Board.

| Table 10-11. Benefits of Operations Strategy From Implemented Projects | |
|---|---|
| **Operations Strategy** | **Example Benefits** |
| Dynamic speed limits | Crashes reduced 10%–30%<br>Secondary crashes reduced 50%<br>Improved reliability |
| Dynamic shoulder running | Travel times reduced up to 25%<br>No impact on safety |
| Ramp metering | Crashes reduced 15%–40%<br>Travel times increased 10%+ |
| Transit signal priority | Bus times improved 2%–15%<br>Minimal impact to side streets |
| Adaptive signal control | Delay reduced 4%–40% |
| Integrated corridor | Estimated B/C of 5:1 to 10:1 |
| Traffic signal control | Emissions reduced 3%–22% |
| Congestion mitigation strategies (for example, incident management) | $CO_2$ reduced 7%–12% |
| Variable speed displays | $CO_2$ reduced 10%–20% |
| Automated vehicle location/Computer aided dispatching | Improved schedule adherence by 9%–23% |

The results of the analysis will show what to expect in terms of change in performance characteristics. The specific impacts will vary by problem context, but to give some sense of the level of magnitude of such impacts, the information shown in Table 10-11 was gathered from a number of studies.

Those interested in the use of scenarios in analysis and evaluation should find the latest update on this effort to include a methodology in the *Highway Capacity Manual*.

## F. M&O Strategies Included in the Plan and TIP

Many planning agencies have developed procedures for applying modeling techniques and economic assessments to choose among various capital investment options. This already challenging process becomes even more complex when transportation operations projects and programs are included within competing investment scenarios. For example, evaluation techniques can rarely weigh the benefit from a coordinated set of corridor traffic incident management strategies. Operations practitioner involvement in the analysis is critical to ensure that the full range of benefits of these operations programs is considered. Getting them involved at this stage can help them see the importance of their expertise within the transportation decision-making process. Ultimately, interaction in this evaluation process can lead to improved mutual understanding and often raises new coordination steps for subsequent updates to the transportation plan.

Estimating the benefits and costs associated with candidate alternatives is a critical element of any evaluation process. Table 10-12 shows the primary measures of effectiveness or evaluation criteria associated with different M&O strategies. Where an evaluation produces information on the relative merits of the alternatives being considered, the measures of effectiveness shown in Table 10-12 could be the basis of comparison (see chapter 7 on evaluation).

There are a variety of ways that M&O strategies can be evaluated and priorities established. Table 10-13 shows the approaches several MPOs use to evaluate M&O projects. Notice in some cases dollars are set aside before any assessment to ensure a minimum amount of investment is going to M&O strategies. Another important observation is that many MPOs rely on TSM&O committees or subcommittees for the prioritization of such strategies.

**Table 10-12. Example Measures of Effectiveness for M&O Strategies/Projects**

| TSM&O Strategy | Mobility (Travel time savings) | Reliability (Total delay) | Safety (Number and severity of crashes) | Emissions | Energy (Fuel used) | Vehicle Operating Cost Savings | Agency Efficiency |

**Table 10-13. Example Processes for Selecting TSM&O Projects**

| TSM&O Project Selection Process Summary | |
|---|---|
| **MPO** | **Project Selection Process** |
| DRCOG (Denver) | Three program pools serve as the core mechanism for federal funding for operations in the region: ITS, TDM, and traffic signal system Improvements. There is a separate project selection process for each of three pools. Stakeholder groups apply a consensus-based scoring process with different selection criteria for each funding pool. Decisions are based on regional operations priorities in regional operations-focused planning documents. |
| GTC (Rochester, NY) | There are set-aside funds for the HELP (highway emergency local patrol) program and Regional Traffic Operations Center staffing. Other operations projects compete with all other projects for TIP funds. All projects are ranked using a set of common criteria and mode-specific criteria. TSM&O is a category with its own mode-specific criteria. |
| MAG (Phoenix) | Selection of ITS/operations projects is based on priorities set forth in the Regional ITS Strategic Plan using a competitive process with the following criteria: (1) relevance to regional ITS plan, (2) compliance with regional ITS architecture, (3) congestion mitigation potential, and (4) emissions reduction potential. ITS/operations projects do not compete with other transportation projects for funding. All proposed ITS projects are reviewed by the ITS committee. It provides project recommendations that are then reviewed by other committees. |
| MetroPlan (Orlando) | Once a year, an operations stakeholder committee meets to select TSMO projects to be funded by the TSMO set-aside, prioritize them, and set a schedule for implementation. The committee ranks projects based on expected system impact, cost-efficiency, coordination with the ITS system architecture, strategic -plan and geographic equity among MetroPlan's member local governments. |
| NCTCOG (Dallas-Ft. Worth) | NCTCOG uses separate project selection criteria for the following types of TSMO projects: (1) intersection improvements, (2) ITS, and (3) traffic signal improvements. NCTCOG staff then evaluate the merits of each project using criteria and weights identified in the call for projects. While most projects go through a competitive proposal and technical evaluation process, some projects are selected because they qualify for targeted, strategic state or local programs. |
| PPACG (Colorado Springs) | Projects are prioritized based on their ability to fulfill the goals of the RTP and to meet criteria specified for each specific funding program. TSM&O strategies compete for funding in the Maintenance & Operations and Congestion Mitigation Air Quality (CMAQ) funding program categories. |
| PSRC (Seattle) | Operations projects compete against all others in the TIP selection process. Operations project sponsors may apply for federal transportation funds from PSRC's programming process through either a regional competition or through one of four countywide competitions. |
| Portland Metro | Operations projects receive funding through the TSM&O Program funding set-aside and the open competitive process. The MPO works through its operations stakeholder group to evaluate and select projects for the TSM&O program funds; one-third of these funds go to regionwide projects and two-thirds go to corridor-level projects. The regionwide projects are selected by consensus whereas the corridor-level projects are selected using specific evaluation criteria and analysis. |
| SANDAG (San Diego) | The MPO applies a 100-point scoring process in the selection of TSM&O as well as other types of projects. The scoring criteria are grouped into three broad categories: serves travel needs (40 percent weight), network integration (20 percent weight), and addresses sustainability (40 percent weight). Many ITS and operations projects are incorporated into larger capital projects. |

Source: FHWA, 2013b

There are several ways to determine the relative worth of one project over another (see chapter 7). The primary method is to conduct a benefit/cost analysis, where benefits are expressed in monetary terms. The FHWA has developed a simple spreadsheet-based benefit/cost tool called TOPS-BC that provides:

- The ability to investigate the expected range of impacts associated with previous deployments and analyze many M&O strategies.
- A screening mechanism to help identify appropriate tools and methodologies for conducting a B/C analysis based on analysis needs.

- A framework and default cost data to estimate the life-cycle costs (including capital, replacement, and continuing O&M costs) of various TSM&O strategies.
- A framework and suggested impact values for conducting simple sketch planning level B/C analysis for selected TSM&O strategies. [Sallman et al., 2013]

Compared to more traditional infrastructure improvements, M&O improvements typically exhibit a greater proportion of their costs as continuing operations and maintenance, as opposed to upfront capital costs. Thus, the tool provides a user with the capability to examine the total expected life-cycle costs of every strategy. The benefits of a strategy are associated with the expected effect on travel flow, for example, change in travel time, reduction in the number of crashes, improved travel-time reliability, and the like, with each criterion estimated monetarily (using appropriate economic value factors, such as the value of time and value of a human life).

Caltrans has developed a similar tool that provides users with outputs relating to life-cycle costs and benefits, net present value estimates, benefit/cost ratios, rate of return and payback values. [Caltrans, 2009] The benefits are estimated as travel time savings, vehicle operating cost savings, crash cost savings, and emission cost savings. The tool also produces results on person-hours of time saved, additional $CO_2$ emissions saved (in tons), and additional $CO_2$ emissions saved (in millions of dollars). The emphasis on $CO_2$ emissions comes from state laws that require state agencies to reduce greenhouse gas emissions.

Another interesting way of portraying the relative effectiveness of M&O strategies is called cost effectiveness. In this approach, the benefits are not monetized, but simply estimated with some quantifiable metric. The analysis then assesses the dollar expended per unit of benefit achieved. An example is shown in Figure 10-14 where the impact measure is the planning time index (PTI), a measure of the reliability of the system or facility (the larger the number, the worse the reliability). The x-axis in the figure shows the ratio in improvement in the PTI; the larger the ratio the greater the improvement. Thus, the strategies that are in the upper right quadrant of the figure are the "best" strategies because they have the largest deficiency in reliability and show the greatest improvement with respect to level of investment.

Readers interested in additional information on TSM&O evaluation and prioritization methods should refer to chapter 7 on evaluation and the FHWA Traffic Operations website at: http://www.ops.fhwa.dot.gov/plan4ops/news.htm.

## G. Shared Funding and Resources

In developing strategies to fund TSM&O activities, regions have an opportunity to promote new relationships and arrangements that support broad regional systems management perspectives and better link operations with regional planning. For example, a planning and programming process that places a high priority on inter-jurisdictional coordination can encourage normally independent practitioners to collaborate and identify opportunities for shared equipment and facilities. Funding strategies can also be used to help ensure implementation of TSM&O objectives developed through the planning process or to attract new operations stakeholders to planning forums.

Funding and resource sharing refers to a variety of arrangements by which transportation and other operating agencies collaborate to submit funding requests, develop pooled funding mechanisms, or share equipment and facilities. As a coordination opportunity, this also refers to efforts to coordinate between visions of transportation systems management that are discussed in plans and the regional funding policies and commitments that are needed to make those visions a reality.

The structure of resource sharing arrangements may evolve over time in response to changing regional needs and changing relationships among agencies. Initially, sharing may be limited to supplying staff, equipment, or facilities in support of regional meetings or other regional collaboration activities. If appropriate, participating public and private organizations may develop more formal sharing arrangements, including pooling of funds and other resources to sustain cooperative regional efforts. In some regions, agencies may provide funding to support a regional entity charged with leading regional collaboration or an entity that owns and operates regional transportation system assets.

There are several opportunities to coordinate planning and operations:

- *Link funding to planning goals and objectives*. Increasingly, local and regional transportation plans include language supporting improved transportation systems management, promoting more efficient use of existing infrastructure and adopting a more customer-oriented approach to transportation service provision. Yet the funding and staff resources to implement planning objectives are often lacking. Several approaches have been used to more closely link funding to operations goals. One approach is to have regional stakeholders determine minimum budget requirements to support long-range plan objectives in each program area.
- *Develop innovative operations funding sources*. New funding mechanisms can help create bridges between planners and operations managers. One strategy is to fund TSM&O efforts as part of the initial capital investment for a project. Planners and operators increasingly see that funds for TSM&O associated with a particular project or corridor are best secured in coordination allocations for major new construction or rehabilitation. Working together, planners and operators can make the case that proper management of new transportation facilities will maximize the long-term benefits of the initial investment.
- In the search for funding for system operations, some regions have turned to land developers. The practice of requiring developers to fund transportation improvements as a way to mitigate the transportation impacts of their projects is well established, but relying on this as a source of TSM&O improvements is relatively new. Developer concessions can provide an important source of revenue and can also encourage more detailed planning for TSM&O programs.
- *Build on emergency response funding needs to create regional opportunities for regional operations collaboration*. The recent focus on improving emergency preparedness and response has heightened the need for coordination between planning and operations.
- *Share office facilities*. Sharing office facilities inspires enhanced collaboration. In some cases, office sharing is arranged intentionally because there is recognition that transportation agencies working in the same space may do their job more effectively. A common example is a traffic management center (TMC) shared by traffic operators, transit staff, and public safety personnel.
- *Use the unified planning work program to define commitments to M&O planning*. Specific enumeration of regional M&O activities in the agency's Unified Planning Work Program (UPWP) is a way to ensure that such activities are implemented. This also builds the understanding that the MPO intends to take a leadership role on regional M&O issues.

## VII. DISSEMINATION OF OPERATIONS DATA

The increasing application of sensors and advanced locational technologies has begun to change dramatically the types of data and information disseminated to the public. For example, Tables 10-14 to 10-16 show typical types of data collection methods, types of data, and means of dissemination that are now quite common.

The need for data such as that shown on the tables suggests some important characteristics for system monitoring programs. First, travel times are probably the most important piece of information desired by travelers. Second, the monitoring system should characterize the reliability of the transportation network during the time of travel. Third, the monitoring system should identify the sources of unreliability (for example, incidents or systemic design deficiencies), and finally the monitoring system should help owners and operators of transportation systems know what the impacts are of an unreliable system. [List et al., 2014]

## VIII. THE CONNECTED TRANSPORTATION SYSTEM

Advancements in transportation follow, in many ways, the transformation of society that is caused by the creative use of information technologies. Many of the M&O strategies discussed in the previous sections rely on the use of surveillance and communications technologies. Transportation is arguably entering into one of the most transformative eras of personal mobility caused by the application of advanced technologies to both the vehicle and infrastructure. Autonomous vehicles, vehicle-to-vehicle (V2V) communications, and vehicle-to-infrastructure (V2I) sensing and communications are going to potentially revolutionize how transportation systems operate. These technologies are, in essence, enabling a connected transportation system, with significant impacts on TSM&O programs.

## A. Autonomous Vehicles

The National Highway Traffic Safety Administration (NHTSA) has proposed a five-level continuum of autonomous vehicles, with different benefits of the technology realized at different levels of automation:

- *No Automation (Level 0)*—The driver is in complete and sole control of the primary vehicle controls—brake, steering, throttle, and motive power—at all times.
- *Function-Specific Automation (Level 1)*—Automation at this level involves one or more specific control functions. Examples include electronic stability control or precharged brakes, where the vehicle automatically assists with braking to enable the driver to regain control of the vehicle or stop faster than possible by acting alone.
- *Combined Function Automation (Level 2)*—This level involves automation of at least two primary control functions designed to work in unison to relieve the driver of control of those functions. An example of combined functions enabling a Level 2 system is adaptive cruise control in combination with lane centering.
- *Limited Self-Driving Automation (Level 3)*—Vehicles at this level of automation enable the driver to cede full control of all safety-critical functions under certain traffic or environmental conditions and in those conditions to rely heavily on the vehicle to monitor for changes in those conditions requiring transition back to driver control. The driver is expected to be available for occasional control, but with sufficiently comfortable transition time. The Google car is an example of limited self-driving automation.
- *Full Self-Driving Automation (Level 4)*—The vehicle is designed to perform all safety-critical driving functions and monitor roadway conditions for an entire trip. Such a design anticipates that the driver will provide destination or navigation input, but is not expected to be available for control at any time during the trip. This includes both occupied and unoccupied vehicles. [NHTSA, 2013]

A report by the RAND Corporation identified the potential benefits of autonomous vehicles as being, (1) a dramatic reduction in the frequency of crashes, as much as one-third of fatalities and overall crashes simply by including forward crash avoidance and lane departure sensors; (2) increased mobility for the blind, disabled, or those too young to drive with a level 4 application; (3) a reduction in the costs associated with road congestion given that occupants of vehicles could undertake other activities with level 3 and above technology applications; (4) increased commuter willingness to travel longer distances to and from work, causing people to locate further from the urban core; and (5) a likely decrease in the cost of energy consumption and reduce emissions. [Anderson et al., 2014]

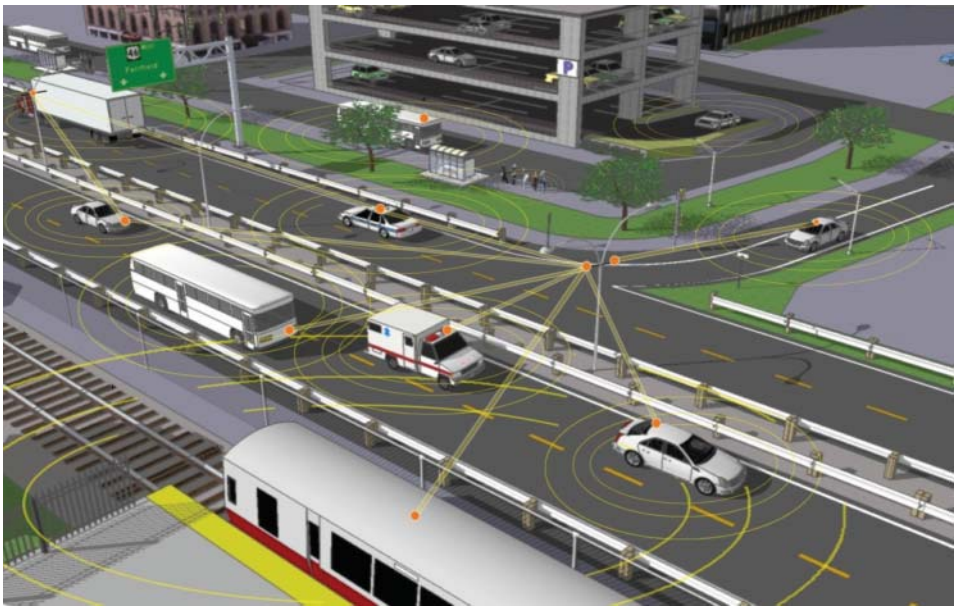
It seems likely that automobile manufacturers are already preparing the market for autonomous vehicles, and thus the future of personal mobility in the United States and other advanced countries will be tied to market acceptance of such vehicles and also how infrastructure is prepared to handle these vehicles. Test runs have already been made of autonomous vehicle operations in real-world conditions, and thus the concept has been shown to be feasible. However, an important challenge to transportation officials will be the transition from motor vehicles that do not have such technology to a fleet that is largely autonomous. For example, a likely scenario in this transition will be the use of lanes (perhaps the managed lanes of today?) for autonomous vehicles to separate their operation from traffic flows that are under manual control. This type of separation for high-speed operation could occur on the line-haul portion of a trip, and then mixed operations could occur at either end of the high-speed trip where speeds on local streets would be lower.

Autonomous vehicles also raise important questions relating to other parts of the transportation system. For example, what will be the impact of autonomous vehicles on transit service? Transportation for the elderly and mobility impaired? Teenage drivers? Freight movement? Parking? In the bigger picture, autonomous vehicles could result in more efficient utilization of existing highways, thus reducing the need for highway expansion. Why are we planning to build highways for the demands expected in 2040 when the very nature of how travelers make their trip could be different? What impact will this have on the construction industry? on local economies? Thus, while autonomous vehicle technologies provide tremendous benefits to travelers and to some parts of the economy, they raise important questions on the consequences and implications to many of the features of transportation system management and operations that we take for granted today.

## B. Vehicle-to-Vehicle Technologies

Many of the technologies that are part of autonomous vehicle operations relate to technologies that enable communication and interaction among vehicles using the road network. [Harding et al., 2014] The major advancement in

**Figure 10-15. Vehicle-to-Vehicle Technology Applications**



Note: Vehicles "talk" to each other exchanging information such as vehicle size, position, speed, heading, lateral/longitudinal acceleration, yaw rate, throttle position, brake status, steering angle, wiper status, and turn signal status, enabling safety and mobility applications.

Source: Harding et al., 2014

this regard is the use of dedicated short-range communications (DSRC) technologies that allow vehicles to exchange information on position, infrastructure conditions, and vehicle operations. A visual representation of the V2V concept is shown in Figure 10-15.

A good example of the benefits of V2V technologies is the set of technologies that permit one vehicle to sense the potentially dangerous position and operations of another vehicle, and to bring the first vehicle to a stop if the likelihood of a crash is high. Figure 10-16 show the different types of crash situations where V2V applications could be instrumental in reducing the number of crashes.

Based on 2004 to 2008 crash data, the U.S. DOT has concluded that a fully mature V2V system could potentially address 79 percent of all vehicle target crashes, 81 percent of all light-vehicle target crashes, and 81 percent of all heavy-truck target crashes annually. Improving the safety environment for motor vehicle operations is one of the major benefits of V2V applications.

V2V capabilities, already in place in newer vehicles, are likely to be implemented fleet-wide before full market penetration of autonomous vehicles. Thus, in the short term, defined as over the next 10 years, planners can expect greater use of V2V communications among vehicles on the roadway.

## C. Vehicle-to-Infrastructure Technologies

The driver-infrastructure interface has been an important characteristic of road design since the first modern roads were constructed, most often taking the form of traffic signs and pavement markings. The likely future connected transportation system will include a combination of V2V and vehicle to infrastructure (V2I) communication. Similar in concept to V2V technologies, V2I capabilities provide a communications interface between vehicles and infrastructure, such as communications with traffic signals, warning messages, vehicle gap acceptance, vehicle position, construction work zone warnings, parking space occupancy, and traffic management centers that would allow transportation system managers to oversee the performance of a road network. [Anderson, 2013; FHWA, 2014] Figure 10-17 shows an example of V2I communications, in this case warning a driver that there are pedestrians in an upcoming crosswalk.

**Figure 10-16. Vehicle-to Vehicle Technology Improved Safety Scenarios**

| Scenario and warning type | | Scenario example |
|---|---|---|
| **Rearend collision scenarios** | **Forward collision warning**<br>Approaching a vehicle that is decelerating or stopped. |  |
| | **Emergency electronic brake light warning**<br>Approaching a vehicle stopped in roadway but not visible due to obstructions. |  |
| **Lane change scenarios** | **Blind spot warning**<br>Beginning lane departure that could encroach on the travel lane of another vehicle traveling in the same direction; can detect vehicles not yet in blind spot. |  |
| | **Do not pass warning**<br>Encroaching onto the travel lane of another vehicle traveling in opposite direction; can detect moving vehicles not yet in blind spot. | |
| **Intersection scenario** | **Blind intersection warning**<br>Encroaching onto the travel lane of another vehicle with whom driver is crossing paths at a blind intersection or an intersection without a traffic signal. | |

Source: Harding et al., 2014

**Figure 10-17. Example of Vehicle-to-Infrastructure Capability**

Source: Walker, undated

Unlike autonomous vehicles and V2V technologies, which are primarily in the domain of private companies, the V2I emphasis on "smart" infrastructure leads to important roles for transportation agencies, in particular, state DOTs. Some of the leading state DOTs in this type of technology application, California, Colorado, Michigan, and Washington state, have placed great emphasis on understanding the future needs of V2I capabilities, in some cases, even creating department units focusing on system operations and technology applications. Over the next several years, more state DOTs are likely to join the ranks of agencies that are investing heavily in connected technologies.

## IX. SUMMARY

Transportation system planning has traditionally focused on the road and transit facilities needed in the future to handle expected travel demands. This has led to a process heavily dominated by capital projects and methodologies aimed at expanding the physical capacity of the system. Starting in the 1970s, many transportation professionals became interested in examining strategies to enhance the performance of the transportation system through operational improvements. This chapter has examined this approach to operations planning. The process involves many different actors in a state or regional transportation system, from the providers of transportation services to those who plan and finance the system. With the advent of intelligent transportation system (ITS) technologies in the 1990s, many transportation agencies have implemented advanced surveillance and information technologies for managing system operations. This characteristic of transportation system operation will likely continue in future years.

Operations management has traditionally focused on "keeping the system(s) running by implementing a variety of projects to improve travel safety, reduce congestion, or increase capacity (traffic flow or throughput)." Given growth in traffic volumes, the lag time in getting construction projects online, the complexity of the operational improvements that are implemented and key societal trends, system operations must be thought of as more than just a project to resolve a problem. The operation of the transportation system is both a short-term project and a long-term strategy that will enable a continuous, high level of performance under varying conditions and demands. This concept extends well beyond thinking of operations as merely a project or a process that responds to a problem situation. To be effective in sustaining performance and efficiency as well as meeting user expectations, operations and the implementation of operational improvements must be recognized as essential strategies for system management, and they should be formally and strategically planned through the coordination between planning and operations.

As the operations community looks to expand its role in the regional transportation planning process, these multi-agency working relationships can be significant.

For *planners*, collaboration with operators can:

- Help them better understand how operational strategies can meet regional transportation goals.
- Provide access to systemwide, 24-hour travel data that can be used to better characterize existing system performance and travel conditions, identify the most critical transportation problems, and prioritize funding.
- Provide operations data and expertise to improve forecasts of future conditions, broaden the understanding of existing conditions, and analyze the effectiveness of alternative investments.
- Foster greater consideration of the day-to-day functioning of the transportation network and the real conditions facing travelers, which can help frame transportation goals, objectives, and priorities.
- Reveal how transportation plans can address issues such as reliability, security, and safety—issues that are difficult to address solely with traditional infrastructure investments.

For *operators*, collaboration and coordination with planners can:

- Help operators have a greater understanding of how the long-range planning process supports transportation system management and operations (TSM&O) activities and how such activities fit into the context of regional goals and objectives.
- Provide increased opportunities and incentives for getting involved in the planning process, thereby, helping shape system goals and objectives.
- Provide regional leadership and greater participation by stakeholders in regional TSM&O efforts.

- Clarify the role of operations in meeting the region's transportation vision and goals.
- Direct attention to the value of TSM&O strategies.
- Increase resources assigned to operations projects and programs.

Ultimately, greater coordination and collaboration among planners and operators improves transportation decision making and benefits the traveling public, businesses, and communities.

The ability to bring a multi-agency operations perspective to the planning table should enhance the decision-making process and result in increased system performance as, for example, when incidents get cleared in a timely and effective manner.

# Planning for Parking[1]

## I. INTRODUCTION

Parking is an essential component of a community's transportation system. The number and use of parking spaces vary widely among activities in each community, reflecting the size, intensity, and location of specific land uses; availability of alternative means of travel; and community attitudes about environmental quality and economic development. Most often the number of spaces is dictated by local zoning requirements that require minimum amounts of parking for the type and intensity of use at a particular location.

The traditional and still widely held view is that adequate and convenient parking must be provided for commerce and a community to thrive. For example, the planning advisory service of the American Planning Association (APA) receives more requests on parking requirements than any other topic. The Colliers 2012 North American Parking Rate Survey found that 55 percent of the 56 North American cities surveyed considered the downtown parking garage supply as "fair" (60 to 80 percent full), while 32 percent indicated it was "limited" and only 13 percent said "abundant." [Colliers International, 2012]

Conversely, some have argued that the incorporation of minimum parking requirements in zoning ordinances and the provision of free parking are primary causes of suburban sprawl that makes it difficult to achieve travel demand management (TDM) objectives (see chapter 14 on travel demand management). Shoup, for example, states that parking requirements in zoning ordinances constitute "a great American planning disaster" because they "subsidize cars, distort transportation choices, warp urban form, increase housing costs, burden low-income households, debase urban design, damage the economy, and degrade the environment." [Shoup, 2005]

When land cost or availability triggers the need to use structured parking, developers are far more likely to question the required number of spaces. In such instances, they are much more amenable to develop shared parking or TDM solutions or pass along the cost of parking to the users via fees. [MAPC, 2007] The market largely decides how much new commercial space is developed downtown with paid parking as opposed to in the suburbs with free surface parking. Free parking, zoning requirements, land value, and density are so subtly intertwined in the market lease rate of new space in a particular locale that one cannot point to any one factor such as free parking or parking zoning requirements as the dominant cause of travel behavior.

The availability and price of parking are also key determinants in mode choice, which is a major focus of transportation planning and policy. The reliance on the personal automobile—and the need to park it at both ends of a trip—has increased in the last two decades even as TDM strategies and the reduction of single-occupant vehicle (SOV) trips have been a central focus of many transportation planners. In particular, the price of parking is an important factor in travelers' decisions to drive. Parking fees are generally below the actual cost of owning and operating the space due to market forces—when most of the other parking in the community is free, it is difficult to charge a user the full cost of providing a space. Two general exceptions are: (1) core areas of the largest cities where monthly parking charges exceed $300 per month, and (2) airport parking (parking revenues constitute one of the largest revenue sources for airports).

It is unlikely that any fundamental change in parking markets will occur without sustained government intervention. In the mid-1990s, an initiative by three federal agencies to lower the cap on tax-free employer-provided parking from $165 per month to $135 per month or less never found congressional support and languished without action.

[1]The original chapter in Volume 3 of this handbook was written by Mary S. Smith, Senior Vice President, Walker Parking Consultants Inc. Changes made to this updated chapter are solely the responsibility of the editor.

Instead, in 1998, the Transportation Equity Act for the 21st Century (TEA-21) increased tax-favored benefits for employers and employees to a current (2015) $250 for parking and $130 transit and vanpooling. In 2012, only 16 U.S. cities had median monthly parking rates exceeding $175 per month. [Colliers International, 2012] Lowering the cap on employer-paid parking thus would only affect locations where parking is already market priced, and significant transit use and trip reduction already occur. In addition, lowering the parking benefit may encourage more tenants to move to the suburbs where parking is "free."

Unless and until government has the will to either mandate the unbundling of parking fees from all lease rates (that is, landlords charge parkers separately for parking spaces) and/or tax all employer-provided parking, which will require imputing a value of "free parking" in the suburbs, it is difficult to incorporate the real price of parking into a commuter's travel decision.

The next section describes typical organizational structures for parking management programs. The following section discusses parking zoning requirements, one of the most important factors in describing the amount and type of parking that is provided at all land uses. The types of strategies and decisions for parking supply options that reflect zoning and other factors and the combination of such strategies into parking management programs are discussed in the next two sections. The next three sections focus on the methodology for predicting parking demand and needs analysis, including the results associated with common land uses and a shared parking methodology. The next section discusses parking costs and how they are estimated as part of decision making, and the final section presents the key characteristics of parking finance.

## II. PARKING MANAGEMENT ORGANIZATIONS

Parking responsibilities in many cities are often fragmented among numerous departments or agencies. In a municipal context (with institutional equivalents in parentheses), public works (building and grounds) may control most of the physical aspects, such as building and maintaining on- and off-street facilities, the police department (security) provides enforcement, and finance (business office) is responsible for revenue collection. Typically, parking is far down the list of concerns and priorities of each department. Parking is often politicized and lacks clarity of goals and attention to implementation.

A more successful model is a professional organization that is responsible for all or nearly all functions associated with parking management. Where it is necessary and appropriate to have separate functions (for example, planning and zoning will continue to administer parking requirements), the parking management organization should have a designated liaison to coordinate and contribute to policy decisions.

Common goals for parking programs include:

- Revenue should be tied to expenses and operations as closely as possible. For example, parking meter revenue should be compared to the expense of obtaining the revenue. This principle holds true for all parking management functions, even those that have less revenue than expenses. This is especially true in programs that have privatized parking operations.
- Budget preparation, analysis, allocation, and adjustment should be under the control of the parking management organization.
- The locations of parking management functions within the city governmental structure should reflect the importance of parking management issues as they are perceived in the city.
- Parking management often includes monitoring and environmental regulatory requirements. The structure and budget of the parking management organization should be flexible enough to meet these responsibilities.

### A. Types of Parking Organizations

Most parking programs are part of a municipal transportation department. Parking enforcement is usually run by the transportation department as well, unless it is outsourced. This structure is particularly common for medium and small cities. However, for larger cities, three other types of parking organizations are often found—a parking authority, separate department, or a nonprofit organization. Each is described here.

### Parking Authority

A parking authority offers more independence than a city department or division. Authorities are able to issue bonds for the construction of new parking facilities when empowered by state-enabling legislation. As part of the extended city government, an authority can have the same personnel policies (if desired), particularly if most or all of the personnel have been in city departments previously. This organizational structure allows considerable flexibility and the ability to respond to issues quickly.

### Separate Department

Many cities have separated the transportation and parking functions from public works and have created a department devoted solely to parking. The primary advantage of such a structure is to emphasize the importance of transportation and parking issues for the city and its citizens. Generally, there will be less conflict of interest and more focus on these issues, and the coordination of parking and street traffic activities will be improved. Above all, there will be fewer layers between the parking manager and the municipal chief executive officer (CEO—mayor) and chief operating officer (COO—city manager). The creation of a new department would have to be based on municipal law.

### Nonprofit Organization

One of the more recent institutional models for parking management is a nonprofit organization (NPO) charged with the specific needs and concerns of an activity center such as a downtown or suburban major employment center. Aside from the enabling legislation, the main difference between an NPO and a parking authority is that a nonprofit organization may have a broader perspective on transportation issues than a parking authority, which would be focused solely on parking. Both may be concerned with supporting and encouraging the economic vitality of an activity center, but the NPO might be involved in many more transportation and nontransportation activities.

Table 11-1 summarizes the strengths and weaknesses of these three options. It is important to note that many communities have moved to a privatized model of parking management. In this model, communities accept a tender for a private company to enforce parking meters and share in the revenues. The contract regulates parking rates, operating standards, and maintenance of all parking assets, but the actual operation (enforcement, for example) is the responsibility of the concessionaire. Even in these programs, however, the community needs to have some centralized parking policy and planning function in the government.

### Parking Management as an Enterprise Fund

A parking management organization could operate as an enterprise fund under any of the previously discussed organizational structures. The defining characteristic of an enterprise fund organization is that it must generate sufficient revenue to cover its immediate expenses as well as for investment in necessary assets for the future as necessary. For parking, this means an enterprise fund would need to cover operating costs, debt service, debt service reserve funds (or any other required funds connected with bond issues) and sinking or reserve funds for significant future construction or maintenance.

A parking enterprise fund requires parking activities to be self-sufficient and that they be managed like a business, most importantly, generating income in excess of expenses. This does not mean that the primary purpose of parking management is to generate profit; rather, parking investment decisions need to consider the relationship between expected revenues and expenses. In some cases, the executive order or legislation creating an enterprise fund specifies the level of excess revenue that may remain in the enterprise fund and the disposition of any additional revenue.

## III. ZONING REQUIREMENTS[2]

Community zoning and planning guidelines often require a minimum number of parking spaces for a proposed development, depending on the type of development and other means of accessing a site, for example, transit. Zoning standards typically include formulas for determining how many parking spaces must be provided for specific types of land uses. The intent of most local governments is to require property owners to provide sufficient off-street parking spaces without spillover demand, that is, overflow onto public streets or adjacent private property. An example of a parking zoning requirement from Eugene, Oregon, is shown in Table 11-2.

[2]Note that part of the following discussion was paraphrased by the original author from the Parking Consultants Council update of *Recommended Zoning Ordinance Provisions for Parking*, 2007.

| Table 11-1. Strengths and Weaknesses of Parking Organizational Structures | | |
|---|---|---|
| | **Strengths** | **Weaknesses** |
| Independent parking authority | • Parking functions are placed in an entity with one purpose—to deliver parking.<br>• Can maintain some independence while also working closely with the city.<br>• Requires a board of directors to set policy, maintain fiscal responsibility, and guide staff.<br>• Easy to create new positions/set salary scales different from government and initiate rewards based on merit.<br>• Can make decisions and implement programs quickly.<br>• Has power to issue bonds to finance projects.<br>• Can also benefit from city guarantee. | • Responsible for debt.<br>• New legislation is often required (state and local).<br>• Boards of directors can sometimes be unwieldy or cumbersome depending on requirements.<br>• Civil service may make transferring employees difficult and cumbersome. |
| Nonprofit organization | • Parking functions are placed in an entity with one purpose—to deliver parking.<br>• Can maintain some independence while also working closely with the city.<br>• Flexibility regarding the size and characteristics of the board of directors.<br>• Easy to create new positions, set salary scales different from government, and initiate rewards based on merit.<br>• Can make decisions and implement programs quickly. | • The ability to issue bonds, while possible, may be more difficult and complex.<br>• New legislation could be required to delegate functions.<br>• Civil service may make transferring employees difficult and cumbersome. |
| City department | • Easy to transfer employees from other city departments.<br>• New positions can be created under civil service regulations, which are less subject to political pressure.<br>• Easy to earmark revenues for general fund activities. | • Parking gets buried in bureaucracy and does not receive the needed attention.<br>• Parking policy more likely to remain the purview of staff and elected officials unless citizen advisory committee formed.<br>• Civil service and budgeting process can be cumbersome and time consuming.<br>• Financing for parking facilities must compete with other municipal projects if general obligation bonds are requested. |

Zoning policies that require an excessive amount of parking spaces are inefficient and costly because the land area and resources devoted to parking spaces reduce the amount of development that could have occurred on the site. Based on studies of density before and after parking requirements were added to the zoning ordinance of Oakland, California, Shoup [2005] concluded that the parking requirements increased the cost per dwelling unit by 18 percent, decreased density by 30 percent, and lowered land values by 33 percent. A study by Willson [1997] estimated that increasing the parking requirement for an office building from 2.5 to 3.8 spaces/1,000 sq. feet (3.7 to 4.1 spaces/100 $m^2$) would reduce density by 18 percent and land values by 32 percent.

Excessive paved parking areas are also undesirable to the community from both an aesthetic and an environmental perspective.

| Table 11-2. Example of a Parking Zoning Ordinance, Eugene, Oregon | |
|---|---|
| **Required Off-Street Motor Vehicle Parking** | |
| **Uses** | **Minimum Number of Required Off-Street Parking Spaces** |
| **Residential Dwelling** | |
| One-family dwelling | 1 per dwelling |
| One-family dwelling – Flag lot | 2 per dwelling |
| Secondary dwelling (either attached or detached from primary one-family dwelling on same lot) | 1 per dwelling |
| Rowhouse (one-family on own lot attached or adjacent residence on separate lot with garage or carport access to rear of the lot) | 1 per dwelling |
| Duplex (two-family attached on same lot) | 1 per dwelling |
| Triplex (three-family attached on same lot) | 1 per dwelling |
| Four-plex (four-family attached on same lot) | 1 per dwelling |
| Multiple-family (three or more dwellings on same lot) not specifically addressed elsewhere | 1 per dwelling |
| Multiple-family in the R-3 an R-4 zones within the boundaries of the City recognized West University Neighbors and South University Neighborhood Association. | 1 space per each studio, 1 bedroom or 2 bedroom dwelling.<br>1.5 spaces for each 3 bedroom dwelling (0.5 spaces required for each additional bedroom beyond a three-bedroom dwelling).<br>Fractions of 0.5 or more are rounded up to the next whole number. Rounding shall occur after the total number of minimum spaces is calculated for the multifamily development.<br>One tandem space shall be counted as two parking spaces.<br>Tandem spaces shall not be allowed for studio or 1- or 2-bedroom dwellings. |
| Multiple-family subsidized low-income housing in any area | 0.67 per dwelling or 3 spaces, whichever is greater |
| Multiple-family subsidized low-income senior housing in any area | 0.33 per dwelling or 3 spaces whichever is greater |
| Multiple-family subsidized low-income disabled housing in any area | 0.33 per dwelling or 3 spaces, whichever is greater |
| Multiple-family subsidized low-income senior housing partial in any area | 0.67 per dwelling or 3 spaces, whichever is greater |
| Multiple-family subsidized low-income specialized housing in any area | 0.33 per dwelling or 3 spaces, whichever is greater |
| Manufactured home park | 1 per dwelling |
| Controlled home and rent housing where density is above that usually permitted in the zoning, yet not to exceed 150% | 1 per dwelling |

## A. Minimums or Maxima?

Many transportation professionals and city officials have debated whether parking ordinances should require a maximum or minimum amount of parking, or both. Some of the early recommendations reflected the proximity of transit services, for example, minimums and maxima could be provided for various land uses as a function of distance from transit stops. [Weant and Levinson, 1990] In Boston, for example, there is no required parking in the central business district (CBD) that is served with many transit lines, but there is a cap on total commercial parking spaces (implemented primarily for environmental quality reasons). All owners of parking, other than residential, must have a

license for the number of spaces provided. Any developer wishing to develop new parking must buy out enough licenses to cover the number of spaces proposed, and the older facilities must close. There is also an extensive park-and-ride system in the area.

Other cities with maximum, rather than minimum, parking requirements include London and San Francisco. London changed its parking policy from minimums to maxima in the late 1960s; the new maximum ratios were generally less than half the former minimum values. San Francisco also limits parking in the CBD.

In Manhattan, land values are so high that new developments provide only the bare minimum of spaces necessary to finance and lease the building; in many cases, no parking is provided. The high market price of parking (the median for unreserved monthly parking in midtown and downtown Manhattan in 2012 was over $562/month) strongly influences the choice of using transit to commute to Manhattan. [Collier International. 2012] Reimbursement by employers for parking charges also affects the decision to drive and park. A 2007 study, for example, found that 38 percent of motorists parking in Midtown and Lower Manhattan have free parking provided or reimbursed by their employers, and an additional 19 percent park at unmetered on-street spaces. [Transportation Alternatives, 2007]

A study of residential parking in the Bronx and Brooklyn provided some interesting observations:

- Car ownership varied according to factors including geography, household characteristics, and building size, but not the amount of parking required by zoning.
- Vehicle ownership varied from building to building, making shared-parking resources important.
- In zoning districts, required parking is often waived for smaller buildings and sites, substantially lowering the effective parking requirement.
- Car-owning households make decisions about where to park based on the options available in their neighborhood, not just in their building.
- Inner Ring residents generally pay a fee for off-street parking, though the amount they pay varies.
- The often substantial costs of providing parking and the revenues generated by parking are important factors in developers' decisions about whether to build parking.
- Affordable housing is more susceptible than market-rate housing to the cost implications of requiring accessory parking, and its residents own fewer vehicles. [New York City, 2013]

Some have wondered if property developers would actually reduce parking if parking requirements were lowered or waived. For example, office developers, as well as their lenders and tenants, usually want to provide as much parking as other competitive buildings. This tends to perpetuate parking requirements based on *wants* rather than *needs*. Today, the number of spaces provided by competitors is often mandated by minimum parking requirements in the local zoning ordinance. However, history has shown that if there is justification for reductions, developers will embrace them. This is evident in the reduction of accepted parking ratios for shopping centers that has occurred over time. If the marketplace is allowed to establish a better, more natural equilibrium on how many spaces are required, and if shared parking, higher density, and better pedestrian connections are encouraged in zoning ordinances, parking ratios will likely decline over time.

In sum, parking zoning requirements need to trade off the problems of spillover parking because insufficient parking was provided and the potential negative impacts of over-requiring parking. As early as 1964, the American Society of Planning Officials (now known as the American Planning Association) was warning against employing a single standard for parking space requirements:

> *"No one set of standards, with the exception of off-street parking for industrial use, is recommended. The underlying assumptions used in drafting local regulations are often unknown and may not be applicable to other localities. The best approach, of course, is to develop off-street parking requirements based on local parking and traffic studies and the characteristics of the various zoning ordinance use districts." [Weant and Levinson, 1990]*

The suggestions were further outlined in a report from the American Planning Association called, *Flexible Parking Requirements* [Smith, 1983], which has been periodically updated to become one of the leading technical guides on parking standards. A more recent observation comes from Shoup [2014]:

> *"Minimum parking requirements limit urban development. They often force developers to provide more parking than necessary, or to construct smaller buildings than the zoning allows. Parking requirements promote an unsustainable city. If cities require ample off-street parking everywhere, most people will continue to drive everywhere …… cities get the traffic they plan for and the behavior they subsidize."*

It seems likely that as cities begin to adopt policies on sustainability and livable/walkable communities, removing the minimum requirement for parking will be part of the strategy.

## B. Flexibility in Zoning Requirements

Parking in urban areas serves many different markets. Thus, parking demands will vary depending on the types and locations of land uses and activities that occur in a typical day. Key variables for a particular site include the size of buildings, access and distance to public transit, ridesharing patterns, shared parking, and applicable zoning requirements. If parking fees are charged in a CBD or activity center, the amount of required parking may be substantially different from an activity center having no fees. The traditional means of accommodating varying parking demands include using different parking requirements in different zoning districts, planned unit development permits, and special and conditional use permits (see chapter 3 on land use and urban design).

Zoning ordinances can be used to adjust parking requirements for different land use contexts. Some of the provisions by which cities are building flexibility into parking requirements include: (1) shared parking, (2) fees-in-lieu, (3) off-site parking, (4) credits for ridesharing programs, (5) credits for public transportation accessibility, and (6) accepting a credible parking study that evaluates the site-specific circumstances and expected demand.

The Parking Consultants Council's *Recommended Zoning Ordinance Provisions* [2007] recommends language to protect a city's interests while allowing flexibility to address the most common circumstances that influence parking demand. In addition to addressing changes in ownership and land use issues, certain adjustments to parking requirements can be handled by specifying a development credit that can routinely be taken if an analysis has been made of parking demand by a qualified parking or traffic consultant. Further, flexibility in zoning ordinances might require a developer or owner to provide additional parking in later years up to a certain threshold if the city finds that projected demand is exceeded. This *land bank* provision requires the developer to submit a plan detailing how additional spaces could later be provided in either surface lots or structures. The developer who does not wish to accept the land bank condition must go through the normal zoning variance procedure, usually appearing before a zoning board of appeals or a city council to receive a permanent, irrevocable reduction in the requirements. In some cases, land banking provides all parties with a necessary level of comfort for a lower parking ratio. The developer can provide more green space on the site initially and then apply to have the pledge released and/or a permanent variance issued after a period of successful operation at the lower ratio.

Some additional options for parking flexibility in zoning requirements include:

- *Captive Market*—A captive market is one where potential consumers face a very limited number of competitive suppliers, in this case, parking spaces. It often occurs among land uses that are not self-contained within a development. The captive market effect is one of the most significant determinants of parking demand in CBDs. Therefore, a zoning ordinance should allow parking requirements to be adjusted for captive market effects independent of shared parking effects.
- *Fees-in-lieu*. It may be in the best interests of a city to develop public parking in a densely developed activity center, rather than have property owners provide their own parking. With the high cost of constructing a parking structure and with the competing demands on city resources, a number of cities have asked developers (who will directly benefit with reduced parking space requirements) to pay some or all of the costs of developing parking in municipal facilities.
    - A problem with this strategy occurs when development is slow, small, or randomly located. If funds are available to develop parking in reasonable proximity to each development in a timely manner, a developer

might be willing to enter into such an agreement. However, a developer who has contributed $100,000 to a fund in lieu of 10 parking spaces does not want the funds to sit for five years waiting for more money to become available, or for it to be used to fund a parking structure six blocks away. Success is more likely when rapid development is expected in a defined area and when an off-street parking facility is or will be available on a set schedule and connected to the sites that are providing the funds.

- *Off-Site Parking*—Many cities have added clauses in their zoning that allow for off-site parking to be substituted for on-site parking under certain conditions.
- *Ridesharing*—Ridesharing generally refers to various forms of carpooling, vanpooling, and subscription bus service associated with employees' trips to and from work. Properly formulated ridesharing programs can reduce both traffic and parking demand. Zoning credits for ridesharing programs are a particularly effective means of achieving transportation management goals. Ridesharing credits are also a means of adjusting parking requirements for any development site that runs a dedicated shuttle. The most common application is hotels that cater to those wanting convenient access to an airport. However, other sites may also run shuttles and thus merit reduced parking requirements.
- *Right-Sizing Parking*—Parking rates are often available for development types that are not similar in context to what is being proposed. For example, suburban parking rates would likely be inappropriate for urban sites. Right-sizing of parking supply ties the amount of parking to the needs and parking goals of the site and community by conducting a parking demand study and linking the results to the types of needed strategies.
- *Shared Parking*—The Urban Land Institute's (ULI's) *Shared Parking* [Smith, 2005] provides a methodology for calculating shared parking effects without resorting to a single, catch-all formula (see later section on shared parking).
- *Transit*—Even smaller communities may have areas that are well served by public transit. A reasonable reduction in the parking requirements for developments within a certain distance of a regularly scheduled transit service might be appropriate.

An example of flexibility in zoning requirements comes from San Diego where local communities have used a variety of techniques as part of the region's Smart Growth policy. Here are some examples:

- The city of Carlsbad offers density bonus incentives to affordable housing developments. The following multifamily dwelling unit rates apply: 0- to 1-bedroom unit requires 1 parking space and a 2- to 3-bedroom unit requires 2 parking spaces.
- The city of Escondido reduces its standard retail parking requirements to 3 spaces per 1,000 square feet of gross floor area in the downtown retail core parking district.
- The city of El Cajon provides allowances for parking in smart growth settings within the downtown area.
- The city of La Mesa allows parking reductions in their Mixed-Use Urban Overlay Zone. They allow a minimum of 2 parking spaces per 1,000 square feet of commercial floor area.
- The city of San Diego offers parking reductions for developments located in the Transit Overlay Zone or developments that are deemed "very-low" income. Multifamily residential requirements are reduced as follows: studio units require 1 space, 1-bedroom units require 1.25 spaces, 2-bedroom units require 1.75 spaces, and 3-plus-bedroom units require 2 spaces. Commercial office requirements are reduced to 1.0–2.9 spaces per 1,000 square feet. Retail requirements are reduced to 1.0–4.3 spaces per 1,000 square feet.
- The city of Chula Vista details special parking requirements for their Urban Core Specific Plan area. Residential multifamily units in the transit focus area have the reduced requirement of 1 parking space per dwelling unit.
- The city of Coronado provides reduced parking requirements for the Orange Avenue Corridor Specific Plan. Commercial parking requirements are reduced to 1 parking space per 500 square feet of floor area. The city also provides reductions for affordable housing. [SANDAG, 2010]

Other examples are noted in [MAPC, 2010] and include: (1) Los Angeles allows a reduction of 0.5 spaces per unit for deed-restricted affordable units and additional reductions for units within 1,500 feet of a transit line;

(2) Eugene, Oregon, allows reduction of parking requirements on a case-by-case basis, subject to a parking study documenting that the reduced amount of parking will be sufficient; (3) Seattle grants reductions in minimum parking requirements for affordable housing (down to 0.5 to 1 space per unit, depending on income, location, and unit size), housing for seniors or people with disabilities, multi-family developments with car-sharing programs, and developments in dense, mixed-use neighborhoods; (4) Santa Monica, California, reduces parking from 2 spaces per unit to 1.5 for two bedroom affordable housing units; and (5) Hartford, Connecticut, allows reductions of up to 30 percent of required parking in exchange for implementing TDM programs such as discounted carpool parking, rideshare promotions, subsidized transit passes and shuttle services to off-site parking. See also [PSRC, undated].

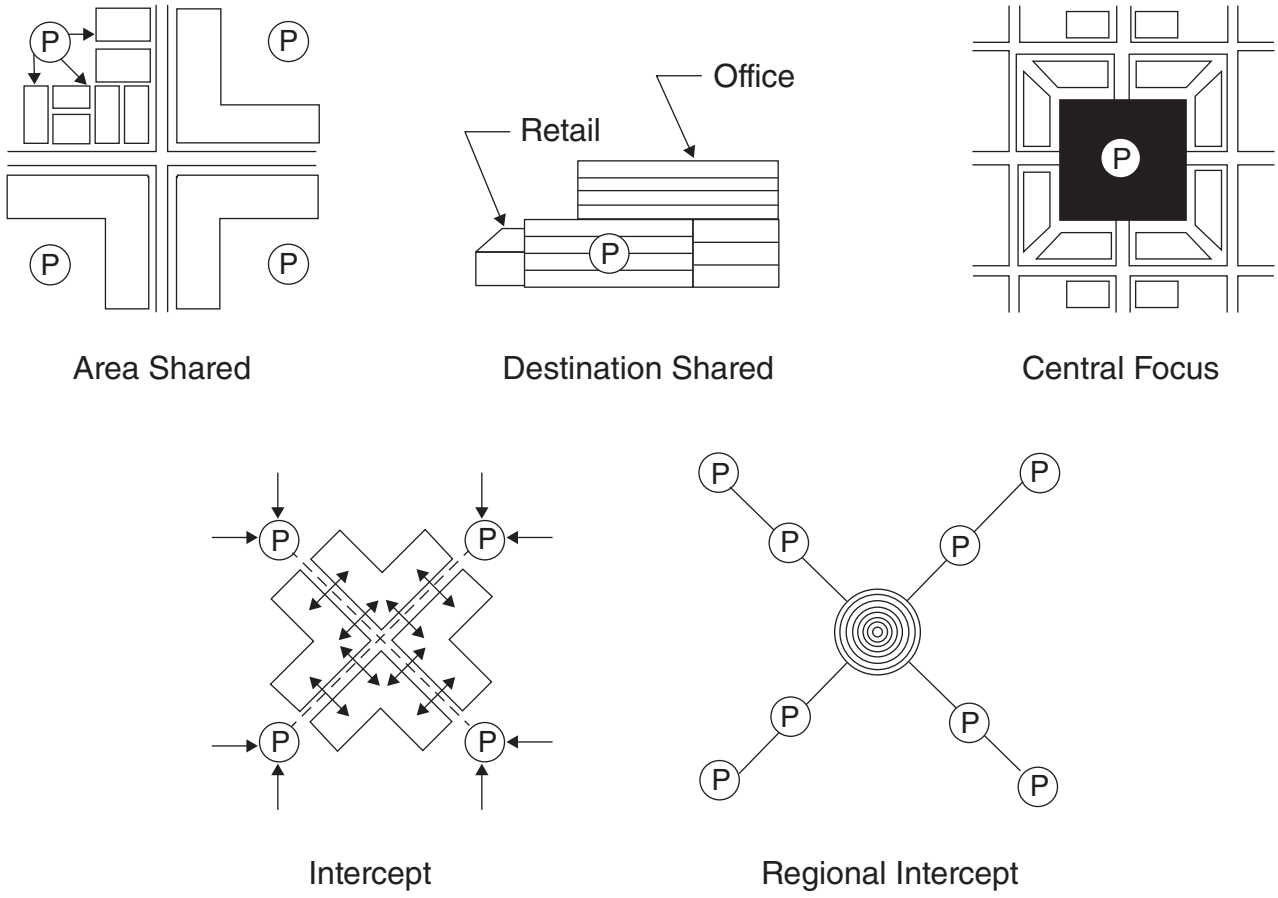
# IV. STRATEGIES AND DECISIONS FOR PARKING SUPPLY OPTIONS

## A. Parking Strategy Concepts

At a strategic level, a region or community can conceptualize parking strategies in very broad terms. For example, five conceptual models of parking development were defined and analyzed in a downtown parking study for Denver. [Walker Parking Consultants, 1992] Although dated, these models are still relevant today in terms of different parking supply strategies that might be considered by a community. They provide a useful means of evaluating alternatives for parking expansion. Note that different strategies may be required for long- and short-term parking. Figure 11-1 shows the five major parking management strategies that were considered in this study.

The study defined a base alternative, called a laissez-faire alternative, as a reference for the other alternatives. In this alternative, the private sector and financing requirements for new development dictated how much and what type of parking was provided for new and existing parking demand. Parking was neither required nor constrained by

**Figure 11-1. Alternative Parking Development Scenarios, Denver**



Source: Walker Parking Consultants, Inc., 1992

zoning, but was allowed as a use by right. The laissez faire model currently flourishes in many cities and suburban areas. The laissez faire solution is essentially market-driven and, therefore, parking locations are completely flexible and unplanned—the product of economic development, demolition of buildings, and parking needs as required by financial institutions and developers for new projects. This approach for both long- and short-term parking has been highly successful in such cities as Indianapolis, which had never required parking in its downtown. The city has not intervened in the private marketplace; it has only built public parking facilities for publicly financed projects. Instead, there is a flourishing private parking system that charges market rates for parking and offers multiple pricing options based on convenience to destinations in the CBD.

*Area-Shared*. An area-shared parking model provides parking for essentially all uses within a reasonable walking distance. This model is often employed by cities that provide parking for the CBD, but it is also found in commercial operations that provide parking for a particular area. Public/private joint ventures are also an option. An excellent example of an area-shared project is the Post Office Square facility in Boston. Developed by a public-private consortium, an inadequate and antiquated 750 space, above-ground parking structure was torn down and replaced by a 1,400-space underground garage. At street level, the top of the parking structure was a park themed as a public square.

*Destination-Shared*. Similar to the area-shared model, the destination-shared model targets a specific project or several uses near each other. This model suggests private-sector development rather than public investment. However, some destination-shared parking facilities might be joint public-private venture opportunities. Public-private partnerships could occur where a specific project receives a subsidy to build parking or where the city builds a parking structure and leases the air rights for a mixed-use development built by a private developer. An excellent example is the World of Wonders garage at Circle Centre in downtown Indianapolis. The World of Wonders garage not only serves Circle Centre but also the nearby Indiana Convention Center and RCA Dome.

The destination-shared model is intended to minimize parking occurring indiscriminately throughout the activity center. The model is based on the conventional development context, wherein each individual project is constructed with its own individual parking facilities. The difference between this model and the laissez-faire model is that the destination-shared concept specifically identifies where parking structures will be permitted, and these structures are built in such a manner as to permit sharing among a number of destinations.

*Central Focus*. The central focus model creates a large, centralized parking facility in the center of a zone with a pedestrian distribution system connecting the facility to many diverse destinations. A good example is the Grant Park underground parking facility in Chicago, which runs several blocks on the lakefront, providing substantial parking for many uses within the area that do not have their own parking facilities. The central focus parking concept could be a depressed, below-grade structure with either air rights development or park and green space on the top.

Good vehicular access in the center of activity is essential. Otherwise, by bringing all of the vehicles within a core area, a centralized parking facility could create additional congestion, result in air pollution, or produce other negative impacts.

*Intercept*. This model intercepts parkers at the perimeter of an activity center. In larger cities where the intercept would occur more than 1,000 ft from the core, the intercept model depends on a shuttle system to move the parker conveniently, quickly, and economically to destinations within the core. The intercept model is based on the philosophy that auto congestion within the core creates air pollution and unnecessary congestion, and that the environment within the activity center should be kept pedestrian in scale and free of auto traffic. Many university campuses, for example, have adopted a strategy of moving parking to the periphery to intercept traffic so that new buildings can be built on parking lots.

However, given the laissez-faire parking development policy in many activity centers today, there is simply too much parking to adopt the intercept concept. To encourage the use of intercept parking, parking rates must be considerably higher than those in the intercept lots. Simply providing intercept parking is not enough; the program must be accompanied by disincentives to park within the core. Likewise, the availability of surface parking lots and parking structures within the core must be reduced, so as to force long-term employee parking to the perimeter.

Shorter-term shopping trips or residential parking in close proximity to residential units do not work with intercept parking; therefore, the intercept concept generally is combined with short-term parking within the core and destination-shared parking near residential units. This is the model employed in larger cities such as Chicago where monthly parking rates for unreserved spaces in the central core are as high as $425 per month, but all day parking in the fringe is available for as low as $100 per month ($2015).

*Regional Intercept*. Much like the intercept model, the regional intercept model intercepts parkers farther away from the activity center. The benefits are similar to the intercept model, in addition to further improving air quality.

The key to a viable solution is a regional transportation system that offers rapid, reliable, and convenient access to the activity center. This approach offers close-in, destination-shared parking for short-term and residential parking needs, while employee long-term parking would be intercepted at regional facilities built along high-occupancy vehicle (HOV) and express transit corridors most often at freeway interchanges. Most cities that employ this strategy successfully have rail transit, including Atlanta, New York City, San Francisco, and Washington, DC. However, a few, such as Ottawa, Ontario, and Pittsburgh, are keyed to bus or busway systems.

Although the five models just described were presented individually, in reality, a combination of options can be applied in many cities. For example, Calgary, Alberta, has actively pursued *destination-shared* facilities for short-term parking and the *intercept model* for the employees either at the CBD or at dispersed regional locations to encourage transit use.

Table 11-3 shows how the various combinations of strategies support the strategy goals of a city, in this case, Denver. The options of interest to Denver officials were destination-shared facilities for short-term parking together with destination-shared or intercept options for long-term parking.

**Table 11-3. Effect of Parking Development Scenarios on Mobility Goals**

| **Short-Term Strategy** | **Laissez-Faire** | **Destination-Shared** | **Destination-Shared** | **Destination-Shared** | **Destination-Shared** | **Destination-Shared** |
|---|---|---|---|---|---|---|

## B. Community and Parking Program Goals

The types of strategies included in a parking management program will reflect the community's overall goals and/or the specific goals for its parking program, if such have been articulated. The following list from the city of Ottawa illustrates typical goals for a parking management program:

- Provide and maintain an appropriate supply of affordable, secure, accessible, convenient, and appealing public parking.
- Provide and promote affordable short-term parking services, and fair and consistent enforcement services, that support local businesses, institutions, and tourism.
- Promote, establish, and maintain programs and facilities that encourage the use of alternative modes of transportation, including public transit, car/vanpooling, taxis, auto sharing, cycling, and walking.
- Support residential intensification and resolve parking problems within residential areas caused by significant traffic generators or conflicting uses of the roadway, including implementing on-street permit parking programs to relieve area residents and visitors from parking regulations directed at the nonresident.
- Ensure the revenues generated by the municipal parking program are sufficient to wholly recover all related operating and life-cycle maintenance expenditures; contribute to a reserve fund to finance future parking system development, operation, and promotion; and then assist in the funding of related initiatives to encourage the use of alternative modes of transportation. [City of Ottawa, 2009]

An example of parking goals and corresponding strategies from a small community comes from Corona del Mar, California, where a variety of parking management strategies were being considered. [Corona del Mar, undated] Table 11-4 shows the range of strategies and corresponding goals.

Master development plans often include more specific goals or principles that guide the consideration of parking actions in the development concept. For example, the following principles were used for the parking management plan for a major development in Chula Vista, California.

- Encourage a "park once, walk further" environment. Strategies seek to create and support a "park-once" district, in which people will be able to park once and use the extensive network of pedestrian facilities and walk further to multiple destinations.
- Parking should not be overprescribed and should be right-sized. The goal of the parking management plan (PMP) is to find the correct balance between providing adequate parking to support the requirements of an emerging planned commercial development while minimizing the negative aspects of excessive land area or resources devoted to parking.
- Total commercial parking demand will consider walkability, transit, and mixed-use reductions. Adjustments are made to account for the number of people who arrive at the project site by means other than a personal vehicle, who make other stops within the project by foot or bike after parking once, and to account for the mixed use character of the development. It is anticipated that these elements will be implemented in the project over time and that their benefits will be realized as the project is implemented.
- Shared parking, when feasible. Shared parking is the use of a parking space to serve two or more individual land uses without conflict or encroachment. The degree at which shared parking can be implemented will be dependent on the location, timing, and types of commercial land uses in the plan.
- Provide flexible and evolving PMP to accommodate uncertainty and change. The PMP responds to the fact that the proposed land uses will be market-driven and will require implementation strategies which are adaptable, based on evolving market conditions, and incentive-based.
- Conformity with the project and form based code requirements with alternative/refined parking ratios. Provide for monitoring of the parking supply by the master developer and future Parking District Council to refine the parking ratios over time. [Nelson Nygaard and Linscott, Law, and Greenspan, 2015]

No one action or tactic can simultaneously achieve all desired goals (minimize auto usage and traffic congestion, maximize transit patronage, provide adequate parking, foster economic growth, among others). This is partly because

**Table 11-4. Example Strategies and Goals from Corona del Mar, California**

| Strategies | Goals | Components |
|---|---|---|
| **Strategy 1**<br>Short Term<br>Revise the zoning code to create appropriate development standards. | • Parking Supply = Parking Demand in Corona del Mar<br>• More flexible regulations<br>• Empower creative solutions<br>• Maximize use of existing parking supply<br>• Increase convenience and attractiveness of biking | • All non residential uses = 2 spaces per 1,000 square feet<br>• Exempt small add-ons and use changes (<5,000 square feet) from minimum parking requirements.<br>• Establish an optional parking in-lieu fee to meet parking requirements.<br>• Allow for shared parking among different land uses by right.<br>• Establish bicycle parking requirements for all new non residential development. |
| **Strategy 2**<br>Short Term<br>Extend the time limits on Highway 1 and adjust pricing in off-street lots. | • Add flexibility and convenience for visitors.<br>• Ensure turnover and prevent long-term parking in most convenient spaces.<br>• Encourage use of underutilized off-street lots. | • Extend time limit to two hours on Highway 1 from Avocado Avenue to Hazel Drive.<br>• All existing public off-street lots retain 10-hour limits, but would become free of charge. |
| **Strategy 3**<br>Short Term<br>Increase public parking supply through shared parking agreements with willing private property owners. | • Cost-effectively increase supply of public parking.<br>• Encourage use of underutilized off-street lots/garages. | • Conduct additional outreach to property owners as a means to increase the supply of publicly available off-street parking.<br>• Work with private parking lot owners to maximize the use and value of their parking lots.<br>• Key issues for further study: displacement of current tenants, managing liability and insurance, maintenance and operations, and cost sharing. |
| **Strategy 4**<br>Short Term<br>Better manage employee parking. | • Reduce employee parking spillover into residential neighborhoods.<br>• Maximize use of existing parking supply. | • The city would designate specific off-street lots or garages for employee parking only during specific hours.<br>• Employers could purchase permits on behalf of employees.<br>• Additional incentives should be offered to employees to reduce driving. |
| **Strategy 5**<br>Short Term<br>Restripe existing parking to maximize parking supply. | • Maximize use of existing parking supply. | • Review and restripe as feasible mid-block red curbs on highway.<br>• Restripe existing lots to maximize parking supply. |
| **Strategy 6**<br>Short Term<br>Increase supply of secure and convenient bicycle parking. | • Provide secure bicycle storage.<br>• Create a more welcoming environment for potential bicycle riders.<br>• Encourage bicycle trips as a way to reduce the demand for automobile parking. | • Install bicycle parking at high-volume locations.<br>• Potential locations include: Clock Tower, Port Theater, Starbucks (East Coast Highway at Goldenrod), and Rose Bakery Café. |

(*continued*)

Table 11-4. (*Continued*)

| Strategies | Goals | Components |
|---|---|---|
| **Strategy 7**<br>Short Term<br>Improve awareness of and access to underutilized parking facilities with way finding improvements. | • Improve customer convenience.<br>• Ensure awareness of existing parking resources.<br>• Reduce congestion associated with searching for parking. | • Develop a coordinated way finding program for public and private lots.<br>• Reduce the amount of unnecessary parking signage where feasible, especially in private lots.<br>• Develop coordinated signage for use in private lots.<br>• Supplement parking signage with area maps for pedestrians. |
| **Strategy 8**<br>Short Term<br>Establish a monitoring and evaluation program. | • Facilitate timely adjustments to parking plan and strategies as parking conditions evolve. | • Collect annual parking occupancy data to calibrate parking demand in the area and determine whether ongoing adjustments are needed. |
| **Strategy 9**<br>Long Term<br>If needed, implement pricing to ensure parking availability. | • More convenient and accessible for residents and visitors.<br>• Generate adequate turnover. | • *Meter location*: Highway 1 (Avocado Avenue to Poppy Avenue), all public lots/garages<br>• *Meter type*: Include credit cards, pay-by-phone, and wireless technology<br>• *Target occupancy rates*: 85% (on-street) and 90% (off-street)<br>• *Hours*: To be determined<br>• *Pricing*: As low as needed to achieve target rates<br>• *Parking revenue*: Net revenue reserved for local improvements |
| **Strategy 10**<br>Long Term<br>If supported by residents, consider a residential permit program (RPP). | • Mitigate impacts of spillover parking into residential neighborhoods. | • *District initiation*: Only if spillover problem and strong community support<br>• *District boundaries*: Limited to areas impacted by spillover parking<br>• *Eligibility*: Restricted to district residents<br>• *Hours of operation*: 2-hour parking, 8 a.m.–6 p.m., Monday–Saturday<br>• *Permit type*: "Virtual" permits for residents, "hangtags" for guests/visitors<br>• *Number of permits issued*: Limited number per household<br>• *Guest parking*: One free annual pass, option to purchase temporary passes |
| **Strategy 11**<br>Long Term<br>If needed, implement a free shuttle service to remote parking facilities. | • Manage parking impacts during periods of high demand. | • Provide a free shuttle service to ensure access for non-residents.<br>• Potential routes to remote parking facilities at Fashion Island or City Hall<br>• Could be limited to weekend and/or summer peak periods |

| Table 11-4. (*Continued*) | | |
|---|---|---|
| **Strategies** | **Goals** | **Components** |
| **Strategy 12**<br>Long Term<br>As needed, implement a peak period valet service. | • Facilitate convenient drop-off and pick-up in areas of high parking demand.<br>• Enable more efficient use of parking supply. | • *Time of operation*: Holiday seasons; Friday evenings (6–10 p.m.), and Saturdays (12–10 p.m.)<br>• *Cost, Option A*: Free, if locally subsidized<br>• *Cost, Option B*: $6 w/o validation; $3 w/ validation<br>• *Drop-off/pick-up locations*: Along Highway 1; Off-street lots within area<br>• *Valet technology*: Customer convenience |

Source: Corona del Mar, undated

fundamental conflicts arise among various goals. For example, tactics that increase the parking supply may reduce the incentive to use public transit. Some of these strategies may be quickly discarded for failure to meet the goals and objectives of a community or institution, while others require more detailed consideration.

## C. Performance Measures and Definitions

The use of parking-related performance measures depends on decision-making circumstances. For example, at the facility or parking lot level, interest would be primarily on the productivity or utilization of the parking spaces. Some of the performance measures relevant at this level include:

*Duration*—The length of time a vehicle is parked. *Average stay* or *average duration* is the average length of time all vehicles are parked in a facility over a specific period. All-day parking refers to vehicles parked for the hours of a typical working day.

*Parking Adequacy*—The degree to which the supply of parking is adequate to handle the parking generation (demand). Where appropriate, an equally acceptable approach is to compare the peak parking generation rate (or demand) on the design day to the effective supply.

*Parking Capacity*—The number of vehicles that can be parked in a given facility; *parking supply* is the total number of spaces available to serve a destination.

*Turnover*—The number of different vehicles parked in a specific area or facility in a given period of time divided by the number of spaces. Turnover may be calculated during the course of an entire day or separately for daytime and evening parking. If parking spaces in a facility are underutilized, the turnover rate will be very low. A common misconception is that the average turnover can be calculated by dividing the time period by the average stay (for example, 8 hours/2 hours average = 4 turns per day). This is really the maximum or *potential turnover* possible in a given time period and can only be achieved when the spaces are 100 percent occupied throughout the time period. Employee parking typically turns over 1.1 to 1.2 times per day due to in and out activity, while most customer parking may turn over 2 to 7 times per day. Multiday parking, as occurs at airports and hotels, will turn over less than one time per day, while airport short-term parking may turn over 10 or more times per day if effective segregation of long- and short-term parkers is achieved.

*Utilization*—The usage of a space or facility over a given period of time. Parking occupancy may be measured and recorded at hourly intervals or only at the expected peak period.

At the program level, transportation officials would want to know about how a parking program is helping to achieve community goals, as well as how the parking program is perceived by residents. The following performance measures from the city of Victoria, British Columbia, illustrate the types of measures that can be used at this level of decision making. [City of Victoria, 2007] Note that those measures for which a baseline has to be established

are denoted as "B;" the type of performance measure has also been indicated as: Percentage (%), Trend (T), or Descriptor (D).

**Customer Service**

- Percentage of citizens reporting satisfaction measured in the citizen survey and other surveys (B, %).
- State of new vision, mission, and values for parking officers (by fiscal quarter) (D).
- Parking Services staff to attend the specialized customer service training (100% attendance by 4th quarter 2007) (B, %).
- Establish new contract for parking officers (by fiscal quarter) (D).
- Enhance information of new Parking Services website (T).

**Create Incentives to Position Downtown as the Destination of Choice**

- Numbers of customers using alternatives payment methods (B, %).
- Number of holiday courtesy and warning tickets issued (B, %).
- Number of small vehicle parking spaces (20 spaces, % increased based on demand).
- Number of parking spaces for persons with disabilities (33 spaces, % increased based on demand).
- Number of van/car pool parking spaces (16 spaces, % increased based on demand).
- Number of bike lockers in parkades (60 lockers, % increased based on demand).

**Promote a Safe and Inviting Downtown Parking Environment**

- Complete safety and security improvements at each parkade and surface lot (4th quarter 2008) (D).
- Complete rehabilitation on all City-owned parkades (over 5 years) (D).
- Number of times the parkades and surface lots are cleaned (B, %).
- Condition of the parkades according to facility condition index (B, %).
- Provide 24 hr. security at all City parkades (4th quarter 2007).

**Improve Parking Technology to Make It More User-Friendly**

- Number of multipay ticket dispenser installed (over 5 years) (by fiscal quarter, %).
- Number of parkade ticket dispenser upgrades (completed).
- Percent of ticket dispenser signage upgraded (B, %).
- Number and type of signs related to parking identification and way-finding signs (D, B, %).
- Reduction in the number of tickets disputed and court cases (B, %).
- State of the advanced parking technologies (D).
- Numbers of parking card reload locations (B, %).
- Percentage of varying alternative payment methods (T, %).

**Ensure the Parking System is Self-sufficient and Sustaining**

- Increase in parking meter rates ($2.00/hr., review annually).
- Increase monthly parking rates in parkades ($110 Centennial Square. $140 Johnson Street; $160 Broughton Street; $160 Bastion Square $175 View Street, review annually).

- State of parking revenues versus expenses (T).
- Introduce longer metered zones in specific areas (D, based on demand).
- Increase in parking fines ($15.00 to $20.00 and so forth).

**Ensure Parking Demands Are Addressed for Both Today and the Future Downtown Parking Assessment (Completed)**

- Number of short-term parking spaces and usage (B, T, %).
- Number of long term parking spaces and usage (B, T, %).
- Parking and Transportation reserve fund (by fiscal quarter).

As can be seen in these performance measures, they can range from gauging customer satisfaction with the community's parking program to monitoring the parking supply in meeting future parking demands. Other communities have used performance measures relating to revenue generated and environmental impacts associated with the program.

## D. Facility Location and Urban Design

Urban design considerations include the overall design of a building, its scale and mass, and the way that parking blends into the fabric of existing buildings. Of particular importance are the treatment of streetscape and whether the parking facility creates an intrusion into the overall scale and character of a given area. Another major concern is whether a parking structure is a singular use, auto-oriented facility, or whether it becomes a mixed-use project or part of a new redevelopment.

Parking facilities should be located so that:

- Entrance and exit points are placed where roadway access is clear, safe, and congestion free.
- Convenient pedestrian access is provided by minimizing walking distances.
- Site and design facilities blend with, rather than intrude upon, the surrounding environment.

A parking facility can become a catalyst for major public improvements such as the creation of a new public open space or park. Parking can provide a major visual statement about the type of land use that occurs at a particular site, such as parking structures at major sports facilities and airports. Within an urban activity center, parking can form a transition buffer between two different land uses, or it can define a major public space.

On the other hand, parking structures can also have some adverse effects by creating a wall of inhospitable, non-pedestrian space that creates imposing facades upon an otherwise pedestrian environment. This type of environment generally has been created along streets where parking structures have been built as a backside to major developments.

From an urban design perspective, surface parking creates several problems. A surface parking lot reduces streetscape continuity. The lots are generally not well landscaped and negatively affect the overall quality of environment. In addition, a proliferation of curb cuts can affect the pedestrian walkway system. Urban design guidelines can address these issues by governing the siting, design and construction of parking structures or surface parking lots, including:

- Extensive landscaping along the buffer of lots should be provided; landscaping needs must also recognize security and life safety concerns and avoid blind spots.
- The number of curb cuts cutting across pedestrian walkways should be limited.
- Existing buildings should not be torn down for the use of surface parking, unless it is an interim use leading to the construction of a new building.
- New parking structures within an activity center should include mixed-use development at the street level and design treatments to the building itself should be used to minimize its impact upon the local character. Height, massing, and the use of materials should be controlled through design standards.

- Parking structures should be prohibited from major pedestrian streets, and directed instead to secondary streets dedicated more to auto access. Parking access should be avoided from main shopping streets.
- Incentives should be provided to encourage below-grade parking structures, combined with mixed-use projects or public open space.
- Access to and from parking facilities should be coordinated with major access streets and the service roadways intended to carry major traffic into the city center or major activity center.
- Parking facilities should be located where they would offer the greatest opportunity to identify a given land use and provide a clear definition of form, linkages, and connections.
- Parking facilities should be located where they have a positive urban design effect on a given area, such as the infill of gaps in the streetscape.

Some developments may be occurring on city blocks where the full development potential has not yet occurred. This creates a challenge in the parking analysis for strategies such as shared parking in that the developer does not know what possibilities might exist in the future for these types of strategies. In some communities, where future development is expected to provide opportunities for shared parking, the development proposal must address the entire block on which the proposed project is located. Future shared parking strategies could then be reflected in the conceptual block planning process. The block layout would include parking for the maximum square footage allowed for the block.

## V. PARKING MANAGEMENT

Parking management includes various parking policies and actions that can be used to manage the supply of, and demand for, parking. Most actions have occurred in major commercial and institutional activity centers. Litman [2006] identified three types of strategies that are usually found in a parking management program.

**Strategies that increase parking facility efficiency**

- Share parking.
- Regulate parking.
- Establish more accurate and flexible standards.
- Establishing parking maximums.
- Provide remote parking and shuttle services.
- Implement smart growth policies.
- Improve walking and cycling conditions.
- Increase capacity of existing parking facilities.

**Strategies that reduce parking demand**

- Implement mobility management.
- Price parking.
- Improve parking methods.
- Provide financial incentives.
- Unbundle parking.
- Reform parking taxes.
- Provide bicycle facilities.

**Support strategies**

- Improve user information and marketing.
- Improve enforcement and control.
- Establish transportation management associations and parking brokerage.
- Establish overflow parking plans.
- Address spillover problems.
- Improve parking facility design and operation.

The following sections describe five key characteristics of parking management programs: (1) pricing, (2) on-street supply, (3) enforcement and adjudication, (4) off-street supply within an activity center, and (5) marketing.

## A. Pricing

Price is a major factor influencing travel behavior, and thus the price of parking could be an important influence on decisions to travel to a particular location by a certain mode. From a parking owner's perspective, a pricing strategy could be formulated for several reasons: generate revenue, control who parks where and when, and encourage the use of alternative modes of transportation. Parking pricing in municipally owned facilities is set by public officials, but it often is well below what the market would otherwise bear. Sometimes this is done with intent, for example, where the community wants to encourage business and commerce to locate in a particular area. In other cases, parking pricing may be closer to the market price simply to encourage drivers to shift modes. The cost of parking in real dollars consistently declines over time, making it more difficult (politically) to raise rates. Only when the parking system is required to finance capital expenditures or support restoration and repair of older structures does the community consider the cost and market value of providing parking. Meanwhile, because the pricing of privately owned and operated facilities is influenced and restrained by municipal parking rates, commercial parking may not be viable and the burden of providing parking falls increasingly on the shoulders of a municipality.

Most companies and agencies do not charge the full cost of parking to users. The ideal, of course, is to charge market rates for parking, raising them every year to keep pace with inflation and market factors, and to develop reserves to finance new projects, capital maintenance, and repair.

### *1. Short-Term Pricing*

Visitor parking should generally be available close to destinations. The fee structure of a particular facility or system is often set to ensure that visitors' needs are met first. Short-term parkers usually are not as price sensitive as long-term parkers. In many cases, there is a compelling reason to go to a destination; the price of parking is not often a major concern, although if a competitive destination has equally acceptable products and services, short-term parking cost might be the tie breaker to the traveler.

A strong combination of retail with other land uses can also be a strong attraction affecting parking price sensitivity. When Circle Centre, a public-private joint venture retail and entertainment center in downtown Indianapolis, was about to open, there was much speculation about whether it could succeed with the relatively modest parking fee of $1 for a stay of up to 3 hours. The fee structure then jumped to $2 per hour, primarily to discourage parking longer than three hours to keep the more than 50,000 downtown employees from using the parking intended for visitors. In the end, the parking fee was a non-issue to shoppers, and shortly after opening the project was ranked among the top 5 percent of retail centers nationally in terms of annual sales per square feet.

Shoup [2005] has written extensively on the benefits of using *demand-responsive pricing* for on-street parking meters. He suggests that meter rates should be raised until the typical occupancy is 85 percent of capacity. He further recommends that the incremental revenue gained from raising meter rates be used for the benefit of the neighborhood served by the meters. For example, a rundown area of Pasadena, California, became a vibrant retail/dining district due in large part to raising meter rates and using the money initially to make capital improvements (repair sidewalks and develop pedestrian corridors through alleys) and, over the longer term, to clean streets and sidewalks and support police patrols. By promising to use the additional revenues from increased meter rates for these purposes, local

businesses supported the meter rate increase. Importantly, the meter rate increase was not the only component of the city's plan; zoning requirements for required parking spaces that inhibited adaptive reuse of existing buildings were modified and the city developed a number of parking structures to serve the remainder of the short-term parking need as well as employee parking.

### *2. Long-Term Pricing*

Parking price can and does play a major role in mode choice and in parking location choice by employees and other long-term parkers. In large activity centers like the CBD, parkers usually have a variety of options. If price is a concern, an employee can find reasonably priced, if not free, parking on the perimeter of the activity center and walk three or more blocks to his or her place of employment. Shuttle and park-and-ride programs may make low-cost perimeter parking more accessible in large CBDs.

Table 11-5 shows the pricing mix for parking in several large U.S. cities and London as of 2009. Although the prices will vary over time, the relative pricing among cities will not likely change that much. It is interesting to note the large differences in the number of on-street and off-street parking spaces in the different cities, as well as the differences in prices.

True market pricing generally only exists in the CBDs of cities where commercial parking constitutes the largest share of parking supply. Many properties in these areas were developed before the private automobile became the predominant mode of transportation and, therefore, do not provide adequate parking for tenant and customer needs by today's standards. Off-street commercial parking pricing is not overly influenced by on-street meter rates set by the municipality. Generally, if a commercial parking facility exists, it is because the on-street parking alone cannot serve the needs of the area.

Some communities have begun to use variable pricing as a means of efficiently operating their parking supply as well as encourage the use of alternate modes. In 2011, San Francisco implemented *SFpark*, a variable pricing program for on-street parking to achieve a target parking of one or two open spaces per block. Seven pilot zones were designated to install sensors in each curb space on every block with the goal to achieve an occupancy rate of between 60 and 80 percent through variable pricing throughout the day. Meter rates vary based on time of day and day of week, and rates are adjusted over time in response to demand. Rates are adjusted on a block-by-block basis, using occupancy

**Table 11-5. Pricing in Major U.S. Cities and London, 2009**

| City | Pop. | Land Area (square miles) | Population Density (per square mile) | CBD (square miles) | Metered On-Street Parking Spaces | Off-Street Public Parking Spaces | Daily Parking Rate (median) | Monthly Unreserved Rate (median) |
|---|---|---|---|---|---|---|---|---|
| New York | 8.1 million | 305 | 26,557 | 9.3 | 85,930 | 102,000 (CBD) | $44.00 (Midtown) | $550.00 (Midtown) |
| Boston | 617,000 | 48.4 | 12,748 | N/A | 7,300 | 134,000 | $34.00 | $402.50 |
| Chicago | 2.7 million | 237 | 11,392 | 1.6 | 4,500 | unknown | $31.00 | $325.00 |
| Milwaukee | 595,000 | 96 | 6,198 | 1.5 | 6,400 | 25,000 (CBD) | $12.00 | $110.00 |
| Minneapolis | 383,000 | 58 | 6,603 | 1 | 6,611 | 16,102 | $17.25 | $187.00 |
| Philadelphia | 1.5 million | 135 | 11,111 | 1.5 | N/A | N/A | $26.00 | $314.00 |
| Portland, OR | 584,000 | 145 | 4,028 | 4.6 | 7,800 | 58,130 | $9.00 | $185.00 |
| San Diego | 1.3 million | 342.5 | 3,796 | 2.27 | N/A | N/A | $26.00 | $180.00 |
| San Francisco | 805,000 | 47.6 | 16,912 | 0.53 | 25,000 | 15,000 | $25.00 | $350.00 |
| Seattle | 609,000 | 142.6 | 4,271 | 1.48 | 13,500 | 50,000 | $28.00 | $290.00 |
| Washington DC | 602,000 | 64 | 9,406 | N/A | 6,700 | 150,000 | $14.00 | $215.00 |
| London | 7.8 million | 620 | 12,581 | N/A | N/A | N/A | $56.68 (city) | $1,020.29 (city) |

Source: US Census, 2010; Colliers International Global CBD Parking Rate Survey, 2009; as reported in New York City Department of City Planning, undated

data from the parking sensors installed in most on-street parking spaces in the *SFpark* areas. The conclusions from a pilot study evaluation of the program noted: (1) average parking rates were lower, (2) parking availability improved, (3) it was easier to find a parking space, (4) it was easier to pay and avoid parking citations, (5) greenhouse gas emissions decreased, and (6) vehicle miles traveled decreased.

In 2010, Seattle adopted an ordinance that set rates for on-street parking between a minimum of $1.00 per hour and a maximum of $4.00 per hour. Rates are set per block over the 31 districts and are set once a year. All meters have the ability to use the PaybyPhoneParking app. The public response has been positive and is likely due to the data-driven decision-making process. The business community accepted the changes as city revenue was not the goal and the fact that data on utilization dictated the rates. [SFTCA, 2009]

One of the key characteristics of today's pricing schemes is the use of technology that aims to make the parking program more efficient and easier for those parking to pay. In downtown Los Angeles, for example, the city is using a smart parking platform to help drivers find available parking, using ground sensors to detect parking space vacancies that are communicated through smartphone apps as well as the city's website. The city can then change the price of parking in highly congested areas. Traffic congestion has dropped by 10 percent since the project was implemented. In Washington, DC, smart parking systems use sensors to determine availability of spaces. Just over 57 percent of all parking transactions in Washington, DC, are paid for via a mobile app. This type of technology can be an important capability in parking enforcement as well. Other technology trends that will likely take hold in the near future include: contactless payment systems, electric vehicle charging while the car is parked, more use of solar equipment, license plate sensing payment systems, and a host of mobile phone apps that will provide more information to potential parkers of where space is available and at what price. For a review of technology trends and applications globally, see. [Joshi et al., undated]

## B. On-Street Parking

On-street parking, although limited in terms of capacity, is often a key resource to activity centers. Older CBDs and institutional activity centers have some streets intentionally designed to provide on-street parking in addition to moving traffic lanes. However, only 5 to 10 percent of the parking needs in a downtown are on-street. [Kuzmyak et al., 2003]

Managing on-street parking in essence means controlling who parks where and preventing spillover parking into adjacent neighborhoods. Parking management actions involving on-street supply include adding or removing spaces, changing the permitted time limit, restricting parking to certain times or users, and employing on-street spaces for preferential carpool parking.

### *1. Adding or Removing Spaces*

In smaller towns and cities, adding on-street parking by providing angled parking stalls where parallel parking stalls previously existed may be the most cost-effective means for adding parking capacity. Going from parallel parking to 60-degree parking can double the number of spaces. Changing a street to one-way, or combining the width of parallel parking spaces on each side of the street to a single line of angled stalls, can often result in added parking solely for the cost of pavement markings and a few signs. Angled parking also has a traffic calming effect and is promoted by neo-traditionalist planners for that reason. Given that this approach would only be applied on streets where desired vehicle speeds are low, relatively narrow travel lanes may be appropriate. Generally, a shallower parking angle is preferred. Perpendicular parking, although more efficient, is usually avoided because of increased traffic conflicts.

Conversely, on-street parking does affect traffic movement and safety on streets used for through-traffic movement. Conflicts over the use of curb space for bus stops and deliveries can also be a significant concern. In larger cities, prohibiting parking in peak hours has often been used to serve peak-hour traffic needs while still providing convenient mid-day parking for storefront businesses.

It is also important for city parking officials to review on-street parking restrictions periodically to make sure they are still needed. A dedicated loading zone required for retail stores along the block may no longer be necessary when the use changes to office. Street traffic in an area may no longer require peak period prohibitions. For example, prior to opening Circle Center, the City of Indianapolis conducted a block-by-block review of on-street parking controls and removed 50 percent of the rush hour restrictions on on-street parking. The enforcement of meters was privatized.

These improvements reduced complaints about parking from 172 to 22 per month and reduced towing from 1,000 to 160 vehicles per month. However, with the growth of the downtown in subsequent years, the city found that double-parking of service vehicles was inhibiting movement. Therefore, in 1999 the city doubled the number of loading zones, removing some metered spaces, and doubled the fine for loading zone violations.

### *2. Metered and Time-Limit Parking*

The most common parking management action for on-street spaces is metering the space. The primary purpose is to keep the spaces available for short-term parking. Although originally intended solely to cover the cost of enforcement, over time many cities have obtained significant revenues from parking meters (and why private concessionaires are interested in parking meter public/private partnerships).

More recently, as CBDs try to compete with suburban shopping centers, the parking meter has become a contentious issue. In many cases, downtown merchants do not want to impose additional costs on their customers. The short-term parker, however, is not price sensitive, but rather convenience sensitive. If there is any negative effect of parking in downtowns compared to the suburban shopping center, it is the lack of convenient parking, not the lack of free parking. The on-street parking immediately in front of a store is usually not available to serve thriving, storefront retail much less a restaurant. Removing meters does not solve this problem and only exacerbates the problem of financing off-street parking at rates reasonable to a public used to free on-street parking.

Given the political process, it is easy for the city to grant requests for special time limits: the 5-minute meter in front of the copy shop, or a 15-minute limit at the meat market. These limits are almost never enforced; moreover, the proliferation of multiple meter limits and fees only adds confusion and complication to the on-street parking system. Wherever possible, meter limits should be simplified to 1-hour or 2-hour limits for short-term parking with 10-hour limits for peripheral meters that can be used by employees.

A municipality should periodically review its meter and time-limit system for currency and efficiency. One possibility is performance-based pricing of metered parking in which prices are raised until occupancy typically is about 85 percent. Today's pay-and-display and pay-by-space meters allow different rate structures to be used at different times of the day, which provides even greater flexibility in managing on-street spaces. Moreover, by removing individual meters, more spaces are often accommodated naturally by parkers, and parking revenues are significantly increased. After three years in operation, Seattle found that its pay-and-display system had nearly doubled the revenue per parking space per day although half of that was from a rate increase.

### *3. Preferential Parking*

Some cities, notably Portland, Oregon, have successfully adopted programs that reserve on-street parking (typically in peripheral areas that would otherwise be 10-hour meters) for carpools. Many corporations do the same in parking lots, as well as preserving spaces close to entrances for those awarded for exceptional service to the company ("employee of the month").

### *4. Residential Parking Permits*

One of the most common consequences of parking shortages in activity centers is spillover parking into adjacent neighborhoods. Where these neighborhoods are residential, the residential parking permit (RPP) program is the most viable strategy for controlling the problem. Where the spillover is almost entirely employee parking, on-street spaces may be restricted to 1- or 2-hour parking or to those displaying a residential permit. The restrictions may apply during certain hours, such as 8:00 a.m. to 6:00 p.m. Area residents pay a modest fee for a residential permit that allows the vehicle to be parked on the street. The time limit allows short visits by service vehicles and guests of the residents; longer stays require the parker to obtain a visitor pass card from the resident and place it in the vehicle.

Targeting restrictions on a particular time period or for a particular group might not always work. For example, where the spillover is largely composed of university students parking for a single class or tourists visiting a local site, it makes sense to allow no parking by anyone without displaying a residential permit. The environment of the neighborhood is not only enhanced by the reduction of nonresident parking, but also by the reduction of vehicular traffic seeking a parking space. State or local enabling legislation may be required to implement a residential parking permit program.

Technology is also used in permit parking programs. Hoboken, New Jersey, has added radio frequency identification (RFID) technology (similar to that used in toll road prepaid tags) to its permits to allow enforcement officers to distinguish between residents and nonresidents and to identify counterfeit parking permits. Parking enforcement officers can read the information on the permit automatically. Citizens can renew permits online. Moreover, the electronic

memory and communication of these systems allows for the collection of data on parking utilization, which helps not only with program management but also future parking planning as well.

## C. Enforcement and Adjudication

Parking duration and turnover studies find substantial overtime parking at meters even with extensive enforcement. Illegal parking not only allows parkers to avoid paying for their use of scarce spaces, but also may negatively affect traffic flow on arterial streets. Experience in many cities has shown that strict enforcement more than pays for itself.

More recently, pay-and-display, pay-by-space meters, and RFID parking permits have improved enforcement capability by speeding the process of writing tickets that stand up to judicial review and of recording the data for use by the parking management office. Areas where violations are a problem can be identified and enforcement enhanced, rates and policies can be changed, and other strategies implemented.

A study of the relationship among parking revenues, fee schedules, fines, and enforcement practices indicated that the level of enforcement and the rate schedule are more important determinants of parking behavior than the fine schedule. [Adiv and Wan, 1987] Thus, while increasing fines will increase total revenues, strict enforcement and higher fees are more beneficial to the system as a whole. The study concluded that while about one in three users either parked for free or exceeded the time limit, the meters were effective in their major goal of keeping the spaces available for short-term parking.

The adjudication of disputed tickets can be another challenge to a parking management program. Parking tickets are often administered via the courts, which can consider them a nuisance. Some judges are known to routinely throw out tickets on almost any excuse; other agencies make little effort to collect outstanding tickets. As a result, the prompt voluntary payment of tickets is generally low, between 10 and 33 percent.

The most successful strategy for resolving problems in fine collection is to establish an in-house bureau dedicated to ticket collection or to retain a professional ticket collection firm to aggressively pursue ticket collection. Key components include towing and booting programs. As tickets are issued, the enforcement personnel check the license plate against a "hot list" of scofflaws. When a vehicle is identified as a frequent violator or associated with significant unpaid tickets, the vehicle is towed and impounded or immobilized via a "boot" applied to one wheel until outstanding tickets have been paid. In some states, such as California, vehicles cannot be re-registered if there are unpaid parking tickets.

Many communities have effectively decriminalized parking tickets by establishing a procedure for resolution at an administrative rather than court level. A trained paralegal officer or panel hears evidence in disputed ticket cases and has authority to determine fault and assess fines as appropriate. Generally, the procedure allows the parking ticket or the computerized ticket writer's log to be *prima facie* evidence and the ticket writer need not be present at the hearing. Enabling legislation for administrative adjudication is usually required. Some cities have made the process extremely citizen-friendly, allowing walk-in hearings, write-in explanations, periodic amnesty programs, and credit card payment of outstanding tickets and fines.

## D. Off-Street Supply Actions

Communities can manage their off-street parking supply in various ways—expand or restrict parking supply, encourage shared parking, and build park-and-ride facilities. Some of the most common are discussed next.

### *1. Area-Wide Limits*

CBD parking supply limits have been used in several cities, including Boston, New York, Portland, San Francisco, and Seattle. Institutional activity centers such as universities have also restricted parking supply to encourage use of alternative modes. In the early 1990s, the University of Illinois at Champaign-Urbana decided to stop building more parking, at least on an interim basis, and used the pressure of parking shortages to help develop an improved public transportation service. Rather than operating its own shuttle system, the university worked with the local transit agency to expand citywide transit and shuttle service between outlying commuter and student lots and campus buildings. All students were assessed a transportation fee as part of the students' annual fee payment and received a pass for free use of the entire transit system; faculty and staff can purchase a subsidized pass for the system as well. This type of fee system along with campus shuttles is now common at many universities.

### *2. Shared Parking*

Shared parking is desirable from both a land development and a transportation perspective. The potential savings in paved parking area (both lots and structures) from shared parking and mixed-use developments are significantly greater than the savings that might occur from changing design days and effective supply factors for single-use land developments. This can be accomplished in most land developments of reasonable size, including greenfield development in suburban locations. In the left of Figure 11-2 is a site plan modeled from an actual development in a rapidly growing corridor in suburban Indianapolis. This development on former farmland is layered with a first row of buildings housing a pharmacy, restaurants, and banks; a second row with a shopping center; and then office buildings and a day-care center in the third layer from the highway. Parking is not shared; spaces used by the offices on weekdays sit vacant in the evenings and weekends, when parking at the retail and restaurant buildings peak, and vice versa. A patient visiting a doctor in one of the office buildings has to drive around the center to the pharmacy to pick up prescribed medications because there is no easy, attractive pedestrian path between the third row of buildings and the first.

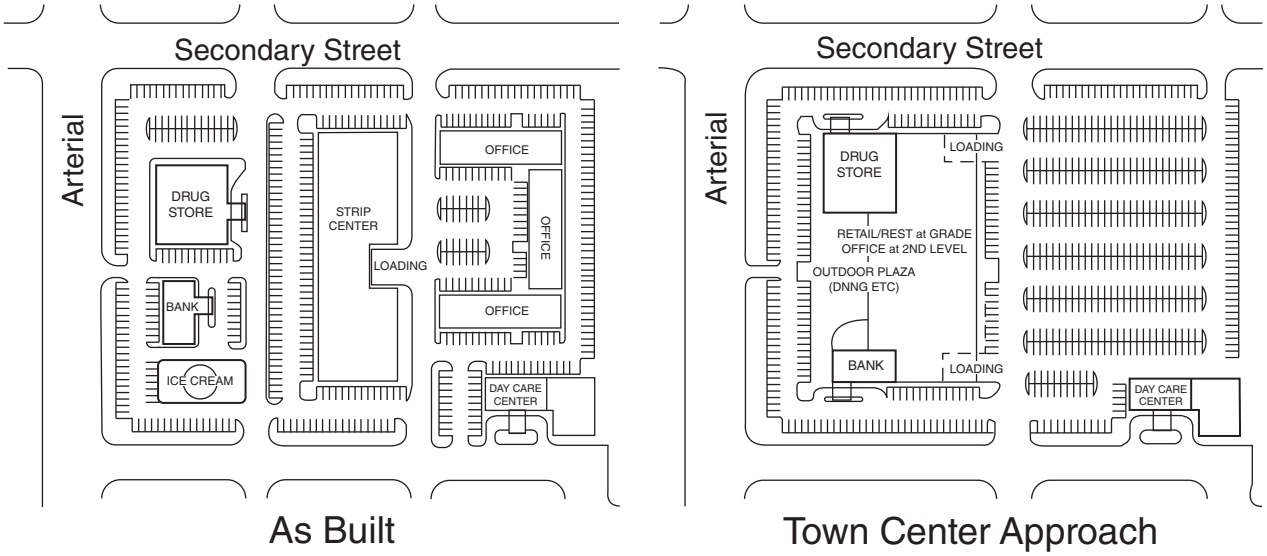
It would have been better to create a mini-town-center, like that shown on the right of Figure 11-2, with retail, banks, and restaurants at grade, and offices located on the second floor. The patient could also have stopped at the dry cleaners and the card shop in the center, as well as have had lunch at the sandwich shop. The buildings could have been pushed to the street, with nearly all parking behind creating a far better urban form and pedestrian environment. Furthermore, the town center approach would allow 50 percent more gross leasable area (GLA) to be developed, due to the efficiency of the site design and shared parking.

### *3. New Technologies*

An evolving aspect of parking management is the use of new technologies for managing parking supply. Automated systems such as *parking availability displays* (PAD) and *individual space guidance* (ISG) systems can achieve some increase in required effective supply factors without excessive labor. PAD systems, as seen in Figure 11-3, help direct patrons to areas with available spaces, particularly on upper levels of parking structures. This system is cost-effective, costing less than $20 per stall (2006 dollars) where revenue control systems are otherwise provided, and less than $50 per stall where computers and software must be provided to operate the system. (The larger the number of spaces in each counting zone, the lower the cost per stall).

ISG systems monitor the occupancy of each stall and direct parkers to the nearest vacant stall. This system is in operation at several airports, including Baltimore-Washington International Airport, where it has been found to increase the effective supply factor to 93 to 95 percent as compared to 85 to 90 percent without ISG. It generally costs $500 per stall (2006 dollars) and is not typically considered cost-effective unless the number of spaces initially provided is reduced.

**Figure 11-2. Comparison of Land Development with and without Shared Parking**



Source: Walker Parking Consultants, Inc., 1992

For example, a 2,000-space structure costing $15,000 per space without ISG would cost $30 million. With ISG, the cost per space increases to $15,500 per space, but the proposed capacity will be reduced by 5 percent to 1,900 spaces and the construction cost reduced to $29.45 million. ISG must be regularly calibrated and maintained, but there is also a saving of the debt service and operating costs on the spaces eliminated. However, assuming 1,900 spaces could still be provided without ISG, there will be $1,500,000 in construction cost savings due to the elimination of ISG. This money would be available to pay for staff to direct parkers to available spaces in peak periods. In general, the more hours and more days that the parking generation rate exceeds the effective supply factor (for example, 93 percent of the spaces will be parked at the peak hour on many days of the year), the more cost-effective ISG will be.

These types of strategies can also be part of a much broader wayfinding strategy that guides motorist to available spots.

## E. Marketing

Marketing is an important part of parking management. While by itself it does not increase parking supply or reduce demand, it is valuable to publicize steps taken to improve parking in an activity center. The negative effect of increased parking fees on employee recruitment should be minimized by explaining the need for the increase and the overall benefits of changes in parking policies to the individual, the business, and the activity center.

An excellent marketing program in a CBD is maintained by Indianapolis Downtown, Inc. It provides information on parking policies downtown, a facility finder service that identifies parking facilities near a specific location and promotes a "Best Bargains" program comparing pricing of parking in many facilities to overcome a perception that parking has become expensive downtown due to events at the convention center and sports facilities. The home page for all these services is http://www.indydt.com/parking.cfm.

# VI. PARKING DEMAND AND NEEDS ANALYSIS

The need for parking is closely related to the level of trip-making made for different purposes. According to the 2009 National Household Transportation Survey (NHTS), Americans averaged 1,385 trips per year, or 3.79 trips per person per day. [FHWA, 2013] Eighty-six percent of these trips were by personal vehicle. Only 15.6 percent of trips were commuting or work-related. However, as noted by Pisarski, commuter trips are more important in transportation planning than would be indicated by their proportion of total trips because of the impact they have on the economy, development within a community, congestion during peak hours, and air pollution. [Pisarski, 2006]

From a parking perspective, significantly more parking spaces are required per commuting trip than for shopping or other trip purposes because a commuter parking space serves one to two trips per day, whereas a customer space may

serve 2 to 10 trips per day. Commuter parking is generally far less variable by time of day and season and thus more predictable. Commuter parking can be shared with evening and weekend customer parking, is generally far more price-sensitive than customer parking and is more easily influenced by local transit alternatives. One study found that increasing parking prices by 1 percent would decrease auto commuting trips by 8 percent, but customer use of the space by only 2 percent. [TRACE, 2005] Thus, the influence of parking pricing in commuting choices is four times as great as in visitor/customer trips.

Because trips are made to accomplish some activity at the end of the trip (called derived demand), trip-making and thus parking are strongly influenced by land-use characteristics. Parking demand varies widely among otherwise similar land uses. The variations reflect differences not only in the level of activity by a particular tenant, but also in the density of development, availability of public transportation, local policies, price of parking and local economic health. In areas with mixed land uses, such as the CBD, parking demand is often reduced because of the joint use of parking facilities for the different types of establishments found nearby.

Over the long-term, parking demand also varies as employment densities, transportation policies, and car ownership levels change. The density of employees per unit floor area in offices, for example, dropped from about six employees per 1,000 square (sq.) feet (or ksf) (6.5 employees per 100 meters$^2$ [m$^2$]) in the 1960s to below four employees per ksf (4.3 employees per 100 m$^2$) by 1985. [Weant and Levinson, 1990] The density of employees in downtown commercially developed office space declined from 3.9 employees per ksf (4.5 employees per 100 m$^2$) in 1985 to 3.5 employees per ksf (3.8 employees per 100 m$^2$) in 1995, but rebounded to 3.7 employees per ksf (4.0 employees per 100 m$^2$) by 2003. Similar patterns are found for suburban and governmental office space during the same timeframes.

## A. Definitions

Many terms and concepts are used in parking analysis. Besides those introduced above in the section on performance measures, these include:

*Activity Center*—A relatively large concentration of development that is a major focus of activity within an urban area. While CBDs are historically the dominant form of activity center, the suburban activity center is the most prevalent form of commercial development in North America today. Suburban activity centers typically have multiple land uses and may consist of multiple mixed-use developments. Institutions such as major government centers, colleges, universities, and medical centers also create activity centers (see chapter 18 for more discussion on activity centers).

*Central Business District (CBD)*—The traditional core of the business, commercial, financial, and administrative activities of a community. A *CBD fringe* area may extend the CBD another two or three blocks in each direction. The fringe area often includes industrial and other lower-density uses and may have substantial on-street and surface parking serving the core area at lower rates.

*Commercial Parking Facilities*—Parking facilities that are operated for a profit, often by a professional parking operator. Commercial facilities are usually public; however, some commercial facilities may be entirely reserved (usually leased on a monthly basis) to a specific group of users and therefore are *private*.

*Design Day*—The level of parking demand that recurs frequently enough to justify providing parking spaces for daily use.

*Effective Supply*—The level of occupancy for optimum operating efficiency. A parking facility will be perceived as full at somewhat less than its actual capacity, generally in the range of 85 to 95 percent full, depending on various factors. A single facility also provides for flexibility in handling demand fluctuations; vehicle maneuvers and vacancies created by reserving spaces for specific users, such as disabled parking; losses due to misparked vehicles; or snow. In contrast, many small parking lots with many spaces reserved for specific users operate far less efficiently than a large single facility of comparable capacity with all spaces available to any user. The available spaces in a single large facility reduce the need to search many lots for the last few available spaces. Adding an effective supply cushion to the design day demand also provides for some flexibility in handling demand fluctuations.

*Employee Parking*—Parking provided for employees, most often long-term parking.

*Intermodal*—A characteristic of trip-making and of a transportation facility where a change of mode can occur. An *intermodal parking facility* allows a traveler to transfer from a private vehicle to some form of public transit. Parking facilities at airports, train stations, and other transportation transfer locations are intermodal terminals.

*Long-Term Parking*—Generally defined as parking for three hours or more.

*Mechanical Parking Structures*—Parking structures that employ elevators and other devices to move vehicles to parking stalls not accessible by pedestrians. This type of facility fell out of favor due to reliability problems and the high cost of maintenance as the facilities aged. Electronics and other technological advances have made these facilities feasible again since the 1990s, especially where there is no space for a traditional self-park structure. There are two types of mechanical access structures. The first is a simple *low rise* or *car stacker* that allows double or triple stacking of vehicles in a single parking space. The second type is a *high-rise* or *automated mechanical structure,* which uses lifts, elevators, or other mechanical devices to move vehicles to and from street level to an elevated space.

*Mixed-Use Parking Structures*—Parking structures that include retail and other uses, usually on the ground floor. This approach helps create a more pedestrian-friendly building façade at street level. Other uses may be built over parking structures, although usually at a substantial cost premium. In many urban areas, it is now quite common for parking structures to be developed in conjunction with other uses.

*On-Street Parking*—Parking that is provided on the street, either metered or free.

*Off-Street Parking Facility*—Parking facilities that are located on land adjacent to a street or road. Off-street parking facilities today range from driveways, carports, and multi-car garages at residences to parking structures in excess of 10,000 spaces.

*Parking Demand*—The number of spaces that should be provided to serve a use or group of uses under a specific set of circumstances, including pricing and effective supply considerations.

*Parking Generation*—An observed accumulation of vehicles. Traditionally, parking planners and industry publications select a design day, measure parking generation rates in the peak hour of parking accumulation on that day and then divide the expected number of parked vehicles by the effective supply factor to determine the recommended number of spaces (that is, parking demand) for that location or land use.

*Parking Structures*—A constructed facility for parking. Building codes distinguish *parking garages* (enclosed structures, often underground, that must have sprinklers and mechanical ventilation) from *open parking structures* (above-grade multistory parking facilities that are naturally ventilated). Owning and operating a space in a parking structure typically costs at least three times as much as a surface lot space, excluding land. There is more incentive for the owner or manager of the property to charge the user for parking in a structure. Regional variations in the terms used for parking are also quite common; for example, parking structures may be called parking *decks* or *ramps* in certain areas, while the British term is *car park*.

*Private Parking Facilities*—Parking facilities that are reserved for specific users.

*Public Parking Facilities*—Parking facilities that serve anyone who wishes to use them, often for a fee.

*Self-Park Facilities*—Parking facilities where the user parks the vehicle.

*Short-Term Parking*—Parking for less than three hours.

*Surface Lots*—Parking that is provided on at-grade lots and may be "free" to the user. The cost of building and operating "free parking" is either borne by the landowner or passed through to the tenants in the lease rate. The vast majority of parking supply in the United States is found in surface lots.

*Valet Parking*—Parking in which the vehicle is dropped off and is then parked by a parking lot operator. This has become more common in recent years as a customer service at locations with parking shortages or long walking distances.

*Visitor Parking*—Parking designated for visitors to a particular site. It is usually short term; however, it may be long term at an ambulatory surgery center, airport, or a hotel.

## B. Parking Demand Formulas

Standard practice for estimating parking demand is to use equations that relate parking spaces to some quantitative measure of land use. The following paragraphs discuss some of the issues associated with the use of such formulas.

### *1. Units*

Parking demand and generation rates are generally stated as a ratio of *x* spaces per *y* units, with the unit being an appropriate measure of a particular land use. In most cases, the land-use unit is building area ($m^2$ or $feet^2$ [$ft^2$]). Other units include dwelling units, hotel rooms, seats, or persons. The unit should be calculable at the time of planning. Demand ratios based on numbers of employees should generally be avoided since they may be variable over time. Similarly, although store sales may be a reliable predictor of parking demand for retail uses, it is difficult for planners to evaluate parking needs on this basis, because projected store sales are merely educated guesses of future activity levels. Airports generally use the number of passengers arriving and departing an airport for the design of terminals, but parking consultants typically use originating enplanements for parking planning because transferring passengers at hubs do not generate significant incremental parking demand.

In some cases, particularly those of assembly space such as auditoriums, a threshold capacity in allowable number of persons is licensed or posted and could serve as the basis for parking requirements. Certain land uses, specifically hospitals and universities, are variable due to age and mix of buildings such that it is difficult to determine a single consistent land use. A parking study specific to the institution is thus the only reliable way to evaluate parking demand. Similarly, there is a high degree of variability of parking demand for governmental buildings, except for buildings used primarily for office use.

In the past, parking ratios were sometimes stated as one space for each *x* square feet of usable space. However, most in the industry now prefer to use a ratio stated as *x* spaces per 1,000 sq ft (denoted as ksf). Therefore, the more recent studies of parking requirements, such as *Parking Generation* and *Shared Parking*, have generally employed spaces per 1,000 $ft^2$ or spaces per 100 $m^2$ (the remainder of the chapter will use the ksf rate). [ITE, 2010; Smith, 2005]

Another important aspect of area-based ratios is how they are defined. Because there is wide variation among both national standards and zoning ordinances on this issue, the modifiers *gross*, *net*, *leasable*, and *rentable* are frequently added to clarify the term *floor area* as follows:

*Gross Floor Area (GFA)*—Total floor area, including the exterior building walls, of all floors of a building or structure.

*Gross Leasable Area (GLA)*—Gross floor area that is available for leasing to a tenant.

*Net Floor Area (NFA)*—Total floor area, excluding exterior building walls.

*Net Rentable Area (NRA)*—Net floor area that is available to a tenant; also called net leasable area (NLA).

Vehicular parking and loading areas and the floor area occupied by mechanical, electrical, communications, and security equipment are deducted from either GFA or NFA, as these spaces do not contribute to parking demand. While older ordinances tended to use NFA, most industry standards today use GFA for nearly all land uses, with GLA being used for shopping centers and a few others (see, for example, *Dimensions of Parking* [ULI and National Parking Association, 2014]; *Parking Generation* [ITE, 2010], and the Parking Consultants Council's *Recommended Zoning Ordinance Provisions for Parking* [PCC, 2007]).

Generally, GLA is the GFA minus the floor area of elevator shafts and stair towers, public restrooms, permanently designed corridors, public lobbies, and common mall areas. Merely enclosing the space connecting tenant spaces does not add significantly to parking demand. For example, if the GLA is the same, the common mall areas of enclosed shopping centers do not generate significantly more demand than either a shopping center with open-air courtyards or a strip mall with all stores opening to the parking lot. Likewise, connecting the lobbies of a pair of office towers with an atrium does not generate additional parking demand, thus the atrium should be excluded from parking demand calculations. In smaller buildings, the difference between GLA and GFA is negligible.

Recommended parking ratios from *The Dimensions of Parking* [ULI and NPA, 2014] are shown in Table 11-6. Periodic parking surveys could also be conducted to help develop an adjustment factor for base parking rates to reflect actual parking behavior in the study area.

| Table 11-6. Recommended Parking Ratios | |
|---|---|
| **Use** | **Parking Ratio** |
| **Residences and Commercial Accommodations** | |
| Single family dwelling unit (Dwelling Unit [DU]) | • <2,000 sq. feet (186 sq. meters): 1/ DU<br>• 2,000-3,000 sq. feet (186-279 sq meters): 2/DU<br>• >3,000 sq. feet (279 sq meters): 3/DU |
| **Multifamily DU** | |
| Rented | 1.65/DU |
| Owned | 1.85/DU |
| Accessory | Add 1/accessory DU |
| Sleeping rooms | 1/unit or room, plus 2 for owners /managers |
| Commercial lodgings | 1.25/room plus 10/1,000 sq ft (10.8 per sq meters) of gross floor area for lounge and/or restaurant, plus conference/banquet facilities at the following rates:<br>• <20 sq ft (1.86 sq meter): 0<br>• 20 sq. feet (1.86 sq meters)/room: 30/1,000 sq ft (32.3/100 sq meters) of GFA<br>• 20 to 50 sq. ft (1.86 – 4.65 sq. meters)/room; scaled proportionally between 20 and 50 sq ft/room (1.86 to 4.65 sq meters)<br>• >50 sq feet (4.65 sq meters)/room; 20/1,000 sq ft (21.5/100 sq meters) of GFA |
| Housing for seniors | 0.5/DU |
| Congregate care or assisted living | 0.35/DU |
| Group homes, convalescent homes, and nursing homes | 0.5/bed |
| **Retail Sales and Services (not in shopping center unless so noted)** | |
| General and convenience retail | 2.75/1,000 sq ft (2.96/100 sq meters) of GFA |
| Grocery stores | 6.75/1,000 sq ft (7.26/100 sq meters) of GFA |
| Heavy/hard goods | 2.5/1,000 sq ft (2.69/100 sq. meters) of GGA including outdoor sales areas |
| Discount superstores | 5.5/1,000 sq ft (5.92/100 sq. meters) of GFA including outdoor sales areas |
| Specialty stores | 4.5/1,000 sq ft (4.84/100 sq. meters) of GFA including outdoor sales areas |
| Shopping centers with not more than 10% of gross leasable area (GLA) in nonretail sales and service uses. | • <400,000 sq ft (37,160 sq. meters) of GLA; 4.0/1,000 sq. feet (4.3/100 sq meters) of GLA<br>• 400,000–600,000 sq. feet (37,160–55,740 sq meters) of GLA: scaled proportionally between 4.0 and 4.5/1,000 sq ft (4.3 and 4.84/100 sq. meters) of GLA<br>• >600,000 sq ft (>55,740 sq. meters) of GLA: 4.5/1,000 sq ft (4.84/100 sq. meters) of GLA |
| Shopping centers with more than 10% of GLA in nonretail sales and service uses. | Should be established in accordance with a shared parking study prepared specifically for the subject project |
| **Food and Beverage Services** | |
| Fine or casual dining (with bar) | 20/1,000 sq ft (21.5/100 sq. meters) of GFA |
| Family restaurant (without bar) | 15/1,000 sq ft (16/100 sq. meters) of GFA |
| Fast food restaurant | 15/1,000 sq ft (16/100 sq. meters) of GFA |
| Night club | 19/1,000 sq ft (20.5/100 sq. meters) of GFA |

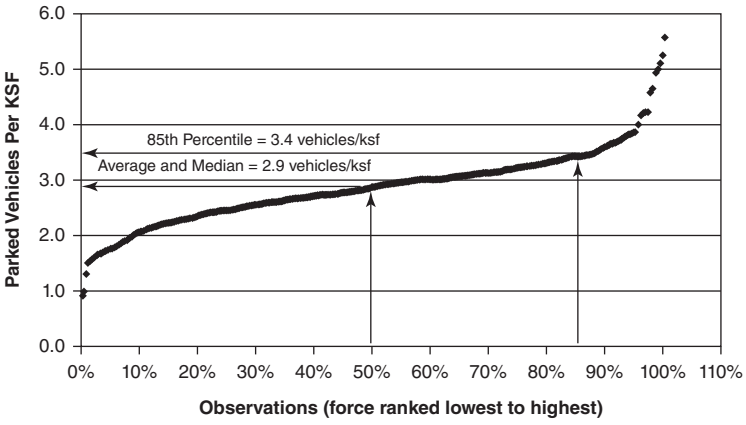
### *2. Design Day and Design Hour*

The design day is typically selected from among the top 10 to 20 activity days per year. Unfortunately, *shopping center* is the only land use for which data on parking needs throughout the year have been extensively studied to determine a design day and hour. For shopping centers, the 20th highest hour in the year is recommended as the design hour; this hour is usually the second or third busiest hour on the second Saturday before Christmas. [Urban Land Institute and International Council of Shopping Centers, 1999]

For other uses, ITE's *Parking Generation* presents regression curves for an average of the peak accumulations observed as well as 33rd and 85th percentile values. This text suggests that the average ratio may be acceptable for some uses, but not for others (see Figure 11-4). This database is simply the information that has been reported to ITE. The average ratio reported is simply the average of the peak accumulations observed. Moreover, in the vast majority of cases, there are less than 10 studies constituting the database, and the data set is not reliable from a statistical perspective. For this reason, many, including a 1990 ITE committee report, have suggested the 85th percentile in *Parking Generation* as an appropriate design standard. [ITE Technical Council, 1990] Most practitioners generally employ the 85th percentile, as does the Parking Consultants Council [2007].

**Figure 11-4. Definition of 85th-Percentile Design Day**



Source: Special sort of ITE Parking Generation Database for Land Use Code 701: Office

The 85th percentile means that 15 percent of the sites observed would require more parking than the specified value. The data reflect the observations submitted and are not counts on a generally accepted design day. Moreover, the vast majority of the studies occurred at sites with free, unconstrained parking and thus do not reflect the influence of parking price or transit use. In sum, care must be taken on applying ITE's data on parking generation rates. For a critique of parking generation rates, see Shoup [2005].

### *3. Effective Supply*

When determining the adequacy of an existing multifacility parking system, a parking analyst will usually assign effective supply factors to each of the different facilities to determine the overall effective supply and then compare the effective parking supply with the design day parking generation. To provide the desired effective supply,

the expected parking generation rate at the peak time on the design day is divided by the effective supply factor. For example, if 1,000 vehicles are expected to be parked at the peak hour on the design day with a 90 percent effective supply factor, 1000/0.90 = 1,111 spaces would be required for the system to work reasonably well in that hour.

This approach is not used when parking ratios are incorporated into zoning requirements and other planning standards; therefore, most industry publications suggest using effective supply factors in developing recommended parking ratios for the zoning code. The intent of the effective supply concept is that the system will work reasonably well on the design day, but there may be difficulty finding an available space in hours above the design hour. This is truly a practical need; for example, parking facilities with access and revenue controls are often closed before the parking facility becomes completely full, because it is just too difficult to find available space, and most of the remaining stalls are reserved for particular users, such as disabled parking. Users may perceive that there is a serious or even severe parking problem even though there may be spaces available somewhere in the system.

### *4. Size*

The size of a development influences parking behavior. The peak accumulation of vehicles at a large multitenant building is more likely to fit a standard accumulation than is the peak accumulation of parking in a small building in the same land-use category. It is simply a case of probability. For example, among 50 small office buildings, a number will have a demand high enough to require 3.8 spaces/ksf. If the tenants of those 50 buildings move into a single, large building, the accumulation of vehicles will average out, and a 3.0 spaces/ksf (3.2 spaces/100 $m^2$) supply would be sufficient. It is appropriate, therefore, for a community to have a higher ratio for smaller concentrations of a specific land use than that required for larger buildings. However, single-tenant buildings, especially larger ones, may need special study. When there are multiple departments with different functions, the parking needs will be similar to a large multi-tenant building; however, a single-tenant building that houses one large function may have higher parking needs.

Size has the reverse impact on large shopping centers. Shopping center size usually reflects its primary markets—neighborhood, community, or regional—and thus differences in shopping and parking patterns. More specifically, the larger the center, the longer the length of stay, increasing the percentage of daily vehicles present at any one time (see Table 11-7).

### *5. Accessory Uses*

Accessory uses are areas within a specific land use that are not the principal activity, but are necessary to the successful tenancy of that use. Examples include storage, stock, office, and kitchen spaces. Some believe that this floor area should be calculated at different rates for parking generation. However, most national standards have been based on studies wherein these areas have been considered as part of the floor area used to calculate parking ratios for the entire activity. Therefore, it is usually appropriate to include accessory areas in the parking-related floor area calculations for the primary use.

### *6. Complementary Uses*

A complementary use is a space that is used or leased by a different land use, but designed to serve or enhance the primary use. Although the complementary use normally would have substantially different parking characteristics from those of the primary land use, the interrelationship with the primary use results in lowered parking demand, primarily through captive market effects. For example, a deli or sandwich shop that might otherwise require more parking spaces per unit of floor area can be allowed in an office building without increasing the ratio of the primary activity generator. An Urban Land Institute (ULI)/International Council of Shopping Centers (ICSC) study examined this issue and found that small concentrations of complementary uses do not change the parking requirements from those of the primary land uses. Thus, for small concentrations of complementary uses, the full GFA/GLA (that is, the sum of the primary and complementary uses generally) should be used in the projections of parking requirements using the ratio for the primary use.

The ULI/ICSC study found that where more than 10 percent of the GLA of a shopping center is occupied by restaurant or entertainment uses, the parking ratio should be increased, and that when more than 20 percent of the GLA is in restaurant/entertainment uses, shared-parking analysis should be employed. *Shared Parking* [Smith, 2005] and Parking Consultants Council updates recommend using shared-parking analysis when more than 10 percent of the GLA is occupied by complementary uses.

| Table 11-7. ICSC Shopping Center Classification | | | | |
|---|---|---|---|---|
| **Type of Center** | **Concept** | **Square Feet (including Anchors)** | **Sample Size** | **Type** |
| **Malls** | | | | |
| Regional Center | General merchandise fashion (mall typically enclosed) | 400,000–800,000 | 2 or more | Full-line department store; mass merchant; discount department store; fashion apparel |
| Super Regional Center | Similar to regional center but has more variety and assortment | 800,000 + | 3 or more | Full-line department store; junior department store; mass merchant; apparel |
| **Open-Air Centers** | | | | |
| Neighborhood Center | Convenience | 30,000–150,000 | 1 or more | Supermarket |
| Community Center | General merchandise; convenience | 100,000–350,000 | 2 or more | Discount department store; drug; home improvements; large specialty/discount |
| Lifestyle Center | Upscale national chain specialty stores; dining and entertainment in outdoor setting | Typically 150,000–500,000, can be smaller or larger | 0–2 | Not usually anchored in the traditional sense, but may include book store; other large-format specialty retailers; multiplex cinema; small department store |
| Power Center | Category; dominant anchors; few small tenants | 250,000–600,000 | 3 or more | Home improvement; discount department store; warehouse club; off-price |
| Theme/Festival Center | Leisure; tourist-oriented; retail and service | 80,000–250,000 | N/A | Restaurants; entertainment |
| Outlet Center | Manufacturers' outlet stores | 50,000–400,000 | N/A | Manufacturers' outlet stores |

## C. Sensitivity of Parking Recommendations

How much parking is enough? Quite simply, it depends. The following issues should be considered when developing an appropriate parking demand ratio for a land use.

1) How unified is the parking system? Is there one big facility or many scattered smaller facilities? Are spaces reserved for specific users that cannot be used by other parkers when vacant?

2) What is the level of confidence in the parking generation data (that is, predicted occupancy)? Where data are collected at an existing site and projected into the future, it is still appropriate to select a design day and employ an effective supply factor so that the system works reasonably well.

   When sources such as *Parking Generation* [ITE, 2010] are employed, the variation in density of activity occurring due to the specific tenants present must also be considered, along with the fact that tenants change over time. "Shopping center" is the only land use for which a large sample of data has been specifically collected in a widely accepted design hour; moreover, the accepted design hour (the 20th highest hour in the year) is relatively high. The level of confidence in office building parking ratios is also relatively high because the data sample in *Parking Generation* is large (178 study sites), the coefficient of variation is relatively low (26 percent) and there is not much variation in parking accumulation by season of the year (thus, when the data were collected is not a critical issue). For many other uses, coefficients of variation are high and the level of confidence is relatively low.

3) What is the shock absorber or failsafe when parking generation exceeds effective supply? Will there still be enough spaces if the operator manually directs parkers to the difficult-to-find spaces in those circumstances? Will automated systems be able to help parkers find spaces with less frustration? Is off-site temporary parking

available, and will it likely be available throughout the planning horizon? Is there the potential to share parking and use the parking resources more efficiently? Would spillover parking into an adjacent neighborhood be acceptable? Is it acceptable to turn some people away?

4) Will the knowledge of a likely tight supply modify visitation patterns or mode choices to the site? For example, a parking study at one shopping center that clearly needed more spaces than the generally accepted ratios in the design hour found that shoppers came earlier or later in the day to avoid the congestion in midafternoon. The media annually publicize the congestion at airports on peak holiday travel days, resulting in more travelers choosing to be picked up/dropped off at the airport rather than park for the length of the trip.

5) Is transit an alternative to automobile use? Is there a potential benefit to the community in limiting parking supply to encourage market pricing of parking and/or to encourage more use of alternate modes of travel?

6) With any of the above approaches, for hours exceeding the peak hour on the design day, how many times a year would this be acceptable to the business owner? To the users? To the community?

In many older references, the recommended parking demand ratio was based on the 85th percentile ratio and then factored up by dividing by an effective-supply factor to arrive at the ratio of spaces to be provided per unit of land use. This was never the case with the ratio for shopping centers. In the original 1978 study of shopping center parking demands, the 20$^{th}$ highest hour was selected as the design hour, but the recommended parking ratio was set at the average of the observed accumulations across a large sample of data taken in that particular hour, without any additional effective-supply cushion. This approach recognizes that for the average center during 19 hours per year there will be no vacant spaces at all, and that in other hours there will be difficulty finding available space because there is no effective-supply cushion for these hours. Shopping centers that are more successful than the average center will have real and perceived parking shortages in more hours per year, while less successful centers may never have any perceived, much less real, parking shortages.

As previously discussed, there is growing acceptance in the industry that parking is often oversupplied when traditional zoning ratios are used. The second edition of *Shared Parking* used the 85th percentile accumulation with no additional effective-supply factor for recommended parking ratios. *Recommended Zoning Ordinance Provisions* adopted all of the *Shared Parking* ratios and added a number of ratios for other uses using the same philosophy. [Parking Consultants Council, 2007] These ratios are specifically intended to be the recommended *minimum* number of spaces to serve that quantity of that land use. If a community sets maxima in lieu of or in addition to minimum ratios, they should consider adding an effective-supply ratio to the minimum parking ratios found in these two publications to arrive at appropriate maximums. Fundamentally, this is a shift in thinking regarding how much parking a community should require.

An extra cushion of spaces for effective-supply considerations or even more spaces for leasing or other reasons might still be provided, but it should not be required by zoning or governmental approvals as the minimum number of spaces required to protect the community's interests. The provision of extra spaces should be a professional judgment made in consultation with the owner based on the advantages or disadvantages of a limited supply in peak hours at that particular site.

## D. Reducing Parking Demand

There are many factors that can influence the demand for parking and thus the number of spaces that should be provided. Managing the supply and price of parking can have a significant effect on trip generation. Employee trips destined to work-related parking are just one of the target markets for parking management strategies. Those searching for parking spaces for other trip purposes, such as shopping, personal business, or recreation, could also be affected. For example, studies in several communities have shown that the amount of traffic on local streets engaged in searching for parking spaces can be quite high: 45 percent in Brooklyn, New York; 28 percent in Manhattan, New York; and 30 percent in Cambridge, Massachusetts. [City of Seattle, 2008]

Individual parking actions can have clearly identifiable effects on parking demand. For example, the impact on parking demand of increasing the price of parking can be estimated by using elasticity measures that reflect the demand-price relationship. However, for many communities where a parking program or strategy consists of many different actions,

Source: City of Pasadena, 2006

it is often more difficult to assess the relationship between the parking program and the likely change in parking demand. For example, Figure 11-5 shows the types of actions that cities have used in developing a community-wide parking management strategy. Identifying the individual contribution of each action shown in this figure to overall trip reduction would be very challenging.

The town of Nantucket, Massachusetts, which faces many of the challenges of resort and tourist communities with both residents and visitors often vying for the same parking spaces, developed the following strategies and actions in order of priority. [Nelson Nygaard Consulting Associates, 2010]

- Remote parking
- Parking cash-outs or universal transit passes
- Handheld units
- Demand-responsive pricing
- Automated license plate reading technology
- Multispace pay and display
- In-car meters
- Valet
- Parking benefit district
- In-lieu fees
- Shared parking
- Residential parking benefit districts
- Reverse-angle parking
- Curbside sensors
- Pay with cell phone
- Zoning/parking maximums
- Unbundle parking
- Pay before you exit
- Real-time space availability displays

- Multispace pay by space
- Tandem and stackers
- Smart cards
- First few minutes free meter

The Nantucket study also provides excellent reference material for each of these proposed actions, especially as applied in smaller communities.

These examples of parking management programs illustrate the fact that communities often utilize many different actions and measures to manage their parking more efficiently and effectively. However, each community is different, and a wide variety of factors could affect parking demand. For example, ITE parking demand ratios reflect suburban sites where usually major land uses are separated, and there is little transit ridership or few walk-in patrons. In most cases, parking is free or low cost. Thus, they need downward adjustments where these conditions do not apply, especially in the CBDs. In addition, most planners today look at parking, especially in a suburban context, as part of a much larger mobility program. For example, Table 11-8 comes from a study that looked at parking programs in suburban downtowns in the Chicago metropolitan area. [Banks, 2011] As noted by the study, "To accommodate future growth and develop livable communities, with safe options for a variety of travel modes, we must take a proactive approach to managing parking so as to avoid the negative externalities and get the best and highest use out of our available land."

In parking analysis, factors that tend to dampen the demand for parking are incorporated into the analysis as adjustment factors. For example, in areas with high levels of transit use, the number of parking spaces could be reduced. Similarly, if shared parking opportunities exist in the development complex, the amount of parking required for each development could be reduced as well. Table 11-9 shows some of the adjustments that are typically made as part of parking demand analysis. In most cases, the allowable adjustments are codified in local zoning or planning requirements, or are established by the planning agency.

**Table 11-8. Parking and Other Strategies for Suburban Downtowns, Chicago**

| Parking Management Tool | Description / Example |
|---|---|
| Context-sensitive solutions | Reduce minimums for senior and affordable housing. |
| Improve bicycling infrastructure and the pedestrian environment | Provide secure bike racks, improve crosswalk visibility, create bike lanes, etc. |
| Work with employers to incentivize carpooling, bicycling, walking | Employers can offer workers benefits such as: the cash equivalent of a parking space, access to a shared company vehicle, cash per mile ridden for bicyclists, etc. |
| Shared parking | Share parking facilities among multiple uses with disparate peak demand periods. |
| Land banking/land reserves | Require developers to provide parks and open space that could be converted to parking, if needed. |
| Paid parking, no time limits | Install meters or paid parking systems without time limits, as price should be influential enough to adjust behaviors. |
| Progressive parking pricing | To encourage turnover, the price is progressively higher per hour in high activity areas (for example, $1 for the first hour, $2 for the next hour, $5 for each hour following). |
| Unbundled parking | Reduce parking requirements for developers who unbundle parking spaces from rents/mortgages; or require developers to unbundle parking. |
| Create a Parking Benefit District or Parking Management Authority | All paid parking revenue is deposited into a fund for the area where the meters are located, to be used for whatever the tenants and land-owners desire. |
| In-lieu fees | Charge developer fees in-lieu of providing required parking with funds dedicated to providing parking at a centralized garage/municipal lot, and/or improving the streetscape. |
| Eliminate parking minimums | With no parking minimums, developers will likely provide a more limited supply, and small businesses will have more incentive to open new locations. |

Source: Banks, 2011

| Table 11-9. Parking Requirement Adjustment Factors | | |
|---|---|---|
| **Factor** | **Description** | **Typical Adjustments** |
| Geographic location | Vehicle ownership and use rates in an area. | Adjust parking requirements to reflect variations identified in census and travel survey data. |
| Residential density | Number of residents or housing units per acre/hectare. | Reduce requirements 1% for each resident per acre. Reduce requirements 15% where there are 15 residents per acre, and 30% if there are 30 residents per acre. |
| Employment density | Number of employees per acre. | Reduce requirements 10–15% in areas with 50 or more employees per gross acre. |
| Land-use mix | Range of land uses located within convenient walking distance. | Reduce requirements 5–10% in mixed-use developments. Additional reductions with shared parking. |
| Transit accessibility | Nearby transit service frequency and quality. | Reduce requirements 10% for housing and employment within 1/4 mile of frequent bus service, and 20% for housing and employment within 1/4 mile of a rail transit station. |
| Carsharing | Whether a carsharing service is located nearby. | Reduce residential requirements 5–10% if a carsharing service is located nearby, or reduce 4–8 parking spaces for each carshare vehicle in a residential building. |
| Walkability | Walking environment quality. | Reduce requirements 5–15% in walkable communities, and more if walkability allow more shared and off-site parking. |
| Demographics | Age and physical ability of residents or commuters. | Reduce requirements 20–40% for housing for young (under 30) elderly (over 65) or disabled people. |
| Income | Average income of residents or commuters. | Reduce requirements 10–20% for the 20% lowest income households, and 20–30% for the lowest 10%. |
| Housing tenure | Whether housing units are owned or rented. | Reduce requirements 20–40% for rental versus owner occupied housing. |
| Pricing | Parking that is priced, unbundled, or cashed out. | Reduce requirements 10–30% for cost-recovery pricing (i.e., parking priced to pay the full cost of parking facilities). |
| Unbundling parking | Parking sold or rented separately from building space. | Unbundling parking typically reduces vehicle ownership and parking demand 10–20%. |
| Parking & mobility management | Parking and mobility management programs are implemented at a site. | Reduce requirements 10–40% at worksites with effective parking and mobility management programs. |
| Design hour | Number of allowable annual hours a parking facility may fill. | Reduce requirements 10–20% if a 10th annual design hour is replaced by a 30th annual peak hour. Requires overflow plan. |
| Contingency-based planning | Use lower-bound requirements, and implement additional strategies if needed. | Reduce requirements 10–30%, and more if a comprehensive parking management program is implemented. |

Source: Litman, 2013b, Reproduced with permission of Todd Litman.

Table 11-10 shows the types of actions that can be taken as part of a parking management program, the likely reduction in parking spaces associated with each action, and the likelihood that a notable traffic reduction will occur.

A more specific example comes from the city of Pasadena, which adopted a traffic reductions strategy aimed at reducing the amount of traffic in the city. [City of Pasadena, 2006] The strategy consisted of the following actions:

- *Charge the right price for curb parking*—Charge the lowest price that will leave one or two vacant spaces on each block—that is, performance-based pricing. This will eliminate the traffic congestion caused by drivers cruising for parking.
- *Return the meter revenue to the neighborhoods that generate it*—Revenue return will make performance-based prices for curb parking politically popular. Revenue will support, (a) additional commercial parking benefit districts, and (b) establish residential parking benefit districts.

| Table 11-10. Potential Impacts of Parking Management Actions | | | |
|---|---|---|---|
| **Action** | **Description** | **Parking Space Reduction** | **Significant Traffic Impact** |
| Shared parking | Parking spaces serve multiple users and destinations. | 10–30% | |
| Parking regulation | Regulations favor higher-value uses such as service vehicles, deliveries, customers, quick errands, and people with special needs. | 10–30% | |
| More accurate and flexible standards | Adjust parking standards to more accurately reflect demand in a particular situation. | 10–30% | |
| Parking maximums | Establish maximum parking standards. | 10–30% | |
| Remote parking | Provide off-site or urban fringe parking facilities. | 10–30% | |
| Smart growth | Encourage more compact, mixed-modal development to allow more parking sharing and use of alternative modes. | 10–30% | √ |
| Walking and cycling improvements | Improve walking and cycling conditions to expand the range of destinations served by a parking facility. | 5–15% | √ |
| Increase capacity of existing facilities | Increase parking supply by using otherwise wasted space, smaller stalls, car stackers, and valet parking. | 5–15% | |
| Mobility management | Encourage more efficient travel patterns, including changes in mode, timing, destination, and vehicle trip frequency. | 10-30% | √ |
| Parking pricing | Charge motorists directly and efficiently for using parking facilities. | 10–30% | √ |
| Improve pricing methods | Use better charging techniques to make pricing more convenient and cost-effective. | Varies | √ |
| Financial incentives | Provide financial incentives to shift mode such as parking cash-out. | 10–30% | √ |
| Unbundle parking | Rent or sell parking facilities separately from building space. | 10–30% | √ |
| Parking tax reform | Change tax policies to support parking management objectives. | 5–15% | √ |
| Bicycle facilities | Provide bicycle storage and changing facilities. | 5–15% | √ |
| Improve information and marketing | Provide convenient and accurate information on parking availability and price, using maps, signs, brochures, and the Internet. | 5–15% | √ |
| Improve enforcement | Ensure that regulation enforcement is efficient, considerate, and fair. | Varies | |
| Transportation management associations | Establish member-controlled organizations that provide transport and parking management services in a particular area. | Varies | √ |
| Overflow parking plans | Establish plans to manage occasional peak parking demands. | Varies | |
| Address spillover problem | Use management, enforcement, and pricing to address spillover problems. | Varies | |
| Parking facility design and operation | Improve parking facility design and operations to help solve problems and support parking management. | Varies | |

Source: Litman, 2013b, Reproduced with permission of Todd Litman.

- Invest in a portion of parking revenues in transportation demand management programs.
- Provide Universal Transit Passes.
- Require the unbundling of parking costs. Unbundle from housing costs, commercial leases, and from the costs of other goods and services.
- Require parking cash-out.
- Strengthen transportation demand management requirements.
- Improve transit.

- Improve bicycle and pedestrian facilities and programs.
- Remove minimum parking requirements for off-street parking.
- Set maximum parking requirements.
- Establish congestion pricing.

Given the importance of parking, it is not surprising that the Pasadena trip-reduction strategy targeted parking in 7 of its 12 actions.

Table 11-11 shows the expected impacts of the parking component of the trip-reduction strategy aimed at reducing trips by 10 percent. This presentation is very typical of most studies in that the impact of the primary measures as stand-alone actions are estimated along with the supporting measures that would be necessary for the full impact to occur.

The study also looked at the measures needed for a 25 percent reduction in trips. A $10.00 per workday parking cash-out program will reduce employee commute trips by approximately 40 percent; a $200 per month per parking space charge would result in a 20 to 40 percent reduction in household vehicle ownership and trips at the affected multifamily residences, and a charge of $6.00 per entry or exit will result in at least a 30 percent drop in peak hour entries and exits at Pasadena's borders.

In the United States, community- or area-wide parking management strategies are often part of transportation demand management (TDM) plans, which focus on reducing the use of the single occupant vehicle (SOV). Where the use of TDM strategies is contemplated, parking pricing is often critical to achieve program goals. Studies of TDM programs have consistently shown that free parking is the single largest deterrent to success. The following parking pricing options could be considered as part of TDM plans:

- *Fees for Parking*. A fairly high increase in cost is required to achieve a significant reduction in SOV commuting. Demand elasticity for parking appears to be situation dependent, reflecting the cost of alternative modes, commuting distances, and market pricing at competitive facilities.

**Table 11-11. Sample Strategies for a 10 Percent Reduction in Traffic, Pasadena, California**

| | |
|---|---|
| **Primary Measures** | |
| **Require parking cash-out,** with a $5.00 per workday payment to non-drivers, for all employees at all worksites, both new and existing | Typical effect observed: a $5.00 per workday parking cash-out program will reduce employee commute trips by approximately 20 percent. Some additional reduction in non-work trips (e.g., shopping trips on the way home from work) would be expected as a result. |
| **Require unbundling of parking costs** from housing costs at all multi-family developments both new and existing, with a minimum price per parking space of $100 per month. | Typical effect observed: a $100 per month per parking space charge (offset by an equal reduction in rents) will result in a 15 to 30 percent reduction in household vehicle ownership and trips at the affected multi-family residences. |
| **Institute congestion pricing** at Pasadena's borders, with a minimum charge of $3.00 per entry or exit during peak hours. | Typical effect observed: a charge of $3.00 per entry or exit will result in at least a 20 percent drop in peak hour entries and exits at Pasadena's borders. |
| **Supporting Measures** | |
| Charge the right price for curb parking<br>Return meter revenue to the neighborhoods that generate it<br>Invest parking revenues in TDM programs<br>Provide Universal Transit Passes<br>Strengthen TDM requirements<br>Improve bicycle/pedestrian facilities and programs<br>Remove minimum parking requirements<br>Set maximum parking requirements | |

- *Discounts for Ridesharing*. Discounts, if not elimination of parking charges, should be considered for carpools and vanpools. This strategy is most effective when combined with other non-pricing strategies, such as preferential locations and aggressive rideshare matching programs. The planner must also be concerned with the cost-effectiveness of such programs and their impacts on transit ridership. When the California Department of Transportation added a discount and preferential parking program for carpool parking, 90 percent of the spaces were used by existing pools, and two-thirds of the new pool participants switched from transit. Trips to the site actually increased and transit use declined by more than 200 persons per day. This finding suggests that it may be more beneficial to encourage transit use and park-and-ride than ridesharing, especially given reported decreases in ridesharing during the past few decades.
- *Transit Subsidies*. In addition to raising the cost of parking, lowering the cost of transit by either subsidizing or paying the full cost of transit can be a key component to a successful TDM plan. Again, the first in line for such subsidies will generally be those who already use transit, and it will be critical to combine this tactic with increasing the cost of SOV parking to achieve any real benefit.
- *Transportation Allowances*. Rather than target a single mode of transportation, a transportation allowance provides a cash payment to each employee to pay for the commute, whether by driving (and thus parking) or transit, or to be pocketed by walking or bicycling.
- *Cash-Out Programs*. Similar to the transportation allowance, the cash-out program provides a monthly payment equal to the monetary value of a previously free parking space. Employees can then spend it on parking at that rate, use it for other modes of transportation, or simply pocket it.
- *Parking Taxes or Surcharges*. In a community where commercial parking exists but fees are still not adequate to encourage alternative modes, parking taxes or surcharges can be used to force the market rates to a more acceptable level. However, it must be applied to a broad area. When Madison, Wisconsin, applied a peak period surcharge to four of its municipal garages, some commuters did switch to transit, but many more simply switched parking location. [VTPI, 2015]

Chapter 14 on transportation demand management provides more discussion on the use of parking strategies as part of a TDM program.

## VII. COMMON LAND USES

Table 11-12 illustrates the types of data that is found in ITE's *Parking Generation* following the ITE land-use coding system. [ITE, 2010] In this case, codes 000 through the 500 series generally encompass transportation ports and terminals, industrial, residential, recreational, and lodging. The table also compares the ITE data with the recommended ratios in *Shared Parking* and *Recommended Zoning Ordinance Provisions*.

*Parking Generation* data represent the average peak of the observed accumulation and not necessarily *demand* or *required spaces* for zoning purposes. The information in the *Parking Generation* tables is only provided for the 73 land uses (out of 91) where ITE had enough data to present them graphically. Only about half of the graphical presentations have fitted curves where the regression analysis found a consistent relationship between the quantity of land use and parking generation. The tables include two of the statistical indices that assist in understanding the statistical reliability of the sample. The first is the coefficient of variation, which measures the reliability of the average ratio (the lower the percentage of variation the better); the other is the coefficient of determination ($R^2$) that measures the reliability of the regression equation (the higher the factor the better.)

Fitted curves are provided only where there were at least four study sites and $R^2$ exceeded 0.6. Generally, the coefficients of variation for those data sets were 50 percent or less (exceptions where the coefficients of variation were much higher were the relationship between parking spaces and employees for banks, ratios for airports on Saturdays, and ratios for warehouses on a GFA basis [see chapter 2 for a discussion of coefficient of variation]).

In some cases, the lack of a fitted curve, which is identifiable in Table 11-7 where no $R^2$ is listed, was simply because there were not enough study sites or enough variation in the size of the study sites for the regression analysis to determine a fitted curve. In other uses, such as restaurants, there is significant variation in parking generation, which

*The same ratio is recommended in *Shared Parking*, Second Edition

likely reflects the level of patronage of the restaurant. Even where there is a linear relationship, the sample may not be reliable. In many cases, the fitted curve is significantly different from the average ratio. Where the slope of the fitted curve is greater than the average ratio, parking generation ratios increase as the land use size increases; where it is less than the average ratio, generation rates decrease as land use size increases.

The following sections discuss special considerations for determining parking demand at some common land uses (note that not all uses are discussed).

## A. Airports

ITE states its airport parking ratios in terms of parking spaces per daily enplanements (total number of passengers using a terminal), which is presumed to be average daily enplanements, not enplanements on the date studied. Many parking planners use originating enplanements (OE) instead of total enplanements, because this factors out transfer passengers, who do not generate public parking demand. Further, it is more common to use a ratio of parking spaces per 1,000 annual OE because most airports use annual enplanements in planning forecasts.

In a survey of parking supply at U.S. airports, Donoghue [1997] found a relationship between the size of the airport in terms of OE and parking supply, with generally lower ratios for larger airports. However, the range in spaces per 1,000 OE was very large. For example, the midsized airports with 900,000 to 3.5 million OE exhibited ratios ranging from 0.14 spaces/1,000 OE to 1.18 spaces/1,000 OE—nearly a factor of 10 between lowest and highest value. These are supply ratios, not demand ratios; many airports build parking for a planning horizon of 10 years or more (to avoid more frequent disruption of the airport parking system as enplanements grow) and may or may not have excess spaces at the time of study. Also, off-airport parking supplies at many airports accommodate some portion of the demand. Therefore, care should be taken in using published data on airport parking supply (for example, *Parking Generation* has 20 data points for airports, of which 15 are from Canadian airports in small markets).

Landrum & Brown et al. [2010] concluded that although there is a great deal of variation in parking demand for airports, a general rule of thumb is that parking supply should range from 900 to 1,400 spaces per million enplaned passengers, with 25 to 30 percent of the spaces designated for short-term parking.

Generally, airport parking is not controlled by local zoning and detailed parking studies are needed to project future parking needs. Airport parking demand is highly complex, being both a captive market and a lucrative one that has attracted competition from off-airport commercial providers. Because the revenue stream from parking is usually the second or third highest source of net revenue to the airport and because airport activities tend to increase over time, airport managers usually want to know in some detail what parking demand is likely to be. In addition, considerable data for parking projections are available from the revenue control systems used at airports. Therefore, while the following analysis of airport parking demand is not going to support an industry standard ratio of parking spaces/OE, it is generally beneficial for understanding the complexity of parking demand, design days, and effective supply considerations.

Airport parking demand is typically evaluated in four areas:

*Hourly* or short-term parking serves kiss-and-fly as well as "meeters and greeters" who stay 3 hours or less. The term *hourly* is preferred by many in the industry because the term *short term* is less understood by various parties, including the traveling public. Since the terrorist attacks of September 11, 2001, hourly parking, both in terms of annual parkers and spaces required, has decreased significantly. Security at airports has considerably increased, and nontravelers are no longer allowed to wait at gates. Therefore, the length of stay for hourly parking has significantly declined, increasing turnover factors. Cell phone lots where drivers who otherwise would have circled terminal roadways, waited at the terminal curb, or parked at the terminal parking facility to wait for arriving passengers, now allow meeters and greeters to wait in their vehicle at a more distant location and come to the terminal only when the passengers are ready to be picked up.

*Daily* parkers are typically willing to pay a relatively high daily rate for convenient terminal parking. The demand by this group is price sensitive, and differential pricing of economy lots and daily offerings can significantly affect demand for terminal parking.

*Economy* parking is generally provided for multi-day stays. Although those choosing economy parking may comprise only 10 to 20 percent of parkers, it may require 50 to 70 percent of the total parking supply—the reverse side of the 80/20 rule. The quantity of remote parking required at an airport can be greatly affected by commercial off-airport parking.

*Employee parking* is generally provided off-site with shuttle service. It is often difficult to keep employees out of terminal parking without relatively high daily parking rates and very tight revenue controls.

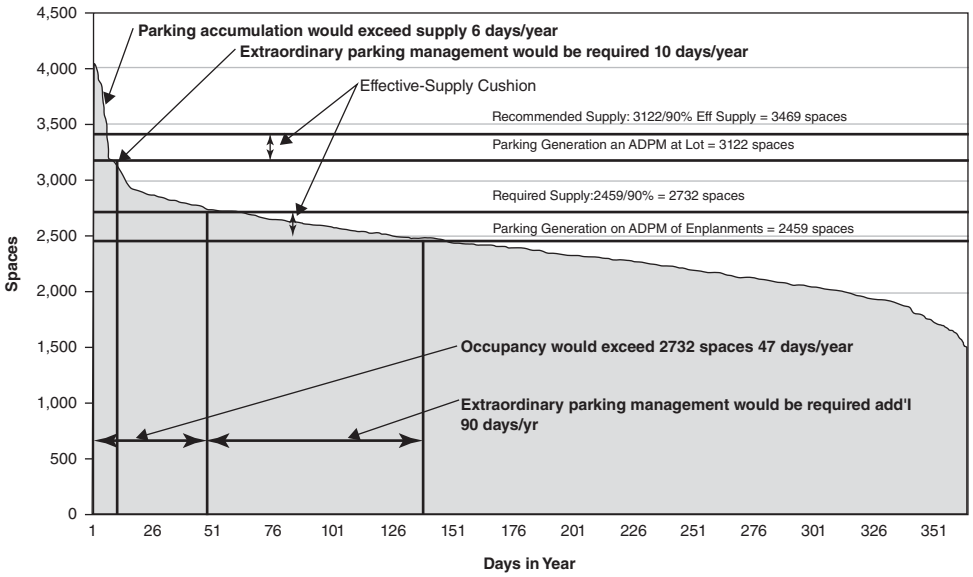
Once a pricing structure is in place, it is difficult to use spaces allocated for one group for another group, and because rates are often set by political bodies, it is difficult to change rates to accommodate the seasonal differences in travel that affect parking demand at different facilities. Therefore, it is important to look at the demand for parking at each parking service, rather than the overall number of spaces occupied on a design day. Also, because economy parking facilities peak at different times of the year than terminal parking, this further complicates issues relating to design day and effective-supply cushions. Figure 11-6 shows the peak hour of accumulation of parked vehicles at one airport's economy parking facility on each day in one year, in descending order.

Traditionally, the design day for airport terminal facilities is the *average day peak month* (ADPM) for enplanements. Often, this month may be in summer when business travel is at typical levels, but there is also a high level of leisure travel as opposed to the peak leisure travel period of Thanksgiving in an otherwise average month. A common standard for effective supply factors at airports is 85 percent for terminal parking and 90 percent for economy parking.

As an example, if the design day for an economy lot were to be the ADPM for enplanements (the design day for terminal design), and no effective-supply adjustment were provided, the parking generated at this lot would exceed the supply 47 days per year, and it would be so difficult to find spaces that extraordinary parking management strategies would be required on an additional 90 days per year (see Figure 11-6). Based on the airport's past practices, some cars would be allowed in and directed to available spaces, while other patrons would be directed to off-airport parking. If off-airport parking is reported to be full, patrons would be given coupons to park in terminal parking at economy rates. Because economy parking demand does not vary significantly from hour to hour throughout the course of the day, these strategies would be required in most hours of the 47 + 90 = 137 days in a year. The delay in finding a space would be significant on more than one-third of the days, causing a perception of parking shortages at the airport. This in turn could result in local political pressure to "fix the parking problem."

If instead the occupancy on the ADPM for the lot is used and the lot is assumed to have a 90 percent effective supply factor, the number of hours or days when extraordinary parking management is required is significantly reduced. If the average peak-hour parking occupancy in the busiest month at this lot was 3,122 parking spaces, a lot with

**Figure 11-6. Design Day and Effective-Supply Considerations at an Airport Economy Parking Lot**



Source: Courtesy of Walker Parking Consultants, Inc.

3,122/0.9 = 3,469 spaces would be required to accommodate the design day demand. With this design day, parking generation would exceed the capacity on only six days (all in either the peak Thanksgiving or Christmas travel periods when parking shortages are expected by the traveling public).

Special parking management strategies would be required on an additional four days per year. For this particular airport, using the ADPM for the economy parking with an effective supply factor of 90 percent was considered a far more acceptable design approach than using just the ADPM for enplanements overall. For terminal parking, the ADPM for the combination of daily and hourly parking, which occurred in a different month, was similarly employed with an 85-percent effective supply factor.

Another factor in estimating parking demand, especially at large airports, is the number of passengers and employees who will use transit to access the airport. Figure 11-7 shows the percentage or market share of those going to the airport in the 13 largest transit-oriented cities in the United States. As shown, when you have almost 24 percent of the trips into your airport coming via rail or bus/van (as in San Francisco), one must be very careful at estimating a parking demand simply using OEs as was described earlier.

In sum, the selection of design days and effective-supply factors is based primarily on professional judgment, which recognizes an owner's acceptance of extraordinary parking management actions that might be required. At airports, the specific combination of pricing, differing parking products, and off-airport availability further complicates parking planning.

**Figure 11-7. Market Shares to Rail and Bus/Van in the 13 Most Transit-oriented U.S. Airports**

## B. Intermodal Parking

Intermodal parking lots and garages facilitate the transfer of users from one passenger vehicle to other modes of travel; park-and-ride facilities are the primary form of such terminals. Many rapid transit and commuter rail operators have developed parking facilities at stations to increase the convenience, attractiveness, and coverage of the service (the key constraint to expanding service is often the limited amount of parking at stations, rather than constraints related to the train service).

There are three basic types of park-and-ride facilities (adapted from the Technical Committee on Transport [2005]):

- *Local* park and ride lots that serve as collectors, such as parking facilities at express transit facilities, central bus terminals, and at stops along existing regional bus routes.
- *Remote* park-and-ride lots, intercepting automobile trips near their origin, generally along regional transportation corridors, with express bus or rail service to the CBD or activity center.
- *Peripheral* park-and-ride lots on the edge of activity centers, usually within 1.5 miles of the destination.

Park-and-ride lots are an important component of a region's transit strategy in that they provide a means of transferring from another mode to transit. Valley Metro, the transit agency for the Phoenix metropolitan area, conducted a study in 2013 of the utilization of its park-and-ride lots. [Valley Metro, 2013] The study concluded:

- Park-and-ride lots with express or rapid bus service served different travel markets than light rail park-and-ride lots.
    - Bus lots primarily served work trips (98 percent of total trips), while light rail lots tend to serve fewer work trips (53 percent) and more college or university trips (39 percent).
    - Light rail lots experienced higher parking utilization rates than bus lots.

    - Light rail lots had a 56 percent parking utilization rate compared to bus lots with a 46 percent utilization rate.
- Bus, light rail, and vanpool park-and-ride lot users predominantly accessed their lots by driving alone. However, light rail and vanpool lot users drove alone at a higher rate.
    - The survey found that 89 percent of vanpool lot users and 87 percent of light rail lot users drove alone, while 76 percent of bus lot users drove alone.
- A correlation between the number of cars parked at a light rail lot and the distance to downtown Phoenix was demonstrated by the survey data.
    - Analysis showed an almost direct 1:1 relationship between numbers of vehicles parked in light rail lot facilities and light rail lot distance to downtown Phoenix.
- On average, light rail park-and-ride lot users traveled farther to the lot than express and rapid bus lot users and vanpool users.
    - For light rail lot users, the average distance between their trip origin and lot is 5.1 miles while that distance was only 4.2 miles for vanpool lot users and 3.9 miles for bus lot users.
    - Lot facilities within 1.5 miles of a freeway were more utilized than those farther away. This typically resulted in the travel market sheds for lots near freeways to be larger.
    - Lots within 1.5 miles of a freeway averaged a 53 percent utilization rate while those at further distances averaged only a 28 percent utilization rate.
    - Lot users drove longer distances (4.3 miles) to lots within 1.5 miles of a freeway than to lots further from freeways (3.1 miles).
- Proximity to users' homes was the primary reason stated for choosing a park-and-ride lot, while the transit route that serves the lot facility was the second most common reason. (Survey respondents could select as many reasons for using their lot as applied.)
    - 75 percent of responses for users of all lots indicated that being close to home was a major reason. Bus lot users were more likely to list this as a reason (81 percent of responses) than light rail lot users (59 percent of responses).
    - 43 percent of responses for users of all lots indicated that a major reason was because their transit route serves it.
- The most-requested park-and-ride lot improvement was for covered parking, followed by real-time transit information.
    - Survey respondents could select up to two improvements they would most like to see. Approximately 25 percent of respondents requested covered parking, while just over 21 percent requested real-time transit information.
- A higher level of rapid bus service correlated with a higher number of cars parked in a lot.
    - An almost direct 1:1 relationship existed between the number of daily inbound rapid bus trips (HOV-based rapid service only) to the number of cars parked at a bus park-and-ride lot.
- Light rail park-and-ride lot users were 20 times more likely to be going to a university/college than bus lot users.
    - College/university trips comprised an average 39 percent of all trips for light rail park-and-ride users. For the four light rail lots closest to Arizona State University (ASU) and GateWay Community College, this trip purpose was much higher ranging between 43 percent and 65 percent of all trips. In contrast, college/university trips comprised less than 2 percent of all trips for bus lot users. An explanation of these results may be the expense of parking on the Arizona State University (ASU) campus. The two lots closest to ASU have 69 percent and 92 percent utilization ranking them the two most highly utilized of the light rail lots.
- Vanpool use at park-and-ride lots was greatest at highly visible lots adjacent to freeways.

- Five park-and-ride lots adjacent to the freeway had the highest vanpool utilization with five to eight vanpools (out of 45 vanpools responding to the survey) regularly using each.
- Vanpools used only 16 of the 29 lots surveyed. Limited utilization by vanpool commuters could be a result of lot geographic locations being inconsistent with trip origins, knowledge of lot facility locations, low visibility of lot facilities, and knowledge of authorization to use the lot facilities.

- The reason vanpool commuters most often chose their lot was because it is close to home. Other top reasons included availability of covered parking and being close to a freeway. The results indicate that convenience was a high priority for them.

Parking demand is generally stated as a ratio of spaces per boarding passenger on the average day of the peak month of ridership. The number of spaces per passenger at rapid transit stations varies substantially, depending on where the station is located. Characteristics for park-and-ride lots that may serve either rail or bus services are shown in Table 11-13. Table 11-14 shows characteristics of those who use park-and-ride lots, as seen in recent surveys of park-and-ride lot users representing a range of travel markets.

Ridership demand can be dramatically different at two successive stops on the same transit line because of the nature of the communities and market areas each station serves, as well as parking availability and the policies in place. One city may provide parking at a station for residents only; another station might allow parking for all users. Still others may have no parking at all. Railroad stations that serve long-distance routes have somewhat different parking demands than commuter rail stations given the differences in length of stay and in pick-up and drop-off characteristics. Many stations serve both on-site and kiss-and-ride demands; a parking study should consider both in the analysis. See [Turnbull et al., 2004] for a review of the impact on parking demand with changes in parking lot capacity.

A study that compares the competitive position of the target station with other stations is often necessary to estimate parking demand. In a metropolitan area, this is sometimes done through a regional travel demand model in which the availability and cost of parking and the characteristics of the transit operations serving the station help define the transportation network.

## C. Residential Uses

Residential parking demand is influenced by neighborhood socioeconomic characteristics, development density, and the availability of public transit and pedestrian access. Each can influence household auto ownership levels. Therefore, unit residential parking demands are greatest in low-density, affluent suburban and exurban areas. Unbundling parking fees from rental/purchase of units also affects parking requirements and might be mandated in communities or districts where alternative transportation modes are encouraged.

Residential parking needs have increased during the past 50 years. In 1960, 21 percent of households in the United States had no vehicle, whereas the 2009 National Household Travel Survey found only 8.6 percent of households without vehicles. [FHWA, 2013] Moreover, a large share of households without vehicles is comprised of elderly women living alone, minority households, higher density neighborhoods, and low income households. Recent immigrants are also less likely to have vehicles available. Geographically, most households (59 percent) without vehicles are renters in central cities; the New York metropolitan area accounts for 20 percent of all zero-vehicle households.

The required number of parking spaces for owned units (single-family homes and condos) is usually higher than that for rental units. In the 2001 National Personal Transportation Survey, only 3 percent of owner households did not own vehicles as compared to 17.6 percent of rental households.

Many professionals believe that recommended parking demand ratios for multifamily housing units should be based on the number of bedrooms in the unit; however, there are few data in the literature to develop recommended ratios. Therefore, while [Smith, 2005] provides ratios solely based on number of dwelling units, Parking Consultants Council [2007] provides recommendations based on number of bedrooms in apartments and condos, and square feet of single-family dwellings. Adjustments should be made based on the socioeconomic characteristics of the tenants and on the availability of transit in the vicinity. Given the availability of data on vehicle ownership per household by census tracks in cities, ratios for local zoning ordinances generally should be based on local characteristics of home ownership.

There are a number of various residential source data in ITE's *Parking Generation* for accessory units, a residential design that is increasingly popular in new urbanist developments. Recommendations are also made for sleeping rooms, which range from bed and breakfast and boarding house operations to convents and other group living arrangements in homes.

Assisted living or congregate care facilities include multi- or single-family dwelling units with centralized amenities such as dining, housekeeping, and transportation. Residents live relatively independently without constant supervision

and care. These facilities bridge the gap between independent living and nursing home care and are defined by ITE in the 200 series of land-use codes with residential uses, rather than with nursing homes and other institutional care facilities in the 600 series. Although there are only 33 studies in ITE's *Parking Generation* database, the observed parking ratios were found to be statistically reliable. A minimum ratio of 0.34 spaces per dwelling unit is recommended.

## D. Hotels

Determining parking demand for hotels is complicated by the variety of hotels in the marketplace, from low budget, no frills motels to the largest convention hotels. However, the demand for hotel parking can be shown to be directly related to the demand of the component uses of the particular hotel. Thus, parking demand can be determined through a shared parking analysis of the hotel and its particular components. The separation of hotels into multiple categories (hotels, business hotels, resort hotels, and motels) in ITE's *Parking Generation* suggests that there are sufficient data to estimate reliable parking ratios based on beds for business hotels and motels, both of which have only limited meeting and banquet facilities and may not have restaurants. There is more variation in the parking generation rates observed for full-service hotels. Resort hotels have significantly higher parking generation rates; in fact, the average ratio has been shown to be 1.3 spaces per room, with peak demand occurring between the hours of 2 and 3 p.m. due to check-in/check-out times. This is much higher daytime demand than other hotel types. This is likely true for a number of reasons, not the least of which is that resort visitors are more likely to stay many days and not check out in the early morning. Guests at resort hotels frequently store luggage after checkout time and continue to enjoy the resort, while others may arrive before check-in and also store luggage.

Parking generation at full-service hotels is also consistently higher than at business hotels (without restaurant and meeting/banquet space). Therefore, a shared parking analysis using separate ratios for the number of guestrooms, restaurant(s) and/or lounge(s), employees and convention or meeting rooms is recommended. This is a far easier way to adjust for the differences in hotel products than to try to define separate ratios for each hotel type. In ULI's *Shared Parking* [Smith, 2005], different ratios, time-of-day adjustments, and seasonal adjustments are also provided for guests at leisure and business hotels.

The parking ratio for restaurants in hotels is significantly lower than for stand-alone restaurants and should only be used if the restaurants are not expected to draw a significant number of non-hotel-guests. It is increasingly common for budget and business hotels (as classified by ITE) to have a branded, franchise restaurant on-site, serving guests as well as the surrounding area.

One refinement of ratios from older references is that different ratios are recommended for convention/meeting space depending on the amount of space provided. Below 20 $ft^2$ per guest room (or 215 $m^2$ of meeting space), no additional parking for the meeting space is required; different ratios are provided for GFA of 20 to 50 sq. ft. per guest room (215 to 540 $m^2$ of meeting space) and more than 50 $ft^2$ per guest room (540 $m^2$ of meeting space).

## E. Recreational and Entertainment Uses

ITE's *Parking Generation* data for live-performance theatres come from an intensive study of four theaters in a resort area in rural Tennessee. Additional analysis of live theater venue attendance and scheduling in *Shared Parking* has led to a recommended ratio of 0.40 spaces per seat for live performing arts venues. Live-performance theaters are typically single auditoriums. Where multi-theater complexes exist, the parking ratio should be adjusted for likely simultaneous use.

Multiscreen cinema complexes providing thousands of seats were a significant development trend in the 1990s with parking needs that outpaced the available planning literature. The increasing size of cinemas and changing design practices, such as stadium seating, brand fast food and the like, makes a seats-based ratio the most appropriate. Parking spaces per screen is another ratio that is sometimes used, but seats per screen varies widely; multiscreen cinemas often have larger and smaller auditoriums in the same complex. If the number of seats is not available, a good rule of thumb for converting GFA to seats is 20 $ft^2$ (1.86 $m^2$) per seat.

A peak parking demand of one space for every two seats is appropriate for a single screen theater and one space per three seats is appropriate for a theater with up to five screens. This ratio can be reduced as the number of screens increases. *Shared Parking* now recommends a ratio of 0.29 spaces per seat for cinemas with more than 10 screens.

*Parking Generation* has no data on arenas and stadiums. The parking demand at arenas and stadiums is generally calculated by defining the design event as a busy regular season game if there is a franchise tenant. An appropriate adjustment for local transit service and charter bus service is taken, then the mode split to personal vehicle is divided by expected auto occupancy. Modes of arrival and vehicle occupancy at these facilities can vary substantially by type of event. After the design day is chosen, *Shared Parking* recommends 0.31 spaces per seat for football stadiums, 0.35 spaces per seat for baseball stadiums, and 0.33 spaces per seat for arenas.

Casinos (ITE land use code 473) are a relatively new phenomenon for parking studies. *Parking Generation* does not have parking generation ratios for this activity. Further complicating the issue is that most casinos are mixed-use developments with hotels, retail, and other land uses. While land-based casinos have relatively low turnover (30 percent or fewer of the spaces turn over in the peak hour), a ratio of parking spaces to licensed occupancy can be determined for similar existing casinos and applied. Riverboats may—or may not—have a significant overlap of gamblers arriving for the next cruise before those on the previous cruise depart. The degree of overlap is significantly influenced by the embarkation/debarkation procedures and the time in port. Additional factors are the percentage of users expected to arrive by charter bus and the existence of other attractions nearby.

## F. Educational Institutions

The data in *Parking Generation* for elementary schools and urban high schools vary widely, while those for suburban high schools are more consistent. The Parking Consultants Council recommends the higher value of 0.2 spaces per auditorium or gym seat, or 0.25 spaces per student for elementary schools. Its recommendation for high schools is the higher total value of 0.3 spaces per auditorium or gym seat, or 0.3 spaces per student. *Parking Generation* suggests 85th-percentile parking demands of about 0.25 to 0.34 per school population, the traditional unit of measure. Another measure, spaces per registered vehicle, shows a range of 0.6 to 0.7 spaces per registered vehicle.

Similarly, Dorsett [1993] reviewed data from various parking studies and used regression analysis to determine how strong a relationship existed between total student/staff population and parking demand. He found that a regression

line would have predicted the actual number of occupied parking spaces only 13 out of 22 times with a 20-percent margin of error. The remaining nine cases fell outside the 20-percent margin of error. Dorsett noted that city and campus transit services, student to staff ratios, parking policies, class schedules, and on-street parking in nearby neighborhoods influenced demand.

Given the combination of many different factors that could influence parking demand at a university, a parking study should be conducted when new parking facilities are being considered.

A relatively large sample of data on day care centers (37 studies) in *Parking Generation* provides an average ratio of 0.24 spaces per student and an 85$^{th}$-percentile ratio of 0.34 spaces per student. There appears to be some reduction of parking needs in larger facilities. While there is slightly better statistical reliability exhibited in ratios based on employees rather than students (32 percent coefficient of variation on an employee basis versus 39 percent on a student basis), facilities are typically licensed for a particular number of students, and therefore, basing ratios on that figure appears to be most appropriate. The Parking Consultants Council recommends a ratio of 0.3 spaces per student in licensed capacity. *Parking Generation* data suggest a parking generation ratio of 0.4 spaces per seat for churches and other places of worship.

## G. Medical Institutions

Whitlock [1982] concluded that a single parking generation ratio for hospitals based on the number of beds was not appropriate. He recommended four variables be considered for such an analysis—typical daily staff population, typical daily visitor population, percent of staff driving, and percent of visitors driving. Since this study, there has been a revolution in the delivery of health care shifting from inpatient to outpatient care, therefore making a single ratio of spaces per bed even less reliable.

Dorsett [1995] recommended studying four user groups—employees, physicians, visitors, and patients—and identifying when and in what numbers each user group would be on the medical campus and the mode share of each. This study also concluded that using only one ratio was inappropriate.

Many hospitals have several parking facilities, each reserved for specific users. Therefore, it is important to look at the demand in terms of user characteristics because the peak hour demand for each user group differs. Typically, the outpatient lot may need to be designed for parking demand at 10:00 a.m., and the employee lot for demand at the 3:00 p.m. shift change. Because of the site-specific characteristics of demand, the most reliable means of projecting parking demand at hospitals is to conduct a detailed parking study.

*Parking Generation* also found a high degree of data reliability for parking at medical clinics, which are defined as Medical-Dental Office facilities. A ratio of 4.27 spaces/ksf (5.1 spaces/100 $m^2$) is recommended for this use. Note that this ratio is not significantly different from the ratio for medical and dental office buildings. Therefore, a medical office building that has outpatient facilities as part of its space may consider both as complementary uses and not require adjustment of the base ratio for a medical office building.

## H. Convention Centers

Parking demand varies significantly at convention facilities, reflecting the different types of events that occur. The facilities are constructed to draw regional if not national tourists for conventions. There are also differences between convention centers that have a combination of exhibit and meeting space, and exposition halls that are predominately exhibit halls. The parking demand for a regional event where many people drive in for the day will be considerably higher than for a large national event where most delegates arrive by taxi, shuttle from airports or rail stations, or walk from nearby hotels. Certain types of conferences may also have significantly higher parking demands, such as religious groups and franchise or distribution network meetings. However, the peak parking demand for a convention center almost always occurs when a public show is booked into the facility during periods of low convention activity. These events include boat and home shows that draw many local residents, most of whom drive and park.

There will be a relatively low turnover for a national convention (1.5 to 2 parkers or turns per day) with peak arrivals in the morning and peak departures in the afternoon; a boat show will have a higher turnover (three to five parkers per day) and in and out activity all day long.

By their very nature, convention centers have tended to be located in larger activity centers with convenient hotels. Thus, the convention center's dedicated parking may be designed for the needs of a moderate, mid-week national convention, with the greater needs of public shows on the weekend accommodated by other parking services in the vicinity. When a mega-show is scheduled, a parking and transportation management plan should be developed by the center's management and the show organizer to encourage alternative modes of travel to the center. Analysis of parking studies and event calendars in *Shared Parking* resulted in a recommendation of 6.0 spaces/ksf (6.5 spaces/100 $m^2$) of GLA for larger convention centers. In order to create a better transition from the *Shared Parking* ratios for convention spaces at hotels, the Parking Consultants Council has scaled ratios for quantities ranging from less than 25,000 sq. ft. (2,325 $m^2$) to more than 250,000 sq. ft. (23,225 $m^2$). (Note that by definition gross leasable space excludes the common areas, such as pre-function space, of these facilities.)

## I. Office Space

Office space varies significantly by density of employees, location of facility, and type of office activity. A multi-tenant, general office building, originally class A office space but now older and dated compared to the newer market entries, will likely have a higher density of employees than a newer class A luxury building occupied by law and financial firms. This suggests that employee densities tend to increase over time as the building ages without substantial reinvestment. A building with a corporate headquarters as its single tenant will often have lower densities than a multi-tenant building of the same size; however, a building solely occupied by back-room operations such as data processing and telemarketing has significantly higher densities.

A study of 10 office buildings in Southern California in 1992 found employment densities ranging from 2.0 to 8.2 employees/ksf (2.2 to 8.8 employees/100 $m^2$). [Willson, 1992] The peak parking accumulation at buildings in the 2.7 to 3.2 employees/ksf (2.9 to 3.2 employees/100 $m^2$) density range had peak parking accumulations of 2.0 to 2.2 employees/ksf (2.2 to 2.4 spaces/100 $m^2$). There was considerable variation in the other results. A building with 2.0 employees/ksf (2.2 employees/100 $m^2$) had a peak demand of 1.8 spaces/ksf (1.9 spaces/100 $m^2$), while another with five employees/ksf (5.4 employees/100 $m^2$) had a demand of 1.4 spaces/ksf (1.5 spaces/100 $m^2$). The office use with higher total employment had significantly lower employee presence and parking needs, apparently due to multiple shifts.

The added presence of visitors further complicates the analysis. Medical office buildings may have more than one visitor per employee at any given time. The typical office building will have only five to seven visitors per 100 employees present at the typical peak hour for parking needs (late morning), while back room operations may have negligible visitor parking. Offices of consumer service providers—insurance and employment agencies, real estate offices and the retail bank branch—will have similar employment density but a different visitor demand profile than that of general offices and medical offices. The medical office data in *Parking Generation* have a range of 3.95 to 5.65 vehicles/ksf, where the 85th percentile figure is 4.27 vehicles/ksf and the 33rd percentile figure is 2.68 vehicles/ksf; the average is 3.20 vehicles/ksf.

Medical office parking may also vary by site. Space located on hospital campuses is more likely to be leased to physicians, such as surgeons, who have to spend significant time at the hospital and who have more restricted office hours than a doctor practicing at a neighborhood medical office.

It is recommended that office ratios be subdivided into discrete categories. ITE broke its data for *Parking Generation* into five categories: (general) office building, medical and dental offices, government office, post office, and judicial complexes. *Shared Parking* recommended parking ratios for general offices (with three size ranges), medical offices, data processing offices, and branch banks. The Parking Consultants Council adopted the same ratios and recommended using the bank ratio for all consumer service offices, such as insurance and real estate offices.

No ratio is provided in this chapter for government/post office/judicial offices. Rather, a shared parking analysis by type of offices is appropriate for these land uses. Areas where the public goes to receive services might be treated as consumer offices; areas generally used only by employees would be general offices; and meeting and assembly spaces would be evaluated based on design attendance and time of day factors.

Many office developers believe that parking demand is increasing at office buildings. Data collected by the Building Owners and Managers Association indicated that there has been a slight increase in the density of employees in office space since 1995, after a long period of decline. However, the density remains well below that of 1985. Also, these

ratios are based on GFA (primarily because ITE uses GFA for its parking and traffic generation reports), while many in the office development community "think" in GLA or NRA. If NRA is 80 percent of GFA, the 3.8 spaces/ksf ratio for small office buildings is equivalent to 4.75 spaces/ksf NRA, and the 2.8 spaces/ksf ratio for buildings over 500,000 $ft^2$ is equivalent to 3.5 spaces/ksf NRA.

## J. Retail Space

As previously noted, a shopping center is the only land use where there has been extensive study of parking accumulations during a design hour. *Parking Requirements for Shopping Centers* was first published by the Urban Land Institute in 1982 and updated in 1999. The currently recommended parking ratio varies from 4.0 spaces/ksf (4.3 spaces/100 $m^2$) of GLA for smaller centers to 4.5 spaces/ksf (4.8 spaces/100 $m^2$) for larger centers. *Shared Parking* contains additional recommendations regarding time of day and seasonality of shopping center demand.

*Parking Requirements for Shopping Centers* looked at the impact of limited amounts of entertainment uses (food court, cinema, and restaurant uses) on shopping center parking demand. It recommends that the above ratios be increased when dining and entertainment occupy 10 to 20 percent of the GLA and that shared parking analysis be employed where these uses comprise more than 20 percent of the GLA. *Shared Parking* further studied this issue and concluded that it may be more reliable to use shared parking analysis when entertainment uses exceed 10 percent of GLA because the specific mix of dining versus entertainment dramatically impacts the parking required. Table 11-15 summarizes desired shopping center parking ratios.

Because retail is not found only in shopping centers, *Recommended Zoning Ordinance Provisions for Parking* provides recommended parking ratios for some additional types of retail development. These ratios are recommended for freestanding buildings or when buildings in a development are spatially separated in such a way as to discourage the sharing of parking. *Shared Parking* in fact found that when more intense retail uses such as grocery stores are provided in convenience/ neighborhood centers with less intense uses such as dry cleaners or video stores, the overall parking ratios average out to be reasonably modeled by the recommended shopping center ratios.

## K. Eating and Drinking Establishments

Restaurants have become significant uses in commercial developments since the early 1990s, a major driver being the changing U.S. household. In 1967, only 29 percent of a household's total food dollar was spent away from home; by 2010 this figure had climbed to 46 percent. [Thompson, 2013]

*Parking Generation* does not include regression equations for most data sets in this category, partly because there was not that much variation in size of use. One of the largest samples, family restaurants, had a size range of only 2,000 to 10,000 sq. ft. (186 to 930 $m^2$) with considerable scatter of data points.

While there are numerous variations in types of restaurants, the following classifications are used in *Shared Parking*. These groupings have reasonably similar parking demands. Given that parking planning may begin long before a particular restaurant tenant lays out seating areas, spaces per unit area is the most appropriate unit for parking demand ratios.

Casual and fine dining restaurants include two types of restaurants. One is the premier white tablecloth or gourmet restaurant serving food and beverages at relatively high cost. Some of these restaurants only serve dinner, and many do

**Table 11-15. Shopping Center Parking Ratios**

| **Gross Leasable Area (GLA) Not More Than 10% GLA in Non-Retail Uses** | **Recommended Spaces/100 $m^2$ GLA ( /ksf)** |
|---|---|

not have a significant bar area. However, when provided in mixed-use developments, some are likely to serve lunch. Casual restaurants bridge the gap between fine dining and family restaurants, with more moderately priced meals but extensive alcoholic beverage service. Many of these restaurants are heavily themed, following the Hard Rock Cafe model, with entertainment as part of the dining experience. Because they typically do not take reservations, there may be long waiting lines and heavy activity in the bar at busy times. While some have suggested separating the two categories, an analysis of the database in *Parking Generation* found that there was not a statistically significant difference in the parking ratios between these two groups. Therefore, the recommended base ratio for casual and fine dining restaurants (with full liquor service) is 20 spaces/ksf (22 spaces/100 $m^2$) of GFA.

Family restaurants usually serve breakfast as well as lunch and dinner, and they typically do not have a bar area. Alcoholic beverages, if served, are provided at dining tables only. With little or no waiting and no bar area, 15.0 spaces/ksf (16.0 spaces/100 $m^2$) of GLA is the recommended parking ratio.

Fast food restaurants generally have counter ordering with a self-serve seating area. Restaurants of this type usually have drive-through service. *Parking Generation* unfortunately subdivides fast food restaurants into multiple categories, weakening the overall reliability of its analysis. A review of the composite information by the *Shared Parking* update team determined that 15.0 spaces/ksf (16.0 spaces/100 $m^2$) of GLA is also the recommended parking ratio for fast food uses. However, fast food restaurants have peak parking needs on weekdays rather than weekends, hence the separation from family restaurants for shared parking analysis.

## VIII. SHARED PARKING METHODOLOGY

Shared parking has two basic components: (1) some people visit a site while in the general area of a primary destination (for example, a restaurant in a large office building); and (2) some activities at a site peak at different times than others. An example of the latter is an entertainment complex located within a large shopping center where peak demands often occur at night and on the weekends.

Shared parking analysis, developed by the Urban Land Institute (ULI), examines parking characteristics relating to time of day, day of week, season, and the interaction of mixed-use developments to determine the peak accumulation of vehicles. [Smith, 2005] Parking demand for each component may peak at different days of the week or hours of the day; therefore, fewer parking spaces are generally needed than would be required if each component were a freestanding development. An example of this is parking demand for restaurants that primarily do business in the evening hours and thus can use the parking spaces of nearby office buildings whose employees have left for the day.

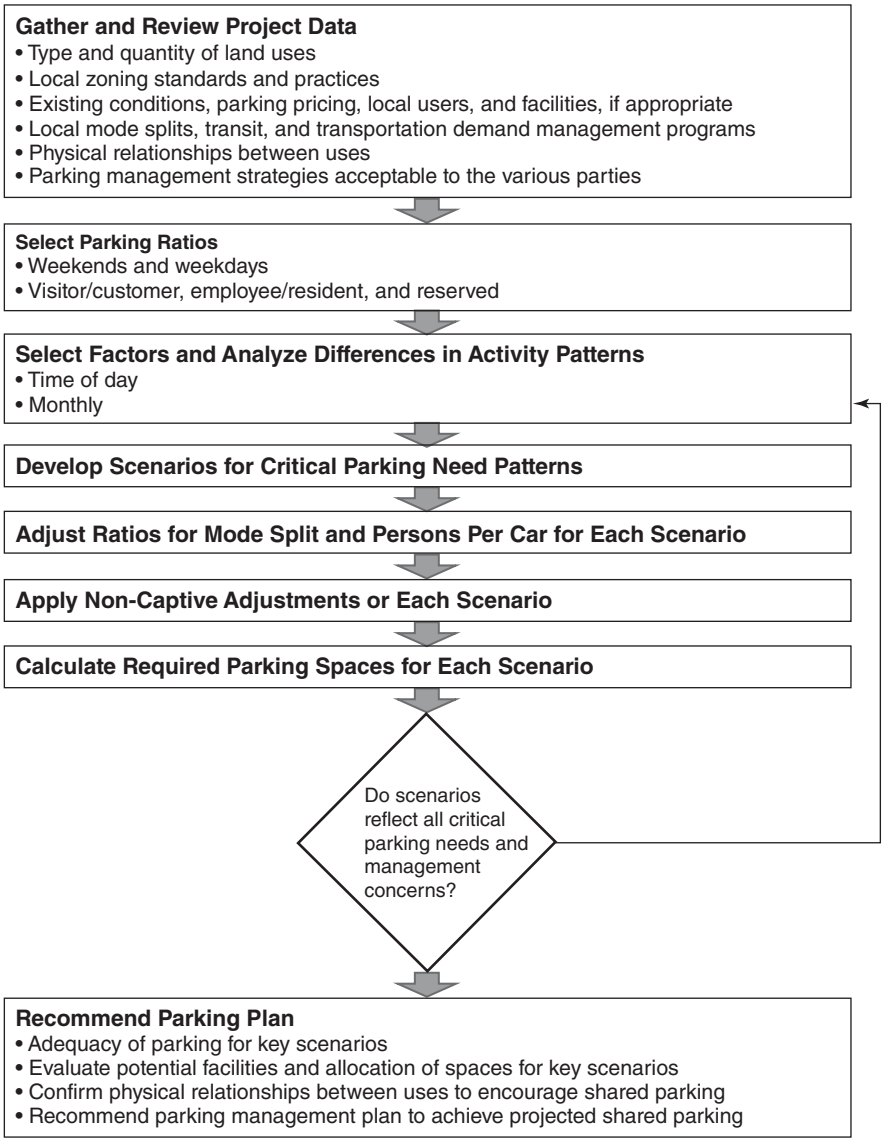
*Shared Parking* [Smith, 2005] quadrupled the number of land uses covered from an earlier edition and, more importantly, updated nearly all of the recommended default values for parking ratios, time-of-day, and seasonal adjustments. A significant change in methodology was the separation of parking ratios into visitor/customer, employee, and resident ratios, which facilitated the analysis of captive market and mode adjustments, and also parking management planning, which is critical to the success of shared parking plans. The methodology is presented in a flow chart shown in Figure 11-8.

Figure 11-9 presents the typical variation of parking needs by time of day for some of the more common uses occurring in shared parking situations. These variations differ according to whether it is a weekday or weekend. Figure 11-10 presents typical variations by month of year. Note that these exhibits have combined the separate factors for employee and customer parking in *Shared Parking* and represent the overall variation in parking demand at those land uses. The following sections discuss in brief the critical analysis assumptions in shared parking analysis.

### A. Captive Market

The term captive market was originally borrowed from market researchers to describe people who are already present in the immediate vicinity of a development and are thus likely patrons of a new use. In shared parking analysis, it is used to reflect the adjustment of parking needs due to the interaction among land uses. Captive market effects not only accrue from onsite development, but also from nearby uses, such as office buildings. In parking analysis, planners use the complementary factor (that is, the noncaptive ratio), which is the percentage of users who are not already counted as being parked. Generally, the analyst considers a vehicle as being generated by the land use that was the primary trip purpose (or destination).

**Figure 11-8. Shared Parking Methodology**



Source: Smith, 2005

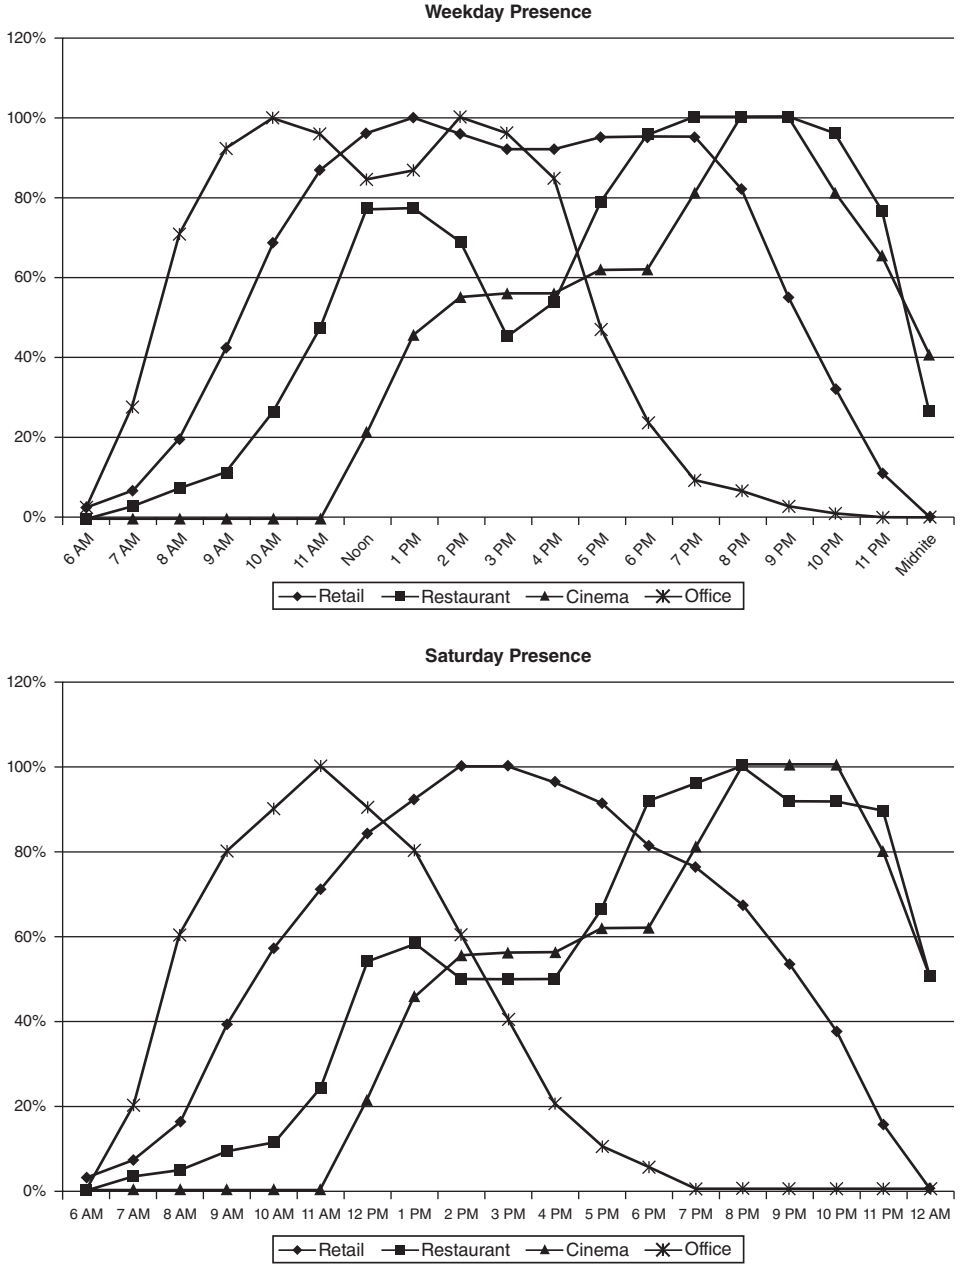
### *1. Development Synergy and Multipurpose Trips*

Certain types of developments achieve much greater interaction among uses than others. When such synergy exists, a successful project may have lower parking demands than if the uses were built separately and will likely have a greater patronage than would otherwise be expected. For example, a restaurant may have greater noontime patronage than it would otherwise because it is located within walking distance of a large employment center. In other words, it may have more customers per day while having a lower noontime parking demand than stand-alone developments. Similarly, retail employees are a major component of those eating at a shopping center's food court.

Today's town center with significant dining and entertainment uses is predicated not only on the possibility of visiting multiple destinations on single trips, but also on multiple destinations being visited at the same time. A family visiting a town center may split up with the children going to the cinema, one parent going shopping and the other going to a bookstore. The length of stay is longer and the planner must consider the effects of sequential visits (which add to parking needs without generating vehicle trips) as well as simultaneous ones (which generate no additional parked vehicles or trips) in the parking analysis.

CBDs are among the best examples of successful shared parking. The CBD usually has the largest concentration of employment and commercial activity in a region. CBD (and outlying business districts) parking supply, demand, and

**Figure 11-9. Variation of Parking Demand by Time of Day, Weekday and Saturday**



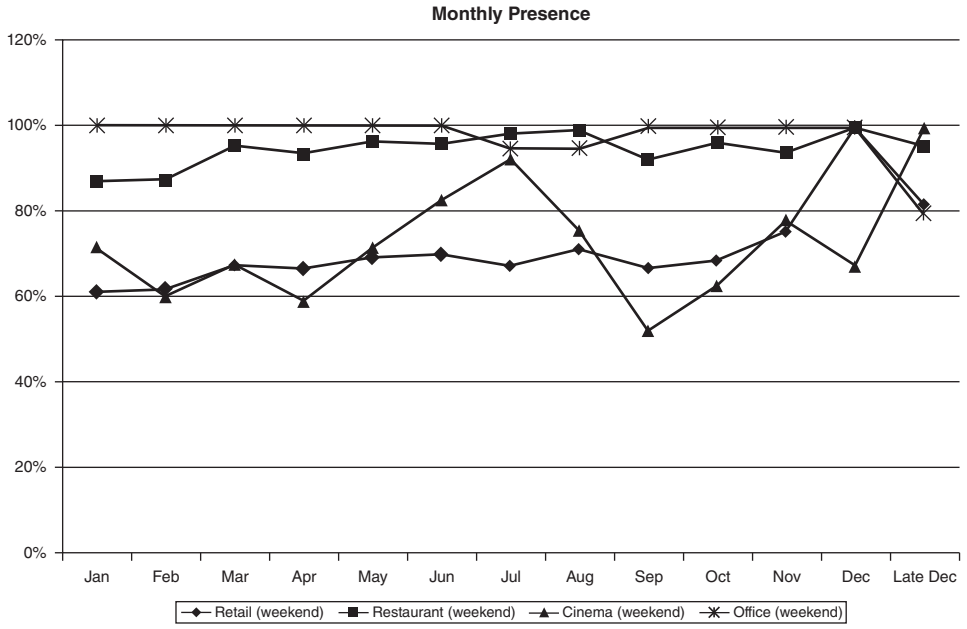
Source: Adapted from Smith, 2005

needs studies have been conducted for many years. The primary purposes for parking downtown in larger cities are (in relative importance)—work, business, and shopping. Because length of stay (parking duration) varies with trip purpose, every four work commutes result in three parked cars during peak parking demand, while four non-work parkers will generally need one space at peak occupancy. The peak occupancy (accumulation) occurs between 11:00 a.m. and 3:00 p.m.—about three-quarters of this accumulation represents motorists parked for work purposes.

CBD parking demand estimates are increasingly derived from land use-based approaches to avoid the costs of detailed parker interviews. The effective-parking supply is determined by analysis area. The peak accumulations of parkers are assumed to approximate the aggregate hour-to-hour downtown parking demand. This demand is then allocated to various subareas based on their share of downtown employment and other activities.

The ability to choose alternative modes is much greater in the CBD than in other parts of a metropolitan area. As a result, overall parking demand ratios in CBDs range from 1.4 to 3.3 spaces/ksf (1.5 to 3.5 spaces/100 $m^2$) with 1.9 to 2.3 spaces/ksf (2.0 to 2.5 spaces/100 $m^2$) being most common.

**Figure 11-10. Variation in Demand for Parking by Month**



Source: Smith, 2005

### *2. Mode Adjustment*

A mode factor is applied to adjust the base ratio, which assumes virtually 100-percent arrival by automobile. Mode split, as used by the traffic engineering profession, is stated on a person basis; parking ratios require that the mode split be converted to a vehicle basis. This is accomplished by estimating the mode split and then dividing by the average persons per car. Some have called this a driving ratio, because it represents an adjustment to the number of vehicles driven to the site. The availability of local transit and the price of parking are primary considerations in determining the mode split at a particular site. Separating the parking ratios into employee and customer components allows for more accurate projections of parking needs, especially in light of the availability of local data on mode split and persons per car for commuters from the U.S. Census.

## IX. PARKING COSTS

The cost of parking directly affects developers, landowners, and auto users, as well as influences the financial feasibility of a parking structure. Groups wanting to encourage alternative modes believe that the user should be charged the actual cost of using a parking space to make a fair comparison among mode choices. In other cases, institutions and communities have faced substantial "sticker shock" when looking at the cost of building structured parking to serve their users. An understanding of the cost of parking is thus important to the efficient use of parking resources, which may reduce or eliminate the need for new spaces.

Parking facility cost has two distinct components: the capital cost (or cost to own, which includes construction and financing) and the operational cost. The illustrative capital and operational costs discussed below help to compare different options and understand the order of magnitude of parking costs. They should be considered as a "snapshot in time" in that costs will vary over time due to inflationary pressures.

## A. Capital Costs

*Capital costs* include all of the costs associated with constructing a project, including land acquisition, site preparation, construction, soft costs, and financing. The *construction cost* is the total amount paid to the contractor(s) for building a parking facility, including demolition and site preparation, and the so-called soft costs, beginning with the design fee and reimbursable expenses, the cost of surveys, geotechnical testing and materials testing during construction. Additional services not covered by the standard design contract, such as full-time on-site representation and feasibility

studies, are also added into a project cost estimate. Finally, the cost of administering the construction contract as well as financing costs are included.

Construction costs for parking structures vary substantially by locality, reflecting labor costs and construction practices. The U.S. northeastern states have higher labor costs than the southeastern states, primarily because of union wages; Midwestern states have higher costs for material durability than the southwestern states. California and Florida lead the country in the delivery of parking projects by the design/build delivery system; this has allowed designers to put the lessons of construction efficiency into practice on traditional design/bid projects, resulting in generally lower costs.

Market factors also can cause significant cost variations even within one construction season. For example, after a period of relatively slow increases, parking construction costs increased 20 to 30 percent between 2003 and 2006, primarily because of increased material costs. Because 60 percent or more of a parking structure's cost will accrue in the concrete structural system and associated items such as expansion joints and sealers, the capabilities and workload of local cast-in-place and precast concrete contractors will have a substantial influence on the cost of the facility. Timing is crucial; if a structure is bid after most of the contractors have booked work for the season, the bids will likely exceed normal estimates. Table 11-16 shows the median parking structure cost in selected cities in the United States for 2014.

**Table 11-16. Median Parking Structure Construction Costs 2014**

| | City Index | Cost/Space | Cost/SF |
|---|---|---|---|
| Atlanta | 87.5 | $15,783 | $47.29 |
| Baltimore | 92.8 | $16,739 | $50.15 |
| Boston | 117.6 | $21,212 | $63.56 |
| Charlotte | 80.8 | $14,575 | $43.67 |
| Chicago | 117.6 | $21,212 | $63.56 |
| Cleveland | 99.4 | $17,930 | $53.72 |
| Denver | 93.3 | $16,829 | $50.42 |
| Dallas | 85.2 | $15,368 | $46.05 |
| Detroit | 102.8 | $18,543 | $55.56 |
| Houston | 86.6 | $15,621 | $46.80 |

Parking construction costs are usually stated in cost per square feet (or square meter) and cost per space for comparison with industry norms and other projects. Cost per unit area gives an idea of the basic elements and amenities incorporated into the design—for want of a better term, the quality of the finished building.

The cost per space reflects the *efficiency* (sq. ft. or $m^2$ of parking area per space) of the parking design. In two different projects, the same level of architectural durability and engineering systems can result in a similar cost of say $35 per sq. ft. ($375 per $m^2$). However, if one achieves an efficiency of 300 sq. ft. per space (27.7 $m^2$ per space) versus 350 sq. ft. per space (32.3 $m^2$ per space), the more efficient design will cost $10,500 per space, or 14 percent less than the $12,250 per space cost of the less efficient design. Table 11-17 compares efficiency and cost per unit area to cost per space. Because construction cost per space is the most commonly used index, all tables presented relate other costs back to construction cost per space.

Surface lot parking is the least expensive to construct whereas underground parking costs vary widely because the number of floors below grade and the soil conditions affect the cost dramatically. This is seen in Table 11-17 and on an annualized basis in Figure 11-11. As shown in both, the importance of the cost of land is very evident, which is reflected in the location of the lot. In addition, parking garages, either vertical or in the subsurface, show dramatically different cost structures. The data shown in the table and figure would have to be adjusted for other areas, given that outside of New York City, the Bay Area has some of most expensive land in the United States.

The efficiency of parking designs varies widely. (Note: Any mixed-use areas, such as grade-level retail, should not be included in the efficiency calculation to avoid distorting comparisons.) A typical surface lot or structure with circulation through the parking areas can achieve efficiencies of 270 to 350 sq. ft. per space (25 to 33 $m^2$ per space). Efficiencies below 300 sq. ft. per space (28 $m^2$ per space) were almost never seen before the downsizing of the automobile in the 1970s and the subsequent development of compact-only stalls. In many locales, efficiencies of 300 to 325 sq. ft. per space (28 to 30 $m^2$ per space) are the goal of most designs today. Efficiencies of over 325 sq. ft. usually reflect a site constraint requiring short rows or single-loaded aisles and should be avoided where possible. Short-span garages (with columns between parking spaces rather than between bays) have efficiencies over 325 sq. ft. per space, but they may be dictated by mixed land uses above the parking facility. Facilities with special requirements for express ramps and loss of parking areas to toll plazas or other parking-related functions will also have efficiencies of 322 to 377 sq. ft. per space (30 to 35 $m^2$ per space). Table 11-18 shows the construction cost per space related to the amount of square feet (square meters) per space and the cost per square foot (meter). The values are in 2006 dollars, and illustrate the relationship between the factors that are part of the design process.

There has been significant publicity regarding high-rise, automated mechanical parking structures as an alternative to self-park structures. The advantages of these facilities include smaller site requirements, more spaces in a smaller building mass (height and footprint), significantly fewer security issues, and environmental advantages because vehicles are not searching for a space. However, the total completed construction and operating costs are often understated in marketing materials and media reports, particularly where turnover of spaces requires more than the minimum number of devices to move vehicles around in the facility. In addition, the savings in the footprint are often negated by access drives and queuing at the entrance and exit chambers where cars are surrendered by and returned to parkers, particularly for larger facilities with higher turnover. As a result, the construction cost of a high-rise, automated mechanical parking structure is 50 to 100 percent more than the cost of an above-grade parking structure and is similar to the cost of underground parking structures. [Monahan, 2001]

During the planning stage, the project budget for a parking facility of any type will include an *estimated construction cost* that represents an approximation of what a contractor would bid for the project based on the contract drawings plus *design contingencies* (for issues not yet addressed in the design) and a *field contingency* for unforeseen site conditions and design changes during construction. The design contingency is generally carried as 15 percent of the estimated cost at completion of the schematic phase, 10 percent at the end of design development, and 5 percent at the end of preparation of construction documents to allow for market conditions at the time of bid. Traditionally, once the project is bid and awarded, correction of minor errors and omissions in the design drawings are paid out of the field contingency. A study of design-caused changes concluded that the owner should anticipate and carry at least a 2-percent contingency for deficiencies in designs produced in accordance with customary architectural/engineering practices. This 2-percent design contingency is in addition to the normal 5-percent field contingency for unforeseen conditions and owner-initiated charges. The report notes that almost every design is unique and that it would be prohibitively expensive and time consuming to require the design team to produce perfect plans and specifications. This is not to say that the owner should not seek a designer with a superior track record in the quality area, which today is usually measured by monitoring design-caused change orders.

For budget purposes, the total project cost before any design occurs should be 35 percent greater than the construction cost. As design proceeds and is refined, the design contingency is reduced. Exclusive of land and financing costs, the project cost will typically be 10 to 15 percent greater than the construction cost at the completion of the project. As noted earlier, land costs can dramatically affect the capital cost.

## B. Operating Costs

Several factors contribute to the variations in operating expenses among different parking facilities. The first consideration is the size of the facility. Larger facilities have lower costs per space resulting from economies of scale. A lot or structure that is part of a parking system, whether municipal, institutional, or private, will usually cost less to operate than an independent facility. Location is also an important consideration—above ground or below, warm climate or winter snow, high or low crime, high or low wage scale, and such. Hours of operation, ratio of contract parking patrons to daily parking patrons, automated payment versus cashiers, or whether fees for parking are charged also will influence operating expenses.

To determine operating expenses for parking facilities, first define what is included. The following categories are almost always included in operating expenses:

- Labor costs (wages and benefits)
- Management fees and costs
- Security costs
- Utilities
- Insurance
- Supplies and other miscellaneous expenses
- Maintenance, including routine maintenance, preventative maintenance, snow removal, and elevator and parking equipment maintenance

Taxes (for example, sales, property, parking, or some other type) are not included because of the wide range of taxes among facilities. A municipally owned structure, for instance, would pay no property tax, while a privately owned structure could have a substantial property tax bill. Some cities have a substantial parking tax, while others may have little or no tax. Debt service is also not included in these figures because it is not considered an operating expense.

Table 11-19 shows what goes into an estimate of O&M costs. The data in the table were gathered from a survey sent to operators of parking structures throughout the United States. [National Parking Association, 2006] The database included 156 parking structures. Additional unpublished data from 73 surface lots are also included (adjusted to 2006 dollars to be comparable). Many of the respondents reported little or no cost in one or more areas, presumably because accounting practices do not charge the parking system for those expenses.

The median values indicate an annual operating expense for a typical parking structure of $604 per space. Half of the operating costs are associated with revenue collection; revenue collection and security constituted nearly two-thirds of the total cost. The basic operating expense for an unattended facility with no security cost was $177 per space per year in 2006 dollars. Larger structures located in warm climates may have lower costs, but smaller structures located in the Snow Belt can expect to spend a greater amount per space, especially if an adequate amount is spent on structural maintenance.

The size and age of a structure influence costs, but hours of operation and type of use have the greatest impact on the bottom line. A facility with the primary purpose of providing parking for frequent events requires more cashiers than a general parking facility. If the cashiers are paid a higher wage and benefits, the increased hours of operation can increase expenses rapidly. Valet services also increase costs substantially.

Parking facility owners who fail to maintain parking facilities properly could incur significant capital repair expenses later in the life of the facility. Lending institutions, however, often require sinking funds for future repairs, which in turn require appropriate budgets for future structural repairs. Budget adjustments to the operating costs were thus made as shown in Table 11-19.

Car stackers have little operating cost, but they are considered somewhat inconvenient by many patrons. Given that the capital cost to stack two floors of cars in one floor with stackers is more than the cost to build two floors in a self-park structure, car stackers are generally only used to gain spaces in existing garages with high ceilings or as a temporary solution in parking lots.

## C. Combined Costs

Combining the construction, financing, and operating costs for the various parking options gives a picture of the comparative overall annual costs per parking space (land costs are not included). The monthly revenue to break even gives a picture of necessary charges to users. Table 11-20 cross-tabulates construction cost per space versus annual operating cost per space to show the monthly revenues required per space to break even. This spreadsheet highlights 2006 figures for surface lots, aboveground structures, and underground structures. At the bottom is a conversion of monthly revenues to the hourly rates required for various combinations of days of revenue collection per year and turnover factors.

The Victoria Transport Policy Institute (VTPI) has developed a spreadsheet that planners can use to estimate the cost for parking spaces that includes both construction and O&M costs. The spreadsheet can be found at: www.vtpi.org/parking.xls.

## D. Parking Scenario Comparisons

Table 11-21 compares seven alternative parking options to gain 500 spaces at a hospital located on the fringe of the CBD. It addresses two basic questions: How do project costs compare? What are the comparative costs per added space?

Financing costs in this table include the cost of obtaining the funds necessary for the project. Where conventional financing is obtained, the cost of financing typically would be added into the amount borrowed and is usually at least 10 to 15 percent of the project cost. For early project planning, a factor of 25 percent to 35 percent for design, financing, and miscellaneous project costs added to an estimate based on the typical construction cost per space is a reasonable budget figure. Financing methods are discussed later in this chapter.

However, for a more realistic comparison of the cost to own and operate parking facilities, a total project cost, including a 15 percent factor for all soft costs, was assumed to be financed at a cost of capital of 7 percent over 20 years for the structures and land acquisition, and over 10 years for lots. Parking facilities are rarely financed for longer terms because they typically begin to require significant restoration and refurbishing at that age. The cost of financing each

project has been added to Table 11-21. Note that both the annualized capital cost per space as well as the cost per added space is given along with the revenue that must be generated from each space.

Option A, building on a site already owned but without parking, is the most cost-effective at $3,450 per added space. Option B assembles a site by acquiring a full block of older tract housing and developing a 500-space surface lot. Land acquisition and demolition costs $14 per sq. ft. ($150 per $m^2$) and construction results in a cost per added space of

| 4 turns/day, avg. stay 1.5 hours, 300 days a year | | | | | | $1.37 | |

about $9,500 for Option B1. If, instead, the land costs $28 per sq. ft. ($300 per $m^2$) as in B2, the cost per added space jumps to almost $15,600. Option C develops a structure on part of the surface parking in Option A; the cost per space and the cost per added space are identical at $14,375, and thus more cost-effective than buying the expensive property for a surface lot as in B2. Option D develops a structure on the site of an existing 100-space parking lot. A 600-space, seven-level structure would be required to add 500 spaces, at a project cost of $17,250 per added space, $2,875 more per added space than option C.

For illustrative purposes, two additional options have been included. The first is option E, acquiring a smaller portion of the B2 site, and building a six-level structure for 500 spaces with a land cost of $28 per sq. ft. ($300 per $m^2$).

This option has a project cost of almost $16,500 per added space, which is less than the cost per added space of D. If it is possible to use the deck in the evenings and weekends by customers of area businesses, the overall cost to the hospital for structured parking would be considerably reduced. Option F builds a high-rise, mechanical access garage on part of the site used in Option C, which is an owned, unused parcel. The cost per added space is nearly twice the cost of the self-park facility.

As noted, building surface parking on already owned vacant land is the most cost-effective, but it is often the least realistic; few owners with parking problems would likely have this much undeveloped land available. It might be easier to find a location on an existing medical campus for the structure in Option C, which is similarly the most cost-effective among the structure alternatives. Building a surface lot on low-cost land is also very cost-effective. It has the added advantage of "banking the land" for future expansion of the hospital. It is, however, more expensive to buy land at about $28 per sq. ft. ($300 per $m^2$) to build a lot than it is to build a 500-space structure per C, but it is more cost effective than D.

## X. FINANCING PARKING FACILITIES

Parking facilities can be financed by public agencies, private sector investment groups, or a combination of public-private groups. Business improvement districts, or special benefit assessment districts, are sometimes used to finance parking improvements when authorized by law. Land for parking can be acquired by purchase, lease, condemnation, dedication by land developers or donation. Other means of land acquisition include reclamation, multiple use of public lands, and air rights.

Parking facilities are difficult to finance because they are specialized and uniquely subject to changes in the parking demand of the generators they serve, which in turn make them relatively high risks in the eyes of the financial markets. Lenders and investors are concerned with both the strength and the longevity of the intended market for facilities as well as the possible alternative users or uses of the facilities. In most cases, the general credit of the owner will be equally, if not more, important than the projected revenue and expenses of the parking facility itself.

When a parking facility is constructed as part of a private development, it is generally a relatively minor part of the project financing package. Lenders may be more interested in the number of spaces provided being adequate to market the retail or office space, for example, than in the line item projections for parking revenues and expenses in the project pro forma.

Few, if any, facilities financed with public bonds can show adequate coverage of the debt service to be secured solely by the parking revenues of the facility itself. These difficulties often necessitate approaches such as using general obligation (GO) bonds or system revenue bonds. The lenders will typically be far more interested in either the credit rating of the municipality (in the case of GO bonds) or the finances of the parking system as a whole (with revenue bonds) than in the projections of revenues and expenses for the parking facility itself.

Conversely, in those situations where a parking facility can be profitable, the financial markets have seen investment opportunity. Parking-centered real estate investment trusts have been established, and several commercial parking operators have done initial public offerings on the various stock exchanges. The key to these investments has been a careful assessment of the strength of the parking management team and the assets—both owned properties and long-term leases and contracts for managing properties.

The most likely sources of public funds to support a parking facility include:

- General fund/obligation of the city, county, or state.
- Revenue bonds secured by revenues from other parking facilities and meter revenues.
- In lieu and impact fees.
- Taxes, including:
    - Ad valorem (property taxes; most general fund pledges are ad valorem).
    - Special assessment district (where property owners are taxed to supply any deficits).

- Tax increment district (the additional sales and property taxes generated by private redevelopment in the district are dedicated to paying for associated municipal expenditures).
- Sales taxes in a defined or general area.
- Hotel and lodging taxes in a defined area.

Other revenue sources such as grade-level retail space income, development fees, or income from air rights can help to finance parking facilities.

## A. Types of Public Financing

When public financing is contemplated, a key decision must be made on the type of bonds to be issued. Table 11-22 summarizes the four main types of public parking financing and some of the key issues related to each. The cost of financing with a GO bond—backed by the full faith and credit of the governmental entity—either as the sole pledge

**Table 11-22. Municipal Bonds for Parking**

| | General Obligation Bonds | Revenue Bonds | General Obligation Revenue Bonds | Certificates of Participation |
|---|---|---|---|---|
| **Definition** | Pledge the full faith and credit and unlimited taxing power to pay debt service. | Pledge the revenues of a specified source to pay debt service. Additional assurances are covenanted within the bond documents. | Pledge specified revenues and the issuer's full faith and credit and unlimited taxing powers. | A government agency enters into an agreement with another party (lessor) to lease an asset. Lease payments are sufficient to pay the purchase price and associated interest cost of acquiring the asset. |
| **Source of payment** | Property taxes | Specified revenues | Specified revenues and property taxes | Tax revenues subject to annual appropriations (budget process) |
| **Purposes** | Projects that benefit the whole community | Projects that benefit specific users | Whole community and/or specific areas | |
| **State law/Charter** | Debt limit?<br>Voter approval required? | Debt limit?<br>Voter approval required? | Debt limit?<br>Voter approval required? | Not subject to debt limit<br>No voter approval required |
| **Risk/Cost** | Highest security-lowest cost | Higher than general obligations because of limited revenue stream. The degree of risk depends on the individual financing package. Investors require coverage usually in the range of 125% to 200%. | Same as general obligation bond | Higher than general obligation depending on essentiality of project/use. |
| **Credit rating impact** | Full impact | Credit rating is dependent on the degree of security the financing package has. The credit rating for a revenue bond is independent of an issuer's general obligation rating. | Usually a full impact on the credit rating. May be mitigated depending on the revenue stream. | Full impact, usually half grade to full grade lower than general obligation bond. |

Source: Schaefer, T. "Municipal Bond Basics for Parking Providers," Springsted Public Finance Advisors

or as a back-up to specified revenues will usually be significantly lower than with pure revenue bonds—backed solely by a specified stream of parking revenue.

In the former case, the lenders will be principally interested in the credit rating of the issuing municipality or entity. With revenue bonds, lenders typically require that there be coverage or a margin of safety by which either gross or net revenue exceeds the annual payment of debt service. Projected pledged net revenues after operating expenses generally must be 1.25 to 2 times the annual debt service to gain capital market access through revenue bond financing. Additionally, the lender may impose what can be significant covenants on parking revenue bonds, including:

- *Debt service reserve fund*—The entity is required to maintain a fund with an amount sufficient to pay one year's debt service (federal tax laws set a three-fold limit).
- *Operating reserve fund*—The entity is required to maintain a fund of two to three months' operating expenses.
- *Capital maintenance fund*—The entity is required to maintain a fund for periodic major maintenance and restoration so the parking facility can continue to generate sufficient revenue to repay the bonds.
- *Parking rate covenant*—Knowing that, historically, parking demand can be volatile and/or municipalities may have failed to raise rates sufficient enough to keep pace with inflation of costs, lenders may impose a requirement that rates will be adjusted as required to pay operating expenses and maintain all required reserve funds.

The disadvantages to GO bonds are that: (1) they often require voter approval and (2) most jurisdictions have many competing demands on their GO pledge from non-revenue-generating facilities (for example, local government services, schools, parks). Special assessment and tax-increment bonds may be attractive to the municipality and the general public because there is no burden placed on the typical homeowner; however, opposition from the affected taxpayers or tax receiving agencies (such as school districts) can make acceptance of these districts difficult.

A key concept of net revenue bonds is that operating expenses are paid first to protect the revenue-generating capacity of the facility. A gross revenue bond presumes a third party will guarantee the revenue generating capacity.

Cooperation between public agencies with bond authority may also be used to structure a financing strategy. Lease revenue and economic development bonds may be issued whereby one tax-exempt agency constructs the facility and leases it to the other, subject to statutory powers. The lease payments become a contingent liability on the leasing agency's balance sheet, contingent on the terms of the lease.

Certificates of participation (COPs) are a lease arrangement that still qualifies for tax-exempt bonds if the appropriate tests are met. The private entity is the developer, lessor, and nominal owner of the facility, while the public agency leases the facility for a specified term. The public agency may operate the facility or may retain a parking management firm to operate it. The title to the completed parking facility is in the name of the public agency and held by a trustee over the term of the lease. The purchasers or investors in the COPs provide the funds for the construction and are repaid from the lease payments. Generally, COPs are backed by a pledge of the public entity to pay the lease from general funds if parking revenues are insufficient to repay the bonds. While not a GO, the credit rating of the municipality would be seriously affected by a failure to appropriate funds to pay the lease. These bonds can achieve an investment grade rating with a great deal of flexibility and without the restrictions of GO bonds. They are, thus, an attractive form of public financing for parking facilities.

## B. Tax-Exempt Bond Requirements

Another critical decision that must be made early is whether tax-exempt or taxable bonds can be used. While a bond counsel should review all proposed projects for conformance, the following outlines the general requirements that must be met to use tax-exempt bonds:

- Not less than 90 percent of the spaces must be available to the general public on a daily, monthly or yearly basis, excepting only governmental and not-for-profit institutional uses. If monthly spaces are offered on a first-come, first-served basis, but many or even most of them are leased by employees of a single corporation, this is still generally considered public use. Complications arise with agreements to lease parking spaces directly by a single corporation itself.

- Not less than 95 percent of the bond proceeds must be spent on the public parking facility. This test can be complicated where a public-private joint development occurs, and it is difficult to trace the uses of the funds. For example, a public parking facility is to be constructed with street-level retail leased to tenants and apartments built in the air-rights. The parking spaces are shared and serve area parkers in the daytime and the residents at night. How much of the land acquisition, foundation, and site utilities—much less the construction cost of the parking facility—can or should be allocated to the parking facility and how much to the private development components?
- No more than 10 percent of the annual debt service may be paid for or guaranteed by a corporate or non-public entity. Thus, when revenue from retail or air-rights development is expected to help repay the bonds, it may comprise no more than 10 percent of the total revenue stream to retain tax-exempt financing. Also, even if all spaces are to be used by the public on a daily fee basis, the bonds cannot be guaranteed by a corporation in excess of this threshold to reduce the municipal or investor risk without losing the tax-exempt status.
- Agreements for the management and operation of the facility may not exceed a 5-year term, must provide for payment to the operator by either a periodic fixed fee or fixed percentage of the gross revenue and must give the public entity the option to cancel at the end of any 2-year period. Because concession-style and long-term agreements cannot be used with tax-exempt financing, the interest in and viability of leaseback arrangements with commercial parking operators has been sharply reduced.

Obviously, the structure of the public/private partnership is critical to obtaining tax-exempt financing, which can carry an annual interest rate of as much as 2 percent less than taxable financing. Combinations of taxable and tax-exempt bonds can still be issued for public-private developments where the strict tests for tax-exempt bonds cannot be met (for example, a taxable series of bonds funds from a garage leased or reserved for a private entity, while the tax-exempt series goes toward the public portion of the garage). Also, tax increment districts with single- or limited-development projects may run afoul of the test relating to sources of funds for repayment of the bonds, jeopardizing tax-exempt financing.

## C. Sizing a Bond Issue

The typical bond issue includes a number of different elements. As discussed previously, construction cost, land acquisition and related design fees, and miscellaneous expenses are considered part of the project cost. The total project cost will typically be 10 to 15 percent greater than the land and construction cost. There are also costs of issuance for counsel, printing, rating agency and trustee fees, and closing costs that are typically 0.05 to 1 percent of the amount financed. Other expenses related to the issuance include the underwriter's spread and bond insurance, which can help hold down the interest rate.

It is typical for bond issues to be sold before the start of construction. Much of the preparatory and design costs may have already been incurred; therefore, it is important to carefully track such expenses for incorporation in the bond amount. Because the first bond payment may occur during construction or before sufficient revenues occur to pay the first payment, it is common to structure the bond payments to defer principal payments for a year or two and to include in the bond an amount sufficient to make interest payments in that period. This is known as capitalized interest. When bonds are not sold early in the process, bond anticipation notes may be issued that provide the necessary funds for cash flow until the bonds are sold. Interest on this interim financing would then be included in the permanent financing.

Conversely, because the bond funds are paid to the municipality, they may be invested until required to pay contractors. A National Parking Association study found that owners should estimate the potential interest earned during the construction draw down using percentage curves given in the study rather than a straight-line monthly draw down. [Heeseler and Arons, 1984] Also, there would be interest earned during the first year on the debt service reserve and the capitalized interest. These deductions from the bond amount help to moderate the overall total of funds to be borrowed.

# XI. SUMMARY

Parking is an essential complement to transportation systems and land development. The planning, design, and pricing of parking facilities have been concerns of communities, property owners, and providers of goods and services since the early days of travel. Planning parking facilities calls for addressing key questions, including where parking should

be located, how much parking should be provided, what type of parking should be developed, what the costs will be, how the parking will be financed and managed, and how best to integrate parking facilities into the urban setting.

This chapter has presented material on the planning, operating, and financing of parking facilities. Of all the options available to public officials for influencing urban development and transportation strategy, managing the parking supply is the most influential—and likely the most controversial. Parking can be a significant portion of a development's cost, so strategies to reduce this cost are welcomed by developers, subject to the requirements related to the financial feasibility of the project. Transportation planners should understand the basic structure of the parking supply in a study area, the different types of policy and planning strategies that could influence the use of this parking and the degree to which changing parking will be politically feasible. There are many examples in the U.S. and in other countries where parking actions are integrated into much broader regional transportation and urban development strategies. The Puget Sound Regional Council (PSRC), for example, has developed a parking management checklist that planners can use to determine how parking fits into broader community goals (see [PSRC, 2003]). Such integration is the desired approach toward a comprehensive transportation strategy for a community or metropolitan area.

Litman [2006] has developed the following list of parking management principles that best summarize the major content of this chapter. The principles to support parking management include:

- *Consumer Choice*—People should have a variety of parking and travel options from which to choose.
- *User Information*—Motorists should have information on their parking and travel options.
- *Sharing*—Parking facilities should serve multiple users and destinations.
- *Efficient Utilization*—Parking facilities should be sized and managed so spaces are frequently occupied.
- *Flexibility*—Parking plans should accommodate uncertainty and change.
- *Prioritization*—The most desirable spaces should be managed to favor higher-priority uses.
- *Pricing*—As much as possible, users should pay directly for the parking facilities they use.
- *Peak Management*—Special efforts should be made to deal with peak demand.
- *Quality versus Quantity*—Parking facility quality should be considered as important as quantity, including convenience, comfort, aesthetics, and security.
- *Comprehensive analysis*—All significant costs and benefits should be considered in parking planning.

Some useful guides on parking management strategies include: [Willson, 2000; DVRPC, 2004; MTC, 2007, 2015; Litman, 2008, 2013a, 2013b, 2014, 2015; Weinberger et al., 2010; CMAP, 2013; Meier et al., 2015; Maryland Governor's Office of Smart Growth, Undated; U.S. EPA, undated]

# Transit Planning[1]

## I. INTRODUCTION

Transit services provide mobility and accessibility in communities of all sizes. In large cities, transit services carry volumes of trips that could not be handled efficiently by other modes of transportation, especially to and from major activity centers such as central business districts (CBDs). Private cars, vans, or taxis would have great difficulty serving passenger travel effectively in cities like Toronto, Ontario; New York City; San Francisco, California; and Washington, DC, given the limited road network and the amount of travel, especially during peak periods. The presence of public transit can also affect land-use patterns and directly influence the quality of life in such cities. Vibrant urban areas like Denver, Colorado; Portland, Oregon; Salt Lake City, Utah; or Vancouver, British Columbia, are made viable by excellent transit systems that provide convenient transit service throughout the city. Large cities are livable and desirable places to live in part because of high-capacity transit systems.

In midsized cities, transit can play an important role in facilitating access to all major activity centers, thus reducing car dependency, traffic congestion, and parking demand. And in small U.S. and Canadian cities, where auto ownership rates are very high, transit can serve a social service function. In these communities, many riders who are physically or economically unable to travel by private automobile, such as the young, elderly, and low-income families, use transit as their sole means of mobility. Transit often provides the only means of reaching employment centers, educational opportunities, or life-essential activities such as health care.

Today, transit is increasingly recognized as an element of livability and economic progress in many cities. Federal, state, provincial, and local government investments in transit systems consider not only how many riders will be served, but also transit's role as a factor in the economic development and sustainability of cities. In addition, transit is often viewed as a means of reducing traffic congestion and parking demand in high-density areas.

Since the low point of public transportation ridership in the United States in 1970, the number of cities in the United States and Canada with rapid rail transit (RRT) systems has increased from 7 to 15, 20 cities have introduced new light rail transit (LRT) and modern streetcar systems, and many cities have upgraded bus systems, with at least 12 cities in the United States and 10 cities in Canada having bus rapid transit (BRT) services. In addition, a number of cities have constructed regional (commuter) rail systems, automated guided transit, and people movers, with the most common serving airports. New waterborne transit modes and a variety of demand-responsive services have also been implemented. The result of this investment in transit is that 2014 saw the highest level of public transit ridership in the United States since 1956.

Intermodal integration has been an important policy theme running throughout many of these investments. The concept of seamless travel—in time, space, fares, and information—through coordinated planning of modes and applications of new technologies is a recognized goal of today's comprehensive transit planning. The integration of different transit modes is supplemented by coordinating auto and transit trip interfaces, predominantly through park-and-ride and kiss-and-ride facilities, and by enhancing pedestrian and bicycle access.

The next section discusses different models of transit ownership and governance. This section is followed by a discussion on contemporary transit in North America, including an overview of how the transit industry has evolved over time. The following section provides statistics on transit service, including ridership, trip lengths, and

[1]The original chapter in Volume 3 of this handbook was written by Jeffrey M. Casello, Ph.D., P.E., Associate Professor, School of Planning and Department of Civil and Environmental Engineering, University of Waterloo, and Vukan R.Vuchic, UPS Foundation Professor of Transportation Engineering (retired), University of Pennsylvania. Changes made to this updated chapter are solely the responsibility of the editor.

operating speeds. One of the distinguishing characteristics of transit planning is the many different modes of transit that are found around the world. The next section presents a classification of transit modes and their components. Costs are always important in any type of service provision, and the next section discusses the cost structure for transit service, followed by an overview of the ways in which system performance and quality of service can be analyzed. This section is followed by a description of typical transit planning procedures, including estimating transit ridership. Passenger stations and stops are an important component of transit systems, and the next two sections describe both the planning process and design approaches for passenger stations. The following section examines network structure and how individual transit lines are combined to form a system. This leads into a discussion of transit route planning and of analysis approaches for assessing route-level performance. The chapter ends with a section on future transit issues.

## II. OWNERSHIP AND GOVERNANCE

Beginning in the late nineteenth century, as North American cities grew and expanded outward, walking distances also increased. This created a demand for some form of mass transportation. Because demand was very high, providing transit service became a lucrative and competitive private industry. Competition within the industry, however, had both positive and negative effects on transit system operation and passenger attraction. Service on the highest demand routes, and in the highest demand hours, was often excellent, with many providers competing to capture riders. In off-peak hours or on lightly used lines, service was often less frequent, less reliable, and therefore less desirable. Unregulated competition often resulted in the largest providers establishing unreasonably low fares to drive other providers out of business (cut-throat competition). When a company established a monopoly condition, it would raise fares to very high levels, which riders had to pay due to a lack of competition. Unregulated and competing services also often resulted in poor system integration. Transfers between lines were uncoordinated and inconvenient, requiring multiple wait times and often multiple fares.

By the 1960s, after decades of continued growth in automobile use, many cities had considered or had implemented public takeover of transit services. [Meyer and Gomez-Ibanez, 1981] For example, by 1974, 90 percent of transit trips in the United States were served by public agencies. [Muller, 2004] As with the public provision of many services, the movement toward public ownership of transit systems presented both opportunities and challenges that are still debated today. In principle, a single, public provider of transportation services can advance many of the community objectives inherent in urban passenger transportation. Consolidation leads to improved integration of services, including the formation of areawide transit networks that expand the range and convenience of travel by offering coordinated fares, routes, and schedules. Public ownership also makes government funds for investment in transit infrastructure easier to obtain and to use effectively (note: public ownership does not necessarily mean public day-to-day operation, which in many cases is contracted to private providers). Public ownership means that service decisions can be made with the public welfare in mind. Public ownership of transit service provision has taken many different institutional forms, as discussed below.

### A. Local Agency

Some transit agencies are owned and operated by a city government. The benefits of city ownership are that planning, design, and operation are locally controlled and can therefore be better integrated with other municipal functions, such as land-use planning. Disadvantages include stronger budgetary competition for funding among municipal services and the inability to provide transit services outside of the city limits without some form of contracting arrangement.

Some transit agencies are owned and operated by county governments in the United States and regional governments in Canada. Higher-tier government structures have evolved from the need for coordinated transit services across many municipal jurisdictions. In Ontario, for example, a regional government operates the comprehensive and coordinated Grand River Transit system for several cities and townships with a total population of about 500,000.

In a few cases, states own and operate transit agencies outside of the traditional department of transportation. Examples of such statewide transit agencies in North America are found in Delaware, Maryland, New Jersey, and British Columbia.

## B. Transit Authority or District

A regional transit authority or district is a more common model for multijurisdictional service in North America. These agencies, created by acts of state legislatures, are given the task of constructing and operating major transit systems. Examples of such systems in U.S. cities include Atlanta, Georgia (Metropolitan Atlanta Rapid Transit Authority [MARTA]); Denver, Colorado (Regional Transportation District [RTD]); Washington, DC (Washington Metropolitan Area Transit Authority [WMATA]) and Philadelphia, Pennsylvania (Southeastern Pennsylvania Transportation Authority [SEPTA]). In some cities, transportation authorities oversee other transportation agencies. New York City's Metropolitan Transportation Authority (MTA) is an example of this. It operates and manages New York City Transit, two regional rail systems (Long Island Rail Road and Metro North), and some major highway facilities. The underlying motivations for creating regional agencies are that they are better able to provide and coordinate multijurisdictional service to larger areas, and in some cases might be in a better position to raise regional funding to support the transit system.

Regional transit districts, such as San Francisco's Bay Area Rapid Transit District (BART), are similar to authorities in their formation and scope of their operations, but differ in one important regard. Districts are usually given the power to tax and thus directly raise revenue for capital investment.

## C. Cooperative Arrangements

The need for coordinated and integrated services favors a single agency model for providing transit in a metropolitan area. Several organizational forms, however, are used to allow multiple operators in a region to cooperate and provide integrated services. Transit agencies that provide complementary or adjacent services within an area may form *tariff associations*, where contracts establish fares that are valid on both systems, and methods are agreed to redistribute jointly collected revenue. A *transit community* also offers joint fares that are valid on multiple systems, but extends the arrangement to include coordinated routing and schedules.

The most elaborate integration scheme is known as a *transit federation*. This concept, introduced in Germany in the 1960s, provides not only joint fares and operation among agencies, but also integrated planning of lines and networks. The transit federation may seek funding for capital investments in the systems of individual members. Operationally, members of the federation may jointly utilize their vehicle fleets. In Tokyo, Japan, such fleet-sharing is used extensively for the joint services between the Tokyo Rapid Transit Authority (TRTA) and several railway companies.

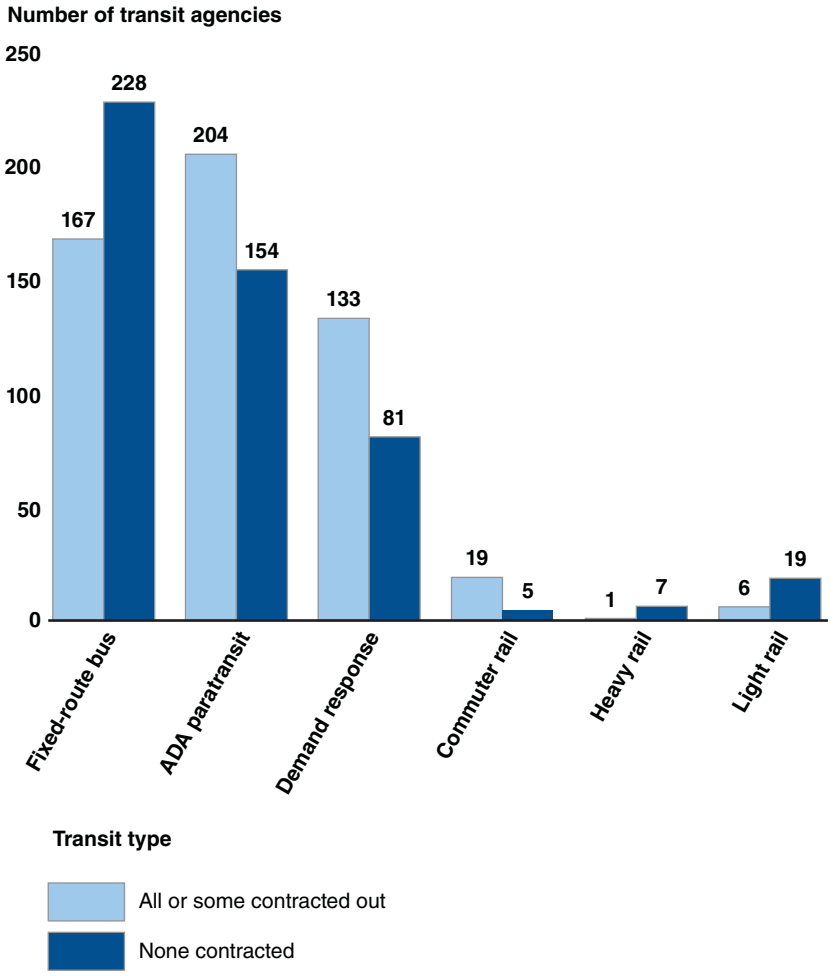
## D. Privatization

Public transportation systems in many cities have introduced changes in organizational structure, management style, and labor relations to capture the positive aspects of private (competitive) contracting, while balancing the need for public oversight and the advancement of social goals. This has most often taken some form of privatization. For example, vehicle maintenance, some administrative functions, and most major planning and engineering studies are done by private contractors hired by the public agency. Private operation of paratransit or demand-responsive transit is also common.

More significantly, many transit agencies now use private contractors to provide fixed-route passenger (revenue) service. In 1980, for example, San Diego began using private operators to provide bus services; by 2001, 44 percent of San Diego's bus services were privately contracted. Similarly, Denver began private contracting for its bus service as a result of state legislation in 1988, which required that 20 percent of bus service be tendered. A survey conducted by the U.S. Government Accountability Office (GAO) [2013] identified 463 transit agencies in the United States that contracted out some aspect of their operations. By size of agency, 52 percent of small agencies, 69 percent of medium agencies, and 92 percent of large agencies had at least one service that had been contracted out (see Figure 12-1).

In Europe, competitive services are mandated by the European Commission. For example, Swedish transport law requires that all public transport services be openly bid, but the public agency may also bid to provide the service. Public objectives—service quality, fares and safety, for example—are specified as part of the bid documents. For a review of different privatized tendering practices, see [Hensher, 2007].

Figure 12-1. Contracted Services in U.S. Transit Agencies, 2013



Source: USGAO, 2013

The private contracting of fixed-route public transport has generally shown positive results. In most cases, operating costs have been reduced, though some studies note that the initial benefits of tendering have been later offset by increasing costs to the public agency. The source of the cost reductions is typically reductions in expenses associated with labor.

## III. CONTEMPORARY TRANSIT IN NORTH AMERICA

### A. Ridership

Transit ridership in the United States has increased since 1990 as measured in both passenger-miles traveled and unlinked passenger trips. Unlinked passenger trips are defined as the number of passengers who board public transportation vehicles no matter how many vehicles they use to travel from origin to destination. For example, a traveler who boards a bus and then transfers to a subway has taken two unlinked passenger trips. As seen in Table 12-1, the number of trips by bus and heavy rail (subways) declined in the first half of the 1990s, but has now recovered. All other modes have seen large gains in trips served in the same period, with the exception of trolleybuses. Commuter rail carried 50 percent more trips in 2014 than in 1990, demand-responsive transit trips grew by 111 percent, and light rail transit (LRT) trips grew by 267 percent in 24 years. Some of the trends contributing to ridership increase have included an increasing population, continued densification in city cores, continued investment in service and infrastructure by various levels of government, and recovery from economic recessions. The shaded areas in Table 12-1 indicate the years where economic recessions occurred in the United States as defined by the U.S. National Bureau

| Table 12-1. Trends in U.S. Passenger Trips by Mode | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Year | Total Ridership (000s) | Heavy Rail (000s) | Light Rail (000s) | Commuter Rail (000s) | Trolleybus (000s) | Bus (000s) | Demand Response (000s) | Other (000s) |
| 1990 | 8,956,479 | 2,420,196 | 146,443 | 327,547 | in Other | 5,740,648 | 106,984 | 214,660 |

of Economic Research. As shown, ridership is likely to decline during economic recessions as the number of people employed declines as well.

As shown in Table 12-2, total passenger-miles by rail increased between 1990 and 2013, with commuter rail increasing by 80 percent. LRT and demand-responsive (such as dial-a-ride) passenger-miles grew more rapidly, with LRT growing from 350 million in 1990 to more than 2.5 billion in 2013, for a total increase of 663 percent during the period. Passenger-miles traveled by demand-responsive modes grew from approximately 364 million in 1990 to nearly 852 million in 2012, a 134 percent increase.

Table 12-3 shows the number of passengers carried on an average weekday in the third quarter of 2015 for the top 12 transit systems in the United States and Canada. This table includes all of the systems in a particular metropolitan area that report ridership statistics to the American Public Transportation Association (APTA). About half of all transit trips in the United States are served by 10 major transit agencies, with transit services in the New York City metropolitan area having by far the largest transit ridership in North America.

## B. Trip Lengths and Operating Speeds

Table 12-4 shows U.S. national characteristics for average trip lengths and vehicle operating speeds for all major transit modes. Operating speeds reflect the degree of right-of-way separation for the different modes as well as the time it takes passengers to get on and off the vehicle. Buses and trolleybuses, which operate in mixed traffic, have the lowest average operating speeds, 12.8 miles per hour (mph) (20.4 km/hr). LRT and BRT mostly use rights-of-way separated from general traffic, and therefore operate at a higher average operating speed, 15.7 mph (25.1 km/hr). Heavy-rail

| Table 12-4. Average Trip Lengths and Operating Speeds for Major U.S. Modes, 2012 | | |
|---|---|---|
| | **Average Trip Length (miles)** | **Revenue Service Speed (mph)** |
| Bus | 3.9 | 12.8 |
| Trolleybus | 1.6 | 7.1 |
| Light Rail | 5.2 | 15.7 |
| Heavy Rail | 4.7 | 20.0 |
| Demand Response | 8.3 | 15.3 |
| Commuter Rail | 23.7 | 32.8 |

| Table 12-5. Utilization Rates for U.S. Transit Modes, 2012 | | |
|---|---|---|
| **Mode** | **Passenger-Miles per Revenue Vehicle-Mile** | **Passenger-Miles per Revenue Vehicle-Hour** |
| Bus | 10.4 | 132 |
| Trolleybus | 14.3 | 101 |
| Light Rail | 25.5 | 400 |
| Heavy Rail | 27.5 | 551 |
| Demand Responsive | 1.2 | 17 |
| Commuter Rail | 35.0 | 1153 |

Source: *APTA Fact Book*, http://staging.apta.com/resources/statistics/Documents/FactBook/2014-APTA-Fact-Book-Appendix-A.pdf, Reproduced with permission of the American Public Transportation Association.

systems operate on exclusive rights-of-way only, and have station spacings much farther apart than LRT and (often) BRT systems, and thus have an average operating speed of 20.0 mph (32.2 km/hr). Buses, light rail, and heavy rail serve trip lengths averaging 3.9, 5.2, and 4.7 miles (6.3, 7.4, and 7.6 km), respectively.

Demand-responsive systems serve much longer trips, averaging 8.3 miles (13.4 km), but at slightly lower speeds than heavy-rail or light-rail systems. Commuter rail networks, as is their function, serve longer trips (a 23.7 mile [38.1 km] average trip distance) at much higher speeds (an average speed of almost 33 mph or 53 km/hr).

The ratio of passenger-miles traveled to revenue vehicle-miles (or vehicle-hours) operated offers insight into vehicle loadings (utilization) and trip lengths. A revenue vehicle-mile is defined as a mile traveled while the vehicle was providing service (for example, this does not include dead-head miles to and from starting point). Table 12-5 shows these ratios for all modes using the average values from 2012. Demand-responsive transit services averaged approximately 1 passenger-mile per vehicle-mile and 17 passenger-miles (27.5 passenger-km) per revenue vehicle-hour. These utilization rates result from low vehicle capacities and dispersed origins and destinations. At the other end of the spectrum, commuter rail systems averaged 35 passenger-miles per vehicle-mile and 1,153 passenger-miles (1,856 passenger-km) per vehicle-hour because of the larger vehicle capacity, high operating speeds, and a more focused route structure. Other modes show utilization rates that are consistent with their typical vehicle capacities.

## IV. CLASSIFICATION OF TRANSIT MODES AND THEIR COMPONENTS

Transit modes are defined by their rights-of-way, technologies, and operational characteristics.

**Right-of-Way.** In most cases, right-of-way interacts with transit technology and influences the type of service, costs, and performance characteristics of a transit mode. There are three basic categories of right-of-way (ROW):

- Category A is defined as physically separated and fully access-controlled ROW without intersections or legal access by other vehicles or persons. These exclusive paths can be designed with alignments on aerial structures, in tunnels, or at-grade with physical separation from other travel flows (see Figure 12-2).
- Category B includes ways that are longitudinally separated from other traffic, as shown in Figure 12-3, but are subject to traffic controls at intersections. Pedestrians may also cross the transit right-of-way in some locations.

**Figure 12-2. Types of Full Grade Separation, ROW Category A. (a) Transit tunnel in Seattle, (b) Automated transit in Dubai, (c) Light rail transit in Los Angeles, (d) Monorail in Seattle.**

- Category C represents transit operating on streets in mixed traffic (see Figure 12-4). It is the lowest cost and least impacting alternative, but because transit vehicle movement is dependent on the flow of general traffic, category C offers the lowest service performance. In some cases, category C performance may be improved by incorporating transit priority elements such as queue jump lanes (short lanes enabling transit vehicles to move past areas of congestion to more easily access intersections) and transit signal priority (enabling transit and emergency vehicles to hold green lights at intersections or truncate red lights).

As the degree of separation between travel modes increases from category C to category A, the performance (speed, capacity, and reliability) of the transit system improves, but investment costs also increase.

### Glossary of Common Transit Terms

Transit planning uses some unique terms, many of which derive from transit's rail origins. Some common terms used in this chapter include:

- *Consist*—A consist includes more than one transit vehicle connected to provide a multi-vehicle train.
- *Deadhead*—When a vehicle travels not in service, most commonly between the transit storage facility and the start or end of service (garage deadhead) but sometimes between the terminus point of one route and the start of another (interline deadhead).
- *Dwell*—The time when a transit vehicle is in service but not moving. Sometimes used to describe time waiting at an intersection but more commonly used to refer to waiting time at a stop or station while passengers board or alight or the vehicle waits for the scheduled departure time.
- *Headway*—Literally the space or time between vehicles but often used to describe the frequency of service; a route operating on a "15-minute headway" has a service frequency of 15 minutes. Headway is the inverse of frequency. A 15-minute headway means a (60 mins/15 mins) or 4 buses per hour frequency.
- *Layover*—Also referred to as "recovery time," an additional buffer of time built into schedules at the end of trips (or at major midpoint transfer locations) to account for delays and ensure that the next trip or trip segment departs on time.

**Technology.** Transit mode technology refers to the physical components of vehicles and guideways. A vehicle or consist, a term that represents one or more vehicles coupled together, is the key supply-side unit of analysis. There are four fundamental technological components.

*Support* is the vertical contact between the vehicle and riding surface that supports the vehicle weight. Most commonly, vehicles are supported by rubber (pneumatic) tires on pavement or by steel wheels on steel rails.

The way in which vehicles are guided is described as their *guidance mechanism*. Buses and other highway vehicles are steered by a driver, while rail and other transit vehicles using fixed guideways are guided by their travel way and special guidance wheels.

The third component of transit technology is the *propulsion source* and the *transfer of tractive force*. Typically, transit vehicles are powered either by an internal combustion engine, usually diesel, or by electric motors. Compressed natural gas (CNG) and hybrid vehicles have been increasingly used during the past decade. The manner in which the motor force is transferred to move the vehicle is typically through friction between the rubber tires or steel wheels and the riding surface. Other propulsion technologies include linear induction motors, which use magnetic forces to accelerate the vehicle.

*Vehicle control* or the means for determining speeds and maintaining longitudinal spacing between vehicles/consists is the final technology component. Vehicles/consists may be controlled manually, subject only to the driver's judgment; manually, subject to fail-safe signal systems; or with varying levels of computerized control or feedback to maintain spacing (such as automated vehicle locator systems common on BRT routes). Fully automated, driverless vehicles/consists have preprogrammed computer-controlled acceleration, braking, and stopping. Automated vehicles/consists can only be used on category A rights-of-way.

**Operational Characteristics.** Transit service varies by the types of lines and trips. Short-haul lines usually operate with high frequency and serve high-density areas such as central business districts (CBDs), campuses, or neighborhoods. *City transit* encompasses most bus and rail lines serving the entire city; *suburban transit* mainly serves suburban areas, connecting them to the core and increasingly to each other; and *regional transit* serves entire metropolitan areas with long distances between stations and operating at high speeds.

Transit service can operate with different stop patterns. Lines that serve all stops/stations are defined as *local services*. For *skip-stop service*, each successive vehicle/consist stops at different stations on a predetermined basis to provide higher operating speed and shorter travel times. Finally, *express services* stop only at a few stations along a line, usually operating along the same path as local transit service, which serves all stations. Express service may have separate tracks/lanes or may use the same alignments as local service, but bypass vehicles/consists stopped at local stations.

*Hours of operation* is the final distinguishing operational characteristic of transit service. Regular transit usually operates for 16 to 18 hours per day. Commuter transit operates only in peak hours, usually serving highly directional travel. Irregular or special transit services operate only during special events or emergency situations.

## A. Definition of Transit Modes

There is no rigorous definition of what differences in right-of-way category, technology, or type of service lead to a separately defined mode. However, it is common to consider systems that differ substantially in one or more performance characteristics as separate modes. For travel demand modeling, this is an important issue in that distinct transit modes must be defined in terms of operating characteristics in order to model traveler mode choice decisions (see chapter 6 on travel demand modeling). Modes are defined here first by right-of-way (ROW) category because the three right-of-way categories—A, B, and C—represent different sets of performance/investment cost packages.

*Street transit* is a generic classification of modes using ROW Category C. Although street transit includes first- and last-mile shuttles and local circulators, buses, trolleybuses, and streetcars/tramways, regular bus is the most widely considered street transit mode. Buses mainly use internal combustion engines, and employ visual/manual control. Double-deck and articulated buses may also be used for more route capacity. Streetcars/tramways are guided by rails, and streetcars may be coupled to create up to three- or four-vehicle consists, enhancing line capacity and labor productivity.

*Semi-rapid transit* is a second generic class of modes that mainly utilizes ROW category B, and on occasion, ROW A or C. As such, these modes exhibit a higher performance than street transit modes. Semi-rapid transit includes medium-capacity and medium-performance transit modes such as light rail transit (LRT), most forms of bus rapid transit (BRT), and a number of automated guided transit modes. (In some cities, these rail and bus modes are named rapid transit, although they technically belong in the semi-rapid transit category.)

*Rapid transit* operates only on category A, has large consists and line capacity, fast speed, great reliability, and enhanced safety. A logical extension of building an exclusive right-of-way for transit is to maximize its capacity and operating productivity through the use of large, electrically powered vehicles coupled in trains. As such, the dominant mode in this category is rapid rail transit (RRT), commonly referred to as metro or heavy rail. A second, much less common

form, is a rubber-tired rapid transit system that uses a combination of rubber tires and conventional rails for support and guidance (used, for example, in Montreal; Mexico City; Santiago, Chile; and on several lines in Paris).

*Regional rail*, also known as commuter rail, is distinguished from RRT by the use of even larger vehicles and higher speeds made possible by operation on railroad alignments with longer interstation spacing. Light rail vehicles (LRVs) may also be used in rapid transit applications, often referred to as light rail rapid transit (LRRT). Examples of this mode with fully automatic operations include the SkyTrain in Vancouver, British Columbia; Metro in Dubai; and the Docklands Light Rail in London. In recent years, some LRT trains have operated on regional and intercity rail tracks for sections of their network.

Several electric rail transit systems operating on category A, including RRT, LRRT, and all automated guideway transit (AGT) services, are fully automated and operate without drivers. As such, AGT and automated people movers (APM) meet the definition of rapid transit by category, but they are not considered rapid transit because of their substantially smaller vehicles and lower line capacities.

*Terrain-specialized modes* use distinctly different technologies from conventional transit and are designed for operation on very steep terrain, traversing deep valleys and crossing water bodies. Most common forms include funiculars, cable cars, and ferries.

*Paratransit services* typically use smaller vehicles with low to medium capacity, often built on a truck chassis, which also enables easier procurement of maintenance services in smaller communities. They differ from regular transit because of variable schedules and routings to accommodate individual users' demands.

## B. Bus Transit Modes

Bus transit modes consist of internal combustion engine-powered buses and electrically powered trolleybuses running on streets, highways, and sometimes on special rights-of-way. They can operate on most streets with very little special infrastructure. This allows buses, for example, to provide service over extensive road networks. Bus transit also enables service designs targeted to specific markets where rail lines do not exist (see market segmentation in chapter 2). However, buses are subject to traffic conditions and are generally noncompetitive with private cars with respect to service speed and reliability. In some cases, traffic engineering measures giving priorities to buses can be used to improve service reliability, especially at bottleneck points.

Because of their low investment costs, buses are the most economical mode to operate on moderate and lightly traveled transit lines. However, buses have fewer economies of scale than rail lines. With increasing passenger volumes, bus costs per passenger remain relatively constant, so that for heavy passenger volumes, buses become less economical, although many routes will likely have excess capacity during some periods during the day. They also often have a much lower public image and smaller influence on urban development than fixed-guideway systems. The increased infrastructure, passenger amenities, and branding associated with BRT can alleviate this somewhat.

### *1. Bus Systems*

In 2012, there were 1,370 bus, trolley bus, and bus rapid transit systems in the United States, carrying nearly 5.3 billion unlinked trips, or 51.3 percent of all transit trips. [APTA, 2014b] Buses and trolleybuses accounted for about 36.7 percent of the passenger-miles carried on transit.

Buses can be classified by their propulsion systems, body type, size, capacity, and method of guidance (see Figure 12-5).

**Propulsion System.** The most common propulsion system for buses is the diesel motor. Just more than 67 percent of bus fuel consumption in 2012 was conventional diesel fuel. [APTA, 2013] However, in recent years, bus manufacturers and transit agencies have been attempting to reduce the negative environmental impacts associated with transit buses. [IAPT, 2013] These efforts have led to the addition of emission-reducing technologies to standard motors, including particulate filters for ultra-low sulfur fuels, as well as new propulsion systems and combinations of diesel and electric motors in so-called hybrid vehicles. Alternative fuel vehicles, including (in order of decreasing frequency of use) compressed natural gas (CNG), biodiesel, liquefied natural gas (LNG), propane, and electric (battery-powered) motors, now constitute about 32 percent of energy use for buses operated in the United States. Currently, the

technology exists to fast charge an electric bus for a limited amount of time in operations. In addition, more buses are being added to the fleet that use "clean" diesel fuel.

Trolleybuses are electrically powered buses having two overhead cables for power pick-up by trolley poles (see Figure 12-6). The poles allow buses to move up to 13 ft (4 m) laterally from the overhead wires, so that a trolleybus can use the lane under the cables as well as one adjacent lane to each side. Generally, trolleybuses can operate short distances off wire. Overall, trolleybuses represent an environmentally friendly transit mode that provides the lowest noise level of all transit modes, no exhaust, and effective operation on hilly streets. Due to these features, San Francisco; Seattle; Vancouver, British Columbia; and many cities in Switzerland, Greece, Russia, and East European countries have extensive trolleybus networks.

**Vehicle Body Type, Size, and Capacity.** A standard bus is typically a two-axle vehicle, 40 feet (ft) (12 m) long and 8.5 ft (2.5 m) wide. Its capacity may vary from 40 to 60 passengers, the lower number being with all passengers seated and the higher number including those standing. Many cities also use 30- and 35-ft (10- and 11-m) buses for lightly traveled routes. The entire family of transit buses includes minibus, 16 to 23 ft (5 to 7 m) with 12 to 20 seats and eight to 15 standing spaces; midi-bus, 26 to 33 ft (8 to 10 m); and extra-long 45-ft (15-m) two-axle buses, which require special permission to operate on specified routes. At 14 ft (4.3 m) tall, double-deck buses—most famously used in London and Hong Kong—are also used in a number of North American communities where they provide advantages in terms of a higher proportion of seats than articulated buses (making them a good choice for longer terminus-to-terminus trips) and better ability to serve older downtowns with short blocks.

In addition to meeting passenger demand, a critical criterion in selecting vehicle length is its turning radius and clear turning path, shown with typical dimensions in Figure 12-7. Bicycle racks on the front of buses increase the minimum outside turning radius by a few feet.

An articulated bus is a three-axle vehicle, 52.5 to 59 ft (16 to 18 m) in length, with two body sections connected with a joint that allows horizontal and vertical "bending" of the vehicle in curves, while providing continuous interior for passenger accommodation. This bending effectively shortens the vehicle wheelbase, which permits these very long buses to travel where wide turning paths would otherwise prevent operation. Articulated buses typically have seating capacities of approximately 65 seats and an additional 35 to 50 standees for a total vehicle capacity of over 100 spaces. For heavy passenger loads (as in developing countries and cities such as New York City), articulated bus capacities of up to 125 spaces can be achieved by providing fewer seats and achieving higher standing passenger densities of 1.8 $ft^2$/persons (6 persons/$m^2$) instead of 2.2 or 2.7 $ft^2$/persons (5 or 4 persons/$m^2$) common for developed countries. Articulated buses usually show benefits of higher labor and vehicle productivity (passenger-mile per revenue-hour or per revenue-mile), but with some disadvantages in comfort and vehicle performance (lower acceleration and deceleration rates). Articulated buses were shown in Figure 12-5.

Low-floor buses with access points only 10 to 15 inches (25 to 35 cm) above the street surface are now used extensively in many cities around the world. The main purpose of this design is to provide easy boarding and alighting for disabled or mobility-impaired persons. An equally important benefit is easier and faster boarding for all passengers, decreased dwell times, and faster overall service. The vehicle's floor and aisle are at the same level in the front and usually rise by two steps or a sloped floor to accommodate the powered rear axle and engine compartment.

High-floor buses are also still common. Typically, access is via steps, but in a few cities platforms are being constructed to provide level access. High-platform boarding and alighting is commonly associated with the concept of BRT (see later section). High-floor buses without steps are limited to operation on lines with high platforms, usually on the left side. They cannot serve branch lines on regular streets where such platforms do not exist.

**Bus Guidance.** Several types of buses have the ability to be both steered or be guided on a guideway to combine the benefits of travel on streets with the safer and more reliable operation of a guided mode. The best known examples are the O-Bahn services in Essen, Germany, and a 7.5-mile (12-km) long line in Adelaide, Australia. Horizontal wheels run along 8-inch (0.2-m) high guiding curb surfaces on the bus track. When the bus leaves the guided section, the driver retracts the wheels and continues to drive the bus in the conventional steered mode. Compared to other guided modes, such as LRT, guided bus requires lower investment costs and is simpler to build, but cannot realize the advantages of labor productivity (through coupled vehicles) or electric traction as found in LRT. As such, few guided bus systems are currently in operation.

Recently, bus models with optical guidance have also been introduced, primarily on BRT lines with high platforms, to enable precise stopping of buses with a small gap between bus floor and a high platform edge. The vehicle is self-guided, utilizing front-mounted cameras and special pavement markings.

*Bus Travelways*: Most buses operate on urban streets in mixed traffic, along the right curb lane with little or no specialized infrastructure except for bus stop signs, shelters, and waiting facilities (in some cases, concrete bus pads are provided at high boarding stops). In cities that provide priority for bus services, buses also operate on different types of upgraded rights-of-way, as shown in Figure 12-8. Exclusive bus lanes on streets are dedicated to buses, and it is unlawful for nontransit vehicles to enter (see Figure 12-9). In some cases, bus systems use exclusive lanes in the opposite direction from all other traffic. These so-called contraflow bus lanes are most applicable for directionally dominated peak hour travel. However, the highest-quality bus service is obtained on bus lanes located in physically separated street medians (similar to typical LRT right-of-way). Left-turning traffic must be either separated by signals or eliminated.

Buses may also be operated on freeways for some portion of their routes. For freeway routes, stops are located at or immediately adjacent to interchanges. The most intensive use of a freeway for bus services is the approach to the New York City Lincoln Tunnel from New Jersey. This section carries about 700 buses per hour and serves the Port Authority Bus Terminal having more than 200 bus berths. In the morning peak, this section uses a contraflow lane on the outbound roadway.

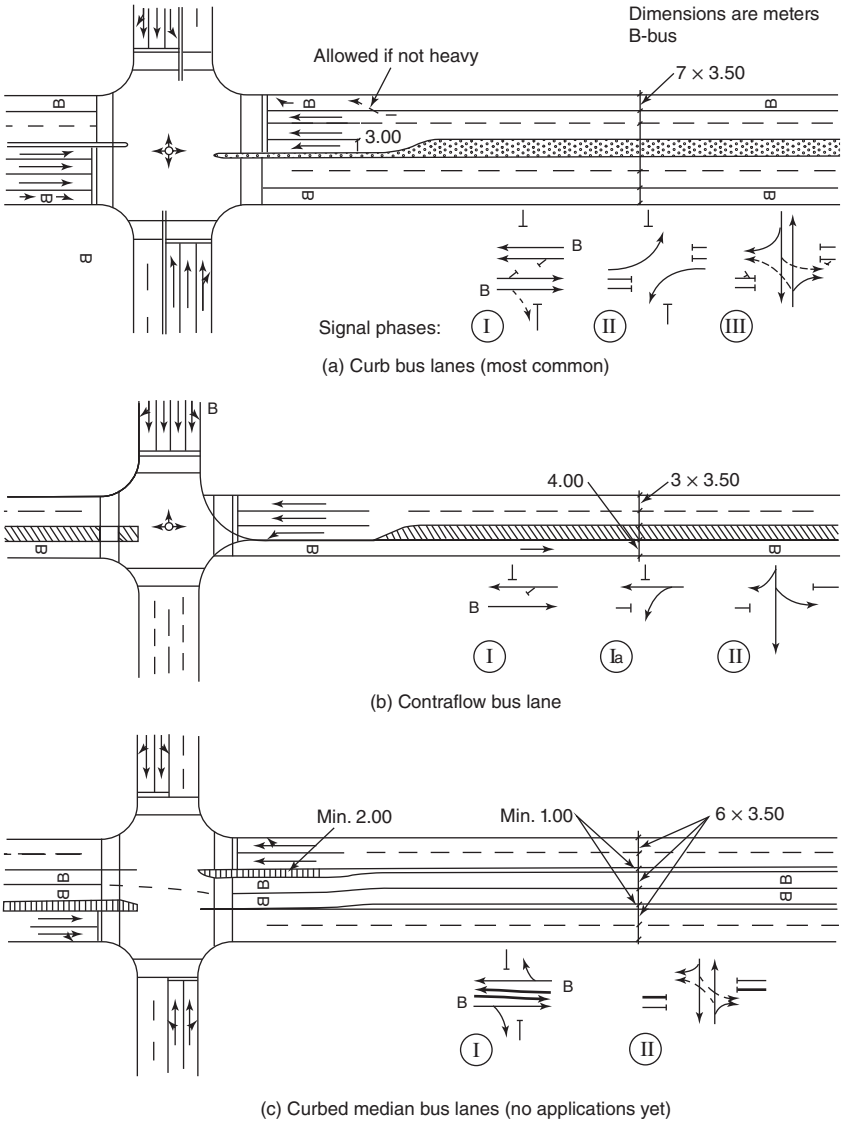
*Busways:* The highest performance bus rights-of-way are associated with busways, roadways dedicated to buses only. Busways are physically protected from other roadways, but usually have intersections with other streets or arterial roads. The most elaborate and best-known busways in North America are those in Ottawa, Canada, and in Pittsburgh, Pennsylvania. Ottawa's 17.4 mile (28 km) BRT network with 26 stations, integrated with a much more extensive network of regular bus lines, carries approximately 220,000 passengers daily. Pittsburgh's three busways serve 26 stations along 18.5 miles (29.8 km), serving approximately 22 percent of Pittsburgh's daily ridership. Examples of busways also include Miami's South Line and the Orange Line in Los Angeles.

In some cities, freeway shoulder lanes have been converted to bus use either during peak periods or in some cases during the entire day. Martin et al. [2012] provide a good overview of these types of facilities and the criteria that must be satisfied for their use.

### *2. Bus Rapid Transit (BRT)*

The success of distinct bus networks with physically separated rights-of-way and busways in cities such as Bogota, Colombia, and São Paulo and Curitiba, Brazil, have stimulated interest and concerted efforts to define a distinctly upgraded bus mode. This mode, known popularly as Bus Rapid Transit (BRT), has been strongly promoted by the

**Figure 12-8. Methods for Achieving Upgraded Right-of-Way for Bus Lanes**



Source: Vuchic, 2007

U.S. Federal Transit Administration (FTA). A number of BRT services have been implemented in U.S. cities, with similar services in many other countries, particularly in South America.

**System Definition and Characteristics.** The family of BRT services encompasses a broad range of characteristics and performance levels, from BRT buses on arterial streets to distinct BRT networks separated from the road system. Experiences from many systems suggest that for a BRT service to improve bus speed, reliability, and identity, it must have the following elements: [Kittelson & Assocs., 2007]

- Partially or fully separated right-of-way (category B or A) on most of its length.
- Service during most daily hours with frequent and reliable service.

**Figure 12-9. Providing Bus Lanes Allows Buses to Bypass Congested Road Segments**

Photo courtesy of Michael Meyer

- Distinct stops and stations with passenger amenities.
- Spacious and distinctly designed vehicles with easy access (multiple door channels).
- Bus preferential treatment at most intersections.
- Monitoring, control and passenger information using intelligent transportation system (ITS) technology.

**Vehicles.** Many BRT systems use vehicles at least partially custom-designed for that specific line or system. Vehicle size and capacity depends on the passenger volume, but for heavily traveled lines, BRT systems commonly use 52.5- to 60-ft (16- to 18-m) articulated buses. In a few cases where lines are mostly on level terrain with few turns (Curitiba), 78.7-ft (24-m) long double-articulated buses are used. Total vehicle capacity, however, depends not only on vehicle dimensions, but also on several other factors.

First, a trade-off exists between seating capacity and total vehicle capacity. Maximum capacity is achieved with a minimum number of seats. However, if the goal is to offer high passenger comfort, a larger number of seats might be desired. Second, floor height and number of doors directly influence bus capacity because of differences in the design of entrances, steps, and aisles. In most cases, BRT buses should have multiple doors for faster passenger exchange and should eliminate the practice of passengers boarding through a single-channel door. Therefore, off-board payment technology at stations and/or other fare-related policies should also be considered for BRT systems to ensure faster passenger loading and reliability. Third, accommodations for the disabled require space for a lift, plate, ramp, and wheelchair placement. Finally, the standard used to compute standing capacity varies among industrialized countries, from systems in medium-sized cities in developing countries, 2.7 $ft^2$/person (4 persons per $m^2$) to very large cities, such as São Paulo and Bogota, 1.8 $ft^2$/person (6 persons per $m^2$). Four to five persons per $m^2$ are achieved under uncomfortable conditions, while six or seven persons per $m^2$ are unrealistic standards for most systems. In addition, crush loads almost always increase dwell times at stops, thus reducing the line capacity.

Vehicle appearance is part of a positive image or branding of the line, resulting in many new designs of vehicles for BRT systems. In some cases, however, excessive innovation and diversity in body design, propulsion, control, and even automatic driving and guidance have questionable applicability, leading to the production of extremely expensive vehicles, reaching a range of $1.5 to $2.0 million per vehicle. The trade-off between high comfort and appeal vs. purchase and operating costs should always be carefully considered.

**Infrastructure.** Physically protected roadways for BRT prevent entry by other vehicles. Appropriate design and enforcement are particularly important at intersections where other vehicles tend to enter bus lanes intentionally or by mistake. Intersection capacity can also be affected because a high-frequency bus line with signal priority may reduce the amount of traffic volume coming from the crossing street. Physically separated roadways and lanes are greatly superior to the lanes designated only by signs and markings. Physical separation also avoids traffic signals and city blocks (and numerous cross streets) that will reduce maximum bus flows.

Although physical separation is operationally feasible, such treatment can run into political pressures when bus lane capacity appears to be available in contrast to congested conditions on adjacent lanes. Such pressures have led to the abandonment of bus lines and degradation of BRT services in a number of cities.

BRT stops and stations must also be carefully planned to provide needed line capacity. BRT stations are spaced farther apart than conventional street bus stops, which promotes a fast and reliable bus service. For example, the street-running Metrobus lines in Los Angeles have been successful in attracting new passengers by having fewer stops and providing faster and more frequent service than conventional buses.

With single buses stopping at stations, a BRT line, even with high platform stations and articulated buses with four doors (for example, the Insurgentes Line in Mexico City), can carry about 6,000 passengers per hour. Higher capacities can be achieved with the operation of several buses in a group or platoon (São Paulo) with multiple station berths where several buses stop simultaneously. Another method to increase capacity is to design several sets of stops staggered along two-lane streets for buses only, which allows leapfrogging of buses (Portland, Oregon). It is also possible to provide two lanes at each station area, which allows express buses to pass. With these arrangements, line capacities may reach 15,000 to 20,000 passengers per hour or even higher.

The major operational features contributing to a greater passenger attraction to BRT relate to the design of lines and services. Instead of numerous overlapping lines with irregular services typical of many bus systems, BRT has few, but

| Table 12-6. Costs for U.S. Bus Rapid Transit Projects | | | | | |
|---|---|---|---|---|---|
| **BRT System** | **Miles** | **Capital Costs ($ million)** | **Cost per Mile ($ million)** | **Federal Funding** | **State and Local Funding** |
| Boston Silver Line, Washington St., Phase 1 | 2.4 | $46.5 | $19.4 | 0% | 100% |
| Cleveland HealthLine | 7.1 | $197.1 | $7.0 | 50% | 50% |
| Boston Silver Line-Waterfront/Phase 2 | 8.8 | $624.2 | $89.1 | 77% | 23% |
| Pittsburgh, MLK Jr. East Busway | 9.1 | $68.0 | $20.0 | 50% | 50% |
| Eugene EmX | 4.0 | $65.9 | $16.4 | 80% | 20% |
| Oakland San Pablo Rapid | 14.0 | $3.2 | $0.23 | N/A | N/A |
| Los Angeles Orange Line | 14.2 | $377.6 | $25.0 | 7% | 93% |
| Las Vegas, MAX and SDX | 19.0 | $51.6 | $2.7 | 82% | 18% |
| Kansas City MAX | 12.0 | $65.9 | $5.5 | 63% | 37% |
| Los Angeles Metro Rapid | 400.0 | $94.0 | $0.24 | 77% | 23% |

Source: Lowe and La, 2012

very distinct lines with frequent and regular services. Thus, BRT is actually much less flexible than conventional bus networks, but is more similar to rail services with respect to its stronger image and reliable service with easy transfers to other lines. Exclusive busways also give BRT an image of greater permanence than bus operations in mixed traffic.

Other key characteristics of BRT service include off-vehicle fare collection and passenger information systems. These aspects of transit service are usually located at the BRT stops/stations so that the act of purchasing a fare or of determining schedules and arrival times will not delay the vehicle departure, thus enhancing service reliability and speed.

Capital costs for busway and BRT projects vary widely, depending on the amount of right-of-way, location, and technology specifications. Typical capital costs for some BRT projects in the United States are shown in Table 12-6. As can be seen, there is quite a range in costs, depending on facility characteristics.

Many of the system elements for upgraded BRT services, such as the provision of separate bus rights-of-way, faster services, and multiple doors, should be considered for conventional bus systems as well. The introduction of BRT requires a considerably greater effort, but it also results in a higher-performance system and associated positive land-use impacts. In essence, it represents a transit service option that fits between conventional bus and LRT services.

BRT usually has lower investment costs, faster implementation times, and simpler technology than LRT because it does not need tracks and line electrification. Generally, the greater extent of separated busways (and other features typical for LRT), the higher its level of service, but the smaller its advantage of lower investment costs over LRT. In extreme cases, such as bus tunnels in Seattle and Boston (Silver Line BRT), investment costs for busways have been comparable or higher than for LRT, while level of service is in most respects (speed, capacity, comfort) has been similar or lower. However, BRT can have many more branch lines and link more easily with other parts of the transit system. Ottawa, Ontario, for example, operates a "spider network" with many different route branches at each end of the BRT service, also common in Australia.

Present trends indicate that the need for medium-capacity transit modes, including mostly LRT and BRT, will be given increasing attention in the future, as cities want to increase the role of transit and decrease car dependency. In developing countries, BRT systems with high capacity, similar to those in São Paulo and Bogota, are likely to be introduced in more cities.

## C. Rail and Other Guided Modes

Electric rail transit systems and other physically guided modes have many features that allow for diverse operations. The main features of most guided modes include:

- Rail systems, which operate the largest transit vehicles (except ferryboats) usually coupled in trains, result in much greater line capacity and labor productivity than that for buses and other transit modes.

- Guided modes require greater investment in transportation infrastructure, suggesting permanence of the service and creating strong identity for the system.
- Guidance systems allow use of narrower rights-of-way than for steered vehicles.
- Rail vehicles have higher riding comfort as a result of larger vehicles and their multiple vehicle suspensions.
- Most guided transit modes use electric traction, which has superior dynamic performance and little noise and air pollution, and enables operation in tunnels (although diesel commuter rail operations are not quiet).

Operationally, as a result of these features, guided modes usually utilize transit right-of-way categories A and B because of their high passenger capacity and operational scale of service. Independent travel ways ensure greater service reliability and provide stronger system image. Guided modes can better integrate into urban areas, due to their defined travel paths and minimal environmental impacts (in most cases). However, guided transit modes often incur very high investment costs, particularly for metro systems and other modes using category A rights-of-way. They can also present challenges to a transit agency when new technology is introduced into the system, often requiring specialized training of personnel and technology-specific support facilities. Although complex, they can also provide opportunities for intermodal integration with other modes in a network.

Four rail modes—streetcars/tramways, light rail transit (LRT), regional rapid transit (RRT) also known as metro or heavy rail, and regional or commuter rail—are the most common forms of rail transit. Several other guided technology modes, grouped as monorails and automated guided transit, are also part of the rail category.

### *1. Streetcars/Tramways*

Streetcars were the dominant mode of street transit in many cities until the 1950s. With the increasing use of private automobiles, streetcar systems declined and most were replaced by bus service. In the United States, the number of streetcar systems in operation decreased dramatically after World War II, such that fewer than 10 cities retained major streetcar lines, including several that operated in tunnels in central cities, such as Philadelphia; San Francisco; Boston; and Newark, New Jersey. In Canada today, the Toronto Transit Commission operates an extensive streetcar system, by far the largest in North America.

Parallel with the development of LRT, there has been a renewed interest in recent years in conventional streetcars, predominantly as center city circulators. In 2001, Portland, Oregon, built a new streetcar line for such a purpose (see Figure 12-3). Memphis, Tennessee; New Orleans, Louisiana; Tacoma, Washington; Atlanta, Georgia (see Figure 12-10), and several other U.S. cities have built new streetcar lines in their central business districts (CBDs).

Streetcars are electrically powered vehicles, usually articulated, which can operate on any type of right-of-way (category A, B or C) as single vehicles or in transit consists of two to four vehicles. They usually receive their power via pantographs (historically, trolley poles were used) from overhead cables. New versions of streetcars allow operations without poles.

**Figure 12-10. Atlanta Streetcar**

Photo courtesy of Amanda Wall Vandegrift

Because streetcars and LRT share basic technological characteristics (rail technology, electric traction, and an ability to use any right-of-way category), the two names are often used interchangeably. However, significant differences exist. The most important distinction is the proportion of the respective lines operated on independent rights-of-way (A and B). Streetcars operate predominantly in mixed traffic and their performance depends on street design and traffic conditions. Light rail, mostly independent of traffic, has higher speed, reliability, safety, and passenger attraction.

Streetcar and LRT rolling stock can be four-axle, single-body vehicles with lengths between 46 and 52.5 ft (14 and 16 m). Modern LRT vehicles are typically articulated with lengths from 65.6 to 164 ft (20 to 50 m) and three to seven body sections. While many modern streetcars are unidirectional, LRT vehicles are bidirectional, which allows use of track crossovers and the operation of shortturn trains, simpler design of terminal stations (track loops are not needed), platforms on either side of the track and other design and operational flexibilities. In some cases, cities have opted for vintage, historic, and replica streetcars, whereas others are using more modern cars.

### *2. Light Rail Transit (LRT)*

LRT is an electrically powered system that operates mostly on right-of-way category B, but can also use categories A and C. Reserved rights-of-way are, in most cases, in the medians of major arterial roads. In central cities, LRT may use either short tunnels (Boston, Massachusetts; Buffalo, New York; Edmonton, Alberta; and San Francisco, California), or be separated at-grade through auto-free zones (pedestrian and transit only), as demonstrated in Calgary, Alberta; Portland, Oregon, and many cities in Europe.

Contemporary LRT vehicles (LRVs) use a number of different trucks and axles including individually powered single axles and even single wheels instead of conventional two-wheel axles. These new designs often included the introduction of low-floor vehicles, which speed passenger boardings and alightings, reduce physical barriers to entry, and allow for better integration of stops in pedestrian areas (see Figure 12-11).

The capacity of LRVs varies widely based on the total length, width, and number of body sections. In North America, standing square feet, square feet per standee, and the number of seats are the usual determinants of service capacity. Manufacturers often provide different metrics that relate to crush loads, which in most North American cities would not be acceptable. Total capacities (seated and standees) for North American LRVs range from 90 to 225 spaces per vehicle.

Capital costs for light-rail systems vary mostly with the degree of right-of-way separation and the number of stations. Table 12-7 shows the capital costs for the LRT systems in the United States that have been constructed since 1990 ($2014). Note that the more expensive per mile systems included much higher levels of engineering and construction challenges.

In addition to operating on exclusive rights-of-way and on streets, LRT alignments can be integrated with urban arterial roads to provide convenient access for passengers with some reduction in line capacity (length of city blocks, for example, becomes an important factor in determining maximum consist flows). Figure 12-12 shows several possible right-of-way B alignments. In the first two diagrams, LRT is operated in the median of the arterial road, requiring right-of-way width of approximately 19.7 to 32.8 ft (6 to 10 m). In special cases, narrower rights-of-way may be used, as in San Francisco, California, where track centers are 11.6 ft (3.55 m) apart. Alternatively, LRT may be operated outside of auto lanes, with operation on two curbed lanes (diagram C) or with a combined alignment on a single side (diagram D).

The most common of these design alternatives is median operation. Typically, the LRVs move on the same traffic signal phase as the through roadway traffic. Figure 12-13 shows the geometric design and signal phasing for intersections with far-side LRT stops. A three-phase traffic signal is utilized: a left-turn phase for east-west vehicles that follows the through phase; a through phase for east-west vehicles and LRT; and a phase for all north-south movements. An example of preferential movement of LRT trains is shown in Figure 12-14.

The degree of right-of-way separation leads to many operational characteristics. For example, LRT may achieve speeds of 62 mph (100 km/hr) on exclusive rights-of-way, while in pedestrian zones typical maximum speeds are 10 to 15 mph (16 to 24 km/hr). Train control also varies. For example, LRT trains can be operated manually through CBD streets (San Diego and Sacramento, California; and others) and as trains come to sections of upgraded rights-of-way, they have barrier-protected crossings and fail-safe block signals, similar to metro systems and can thus move at faster speeds. In San Francisco, LRT trains converging into the center-city tunnel switch from manual driving to fully automated operation; the driver only initiates a preprogrammed train movement.

**Figure 12-11. Light Rail Vehicles. (a) Five-body section articulated light rail vehicle in Jerusalem, Israel; (b) Docklands light rail, London; (c) Light rail in Portland, Oregon; (d) Light rail in Seattle, Washington, using a downtown transit tunnel.**

This variety of vehicle design, right-of-way types, station configurations, and speeds presents many opportunities in the design of LRT lines. LRT lines can serve different functions, even within the same city. In Denver, Colorado, for example, LRT operates in contra-flow lanes in pedestrian-oriented downtown streets with transfers to buses and a pedestrian-mall bus shuttle. Outside of the downtown, the LRT service follows radial corridors in several directions, with speeds of 56 mph (90 km/hr) and sections of up to 5 miles (8 km) on fully separated rights-of-way. The system is well-integrated with suburban bus feeder lines and park-and-ride facilities. Similar arrangements exist in Calgary, Alberta; Dallas, Texas; St. Louis, Missouri; and other cities.

The number of LRT systems has grown very rapidly in North America, with 35 LRT/streetcar systems operating in the United States in 2012. As of 2014, there were another dozen LRT/streetcar systems in the procurement stage.

### *3. Rapid Rail Transit (RRT) (Metro)*

RRT is an electrically powered system of trains operating only on exclusive rights-of-way and with fully access-controlled stations. RRT right-of-way is typically in tunnels within central cities, but aerial structure and separated, at-grade alignments are common in lower density areas. Rapid transit lines typically have 750–800 V power distribution via a third rail alongside the tracks (although the Cleveland line uses catenaries). Some recently built metros have 1,500 V power distributed by overhead cable (Hong Kong, Milan, most metro lines in Tokyo).

"New U.S. Light Rail Transit Starter Systems—Comparative Total Costs per Mile," May 6, Accessed Feb. 5, 2016, from, https://lightrailnow.wordpress.com/2014/05/06/new-u-s-light-rail-transit-starter-systems-comparative-total-costs-per-mile. Reproduced with permission of *LightRailNow!*

Train lengths are typically four to eight cars, but may be operated with 2- or 10-car consists. Access to the train is via high platform, each car having two to four, sometimes five, double-channel doors.

RRT systems use fail-safe train control systems, which consist of signals controlling occupancies of fixed sections of track, known as blocks. Fixed-block systems detect a train when it enters that section of track, and do not permit following trains to enter that block. This system, which is more than a century old, is known as automatic train protection (ATP). Signals, which may be wayside (located along the tracks) or cab signals displayed on driver's panel in the train, show the occupancy of the block the train is approaching.

To increase line capacity by operating shorter headways (the frequency of service or literally the space between vehicles), several new control systems have been implemented, which continuously record positions of each transit vehicle. This *moving block* technology, a form of communications-based train control (CBTC), differs from traditional control systems in that the locations of all trains are known exactly, rather than limited to a train's presence in a signal block section of track. With such CBTC systems, a centralized train control center monitors and controls the movements of all transit vehicles. This system is known as automated train control (ATC).

In some cases, the commands sent by the center are received and followed by vehicle operators. More commonly, particularly on recently built systems, ATC is used in conjunction with automatic train operation (ATO), where the trains have a series of operational performance levels (PLs) programs, consisting of different acceleration and braking rates, and maximum speeds for optimal travel between stations. PLs for each train can be changed for rail sections between stations.

Trains with ATO may have operators (drivers) whose responsibilities include starting the train at each station, making stop announcements, opening and closing doors, or acting as a point of contact for passengers in case of emergency. Several metro lines, such as the Paris Meteor line and the Singapore Northeast line, are driverless, meaning that no crew member is present on the train. Some systems use a hybrid approach. Vancouver's automated LRT, the SkyTrain, employs what are known as roaming conductors, who board the automated trains for several stops, then perform other duties at stations. The trains always operate without drivers.

RRT vehicles vary in length from 49 to 75 ft (15 to 23 m) and in width from 8.2 ft (2.5 m) (rubber-tired metro vehicles) to 10.5 ft (3.2 m). Train consists range in length from 164 ft (50 m) in Lyon, France, to 710 ft (216 m) in San Francisco, California (BART). Capacities of vehicles are approximately 40 to 70 seats and can carry between 160 to 250 riders, depending on the car size and the willingness of riders to experience crush loads.

Rapid transit alignments can include tunnels, elevated sections, or at-grade operations. Tunnel sections are used in central cities and always provide full control of access. However, underground alignments require the greatest investment cost. Elevated alignments are often used outside of central cities along wide arterials or separate rights-of-way because of their considerably lower construction impacts. Modern aerial structures use pre-stressed concrete with small cross-sections that produce few negative impacts. Aerial structures are approximately 26 ft (8.0 m) in width with varying column heights. RRT systems operating at-grade are least expensive to construct, but require physical barriers

to secure the track from illegal entry. At-grade systems also require that travel ways for intersecting modes (autos, pedestrians) be fully grade-separated.

Capital costs for RRT systems depend heavily on when the line was built and the method of achieving grade separation. San Francisco's Colma-Airport line (opened in 2003) was constructed with high aerial structures and a long tunnel, resulting in construction costs of approximately $256 million per mile ($159 million per km). At the other extreme is San Francisco's Dublin (1997) line, which utilized freeway median for much of its length. This line was constructed for $37 million per mile ($23.0 million per km). Typical values may be derived from Washington Metro's Green Line (2001)—6.5 miles (10.5 km) at $138 million per mile ($85.7 million per km), and San Juan's (Puerto Rico) Tren Urbano (2004)—10.7 miles (17.2 km) at $112 million per mile ($69.8 million per km). In some cities, such as New York City, London, and Berlin, the cost of building RRT is extremely expensive because of the difficulty in engineering and construction. In 2015, the Second Avenue Line extension in New York City was estimated to cost $2.7 billion per mile ($1.7 billion per km); in Paris a line extension is costing $403 million per mile ($250 million per km) and in Berlin $726 million per mile ($450 million per km).

RRT provides perhaps the best urban transit mode performance in terms of capacity, speed, frequency, reliability, safety, and impact on surrounding land use. The vehicle and platform design in combination with prepaid fares allows for rapid boarding and alighting and minimum station delays. Because the rights-of-way are protected, rapid transit lines can achieve speeds of 50 to 62 mph (80 to 100 km/hr), with exceptional cases of 81 mph (130 km/hr) (San Francisco BART). Average speed, which includes the time at stops, would be lower. Line capacities on rapid

**Table 12-8. Major Metro Systems' Characteristics**

| City | System Length (mi/km) | Stations | Approx. Annual Ridership (millions) |
|---|---|---|---|
| Shanghai, China | 321/548 | 337 | 2,500 |
| Moscow, Russia | 204/328 | 196 | 2,491 |
| Tokyo, Japan Metro Corp. | 199/320 | 179 | 2,351 |
| New York (MTA) | 660/1062 | 468 | 1,832 |
| Mexico City, Mexico | 141/226 | 195 | 1,685 |
| Paris, France | 137/220 | 303 | 1,527 |
| London, England | 250/402 | 270 | 1,362 |
| Tokyo TOEI | 66/106 | 106 | 866 |
| Montreal | 43/69 | 68 | 358 |
| Washington, DC. | 117/188 | 91 | 209 |

transit systems can theoretically reach 85,000 riders per hour per direction (recent passenger loads from Hong Kong), but typical maximum loads are about 40,000 riders per hour (average loads on most lines in the United States are much less).

Table 12-8 shows the characteristics of several major metro systems. The rapid transit system in Moscow consists of 12 lines and spans 204 miles (328 kms). The system carries more than 2.4 billion trips annually, or just over 6.5 million per day at an average operating speed of 9.7 mph (15.5 km/hr). Tokyo's system is composed of two companies providing service on 12 lines. Together these services also carry more than 6 million passengers daily. The average speed reported by the TOEI Corporation for its lines is approximately 20 mph (32 km/hr).

Rapid transit stations represent major infrastructure investments, and they often have major impacts on their surroundings. Several planning principles should be followed in their planning and design:

- Locate stations such that adequate area coverage is provided while maintaining sufficient spacing so that the line maintains desired operating speed.

- Provide efficient transfers among lines of each transit mode (complementing bus, streetcar networks, etc.) as well as for maximum integration of modes, including pedestrian, bicycle, street transit and, in outlying areas, kiss-and-ride and park-and-ride facilities, usually in this priority sequence.
- Include station planning for passenger movements into and out of stations through fare collection devices and between levels for transfers at grade-separated stations.
- Consider fire safety and other emergency evacuation requirements in both design and passenger information systems.
- Supply comprehensive information regarding the transit system, including a list of all routes served by the station, maps, and schedules for the line and network and, in contemporary systems, real-time information on transit vehicle arrivals and departures.
- Coordinate location with existing or future planned higher density destinations and mix of land uses in the station area.

Station planning and design for RRT systems are described in further detail in later sections.

### *4. Regional Rail*

Regional rail, also known as commuter rail, is a system of electric or diesel-powered trains operating on railroad rights-of-way, providing very high-performance service on long lines, typically between central cities and the suburbs (see Figure 12-15). Regional rail systems usually have longer lines, higher operating speeds, and higher passenger comfort than rapid rail transit. Many regional rail networks have fully protected at-grade crossings in outlying suburban areas, but grade-separated tracks, often in tunnels or elevated structures, in central cities.

As a railroad-based system, regional rail uses signal control and the highest standards of alignment geometry, the longest station spacing (between 5 to 10 miles [8 to 10 km], typically) and, therefore, the highest operating speed of all transit modes. These elements make regional rail services highly competitive with longer distance auto travel. However, freight track is designed to standard gauges, and thus regional rail vehicles must be able to operate safely on such track. The mere existence of freight track should not be construed as meaning regional rail operations could be started without possibly costly upgrades.

Contemporary regional rail vehicles introduced in recent decades in cities like New York City (on all three systems: Long Island Rail Road, Metro North, and New Jersey Transit), Chicago, Philadelphia, and Boston, have maximum dimensions allowed by railway standards, which are (in most countries) a length of 85.3 ft (26 m) and a width of 10.5 ft (3.20 m). Such cars designed for maximum seating can have capacities of 110 to 128 seats. As trains of 5 to 10 cars could not provide sufficient seating in some cases, cities have introduced multilevel cars. In North America,

**Figure 12-15. New Jersey Transit Multilevel Regional Rail Vehicles**

Photo courtesy of Bombardier Transportation

Chicago's Metra and San Francisco's Caltrain have used multilevel cars for many decades. In recent years, the Long Island Railroad, Boston, New Jersey Transit as well as most regional rail systems opened since the 1970s (Toronto, Tri-Rail in Florida, Los Angeles Metrolink), have introduced different designs of multilevel cars with capacities of up to 150 seats and 200 spaces for standees. A similar trend toward multilevel cars has taken place in many other countries, including France, Germany, Spain, and Australia.

Most regional rail systems in North America are diesel powered with a locomotive pulling 5 to 10 trailer cars. Such trains are designed as push-pull units, with the locomotive driven by an engineer at the head of the train, while in the reverse direction, the train operator drives from a cabin at the opposite end of the train, remotely controlling the locomotive that pushes the train.

Because regional rail systems are operated in corridors with active freight and intercity railroads, rail cars in North America are required to be designed with sufficient vehicle buffering strength to meet federal railroad safety criteria in the event of an accident. These requirements result in very heavy regional rail vehicles. They also allow LRVs to use railroad tracks only when these two types of services are separated in time as they are in San Diego, for example. Some European cities have relaxed this constraint to allow LRVs to operate on intercity railway tracks. This arrangement was reached by designing the train control system so as to prevent any possibility of collisions, as well as in the United States where a focus has been on minimizing the damage when collisions occur.

Most regional rail systems in North America have high-floor vehicles and low platforms, with passengers negotiating up to four steps. A design with high-floor vehicles and high-platform stations is operationally much better, since it allows much faster boarding/alighting and accessibility. This design requires different solutions when freight train profiles must be provided for at each station. Another design is where suburban stations have low platforms and require cars with steps, while center-city stations have high platforms, as is the case in Philadelphia on SEPTA's regional rail system. This arrangement with manual control of step covers requires the train crew to move the plates above the steps, thus, requiring large train crews.

Stations on most regional rail systems in North America have open fare access and involve low maintenance cost, but old systems still use labor-intensive fare collection on trains. Recently opened regional rail systems, such as Los Angeles' Metrolink, use a much more efficient self-service fare collection system.

With their heavily commuter-oriented ridership, most regional rail systems depend on station access in suburbs via kiss-and-ride and park-and-ride modes. [Coffel et al., 2012] For this reason, regional rail systems have constructed park-and-ride lots and garages at many stations. The investment in such parking facilities from a systems point of view is very effective because the provision of station parking in remote suburbs more effective from a public policy perspective than longer distance travel by car.

The capital costs of regional rail systems will vary by the degree to which additional infrastructure will be necessary over and above what is provided by the freight rail track. In Nashville, Tennessee, the cost for new service with very little incremental investment was $1.3 million per mile; in Seattle with more investment in track and stations, the cost was $26 million per mile. The Federal Railroad Administration, for example, in an effort to mitigate the effects of train horn noise, requires "quiet zones" around crossings where trains are not allowed to sound their horn when approaching public highway-rail grade crossings, except in emergency situations. In order to maintain the safety of vehicle and pedestrians/bicyclists crossing at such locations, investment must be made in medians or four-quadrant gates.

### *5. Monorails*

Monorails represent a fundamentally different technology from conventional rail. Like conventional rail, monorails are both supported and guided by a guideway. However, they run along a single beam, which may have several different designs, but is always on an elevated structure. There are two primary configurations for monorails—vehicles may be supported (ride above the guiding beam) or may be suspended (ride below the beam or rail) as is found in the Oakland Airport connector. In both cases, the vehicle is powered by electric motors that transfer their force via rubber tires running along the beam or steel wheels running along a single rail. Typically, horizontally aligned rubber tires provide the horizontal stability for the vehicle. Various configurations exist in the number and alignment of rubber tires used as well as the shape of beam on which the monorails are operated. The supported types require a lower structure than suspended ones, and they are more common. Figure 12-16 shows a monorail in Dubai.

Monorail vehicles vary in size, configuration, and capacities. Jacksonville, Florida; Las Vegas, Nevada; and Seattle, Washington are the only cities in the United States operating monorail transit systems in revenue service.

**Figure 12-16. Monorail in Dubai**

Photo courtesy of Michael Meyer

Outside of North America, a number of cities operate monorail transit systems, with the most developed systems being in Japan. Tokyo, Osaka, cities in Okinawa, and several other cities have several heavily used public transit monorail systems. It is difficult to compare the loading capacity of monorail vehicles from Japanese cities with the U.S. market because passenger load factors are much higher than in North America. However, using a North American standard of 2.7 $ft^2$/person (3 persons per $m^2$), the capacities of small, standard, and large four-car monorails are approximately 190, 350, and 420 passengers, respectively.

Fixed infrastructure costs can range from about $44 million to $118 million per mile ($27 million to $73 million per km) with an additional $25 million to $55 million for equipment and rolling stock. Proponents claim that monorails may operate with headways of 90 to 120 seconds. The minimum headways operated in practice are on the Tokyo monorail at 3 minutes 20 seconds, producing a line capacity of about 10,500 passengers per hour. Benefits include electric traction, the quieter operation of rubber tires, the ability to traverse steeper grades, and a smaller footprint for elevated sections. The disadvantages of monorails include the ability to run only on elevated sections, complicated switching, and greater operational complexity than rail systems.

### *6. Automated Systems*

For most transit agencies—and especially in North America—labor costs account for a very large share of operating costs. This cost structure creates pressure on transit operators to provide service with large transit vehicles (high productivity of the driver) at long headways, instead of smaller transit vehicles running at short headways, which would likely be most attractive to passengers. Fully automated trains without drivers allow the transit agency to utilize its fleet such that more frequent consists using automated train operations (ATO) are operated at the same cost as fewer consists at longer headways. This is particularly beneficial because high frequency operation becomes economically feasible during off-peak periods. ATO can also achieve benefits of higher operating efficiency (lower energy consumption and vehicle wear and tear) and greater riding comfort.

Driverless operation can be used only on guided systems with fully controlled right-of-way. There are several dozen fully automated systems in many countries, and they can be classified in three categories—automated people movers, automated guideway transit, and automated metros.

**Automated People Movers.** The most common use of fully automated transit systems is for shuttle-type operation (short lines with two or several stations and frequent service) in high-density areas such as airports, sport complexes,

fairgrounds, or hospital complexes. These systems, usually known as automated people movers (APMs), typically consist of rubber-tired vehicles with capacities of between 40 and 100 spaces, mostly for standees, sometimes operated in two- to three-car consists. They usually provide frequent services (headways of 3 to 5 minutes). In many situations they represent internal circulators where no fares are charged. In such cases, APMs are not planned and evaluated in relation to the number of passengers they are expected to serve and fare revenues, as is typical for planning of regular transit lines. Rather, they are planned as integral parts of the developments they serve.

APMs are operated in an increasing number of airports. Among some 30 such systems in operation, the Atlanta Hartsfield-Jackson Airport people mover is an example of an APM as it is the main connector between terminal buildings, serving about 225,000 passengers per day.

**Automated Guided Transit (AGT).** Automated guided transit (AGT) is a fully automated (driverless) system consisting of electrically powered, guided, rubber-tired or rail vehicles operating on exclusive right-of-way. AGT systems utilize medium-capacity (80 to 120 spaces) vehicles operated as one- to six-car consists. These systems are often used to provide circulation in dense urban areas such as downtown people movers (DPM) in Detroit (rail system) and Miami (rubber-tired guided system). The Miami system has 21 stations throughout its CBD, and they are well integrated with the city's heavy rail and many local and regional bus lines. This DPM, locally known as Metromover, serves as a collector-distributor to the Metro and regional bus lines, as well as for many intra-CBD trips, reducing the demand for provision of large parking garages and contributing to its pedestrian atmosphere and livability.

Since the 1980s, several AGT lines have been built as major transit lines in their respective cities. The VAL system, consisting of two rubber-tired, married-pair vehicles, has served two lines in Lille, France, which carry over 100,000 passengers per day. The same technology has been used by several other French cities and by one line in Taipei, Taiwan. Several Japanese cities operate four- and six-car rubber-tired AGT consists on regular transit lines.

A particularly successful AGT system has been Vancouver's 32-mile (52-km) SkyTrain network. It consists of two-, four-, and six-car automated rail consists operating at high frequencies throughout the day. During most hours, headways of 3 minutes are provided; during the peaks and night hours the headways are shortened and lengthened. This frequent, fast, and reliable service attracts 69 million riders annually.

Shortcomings of full automation include, (1) higher investment cost in the system; (2) much more complicated control technology, requiring higher skills of operating personnel; (3) the need for extra supervision of the tracks and stations; (4) organization of special procedures for handling emergencies; and (5) the need for fully protected rights-of-way. The decision to introduce driverless train systems is complex and must be based on careful analysis of all the advantages and disadvantages for each specific planned transit line or network.

**Automated Metros.** As previously discussed, automation with driverless trains is particularly beneficial for transit lines requiring medium-capacity systems because short headways are feasible even on lines with moderate passenger volumes. Many metro systems have high ridership, which makes operation of short headways with conventional technologies feasible during most daily hours. As a result, the benefits of full automation are not as significant on metro systems. However, the feasibility of providing frequent services at all times, as well as the other benefits of driverless operation, such as the adaptability of services to changes in demand or operations, improved communications and supervision systems, make driverless operation of conventional metro systems justified and attractive in certain conditions.

The implementation of driverless metros has been slow, and it is still limited to new metro lines only. The best known examples of driverless metro lines have been the Line 14, Meteor of the Paris Metro, the Northeast Line of the Singapore Metro, and several others. Paradoxically, most fully automated metros, as well as AGT systems, do not utilize the option of tailoring consist lengths to changes in passenger volume, one of the potentially most significant benefits of driverless operation. The SkyTrain in Vancouver is one of a few automated systems adopting this strategy.

Despite these difficulties in introducing transit systems with driverless trains, their number is expected to increase in the foreseeable future, mostly as APM systems, but also as AGTs and automated conventional metros.

A major issue in North America with the automation of metro systems may be the resulting loss of jobs for train operators. One solution has been to reassign drivers to other duties within the transit agency. A second concern is that

potential riders may perceive driverless operation to be less safe (in terms of vehicle operations) and less secure (in terms of crime). However, experiences with fully automated systems in Asia, North America, and Europe have shown that ridership increases over time as riders experience the system.

## D. Paratransit and Specialized Services

Paratransit or demand-responsive transit differs from conventional transit in that demand-responsive transit routing and scheduling are adaptable to individual users' desires in varying degrees. Trip times, origins, and destinations are coordinated between the user and the providing agency, and charges are usually based on trip duration and length. In many cases, paratransit services may not be available to the general public.

Paratransit services are classified in two categories:

- *Semi-public paratransit*, available to certain categories of users, such as members of a specific community, university or hospital complex, or to subscribers of specified vehicle uses. Subscription vans or buses as well as car sharing programs are examples.
- *Public paratransit*, available to any individual or group of persons. Examples are taxi and jitney services, as well as buses that operate "flexible service" by deviating off route in a variety of ways.

Paratransit's flexible or personalized operation greatly increases passenger convenience and attraction. It provides necessary accessibility for disabled passengers and for the public. It can make transit services more competitive or feasible in areas where ridership has been traditionally low.

Paratransit systems are increasingly being integrated with traditional or fixed-route services. Their use as complementary services has potential to increase ridership throughout a transit system. In developing countries, the regulation and coordination of paratransit services with upgraded regular transit systems are major tasks for transit planners, which involves not only technical planning but also political and financing decisions.

Different modes of paratransit have important roles in urban areas, providing services that exhibit characteristics between those of private auto and transit. However, all paratransit consists of organizationally different types of services and very little, if any, infrastructure. Therefore, paratransit does not require long-range, comprehensive planning of facilities, but only its consideration in transportation policies, which determine the respective roles of different modes in urban transportation. General characteristics of major paratransit modes are discussed below.

### *1. Semi-Public Paratransit*

Semi-public paratransit can be grouped into three categories:

*Vanpools.* Many offices, factories, or institutions with large numbers of employees who commute by car encourage vanpool travel by purchasing or leasing 7- to 15-seat vans and assisting groups of employees to commute together. Vans have much lower per-commuter costs and require less parking area per commuter. Vanpools should be considered as part of a broader transportation demand management strategy and as complementary strategies for such initiatives as high-occupancy lanes, lower parking charges, and preferential parking locations (see chapter 14 on travel demand management). Shortcomings are high turnover of participants and the need for continuous organization and supervision of their operations.

*Subscription Buses.* When there are a large number of commuters traveling between two areas or along certain corridors, subscription buses may be more economical and efficient than vanpools. This service is organized either by large employers or by a group of residents who hire bus services with fixed routings and schedules. Subscription bus commuters have a larger choice of stops, routings, and departure times than vanpools, which only offer a single departure between two points during every peak period.

*Car Sharing*. Beginning in the 1990s, a new type of car rental organization was introduced in many North American and European cities. These car-sharing organizations provide a fleet of vehicles at a number of locations in a city, which may be used by individuals who subscribe to the service. Vehicles are picked up and left at any of the system's locations within the city. In addition to their fixed subscription fee, users are charged on the basis of time and distance traveled.

Experiences in different cities have shown that car sharing is more complementary than competitive with transit services. A number of auto owners in central cities find that by supplementing transit service with car sharing, they are able to give up their personal cars, thus eliminating parking and maintenance costs.

### *2. Public Paratransit*

The three major modes of public paratransit—taxis/Uber/Lyft, jitneys, and flexible transit services—take various forms and could have significant roles in cities.

*Taxis/Uber/Lyft*. Taxis have traditionally been the major means of providing personalized, for-hire service, transporting either individuals or groups of up to five persons from an origin to a desired destination for fares that depend on travel time and distance traveled. In recent years, services such as Uber and Lyft have entered the market, competing with taxi services. The role of taxis and Uber/Lyft services is to provide individualized service for trips when transit services cannot offer adequate service, such as trips from airports to suburban locations, often trips within downtowns, or trips made with luggage. Generally, in medium-sized cities, taxis meet the need for travel of people who do not own autos; in large cities, taxis and Uber/Lyft replace many private auto trips because they are more easily obtained and require no parking. Many transit systems also use taxis to provide a portion of service, and some have begun to explore how Uber/Lyft-type services could provide the "last mile" connectivity to destinations that are not directly connected to line haul transit services. Conventional transit—particularly in smaller or suburban systems—may use taxis to provide service in lower-density areas or at lower demand times of the day. Demand responsive services for people with a disability may also dispatch a portion of trips to taxi providers.

*Jitneys*. Jitneys are privately owned and operated vehicles with capacities of 5 to 15 passengers, usually providing service on fixed routes. In many developing country cities, jitneys provide a significant portion of available transit services. They may also compete directly with publicly provided fixed-route transit, offering a different type of service. Usually, jitneys operate more frequently and have higher speeds than buses because jitneys do not stop at all stops. They offer seats to passengers, but often accept more passengers than seats. Their safety features are regulated in some cities (Hong Kong and Istanbul, Turkey), but in many cities their safety record is far below the standards of transit systems. Jitney vehicles are designed with small seats, offer little structural protection in accidents, and may even operate with open doors. On lightly traveled routes and times, jitney service is irregular, and on longer routes they may depart only when all seats are filled. The fares charged by jitney operators are typically regulated, but instances of overcharging may occur.

Jitneys are known under different names, such as *publicos* in San Juan, Puerto Rico; *por puestos* in Caracas, Venezuela; *jeepneys* in Manila, The Philippines; *Trotros* in Accra, Ghana; and *minibuses* in Mexico and South African cities. In the United States and Canada, there are very few jitney services, with the best known being jitneys in Atlantic City, New Jersey.

Although jitney use is encouraged by many economists and the World Bank because they require little or no public subsidy, they often contribute to chaotic traffic conditions in already congested streets. When a city wants to upgrade transit services by introducing higher-quality bus or rail systems, it must control jitneys and limit their directly competing services. This has been done in cities where rail or BRT services have been introduced, such as Istanbul, Turkey; Mexico City, Mexico; Cape Town, South Africa; and others.

*Flexible Transit Service.* Flexible transit services vary vehicle routings and stop locations in response to requests from individual passengers. [Koffman, 2004] These services are called demand-responsive services. Two forces combined to advance the use of these services. First, with the Americans with Disability Act (ADA) of 1990, demand-responsive service for disabled passengers was no longer automatically an acceptable substitute for fully accessible, fixed-route service. Instead, transit agencies were required to determine the most effective way of providing transportation to disabled customers, including mainstreaming—serving them with regular, fixed-route services—where possible. Financial requirements necessary to accommodate the growing demand for disabled passengers motivated transit agencies to seek more cost-effective service. Thus, transit agencies began to coordinate the design and schedule of flexible services in conjunction with their fixed-route services.

Second, regular fixed-route transit systems have difficulties attracting strong ridership in low-density areas. For example, low-density residential areas and dispersed developments with circuitous street networks present challenges to efficient transit operations. With ADA heightening the importance of flexible services, transit operators saw an opportunity to introduce some combination of demand-responsive and fixed-route services to generate increased ridership in such areas or during certain time periods. This flexible service is also known as hybrid-type transit service.

The most common form of flexible transit is route deviation. In this case, the transit operator provides service in an area with a combination of fixed-route service and on-call pick-up and drop-off locations. For example, an operator

in a route-deviation zone might be informed by a dispatcher that a customer is waiting two blocks away from the traditional route. In response, the driver will vary his or her route to pick up the passenger at that location and then return to the basic route. Similarly, a passenger may request a specific drop-off location several blocks away from the fixed route.

In a second system, known as point deviation, a transit vehicle departs from the fixed route at a station. The vehicle then operates without a fixed route, picking up and discharging passengers either as requested by passengers on-board or guided by dispatch before returning to the fixed route at a station downstream from the departure point. Operators may also provide demand-responsive connector service. In this case, transit vehicles pick up passengers at user-specified locations and transport them to a fixed-route terminal or transfer station.

The length of the route open to route deviation, as well as the distances away from the fixed route that the operator is permitted to travel, vary among systems. They are usually prescribed or determined by the dispatcher, who must control these deviations within certain time limits, so that a reasonable basic transit schedule is still retained. Route deviation practices may also vary by time of day. A detailed discussion of deviation practices is given by Koffman [2004].

Another common type of flexible service is dial-a-ride (DAR), where people in a defined area can call a control center and ask for service between specified locations and at a desired time. The dispatcher then plans trips of individual vehicles, usually minibuses, to serve several trips using a route that collects and distributes passengers in the most efficient way. There are two types of DAR service. Many-to-many services serve trips between any two points in the service area. This type of service provides rider convenience, but is provided at very high cost because average minibus occupancies are usually very low. Many-to-one and one-to-many DAR services are often used for travel to traffic generators such as train stations, shopping centers, elderly centers, or hospitals. A variation is zone service or checkpoint service where DAR is provided only within a relatively small area. Those wishing to travel outside this area connect to other services at a timed-transfer point.

Demand-responsive operations require special coordination with passengers and within agencies. Because of the complexity of operation, marketing, and information dissemination are key components to successful demand-responsive systems. Passengers must be aware of the boundaries of demand-responsive zones, the hours of operations, and the requirements for accessing service. For example, many operators require 24-hour advance notice to schedule a customized pick-up or drop-off location, although the trend is toward shorter advance notice being required. In some cases, passengers may schedule trips as near as 10 to 15 minutes prior to a desired departure time. Variable fares are also common with demand-responsive systems.

The coordination of full-access and disabled-only demand-responsive transit remains a challenge for many agencies. Many transit agencies contract demand-responsive service to private operators. Increasing the efficiency of demand-responsive transit through improved communications technologies or vehicle-routing algorithms is a very active research area. It is important to note that the expansion of bus and rail services often requires more paratransit feeder services.

## E. Terrain-Specialized Systems

While the majority of transit services in the world are provided by bus or rail vehicles, many terrain conditions, such as climbing hills or crossing ravines or bodies of water, preclude their use. Numerous terrain-specialized transit systems are used for these situations.

### *1. Cable Cars*

Invented and built in San Francisco, the cable car was actually the first mechanized mode of urban transportation not using animal or human traction. Cable cars were used in a number of cities until more efficient and faster electric streetcars replaced them everywhere except in San Francisco, where terrain and tradition supported this mode.

A cable car is an unpowered rail vehicle that an operator (gripman) drives by pulling or releasing a special lever that grips the cable that is continuously moving in an underground conduit in the center of the track at a constant speed of 9.3 mph (15 km/hr). Braking to a stop is achieved by releasing the grip and using friction brakes on the wheels and rails. Three stationary motors provide power to the continuous cables of the three lines in San Francisco. The total network in the city is 5.1 miles (8.3 km) with longest line length being 2.1 miles (3.4 km). There are lines operating on gradients of up to 21.3 percent. The service carried 7.4 million trips in 2014. [APTA, 2014a] While cable cars use considerable energy on cable friction, their principle of using the same cable for pulling as well as for braking cars in their steady downhill travel results in lower energy consumption than conventional vehicles, which waste energy during downgrade braking.

### *2. Cog Railways*

The practical limit of track gradients for standard rail technology is about 10 percent. To provide rail service on alignments with higher grades, cog railways are often used. These systems utilize conventional steel rails and steel wheels to provide guidance for the vehicle. The traction for the system is provided through a powered, geared wheel in the center of the axle that is aligned with a linear vertical gear laid in the center of the track. Initially, cog railways employed steam engines (still used on the tourist Mount Washington Railway in New Hampshire); now cog rail systems are electrified.

There are no cog railroads used for urban transit in North America, but such lines do exist in several cities overseas, such as Stuttgart, Germany; Lyon, France, and on a number of urban and rural lines in Switzerland.

### *3. Funicular Railways*

Also known as *inclined plane* or *incline*, funicular is the most commonly used technology for very steep transit lines. This technology involves two rail cars (or short trains) with body floors tilted in relation to the rails to be approximately horizontal on the steeply tilted track. They are attached to the two ends of a single cable, which runs along rollers placed in the centers of each track. Thus, both cars move and stop simultaneously. The motor, located in the upper terminal building, provides power to overcome rolling resistance of the cars and cable, as well as the difference in gravity force between the two cars, which depends on their passenger loadings.

Funiculars can be used to traverse grades from 10 percent to 100 percent (45°angle) or even greater, becoming similar to a balanced elevator. While vertical curves in the line alignments for funiculars can be sharp, concave curves are limited to very large radii to avoid lifting of the traction cable under tension causing slippage from the rollers.

Funicular vehicle capacities usually range from 20 to 50 persons. Five funiculars are in operation in the United States: two in Pittsburgh (which at one time had 17); one each in the cities of Johnstown, Pennsylvania; Dubuque, Iowa; and Chattanooga, Tennessee. Pittsburgh's Monongahela line is the oldest in North America, dating back to 1870. The 636-ft (194-m) line traverses a 58-percent grade. In 2014, the system averaged 3,000 daily boardings, making it the most heavily used funicular in North America. [APTA, 2014a]

Outside of the United States, funiculars are operated in many cities, including Hong Kong; Istanbul (one opened in 1870, another in 2006); Haifa, Israel (rubber-tired short trains); Santiago, Chile; Wellington, New Zealand; and Switzerland (more than 50). Naples, Italy, has four funiculars between large sections of its center city located at different elevations. The largest of them, the 4,167-ft (1,270-m) Centrale Line negotiating a 558-ft (170-m) elevation difference, has three-car trains with a total capacity of 450 persons and provides a maximum capacity of 5,400 persons/hr.

A review of the basic components and operating characteristics of the three rail modes for steep alignments—cable cars, cog railways, and funiculars—is shown in Table 12-9.

### *4. Aerial Tramways*

Aerial tramways consist of unpowered vehicles suspended from a cable powered, similarly to funiculars, by a single electric motor at one terminal. They are most often used to traverse steep grades or to provide transport over deep ravines or bodies of water. Three systems are used in the United States. The first, in New York City, connects Manhattan to Roosevelt Island, located in the East River. The vehicle carries 125 persons traveling at an average speed of 15.5 mph (25 km/hr). The line is about 3,084 ft (940 m) long and rises 131 ft (40 m) above the water level. In 2013, this line carried 2,637,000 passengers. The second system is in Mountain Village, Colorado, and the third system is in Portland, Oregon. While the Roosevelt Island tramway serves as a transit line, many applications of this technology are used exclusively for tourist purposes, as is the case with the lines to Sugarloaf Mountain in Rio de Janeiro, Brazil; Avila in Caracas, Venezuela; and Table Mountain in Cape Town, South Africa.

**Table 12-9. Basic Components and Operating Characteristics of Rail Terrain-Specific Modes**

| Technology | Typical (maximum) Grades (%) | Speeds (mph)/(kph) | Example Cities |
|---|---|---|---|
| Cable car | 20 (20) | 9.3/15 | San Francisco |
| Cog railway | 20 (50) | 15.5/25 | Stuttgart, Lyon |
| Funicular | 50-60 (122) | 22.4/36 | Pittsburgh, Dubuque, (IA), Swiss cities |

Source: Vuchic, 2007

Another modern innovation complementing the steep topographical niche once served by funicular railways and aerial trams is the use of outdoor escalators. Medellin, Columbia is perhaps the most famous example of this technology where a network of covered escalators and landings provides transportation access for a hilly and economically disadvantaged area of the city.

## F. Waterborne Transit

Ferryboats are used to provide urban public transportation services across water bodies. They can be classified in three ways:

- *Type of vessels:* Mono-hulls, catamarans (dual-hull), and hydrofoils.
- *Type of service:* Crossing water bodies, such as rivers, bays, or lakes, and transit lines connecting two or more points along a river or shore. The latter are usually much longer than the former.
- *Type of market:* Water taxis, passenger ferries, and auto ferries.

Nearly all ferryboats are powered by diesel motors, including direct diesel propulsion, diesel electric, and diesel-waterjet. Vessel sizes vary from 49-ft (15-m) long water taxis with a capacity of 50 passengers to the 459-ft (140-m) long ferryboats in Seattle, which carry up to 2,500 passengers and 280 automobiles. New York's Staten Island Ferry has a capacity of 6,000 passengers (no vehicles).

Ferries may be uni- or bidirectional with the vast majority being unidirectional boats. Bidirectional boats are usually designed for shuttle services across the water, where short turnaround times are important for high line capacity. The best example of such service and specialized design of the boats, terminals and operations is the Burrard Inlet Ferry, called SeaBus, in Vancouver, British Columbia. These boats are bidirectional and have six double doors on each side, allowing simultaneous alighting and boarding of passengers separately on the two sides so that terminal times amount to only a few minutes. At both ends, the terminals are major intermodal transit hubs. The terminal on the north has many terminating bus lines. On the south side, SeaBus has transfers to SkyTrain, regional rail, and many bus and trolleybus lines. At the other extreme are large ferry boats that carry passengers and automobiles, requiring much longer maneuvering in docking and terminal times for unloading and loading passengers and vehicles.

Ferries are relatively fuel inefficient due to their size and offer relatively slow service. In the United States, the average speed of ferryboat services is only 8.7 mph (14 km/hr). However, new ferries use water pressure to achieve much higher speeds. These so-called fast ferries can attain speeds of 56 mph (90 km/hr). Ferries are operated in 43 metropolitan areas in North America, with the majority of services offered in New York City (Staten Island Ferry carried 22 million riders in 2014) and in Seattle (23 million riders in 2014). In 2014, ferry service in these two cities handled 57 percent of the U.S. ferry ridership. Major ferry services also operate in Boston, New Orleans, and San Francisco.

A hydrofoil is a surface-effect boat with two supporting floats under the hull. As it accelerates, the hydrofoil rises on the floats, greatly decreasing resistance, so that it can reach speeds as high as 40 to 55 knots (70 to 100 km/hr). Its operating cost is higher than that of conventional boats, but the high speed makes it very attractive on long lines. Hydrofoils are used, for example, in Belgrade, Serbia; Helsinki, Finland; Moscow and St. Petersburg, Russia; and other cities for long transit-type services as well as for their connections with neighboring towns on islands along rivers or seacoasts.

# V. TRANSIT COST STRUCTURES

Costs associated with transit systems are divided into two broad categories. *Capital costs* include investments in the durable system components, such as infrastructure, vehicles, and heavy equipment. *Operating costs* are the recurring costs associated with the provision of service, such as labor, fuel, and vehicle maintenance. The magnitude of expenditures on transit systems, the sources of these funds, and the modes and components to which the funds are allocated are reviewed here.

As with other modes of urban passenger transportation, transit usually relies on government funding for capital and a large portion of operating funds. The amount spent annually on capital investments in the United States has more

than doubled in the last two decades, growing from $5.36 billion in 1992 to more than $23 billion in 2012. This funding has come from many sources. Directly generated funds for capital investments, such as fare revenue, grew by more than 262 percent during that decade, local funding increased by 257 percent, federal funding by 201 percent, and state funding increased by about 103 percent. [APTA, 2014b]

Table 12-10 shows transit capital expenditures (in millions of dollars) for 2012 broken down by category of expenditure and by mode. The two largest categories of expenditure were 34 percent for guideways (acquisition and construction of rights-of-way for exclusive use by rail or bus transit), and 24 percent for rolling stock (revenue transit vehicles—buses or trains). Just over $3.3 billion was spent on stations in 2012. Facilities, which include maintenance, storage and administration buildings and equipment, required $1.37 billion, or 8 percent of total expenditures.

Heavy-rail systems received the greatest amount of funding, just over $5.8 billion. More than $4.9 billion was invested in bus systems, $3.0 billion in commuter rail and $3.4 billion in light-rail systems. Demand-responsive systems, due to their limited infrastructure, and trolleybuses received only 3 percent and 0.1 percent of total capital expenditures, respectively.

Table 12-11 shows the operating costs from 2012 for major transit modes. More than $10.5 billion was spent on the operation of bus systems throughout the United States. Forty-five percent of the total expenditures for transit agencies was for vehicle operations. Of that total, nearly 64 percent went to salaries, wages, and benefits of employees, which underscores the relationship between transit service and local economies. [APTA, 2014b]

Transit agencies monitor operations and maintenance costs very closely given the importance of these costs to agency financial stability. These costs also provide agency planners with a tool that can be used to estimate the costs of expected changes in service. For example, a common practice in the industry is to develop cost models based on allocating all variable costs to key cost drivers, most often revenue hours, revenue miles and number of peak vehicles. The following equation is a typical representation of a model for transit service costs.

$$\text{O\&M Costs} = \$42.67\ (\text{revenue hours}) + \$2.64\ (\text{revenue miles}) + \$108,266\ (\text{peak bus}) \qquad (12.1)$$

The unit cost factors would have been developed by taking all of the variable costs associated with transit service in the agency, allocating them fully or partially to one of the three variables, and then dividing by the total number of revenue hours, revenue miles or peak hour buses provided by the agency. So, for example, assume that the cost allocation process ended up with a total of $43,306,400 of variable costs assigned to the "peak-hour bus" category.

| Table 12-11. Operating Expenditures by Mode for U.S. Systems in 2012 ($Millions) | | | | | | |
|---|---|---|---|---|---|---|
| **Mode** | **Vehicle Operations** | **Vehicle Maintenance** | **Non-Vehicle Maintenance** | **General Admin.** | **Purchased Trans.** | **Total Expenses** |
| Bus | $10,386 | $3,484 | $804 | $2,828 | $1,903 | $19,405 |
| BRT | 28 | 3 | 3 | 3 | 0 | 36 |
| Commuter Bus | 163 | 55 | 14 | 58 | 136 | 426 |

| Transit Vanpool | 38 | 14 | 2 | 62 | 67 | 183 |
| Trolleybus | 123 | 50 | 19 | 42 | 0 | 234 |
| Percent of Total Operating Expenses | 45% | 16% | 10% | 15% | 14% | 100% |

Source: APTA, 2014b, Reproduced with permission of the American Public Transportation Association.

Assume that the agency provides 400 buses during the peak hour. The unit cost factor would thus be $43,306,400 divided by 400 or $108,266 per peak hour bus, as shown in equation 12.1.

The cost model shown in equation 12.1 can be used to estimate the costs of providing new services, simply by estimating how many new revenue hours, revenue miles, and peak buses will be utilized in the new service.

Chapter 5 on transportation finance and funding further describes cost estimation.

## VI. SYSTEM PERFORMANCE AND QUALITY OF SERVICE

The performance/cost characteristics of the modes are important considerations when planning new transit lines. [Bruun, 2007; CUTR, 2009] The first category of characteristics includes quality of service measures, which influence the system's ability to attract potential transit passengers. The second category contains measures of interest to the transit operator, including transit supply and efficiency of operation. Finally, a third set of measures aims to assess transit's positive contributions to the community or city in which it is operated. Table 12-12 presents a list of main

| Table 12-12. Transit System Performance Characteristics Grouped by Three Interested Parties | | |
|---|---|---|
| **Passengers: Quality of Service** | **Transit Operator: Passenger Attraction/Efficiency in Operation** | **Community/City: Attractive and Efficient Transit** |
| Service availability (spatially and temporally) | Area coverage/hours of service | Passenger attraction/service quality |
| Service headway/waiting time | Frequency/headway | Economic/social/environmental impacts |
| In-vehicle travel time/travel speed | Cycle speed | Impacts on city |
| Transfer time | Average fleet age | |
| Reliability | Reliability of operations | |
| Security and safety | Safety and security | |
| Comfort and convenience | Line capacity and load factors | |
| User cost/fare | Investment and operating costs | |

transit system characteristics classified in the three categories. Some of these characteristics are quantitative, while others are qualitative. Their relative weights in evaluation vary with the type of transit line and local conditions.

## A. Quality of Service for Passengers

Passenger attraction to transit is largely determined by the total travel time for a given trip, including: (1) access and egress time to the line or route, (2) wait time at a station or stop, and (3) in-vehicle travel time from origin station/stop to destination station/stop. These travel components are a function of transit network design and system operations. Each is discussed below in terms of the quality of service characteristics presented in Table 12-12.

### *1. Service Availability (Access Trip Time)*

Service availability is the basic precondition for using transit, and directly influences passenger mode choice. It is measured by the proximity of a transit stop or station to a transit user's origin and destination. The willingness of persons to use transit depends not only on distance from the service, but also on the mode of access, type of service offered, and local conditions. Long trips on higher performance modes, such as metro and regional rail, attract people from greater distances than short trips by bus. The total access area from which a transit stop or station attracts passengers is known as the area coverage.

In central cities, access to transit stations is mostly by walking. Considering an acceptable access time of 10 minutes (or 2,400 ft [731 ms] at 4 ft per second [1.2 meters per second]), street transit (bus, trolleybus, or streetcar) systems can usually provide full central area coverage. In medium and large cities with extensive rail transit networks, such as Boston, Munich, Prague, and New York City, the central city also has good coverage by LRT, metro, or regional rail lines, each having acceptable walking access distances ($\frac{1}{2}$ mile to $\frac{3}{4}$ mile (800–1,200 m)). For detailed analyses of transit access times, the lengths of access paths from various points, including indirect walking path routings, may be necessary to compute. While walking access remains the standard for calculating population along transit lines, it should also be recognized that an increasing number of passengers are accessing transit by bicycle as cycling becomes more popular.

Access to stations with park-and-ride facilities on a regional rail line is often by feeder bus or automobiles. Determining area coverage requires a consideration of the direction and speed of travel, natural limits of surrounding areas, and the availability of competing modes, particularly the existence of major highways serving the same market.

The cumulative measure of spatial service availability for a network is computed as the ratio of the sum of all stations' area coverage and the total transit-supportive area of the served region. To be considered transit-supportive, an area must exceed minimum thresholds in employment or residential densities. Typical values are three households per acre or four jobs per acre (7.5 to 10 per hectare).

### *2. Service Availability (Access Environment or the First and Last Mile)*

By the very nature of the trip, those who ride a transit system must get to a transit station or bus stop and then arrive at their ultimate destination after leaving the system at the other end of the trip. This is often considered one of the most challenging aspects of transit service. If the perception is that the access and egress portion of the trip is unsafe or inconvenient, potential riders might avoid taking transit. Providing a safe and effective so-called "first or last mile" portion of a total trip, which is often not the responsibility of the transit agency itself (for example, walking to or from a station, or driving to a park-and-ride lot), can be an important factor in attracting and keeping transit riders.

Perhaps one of the best transit guides for this part of the trip experience comes from the Los Angeles Metropolitan Transportation Authority (MTA) and the Southern California Association of Governments (SCAG). In 2013, both agencies published *First Last Mile Strategic Plan, Path Planning Guidelines*. [Los Angeles Metro and SCAG, 2013] As noted in the plan, "though the streets and infrastructure that comprise the first-last mile fall outside the boundaries of Metro's jurisdiction and control, they remain critical components of an effective public transportation system. Simply put, all Metro riders must contend with the first-last mile challenge, and the easier it is to access the system, the more likely people are to use it." Figure 12-17 shows the concept of developing a system of paths and interconnections to the mainline transit service that the transit agency can improve to provide better service to its customers. Determining the paths (and their condition) that transit users follow in getting to and from transit service is a data-intensive effort. Figure 12-18, for example, shows the typical types of data that Los Angeles Metro collects in planning for the first and last mile.

Providing for a safe and effective environment for this portion of a trip will often require close coordination and collaboration with many different agencies and private partners. In some cases, path requirements could be incorporated into the zoning code for developments locating near transit stops, and/or amenities, and safe passage could be the focus of public/private partnerships.

### *3. Temporal Availability*

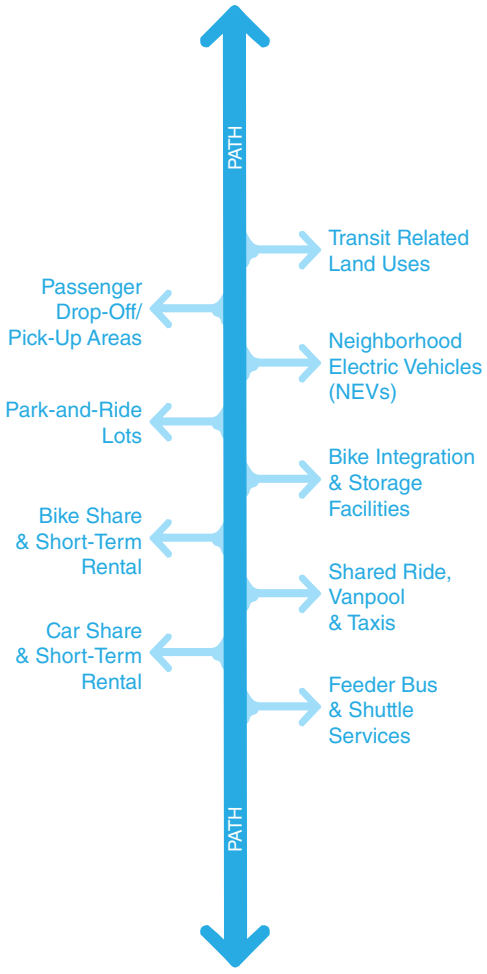
The attractiveness of transit also depends on the availability (or span) of the service through the day. System performance can be measured by the hours of operation. Most transit services operate 16 to 20 hours per day. Large cities commonly have a skeleton network of lines that operate night or owl services between midnight and 5 a.m., thus offering 24-hour service.

### *4. Waiting Time*

The waiting time at a station is a function of service frequency or headway. For short headways, usually below 10 minutes, passenger arrivals tend to be random, so that waiting time is considered to be half of the headway. For headways of 10 minutes or longer, passengers are more likely to plan their arrivals based on the published schedule. If service is reliable, passengers time their arrivals so that their average wait times are nearly as short as for services with short headways. Long headways, however, require the use of schedules and are considerably less convenient. When the trip involves a transfer, the passenger experiences a second wait time, which is often perceived as more onerous than the first wait time.

Recent passenger information systems provide riders with advanced notice from apps on when vehicles are to arrive at designated stops. This new technology application will go a long way to minimize wait time at transit stops.

**Figure 12-17. Los Angeles Metro's First and Last-Mile Focus**



Source: Los Angeles Metro and Southern California Association of Governments, 2013

### *5. In-Vehicle Travel Time*

The amount of time spent in-vehicle is determined by the travel speed of the vehicles and the distances traveled. Buses and other street transit usually have average operating speeds of 7.5 to 12.5 mph (12 to 20 km/hr) in the central city and 9.3 to 15.5 mph (15 to 25 km/hr) in the suburbs. LRT and other semi-rapid transit modes operate at average speeds of 12.4 to 18.6 mph (20 to 30 km/hr). Older metro and long LRT lines (such as in Denver and Baltimore) typically operate at average speeds of 15.5 to 21.8 mph (25 to 35 km/hr), while newer regional metro, such as BART, and regional rail systems are in the average speed range of 18.6 to 37.3 mph (30 to 60 km/hr).

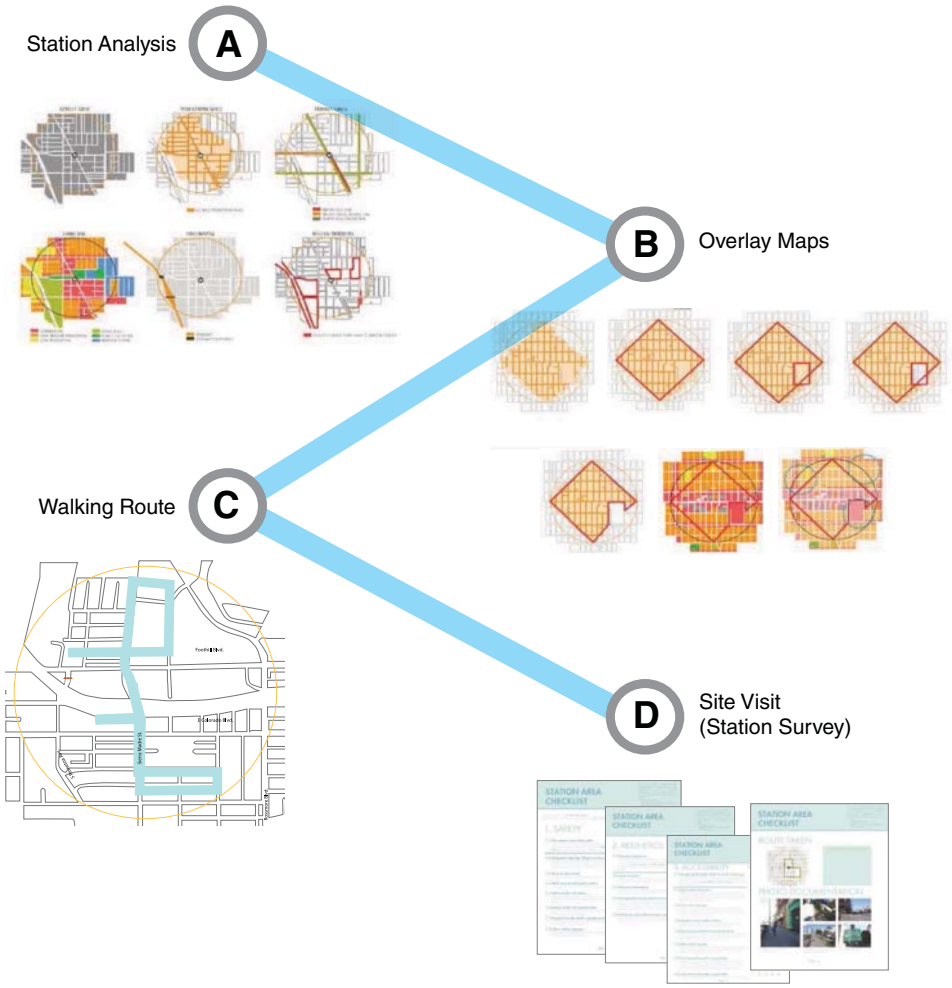
Modal split estimates and comparisons of transit service quality with other modes for individual passenger trips are usually made through computations of the difference or ratio of travel times, depending on the length of the trip being evaluated. Typically, differences are better measures of effectiveness for shorter trips, while ratios are more appropriate when comparing longer trips.

### *6. Reliability*

On-time performance is one of the most important transit service characteristics to riders because unpredictable or frequent delays prevent people with strict schedules from using transit, or when they use it, they must assume considerable flexibility in their travel time. Thus, low service reliability usually results in much longer travel times for passengers, making transit less competitive. Moreover, unreliable service negatively influences a passenger's perception of the system.

Reliability is usually measured by schedule adherence, defined as the percentage of vehicles on a line that arrive within a predetermined limit of their scheduled time, typically 3 to 5 minutes for low-frequency services. Alternatively, system reliability may be measured by the uniformity (or variance) of headways for high frequency services. The coefficient of variation (the ratio of headway standard deviation to mean headway) is also an appropriate measure.

**Figure 12-18. Required Data for Los Angeles Metro's First and Last-Mile Planning**



Source: Los Angeles Metro and Southern California Association of Governments, 2013

Systems commonly place a heavier penalty on running early than running late when it comes to measuring on-time performance since running early or "hot" means a passenger may miss the trip entirely.

Equation 12.2 shows the relationship between mean wait time and mean headway $\overline{h}$ and the coefficient of variation defined as $(\sigma/\overline{h})$. As indicated, the mean waiting time will decrease with the increase of bus service reliability, that is, with a decrease in the standard deviation of headways.

$$E(w) = \frac{\overline{h}}{2}\left[1 + \left(\frac{\sigma}{\overline{h}}\right)^2\right] \tag{12.2}$$

The main factor influencing reliability of transit service is its right-of-way category. Street transit, being subject to traffic conditions, has the lowest reliability, while rapid transit with fully controlled right-of-way has the highest arrival reliability, often in the range of 95 to 99 percent of vehicle arrivals.

### *7. Security and Safety*

Successful transit system plans and designs instill in passengers a sense of well-being while traveling in the system. System safety and security are defined by the frequency of incidents or accidents per million passenger trips or vehicle-km traveled. An important goal of every transit system is to minimize or prevent these events. Following Crime Prevention through Environmental Design (CPTED) principles and integrating exchanges, stations and stops into "people places" that are located adjacent to other uses are important considerations, as is ensuring high quality and safe pedestrian and cycling connections.

### *8. Passenger Comfort and Convenience*

Comfort is influenced by three primary factors: vehicle loading (availability of seats or degree of crowding), vehicle conditions (temperature, cleanliness, and such) and the movement of the vehicle. The most readily quantifiable and most pertinent to systems planning are vehicle loading (that is, the availability of seats), load factor, and the standard used for the maximum number of standing passengers. A measure of vehicle loading is calculated as the number of passengers per spaces offered on the vehicle. Spaces are computed by summing the number of seats and the number of potential standees, which is calculated as the product of the available floor area in the vehicle or car and the number of passengers per area. The area per passenger requirement varies depending on the length of trip and the socially accepted standards in the area where service is offered. Typical design values for major metropolitan areas are in the range of 0.37 to 0.46 persons/$ft^2$ (4 to 5 persons/$m^2$).

Vehicle design, riding comfort, cleanliness, and image are also elements of passenger comfort and attraction. Ease of boarding/alighting, transferring between lines, information systems, and the ability to handle luggage are elements of both comfort and convenience. Accessibility for the disabled and for persons with luggage and baby strollers is required for all new transit systems and vehicles by law in the United States and in many other countries. Integration for bicycles either by exterior racks (common on conventional buses) or inside specially designated rapid transit vehicles is also becoming common.

### *9. User Cost/Fares*

The out-of-pocket expenses incurred for a trip by transit compared to the cost of making the trip by other modes are an important measure of passenger service quality. The transit fare, therefore, represents an element of the transit system affecting passenger satisfaction and decision to use the system. The relative ease of using the fare system, that is, the purchase and utilization of a fare medium during a trip, is also an important consideration for those traveling on transit. For this reason, many transit agencies have instituted open-fare pass systems, that is, an honor system that one has paid a fare, or are using "smart" cards to make the fare transaction as easy as possible. New fare payment options are also being developed (such as with a mobile phone) that will make the fare exchange much easier than in the past.

## B. Measures of Transit System Effectiveness from the Operator's Perspective

A transit operator evaluates system effectiveness from a different perspective than passengers. However, some elements are common, but measured in a different way. The measures of system effectiveness from the operator's perspective usually include:

- *Area Coverage*—The amount of service available to potential customers relating to the access to transit stations and stops.
- *Boardings (Rides) per Vehicle (Platform) Hour*—Total ridership divided by the total hours a bus travels from the time it leaves its base until it returns. This is an indicator of all ridership, including time when a bus is traveling and does not pick up passengers. This measure accounts for the full cost of service and values services that connect many people to many places with many ons and offs all along the route.
- *Cycle Speed*—The average speed to complete a round trip, including running time along the trip and any layover used as a scheduling buffer. Maximizing this speed is a goal for both passengers and the operator, but the operator measures it through cycle speed because this speed directly influences the cost of operations, and thus system efficiency.
- *Farebox Recovery*—The amount of revenue collected from passengers compared to operating cost.
- *Frequency of Service/Headway and Service Span*—The number of departures per time period (frequency) and the time between departures (headway), as well as the overall length of the service day (span). Frequency and headways determine fleet size and the number of vehicles in operation and, therefore—in tandem with service span on each operating day--the number of operators.
- *Investment and Operating Costs*—A system's efficiency as measured by the ratio of performance to costs with respect to items such as various units of work (vehicle-miles operated, speed, and frequency of service, reliability, and such).
- *Line Capacity*—A measure of a transit system's ability to meet the demand for travel with a given quality of service (reliability, comfort, safety, and other factors). Computing capacity is very important in planning

transit lines and, particularly, in comparing and selecting transit modes. To avoid errors caused by different methods of computing capacities for individual lines or modes, several concepts relating to transit line capacity are defined here:

- *Offered capacity* is computed in spaces (seats plus standing spaces) carried past a point along the line, while *utilized capacity* refers to the number of passengers carried. The ratio of utilized to offered capacity is a load factor $\alpha < 1.00$.
- *Practical capacity* is based on actual observations and measurements; it represents passenger volume that is actually carried on a line under real-world conditions. Practical capacity is, therefore, lower than theoretical capacity (see below).
- *Station capacity* is the maximum number of transit vehicles or consists that can pass through a station in a given period of time, typically one hour. The line capacity for a given route is determined by the longest minimum headway at a station (sometimes headways at junctions or street intersections may be more critical than at stations).
- *Theoretical capacity* is the capacity computed based on the minimum headway that can be achieved on a line**.** This calculation assumes ideal operating conditions without any variations in station dwell times (the time a vehicle waits at a stop or station to board or alight passengers), driving regime, and such.
- *Way capacity* is the maximum number of transit vehicles or consists that can pass a point along the line in a period of time. Way capacity measures the transit vehicle throughput that can be achieved on a transit line without stopping at stations. Because the way capacity applies in extremely rare situations (for example, on a highway or rail section where many lines merge and then diverge without stopping), the station capacity usually dictates the line capacity.

- *Passenger Miles per Vehicle (Platform) Mile*—Total miles traveled by all passengers divided by the total miles the bus operates from its base until it returns. This is an indicator of the average distance traveled by all passengers, including the miles when the bus is traveling and the seats are empty. This measure accounts for the full cost of service and efficiency of route design and values services that have riders who travel long distances along the whole route.
- *Platform Service*—The time when a vehicle is in operation away from the base; this includes revenue service, layover/recovery time, and deadhead time.
- *Reliability of Operations*—Usually measured as on-time performance. The system on-time performance is to various extents (depending on rights-of-way) under the control of the operator. Vehicle design, control of operations, and other system elements contribute to a system's reliability, as do a number of scheduling techniques and vehicle maintenance protocols.
- *Revenue Service*—The time when a vehicle is available to the general public and there is an expectation of carrying passengers, including layover/recovery time.
- *Safety and Security*—Monitored primarily by the number or rate of incidents. As with reliability, transit operators can directly influence the systemwide safety and security of systems through appropriate infrastructure (vehicle, guideway, stations, etc.) design, operational practices, and enforcement.
- *Subsidy per Passenger*—Amount of subsidy required to operate service per passenger served.

Loading standards for computation of vehicle capacities vary greatly among cities and transit modes. In most industrialized countries, loading conditions for standees are based on 2.7 $ft^2$/person (4 persons/$m^2$), while in some developing countries a much greater crowding, from 2.2 to 1.8 $ft^2$/person (5 to 6 persons/$m^2$), is used for computations, although the high values in this range cannot be physically achieved in real world conditions.

Offered line capacity is one of the more important measures. Line capacity is computed as the product of the maximum frequency (or minimum headway) and transit consist capacity, which is the product of vehicle capacity and number of cars per consist. The shortest headway is the one that can be operated at the critical point along the line, usually at the station with maximum exchange of passengers. Thus, for example, if the frequency of operations is 6 consists per hour, and a consist includes 3 cars with a car capacity of 100 riders per car, the offered line capacity is $6 \times 3 \times 100$ or 1,800 spaces per hour.

| Table 12-13. Typical Vehicle and Line Capacities of Different Modes | | | | | |
|---|---|---|---|---|---|
| **Mode** | **Consist Size (veh/consist)** | **Vehicle Capacity, $C_v$, (sps/veh)** | **Min. Headway $h_{min}$ (secs)** | **Max. Frequency $f_{max}$ (buses or consists/hr)** | **Max Offered Line Capacity $C$ (sps/hour)** |
| Std bus, single stops | 1 | 75 | 50–70 | 51–72 | 3,800–5,400 |
| Articulated bus, single stops | 1 | 120 | 60–80 | 45–60 | 5,400–7,200 |
| 50% standard, 50% articulated bus, 4 lanes and multiple berthing | 1 | 75–120 | 20–40 | 90–180 | 8,800–17,500 |
| Streetcar, ROW C, double stops | 2 | 180 | 150 (2 signal cycles) | 24 | 8,640 |
| Bus rapid transit, North America | 1 | 120 | 60 | 60 | 7,200 |
| Bus rapid transit, developing countries | 1 | 180 | 30 | 120 | 21,600 |
| Light rail transit, ROW B, single track, double stops | 2–3 | 180 | 240 (3 signal cycles) | 15 | 5,400–8,100 |
| AGT, rubber-tired, Siemens, Bombardier | 2 | 100 | 60–90 | 40–60 | 8,000–12,000 |
| AGT – rail | 6 | 100 | 75–100 | 36–48 | 21,600–28,800 |
| Rapid transit with 8 cars | 8 | 180 | 90–100 | 36–40 | 51,800–57,600 |
| Rapid transit with 10 cars | 10 | 240 | 120–150 | 24–30 | 67,200–72,000 |
| Regional rail – diesel | 10 | 200 | 180–240 | 15–20 | 30,000–40,000 |
| Regional rail – electric | 10 | 200 | 120–180 | 20–30 | 40,000–60,000 |

The minimum headway depends on the length of the consist, the speed of the consist, and the minimum spacing between successive consists, determined by the operating regime. For buses, streetcars, and LRVs that operate on streets under driver control, capacity depends upon the green time per traffic signal cycle available and the dwell times at busy stops (or intersections). Frequencies up to 60 buses per hour can be achieved on a line with exclusive lane and single vehicle stops. When there are multiple berths or where buses can pass each other, 90 to 120 buses per hour have been reported. When a line has two lanes per direction at every stop and buses/trolleybuses can overtake each other, frequencies of up to 180 vehicles/hr can be achieved (Portland, Oregon, and Madison Avenue in New York City).

Rail transit modes running on segregated or exclusive right-of-way, such as LRT and metros, are controlled by signals that usually require headways of at least 90 seconds, so their maximum frequency is 40 consists/hr (in New York City, current operating practices limit headways to at least 2 minutes). Consist capacity on rail systems, particularly metros and regional rail, is much greater than that of buses (1,000 to 3,000 spaces vs. 80 to 160 spaces), so that line capacities of rail systems are typically greater than those of AGT and street transit (buses, BRT, and LRT).

Table 12-13 shows practical or operational capacities in vehicles or passengers per hour under conditions typical for North America and other industrialized countries. The reader is referred to Kittelson et al. [2013] for an extensive presentation on how one can estimate transit capacity.

## C. Transit Impacts on Development

Most North American cities have experienced a decentralization of land-use activities that pose challenges for the efficient provision of transit services and attraction of passengers. [Los Angeles Metro, 2012] In response, many metropolitan areas have planned and constructed rail transit systems in relatively low-density areas with the goal of attracting concentrated development in their service areas.

One such example in the United States is New Jersey's River LINE, a $1-billion, 34.5-mile (55.5-km) LRT line, which opened in 2004. The line connects the cities of Trenton and Camden, New Jersey, along an existing rail corridor running parallel to the Delaware River. The system uses a hybrid diesel-electric vehicle, thus avoiding the cost of

electrification. The River LINE was designed to provide commuter service between the two cities, connect the corridor with the city transit systems in Philadelphia, Camden, and Trenton, and to be well integrated with intercity (Amtrak and New Jersey Transit) services in Trenton. More importantly, the system was planned with 20 stations, each of which was intended to act as a location to accommodate residential and commercial growth in southern New Jersey. Development investments have occurred, and ridership has grown steadily now exceeding initial projections.

A similar system is being planned in the Region of Waterloo, Ontario. The region is expected to grow from its current population of approximately 500,000 to 720,000 by 2031. As part of a comprehensive growth management strategy, the region is planning the construction of a transit system operating on right-of-way B along the central corridor. The intention is to intensify urban land uses along the transit line such that the provincial target of accommodating 40 percent of new growth in developed areas can be met.

One of the ways of linking transit investment to development is called transit-oriented development. [Dittmar, 2004] Transit-oriented development (TOD) is the planning and design of medium- or high-density, mixed land uses around a transit node that acts as the center of the development and provides attractive transportation access to the area. The land-use and urban-design practices around the transit node facilitate pedestrian movements between and within the TOD. The goals are to increase choices of travel modes, to decrease the total number and length of automobile trips, enhance nonmotorized access to activities and increase transit ridership. In addition to providing high-quality, high-capacity transit service, successful TODs (and more generally transit supportive land uses) require comprehensive land-use controls and policies. See chapter 3 on land use and urban design for additional discussion on TODs and other policies that can be used to encourage development near transit stations and along transit corridors.

## VII. TRANSIT PLANNING PROCEDURES

Transit planners participate in a variety of different planning studies. This section describes four major types of transit planning: strategic planning, comprehensive operations or service planning, long-range transit planning, and planning for major transit investments.

### A. Strategic Planning

The objective in creating strategic plans is to develop a clear vision of the desired future state of the transit system and its operating agency. [Lawrie, 2005] The analysis involves assessing the agency's internal organization, services offered, and its role in a coordinated transportation network. The strategic process provides an opportunity to engage stakeholders—agency employees, government or political decision makers, local businesses, and the public—in defining and embracing the transit agency's future directions.

The product of the strategic planning process is usually a document that presents the agency's mission or core values along with foreseen challenges (both internal and external) requiring future action by the agency. Perhaps most important, strategic plans establish desired system performance levels for the transit network using measures of effectiveness such as those discussed earlier. Any proposed change to infrastructure, operations, or agency finance is evaluated against its ability to achieve one or more of the stated system goals.

Successfully implementing the strategic plan requires two major actions. First, the strategic plan should be linked to both the operating and the capital budgeting process in the agency to ensure that financial investments are being made that are consistent with the objectives of the plan. Second, a formal tracking mechanism should be in place to determine if the agency is achieving its goals. There should also be a renewal process and timeline to update the plan, such as every five years.

### B. Comprehensive Operations (or Operational) Analysis

When a transit agency decides to examine all of its routes and services at one time in order to determine where best to change the network and individual services to better reflect today's and future transit markets, it conducts what is called a comprehensive operations (or operational) analysis (COA). For example, the COA for Lynx, the transit system

in Orlando, Florida, stated that "the COA will include an analysis of the route network and recommend short-term and long-term modifications including:

- Adjustments to running times, departure times/locations, transfer times, and stop spacing to improve schedule adherence and customer satisfaction.
- Removal of minimally used bus stops and/or consolidation of bus stops.
- Appropriate vehicle type and service characteristics, including fixed- and flex-route, local, limited, and express service.
- Updated service standards based on industry norms as well as LYNX's productivity requirements, as stipulate by the Florida Transit Commission.
- Capital needs, including improvements to passenger facilities.
- Staffing recommendations.
- Implementation phasing." [Central Florida Transportation Authority, 2014]

Figure 12-19 shows a typical COA process that was used for the Santa Clara County Valley Transportation Authority in California. The figure indicates the type of data collected, the roles of both the public and transit agency board members and staff, and the type of outreach that is typically part of a COA effort. Figure 12-20 shows the type of data analysis that typically occurs in a COA, in this case looking at the different market segments and their relationship to the types of services that the transit agency should offer. Key to conducting a successful COA is relating different transit service types to different markets. Table 12-14, for example, shows what was called the tiers of service in the Broward County Transit (Florida) system, defined by the location within the service area and the key markets they serve. In this case, the different tiers were defined as:

- *Network-Based Service:* Network-based, local, fixed-route service that serve as the backbone of the system. Successful network-based service provides convenient connections to rapid and community service. To meet their role in the future network, Broward County Transit's local services examined service frequency increases and the possible introduction of automatic vehicle location (AVL) technologies, increased onsite supervision, and transit signal priority improvements.
- *Rapid Bus Service:* Major transit corridor service with high service frequencies, limited stop spacing, transit signal priority, enhanced passenger stations, and unique branding.

Table 12-14. Service Tiers and Market Groups, Broward County, Florida

| Service Tier Criteria | Demand Intensity | Corridor Type | Network Role | Key Markets |
|---|---|---|---|---|
| Network-based Services | Medium to high ridership per route mile | Major and secondary arterial roads | Provide core network | All-day, multipurpose |
| Rapid bus service | High ridership per route mile | Major arterials and dedicated rights-of-way | Fastest, highest capacity services | High volume, all-day, multipurpose; major destinations |
| Community-based service | Medium to low ridership per route mile | Local and neighborhood | Community-based network connector or local circulation | Market-specific services tailored to individual community needs |
| Commuter Service | High point-to-point demand | Freeways and major arterial roads | Fast, efficient, peak-hour service | Peak-hour commuters |

Source: Broward County Transit. 2010. *Comprehensive Operations Analysis, 6. Service Framework*. Accessed March 2, 2016, from http://www.broward.org/BCT/COA/Documents/COAServiceFramework.pdf

- *Community-Based Service:* Local circulation catering to specific market needs and connections to network-based services. In some cases, areas now served by BCT's fixed routes may be more suited to flexible options.
- *Commuter Service:* Point-to-point, longer-distance express services that do not make local stops. Geared toward commuters, they provide service to major employment districts in peak hours from hubs such as park and ride lots.

Clearly, service markets will differ by size of service area and type of metropolitan area. [Ceder, 2001] Much of the early analysis in a typical COA will identify what types of service types or tiers make sense for the types of markets that are part of the service district today and those that are evolving to become more important in the future.

Some of the strategies that transit agencies have used to improve the productivity of transit service and, in particular, increase the average speed of service are found in Table 12-15. This table comes from a Transit Cooperative Research Program project that surveyed transit agencies in North America. [Boyle, 2013]

| Table 12-15. Strategies to Increase Average Speed of Buses | | |
|---|---|---|
| **Strategy** | **Number of Agencies Responding** | **Percent of Agencies Responding** |
| **Route-related Actions** | | |
| Streamline routes | 39 | 91% |
| Introduce limited stop service | 18 | 42% |
| Introduce BRT service | 10 | 23% |
| Other | 10 | 23% |
| Total | 43 | 100% |
| **Stop-related Actions** | | |
| Change in stop spacing | 30 | 79% |
| Change bus stop location | 18 | 47% |
| Change bus stop design or length | 13 | 34% |
| Level boarding at transit centers | 8 | 21% |
| Other | 5 | 13% |
| Total | 38 | 100% |
| **Vehicle-related Actions** | | |
| Introduce/increase use of low-floor buses | 33 | 89% |
| Switch from lifts to ramps for wheelchair access | 29 | 78% |
| Introduce/increase use of different size vehicles | 22 | 60% |
| Introduce vehicles with better performance | 17 | 46% |
| Change seating configuration | 8 | 22% |
| Allow bicycle storage inside the bus | 7 | 19% |
| Change door configuration | 4 | 11% |
| Other | 3 | 8% |
| Total | 37 | 100% |
| **External Policy Changes** | | |
| Signal priority or queue jump lanes | 22 | 69% |
| Signal timing | 14 | 44% |
| Bus-only lanes on arterial streets | 13 | 41% |
| Yield-to-bus laws | 13 | 41% |
| Turn restrictions | 9 | 28% |
| Parking restrictions | 8 | 25% |
| Other | 6 | 19% |
| Total | 32 | 100% |
| **Internal Policy Changes** | | |
| Pricing to encourage use of prepaid fare media | 22 | 76% |
| Off-board fare collection | 8 | 28% |
| All door boarding | 7 | 24% |
| Changes in hold policies at transit centers | 7 | 24% |
| Free fares or introduction/discontinuation of fare free zones | 6 | 21% |
| Changes in bus door practices | 3 | 10% |
| Other | 3 | 10% |
| Total | 29 | 100% |

It is beyond the scope of this chapter to go into great detail on COA analyses. Interested readers are directed to the following COA documents that provide good examples of what a COA consists of:

- Indianapolis, Indiana: http://www.indygo.net/pages/transit-planning.
- Rhode Island Public Transit Authority: http://www.ripta.com/coa-project-documents.
- San Joaquin (California) Regional Transit District: http://sanjoaquinrtd.com/coa.

## C. Long-Range Transit Planning

A long-range transit planning study can focus solely on transit investments (and thus likely undertaken by a transit agency), or it can be part of the broader metropolitan transportation planning process (and thus likely undertaken by a metropolitan planning agency). [Sound Transit, 2012; Miami-Dade County, 2013; Central Florida Regional Transportation Authority, 2013] The long-range transit planning process is shown in Figure 12-21. The first steps compare existing and future operating conditions using quantitative/qualitative measures of effectiveness relating to the system's goals and objectives (based on the agency's strategic plan). Here, the goals of transportation and land-use plans are further expanded, examining such things as accessibility, mobility, positive environmental characteristics, and the character of the area served. The necessary data to perform project evaluation include population (often evaluated at the household level to include a disaggregate estimate of age), employment (number of jobs of different classifications), and other social characteristics like income levels and auto ownership. Current land-use patterns are documented, usually by measuring densities and classification of land-use types (agricultural, commercial, retail, and such). Finally, data related to the current travel demand are compiled. These data include travel volumes between origin-destination pairs throughout the study region, observations of link (streets or freeway sections) volumes measured in average annual daily traffic (AADT) or design hour volumes (DHV), and finally ridership on the existing transit system at the route or line level.

To assess future transit services, models are used based on the relationships between system components and system performance (see chapter 6 on travel demand models). The most commonly used transportation planning model is the four-step model, which quantifies system performance by sequentially predicting trip generation, trip distribution, mode split and trip assignment. However, some have argued that this sequential process is inherently weak in its treatment of transit. For example, the mode split decision is made in Step 3, prior to quantifying the performance of the highway network. Essentially, in the first iteration, the mode choice is made based on a comparison of transit costs and uncongested highway travel. To overcome this weakness, a feedback method is used, which iteratively considers

**Figure 12-21. Long-Range Transit Planning Process**

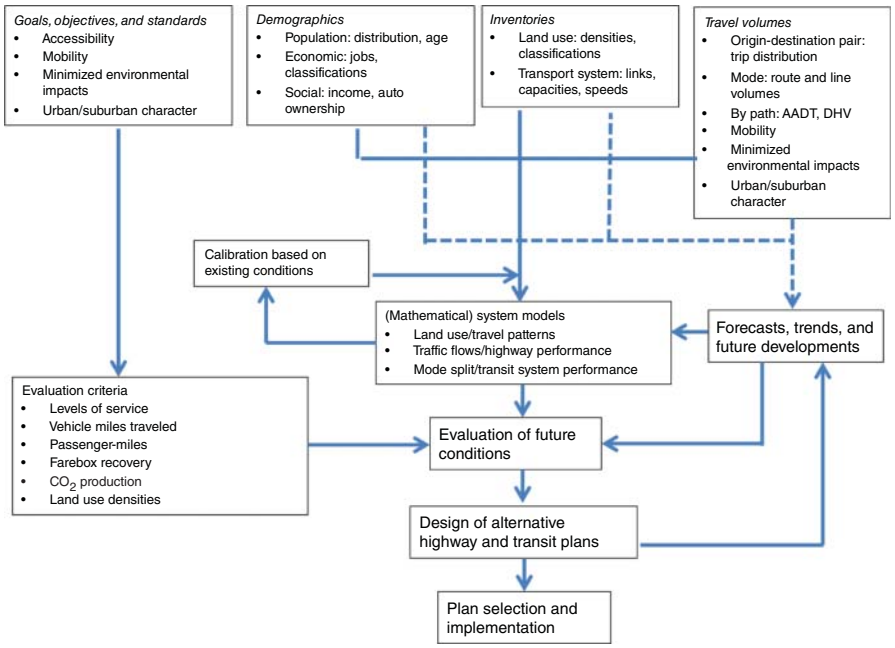

**Figure 12-22. Website from King County Transit, Washington Seeking Public Input on Long-range Transit Plan**

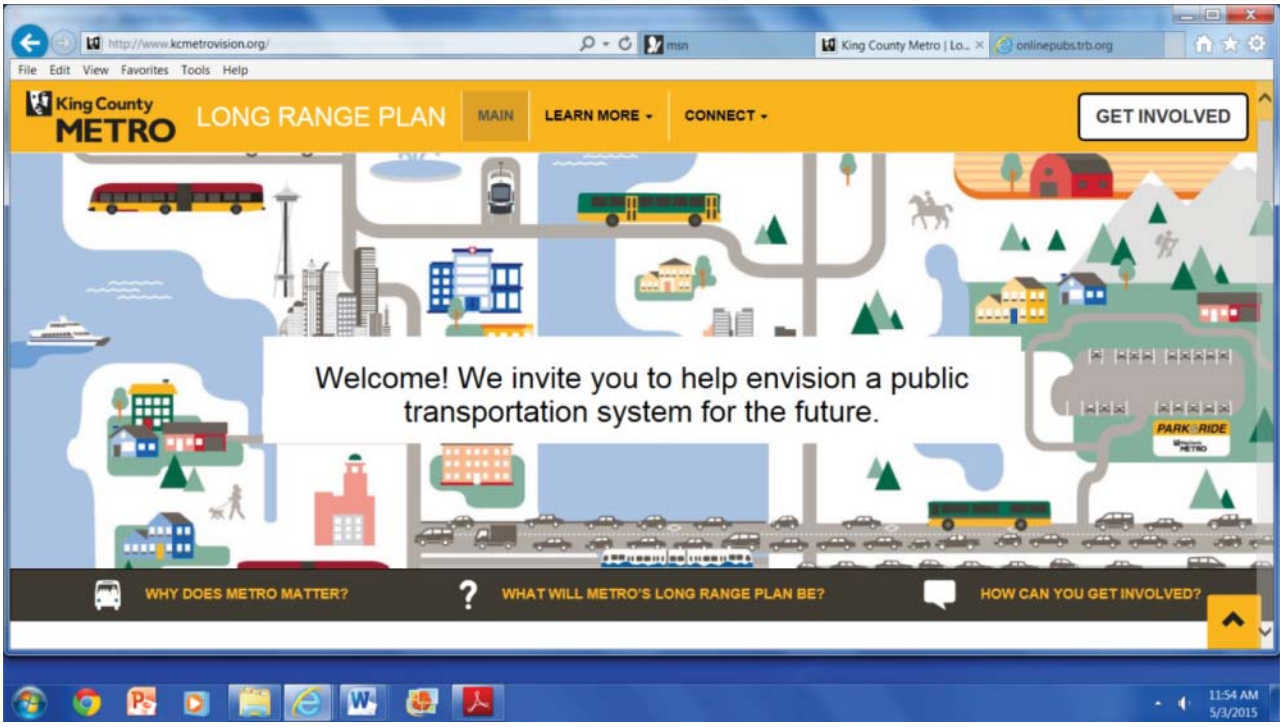


Source: King County Metro, Website, Accessed Feb. 2, 2016, from http://www.kcmetrovision.org.

network conditions in the mode choice step. The problem is iteratively solved until equilibrium is reached among modal flows. As noted in chapter 6, activity-based models are now being developed to overcome some of the model deficiencies with respect to transit planning.

Although not represented in Figure 12-21, public engagement occurs throughout the process. When federal funds are considered for construction of the project, such public participation is a requirement of the planning process. Figure 12-22 shows an image from the King County Metro, Washington, website for its long-range transit planning process. Through such efforts, those who ride the system and those who pay for it through taxes can provide input into the planning process.

### *1. Planning for Major Transit Investments*

In the United States, the FTA has established a structured process that must be followed to receive federal funding for major transit investments. Once referred to as the alternatives analysis (AA) process, the current procedures have been simplified through federal legislation. Transit planners should always check with the FTA to determine the latest requirements for this type of planning. Although no longer called the alternatives analysis process, the FTA definition of alternatives analysis is still a useful explanation of this type of planning. Alternatives analysis can be viewed as a planning process that:

- Includes an assessment of a wide range of public transportation or multimodal alternatives, which will address transportation problems within a corridor or subarea.
- Provides ample information to enable the Secretary to make the findings of project justification and local financial commitment.
- Supports the selection of a locally preferred alternative.
- Enables the local metropolitan planning organization to adopt the locally preferred alternative as part of the long-range transportation plan. [FTA, 2011]

The 2012 federal transportation law, Moving Ahead for Progress in the 21st (MAP-21), eliminated the alternatives analysis requirement and required instead a review of alternatives during the metropolitan planning and environmental review processes. A new project development phase was defined where the environmental review process is

| Table 12-16. Federal Transit Administration Evaluation Criteria for New Starts Transit Projects | | |
|---|---|---|
| **Category** | **Stage of Decision Making** | **Evaluation Measure** |
| Mobility | All | Estimated Annual Trips (Trips by Non-Transit- Dependent Persons plus Trips by Transit Dependent Persons multiplied by 2). |
| Economic Development | Engineering and Federal Grant Decision | Degree to which growth management and land conservation policies have been implemented. |
| | Engineering and Federal Grant Decision | Degree to which conceptual plans for the corridor and station areas have been developed. |
| | Federal Grant Decision | Degree to which local jurisdictions have adopted zoning changes that strongly support a major transit investment in most or all transit station areas. |
| | Engineering | Degree to which a conceptual planning process is underway to recommend zoning changes for station areas. |
| | Engineering and Federal Grant Decision | Degree to which transit agencies and/or regional agencies are working proactively with local jurisdictions, developers, and the public to promote transit-supportive planning and station area development. |
| | Federal Grant Decision | Degree to which a significant number of development proposals are being received for transit-supportive housing and employment in station areas. |
| | Engineering | Degree to which transit-supportive housing and employment development is occurring in the corridor. |
| | Engineering and Federal Grant Decision | Degree to which a significant amount of land in station areas is available for new development or redevelopment at transit-supportive densities. |
| | Federal Grant Decision | Degree to which comprehensive affordable housing plans have been developed and are being implemented that identify and address the current and prospective housing affordability needs along the corridor. |
| | Engineering | Degree to which plans and policies are in place in most of the jurisdictions covered by the project corridor that identify and address the current and prospective housing affordability needs along the corridor. |
| Environmental Benefits | Engineering and Federal Grant Decision | Change in total air quality criteria pollutants—carbon monoxide (CO), mono-nitrogen oxides ($NO_x$), particulate matter (PM2.5), and volatile organic compounds (VOC). |
| | | Change in energy use. |
| | | Change in greenhouse gas emissions. |
| | | Change in safety. |
| Cost Effectiveness | Engineering and Federal Grant Decision | Annualized capital and operating cost per trip. |
| Land Use | Engineering and Federal Grant Decision | Employment served by system in station areas. |
| | | Average population density (persons/square mile) in station areas. |
| | | Central business district (CBD) typical parking cost per day. |
| | | CBD parking spaces per employee. |
| | | Proportion of legally binding affordability restricted housing in the project corridor compared to the proportion in the counties through which the project travels. |
| Congestion Relief | Engineering and Federal Grant Decision | Not yet published as of the date of this handbook. |
| Finances | Engineering and Federal Grant Decision | Current capital and operating condition (25% of local financial commitment rating). |
| | | Commitment of capital and operating funds (25% of local financial commitment rating). |
| | | Reasonableness of capital and operating cost estimates and planning assumptions/capital funding capacity (50% of local financial commitment rating). |

Source: FTA, 2013

to be completed, and what was preliminary engineering and final design was consolidated into an engineering step. [FTA, 2015] In addition, MAP-21 amended the criteria that FTA would use to rate individual transit investment projects. The new criteria, shown in Table 12-16, are part of the information that needs to be produced by the transit project development process. As can be seen, in many cases the criteria are different depending on which stage of the project development process one is at. The approach adopted by FTA is to use threshold values of achievement to assign a "high," "medium-high," "medium," "low-medium," or "low" rating to a particular criterion. Readers are referred to [FTA, 2013] for more detailed information on these criteria.

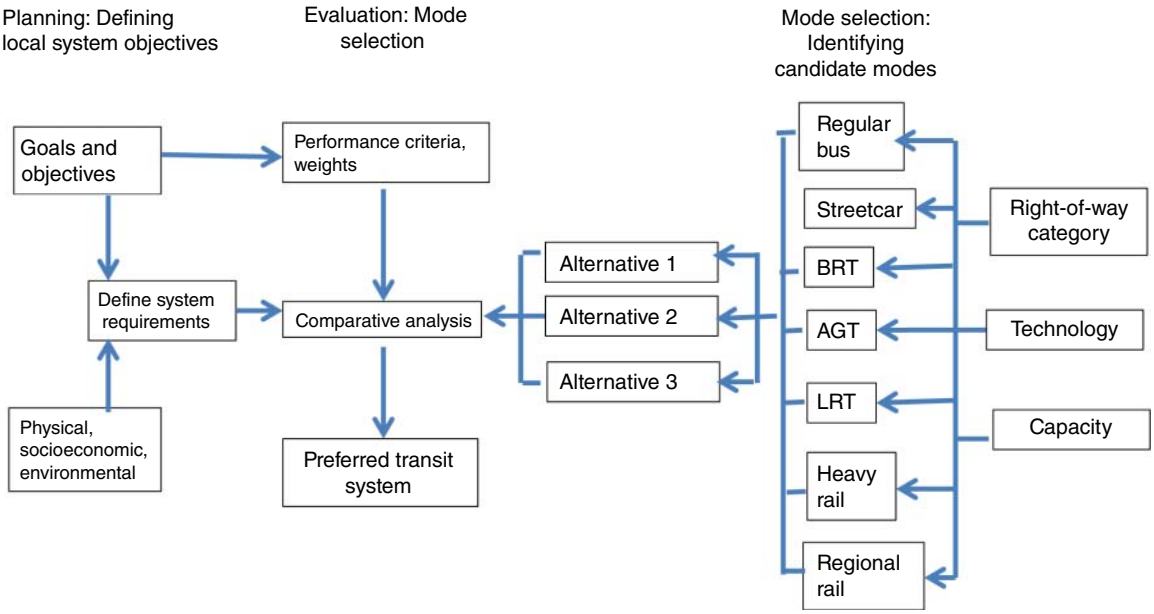
As noted in the definition of the project development process, the evaluation of transit alternatives is strongly linked to the metropolitan transportation planning process and the environmental review process. Readers are referred to chapter 16 on metropolitan transportation planning and chapter 4 on environment and the community for additional information on both processes. In addition, the FTA website http://www.fta.dot.gov/12304.html provides the latest information on analysis and evaluation guidance for major investment planning.

## D. Mode and Technology Selection

The characteristics of the alternative modes being considered will have an important influence on expected ridership demand. System performance includes travel speeds, reliability, comfort, and safety, but in most cases ridership forecasting models use travel speed (and thus travel time) as the primary modal characteristic for modeling purposes. As described earlier, transit modes are defined by the right-of-way (ROW) on which they operate, the technology, and the type of operation. Through the mode selection procedure, the optimal combination of ROW and technology is selected to provide the desired service levels (based on the broader system goals) while considering the investment and operating costs. It is logical when selecting technology characteristics to choose a system with a performance package that is consistent with the ROW on which the transit line operates. Greater investments, resulting in higher performance, can be made in three basic technological characteristics—vehicle guidance, propulsion system, and consist control—as the ROW is upgraded from street running to partial and full right-of-way control.

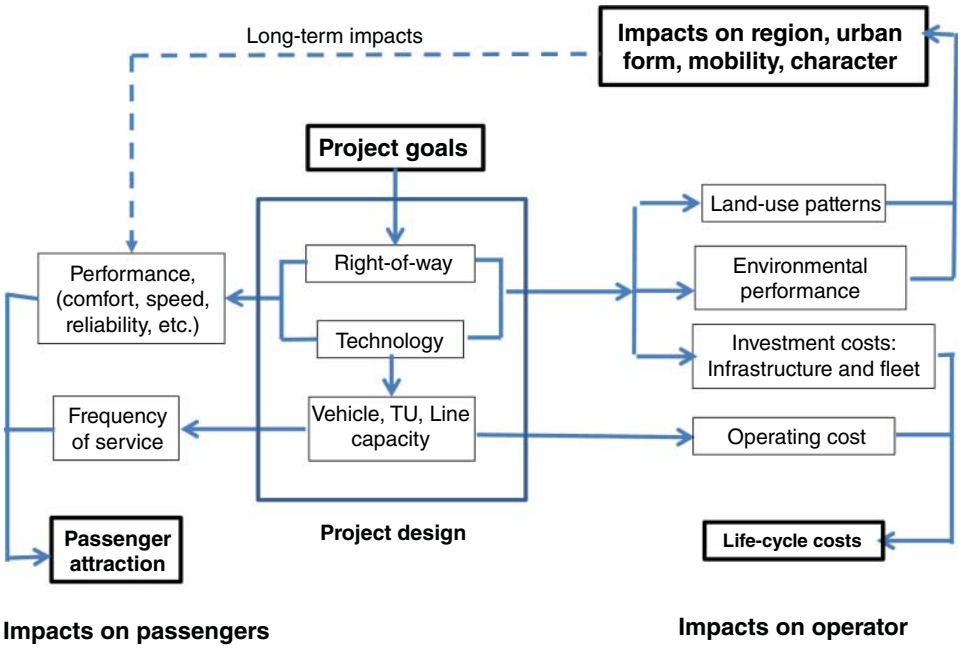
The framework for comparing and selecting a transit mode is shown in Figure 12-23. The first step is to define the goals and objectives of the system subject to the local physical, socioeconomic, and environmental conditions. These goals are translated to specific system requirements, which act as inputs to the comparative analysis. At the same time, candidate modes are selected from the family of modes for the range of defined system requirements based on combinations of ROW, technology, system capacities, and costs.

**Figure 12-23. Transit Mode Selection Procedure**



Source: Based on Vuchic, 2005

**Figure 12-24. Recommended Mode Selection Considerations, Including Regional Impacts**



The performance characteristics of candidate modes are then compared to the system requirements. A suggested approach for this comparison is shown in Figure 12-24. As the ability of modes to attract passengers depends on the ROW category, frequency of service offered, and other features of candidate modes, these must be checked against the estimated ridership demand. A feedback loop into the earlier steps of the modeling process is used to ensure an equilibrium state.

Finally, the mode comparison must evaluate the environmental and land-use impacts of the chosen ROW and technology. In some cases, these impacts may carry considerable weight because, in the long term, greater investments in transit infrastructure can change both the character and the development patterns of a city, which ultimately results in overall greater transit ridership and urban livability.

## VIII. PLANNING FOR PASSENGER STATIONS[2]

The locations where users access transit services, transfer among routes, or interchange with another mode are among the most important components of the system. Examples include: (1) a corner bus stop where a passenger walks from home and boards a local bus, (2) an exchange where passengers can transfer between transit modes, such as between buses or from bus to rail, (3) an express stop on a rail rapid transit line where passengers can transfer between local and express trains, (4) a major international airport where passengers can transfer from domestic and international flights to express and local bus or rail service, and (5) a terminus point at the end of the line where layover space for vehicles and washroom facilities for drivers may be required. These exchanges, stations, or stops can be key bottlenecks in a typical trip, and are often perceived by the user as a negative characteristic of the system.

For more complex facilities, certain features become necessary because of financial or institutional requirements, the number of alternatives to select from, or the sheer amount of travel to accommodate. Because the cost of building and operating a station must be covered somehow, the methods of collecting fares, parking fees, rental fees, or tariffs are an important design and operations consideration. The expected passenger flow through a station is a key study item when estimating its market potential (forecasted traffic).

[2]The sections on transit stations draws from the Terminals chapter in the previous edition of the handbook written by Leon Goodman, P.E., PTOE, Traffic and Transportation Consultant, New York, and Jerome M. Lutin, P.E., New Jersey Transit Corporation. Changes made are the responsibility of the editor.

## A. Vision for a Passenger Station

The first step in the planning process for larger stations is establishing a vision for the station, that is, what role is it intended to play in the transportation system and in the community? A good example of a vision comes from the California High Speed Rail Authority, which developed such a vision as part of the planning process for high-speed trains in California. [California High-Speed Rail Authority, 2011] The planning process linked the development of high-speed rail stations with urban design considerations for the surrounding communities. The following observations were made:

- *The Role of the Station*: Consider the role the station will play in the community and how the physical size of the station will affect that role. Is the station a dominant feature of the landscape? Architecturally, should it blend in with surrounding building aesthetics? Will the station serve as a new "front door" to the community? What does that imply for the organization of land use, the design of streets, and public spaces?
- *New Transportation Hub:* Like a small airport without runways, the California High-Speed Train (CAHST) stations will need to accommodate large numbers of intermodal connections to buses, shuttles, taxis, cars, bicycles, and pedestrians. Development-oriented transit and TOD, (as discussed in chapter 3), can help address the issue of how the station is connected to the community.
- *Multimodal Nature of the Station:* Consider how people will be moving in and out of the station, and how the station will be integrated with other modes of transportation. How will people access cars, transit, bikes, and the street network? How will wayfinding work?
- *The Location of Parking*: It will be important to locate and configure station parking so that it does not create a barrier between the community and the station. For the high-speed rail service, all parking identified as necessary for the project at market rates. This should provide sufficient financial incentive to build needed parking facilities for high-speed train users, including structured parking.
- *Community Growth*: With supportive planning, the accessibility provided by a high-speed rail station can be transformative for some communities. Each community needs to carefully consider how to leverage the coming of high-speed rail and how it fits into their vision for the future. Preparation of new downtown plans or specific plans for the district surrounding the station will be important next steps for most communities. [California High-Speed Rail Authority, 2011]

The Authority also identified the following key lessons from intermodal transit stations in other countries. [California High-Speed Rail Authority. 2011]

- *Have a Vision*: High-speed rail must relate to the activity patterns and developments in the communities it serves and complement the community's vision. Planning for high-speed rail cannot be done in a vacuum. Local planning must consider how the location of the line fits into the vision for the city as a whole. In some cases, the design of the infrastructure and services is modified to better fit with the community, enhancing the economic vitality and quality of life for those living near the station.
- *Focus on Business and Service-Oriented Travel (in Other Words, Know Your Market)*: Business professionals constitute a large percentage of the high-speed rail travel market. In addition, experience has shown that other major markets include leisure and tourist travelers, family travel and governmental services. Station design and functions should provide the ancillary services that will support these types of travel markets.
- *Connect the Station*: The station environment should be pedestrian-oriented with connections, both visual and physical, to and from the station. Local transit should be well-connected with the station, balanced by accommodations for the car. Streets closest to the station should promote pedestrian use.
- *One Size Station Does Not Fit All*: Stations can serve multiple functions in cities. They can be focal points for neighborhood activity, or they can blend into the background. By paying attention to detail, stations can provide an opportunity for "rebranding" a community.
- *Stations Can Be Destinations*: The area immediately around a station, or the station itself, can serve as destinations of considerable note. They can provide new services or be an architectural landmark. The new World Trade Center Transportation Hub in lower Manhattan, New York is an iconic station that along with the nearby 9/11 Memorial is a major tourist attraction. Integration into the city's community vision and other land uses is important so that the station complements, not competes, with other destinations in the city.

- *It Can Change Your City*: High-speed rail represents an opportunity for some of the smaller cities in the corridor to become more important satellite cities to the major hub. High-speed rail provides the opportunity to tap into new economic development strategies, but they will only succeed if careful planning occurs and thought is given to what the market can support.
- *Back to the Future*: Rail stations that are being praised around the world are those that have unique architectural attributes. They return to the "romance of rail's past" with grand entrances and a sense of celebration. Because of the locations in the city center, high-speed rail stations essentially serve as gateways to the city.
- *Political Leadership Required*: Strong political leadership will help move the local vision forward. A vision needs a political champion who will help move the vision forward and work to overcome hurdles that get in the way. [California High-Speed Rail Authority, 2011]

## B. Market Research (Demand Estimation)

Many analysis techniques can be used to estimate the demand for transit stations, in particular the number of riders transferring at the station. Demand estimation can be based on surveys of existing usage, mathematical forecasting models (and the associated computer software), trend analysis, future market analysis, and planning judgment. The analyses will vary considerably on whether the planner is dealing with modifying or expanding an existing facility or developing an entirely new terminal or station.

Typically, forecasting demand for terminals follows three steps:

1) Estimate the overall travel magnitude and growth for the market of interest.
2) Determine the market share that can be expected to be attracted to the facility as a fraction of total demand.
3) Estimate the peak period demand, typically expressed as a rate of flow for passengers and vehicles per unit of time.

Demand modeling is described in greater detail in other chapters and in the technical literature (see chapter 6 on travel demand modeling, chapter 11 on parking, and chapter 16 on metropolitan transportation planning). In each case, the following demand variables must be projected for both short- and the long-term forecast periods:

- Overall loading (such as total passengers, consists, and vehicles).
- Type of loadings (such as cars, trucks, buses, commuters, shoppers, and frequent vs. occasional users).
- Time-period volumes (such as annual, daily, peak period, and peak hour).
- Reliability and predictability of flows.

Such estimates should be based on current-use data usually obtained from up-to-date surveys or from data collected from automated passenger count systems. The planner needs to not only assess present patterns, but also market trends including future industry and economic developments, land-use changes, transportation technology, fuel prices, socioeconomic characteristics of the population, and so on.

Note that the FTA has developed a simplified travel demand model that can be used to estimate fixed guideway transit trips (it does not estimate local bus ridership). Called Simplified Trips-on-Project Software (STOPS), the software package applies a set of travel models to predict detailed transit travel patterns for the No-build and Build scenarios. [FTA, 2013a]

Finally, needs estimates should be updated periodically. This should not only include updated ridership counts, but also a new examination of the market forces that are likely to change future transit markets (for example, the impact of the millennial generation on transit ridership). This can be done as part of a comprehensive operations analysis as described earlier, or as part of a region's long-range transportation planning process. In today's fast-changing world, transit agencies need to keep abreast of the changes in society that will affect their business model.

## C. Performance Analysis Techniques

After the overall demand for a facility has been established it is important next to understand how that demand will distribute itself in the facility, and the performance characteristics of this experience. To do this, planners use a variety of tools.

### *1. Process Analysis*

The *process flowchart* is an important tool for understanding the performance of stations and other interface areas. It shows the activities that a passenger experiences as he/she proceeds through a facility. It also shows the order of the activities and potential alternative paths or sequences, and thus be used to develop process time requirements. A simple flowchart shows the terminal as a single "black-box" processor with simple inputs and outputs of vehicles, passengers, and freight, as applicable. A more complete representation useful for cost determination might also include supporting inputs and outputs—land, employees, and supplies as inputs and environmental effects, employees, and waste materials as outputs. Figure 12-25 shows a process flowchart for an intercity passenger terminal. It traces the flow of passengers from arrival to departure and includes subprocesses such as passenger transfers to intra-city distribution modes.

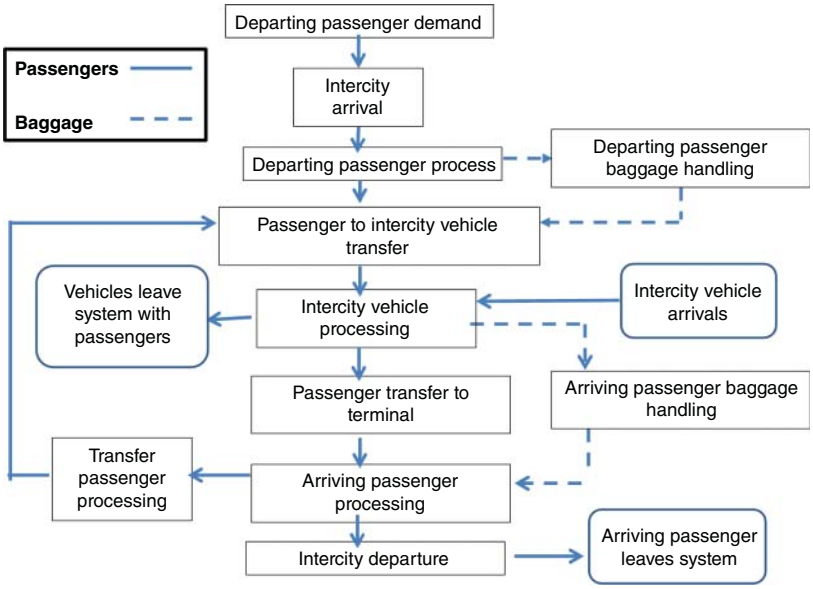
*Processing times* are a major factor in evaluating the level of service of a terminal. Theoretically, total processing time can be estimated by summing the times for each step shown on a process flowchart. Each of these individual times, however, is subject to considerable variation due to system or user characteristics. Waiting for a vehicle arrival is one of the process steps that has variability associated with it. For rail service on its own right-of-way, variability will primarily relate to high passenger loads and the time it takes to board and alight the train. These dependent-on-flow waits can also be a consequence of vehicles that are behind schedule because of accidents, system overload, passenger health issues, or other incidents.

Some processing time variation is due to individual choice, such as when travelers arrive at different times for a scheduled vehicle departure time. This difference is a result of different personalities (some people like to arrive well in advance, while others will get there just in time) and perceptions of the reliability of the mode of travel. Thus, variations in processing times occur for a number of reasons and are often expressed in numerical distributions, either as a simple range of values or as formal, statistical distributions.

*Wait time* is one of the most important measures in transit planning. In terminal planning and design, as in any transportation function, the planner's goal is to eliminate or minimize unproductive time, for example, delays and waiting. For stations, however, waiting cannot be avoided, and may be an integral aspect of station design and operation.

Assume a single-unit processing flow (a fare gate) with a constant service time, and assume that passengers arrive at a constant rate (time between arrivals). As long as the time between arrivals (headway) is greater than the service time,

**Figure 12-25. Process Flowchart of a General Terminal**



all passengers can be served. However, if the headway is less than the service time, a queue will form. In actual systems, times between traffic unit arrivals usually vary. Units sometimes bunch together, as do passengers departing from a vehicle. In addition, there are simply random arrivals, resulting from many people independently deciding when to travel. In the case of varying arrival headways, even if the volume yields an average headway greater than the (constant) service time, some delay is likely. Thus, determining the amount of waiting time and the number of people and vehicles waiting (or to be stored) is the basis of successful terminal design. Adequate storage capacity must be provided.

*Capacity*, the maximum possible flow of units per unit of time through a terminal or other interface should be estimated for planning the physical dimensions of the station and its facilities for handling passenger flows. Capacity determinations are usually linked to some idea of level of service, which is usually measured by waiting times or waiting delays. Level of service can be thought of as the maximum volume that can be accommodated with acceptable or tolerable patterns of delay. Before defining what are acceptable or tolerable criteria, the planner or engineer must understand the relationship among volumes, service times, queues, and waiting time, as discussed below.

### *2. Simulation*

The irregular occurrence of arrivals is the norm for passenger stations. One of the most useful analytical methods for modeling the performance of systems with irregular traffic flows is *simulation.* Simulation models use a mathematical formulation of the events that occur during a process to assess system performance. Thus, in the context of a transit terminal, the focus is typically on the arrival of passengers and vehicles, the placement in the appropriate serving facility (known as a server), loading and unloading, departure of the vehicle, making the server available to another unit, and other such factors. An important distinction is made between two types of simulation—*deterministic*, meaning that all events are characterized by certainty as to when they will occur, how long each process will take, and so on; and *stochastic*, meaning that there are possible variations in these characteristics of the system as they are represented in the simulation model. In particular, operational characteristics modeled as stochastic (such as the time required to load and unload a vehicle) have probabilities associated with each of the possible outcomes, with the associated probability indicating the relative frequency or likelihood of each outcome occurring.

A probability density function is used to represent the dynamic characteristics of a stochastic system. The most common probability density function used for arrivals at transport stations and other transport operations is the Poisson distribution. The random variable for the arrival problem is the number of units that arrive in a given interval of time where the average arrival rate has been determined from repeated observations.

The simulation process generates numerous randomly generated vehicle arrival times to reflect the fact that there is some uncertainty as to when a vehicle will actually arrive. The number of arrivals generated usually must be large enough so that the simulation results, which are often expressed in averages and perhaps distributions, have settled on reasonably stable values. This can be seen in Table 12-17 where 20 bus arrivals and 19 headways are randomly drawn based on an underlying distribution. As can be seen, the mean headway remains fairly stable in this example after about 10 bus arrivals.

### *3. Queuing*

Although simulation is the most widely used method for modeling stochastic traffic flows in transportation, *queuing theory* and *queuing analysis* are also important methods. Queuing analysis uses formulas to provide information of the type similar to that obtained from simulation, but only for well-specified conditions. Queuing analysis thus has the advantages of simplicity and ease of use over simulation, but it is only possible to derive such formulas given certain underlying assumptions.

Queuing formulas provide useful information for the design and analysis of waiting line systems, as well as the implications of a worst case scenario where there is a service breakdown. For instance, the average number of traffic units in the queue and the average number in the system (queue and servers) are important pieces of information for ascertaining the adequacy of waiting areas in stations. The distribution and average of waiting times are important in assessing the adequacy of the entire system in serving passenger demand. From this distribution, the probability of delays greater than any specified value can be obtained.

Four characteristics of queues must be specified for queuing theory to be applicable:

1) A distribution of the traffic arrival headways must be specified, which may be uniform (that is, constant times between arrivals), distributed as a Poisson or random arrival pattern (that is, a negative exponential probability of headways), or some other pattern.

| Table 12-17. Example Simulation of Arrival Times of Buses at a Stop | | | | |
|---|---|---|---|---|
| **Bus Number** | **Random Number Drawn** | **Time Headway (seconds)** | **Arrival Time (seconds)** | **Cumulative Mean Headway (seconds)** |
| 1 | | | 0 | |
| 2 | 32 | 49 | 49 | 49.0 |
| 3 | 99 | 1 | 50 | 25.0 |
| 4 | 61 | 21 | 71 | 23.6 |
| 5 | 16 | 80 | 151 | 37.8 |
| 6 | 66 | 18 | 169 | 33.8 |
| 7 | 10 | 100 | 269 | 44.8 |
| 8 | 49 | 31 | 300 | 42.9 |
| 9 | 83 | 8 | 308 | 38.5 |
| 10 | 12 | 92 | 400 | 44.4 |
| 11 | 36 | 44 | 444 | 44.4 |
| 12 | 31 | 51 | 495 | 45.0 |
| 13 | 92 | 4 | 499 | 41.6 |
| 14 | 8 | 110 | 609 | 46.8 |
| 15 | 74 | 13 | 622 | 44.4 |
| 16 | 84 | 8 | 630 | 42.0 |
| 17 | 33 | 48 | 678 | 42.4 |
| 18 | 16 | 80 | 758 | 44.6 |
| 19 | 28 | 55 | 813 | 44.6 |
| 20 | 64 | 19 | 832 | 43.8 |

Note: Random numbers are integers drawn from the range 0 to 100, all with equal probability.

2) The distribution of service times must similarly be defined. Thus, some underlying distribution of how long it takes for a vehicle or person to be served must be specified.

3) The number of serving channels or stations must be given.

4) A so-called queue discipline, which specifies the order in which arriving traffic units will be served, must be defined. In transportation, usually the first to arrive is the first to be served; however, there are situations where exactly the reverse is true. For example, the last person arriving to a crowded subway car will be the first one departing. In queuing theory terminology, the former discipline is usually referred to as *first in, first out (*FIFO) and the second as *last in, first out* (LIFO).

An important class of results (and the easiest mathematically) is the situation of a single-server queue with Poisson distributed arrivals, service times are assumed to follow a negative exponential distribution, and a FIFO discipline. Various measures of how the queue would perform are presented in Table 12-18. Because the Poisson distribution has a single parameter, the mean, the only parameters in the model are the mean arrival rate $\lambda$ and the mean service rate $\mu$. Both of these would be expressed in traffic units per unit time (as vehicles per hour). The mean headway of arrivals is $1/\lambda$ and the mean service time is $1/\mu$. It should be noted that the mean time between departures from the servicing channel must be greater than $1/\mu$ because the server is not always in use. The mean departure headway must be equal to $1/\lambda$ because there cannot be more units leaving than arrive in the system.

The various equations given in Table 12-18 are self-explanatory. These results are termed *steady-state* results, which means they are the results that would be observed after the system operated for such a long time that the averages or probabilities would not change. In fact, they are actually derived from the situation of an infinite period of operation. It is useful to express many of the formulas in terms of $\rho$, defined as *traffic intensity,* and equal to $\lambda/\mu$; $\rho$ must be less than 1.0, otherwise the waiting line would continually build up as time passed and a steady state would not exist.

Another important set of results involves queues with Poisson arrivals, Poisson service times, FIFO queue discipline, and many service channels. Here the FIFO discipline means that an arrival will enter the first available server, implying that there is just one waiting line. Even though this does not represent actual situations where there is a queue for

| Table 12-18. Single-Station Queuing Relationships with Poisson Arrivals and Exponential Service Times for Steady State Conditions | |
|---|---|
| **Queuing Model** | **Description of Model** |
| $p(n) = \left(\frac{\lambda}{\mu}\right)\left(1 - \frac{\lambda}{\mu}\right) = (\rho)^n(1 - \rho)$ | $p(n)$ = probability of having exactly n units in the system |
| $\overline{n} = \frac{\lambda}{\mu - \lambda} \frac{\rho}{1 - \rho}$ | $\overline{n}$ = average number of units in the system |
| $var\ (n) = \frac{\lambda\mu}{(\mu - \lambda)^2} = \frac{\rho}{(1-\rho)^2}$ | Var $(n)$ = variance of $n$ |
| $\overline{q} = \frac{\lambda^2}{(\mu)(\mu - \lambda)} = \frac{\rho^2}{(1-\rho)}$ | $\overline{q}$ = average length of queue |
| $f(d) = (\mu - \lambda)\, e^{(\lambda - \mu)d}$ | $f(d)$ = probability of having spent time d in the system |
| $\overline{d} = \frac{1}{(\mu - \lambda)}$ | $\overline{d}$ = average time spend in the system |
| $\overline{w} = \frac{\lambda}{\mu(\mu - \lambda)} = \overline{d} - \frac{1}{\mu}$ | $\overline{w}$ = average waiting time spent in queue |
| $p(d \leq t) = 1 - e^{-(1-\rho)\mu t}$ | $p(d \leq t)$ = probability of having spent time t or less in system |
| $p(w \leq t) = 1 - \rho e^{-(1-\rho)\mu t}$ | $p(w \leq t)$ = probability of having waited time $t$ or less in queue |

$\mu$ = Average number of arrivals per unit of time

$\lambda$ = Average servicing rate number of units per unit of time

$\rho$ = Unit intensity or utilization factor

each server, it often approximates the performance of these situations well. If desired, the analyst can use a different (and more complex) set of equations to arrive at the exact result (called the multi-server queuing problem).

***4. Pedestrian Flow Analysis***

The concepts, processes, and analytical techniques described up to this point have used riders or vehicles as the travel units. Pedestrian movement can also be viewed as a travel flow. There are two conceptual approaches to pedestrian flow analysis: linear situations (walkways, stairways, corridors) and area situations (transit platforms, sidewalk corner areas, terminal areas). Pioneering studies by Fruin and others in the early 1970s initially focused on the linear approach, and these studies led to material such as those contained in the *Highway Capacity Manual* (2010) and the *Transit Capacity and Quality of Service Manual* (2013). The time-space concept, particularly appropriate for area analyses, was described in a 1984 paper by Fruin and Benz [1984] and further developed in a 1986 monograph by Benz [1986]. Both references contain additional information on the analytical approaches toward pedestrian flow analysis. Other useful references include [FHWA, 1998; Jia et al., 2009; TRB, 2010]. Many of the more advanced studies on pedestrian flows use proprietary simulation models.

## D. Life-Cycle Planning

Developing plans for new stations or for a major improvement of existing terminals should look beyond the initial construction costs and consider the operating, maintenance, and major capital rehabilitation needs during the projected life of the facility. Maintenance and rehabilitation needs include those relating to the continued economic or transport functioning of the facility (for example, structural integrity and maintenance and cleaning operations, with special consideration given to carrying out maintenance with minimal impact on facility users). Continuing operations considerations include: (1) security, (2) signing and other information systems, (3) safety and maintainability of passenger or freight mechanical-assist systems, (4) sensitivity to long-term, day-to-day functional consequences of initial planning for "low first cost," and (5) ancillary services.

Major assist systems (for example, escalators, elevators, moving sidewalks) need to be designed for minimal life-cycle costs and user impacts. A number of transit systems, for example, incorporate stairways and escalators that are not enclosed from inclement weather conditions. Aside from maintenance considerations, the landing areas in the station concourse level are prime locations for slip-and-fall accidents during rainy weather.

## E. Security

Transit systems and stations have long been recognized as targets for terrorism. After the attacks on September 11, 2001, security planning for transit systems became even more important. Such planning has taken on more urgency after attacks on the transit systems in London, Madrid, and Mumbai. Security planning and design requirements are very specialized and change quite often, so the planner will need to consult closely with local agencies and public safety professionals on a case-by-case basis. To provide some general guidance, the references, *Design and Operating Safe and Secure Transit Systems: Assessing Current Practices in the United States and Abroad* [Taylor et al., 2005] and *Security Planning for Public Transit* [APTA, 2013] are offered as good places to start. Federal and state transportation agencies also provide general guidance. Almost all security strategies include visibility and surveillance, communication, and evacuation. These factors also apply to normal requirements for crime and fire prevention that have always been present in the transit industry.

Communication involves providing information to passengers and providing the opportunities for passengers to communicate with security and customer assistance staff. Public address systems have become a requirement for almost all transit systems, along with visual displays to accommodate hearing impaired users. Most transit stations also provide emergency call boxes and/or panic buttons that customers can use to alert staff to incidents and emergencies and to seek customer assistance information. Such devices should be well marked in well-lighted areas and be in view of closed circuit television (CCTV) cameras.

Transit facilities are sized for peak loads and reflect fire and life-safety codes for evacuating crowds in emergencies. In prior terrorist attacks, those seeking to inflict the highest number of casualties often targeted evacuation routes. Evacuation routes also serve as access ways for emergency responders. Designers should, therefore, provide multiple access and egress routes and consider providing more than is required by local fire codes.

Although it is disturbing to contemplate, there are several distinct types of attacks that should be anticipated in station and terminal planning. These include explosive devices, biological, and radiological devices, sabotage, shooting, and hostage-taking. However, new and more deadly means of inflicting damage are likely to appear in the future. Planners and designers must keep up to date on this unfortunate, but necessary, aspect of terminal planning.

Table 12-19 summarizes the security strategies that have been applied to transit systems. Designers and planners are encouraged to incorporate security strategies, both as a way to reduce the risks of terrorism and to deter criminal activity. The nature of transit systems, where large numbers of passengers must be accommodated and quickly processed, will continue to present a challenge of balancing security against costs and convenience to passengers.

Stations need to be well-lighted, inviting, and provide space with lines of sight as direct as possible. Even when supplemented by remote surveillance (for example, television cameras), there should be no hidden corners and other possible real or perceived trouble spots. This concern is not only related to potential criminal activity, but also to the presence of the homeless in stations, regardless of whether any actual problems arise. The perception of a threatening or uncomfortable situation has a real effect on passenger use of modes and their stations.

The complexity of security planning extends beyond the scope of any single design or engineering discipline, and terminal planners should consider assembling a multi-disciplinary team of specialists to provide the safest and most secure environment for passengers.

## F. Information Systems

Planning for passenger information systems should not be left as an afterthought but should be addressed early in the design process. Initial signage will need to be periodically reviewed and adjusted in light of operating experience to improve any lack of clarity or to reflect new or modified terminal operations. Signage, including electronic information systems, should be designed with this in mind. Flexibility, rather than first impression, should be a guiding principle. In the BART rail system, for example, a major re-signing of all of the stations occurred only 10 years after the opening of the system because of customer confusion in understanding many of the signs. A similar experience happened on the Washington, DC, WMATA system where station signs on the platform were written sideways (for aesthetic reasons), but which were very difficult for arriving passengers to read. These principles should also hold for wayfinding

**Table 12-19. Security Strategies for Transit System Components**

signs that identify paths and directions to the terminal or station (often discussed as part of the concept of the "last mile" connection to transit services).

Intelligent transportation systems (ITS) technology has led to the implementation of a variety of electronic information systems in stations. Common devices include television monitors displaying arrival and departure information; scrolling or stationary variable message signs using light-emitting diodes (LEDs), fiber optics, liquid crystal displays, and dot displays that use an array of two-colored dots that flip to form characters and graphics; Solari split-flap boards, which use hinged leaf signs that flip through a preprinted list of message options; and flat screen plasma displays, which can display full-motion, full-color images. Other devices are interactive electronic kiosks, which use touch screen menus or audio input to allow users to choose from a library of information. Facilities for personal computer access, including wireless (WiFi) devices, are increasingly being provided in terminals, and innovative smart phone apps are being developed by a host of agencies and individuals to make the travel experience even better.

Terminal planners should consider a variety of factors when deciding on appropriate display devices. Some of these considerations are locating devices to assure visibility; providing standing and queuing space for passengers to read or interact with devices without obstructing pedestrian flows; the need for protective enclosures for many devices; and the ability to easily change out devices as they become obsolete.

# IX. STATION DESIGN

Transit station design occurs after the transportation facility plan has been developed and in varying degrees up to the final production of station design plans. Station or terminal design involves developing and evaluating alternative functional and physical configurations. Included within the design stages are the following procedures: (1) establishing design objectives, criteria, standards, and requirements; (2) defining the constraints on station location; (3) developing passenger and vehicle flow data by origin, destination, access mode, line, and headway; (4) preparing alternative station design layouts; (5) evaluating the performance of each design; (6) selecting the design alternative that best meets the standards and criteria; and (7) iterating the process until an optimal design is determined.

## A. Design Parameters and Guidelines

In most large projects, design guidance is developed as part of the project development process, and thus design standards and criteria are often oriented specifically to the project context. The material in this section provides an overview of the types of information that would be part of a station planning/design process. For those interested, the following references are good sources and examples of station design guidance for different modes and for different sized communities.

Table 12-20 defines some of the key terms used in transit station planning and design. Design parameters are those factors necessary to create an environment suitable for processing passengers within the terminal. For a transit terminal, this encompasses (as applicable) stairways, ramps and passageways; escalators and elevators; platforms; fare and exit control; moving walkways; bus and rail facilities; and parking facilities. Station designers should be aware of the latest rules and regulations concerning particular design requirements. For example, FRA guidelines require platforms be at least 8 inches above top of rail and that the platforms for new commuter and intercity rail stations must run the length of the passenger boarding area of the station. This permits level boarding to all accessible cars of the trains stopping at the station.

Of particular importance in platform design are the requirements associated with evacuation of both the platform and passengers from a vehicle/consist at the stop. The parameters governing these elements are often included in building codes issued by the jurisdictions in which the facilities are located. In some instances, because of their special

| Table 12-20. Key Terms for Transit Planning and Design, TransLink, Vancouver, British Columbia | |
|---|---|
| **Concept** | **Example** |
| **Vision:** the approach that shapes the overall direction of the guidelines.<br>Transport 2040 is the primary reference point as the vision for the design guidelines. | **Vision:** transit will be the travel mode of choice in Metro Vancouver. |
| **Principles:** the overarching concepts that frame application of the goals and strategies. | **Principles:** inclusive design must be an automatic design consideration, which means developing places that are attractive, convenient, and easy to use for all people. |
| **Goals:** the desired outcomes that TransLink seeks to realize with the guidelines. | **Goals:** put passengers and pedestrians first. |
| **Strategies:** design objectives that should be met for TransLink to achieve its stated goals. | **Strategies:** make transit passenger facilities universally accessible and inclusive. |
| **Guidelines:** direction on how designs should be developed to achieve the objectives set by the strategies, without prescribing solutions.<br>This document provides the design guidelines for transit passenger facilities. | **Guidelines:** ensure sufficient spatial capacity is provided to avoid bottlenecks where passenger and pedestrian flows meet. |
| **Standards:** measurable design requirements, typically based on technical, safety, or passenger movement requirements.<br>Relevant standards are referred to, but are not included in these guidelines. | **Standards:** the minimum clear width of an accessible route shall be 1830 mm (72 in) for primary, highly frequented routes and 1525 mm (60 in) for secondary routes (1800 mm preferred at all routes). |
| **Specifications:** prescriptive design solutions, technical descriptions or requirements, which can include such elements as dimensions, materials, and placement.<br>Specifications are referred to, but are not included within these guidelines. | **Specifications:** where concrete is used as the basic floor and walkway finish, it will be steel-trowelled with aggregate sufficiently exposed at the walking surfaces to provide slip resistance of 0.55 to ASTM C1028-96 for wet or dry conditions. |

uses, stations are not specifically addressed by local codes; thus, design parameters may need to be drawn from other categories of facilities. Careful study of local building and planning codes would be necessary.

The need to comply in the United States with the Americans with Disabilities Act (ADA) of 1990 is of particular importance in the design of stations. This law requires all public facilities to be accessible to persons with a variety of impairments, including vision, hearing, and mobility limitations. ADA fundamentally altered the approach to facility design. While ADA requirements are not international standards, there is recognition in most countries that accommodating disabled users is an important design criterion, and that such strategies can improve the usefulness of stations for all users. The FTA and Federal Aviation Administration (FAA) have developed specific ADA policies and guidelines of particular relevance for passenger stations. They are focused on addressing common concerns, such as high curbs or steps, long stairways, inaccessible elevators, steep walks, gratings, difficult doors, narrow aisles, wheelchair accommodations, visual and nonvisual aids, among others.
